## ON THE NUMBER OF MAXIMAL INDEPENDENT SETS IN A GRAPH

DAVID R. WOOD

ABSTRACT. Miller and Muller (1960) and independently Moon and Moser (1965) determined the maximum number of maximal independent sets in an n-vertex graph. We give a new and simple proof of this result.

Let G be a (simple, undirected, finite) graph. A set  $S \subseteq V(G)$  is *independent* if no edge of G has both its endpoints in S. An independent set S is *maximal* if no independent set of G properly contains S. Let MIS(G) be the set of all maximal independent sets in G. Miller and Muller [7] and Moon and Moser [8] independently proved that the maximum, taken over all *n*-vertex graphs G, of |MIS(G)| equals

$$g(n) := \begin{cases} 3^{n/3} & \text{if } n \equiv 0 \pmod{3} \\ 4 \cdot 3^{(n-4)/3} & \text{if } n \equiv 1 \pmod{3} \\ 2 \cdot 3^{(n-2)/3} & \text{if } n \equiv 2 \pmod{3} \end{cases}$$

This result is important because g(n) bounds the time complexity of various algorithms that output all maximal independent sets [1–3, 5, 6, 9, 10]. Here we give a new and simple proof of this upper bound on |MIS(G)|.

**Theorem 1** ([7, 8]). For every n-vertex graph G,

 $|\operatorname{MIS}(G)| \le g(n) \ .$ 

*Proof.* We proceed by induction on n. The base case with  $n \leq 2$  is easily verified. Now assume that  $n \geq 3$ . Let G be a graph with n vertices. Let d be the minimum degree of G. Let v be a vertex of degree d in G. Let N[v] be the closed neighbourhood of v. If  $I \in MIS(G)$  then  $I \cap N[v] \neq \emptyset$ , otherwise  $I \cup \{v\}$  would

be an independent set. Moreover, if  $w \in I \cap N[v]$  then  $I \setminus \{w\} \in MIS(G - N[w])$ . Thus

$$|\operatorname{MIS}(G)| \le \sum_{w \in N_G[v]} |\operatorname{MIS}(G - N_G[w])| ,$$

Since  $deg(w) \ge d$  and g is non-decreasing, by induction,

$$|\operatorname{MIS}(G)| \le (d+1) \cdot g(n-d-1) \ .$$

Note that

$$4 \cdot 3^{(n-4)/3} \le g(n) \le 3^{n/3}$$

If  $d \geq 3$  then

$$MIS(G)| \le (d+1) \cdot 3^{(n-d-1)/3} \le 4 \cdot 3^{(n-4)/3} \le g(n)$$

If d = 2 then

$$|\operatorname{MIS}(G)| \le 3 \cdot g(n-3) = g(n) .$$

If d = 1 and  $n \equiv 1 \pmod{3}$  then since  $n - 2 \equiv 2 \pmod{3}$ ,

$$MIS(G) \le 2 \cdot g(n-2) \le 2 \cdot 2 \cdot 3^{(n-2-2)/3} = 4 \cdot 3^{(n-4)/3} = g(n) .$$

If d = 1 and  $n \equiv 0 \pmod{3}$  then since  $n - 2 \equiv 1 \pmod{3}$ ,

$$MIS(G) \le 2 \cdot g(n-2) \le 2 \cdot 4 \cdot 3^{(n-2-4)/3} < 3^{n/3} = g(n) .$$

If d = 1 and  $n \equiv 2 \pmod{3}$  then since  $n - 2 \equiv 0 \pmod{3}$ ,

$$MIS(G) \le 2 \cdot g(n-2) \le 2 \cdot 3^{(n-2)/3} = g(n)$$
.

This proves that  $|MIS(G)| \leq g(n)$ , as desired.

For completeness we describe the example by Miller and Muller [7] and Moon and Moser [8] that proves that Theorem 1 is best possible. If  $n \equiv 0 \pmod{3}$  then let  $M_n$  be the disjoint union of  $\frac{n}{3}$  copies of  $K_3$ . If  $n \equiv 1 \pmod{3}$  then let  $M_n$  be the disjoint union of  $K_4$  and  $\frac{n-4}{3}$  copies of  $K_3$ . If  $n \equiv 2 \pmod{3}$  then let  $M_n$  be the disjoint union of  $K_2$  and  $\frac{n-2}{3}$  copies of  $K_3$ . Observe that  $|\operatorname{MIS}(M_n)| = g(n)$ .

Note that Vatter [11] independently proved Theorem 1, and gave a connection between this result and the question, "What is the largest integer that is the product of positive integers with sum n?" Also note that Dieter Kratsch proved that  $|MIS(G)| \leq 3^{n/3}$  using a similar proof to that presented here; see Gaspers [4, page 177]. Thanks to the authors of [4, 11] for pointing out these references.
