# UNIFIED ASYMPTOTICS FOR INVESTMENT UNDER ILLIQUIDITY: TRANSACTION COSTS AND SEARCH FRICTIONS 

TAE UNG GANG* AND JIN HYUK CHOI**

#### Abstract

This paper investigates the optimal investment problem in a market with two types of illiquidity: transaction costs and search frictions. Extending the framework established by [21, we analyze a power-utility maximization problem where an investor encounters proportional transaction costs and trades only when a Poisson process triggers trading opportunities. We show that the optimal trading strategy is described by a no-trade region. We introduce a novel asymptotic framework applicable when both transaction costs and search frictions are small. Using this framework, we derive explicit asymptotics for the no-trade region and the value function along a specific parametric curve. This approach unifies existing asymptotic results for models dealing exclusively with either transaction costs or search frictions.

Keywords: stochastic control, asymptotics, portfolio optimization, illiquidity, transaction costs, search frictions.

## 1. Introduction

Understanding the impact of illiquidity on optimal investment is one of the key topics in mathematical finance. Illiquidity arises from various factors, such as exogenous transaction costs, search frictions (difficulty in finding a trading counterparty), and price impacts. 1 Building on the idea of [21], this paper investigates an optimal investment problem in a market with two types of illiquidity: transaction costs and search frictions.

Assuming perfect liquidity, where assets can be traded at any time without transaction costs, Merton's seminal works [36, 37] formulate the optimal investment problem using geometric Brownian motion for a risky asset price and a CRRA (constant relative risk aversion) investor, showing that the optimal strategy is to maintain a constant fraction of wealth in the risky asset. Subsequent research has extended this framework to more general stock price processes and utility functions, deriving broader optimal investment strategies.

The perfect liquidity assumption can be relaxed by incorporating transaction costs, such as order processing fees or transaction taxes, which contribute to market illiquidity and have been extensively studied. [33, 18, 46] examine the Merton model with proportional transaction costs, demonstrating that the optimal strategy is to keep the investment within a "no-trade region." The boundaries of this region are determined by the free-boundaries of the HJB (Hamilton-Jacobi-Bellman) equation. Models with transaction costs and multiple risky assets have been investigated (e.g., [1, 32, 39, 9]

[^0]for costs on all assets and [16, 7, 27, 11] for costs on only one asset). More general stock price processes have been considered within the framework of optimal investment with transaction costs (e.g., [14, 15, 5]). Additionally, [22, 38, 26, 19] investigate models with quadratic transaction costs.

Search frictions, or difficulty in finding a trading counterparty, are another source of market illiquidity. Table 1 in [3] presents frequency of trading in various markets, showing that many asset classes are illiquid, with their total sizes rivaling that of the public equity market. An intuitive way to model search frictions is by restricting trade times. For example, [44] considers an investor who can change portfolios only at fixed intervals, while [45, 35, 3] assume that an illiquid asset can only be traded when randomly occurring opportunities arise, modeled by a Poisson process. [40, 13] add the assumption that the asset price is observed only at these trade times. [23] further complicates the model by incorporating random intensity of trade times, regime-switching, and liquidity shocks. [17] considers trading at deterministic intervals with proportional transaction costs.

Due to the lack of explicit solutions to the HJB equations, asymptotic analysis has been employed for small transaction costs or small search frictions. For a small transaction cost parameter $\epsilon \ll 1$, in various models with proportional transaction costs only (e.g., [28, [25, [10, 8, 41, 4, 11]), the first correction terms of the no-trade boundaries are of the order of $\epsilon^{\frac{1}{3}}$, and the first correction term of the value function is of the order of $\epsilon^{\frac{2}{3}}$. In [35, 34, the parameter $\lambda$ is the intensity of the Poisson process, and search frictions can be represented by $\frac{1}{\lambda}$. For small search frictions $\frac{1}{\lambda} \ll 1$, the first correction terms of the optimal trading strategy and the value function are of the order of $\frac{1}{\lambda}$.

Merging the aforementioned frameworks, 21] studies log-utility maximization of the terminal wealth in a model with both transaction costs and search frictions. As in the models with transaction costs only, the optimal trading strategy in [21] is characterized by a no-trade region. In [21], for a small transaction cost parameter $\epsilon$ (with fixed $\lambda$ ), the first correction terms of the no-trade boundaries and the value function are of the order of $\epsilon$, instead of $\epsilon^{\frac{1}{3}}$ or $\epsilon^{\frac{2}{3}}$ in the models with transaction costs only. The asymptotic results imply that the effects of the transaction costs are more pronounced in the market with fewer search frictions.

In this paper, we analyze the power-utility maximization problem with both transaction costs and search frictions. The model setup is the same as that of [21] except that we consider power-utility instead of log-utility. In our model, proportional transaction costs (with parameter $\epsilon$ ) are imposed on an investor, and the investor's trading opportunities arise only when a Poisson process (with intensity $\lambda$ ) jumps. The investor's objective is to maximize the expected utility of wealth at the terminal time $T>0$. As in other models with proportional transaction costs, the optimal trading strategy in our model is characterized by a no-trade region: there are functions $\underline{y}, \bar{y}:[0, T) \rightarrow[0,1]$ such that the investor tries to keep the fraction of wealth invested in the risky asset within the interval $[\underline{y}(t), \bar{y}(t)]$ whenever trading opportunities arise.

The main contribution of this paper is the establishment of a novel framework for asymptotics applicable in scenarios where both transaction costs and search frictions are small, i.e., $\epsilon \ll 1$ and $\frac{1}{\lambda} \ll 1$. We focus on the asymptotics of the no-trade region and the value function. The results in [21] imply that the limits as $\epsilon \downarrow 0$ and $\lambda \rightarrow \infty$ simultaneously do not exist; the resulting values depend on the order of taking these limits (see discussion around (5.1) in Section 5). To address this issue, we compare the asymptotics in [21] with those in the benchmark cases of transaction costs only $(\lambda=\infty)$ and search frictions only $(\epsilon=0)$, leading us to conjecture that a specific scaling relation $\lambda=c \epsilon^{-\frac{2}{3}}$ for $c>0$ is relevant to consider (for details, see discussion for (5.3) in Section $5)$. Our findings confirm that along the parametric curve $\lambda=c \epsilon^{-\frac{2}{3}}$, the first correction terms of the no-trade boundaries and the value function are of the order of $\epsilon^{\frac{1}{3}}$ and $\epsilon^{\frac{2}{3}}$, respectively.

Our framework for finding asymptotics along the parametric curve $\lambda=c \epsilon^{-\frac{2}{3}}$ offers two notable benefits when dealing with small $\epsilon$ and large $\lambda$. First, the coefficients of the correction terms in our asymptotics are explicit in terms of the model parameters. In contrast, the coefficients in the asymptotics in [21] are expressed in terms of solutions to partial differential equations, making them not explicit $\int_{2}^{2}$ Therefore, given model parameters, including $\epsilon$ and $\lambda$, one can compute the auxiliary parameter $c=\lambda \epsilon^{\frac{2}{3}}$ and use the explicit expressions in Theorem 5.3 to estimate the optimal trading strategy and value.

Second, our framework using $\lambda=c \epsilon^{-\frac{2}{3}}$ unifies the existing asymptotic results for seemingly different benchmark models with only transaction costs and only search frictions. Indeed, Theorem 5.3 bridges the benchmark asymptotics, where the case $c \rightarrow \infty$ corresponds to the asymptotics with only transaction costs and the case $c \rightarrow 0$ corresponds to the asymptotics with only search frictions (see discussion around (5.10) in Section 5).

Our proof of the asymptotic analysis involves various estimations. One of the main difficulties in the analysis is the rigorous treatment of subtle limiting behaviors that do not appear in the benchmark models with only transaction costs or only search frictions (see discussion after Theorem 5.3).

The remainder of the paper is organized as follows. Section 2 describes the model. In Section 3, we provide the verification argument and some properties of the value function. In Section 4, we characterize the optimal trading strategy in terms of the no-trade region and present properties of its boundaries. In Section 5, we motivate the relation $\lambda=c \epsilon^{-\frac{2}{3}}$ and provide asymptotic results. Section 6 is devoted to the proof of these results. Section 7 summarizes the paper. Proofs of technical lemmas can be found in Appendix.

## 2. The Model

The model setup is identical to that described in [21], except for the utility function. Consider a filtered probability space $\left(\Omega, \mathcal{F},\left(\mathcal{F}_{t}\right)_{t \geq 0}, \mathbb{P}\right)$ satisfying the usual conditions. Under the filtration, let $\left(B_{t}\right)_{t \geq 0}$ be a standard Brownian motion and $\left(P_{t}\right)_{t \geq 0}$ be a Poisson process with constant intensity $\lambda>0$. Then $\left(B_{t}\right)_{t \geq 0}$ and $\left(P_{t}\right)_{t \geq 0}$ are independent as the quadratic covariation of the two Levy processes is zero.

We consider a financial market consisting of a constant saving account (zero interest rate) and a stock with its price process $\left(S_{t}\right)_{t \geq 0}$ defined by the following stochastic differential equation (SDE):

$$
d S_{t}=S_{t}\left(\mu d t+\sigma d B_{t}\right)
$$

where $\mu, \sigma$ and $S_{0}$ are constants and $\sigma$ and $S_{0}$ are strictly positive.
We assume that the market has two types of illiquidity.

- Proportional Transaction Costs: These costs are imposed on an investor when purchasing and selling stocks. There are two constants $\bar{\epsilon} \in(0, \infty)$ and $\underline{\epsilon} \in(0,1)$ such that the investor purchases one share of stock at the price of $(1+\bar{\epsilon}) S_{t}$ and sells one share at the price of $(1-\underline{\epsilon}) S_{t}$ at time $t$, respectively.
- Limited Trading Opportunities: An investor's trading opportunity is available only when the Poisson process $\left(P_{t}\right)_{t \geq 0}$ jumps. Hence, a larger $\lambda$ implies more frequent trading opportunities on average, resulting in fewer search frictions.

[^1]Let $W_{t}^{(0)}$ and $W_{t}^{(1)}$ be the amount of wealth in the saving account and stock at time $t \geq 0$, respectively. If the investor tries to obtain the stock worth $M_{s}$ at time $s \in[0, t]$, then $W_{t}^{(0)}$ and $W_{t}^{(1)}$ satisfy

$$
\begin{align*}
& W_{t}^{(0)}=w_{0}^{(0)}+\int_{0}^{t}\left((1-\underline{\epsilon}) M_{s}^{-}-(1+\bar{\epsilon}) M_{s}^{+}\right) d P_{s} \\
& W_{t}^{(1)}=w_{0}^{(1)}+\int_{0}^{t} W_{s-}^{(1)}\left(\mu d s+\sigma d B_{s}\right)+\int_{0}^{t} M_{s} d P_{s} \tag{2.1}
\end{align*}
$$

where the pair of nonnegative constants $\left(w_{0}^{(0)}, w_{0}^{(1)}\right)$ represents the initial position of the investor and we use notation $x^{ \pm}=\max \{ \pm x, 0\}$ for $x \in \mathbb{R}$. We assume that the initial total wealth is strictly positive, $w_{0}:=w_{0}^{(0)}+w_{0}^{(1)}>0$.

The trading strategy $\left(M_{t}\right)_{t \geq 0}$ is called admissible if it is a predictable process and the corresponding total wealth process $W:=W^{(0)}+W^{(1)}$ is nonnegative all the time. Since the rebalancing times are discrete, $W_{t} \geq 0$ for all $t \geq 0$ is equivalent to $W_{t}^{(0)} \geq 0$ and $W_{t}^{(1)} \geq 0$ for all $t \geq 0$. Therefore, an admissible strategy $M$ satisfies

$$
\begin{equation*}
-W_{t-}^{(1)} \leq M_{t} \leq \frac{W_{t-}^{(0)}}{1+\bar{\epsilon}}, \quad t \geq 0 \tag{2.2}
\end{equation*}
$$

The above inequalities and $w_{0}>0$ ensure that the corresponding total wealth process $W$ is strictly positive all the time.

For an admissible strategy $M$ and the corresponding solutions $W^{(0)}$ and $W^{(1)}$ of the SDEs in (2.1), let $X_{t}^{(1)}:=W_{t}^{(1)} / W_{t}$ be the fraction of the total wealth invested in the stock market at time $t$. Then, the inequalities in (2.2) imply $0 \leq X_{t} \leq 1$. The SDEs for $W$ and $X$ are

$$
\begin{align*}
d W_{t} & =\mu X_{t-} W_{t-} d t+\sigma X_{t-} W_{t-} d B_{t}-\left(\bar{\epsilon} M_{t}^{+}+\underline{\epsilon} M_{t}^{-}\right) d P_{t} \\
d X_{t} & =X_{t-}\left(1-X_{t-}\right)\left(\mu-\sigma^{2} X_{t-}\right) d t+\sigma X_{t-}\left(1-X_{t-}\right) d B_{t}+\frac{M_{t}+\left(\bar{\epsilon} M_{t}^{+}+\epsilon M_{t}^{-}\right) X_{t-}}{W_{t-}-\bar{\epsilon} M_{t}^{+}-\underline{\epsilon} M_{t}^{-}} d P_{t} \tag{2.3}
\end{align*}
$$

where the initial conditions are $W_{0}=w_{0}$ and $X_{0}=x_{0}:=w_{0}^{(1)} / w_{0}$.
Let $T>0$ be a constant representing the terminal time. The investor's utility maximization problem is defined as follows: for a given $\gamma \in(0, \infty) \backslash\{1\}$,

$$
\begin{equation*}
\sup _{\left(M_{t}\right)_{t \in[0, T]}} \mathbb{E}\left[\frac{W_{T}^{1-\gamma}}{1-\gamma}\right], \tag{2.4}
\end{equation*}
$$

where the supremum is taken over all admissible trading strategies.

## 3. The value function

Let $V$ be the value function of the utility maximization problem (2.4):

$$
\begin{equation*}
V(t, x, w)=\left.\sup _{\left(M_{s}\right)_{s \in[t, T]}} \mathbb{E}\left[\left.\frac{W_{T}^{1-\gamma}}{1-\gamma} \right\rvert\, \mathcal{F}_{t}\right]\right|_{\left(X_{t}, W_{t}\right)=(x, w)} \tag{3.1}
\end{equation*}
$$

The scaling property of the wealth process and the property of the power function enable us to conjecture the form of the value function as

$$
V(t, x, w)=\frac{w^{1-\gamma}}{1-\gamma} \cdot v(t, x)
$$

for a function $v:[0, T] \times[0,1] \rightarrow \mathbb{R}$. The Hamilton-Jacobi-Bellman (HJB) equation for (3.1) produces the following partial differential equation (PDE) for $v$ :

$$
\left\{\begin{align*}
1= & v(T, x)  \tag{3.2}\\
0= & v_{t}(t, x)+x(1-x)\left(\mu-\gamma \sigma^{2} x\right) v_{x}(t, x)+\frac{\sigma^{2} x^{2}(1-x)^{2}}{2} v_{x x}(t, x)+(Q(x)-\lambda) v(t, x) \\
& +\lambda(1-\gamma) \cdot \sup _{y \in[0,1]}\left(\frac{v(t, y)}{1-\gamma}\left(\left(\frac{1+\bar{\epsilon} x}{1+\bar{\epsilon} y}\right)^{1-\gamma} 1_{\{x \leq y\}}+\left(\frac{1-\underline{\epsilon} x}{1-\underline{\epsilon} y}\right)^{1-\gamma} 1_{\{x>y\}}\right)\right)
\end{align*}\right.
$$

where $v_{t}, v_{x}, v_{x x}$ are partial derivatives and

$$
\begin{equation*}
Q(x):=-\frac{\gamma(1-\gamma) \sigma^{2}}{2}\left(x-y_{M}\right)^{2}+\frac{\gamma(1-\gamma) \sigma^{2} y_{M}^{2}}{2} \quad \text { with } \quad y_{M}:=\frac{\mu}{\gamma \sigma^{2}} . \tag{3.3}
\end{equation*}
$$

Note that $y_{M}$ is the Merton fraction, the optimal fraction in the frictionless market.
Lemma 3.1. There exists a unique $v \in C^{1,2}([0, T] \times(0,1)) \cap C([0, T] \times[0,1])$ that satisfies the following conditions:
(i) $v$ satisfies $(3.2)$ for $(t, x) \in[0, T] \times(0,1)$.
(ii) For $x \in\{0,1\}$, the map $t \mapsto v(t, x)$ is continuously differentiable on $[0, T]$ and satisfies

$$
\left\{\begin{align*}
1= & v(T, x)  \tag{3.4}\\
0= & v_{t}(t, x)+(Q(x)-\lambda) v(t, x) \\
& +\lambda(1-\gamma) \cdot \sup _{y \in[0,1]}\left(\frac{v(t, y)}{1-\gamma}\left(\left(\frac{1+\bar{\epsilon} x}{1+\bar{\epsilon} y}\right)^{1-\gamma} 1_{\{x \leq y\}}+\left(\frac{1-\underline{\epsilon} x}{1-\underline{\epsilon} y}\right)^{1-\gamma} 1_{\{x>y\}}\right)\right)
\end{align*}\right.
$$

(iii) $v_{t}(t, x), x(1-x) v_{x}(t, x), x^{2}(1-x)^{2} v_{x x}(t, x)$ are uniformly bounded on $(t, x) \in[0, T] \times(0,1)$.

Proof. See Appendix A.

The next theorem provides the verification. Its proof is similar to the proof of Theorem 3.5 in [21].
Theorem 3.2. Let $V$ be as in (3.1), and $v$ be as in Lemma 3.1. Then, for $(t, x) \in[0, T] \times[0,1]$,

$$
\begin{equation*}
V(t, x, w)=\frac{w^{1-\gamma}}{1-\gamma} \cdot v(t, x) \tag{3.5}
\end{equation*}
$$

Proof. Without loss of generality, we prove $V\left(0, x_{0}, w_{0}\right)=\frac{w_{0}^{1-\gamma}}{1-\gamma} \cdot v\left(0, x_{0}\right)$. Let $M$ be an admissible trading strategy and $(W, X)$ be the corresponding solution of $(2.3)$. Then (2.2) and (2.3) imply

$$
0 \geq W_{t}-W_{t-}=-\left(\bar{\epsilon} M_{t}^{+}+\underline{\epsilon} M_{t}^{-}\right) d P_{t} \geq-\frac{\bar{\epsilon}}{1+\bar{\epsilon}} W_{t-}^{(0)}-\underline{\epsilon} W_{t-}^{(1)}
$$

The above inequalities imply that there is a constant $c_{0} \in(0,1)$ such that

$$
\begin{equation*}
c_{0} W_{t-} \leq W_{t} \leq W_{t-} \quad \text { for } \quad t \in[0, T] \tag{3.6}
\end{equation*}
$$

Then, (3.6) and (2.3) produce

$$
\begin{equation*}
w_{0} c_{0}^{P_{t}} e^{\int_{0}^{t} \mu X_{s} d s} \mathcal{E}(\sigma X \cdot B)_{t} \leq W_{t} \leq w_{0} e^{\int_{0}^{t} \mu X_{s} d s} \mathcal{E}(\sigma X \cdot B)_{t} \tag{3.7}
\end{equation*}
$$

where $\mathcal{E}(\sigma X \cdot B)$ is the Doléans-Dade exponential of the process $\left(\int_{0}^{t} \sigma X_{s} d B_{s}\right)_{t \geq 0}$. Since $0 \leq X \leq 1$, Novikov's condition implies that $\mathcal{E}(4(1-\gamma) \sigma X \cdot B)$ is a martingale. For $\left.\frac{d \tilde{\mathbb{P}}}{d \mathbb{P}}\right|_{\mathcal{F}_{t}}=\mathcal{E}(4(1-\gamma) \sigma X \cdot B)_{t}$, $t \in[0, T]$ and a constant $b>0$,

$$
\begin{align*}
\mathbb{E}\left[b^{P_{t}} \mathcal{E}(\sigma X \cdot B)_{t}^{2(1-\gamma)}\right] & \leq \sqrt{\mathbb{E}\left[b^{2 P_{t}}\right] \cdot \mathbb{E}\left[\mathcal{E}(\sigma X \cdot B)_{t}^{4(1-\gamma)}\right]}=e^{\frac{b^{2}-1}{2} \lambda t} \sqrt{\mathbb{E}^{\tilde{\mathbb{P}}\left[e^{2(3-4 \gamma)(1-\gamma) \sigma^{2} \int_{0}^{t} X_{s}^{2} d s}\right]}} \\
& \leq e^{\frac{b^{2}-1}{2}\left|\lambda T+|(3-4 \gamma)(1-\gamma)| \sigma^{2} T\right.} \tag{3.8}
\end{align*}
$$

We combine (3.7) and (3.8) to conclude that

$$
\begin{equation*}
\sup _{t \in[0, T]} \mathbb{E}\left[W_{t}^{2(1-\gamma)}\right]<\infty \tag{3.9}
\end{equation*}
$$

Let $\tau_{n}:=T \wedge \inf \left\{t \geq 0: P_{t}=n\right\}$ for $n \in \mathbb{N}$ and $\tau_{0}:=0$. We observe that

$$
\text { for } t \in\left[\tau_{n}, \tau_{n+1}\right), \quad\left\{\begin{array}{l}
\text { if } X_{\tau_{n}}=0, \text { then } X_{t}=0  \tag{3.10}\\
\text { if } X_{\tau_{n}}=1, \text { then } X_{t}=1 \\
\text { if } X_{\tau_{n}} \in(0,1), \text { then } X_{t} \in(0,1)
\end{array}\right.
$$

We apply Ito's formula to $\frac{W_{t}^{1-\gamma}}{1-\gamma} \cdot v\left(t, X_{t}\right)$ with 2.3 and 3.10 , and use the fact that $X_{t}$ and $W_{t}$ can only jump at $t=\tau_{n}$ for $n \in \mathbb{N}$ to obtain

$$
\begin{align*}
& \frac{W_{\tau_{n+1}}^{1-\gamma}}{1-\gamma} \cdot v\left(\tau_{n+1}, X_{\tau_{n+1}}\right)-\frac{W_{\tau_{n}}^{1-\gamma}}{1-\gamma} \cdot v\left(\tau_{n}, X_{\tau_{n}}\right) \\
& =\left\{\begin{array}{l}
\int_{\tau_{n}}^{\tau_{n+1}} \frac{W_{s-\gamma}^{1-\gamma}}{1-\gamma}\left(\left(v_{t}(s, x)+x(1-x)\left(\mu-\gamma \sigma^{2} x\right) v_{x}(s, x)+\frac{\sigma^{2} x^{2}(1-x)^{2}}{2} v_{x x}(s, x)\right.\right. \\
\left.+Q(x) v(s, x))\left.\right|_{x=X_{s-}} d s+\left.\sigma\left((1-\gamma) x v(s, x)+x(1-x) v_{x}(s, x)\right)\right|_{x=X_{s-}} d B_{s}\right) \quad \text { if } X_{\tau_{n}} \in(0,1) \\
\int_{\tau_{n}}^{\tau_{n+1}} \frac{W_{s-}^{1-\gamma}}{1-\gamma}\left(v_{t}(s, 0)+Q(0) v(s, 0)\right) d s \quad \text { if } X_{\tau_{n}}=0 \\
\int_{\tau_{n}}^{\tau_{n+1}} \frac{W_{s-}^{1-\gamma}}{1-\gamma}\left(\left(v_{t}(s, 1)+Q(1) v(s, 1)\right) d s+(1-\gamma) \sigma v(s, 1) d B_{s}\right) \quad \text { if } X_{\tau_{n}}=1 \\
\quad+\frac{W_{\tau_{n+1}}^{1-\gamma}}{1-\gamma} \cdot v\left(\tau_{n+1}, X_{\tau_{n+1}}\right)-\frac{W_{\tau_{n+1}-}^{1-\gamma}}{1-\gamma} \cdot v\left(\tau_{n+1}, X_{\tau_{n+1}-}\right)
\end{array}\right.
\end{align*}
$$

Since $\lim _{n \rightarrow \infty} \tau_{n}=T$ almost surely, the above expression produces

$$
\begin{aligned}
& \frac{W_{T}^{1-\gamma}}{1-\gamma} \cdot v\left(T, X_{T}\right)-\frac{w_{0}^{1-\gamma}}{1-\gamma} \cdot v\left(0, x_{0}\right) \\
& =\sum_{n=0}^{\infty}\left(\frac{W_{\tau_{n+1}}^{1-\gamma}}{1-\gamma} \cdot v\left(\tau_{n+1}, X_{\tau_{n+1}}\right)-\frac{W_{\tau_{n}}^{1-\gamma}}{1-\gamma} \cdot v\left(\tau_{n}, X_{\tau_{n}}\right)\right) \\
& =\int_{0}^{T} \frac{W_{s-}^{1-\gamma}}{1-\gamma}\left(\left(v_{t}(s, x)+x(1-x)\left(\mu-\gamma \sigma^{2} x\right) v_{x}(s, x)+\frac{\sigma^{2} x^{2}(1-x)^{2}}{2} v_{x x}(s, x)\right.\right. \\
& \left.\quad+Q(x) v(s, x)) 1_{\{x \in(0,1)\}}+\left(v_{t}(s, x)+Q(x) v(s, x)\right) 1_{\{x \in\{0,1\}\}}\right)\left.\right|_{x=X_{s-}} d s \\
& \quad+\left.\int_{0}^{T} \frac{W_{s-}^{1-\gamma}}{1-\gamma}\left(\sigma\left((1-\gamma) x v(s, x)+x(1-x) v_{x}(s, x)\right) 1_{\{x \in(0,1)\}}+(1-\gamma) \sigma v(s, 1) 1_{\{x=1\}}\right)\right|_{x=X_{s-}} d B_{s} \\
& \quad+\sum_{0<s \leq T}\left(\frac{W_{s}^{1-\gamma}}{1-\gamma} \cdot v\left(s, X_{s}\right)-\frac{W_{s-}^{1-\gamma}}{1-\gamma} \cdot v\left(s, X_{s-}\right)\right) .
\end{aligned}
$$

The stochastic integral term above is a martingale due to Lemma 3.1 (iii) and (3.9). The sum of jumps term above can be written as

$$
\left.\int_{0}^{T} \frac{W_{s-}^{1-\gamma}}{1-\gamma}\left(v(s, y)\left(\left(\frac{1+\bar{\epsilon} x}{1+\bar{\epsilon} y}\right)^{1-\gamma} 1_{\{x \leq y\}}+\left(\frac{1-\underline{\epsilon} x}{1-\underline{\epsilon} y}\right)^{1-\gamma} 1_{\{x>y\}}\right)-v(s, x)\right)\right|_{(x, y)=\left(X_{s-}, Y_{s}\right)} d P_{s}
$$

where $Y_{s}:=\frac{X_{s-} W_{s-}+M_{s}}{W_{s-}-\bar{\epsilon} M_{s}^{+}-\epsilon M_{s}^{-}}$. Since $\left(P_{t}-\lambda t\right)_{t \in[0, T]}$ is a martingale, Lemma 3.1 (iii) and (3.9) imply that the expected value of the above expression is

$$
\mathbb{E}\left[\left.\int_{0}^{T} \frac{W_{s-}^{1-\gamma}}{1-\gamma} \lambda\left(v(s, y)\left(\left(\frac{1+\bar{\epsilon} x}{1+\bar{\epsilon} y}\right)^{1-\gamma} 1_{\{x \leq y\}}+\left(\frac{1-\underline{\epsilon} x}{1-\underline{\epsilon} y}\right)^{1-\gamma} 1_{\{x>y\}}\right)-v(s, x)\right)\right|_{(x, y)=\left(X_{s-}, Y_{s}\right)} d s\right] .
$$

We combine these observations to obtain

$$
\begin{align*}
& \mathbb{E}\left[\frac{W_{T}^{1-\gamma}}{1-\gamma} \cdot v\left(T, X_{T}\right)\right]-\frac{w_{0}^{1-\gamma}}{1-\gamma} \cdot v\left(0, x_{0}\right) \\
& =\int_{0}^{T} \frac{W_{s}^{1-\gamma}}{1-\gamma}\left(\left(v_{t}(s, x)+x(1-x)\left(\mu-\gamma \sigma^{2} x\right) v_{x}(s, x)+\frac{\sigma^{2} x^{2}(1-x)^{2}}{2} v_{x x}(s, x)+(Q(x)-\lambda) v(s, x)\right.\right. \\
& \left.\quad+\lambda v(s, y)\left(\left(\frac{1+\bar{\epsilon} x}{1+\bar{\epsilon} y}\right)^{1-\gamma} 1_{\{x \leq y\}}+\left(\frac{1-\underline{\epsilon} x}{1-\epsilon y}\right)^{1-\gamma} 1_{\{x>y\}}\right)\right) 1_{\{x \in(0,1)\}}+\left(v_{t}(s, x)+(Q(x)-\lambda) v(s, x)\right. \\
& \left.\left.\quad \quad+\lambda v(s, y)\left(\left(\frac{1+\bar{\epsilon} x}{1+\bar{\epsilon} y}\right)^{1-\gamma} 1_{\{x \leq y\}}+\left(\frac{1-\epsilon x}{1-\underline{\epsilon} y}\right)^{1-\gamma} 1_{\{x>y\}}\right)\right) 1_{\{x \in\{0,1\}\}}\right)\left.\right|_{(x, y)=\left(X_{s}-, Y_{s}\right)} d s . \tag{3.12}
\end{align*}
$$

The above equality and Lemma 3.1 imply that for any admissible trading strategy $M$,

$$
\begin{equation*}
\mathbb{E}\left[\frac{W_{T}^{1-\gamma}}{1-\gamma}\right] \leq \frac{w_{0}^{1-\gamma}}{1-\gamma} \cdot v\left(0, x_{0}\right) . \tag{3.13}
\end{equation*}
$$

To complete the proof, we construct an optimal strategy $\hat{M}$ that satisfies the equality in (3.13). We observe that the following map is continuous on $(t, x, y) \in[0, T] \times[0,1]^{2}$ :

$$
\begin{equation*}
(t, x, y) \mapsto \frac{v(t, y)}{1-\gamma}\left(\left(\frac{1+\bar{\epsilon} x}{1+\bar{\epsilon} y}\right)^{1-\gamma} 1_{\{x \leq y\}}+\left(\frac{1-\underline{\epsilon} x}{1-\underline{\epsilon} y}\right)^{1-\gamma} 1_{\{x>y\}}\right) . \tag{3.14}
\end{equation*}
$$

Then, due to Lemma F.2, there exists a measurable function $\hat{y}:[0, T] \times[0,1] \rightarrow[0,1]$ such that

$$
\begin{equation*}
\hat{y}(t, x) \in \underset{y \in[0,1]}{\operatorname{argmax}}\left(\frac{v(t, y)}{1-\gamma}\left(\left(\frac{1+\bar{\epsilon} x}{1+\bar{\epsilon} y}\right)^{1-\gamma} 1_{\{x \leq y\}}+\left(\frac{1-\epsilon x}{1-\epsilon y}\right)^{1-\gamma} 1_{\{x>y\}}\right)\right) . \tag{3.15}
\end{equation*}
$$

We define a measurable function $m:[0, T] \times[0, \infty) \times[0,1] \rightarrow \mathbb{R}$ as

$$
\begin{equation*}
m(t, w, x):=\frac{w(\hat{y}(t, x)-x)}{1+\bar{\epsilon} \hat{y}(t, x)} \cdot 1_{\{x \leq \hat{y}(t, x)\}}+\frac{w(\hat{y}(t, x)-x)}{1-\epsilon \hat{y}(t, x)} \cdot 1_{\{x>\hat{y}(t, x)\}} . \tag{3.16}
\end{equation*}
$$

Let $(\hat{W}, \hat{X})$ be the solution of the SDEs in $(2.3)$ with $M_{t}=m\left(t, W_{t-}, X_{t-}\right)$, and $\hat{M}_{t}:=m\left(t, \hat{W}_{t-}, \hat{X}_{t-}\right)$. By construction, we have $\hat{y}\left(t, \hat{X}_{t-}\right)=\frac{\hat{X}_{t-} \vec{W}_{t}+\hat{M}_{t}}{\hat{W}_{t-}-\bar{\epsilon} \hat{M}_{t}^{+}-\underline{M_{1}^{-}}}$. Then (3.12), 3.15) and Lemma 3.1 produce (3.13) with the equality. Therefore, we conclude (3.5) and the optimality of $\hat{M}$.

The next lemma shows that $x \mapsto \frac{v(t, x)}{1-\gamma}$ is strictly concave and $v$ has uniform bounds independent of $\bar{\epsilon}, \underline{\epsilon}$ and $\lambda$. To treat the concavity part, we define $\tilde{V}:[0, T] \times\left([0, \infty)^{2} \backslash\{(0,0)\}\right) \rightarrow \mathbb{R}$ as

$$
\begin{equation*}
\tilde{V}(t, a, b):=V\left(t, \frac{b}{a+b}, a+b\right) . \tag{3.17}
\end{equation*}
$$

We notice that $\tilde{V}(t, a, b)$ is the value function of our control problem with $W_{t}^{(0)}=a$ and $W_{t}^{(1)}=b$.
Lemma 3.3. (i) For $t \in[0, T)$, the maps $(a, b) \mapsto \tilde{V}(t, a, b)$ and $x \mapsto \frac{v(t, x)}{1-\gamma}$ are strictly concave. (ii) There are constants $\bar{v} \geq \underline{v}>0$ independent of $\bar{\epsilon}, \underline{\epsilon}$ and $\lambda$ such that

$$
\begin{equation*}
\underline{v} \leq v(t, x) \leq \bar{v} \quad \text { for } \quad(t, x) \in[0, T] \times[0,1] . \tag{3.18}
\end{equation*}
$$

Proof. (i) This part of the proof is essentially the same as the proof of Proposition 3.6 in [21].
(ii) Let $M$ be an admissible trading strategy and $(W, X)$ be the corresponding solution of (2.3). Then the right-hand side inequality in (3.7) implies

$$
\begin{equation*}
\frac{W_{T}^{1-\gamma}}{1-\gamma} \leq \frac{w_{0}^{1-\gamma}}{1-\gamma} e^{\int_{0}^{T} Q\left(X_{s}\right) d s} \mathcal{E}((1-\gamma) \sigma X \cdot B)_{T} \tag{3.19}
\end{equation*}
$$

where $Q$ is defined in (3.3). Since $0 \leq X \leq 1$, Novikov's condition implies that $\mathcal{E}((1-\gamma) \sigma X \cdot B)$ is a martingale. Then (3.19) implies that for $\left.\frac{d \tilde{\mathbb{P}}}{d \mathbb{P}}\right|_{\mathcal{F}_{T}}=\mathcal{E}((1-\gamma) \sigma X \cdot B)_{T}$,

$$
\begin{equation*}
\mathbb{E}\left[\frac{W_{T}^{1-\gamma}}{1-\gamma}\right] \leq \frac{w_{0}^{1-\gamma}}{1-\gamma} \cdot \mathbb{E}^{\tilde{\mathbb{P}}}\left[e^{\int_{0}^{T} Q\left(X_{s}\right) d s}\right] \tag{3.20}
\end{equation*}
$$

The definition of $V$ in (3.1), Theorem 3.2 and (3.20) produce the following inequalities:

$$
\begin{equation*}
v\left(0, x_{0}\right) \leq e^{\|Q\|_{\infty} T} \quad \text { for } \quad 0<\gamma<1, \quad v\left(0, x_{0}\right) \geq e^{-\|Q\|_{\infty} T} \quad \text { for } \quad \gamma>1 . \tag{3.21}
\end{equation*}
$$

Since $M_{s}=0$ for all $s \in[0, T]$ is an admissible strategy, we have

$$
\begin{align*}
& \frac{w_{0}^{1-\gamma}}{1-\gamma} \cdot v\left(0, x_{0}\right)=V\left(0, x_{0}, w_{0}\right) \geq \mathbb{E}\left[\frac{1}{1-\gamma}\left(\left(1-x_{0}\right) w_{0}+x_{0} w_{0} e^{\left(\mu-\frac{\sigma^{2}}{2}\right) T+\sigma B_{T}}\right)^{1-\gamma}\right] \\
& \Longrightarrow \quad \frac{v\left(0, x_{0}\right)}{1-\gamma} \geq \frac{1}{1-\gamma} \mathbb{E}\left[\left(1-x_{0}+x_{0} e^{\left(\mu-\frac{\sigma^{2}}{2}\right) T+\sigma B_{T}}\right)^{1-\gamma}\right] \tag{3.22}
\end{align*}
$$

The following inequalities can be checked easily:

$$
\left\{\begin{array}{l}
\text { If } 0<\gamma<1 \text {, then }(1-x+x a)^{1-\gamma} \geq 1-x+x a^{1-\gamma} \text { for } x \in[0,1] \text { and } a>0  \tag{3.23}\\
\text { If } \gamma>1 \text {, then }(1-x+x a)^{1-\gamma} \leq 1+a^{1-\gamma} \text { for } x \in[0,1] \text { and } a>0
\end{array}\right.
$$

We combine (3.22), 3.23) and $\mathbb{E}\left[e^{(1-\gamma)\left(\mu-\frac{\sigma^{2}}{2}\right) T+(1-\gamma) \sigma B_{T}}\right]=e^{(1-\gamma)\left(\mu-\frac{\gamma \sigma^{2}}{2}\right) T}$ to obtain

$$
\begin{align*}
& v\left(0, x_{0}\right) \geq 1-x_{0}+x_{0} e^{(1-\gamma)\left(\mu-\frac{\gamma \sigma^{2}}{2}\right) T} \geq e^{-\left|(1-\gamma)\left(\mu-\frac{\gamma \sigma^{2}}{2}\right) T\right|} \quad \text { for } \quad 0<\gamma<1, \\
& v\left(0, x_{0}\right) \leq 1+e^{(1-\gamma)\left(\mu-\frac{\gamma \sigma^{2}}{2}\right) T} \leq 1+e^{\left|(1-\gamma)\left(\mu-\frac{\gamma \sigma^{2}}{2}\right) T\right|} \quad \text { for } \quad \gamma>1 . \tag{3.24}
\end{align*}
$$

We check that the inequalities in (3.21) and (3.24) still hold after replacing $v\left(0, x_{0}\right)$ by $v(t, x)$.

## 4. The Optimal trading strategy

In this section, we characterize the optimal trading strategy in terms of the no-trade region. We start with the construction of the candidate boundary points $y$ and $\bar{y}$ of the no-trade region.

Lemma 4.1. For each $t \in[0, T)$, there exist $0 \leq \underline{y}(t) \leq \bar{y}(t) \leq 1$ such that

$$
\begin{equation*}
\{\underline{y}(t)\}=\underset{y \in[0,1]}{\operatorname{argmax}}\left(\frac{v(t, y)}{(1-\gamma)(1+\bar{\epsilon} y)^{1-\gamma}}\right), \quad\{\bar{y}(t)\}=\underset{y \in[0,1]}{\operatorname{argmax}}\left(\frac{v(t, y)}{(1-\gamma)(1-\underline{\epsilon} y)^{1-\gamma}}\right) . \tag{4.1}
\end{equation*}
$$

To be more specific, the following statements hold:
(i) The map $y \mapsto \frac{v(t, y)}{(1-\gamma)(1+\bar{\epsilon} y)^{1-\gamma}}$ strictly increases on $y \in[0, \underline{y}(t)]$ and decreases on $y \in[\underline{y}(t), 1]$.

If $0<\underline{y}(t)<1$, then $\underline{y}(t)$ satisfies $\frac{v_{x}(t, \underline{y}(t))}{1-\gamma}=\frac{\bar{\epsilon} v(t, y(t))}{1+\bar{\epsilon} y(t)}$.
(ii) The map $y \mapsto \frac{v(t, y)}{(1-\gamma)(1-\epsilon y)^{1-\gamma}}$ strictly increases on $y \in[0, \bar{y}(t)]$ and decreases on $y \in[\bar{y}(t), 1]$. If $0<\bar{y}(t)<1$, then $\underline{y}(t)$ satisfies $\frac{v_{x}(t, \bar{y}(t))}{1-\gamma}=-\frac{\epsilon v(t, \bar{y}(t))}{1-\epsilon \bar{y}(t)}$.
(iii) For $(t, x) \in[0, T) \times[\underline{y}(t), \bar{y}(t)]$, $-\frac{\underline{\epsilon}}{1-\underline{\epsilon}} \bar{v} \leq \frac{v_{x}(t, x)}{1-\gamma} \leq \bar{\epsilon} \bar{v}$ with $\bar{v}$ appears in Lemma 3.3.

Proof. Recall $\tilde{V}$ in (3.17). Due to Theorem 3.2, the following equation holds:

$$
\begin{equation*}
\tilde{V}(t, 1-(1+\bar{\epsilon}) \eta, \eta)=\left.\frac{v(t, y)}{(1-\gamma)(1+\bar{\epsilon} y)^{1-\gamma}}\right|_{y=\frac{\eta}{1-\bar{\epsilon} \eta}} \quad \text { for } \quad \eta \in\left[0, \frac{1}{1+\bar{\epsilon}}\right] . \tag{4.2}
\end{equation*}
$$

Lemma 3.3 (i) implies that the map $\eta \mapsto \tilde{V}(t, 1-(1+\bar{\epsilon}) \eta, \eta)$ is strictly concave on $\eta \in\left[0, \frac{1}{1+\bar{\epsilon}}\right]$. Let $\eta(t):=\operatorname{argmax}_{0 \leq \eta \leq \frac{1}{1+\bar{\epsilon}}} \tilde{V}(t, 1-(1+\bar{\epsilon}) \eta, \eta)$ be the unique maximizer. Since the map $\eta \mapsto \frac{\eta}{1-\bar{\epsilon} \eta}$
strictly increases on $\eta \in\left[0, \frac{1}{1+\bar{\epsilon}}\right]$, the definition of $\eta(t)$ and 4.2 imply that the left-hand side equation of 4.1 holds with $\underline{y}(t)=\frac{\eta(t)}{1-\bar{\epsilon} \eta(t)}$ and the statements in (i) hold.

Similarly, the following equation hol $\bar{d} s$ :

$$
\begin{equation*}
\tilde{V}(t, 1-(1-\underline{\epsilon}) \eta, \eta)=\left.\frac{v(t, y)}{(1-\gamma)(1-\underline{\epsilon} y)^{1-\gamma}}\right|_{y=\frac{\eta}{1+\underline{\epsilon} \eta}} \quad \text { for } \quad \eta \in\left[0, \frac{1}{1-\underline{\epsilon}}\right] . \tag{4.3}
\end{equation*}
$$

The strict concavity of $\eta \mapsto \tilde{V}(t, 1-(1-\underline{\epsilon}) \eta, \eta)$ ensures the existence of the unique maximizer $\bar{\eta}(t):=\operatorname{argmax}_{0 \leq \eta \leq \frac{1}{1-\epsilon}} \tilde{V}(t, 1-(1-\underline{\epsilon}) \eta, \eta)$. Then, the right-hand side equation of (4.1) holds with $\bar{y}(t)=\frac{\bar{\eta}(t)}{1+\epsilon \bar{\eta}(t)}$ and the statements in (ii) hold.

We observe that (i) and (ii) imply $-\frac{\underline{\epsilon v}(t, x)}{1-\underline{\epsilon x}} \leq \frac{v_{x}(t, x)}{1-\gamma} \leq \frac{\bar{\epsilon} v(t, x)}{1+\bar{\epsilon} x}$ for $x \in[\underline{y}(t), \bar{y}(t)]$. Then, we conclude (iii) by this observation and Lemma 3.3 (ii).

It only remains to check $\underline{y}(t) \leq \bar{y}(t)$. The inequality holds when $\bar{y}(t)=1$. Suppose that $\bar{y}(t)<1$. Then, (ii) implies $\frac{v_{x}(t, \bar{y}(t))}{1-\gamma} \leq-\frac{\epsilon v(t, \bar{y}(t))}{1-\epsilon \bar{\epsilon}(t)} \leq \frac{\bar{\epsilon} v(t, \bar{y}(t))}{1+\overline{\epsilon \bar{y}}(t)}$, where the second inequality is due to the positivity of $v$. This observation and (i) produce $\underline{y}(t) \leq \bar{y}(t)$.

In the proof of Theorem 3.2 , we construct the optimal trading strategy via $\hat{y}$ in (3.15). The next theorem explicitly characterizes $\hat{y}(t, x)$ in terms of $\underline{y}(t)$ and $\bar{y}(t)$ as defined in Lemma 4.1.

Theorem 4.2. For fixed $t \in[0, T)$, the argmax in (3.15) is a singleton and $\hat{y}$ is

$$
\hat{y}(t, x)= \begin{cases}\underline{y}(t) & \text { if } x \in[0, \underline{y}(t))  \tag{4.4}\\ x & \text { if } x \in[\underline{y}(t), \bar{y}(t)] \\ \bar{y}(t) & \text { if } x \in(\bar{y}(t), 1]\end{cases}
$$

where $\underline{y}(t)$ and $\bar{y}(t)$ are determined in Lemma 4.1.
Proof. We rephrase the maximization in 3.15 as

$$
\begin{align*}
& \max _{y \in[0,1]}\left(\frac{v(t, y)}{1-\gamma}\left(\left(\frac{1+\bar{\epsilon} x}{1+\bar{\epsilon} y}\right)^{1-\gamma} 1_{\{x \leq y\}}+\left(\frac{1-\underline{\epsilon} x}{1-\underline{\epsilon} y}\right)^{1-\gamma} 1_{\{x>y\}}\right)\right) \\
& =\max \left\{\max _{y \in[x, 1]}\left(\frac{v(t, y)}{1-\gamma}\left(\frac{1+\bar{\epsilon} x}{1+\bar{\epsilon} y}\right)^{1-\gamma}\right), \max _{y \in[0, x]}\left(\frac{v(t, y)}{1-\gamma}\left(\frac{1-\underline{\epsilon} x}{1-\underline{\epsilon} y}\right)^{1-\gamma}\right)\right\} . \tag{4.5}
\end{align*}
$$

Using Lemma 4.1, we evaluate

$$
\begin{align*}
& \max _{y \in[x, 1]}\left(\frac{v(t, y)}{1-\gamma}\left(\frac{1+\bar{\epsilon} x}{1+\bar{\epsilon} y}\right)^{1-\gamma}\right)= \begin{cases}\frac{v(t, x)}{1-\gamma} & \text { if } x \geq \underline{y}(t) \\
\frac{v(t, \underline{y}(t))}{1-\gamma}\left(\frac{1+\bar{\epsilon} x}{1+\bar{\epsilon} \underline{y}(t)}\right)^{1-\gamma} & \text { if } x<\underline{y}(t)\end{cases}  \tag{4.6}\\
& \max _{y \in[0, x]}\left(\frac{v(t, y)}{1-\gamma}\left(\frac{1-\underline{\epsilon} x}{1-\underline{\epsilon} y}\right)^{1-\gamma}\right)= \begin{cases}\frac{v(t, x)}{1-\gamma} & \text { if } x \leq \bar{y}(t) \\
\frac{v(t, \bar{y}(t))}{1-\gamma}\left(\frac{1-\underline{\epsilon} x}{1-\underline{\bar{y}}(t)}\right)^{1-\gamma} & \text { if } x>\bar{y}(t)\end{cases}
\end{align*} .
$$

Since $\underline{y}(t) \leq \bar{y}(t)$, 4.5 and 4.6 imply

$$
\begin{align*}
& \max _{y \in[0,1]}\left(\frac{v(t, y)}{1-\gamma}\left(\left(\frac{1+\bar{\epsilon} x}{1+\bar{\epsilon} y}\right)^{1-\gamma} 1_{\{x \leq y\}}+\left(\frac{1-\underline{\epsilon} x}{1-\underline{\epsilon} y}\right)^{1-\gamma} 1_{\{x>y\}}\right)\right) \\
& = \begin{cases}\frac{v(t, \underline{y}(t))}{1-\gamma}\left(\frac{1+\bar{\epsilon} x}{1+\bar{\epsilon} \underline{y}(t)}\right)^{1-\gamma} & \text { if } x \in[0, \underline{y}(t)) \\
\frac{v(t, x)}{1-\gamma} & \text { if } x \in[\underline{y}(t), \bar{y}(t)] \\
\frac{v(t, \bar{y}(t))}{1-\gamma}\left(\frac{1-\epsilon x}{1-\underline{\epsilon} \bar{y}(t)}\right)^{1-\gamma} & \text { if } x \in(\bar{y}(t), 1]\end{cases} \tag{4.7}
\end{align*}
$$

and we conclude that the corresponding unique maximizer is as in 4.4.

Our next task is to provide stochastic representations of $v$ and $v_{x}$. One may apply the FeynmanKac formula to PDE (3.2) directly and obtain the stochastic representations. In that case, the representations are written in terms of a stochastic process which is not explicit.$^{3}$ More detailed analysis in the later section requires expressions for $v_{x x}, v_{x x x}, v_{x t}, v_{x x t}$, and it would be useful to obtain representations in terms of explicit stochastic processes. For this purpose, we define $A_{s, t}$, $Y_{s}^{(t, x)}$ and $Z_{s}^{(t, x)}$ for $x \in[0,1]$ and $0 \leq t \leq s \leq T$ as

$$
\begin{align*}
A_{s, t} & :=e^{\left(\mu-\frac{\sigma^{2}}{2}\right)(s-t)+\sigma\left(B_{s}-B_{t}\right)}>0, \\
Y_{s}^{(t, x)} & :=\frac{x A_{s, t}}{x A_{s, t}+1-x} \in[0,1],  \tag{4.8}\\
Z_{s}^{(t, x)} & :=\left(x A_{s, t}+1-x\right)^{1-\gamma}>0 .
\end{align*}
$$

Then we observe that

$$
\begin{equation*}
Z_{s}^{(t, x)}=\left(\frac{1-x}{1-Y_{s}^{(t, x)}}\right)^{1-\gamma} \quad \text { for } \quad x \in[0,1) \tag{4.9}
\end{equation*}
$$

and $A_{s, t}$ and $Y_{s}^{(t, x)}$ solve the following SDEs:

$$
\begin{align*}
d A_{s, t} & =\mu A_{s, t} d s+\sigma A_{s, t} d B_{s}, \quad A_{t, t}=1  \tag{4.10}\\
d Y_{s}^{(t, x)} & =Y_{s}^{(t, x)}\left(1-Y_{s}^{(t, x)}\right)\left(\mu-\sigma^{2} Y_{s}^{(t, x)}\right) d s+\sigma Y_{s}^{(t, x)}\left(1-Y_{s}^{(t, x)}\right) d B_{s}, \quad Y_{t}^{(t, x)}=x . \tag{4.11}
\end{align*}
$$

The following lemma is used to justify our later applications of the Leibniz integral rule.
Lemma 4.3. For nonnegative integers $n$ and $m$ and nonnegative constants $k$ and $l$,

$$
\begin{equation*}
\max _{0 \leq t \leq s \leq T} \mathbb{E}\left[\max _{0 \leq x \leq 1}\left(\left|\frac{\partial^{m} Z_{s}^{(t, x)}}{\partial x^{m}}\right|^{k} \cdot\left|\frac{\partial^{n} Y_{t}^{(t, x)}}{\partial x^{n}}\right|^{l}\right)\right]<\infty . \tag{4.12}
\end{equation*}
$$

Proof. For $n \in \mathbb{N}$, direct computations produce

$$
\begin{align*}
& \frac{\partial^{n} Y_{s}^{(t, x)}}{\partial x^{n}}=\frac{n!A_{s, t}\left(1-A_{s, t} t^{n-1}\right.}{\left(x A_{s, t}+1-x\right)^{n+1}}, \\
& \frac{\partial^{n} Z_{s}^{(t, x)}}{\partial x^{n}}=(1-\gamma)(-\gamma) \cdots(2-\gamma-n)\left(A_{s, t}-1\right)^{n}\left(x A_{s, t}+1-x\right)^{1-\gamma-n} . \tag{4.13}
\end{align*}
$$

Observe that

$$
\begin{align*}
(x A+1-x)^{c} & \leq 1+A^{c} \quad \text { for } \quad c \in \mathbb{R}, x \in[0,1], A>0 \\
|A-1|^{c} & \leq 1+A^{c} \quad \text { for } \quad c \geq 0, A>0,  \tag{4.14}\\
\mathbb{E}\left[A_{s, t}^{c}\right] & \leq \exp \left(\left(\left|c\left(\mu-\frac{\sigma^{2}}{2}\right)\right|+\frac{c^{2} \sigma^{2}}{2}\right) T\right) \quad \text { for } \quad c \in \mathbb{R}, 0 \leq t \leq s \leq T .
\end{align*}
$$

The expression in 4.13) and the inequalities in (4.14) produce 4.12).
Proposition 4.4. Let $A_{s, t}, Y_{s}^{(t, x)}$ and $Z_{s}^{(t, x)}$ be defined as in 4.8), and let $L(t, x)$ be defined by

$$
L(t, x):= \begin{cases}v(t, \underline{y}(t))\left(\frac{1+\bar{\epsilon} x}{1+\bar{\epsilon} \underline{y}(t)}\right)^{1-\gamma} & \text { if } x \in[0, \underline{y}(t)]  \tag{4.15}\\ v(t, x) & \text { if } x \in(\underline{y}(t), \bar{y}(t)), \\ v(t, \bar{y}(t))\left(\frac{1-\underline{\epsilon} x}{1-\bar{\epsilon} \bar{y}(t)}\right)^{1-\gamma} & \text { if } x \in[\bar{y}(t), 1]\end{cases}
$$

(i) For $(t, x) \in[0, T] \times[0,1]$, $v$ has the following representation:

$$
\begin{equation*}
v(t, x)=e^{-\lambda(T-t)} \mathbb{E}\left[Z_{T}^{(t, x)}\right]+\lambda \int_{t}^{T} e^{-\lambda(s-t)} \mathbb{E}\left[Z_{s}^{(t, x)} L\left(s, Y_{s}^{(t, x)}\right)\right] d s \tag{4.16}
\end{equation*}
$$

[^2](ii) For $(t, x) \in[0, T) \times(0,1)$, the function $L$ is continuously differentiable with respect to $x$ and
\[

L_{x}(t, x)= $$
\begin{cases}\frac{\bar{\epsilon}(1-\gamma) v(t, \underline{y}(t))}{1+\bar{\epsilon} x}\left(\frac{1+\bar{\epsilon} x}{1+\overline{\bar{\epsilon}} \underline{y}(t)}\right)^{1-\gamma} & \text { if } \quad x \in(0, \underline{y}(t)]  \tag{4.17}\\ v_{x}(t, x) & \text { if } \quad x \in(\underline{y}(t), \bar{y}(t)) \\ -\frac{\underline{\epsilon}(1-\gamma) v(t, \bar{y}(t))}{1-\underline{\epsilon} x}\left(\frac{1-\underline{\epsilon} x}{1-\underline{\bar{y}}(t)}\right)^{1-\gamma} & \text { if } \quad x \in[\bar{y}(t), 1)\end{cases}
$$
\]

For $(t, x) \in[0, T) \times(0,1), v_{x}(t, x)$ has the following representation:

$$
\begin{align*}
v_{x}(t, x)= & e^{-\lambda(T-t)} \mathbb{E}\left[\frac{\partial Z_{T}^{(t, x)}}{\partial x}\right] \\
& +\lambda \int_{t}^{T} e^{-\lambda(s-t)} \mathbb{E}\left[Z_{s}^{(t, x)} L_{x}\left(s, Y_{s}^{(t, x)}\right) \frac{\partial Y_{s}^{(t, x)}}{\partial x}+\frac{\partial Z_{s}^{(t, x)}}{\partial x} L\left(s, Y_{s}^{(t, x)}\right)\right] d s \tag{4.18}
\end{align*}
$$

Furthermore, $v_{x}(t, 0):=\lim _{x \downarrow 0} v_{x}(t, x)$ and $v_{x}(t, 1):=\lim _{x \uparrow 1} v_{x}(t, x)$ are well-defined and finite.
Proof. (i) We observe that 4.7) and 4.15 imply

$$
\begin{equation*}
L(t, x)=(1-\gamma) \sup _{y \in[0,1]}\left(\frac{v(t, y)}{1-\gamma}\left(\left(\frac{1+\bar{\epsilon} x}{1+\bar{\epsilon} y}\right)^{1-\gamma} 1_{\{y \in[x, 1]\}}+\left(\frac{1-\underline{\epsilon} x}{1-\underline{\epsilon} y}\right)^{1-\gamma} 1_{\{y \in[0, x)\}}\right)\right) \tag{4.19}
\end{equation*}
$$

Let $\tilde{v}(t, x):=e^{-\lambda t} \frac{v(t, x)}{(1-x)^{1-\gamma}}$ for $(t, x) \in[0, T] \times[0,1)$. Then, (3.2) and 4.19) imply

$$
\left\{\begin{array}{l}
0=\tilde{v}_{t}(t, x)+x(1-x)\left(\mu-\sigma^{2} x\right) \tilde{v}_{x}(t, x)+\frac{\sigma^{2}}{2} x^{2}(1-x)^{2} \tilde{v}_{x x}(t, x)+e^{-\lambda t} \frac{\lambda L(t, x)}{(1-x)^{1-\gamma}},  \tag{4.20}\\
\frac{e^{-\lambda T}}{(1-x)^{1-\gamma}}=\tilde{v}(T, x)
\end{array}\right.
$$

Let $x \in[0,1)$ fixed. We apply Ito's formula to $\tilde{v}\left(s, Y_{s}^{(t, x)}\right)$ and use 4.20) and 4.11) to produce

$$
\begin{equation*}
\frac{e^{-\lambda T}}{\left(1-Y_{T}^{(t, x)}\right)^{1-\gamma}}+\int_{t}^{T} \frac{\lambda e^{-\lambda s} L\left(s, Y_{s}^{(t, x)}\right)}{\left(1-Y_{s}^{(t, x)}\right)^{1-\gamma}} d s=\tilde{v}(t, x)+\int_{t}^{T} \sigma\left(1-Y_{s}^{(t, x)}\right) Y_{s}^{(t, x)} \tilde{v}_{x}\left(s, Y_{s}^{(t, x)}\right) d B_{s} \tag{4.21}
\end{equation*}
$$

Observe that the expectation of the stochastic integral term above is zero, because

$$
\begin{aligned}
& \mathbb{E}\left[\int_{t}^{T}\left(\left(1-Y_{s}^{(t, x)}\right) Y_{s}^{(t, x)} \tilde{v}_{x}\left(s, Y_{s}^{(t, x)}\right)\right)^{2} d s\right] \\
& =\int_{t}^{T} \mathbb{E}\left[\left(e^{-\lambda s} \cdot \frac{\left(1-Y_{s}^{(t, x)}\right) Y_{s}^{(t, x)} Z_{s}^{(t, x)} v_{x}\left(s, Y_{s}^{(t, x)}\right)+(1-\gamma) Y_{s}^{(t, x)} Z_{s}^{(t, x)} v\left(s, Y_{s}^{(t, x)}\right)}{(1-x)^{1-\gamma}}\right)^{2}\right] d s<\infty
\end{aligned}
$$

where the equality is due to the definition of $\tilde{v}$ and 4.9 , and the inequality is due to Lemma 3.1 (iii) and Lemma 4.3. Therefore, 4.21 and 4.9) produce (4.16) for $(t, x) \in[0, T] \times[0,1)$. Since $v \in C([0, T] \times[0,1])$, to complete the proof, it is enough to check that

$$
\begin{aligned}
& \lim _{x \uparrow 1}\left(e^{-\lambda(T-t)} \mathbb{E}\left[Z_{T}^{(t, x)}\right]+\lambda \int_{t}^{T} e^{-\lambda(s-t)} \mathbb{E}\left[Z_{s}^{(t, x)} L\left(s, Y_{s}^{(t, x)}\right)\right] d s\right) \\
& \quad=e^{-\lambda(T-t)} \mathbb{E}\left[Z_{T}^{(t, 1)}\right]+\lambda \int_{t}^{T} e^{-\lambda(s-t)} \mathbb{E}\left[Z_{s}^{(t, 1)} L\left(s, Y_{s}^{(t, 1)}\right)\right] d s
\end{aligned}
$$

Indeed, Lemma 4.3 and $\|L\|_{\infty}<\infty$ allow us to apply the dominated convergence theorem above.
(ii) We differentiate 4.15 with respect to $x$ and obtain 4.17) for $x \in(0,1) \backslash\{\underline{y}(t), \bar{y}(t)\}$, and the continuity at $x \in\{\underline{y}(t), \bar{y}(t)\}$ is due to Lemma 4.1. By Lemma 4.1 (iii) and (3.18),

$$
\begin{equation*}
\left.\left\|L_{x}\right\|_{\infty} \leq \overline{C(\bar{\epsilon}}+\underline{\epsilon}\right) \tag{4.22}
\end{equation*}
$$

for a constant $C>0$. We take derivative with respect to $x$ in 4.16), and put the derivative inside of the expectation (Lemma 4.3, $\|L\|_{\infty}<\infty$, and (4.22) allow us to do this) to obtain (4.18).

Figure 1. The graph shows $\underline{y}(t)$ and $\bar{y}(t)$ as functions of $t$. The dashed orange line is the Merton fraction $y_{M}=\frac{\mu}{\gamma \sigma^{2}}$. The parameters are $\mu=0.2, \sigma=1, \gamma=0.9, \lambda=3, \underline{\epsilon}=\bar{\epsilon}=0.05$ and $T=1$.

Finally, $\lim _{x \downarrow 0} v_{x}(t, x)$ and $\lim _{x \uparrow 1} v_{x}(t, x)$ are well-defined because $x \mapsto \frac{v(t, x)}{1-\gamma}$ is strictly concave by Lemma 3.3 (i), and these limits are finite due to Lemma 4.3, $\|L\|_{\infty}<\infty$ and (4.22).

The next proposition presents properties about the boundaries of the no-trade region.
Proposition 4.5. Recall that we denote the Merton fraction as $y_{M}:=\frac{\mu}{\gamma \sigma^{2}}$.
(i) Let $t \in[0, T)$. If $0<y_{M}$, then $\bar{y}(t)>0$. If $y_{M}<1$, then $y(t)<1$.
(ii) If $0<y_{M}<1$ and at least one of $\bar{\epsilon}$ and $\underline{\epsilon}$ is strictly positive, then $\underline{y}(t)<\bar{y}(t)$ for $t \in[0, T)$.
(iii) If $0<y_{M}$ and $\underline{t} \in[0, T]$ is the solution of the equation (if a solution doesn't exist, we set $\underline{t}=0$ )

$$
\begin{equation*}
\bar{\epsilon} e^{\mu T}=\mu(1+\bar{\epsilon}) \int_{\underline{t}}^{T} e^{(\mu+\lambda) s}\left(e^{-\lambda T}+\lambda \int_{s}^{T} e^{-\lambda u} \frac{v(u, \underline{y}(u))}{(1+\bar{\epsilon} \underline{y}(u))^{1-\gamma}} d u\right) d s \tag{4.23}
\end{equation*}
$$

then $\underline{y}(t)>0$ for $t \in[0, \underline{t})$ and $\underline{y}(t)=0$ for $t \in[\underline{t}, T)$.
If $y_{M}<1$ and $\bar{t} \in[0, T]$ is the solution of the equation (if a solution doesn't exist, we set $\bar{t}=0$ )

$$
\underline{\epsilon}=\left(\gamma \sigma^{2}-\mu\right) \int_{\bar{t}}^{T} e^{\left(\gamma \mu-\frac{\gamma(1+\gamma) \sigma^{2}}{2}\right)(T-s)}\left(e^{-\beta(T-s)}+\lambda \int_{s}^{T} e^{-\beta(u-s)} v(u, \bar{y}(u))\left(\frac{1-\epsilon}{1-\underline{\epsilon} \bar{y}(u)}\right)^{1-\gamma} d u\right) d s
$$

where $\beta:=\lambda-(1-\gamma) \mu+\frac{\gamma(1-\gamma) \sigma^{2}}{2}$, then $\bar{y}(t)<1$ for $t \in[0, \bar{t})$ and $\bar{y}(t)=1$ for $t \in[\bar{t}, T)$.
Figure 1 illustrates the no-trade region and $\bar{t}$ and $\underline{t}$ in Proposition 4.5.
Proof. (i) Assume that $0<y_{M}\left(y_{M}<1\right.$ case can be treated similarly). Lemma 4.1 implies that

$$
\begin{equation*}
\frac{v_{x}(t, 0)}{1-\gamma}+\underline{\epsilon} v(t, 0)>0 \Longleftrightarrow \bar{y}(t)>0 . \tag{4.24}
\end{equation*}
$$

The expressions of $Y_{s}^{(t, x)}$ and $Z_{s}^{(t, x)}$ in 4.8, $L$ in 4.15) and $L_{x}$ in 4.17) imply

$$
\begin{aligned}
& \lim _{x \downarrow 0} Y_{s}^{(t, x)}=0, \quad \lim _{x \downarrow 0} \frac{\partial Y_{s}^{(t, x)}}{\partial x}=A_{s, t}, \quad \lim _{x \downarrow 0} Z_{s}^{(t, x)}=1, \quad \lim _{x \downarrow 0} \frac{\partial Z_{s}^{(t, x)}}{\partial x}=(1-\gamma)\left(A_{s, t}-1\right), \\
& \lim _{x \downarrow 0} L(t, x)=\frac{v(t, \underline{y}(t))}{\left(1+\bar{\epsilon} \underline{(t))^{1-\gamma}} 1_{\{\underline{y}(t)>0\}}+v(t, 0) 1_{\{\underline{y}(t)=0\}},\right.} \\
& L_{x}(t, 0):=\lim _{x \downarrow 0} L_{x}(t, x)=\frac{\bar{\epsilon}(1-\gamma) v(t, y(t))}{(1+\bar{\epsilon} \underline{y}(t))^{1-\gamma}} 1_{\{\underline{y}(t)>0\}}+v_{x}(t, 0) 1_{\{\underline{y}(t)=0<\bar{y}(t)\}}-\underline{\epsilon}(1-\gamma) v(t, 0) 1_{\{\bar{y}(t)=0\}},
\end{aligned}
$$

where we use $v_{x}(t, 0):=\lim _{x \downarrow 0} v_{x}(t, x)$ in Proposition 4.4 (ii). $v>0$ and (4.24) imply

$$
\begin{equation*}
L(t, 0) \geq v(t, 0) 1_{\{\underline{y}(t)=0\}}, \quad \frac{L_{x}(t, 0)}{1-\gamma} \geq-\underline{\epsilon} v(t, 0) 1_{\{\underline{y}(t)=0\}} . \tag{4.25}
\end{equation*}
$$

We take limit $x \downarrow 0$ in 4.16) and (4.18) and apply the dominated convergence theorem (justified by Lemma 4.3) to obtain

$$
\begin{aligned}
\frac{v_{x}(t, 0)}{1-\gamma}+\underline{\epsilon} v(t, 0) & =e^{-\lambda(T-t)} \mathbb{E}\left[A_{T, t}-1+\underline{\epsilon}\right]+\lambda \int_{t}^{T} e^{-\lambda(s-t)}\left(\frac{\mathbb{E}\left[A_{s, t}\right] L_{x}(s, 0)}{1-\gamma}+\mathbb{E}\left[A_{s, t}-1+\underline{\epsilon}\right] L(s, 0)\right) d s \\
& \geq e^{-\lambda(T-t)}\left(e^{\mu(T-t)}-1+\underline{\epsilon}\right)+\lambda \int_{t}^{T} e^{-\lambda(s-t)}\left(e^{\mu(s-t)}-1\right)(1-\underline{\epsilon}) v(s, 0) 1_{\{\underline{y}(s)=0\}} d s \\
& >0
\end{aligned}
$$

where the inequalities are due to (4.25), $v>0$ and $\mu>0$ (implied by $y_{M}>0$ ). Therefore, by (4.24) and the above inequality, we conclude that $\bar{y}(t)>0$.
(ii) Suppose that $0<y_{M}<1$ and at least one of $\bar{\epsilon}$ and $\underline{\epsilon}$ is strictly positive. By part (i) result, we have $\underline{y}(t)<1$ and $\bar{y}(t)>0$. In case $\underline{y}(t)=0$ or $\bar{y}(t)=1$, then $\underline{y}(t)<\bar{y}(t)$. Therefore, it remains to consider the case that $0<\underline{y}(t) \leq \bar{y}(t)<1$. By Lemma 4.1 and $v>0$, we have

$$
\begin{equation*}
\frac{v_{x}(t, y(t))}{1-\gamma}=\frac{\bar{\epsilon} v(t, y(t))}{1+\bar{\epsilon} \underline{\bar{y}}(t)}>-\frac{\epsilon v(t, \bar{y}(t))}{1-\epsilon \overline{\bar{y}}(t)}=\frac{v_{x}(t, \bar{y}(t))}{1-\gamma} . \tag{4.26}
\end{equation*}
$$

The above inequality and the strict concavity of $x \mapsto \frac{v(t, x)}{1-\gamma}$ in Lemma 3.3 imply $\underline{y}(t)<\bar{y}(t)$.
(iii) Assume that $0<y_{M}$ ( $y_{M}<1$ case can be treated similarly). Lemma 4.1 implies that

$$
\begin{equation*}
\frac{v_{x}(t, 0)}{1-\gamma}-\bar{\epsilon} v(t, 0)>0 \Longleftrightarrow \underline{y}(t)>0 . \tag{4.27}
\end{equation*}
$$

By the same way as in the proof of part (i), we take limit $x \downarrow 0$ in 4.16) and 4.18) and obtain

$$
\begin{align*}
\frac{v_{x}(t, 0)}{1-\gamma}-\bar{\epsilon} v(t, 0)= & e^{-\lambda(T-t)} \mathbb{E}\left[A_{T, t}-1-\bar{\epsilon}\right]+\lambda \int_{t}^{T} e^{-\lambda(s-t)}\left(\frac{\mathbb{E}\left[A _ { s , t } \left[L_{x}(s, 0)\right.\right.}{1-\gamma}+\mathbb{E}\left[A_{s, t}-1-\bar{\epsilon}\right] L(s, 0)\right) d s \\
= & e^{-\lambda(T-t)}\left(e^{\mu(T-t)}-1-\bar{\epsilon}\right)+\lambda \int_{t}^{T} e^{-\lambda(s-t)}\left(e^{\mu(s-t)}-1\right)(1+\bar{\epsilon}) \frac{v(s, \underline{y}(s))}{(1+\bar{\epsilon} \underline{y}(s))^{1-\gamma}} d s \\
& \quad+\lambda \int_{t}^{T} e^{-\lambda(s-t)} e^{\mu(s-t)}\left(\frac{v_{x}(s, 0)}{1-\gamma}-\bar{\epsilon} v(s, 0)\right) 1_{\{\underline{y(s)=0\}}} d s, \tag{4.28}
\end{align*}
$$

where the second equality is due to $\bar{y}(t)>0$ by part (i). Let $f, g:[0, T] \rightarrow \mathbb{R}$ be defined as

$$
f(t):=e^{-\lambda t}\left(\frac{v_{x}(t, 0)}{1-\gamma}-\bar{\epsilon} v(t, 0)\right), \quad g(t):=\lambda e^{-\lambda t} \frac{v(t, y(t))}{(1+\bar{\epsilon} \underline{y}(t))^{1-\gamma}} .
$$

Then, we can rewrite (4.28) as

$$
f(t)=e^{-\lambda T}\left(e^{\mu(T-t)}-1-\bar{\epsilon}\right)+(1+\bar{\epsilon}) \int_{t}^{T}\left(e^{\mu(s-t)}-1\right) g(s) d s+\lambda \int_{t}^{T} e^{\mu(s-t)} f(s) 1_{\{f(s) \leq 0\}} d s
$$

where we use the equivalence of $f(t) \leq 0$ and $\underline{y}(t)=0$ by 4.27). We differentiate above to obtain

$$
\begin{equation*}
f^{\prime}(t)=-\mu\left(f(t)+(1+\bar{\epsilon})\left(e^{-\lambda T}+\int_{t}^{T} g(s) d s\right)\right)-\lambda f(t) 1_{\{f(t) \leq 0\}} \tag{4.29}
\end{equation*}
$$

We define $\underline{t}$ as

$$
\begin{equation*}
\underline{t}:=\inf \{t \in[0, T]: f(s) \leq 0 \text { for all } s \in[t, T]\}, \tag{4.30}
\end{equation*}
$$

then the set in 4.30) is non-empty because $f(T)=-\bar{\epsilon} e^{-\lambda T} \leq 0$. Since $\mu>0$ (due to $y_{\infty}>0$ ) and $g>0$, the form of ODE (4.29) and definition of $\underline{t}$ above imply $f(t)>0$ for $t \in[0, \underline{t})$. This
observation and (4.27) imply $\underline{y}(t)>0$ for $t \in[0, \underline{t})$ and $\underline{y}(t)=0$ for $t \in[\underline{t}, T)$. To determine $\underline{t}$, it is enough to observe that the solution of ODE 4.29) for $t \in[\underline{t}, T)$ is

$$
\begin{equation*}
e^{(\mu+\lambda) t} f(t)=\mu(1+\bar{\epsilon}) \int_{t}^{T} e^{(\mu+\lambda) s}\left(e^{-\lambda T}+\int_{s}^{T} g(u) d u\right) d s-\bar{\epsilon} e^{\mu T} \tag{4.31}
\end{equation*}
$$

If there is no solution to (4.23), then $f(t)>0$ for $t \in[0, T)$ and $\underline{t}=0$. If there is a solution to (4.23), then such a solution should be unique and $f(\underline{t})=0$.

## 5. Asymptotic Results

In this section, we provide asymptotic results to analyze the utility maximization problem when both transaction costs and search frictions are small. For convenience, we assume throughout this section that $\bar{\epsilon}=\underline{\epsilon}=: \epsilon \in(0,1)$ and $0<y_{M}<1$. We focus on the asymptotics of the no-trade region and the value function as $\epsilon \downarrow 0$ and $\lambda \rightarrow \infty$ simultaneously, and then compare these results with the already-known asymptotic results in the benchmark cases of transaction costs only $(\lambda=\infty)$ and search frictions only $(\epsilon=0)$.

Our heuristic inspection using the results in [21] implies that the limits as $\epsilon \downarrow 0$ and $\lambda \rightarrow \infty$ simultaneously do not exist in general. It turns out that a specific scaling relation $\lambda=c \epsilon^{-\frac{2}{3}}$ for $c>0$ is relevant to consider, as explained below. For the $\log$ utility and fixed $\lambda<\infty$, Section 5 in 21] provides asymptotic results as $\epsilon \downarrow 0$. According to Proposition 5.5 and Proposition 5.7 in [21], one can check the following limits:

$$
\begin{align*}
& \lim _{\lambda \rightarrow \infty}\left(\lim _{\epsilon \downarrow 0} \frac{\text { "no-trade region width" }}{\lambda \epsilon}\right)=\frac{2}{\sigma^{2}} \neq 0=\lim _{\epsilon \downarrow 0}\left(\lim _{\lambda \rightarrow \infty} \frac{\text { "no-trade region width" }}{\lambda \epsilon}\right) \\
& \lim _{\lambda \rightarrow \infty}\left(\lim _{\epsilon \downarrow 0} \frac{\text { "decrease of value" }}{\sqrt{\lambda} \epsilon}\right)=\frac{\sigma y_{M}\left(1-y_{M}\right)(T-t)}{\sqrt{2}} \neq 0=\lim _{\epsilon \downarrow 0}\left(\lim _{\lambda \rightarrow \infty} \frac{\text { "decrease of value" }}{\sqrt{\lambda} \epsilon}\right) . \tag{5.1}
\end{align*}
$$

Therefore, $\lim _{\epsilon \downarrow 0, \lambda \rightarrow \infty} \frac{\text { "no-trade region width" }}{\lambda \epsilon}$ and $\lim _{\epsilon \downarrow 0, \lambda \rightarrow \infty} \frac{\text { "decrease of value" }}{\sqrt{\lambda} \epsilon}$ do not exist in general. On the other hand, it is well known in the literature (see [28, [25, 10, 6]) that in the case of transaction costs only $(\lambda=\infty)$, the asymptotics are as follows:

$$
\begin{equation*}
\text { "no-trade region width" }=O\left(\epsilon^{\frac{1}{3}}\right), \quad \text { "decrease of value" }=O\left(\epsilon^{\frac{2}{3}}\right) \tag{5.2}
\end{equation*}
$$

In the case of search frictions only $\left(\epsilon=0\right.$, see [34, 35]), the decrease of value is $O\left(\frac{1}{\lambda}\right)$ and the width of the no-trade region is zero. We combine this observation with (5.1) and (5.2) and attempt to match the orders. We naturally conjecture that a suitable relation between $\epsilon$ and $\lambda$ for the asymptotics would satisfy

$$
\begin{equation*}
\lambda \epsilon \sim \epsilon^{\frac{1}{3}} \quad \text { and } \quad \sqrt{\lambda} \epsilon \sim \epsilon^{\frac{2}{3}} \sim \frac{1}{\lambda} \quad \Longrightarrow \quad \lambda \sim \epsilon^{-\frac{2}{3}} \tag{5.3}
\end{equation*}
$$

Motivated by the above discussion, we make the following assumption, which holds throughout this section.
Assumption 5.1. (i) For $c>0$ and $\epsilon \in(0,1), \bar{\epsilon}=\underline{\epsilon}=\epsilon$ and $\lambda=c \epsilon^{-\frac{2}{3}}$. (ii) $y_{M} \in(0,1)$.

## Notation 5.2.

(i) Under Assumption 5.1, to emphasize their dependence on $\epsilon \in(0,1)$ (with $\lambda$ dependence through the relation $\lambda=c \epsilon^{-\frac{2}{3}}$, we denote $v, v_{x}, v_{x x}, v_{t}, \underline{y}, \bar{y}, L, L_{x}$, etc. by $v^{\epsilon}, v_{x}^{\epsilon}, v_{x x}^{\epsilon}, v_{t}^{\epsilon}, \underline{y}^{\epsilon}, \bar{y}^{\epsilon}, L^{\epsilon}, L_{x}^{\epsilon}$, etc. (ii) The case of the perfectly liquid market ( $\epsilon=\overline{0}$ and $\lambda=\infty$ ) corresponds to the classical Merton problem, and we denote the value function and optimal fraction as $v^{0}$ and $y_{M}$.
(iii) In the case of search frictions only (no transaction costs, $\epsilon=0$ ), we denote the value function and optimal fraction as $v^{S O, \lambda}$ and $\hat{y}^{S O, \lambda}$ to emphasize their dependence on $\lambda$.
(iv) In the case transaction costs only (no search frictions, $\lambda=\infty$ ), we denote the value function and the no-trade boundaries as $v^{T O, \epsilon}, \bar{y}^{T O, \epsilon}$ and $\underline{y}^{T O, \epsilon}$ to emphasize their dependence on $\epsilon$.

As benchmarks for our asymptotic results, we present the asymptotic results for the cases of transaction costs only (see [6]) and search frictions only (see [34, 35]).

- In the case where there are no transaction costs or search frictions $(\epsilon=0$ and $\lambda=\infty)$, the utility maximization problem becomes the classical Merton problem [36, 37]. The explicit formula and HJB equation for the corresponding value function $v^{0}$ are:

$$
v^{0}(t)=e^{Q\left(y_{M}\right)(T-t)}, \quad\left\{\begin{array}{l}
v_{t}^{0}(t)+Q\left(y_{M}\right) v^{0}(t)=0  \tag{5.4}\\
v^{0}(T)=1
\end{array}\right.
$$

- In the case where there are transaction costs only $(\epsilon \in(0,1)$ and $\lambda=\infty)$, the utility maximization problem becomes the problem investigated in [6]. The asymptotic results are as follows:

$$
\begin{align*}
\bar{y}^{T O, \epsilon}(t) & =y_{M}+\frac{1}{2}\left(\frac{12 y_{M}^{2}\left(1-y_{M}\right)^{2}}{\gamma}\right)^{\frac{1}{3}} \cdot \epsilon^{\frac{1}{3}}+o\left(\epsilon^{\frac{1}{3}}\right) \\
\underline{y}^{T O, \epsilon}(t) & =y_{M}-\frac{1}{2}\left(\frac{12 y_{M}^{2}\left(1-y_{M}\right)^{2}}{\gamma}\right)^{\frac{1}{3}} \cdot \epsilon^{\frac{1}{3}}+o\left(\epsilon^{\frac{1}{3}}\right)  \tag{5.5}\\
v^{T O, \epsilon}\left(t, y_{M}\right) & =v^{0}(t)-\frac{(1-\gamma) \gamma \sigma^{2}}{8}\left(\frac{12 y_{M}^{2}\left(1-y_{M}\right)^{2}}{\gamma}\right)^{\frac{2}{3}} v^{0}(t)(T-t) \cdot \epsilon^{\frac{2}{3}}+o\left(\epsilon^{\frac{2}{3}}\right) .
\end{align*}
$$

- In the case where there are search frictions only $(\epsilon=0$ and $\lambda<\infty)$, the utility maximization problem becomes the problem investigated in 34]. The asymptotic results are as follows:

$$
\begin{align*}
\hat{y}^{S O, \lambda}(t) & =y_{M}+\sigma^{2} y_{M}\left(1-y_{M}\right)\left(2 y_{M}-1\right) \cdot \frac{1}{\lambda}+o\left(\frac{1}{\lambda}\right) \\
v^{S O, \lambda}\left(t, y_{M}\right) & =v^{0}(t)-\frac{(1-\gamma) \gamma \sigma^{4} y_{M}^{2}\left(1-y_{M}\right)^{2}}{2} v^{0}(t)(T-t) \cdot \frac{1}{\lambda}+o\left(\frac{1}{\lambda}\right) \tag{5.6}
\end{align*}
$$

Notice that the no-trade region vanishes in this case, $y^{S O, \lambda}(t)=\bar{y}^{S O, \lambda}(t)=\underline{y}^{S O, \lambda}(t)$.
The following theorem is the main result of this paper. Along the parametric curve $\lambda=c \epsilon^{-\frac{2}{3}}$ (see the discussion for 5.5 ), the boundaries of the no-trade region and the value function have asymptotic expansions in terms of $\epsilon^{\frac{1}{3}}$ and $\epsilon^{\frac{2}{3}}$, respectively.

Theorem 5.3. Let Assumption 5.1 hold and $a_{1}, a_{2}:(0, \infty) \rightarrow(0, \infty)$ be defined as

$$
\begin{align*}
& a_{1}(c):=\frac{\sigma y_{M}\left(1-y_{M}\right)}{\sqrt{2 c}}\left(\left(\frac{3 \sqrt{2} c^{\frac{3}{2}}}{\gamma \sigma^{3} y_{M}\left(1-y_{M}\right)}+1\right)^{\frac{1}{3}}-1\right) \\
& a_{2}(c):=\frac{\gamma(1-\gamma) \sigma^{4} y_{M}^{2}\left(1-y_{M}\right)^{2}}{4 c}\left(\left(\frac{3 \sqrt{2} c^{\frac{3}{2}}}{\gamma \sigma^{3} y_{M}\left(1-y_{M}\right)}+1\right)^{\frac{2}{3}}+1\right) . \tag{5.7}
\end{align*}
$$

Then, for $t \in[0, T)$,

$$
\begin{aligned}
\bar{y}^{\epsilon}(t) & =y_{M}+a_{1}(c) \cdot \epsilon^{\frac{1}{3}}+o\left(\epsilon^{\frac{1}{3}}\right) \\
\underline{y}^{\epsilon}(t) & =y_{M}-a_{1}(c) \cdot \epsilon^{\frac{1}{3}}+o\left(\epsilon^{\frac{1}{3}}\right) \\
v^{\epsilon}\left(t, y_{M}\right) & =v^{0}(t)-a_{2}(c) v^{0}(t)(T-t) \cdot \epsilon^{\frac{2}{3}}+o\left(\epsilon^{\frac{2}{3}}\right)
\end{aligned}
$$

Alternatively, due to the relation $\lambda=c \epsilon^{-\frac{2}{3}}$, the above asymptotics can be written in terms of $\lambda$ :

$$
\bar{y}^{\epsilon}(t)=y_{M}+\sqrt{c} a_{1}(c) \cdot \frac{1}{\sqrt{\lambda}}+o\left(\frac{1}{\sqrt{\lambda}}\right)
$$

Figure 2. The graphs describe "width of the no-trade region" and "value decrease" as functions of $\epsilon$ along the parametric curve $\lambda=c \epsilon^{-\frac{2}{3}}$, where the dashed orange lines are their approximations $2 a_{1}(c) \cdot \epsilon^{\frac{1}{3}}$ and $\frac{a_{2}(c) v^{0}(t)(T-t)}{1-\gamma} \cdot \epsilon^{\frac{2}{3}}$ in Theorem 5.3 The parameters are $c=1, \mu=0.2, \sigma=1, \gamma=0.9, t=0.75$ and $T=1$.

Figure 3. Graphs of $a_{1}(c), a_{2}(c), \sqrt{c} a_{1}(c)$ and $c a_{2}(c)$. The parameters are $\mu=0.2, \sigma=1$ and $\gamma=0.9$.

$$
\begin{aligned}
\underline{y}^{\epsilon}(t) & =y_{M}-\sqrt{c} a_{1}(c) \cdot \frac{1}{\sqrt{\lambda}}+o\left(\frac{1}{\sqrt{\lambda}}\right) \\
v^{\epsilon}\left(t, y_{M}\right) & =v^{0}(t)-c a_{2}(c) v^{0}(t)(T-t) \cdot \frac{1}{\lambda}+o\left(\frac{1}{\lambda}\right)
\end{aligned}
$$

The proof of the theorem is postponed to Section 6. One of the main difficulties in the analysis is the rigorous treatment of subtle limiting behaviors that do not appear in the benchmark cases. For example, $\lim _{\epsilon \downarrow 0} v_{x x}^{\epsilon}(t, x) / \epsilon^{\frac{2}{3}}$ depends on the choice of $x \in\left[\underline{y}^{\epsilon}(t), \bar{y}^{\epsilon}(t)\right]$ in our model, whereas $\lim _{\epsilon \downarrow 0} v_{x x}^{T O, \epsilon}(t, x) / \epsilon^{\frac{2}{3}}=0$ for $x \in\left[\underline{y}^{\epsilon}(t), \bar{y}^{\epsilon}(t)\right]$. We present Lemma 6.3 and Lemma 6.4 to address these subtle limiting behaviors.

Figure 2 illustrates the asymptotics in Theorem 5.3, and Figure 3 shows how the coefficients in the asymptotics depend on $c$. We notice that these functions are monotonic in $c$.

From (5.7), direct computations using L'Hopital's rule produce the following limits:

$$
\begin{equation*}
\lim _{c \rightarrow \infty} a_{1}(c)=\frac{1}{2}\left(\frac{12 y_{M}^{2}\left(1-y_{M}\right)^{2}}{\gamma}\right)^{\frac{1}{3}}, \quad \lim _{c \rightarrow \infty} a_{2}(c)=\frac{(1-\gamma) \gamma \sigma^{2}}{8}\left(\frac{12 y_{M}^{2}\left(1-y_{M}\right)^{2}}{\gamma}\right)^{\frac{2}{3}}, \tag{5.8}
\end{equation*}
$$

$$
\begin{equation*}
\lim _{c \rightarrow 0} \sqrt{c} a_{1}(c)=0, \quad \lim _{c \rightarrow 0} c a_{2}(c)=\frac{(1-\gamma) \gamma \sigma^{4} y_{M}^{2}\left(1-y_{M}\right)^{2}}{2} \tag{5.9}
\end{equation*}
$$

Using the above limits, we can rephrase (5.5) and (5.6) to clarify the connection of our asypmtotics in Theorem 5.3 with the benchmark asymptotic results:

$$
\begin{align*}
\bar{y}^{T O, \epsilon}(t) & =y_{M}+\left(\lim _{c \rightarrow \infty} a_{1}(c)\right) \cdot \epsilon^{\frac{1}{3}}+o\left(\epsilon^{\frac{1}{3}}\right) \\
\underline{y}^{T O, \epsilon}(t) & =y_{M}-\left(\lim _{c \rightarrow \infty} a_{1}(c)\right) \cdot \epsilon^{\frac{1}{3}}+o\left(\epsilon^{\frac{1}{3}}\right) \\
v^{T O, \epsilon}\left(t, y_{M}\right) & =v^{0}(t)-\left(\lim _{c \rightarrow \infty} a_{2}(c)\right) v^{0}(t)(T-t) \cdot \epsilon^{\frac{2}{3}}+o\left(\epsilon^{\frac{2}{3}}\right)  \tag{5.10}\\
\hat{y}^{S O, \lambda}(t) & =y_{M}+\left(\lim _{c \rightarrow 0} \sqrt{c} a_{1}(c)\right) \cdot \frac{1}{\sqrt{\lambda}}+o\left(\frac{1}{\sqrt{\lambda}}\right), \quad\left(\because \lim _{c \rightarrow 0} \sqrt{c} a_{1}(c)=0\right) \\
v^{S O, \lambda}\left(t, y_{M}\right) & =v^{0}(t)-\left(\lim _{c \rightarrow 0} c a_{2}(c)\right) v^{0}(t)(T-t) \cdot \frac{1}{\lambda}+o\left(\frac{1}{\lambda}\right)
\end{align*}
$$

Indeed, Theorem 5.3 bridges the benchmark asymptotics in 5.5 and (5.6) through the parametric relation $\lambda=c \epsilon^{-\frac{2}{3}}$, where the case $c=\infty$ corresponds to 5.5 and the case $c=0$ corresponds to (5.6). In this sense, our approach of using $\lambda=c \epsilon^{-\frac{2}{3}}$ unifies the asymptotics for transaction costs and search frictions.

Section 5 in [21] contains asymptotics for $\epsilon$, which differ from Theorem 5.3. we let $\epsilon \downarrow 0$ and $\lambda \rightarrow \infty$ at the same time through the relation $\lambda=c \epsilon^{-\frac{2}{3}}$ in Theorem 5.3, whereas $\lambda$ is fixed in Theorem 5.4 and Theorem 5.6 in [21]. It is also worth noting that the correction terms in Theorem 5.4 and Theorem 5.6 in 21 are not explicit (in terms of solutions of some PDEs), whereas $a_{1}(c)$ and $a_{2}(c)$ in Theorem 5.3 are explicit in terms of the model parameters. Therefore, given model parameters $\mu, \sigma, \gamma, \lambda, \epsilon$, one can compute the auxiliary parameter $c=\lambda \epsilon^{\frac{2}{3}}$ and use the formulas in Theorem 5.3 to estimate the optimal trading strategy and value.

## 6. Proof of Theorem 5.3

We prove Theorem 5.3 in this section, starting with some technical lemmas. We use Notation 5.2 , Under Assumption 5.1, by Proposition 4.5, there are $\underline{t}^{\epsilon}, \bar{t}^{\epsilon} \in[0, T)$ such that

$$
\left\{\begin{array}{lll}
0<\underline{y}^{\epsilon}(t)<1 & \text { if } & t \in\left[0, \underline{t}^{\epsilon}\right)  \tag{6.1}\\
\underline{y}^{\epsilon}(t)=0 & \text { if } & t \in\left[\underline{t}^{\epsilon}, T\right)
\end{array}, \quad \begin{cases}0<\bar{y}^{\epsilon}(t)<1 & \text { if } \quad t \in\left[0, \bar{t}^{\epsilon}\right) \\
\bar{y}^{\epsilon}(t)=1 & \text { if } \quad t \in\left[\bar{t}^{\epsilon}, T\right)\end{cases}\right.
$$

The following lemma estimates the location of $\underline{t}^{\epsilon}$ and $\bar{t}^{\epsilon}$.
Lemma 6.1. Let Assumption 5.1 hold. Then, there are $\epsilon_{0}>0$ and $\bar{C}>\underline{C}>0$ such that

$$
\underline{t}^{\epsilon}, \bar{t}^{\epsilon} \in[T-\bar{C} \epsilon, T-\underline{C} \epsilon] \quad \text { for } \quad \epsilon \in\left(0, \epsilon_{0}\right]
$$

Proof. We prove the inequalities for $\underline{t}^{\epsilon}\left(\bar{t}^{\epsilon}\right.$ can be treated by the same way). Considering the lower bound of $v^{\epsilon}$ in (3.18), for small enough $\epsilon$, there exists $\underline{t}^{\epsilon} \in[0, T)$ that satisfies (4.23). Hence,

$$
\begin{aligned}
\epsilon e^{\mu T} & =\mu(1+\epsilon) \int_{\underline{t}^{\epsilon}}^{T} e^{(\mu+\lambda) s}\left(e^{-\lambda T}+\lambda \int_{s}^{T} e^{\left.-\lambda u \frac{v^{\epsilon}\left(u, \underline{y}^{\epsilon}(u)\right)}{\left(1+\epsilon \underline{y}^{\epsilon}(u)\right)^{1-\gamma}} d u\right) d s}\right. \\
& \leq C \mu(1+\epsilon) \int_{\underline{t}^{\epsilon}}^{T} e^{(\mu+\lambda) s}\left(e^{-\lambda T}+\lambda \int_{s}^{T} e^{-\lambda u} d u\right) d s=C(1+\epsilon)\left(e^{\mu T}-e^{\mu \underline{t}^{\epsilon}}\right)
\end{aligned}
$$

where $C>0$ is a constant independent of $\epsilon$. This implies that there exists $\epsilon_{0}>0$ such that

$$
\underline{t}^{\epsilon} \leq T+\frac{1}{\mu} \ln \left(1-\frac{\epsilon}{C(1+\epsilon)}\right) \leq T-\bar{C} \epsilon \quad \text { for } \quad \epsilon \in\left(0, \epsilon_{0}\right]
$$

where $\bar{C}>0$ is a constant independent of $\epsilon$ and the second inequality is due to $\lim _{x \downarrow 0} \frac{\ln (1-x)}{x}=-1$.
Similarly, for small enough $\epsilon$, 4.23) produces

$$
\epsilon e^{\mu T} \geq \mu(1+\epsilon) \int_{\underline{t}^{\epsilon}}^{T} e^{(\mu+\lambda) s} e^{-\lambda T} d s=\frac{\mu(1+\epsilon)}{\mu+\lambda} e^{-\lambda T}\left(e^{(\mu+\lambda) T}-e^{(\mu+\lambda) \underline{t}^{\epsilon}}\right)
$$

This implies that there exists $\epsilon_{0}>0$ and $\underline{C}>0$ such that

$$
\underline{t}^{\epsilon, \lambda} \geq T+\frac{1}{\mu+\lambda} \ln \left(1-\frac{(\mu+\lambda) \epsilon}{\mu(1+\epsilon)}\right) \geq T-\underline{C} \epsilon \quad \text { for } \quad \epsilon \in\left(0, \epsilon_{0}\right]
$$

where the second inequality is due to $\lim _{x \downarrow 0} \frac{\ln (1-x)}{x}=-1$ and the relation $\lambda=c \epsilon^{-\frac{2}{3}}$.
Before we start to prove Theorem 5.3, we list three technical lemmas whose proofs are provided in the appendices.

Lemma 6.2. Let Assumption 5.1 hold.
(i) There exist a constant $C>0$ independent of $(t, \epsilon) \in[0, T) \times(0,1)$ such that

$$
\begin{equation*}
\left|\underline{y}^{\epsilon}(t)-y_{M}\right|,\left|\bar{y}^{\epsilon}(t)-y_{M}\right|,\left|\bar{y}^{\epsilon}(t)-\underline{y}^{\epsilon}(t)\right| \leq \frac{C^{\frac{1}{3}}}{\min \{1, \lambda(T-t)\}} . \tag{6.2}
\end{equation*}
$$

(ii) For fixed $t \in[0, T), \underline{\lim }_{\epsilon \downarrow 0} \frac{\bar{y}^{\epsilon}(t)-y^{\epsilon}(t)}{\epsilon^{\frac{1}{3}}}>0$.
(iii) There is $\epsilon_{0}>0$ such that for $(t, \epsilon) \in[0, T] \times\left(0, \epsilon_{0}\right]$, we have $\underline{y}^{\epsilon}(t)<y_{M}<\bar{y}^{\epsilon}(t)$.

Proof. See Appendix C.
Lemma 6.3. Let Assumption 5.1 hold.
(i) For $(t, \epsilon, x) \in[0, T) \times(0,1) \times\left[\underline{y}^{\epsilon}(t), \bar{y}^{\epsilon}(t)\right]$, there is $C>0$ independent of $(t, \epsilon, x)$ such that

$$
\begin{align*}
& \left|v_{x}^{\epsilon}(t, x)\right| \leq C \epsilon  \tag{6.3}\\
& \left|v^{\epsilon}(t, x)-v^{0}(t)\right| \leq C \epsilon^{\frac{2}{3}}  \tag{6.4}\\
& \left|v_{t}^{\epsilon}(t, x)-v_{t}^{0}(t)\right| \leq C\left(1+\frac{1}{\min \left\{1, \lambda^{2}(T-t)^{2}\right\}}\right) \epsilon^{\frac{2}{3}} \tag{6.5}
\end{align*}
$$

(ii) For fixed $t \in[0, T)$,

$$
\begin{align*}
& \lim _{\epsilon \downarrow 0}\left(\sup _{x_{1}, x_{2} \in\left[\underline{\epsilon}^{\epsilon}(t), \bar{y}^{\epsilon}(t)\right]}\left|\frac{v^{\epsilon}\left(t, x_{1}\right)-v^{\epsilon}\left(t, x_{2}\right)}{\epsilon^{\frac{2}{3}}}\right|\right)=0,  \tag{6.6}\\
& \lim _{\epsilon \downarrow 0}\left(\sup _{x_{1}, x_{2} \in\left[\underline{\epsilon}^{\epsilon}(t), \bar{y}^{\epsilon}(t)\right]}\left|\frac{v_{t}^{\epsilon}\left(t, x_{1}\right)-v_{t}^{\epsilon}\left(t, x_{2}\right)}{\epsilon^{\frac{2}{3}}}\right|\right)=0 . \tag{6.7}
\end{align*}
$$

Proof. See Appendix D.
Lemma 6.4. Let Assumption 5.1 hold and $G^{\epsilon}(t, x):=x^{2}(1-x)^{1+\gamma} \frac{\lambda v_{x x}^{\epsilon}(t, x)}{1-\gamma}$. Let $t \in[0, T)$ be fixed, $h(z):=\frac{e^{z}}{1+e^{z}}$, and $x_{\epsilon} \in\left[\underline{y}^{\epsilon}(t), \bar{y}^{\epsilon}(t)\right]$. Then,

$$
G^{\epsilon}\left(t, x_{\epsilon}\right)+y_{M}^{2}\left(1-y_{M}\right)^{1+\gamma} \gamma \sigma^{2} v^{0}(t)-\int_{\underline{z}^{\epsilon}}(t) \quad G^{\epsilon}(t, h(z)) \frac{\sqrt{2 \lambda}}{2 \sigma} e^{-\frac{\sqrt{2 \lambda}}{\sigma}\left|z-z_{\epsilon}\right|} d z \xrightarrow{\epsilon \downarrow 0} 0,
$$

where $\underline{z}^{\epsilon}(t):=h^{-1}\left(\underline{y}^{\epsilon}(t)\right), \bar{z}^{\epsilon}(t):=h^{-1}\left(\bar{y}^{\epsilon}(t)\right)$ and $z_{\epsilon}:=h^{-1}\left(x_{\epsilon}\right)$.
Proof. See Appendix E.

We now proceed to prove Theorem 5.3. The proof consists of three steps. Throughout this proof, $C>0$ is a generic constant independent of $(t, s, x, \epsilon) \in[0, T) \times[t, T) \times(0,1) \times(0,1)$ (also independent of $\lambda$ due to relation $\lambda=c \epsilon^{-\frac{2}{3}}$ ) that may differ line by line.

Let $t \in[0, T)$ be fixed. Since $0<y_{M}<1$, Lemma 6.2 implies that for small enough $\epsilon>0$,

$$
0<\underline{y}^{\epsilon}(t)<y_{M}<\bar{y}^{\epsilon}(t)<1 .
$$

In the end, we are interested in the limiting behaviors as $\epsilon \downarrow 0$. Hence, we assume that $\epsilon>0$ is small enough and the above inequalities hold.

For $x \in\left[\underline{y}^{\epsilon}(t), \bar{y}^{\epsilon}(t)\right]$, using $L^{\epsilon}(t, x)=v^{\epsilon}(t, x)$ and (5.4), we rewrite (3.2) as

$$
\begin{align*}
0= & v_{t}^{\epsilon}(t, x)-v_{t}^{0}(t)+Q(x)\left(v^{\epsilon}(t, x)-v^{0}(t)\right)+v^{0}(t)\left(Q(x)-Q\left(y_{M}\right)\right) \\
& +x(1-x)\left(\mu-\gamma \sigma^{2} x\right) v_{x}^{\epsilon}(t, x)+\frac{\sigma^{2} x^{2}(1-x)^{2}}{2} v_{x x}^{\epsilon}(t, x) \quad \text { for } \quad x \in\left[\underline{y}^{\epsilon}(t), \bar{y}^{\epsilon}(t)\right] . \tag{6.8}
\end{align*}
$$

Step 1. We define $I^{\epsilon}(t, x)$ as

$$
I^{\epsilon}(t, x):=G^{\epsilon}(t, x)-\gamma\left(1-y_{M}\right)^{\gamma-1} v^{0}(t) \lambda\left(x-y_{M}\right)^{2},
$$

where $G^{\epsilon}$ is as in Lemma 6.4. We multiply $\frac{\lambda}{1-\gamma}$ to 6.8) and obtain

$$
\begin{align*}
0= & \frac{\lambda\left(v_{t}^{\epsilon}(t, x)-v_{t}^{0}(t)\right)}{1-\gamma}+Q(x) \frac{\lambda\left(v^{\epsilon}(t, x)-v^{0}(t)\right)}{1-\gamma}+\frac{\gamma \sigma^{2}}{2}\left(\left(\frac{1-x}{1-y_{M}}\right)^{1-\gamma}-1\right) v^{0}(t) \lambda\left(x-y_{M}\right)^{2} \\
& +x(1-x)\left(\mu-\gamma \sigma^{2} x\right) \frac{\lambda v_{x}^{\epsilon}(t, x)}{1-\gamma}+\frac{\sigma^{2}}{2}(1-x)^{1-\gamma} I^{\epsilon}(t, x) \quad \text { for } \quad x \in\left[\underline{y}^{\epsilon}(t), \bar{y}^{\epsilon}(t)\right] . \tag{6.9}
\end{align*}
$$

The above equality with $x=y_{M}$, together with Lemma 6.2 (i) and Lemma 6.3, produces

$$
\begin{align*}
& \frac{\lambda\left(v_{t}^{\epsilon}\left(t, y_{M}\right)-v_{t}^{0}(t)\right)}{1-\gamma}+Q\left(y_{M}\right) \frac{\lambda\left(v^{\epsilon}\left(t, y_{M}\right)-v^{0}(t)\right)}{1-\gamma}+\frac{\sigma^{2}}{2}\left(1-y_{M}\right)^{1-\gamma} I^{\epsilon}\left(t, y_{M}\right) \xrightarrow{\epsilon \downarrow 0} 0,  \tag{6.10}\\
& \sup _{x_{1}, x_{2} \in\left[\underline{y}^{\epsilon}(t), \bar{y}^{\epsilon}(t)\right]}\left|I^{\epsilon}\left(t, x_{1}\right)-I^{\epsilon}\left(t, x_{2}\right)\right| \xrightarrow{\epsilon \downarrow 0 .} 0 \tag{6.11}
\end{align*}
$$

Let $h, x_{\epsilon}, z_{\epsilon}, \underline{z}^{\epsilon}(t), \bar{z}^{\epsilon}(t)$ be as in Lemma 6.4. Note that $\underline{y}^{\epsilon}(t) \leq x_{\epsilon} \leq \bar{y}^{\epsilon}(t)$ and $\underline{z}^{\epsilon}(t) \leq z_{\epsilon} \leq \bar{z}^{\epsilon}(t)$. Since $z \in\left[\underline{z}^{\epsilon}(t), \bar{z}^{\epsilon}(t)\right]$ is equivalent to $h(z) \in\left[\underline{y}^{\epsilon}(t), \bar{y}^{\epsilon}(t)\right]$, the convergence in 6.11) produces

$$
\begin{align*}
& \int_{\underline{z}^{\epsilon}(t)}^{\bar{z}^{\epsilon}(t)}\left|I^{\epsilon}(t, h(z))-I^{\epsilon}\left(t, x_{\epsilon}\right)\right| \frac{\sqrt{2 \lambda}}{2 \sigma} e^{-\frac{\sqrt{2 \lambda}}{\sigma}}\left|z-z_{\epsilon}\right| \\
&  \tag{6.12}\\
& \leq \sup _{x_{1}, x_{2} \in\left[\underline{\epsilon}^{\epsilon}(t), \bar{y}^{\epsilon}(t)\right]}\left|I^{\epsilon}\left(t, x_{1}\right)-I^{\epsilon}\left(t, x_{2}\right)\right| \cdot \int_{\underline{z}^{\epsilon}(t)}^{\bar{z}^{\epsilon}(t)} \frac{\sqrt{2 \lambda}}{2 \sigma} e^{-\frac{\sqrt{2 \lambda}}{\sigma}\left|z-z_{\epsilon}\right|} d z \xrightarrow{\epsilon \downarrow 0} 0,
\end{align*}
$$

where we also use the following observation for the convergence part above:

$$
\begin{equation*}
\int_{\underline{z}^{\epsilon}(t)}^{\bar{z}^{\epsilon}(t)} \frac{\sqrt{2 \lambda}}{2 \sigma} e^{-\frac{\sqrt{2 \lambda}}{\sigma}}\left|z-z_{\epsilon}\right| d z=1-\frac{1}{2}\left(e^{-\frac{\sqrt{2 \lambda}}{\sigma}\left(z_{\epsilon}-\underline{z}^{\epsilon}(t)\right)}+e^{-\frac{\sqrt{2 \lambda}}{\sigma}\left(\bar{z}^{\epsilon}(t)-z_{\epsilon}\right)}\right)<1 . \tag{6.13}
\end{equation*}
$$

We combine Lemma 6.4 and (6.12) to obtain

$$
\begin{align*}
& I^{\epsilon}\left(t, x_{\epsilon}\right)+\gamma\left(1-y_{M}\right)^{\gamma-1} v^{0}(t) \lambda\left(x_{\epsilon}-y_{M}\right)^{2}+y_{M}^{2}\left(1-y_{M}\right)^{1+\gamma} \gamma \sigma^{2} v^{0}(t) \\
& -\int_{\underline{z}^{\epsilon}(t)}^{\bar{z}^{\epsilon}(t)}\left(I^{\epsilon}\left(t, x_{\epsilon}\right)+\gamma\left(1-y_{M}\right)^{\gamma-1} v^{0}(t) \lambda\left(h(z)-y_{M}\right)^{2}\right) \frac{\sqrt{2 \lambda}}{2 \sigma} e^{-\frac{\sqrt{2 \lambda}}{\sigma}\left|z-z_{\epsilon}\right|} d z \xrightarrow{\epsilon \in 0} 0 . \tag{6.14}
\end{align*}
$$

Using the explicit form of the integral in (6.13), the above convergence can be written as

$$
\begin{equation*}
\frac{1}{2}\left(e^{-\frac{\sqrt{2 \lambda}}{\sigma}\left(z_{\epsilon}-\underline{z}^{\epsilon}(t)\right)}+e^{-\frac{\sqrt{2 \lambda}}{\sigma}\left(\bar{z}^{\epsilon}(t)-z_{\epsilon}\right)}\right) I^{\epsilon}\left(t, x_{\epsilon}\right)+\gamma\left(1-y_{M}\right)^{\gamma-1} v^{0}(t) J^{\epsilon}\left(t, x_{\epsilon}\right) \xrightarrow{\epsilon \downarrow 0} 0, \tag{6.15}
\end{equation*}
$$

where $J^{\epsilon}(t, x)$ is defined as

$$
\begin{equation*}
J^{\epsilon}(t, x):=\lambda\left(x-y_{M}\right)^{2}-\int_{\underline{z}^{\epsilon}(t)}^{\bar{z}^{\epsilon}(t)} \lambda\left(h(z)-y_{M}\right)^{2} \frac{\sqrt{2 \lambda}}{2 \sigma} e^{-\frac{\sqrt{2 \lambda}}{\sigma}\left|z-h^{-1}(x)\right|} d z+\sigma^{2} y_{M}^{2}\left(1-y_{M}\right)^{2} . \tag{6.16}
\end{equation*}
$$

In 6.15), we substitute $x_{\epsilon}=\bar{y}^{\epsilon}(t)$ and $x_{\epsilon}=\underline{y}^{\epsilon}(t)$, then subtract the resulting expressions to obtain the following equation:

$$
\begin{align*}
& \frac{1}{2}\left(e^{-\frac{\sqrt{2 \lambda}}{\sigma}\left(\bar{z}^{\epsilon}(t)-\underline{z}^{\epsilon}(t)\right)}+1\right)\left(I^{\epsilon}\left(t, \bar{y}^{\epsilon}(t)\right)-I^{\epsilon}\left(t, \underline{y}^{\epsilon}(t)\right)\right) \\
& +\gamma\left(1-y_{M}\right)^{\gamma-1} v^{0}(t)\left(J^{\epsilon}\left(t, \bar{y}^{\epsilon}(t)\right)-J^{\epsilon}\left(t, \underline{y}^{\epsilon}(t)\right)\right) \xrightarrow{\epsilon \downarrow 0} 0 . \tag{6.17}
\end{align*}
$$

We combine (6.11) and 6.17) and conclude that

$$
\begin{equation*}
J^{\epsilon}\left(t, \bar{y}^{\epsilon}(t)\right)-J^{\epsilon}\left(t, \underline{y}^{\epsilon}(t)\right) \xrightarrow{\epsilon \downarrow 0} 0 . \tag{6.18}
\end{equation*}
$$

Let $z_{M}:=h^{-1}\left(y_{M}\right)$. Observe that (6.2), $\bar{y}^{\epsilon}(t)=h\left(\bar{z}^{\epsilon}(t)\right)$ and $\underline{y}^{\epsilon}(t)=h\left(\underline{z}^{\epsilon}(t)\right)$ imply

$$
\begin{equation*}
\left|\bar{z}^{\epsilon}(t)-\underline{z}^{\epsilon}(t)\right| \leq \frac{C \epsilon \frac{1}{3}}{\min \{1, \lambda(T-t)\}} \tag{6.19}
\end{equation*}
$$

Then, $h\left(z_{M}\right)=y_{M}, h^{\prime}(z)=h(z)(1-h(z)), \lambda=c \epsilon^{-\frac{2}{3}}$ and (6.19) imply

$$
\begin{align*}
& \sup _{z_{1}, z_{2} \in\left[z^{\epsilon}(t), \bar{z}^{\epsilon}(t)\right]} \sqrt{\lambda}\left|h\left(z_{1}\right)-h\left(z_{2}\right)-y_{M}\left(1-y_{M}\right)\left(z_{1}-z_{2}\right)\right| \xrightarrow{\epsilon \downarrow 0} 0,  \tag{6.20}\\
& \sup _{z \in\left[z^{\epsilon}(t), \bar{z}^{\epsilon}(t)\right]} \lambda\left|\left(h(z)-y_{M}\right)^{2}-y_{M}^{2}\left(1-y_{M}\right)^{2}\left(z-z_{M}\right)^{2}\right| \xrightarrow{\epsilon \downarrow 0} 0 . \tag{6.21}
\end{align*}
$$

The limit in (6.21) and the bound in (6.13) produce

$$
\begin{equation*}
\int_{\underline{z}^{\epsilon}(t)}^{\bar{z}^{\epsilon}(t)} \lambda\left(\left(h(z)-y_{M}\right)^{2}-y_{M}^{2}\left(1-y_{M}\right)^{2}\left(z-z_{M}\right)^{2}\right) \frac{\sqrt{2 \lambda}}{2 \sigma} e^{-\frac{\sqrt{2 \lambda}}{\sigma}\left|z-z_{\epsilon}\right|} d z \xrightarrow{\epsilon \downarrow 0} 0 . \tag{6.22}
\end{equation*}
$$

From (6.18), we obtain the following:

$$
\begin{align*}
& 0= \lim _{\epsilon \downarrow 0}\left(J^{\epsilon}\left(t, \bar{y}^{\epsilon}(t)\right)-J^{\epsilon}\left(t, \underline{y}^{\epsilon}(t)\right)\right) \\
&= \lim _{\epsilon \downarrow 0}\left(\lambda\left(\bar{y}^{\epsilon}(t)-y_{M}\right)^{2}-\lambda\left(\underline{y}^{\epsilon}(t)-y_{M}\right)^{2}\right. \\
& \quad-y_{M}^{2}\left(1-y_{M}\right)^{2} \int_{\underline{z}^{\epsilon}}(t) \\
& \bar{z}^{\epsilon}(t) \\
&\left.\left(z-z_{M}\right)^{2} \frac{\sqrt{2 \lambda}}{2 \sigma}\left(e^{-\frac{\sqrt{2 \lambda}}{\sigma}\left|z-\bar{z}^{\epsilon}(t)\right|}-e^{-\frac{\sqrt{2 \lambda}}{\sigma}\left|z-\underline{z}^{\epsilon}(t)\right|}\right) d z\right) \\
&=\lim _{\epsilon \downarrow 0}\left(\lambda\left(\bar{y}^{\epsilon}(t)-\underline{y}^{\epsilon}(t)\right)\left(\bar{y}^{\epsilon}(t)+\underline{y}^{\epsilon}(t)-2 y_{M}\right)-\lambda y_{M}^{2}\left(1-y_{M}\right)^{2}\left(\bar{z}^{\epsilon}(t)-\underline{z}^{\epsilon}(t)\right)\left(\bar{z}^{\epsilon}(t)+\underline{z}^{\epsilon}(t)-2 z_{M}\right)\right.  \tag{6.23}\\
&\left.\quad+y_{M}^{2}\left(1-y_{M}\right)^{2} \sqrt{\lambda}\left(\bar{z}^{\epsilon}(t)+\underline{z}^{\epsilon}(t)-2 z_{M}\right)\left(1-e^{-\frac{\sqrt{2 \lambda}}{\sigma}\left(\bar{z}^{\epsilon}(t)-\underline{z}^{\epsilon}(t)\right)}\right)\left(\frac{\sigma}{\sqrt{2}}+\frac{\sqrt{\lambda}\left(\bar{z}^{\epsilon}(t)-\underline{z}^{\epsilon}(t)\right)}{2}\right)\right) \\
&= \lim _{\epsilon \downarrow 0}\left(1-e^{-\frac{\sqrt{2 \lambda}}{\sigma}\left(\bar{z}^{\epsilon}(t)-\underline{z}^{\epsilon}(t)\right)}\right) \sqrt{\lambda}\left(\bar{y}^{\epsilon}(t)+\underline{y}^{\epsilon}(t)-2 y_{M}\right)\left(\frac{\sqrt{\lambda}\left(\bar{y}^{\epsilon}(t)-\underline{y}^{\epsilon}(t)\right)}{2}+\frac{\sigma y_{M}\left(1-y_{M}\right)}{\sqrt{2}}\right),
\end{align*}
$$

where the second equality is due to $(\sqrt{6.22})$, the third equality is due to integration parts, and the last equality is due to (6.20). Lemma 6.2 (ii), 6.20) and $\lambda=c \epsilon^{-\frac{2}{3}} \operatorname{imply} \underline{\lim }_{\epsilon \downarrow 0} \sqrt{\lambda}\left(\bar{z}^{\epsilon}(t)-\underline{z}^{\epsilon}(t)\right)>0$. Therefore, (6.23) implies

$$
\begin{equation*}
\lim _{\epsilon \downarrow 0}\left(\sqrt{\lambda}\left(\bar{y}^{\epsilon}(t)-y_{M}\right)-\sqrt{\lambda}\left(y_{M}-\underline{y}^{\epsilon}(t)\right)\right)=0 \tag{6.24}
\end{equation*}
$$

We substitute $x=y_{M}$ in (6.16) and $x_{\epsilon}=y_{M}$ in (6.22) and use integration by parts to obtain

$$
\begin{align*}
& 0=\lim _{\epsilon \downarrow 0}\left(J^{\epsilon}\left(t, y_{M}\right)+y_{M}^{2}\left(1-y_{M}\right)^{2} \int_{\underline{z}^{\epsilon}(t)}^{\bar{z}^{\epsilon}(t)} \lambda\left(z-z_{M}\right)^{2} \frac{\sqrt{2 \lambda}}{2 \sigma} e^{-\frac{\sqrt{2 \lambda}}{\sigma}\left|z-z_{M}\right|} d z-\sigma^{2} y_{M}^{2}\left(1-y_{M}\right)^{2}\right) \\
& =\lim _{\epsilon \downarrow 0}\left(J^{\epsilon}\left(t, y_{M}\right)-y_{M}^{2}\left(1-y_{M}\right)^{2}\left(e^{-\frac{\sqrt{2 \lambda}}{\sigma}\left(z_{M}-\underline{z}^{\epsilon}(t)\right)}\left(\frac{\lambda\left(z_{M}-\underline{z}^{\epsilon}(t)\right)^{2}}{2}+\frac{\sigma \sqrt{\lambda}\left(z_{M}-\underline{z}^{\epsilon}(t)\right)}{\sqrt{2}}+\frac{\sigma^{2}}{2}\right)\right.\right. \\
& \left.\left.+e^{-\frac{\sqrt{2 \lambda}}{\sigma}\left(\bar{z}^{\epsilon}(t)-z_{M}\right)}\left(\frac{\lambda\left(\bar{z}^{\epsilon}(t)-z_{M}\right)^{2}}{2}+\frac{\sigma \sqrt{\lambda}\left(\bar{z}^{\epsilon}(t)-z_{M}\right)}{\sqrt{2}}+\frac{\sigma^{2}}{2}\right)\right)\right) \\
& =\lim _{\epsilon \downarrow 0}\left(J^{\epsilon}\left(t, y_{M}\right)-\left(e^{-\frac{\sqrt{2 \lambda}}{\sigma}\left(z_{M}-\underline{z}^{\epsilon}(t)\right)}+e^{-\frac{\sqrt{2 \lambda}}{\sigma}}\left(\bar{z}^{\epsilon}(t)-z_{M}\right)\right)\right. \\
& \left.\cdot\left(\frac{\lambda\left(\bar{y}^{\epsilon}(t)-y^{\epsilon}(t)\right)^{2}}{8}+\frac{\sigma y_{M}\left(1-y_{M}\right) \sqrt{\lambda}\left(\bar{y}^{\epsilon}(t)-\underline{y}^{\epsilon}(t)\right)}{2 \sqrt{2}}+\frac{\sigma^{2} y_{M}^{2}\left(1-y_{M}\right)^{2}}{2}\right)\right), \tag{6.25}
\end{align*}
$$

where we apply (6.20), 6.21) and (6.24) to obtain the last equality. We substitute $x_{\epsilon}=y_{M}$ in (6.15) and combine with (6.25) to obtain

$$
I^{\epsilon}\left(t, y_{M}\right)+\gamma\left(1-y_{M}\right)^{\gamma-1} v^{0}(t)\left(\left(\frac{\sqrt{\lambda}\left(\bar{y}^{\epsilon}(t)-\underline{y}^{\epsilon}(t)\right)}{2}+\frac{\sigma y_{M}\left(1-y_{M}\right)}{\sqrt{2}}\right)^{2}+\frac{\sigma^{2} y_{M}^{2}\left(1-y_{M}\right)^{2}}{2}\right) \xrightarrow{\epsilon \downarrow 0} 0 .
$$

By (6.10), the above limit and $\lambda=c \epsilon^{-\frac{2}{3}}$, we conclude

$$
\begin{align*}
0=\lim _{\epsilon \downarrow 0}( & \frac{c\left(v_{t}^{\epsilon}\left(t, y_{M}\right)-v_{t}^{0}(t)\right)}{(1-\gamma) \epsilon^{\frac{3}{3}}}+\frac{c Q\left(y_{M}\right)\left(v^{\epsilon}\left(t, y_{M}\right)-v^{0}(t)\right)}{(1-\gamma) \epsilon^{\frac{2}{3}}} \\
& \left.-\frac{\gamma \sigma^{2} v^{0}(t)}{2}\left(\left(\frac{\sqrt{c}\left(\bar{y}^{\epsilon}(t)-\underline{y}^{\epsilon}(t)\right)}{2 \epsilon^{\frac{1}{3}}}+\frac{\sigma y_{M}\left(1-y_{M}\right)}{\sqrt{2}}\right)^{2}+\frac{\sigma^{2} y_{M}^{2}\left(1-y_{M}\right)^{2}}{2}\right)\right) . \tag{6.26}
\end{align*}
$$

Step 2. We inspect the integrals of the terms in (6.8) with respect to $x$, from $\underline{y}^{\epsilon}(t)$ to $\bar{y}^{\epsilon}(t)$. By the mean value theorem, there exist $x_{\epsilon}^{*}, x_{\epsilon}^{* *} \in\left[\underline{y}^{\epsilon}(t), \bar{y}^{\epsilon}(t)\right]$ such that

$$
\begin{align*}
& \int_{\underline{y}^{\epsilon}(t)}^{\bar{y}^{\epsilon}(t)} \frac{v_{t}^{\epsilon}(t, x)-v_{t}^{0}(t)}{(1-\gamma) \epsilon} d x-\frac{v_{t}^{\epsilon}\left(t, y_{M}\right)-v_{t}^{0}(t)}{(1-\gamma) \epsilon^{\frac{2}{3}}} \cdot \frac{\bar{y}^{\epsilon}(t)-y^{\epsilon}(t)}{\epsilon^{\frac{1}{3}}}=\frac{v_{t}^{\epsilon}\left(t, x_{\epsilon}^{*}\right)-v_{t}^{\epsilon}\left(t, y_{M}\right)}{(1-\gamma) \epsilon^{\frac{2}{3}}} \cdot \frac{\bar{y}^{\epsilon}(t)-y^{\epsilon}(t)}{\epsilon^{\frac{1}{3}}} \xrightarrow{\epsilon \downarrow 0} 0,  \tag{6.27}\\
& \int_{\underline{y}^{\epsilon}(t)}^{\bar{y}^{\epsilon}(t)} \frac{Q(x)\left(v^{\epsilon}(t, x)-v^{0}(t)\right)}{(1-\gamma) \epsilon} d x-\frac{Q\left(y_{M}\right)\left(v^{\epsilon}\left(t, y_{M}\right)-v^{0}(t)\right)}{(1-\gamma) \epsilon^{\frac{2}{3}}} \cdot \frac{\bar{y}^{\epsilon}(t)-y^{\epsilon}(t)}{\epsilon^{\frac{1}{3}}} \\
&  \tag{6.28}\\
& =\left(\frac{Q\left(x_{\epsilon}^{* *}\right)\left(v^{\epsilon}\left(t, x_{\epsilon}^{* *}\right)-v^{0}(t)\right)}{(1-\gamma) \epsilon^{\frac{2}{3}}}-\frac{Q\left(y_{M}\right)\left(v^{\epsilon}\left(t, y_{M}\right)-v^{0}(t)\right)}{(1-\gamma) \epsilon^{\frac{2}{3}}}\right) \frac{\bar{y}^{\epsilon}(t)-y^{\epsilon}(t)}{\epsilon^{\frac{1}{3}}} \xrightarrow{\epsilon \downarrow 0} 0,
\end{align*}
$$

where the convergences are due to Lemma 6.2 (i) and Lemma 6.3. By $\sqrt{6.24}$ ), we have

$$
\begin{align*}
& \int_{\underline{y}^{\epsilon}(t)}^{\bar{y}^{\epsilon}(t)} \frac{Q(x)-Q\left(y_{M}\right)}{(1-\gamma) \epsilon} d x+\frac{\gamma \sigma^{2}}{24}\left(\frac{\left(\frac{\bar{\epsilon}^{\epsilon}(t)-y^{\epsilon}(t)}{\epsilon^{\frac{1}{3}}}\right)^{3}}{}=-\frac{\gamma \sigma^{2}}{6}\left(\left(\frac{\bar{y}^{\epsilon}(t)-y_{M}}{\epsilon^{\frac{1}{3}}}\right)^{3}-\left(\frac{\underline{y^{\epsilon}(t)-y_{M}}}{\epsilon^{\frac{1}{3}}}\right)^{3}-\frac{1}{4}\left(\frac{\bar{y}^{\epsilon}(t)-\underline{y}^{\epsilon}(t)}{\epsilon^{\frac{1}{3}}}\right)^{3}\right) \xrightarrow{\epsilon \downarrow 0} 0 .\right.
\end{align*}
$$

By (6.3) and Lemma 6.2 (i), we obtain

$$
\begin{equation*}
\left|\int_{\underline{y}^{\epsilon}(t)}^{\vec{y}^{\epsilon}(t)} \frac{x(1-x)\left(\mu-\gamma \sigma^{2} x\right) v_{x}^{\epsilon}(t, x)}{(1-\gamma) \epsilon} d x\right| \leq C\left|\bar{y}^{\epsilon}(t)-\underline{y}^{\epsilon}(t)\right| \xrightarrow{\epsilon \downarrow 0} 0 . \tag{6.30}
\end{equation*}
$$

By integration by parts and Lemma 4.1,

$$
\int_{\underline{y}^{\epsilon}(t)}^{\bar{y}^{\epsilon}(t)} \frac{\sigma^{2} x^{2}(1-x)^{2} v_{x}^{\epsilon, \lambda}(t, x)}{2(1-\gamma) \epsilon} d x=-\frac{\sigma^{2} \bar{y}^{\epsilon}(t)^{2}\left(1-\bar{y}^{\epsilon}(t)\right)^{2} v^{\epsilon}\left(t, \bar{y}^{\epsilon}(t)\right)}{2\left(1-\epsilon \bar{y}^{\epsilon}(t)\right)}-\frac{\sigma^{2} \underline{y}^{\epsilon}(t)^{2}\left(1-\underline{y}^{\epsilon}(t)\right)^{2} v^{\epsilon}\left(t, \underline{y}^{\epsilon}(t)\right)}{2\left(1+\epsilon \underline{\underline{c}}^{\epsilon}(t)\right)}
$$

$$
\begin{equation*}
-\int_{\underline{y}^{\epsilon}(t)}^{\bar{y}^{\epsilon}(t)} \frac{\sigma^{2} x(1-x)(1-2 x) v_{x}^{\epsilon}(t, x)}{(1-\gamma) \epsilon} d x \xrightarrow{\epsilon \downarrow 0}-\sigma^{2} y_{M}^{2}\left(1-y_{M}\right)^{2} v^{0}(t) \tag{6.31}
\end{equation*}
$$

where the convergence is due to Lemma 6.2 (i) and Lemma 6.3 (i).
Now we integrate the right-hand side of (6.8) with respect to $x$ from $\underline{y}^{\epsilon}(t)$ to $\bar{y}^{\epsilon}(t)$ and multiply it by $\frac{c}{(1-\gamma) \epsilon}$, then apply $(6.27)-6.31$ to obtain the following:

$$
\begin{align*}
0= & \lim _{\epsilon \downarrow 0}\left(\left(\frac{c\left(v_{t}^{\epsilon}\left(t, y_{M}\right)-v_{t}^{0}(t)\right)}{(1-\gamma) \epsilon^{\frac{2}{3}}}+\frac{c Q\left(y_{M}\right)\left(v^{\epsilon}\left(t, y_{M}\right)-v^{0}(t)\right)}{(1-\gamma) \epsilon^{\frac{2}{3}}}\right) \frac{\bar{y}^{\epsilon}(t)-\underline{y}^{\epsilon}(t)}{\epsilon^{\frac{1}{3}}}\right. \\
& \left.\quad-\frac{c \gamma \sigma^{2} v^{0}(t)}{24}\left(\frac{\bar{y}^{\epsilon}(t)-\underline{y}^{\epsilon}(t)}{\epsilon^{\frac{1}{3}}}\right)^{3}-c \sigma^{2} y_{M}^{2}\left(1-y_{M}\right)^{2} v^{0}(t)\right) . \tag{6.32}
\end{align*}
$$

Step 3. We multiply $\frac{\bar{y}^{\epsilon}(t)-\underline{y}^{\epsilon}(t)}{\epsilon^{\frac{1}{3}}}$ to 6.26 and subtract 6.32 to obtain

$$
0=\lim _{\epsilon \downarrow 0}\left(-\frac{c \gamma}{12}\left(\frac{\bar{y}^{\epsilon}(t)-y^{\epsilon}(t)}{\epsilon^{\frac{1}{3}}}+\frac{\sqrt{2} \sigma y_{M}\left(1-y_{M}\right)}{\sqrt{c}}\right)^{3}+c y_{M}^{2}\left(1-y_{M}\right)^{2}+\frac{\gamma \sigma^{3} y_{M}^{3}\left(1-y_{M}\right)^{3}}{3 \sqrt{2 c}}\right)
$$

The above equation implies that

$$
\begin{equation*}
\lim _{\epsilon \downarrow 0} \frac{\bar{y}^{\epsilon}(t)-\underline{y}^{\epsilon}(t)}{\epsilon^{\frac{1}{3}}}=\frac{\sqrt{2} \sigma y_{M}\left(1-y_{M}\right)}{\sqrt{c}}\left(\left(\frac{3 \sqrt{2} c^{\frac{3}{2}}}{\gamma \sigma^{3} y_{M}\left(1-y_{M}\right)}+1\right)^{\frac{1}{3}}-1\right)=2 a_{1}(c) \tag{6.33}
\end{equation*}
$$

We conclude the desired asymptotic result for $\bar{y}^{\epsilon}(t)$ and $\underline{y}^{\epsilon}(t)$ by the above equation and 6.24.
It remains to prove the asymptotic result for $v^{\epsilon}\left(t, y_{M}\right)$. Using (5.4), we rewrite (6.26) as

$$
\begin{equation*}
\frac{\partial}{\partial t}\left(\frac{e^{Q\left(y_{M}\right) t}\left(v^{\epsilon}\left(t, y_{M}\right)-v^{0}(t)\right)}{(1-\gamma) \epsilon^{\frac{2}{3}}}\right)-\frac{\gamma \sigma^{2} e^{Q\left(y_{M}\right) T}}{2}\left(\left(\frac{\bar{y}^{\epsilon}(t)-\underline{y}^{\epsilon}(t)}{2 \epsilon^{\frac{1}{3}}}+\frac{\sigma y_{M}\left(1-y_{M}\right)}{\sqrt{2 c}}\right)^{2}+\frac{\sigma^{2} y_{M}^{2}\left(1-y_{M}\right)^{2}}{2 c}\right) \xrightarrow{\epsilon \downarrow 0} 0 \tag{6.34}
\end{equation*}
$$

Then, 6.33 and 6.34 imply

$$
\lim _{\epsilon \downarrow 0} \frac{\partial}{\partial t}\left(\frac{e^{Q\left(y_{M}\right) t}\left(v^{\epsilon}\left(t, y_{M}\right)-v^{0}(t)\right)}{(1-\gamma) \epsilon^{\frac{2}{3}}}\right)=\frac{e^{Q\left(y_{M}\right) T} a_{2}(c)}{1-\gamma} .
$$

The bounds in Lemma 6.3 (i) enable us to use the dominated convergence theorem as below:

$$
\begin{aligned}
\frac{e^{Q\left(y_{M}\right) T} a_{2}(c)}{1-\gamma}(T-t) & =\int_{t}^{T} \lim _{\epsilon \downarrow 0} \frac{\partial}{\partial s}\left(\frac{e^{Q\left(y_{M}\right) s}\left(v^{\epsilon}\left(s, y_{M}\right)-v^{0}(s)\right)}{(1-\gamma) \epsilon^{\frac{2}{3}}}\right) d s=\lim _{\epsilon \downarrow 0} \int_{t}^{T} \frac{\partial}{\partial s}\left(\frac{e^{Q\left(y_{M}\right) s}\left(v^{\epsilon}\left(s, y_{M}\right)-v^{0}(s)\right)}{(1-\gamma) \epsilon^{\frac{2}{3}}}\right) d s \\
& =-e^{Q\left(y_{M}\right) t} \cdot \lim _{\epsilon \downarrow 0} \frac{v^{\epsilon}\left(t, y_{M}\right)-v^{0}(t)}{(1-\gamma) \epsilon^{\frac{2}{3}}}
\end{aligned}
$$

where the last equality is due to $v^{\epsilon}\left(T, y_{M}\right)=v^{0}(T)=1$. We conclude the desired asymptotic result for $v^{\epsilon}\left(t, y_{M}\right)$.

## 7. CONCLUSION

This paper investigates the optimal investment problem in a market with two types of illiquidity: transaction costs and search frictions. Building on the framework established by [21], we extend the analysis to a power-utility maximization problem. Our main contribution is the development of a novel asymptotic framework applicable when both transaction costs and search frictions are small $\left(\epsilon \ll 1\right.$ and $\left.\frac{1}{\lambda} \ll 1\right)$. We derive explicit asymptotics for the no-trade region and the value function along the parametric curve $\lambda=c \epsilon^{-\frac{2}{3}}$ for $c>0$. This approach unifies the existing asymptotic results for models with only transaction costs or only search frictions, providing a coherent methodology for handling both types of illiquidity simultaneously. Additionally, our framework offers explicit expressions for the correction terms, facilitating practical computation of the optimal trading strategy and value. Our asymptotic analysis provides insights into the limiting behaviors
not present in models with only one source of illiquidity. As a future research, we plan to extend our results to a multi-asset model.

## Appendix A. Proof of Lemma 3.1

In the proof, we assume $0<\gamma<1$ (the case of $\gamma>1$ can be treated similarly). Let $a:=$ $\max _{x \in[0,1]} Q(x)$ where $Q$ is in $(3.3), h(z):=\frac{e^{z}}{1+e^{z}}$, and $C_{b}([0, T] \times \mathbb{R})$ be the set of all bounded (with the uniform norm) continuous functions. For $f \in C_{b}([0, T] \times \mathbb{R})$, we define $\phi(f)$ as

$$
\begin{equation*}
\phi(f)(t, z):=\mathbb{E}\left[e^{a T} e^{\int_{t}^{T}\left(Q\left(h\left(\Upsilon_{u}^{(t, z)}\right)\right)-\lambda-a\right) d u}+\lambda \int_{t}^{T} e^{\int_{t}^{s}\left(Q\left(h\left(\Upsilon_{u}^{(t, z)}\right)\right)-\lambda-a\right) d u} K_{f}\left(s, \Upsilon_{s}^{(t, z)}\right) d s\right], \tag{A.1}
\end{equation*}
$$

where $K_{f}$ is

$$
\begin{equation*}
K_{f}(t, z):=\sup _{\zeta \in \mathbb{R}}(f(t, \zeta) g(z, \zeta)) \quad \text { with } \quad g(z, \zeta):=\left(\frac{1+\bar{\epsilon} h(z)}{1+\bar{\epsilon} h(\zeta)}\right)^{1-\gamma} 1_{\{\zeta \geq z\}}+\left(\frac{1-\underline{\epsilon}(z)}{1-\underline{\epsilon} h(\zeta)}\right)^{1-\gamma} 1_{\{\zeta<z\}} \tag{A.2}
\end{equation*}
$$

and $\Upsilon_{s}^{(t, z)}$ for $(s, z) \in[t, T] \times \mathbb{R}$ is the solution of the following SDE:

$$
\begin{equation*}
d \Upsilon_{s}^{(t, z)}=\left(\mu-\frac{\sigma^{2}}{2}+(1-\gamma) \sigma^{2} h\left(\Upsilon_{s}^{(t, z)}\right)\right) d s+\sigma d B_{s}, \quad \Upsilon_{t}^{(t, z)}=z \tag{A.3}
\end{equation*}
$$

Since $K_{f}$ and $Q \circ h$ are bounded and continuous, one can check $\phi(f) \in C_{b}([0, T] \times \mathbb{R})$ by the dominated convergence theorem. From the definition of $a$, we observe that for $z \in \mathbb{R}$,

$$
\begin{equation*}
-\infty<\min _{x \in[0,1]} Q(x)-\lambda-a \leq Q(h(z))-\lambda-a \leq-\lambda . \tag{A.4}
\end{equation*}
$$

We check that $\phi$ is a contraction map: for $f_{1}, f_{2} \in C_{b}([0, T] \times \mathbb{R})$,

$$
\left\|\phi\left(f_{1}\right)-\phi\left(f_{2}\right)\right\|_{\infty} \leq \lambda \int_{t}^{T} e^{-\lambda(s-t)} \cdot \sup _{\zeta \in \mathbb{R}}\left|f_{1}(s, \zeta)-f_{2}(s, \zeta)\right| d s \leq\left(1-e^{-\lambda T}\right)\left\|f_{1}-f_{2}\right\|_{\infty}
$$

where the first inequality is due to A.4 and $\|g\|_{\infty} \leq 1$. Therefore, by the Banach fixed point theorem, there exists a unique function $\hat{f} \in C_{b}([0, T] \times \mathbb{R})$ such that $\phi(\hat{f})=\hat{f}$.

Lemma A.1. $K_{\hat{f}} \in C^{\frac{1}{2}, 1}([0, T] \times \mathbb{R})$.
Proof. Throughout the proof of this claim, $C>0$ is a generic constant independent of $(t, s, z, \delta) \in$ $[0, T] \times[t, T] \times \mathbb{R} \times[0,1]$ and paths. For $\delta \in[0,1]$ and $t \in[0, T]$,

$$
\begin{equation*}
\left|K_{\hat{f}}(t, z+\delta)-K_{\hat{f}}(t, z)\right| \leq\|\hat{f}\|_{\infty} \cdot \sup _{\zeta \in \mathbb{R}}|g(z+\delta, \zeta)-g(z, \zeta)| \leq C \delta, \tag{A.5}
\end{equation*}
$$

where the second inequality is due to $\left\|\frac{\partial g}{\partial z}\right\|_{\infty}<\infty$. By SDE A.3), for $s \in[t, T]$, we have

$$
\begin{aligned}
&\left|\Upsilon_{s}^{(t+\delta, z)}-\Upsilon_{s}^{(t, z)}\right| \leq\left|\sigma\left(B_{t}-B_{t+\delta}\right)-\int_{t}^{t+\delta}\left(\mu-\frac{\sigma^{2}}{2}+(1-\gamma) \sigma^{2} h\left(\Upsilon_{u}^{(t, z)}\right)\right) d u\right| \\
&+\left|\int_{t+\delta}^{s}(1-\gamma) \sigma^{2}\left(h\left(\Upsilon_{u}^{(t+\delta, z)}\right)-h\left(\Upsilon_{u}^{(t, z)}\right)\right) d u\right| \\
& \leq C\left(\left|B_{t+\delta}-B_{t}\right|+\delta+\int_{t+\delta}^{s}\left|\Upsilon_{u}^{(t+\delta, z)}-\Upsilon_{u}^{(t, z)}\right| d u\right) .
\end{aligned}
$$

We apply Gronwall's inequality (see Lemma F.1) to above and obtain

$$
\begin{equation*}
\left|\Upsilon_{s}^{(t+\delta, z)}-\Upsilon_{s}^{(t, z)}\right| \leq C\left(\left|B_{t+\delta}-B_{t}\right|+\delta\right) . \tag{A.6}
\end{equation*}
$$

Using (A.4) and A.6), we produce the following estimate: for $s \in[t, T]$ and $\delta \in[0,1]$,

$$
\begin{align*}
& \mathbb{E}\left[\left|e^{\int_{t}^{s}\left(Q\left(h\left(\Upsilon_{u}^{(t, z)}\right)\right)-\lambda-a\right) d u}-e^{\int_{t+\delta}^{s}\left(Q\left(h\left(\Upsilon_{u}^{(t+\delta, z)}\right)\right)-\lambda-a\right) d u}\right|\right] \\
& \leq C \mathbb{E}\left[\left|\int_{t}^{s}\left(Q\left(h\left(\Upsilon_{u}^{(t, z)}\right)\right)-\lambda-a\right) d u-\int_{t+\delta}^{s}\left(Q\left(h\left(\Upsilon_{u}^{(t+\delta, z)}\right)\right)-\lambda-a\right) d u\right|\right] \leq C \sqrt{\delta}, \tag{A.7}
\end{align*}
$$

where we also used $\left\|\frac{d}{d z} Q(h(z))\right\|_{\infty}<\infty$ for the last inequality. Similarly, A.5) and A.6) produce

$$
\begin{equation*}
\mathbb{E}\left[\left|K_{\hat{f}}\left(s, \Upsilon_{s}^{(t+\delta, z)}\right)-K_{\hat{f}}\left(s, \Upsilon_{s}^{(t, z)}\right)\right|\right] \leq C \mathbb{E}\left[\left|\Upsilon_{s}^{(t+\delta, z)}-\Upsilon_{s}^{(t, z)}\right|\right] \leq C \sqrt{\delta} \tag{A.8}
\end{equation*}
$$

For $\delta \in[0,1]$ and $(t, z) \in[0, T] \times \mathbb{R}$, A.4, A.7 and A.8 produce

$$
\begin{equation*}
|\phi(\hat{f})(t+\delta, z)-\phi(\hat{f})(t, z)| \leq C \sqrt{\delta} \tag{A.9}
\end{equation*}
$$

The above inequality implies that

$$
\left|K_{\hat{f}}(t+\delta, z)-K_{\hat{f}}(t, z)\right| \leq \sup _{\zeta \in \mathbb{R}}|\hat{f}(t+\delta, \zeta)-\hat{f}(t, \zeta)|=\sup _{\zeta \in \mathbb{R}}|\phi(\hat{f})(t+\delta, \zeta)-\phi(\hat{f})(t, \zeta)| \leq C \sqrt{\delta} .
$$

We conclude $K_{\hat{f}} \in C^{\frac{1}{2}, 1}([0, T] \times \mathbb{R})$ by the above inequality and A.5).
Let $\alpha \in(0,1)$ be fixed. Lemma A. 1 and Theorem 9.2.3 in 30 guarantee that there exists a unique solution $\tilde{f} \in C^{1+\frac{\alpha}{2}, 2+\alpha}([0, T] \times \mathbb{R})$ of the following PDE:

$$
\left\{\begin{align*}
& 0=f_{t}(t, z)+\left(\mu-\frac{\sigma^{2}}{2}+(1-\gamma) \sigma^{2} h(z)\right) f_{z}(t, z)+\frac{\sigma^{2}}{2} f_{z z}(t, z)  \tag{A.10}\\
& \quad(Q(h(z))-\lambda-a) f(t, z)+\lambda K_{\hat{f}}(t, z) \\
& f(T, z)= e^{a T}
\end{align*}\right.
$$

By the Feynman-Kac formula (i.e., see Theorem 5.7.6 in [29]), we have $\tilde{f}=\phi(\hat{f})=\hat{f}$.
Observe that $h$ can be continuously extended to $z= \pm \infty$ as $h(\infty):=1$ and $h(-\infty):=0$. Then,

$$
\begin{aligned}
\lim _{z \rightarrow \infty} e^{-a t} \tilde{f}(t, z) & =\lim _{z \rightarrow \infty} e^{-a t} \phi(\tilde{f})(t, z) \\
& =e^{(Q(1)-\lambda)(T-t)}+\lambda \int_{t}^{T} e^{(Q(1)-\lambda)(s-t)} \sup _{\zeta \in \mathbb{R}}\left(e^{-a s} \tilde{f}(s, \zeta)\left(\frac{1-\epsilon}{1-\epsilon h(\zeta)}\right)^{1-\gamma}\right) d s,
\end{aligned}
$$

where the last equality is due to the dominated convergence theorem. Therefore, we continuously extend $\tilde{f}$ to $z=+\infty$ and the above equality produces

$$
\begin{equation*}
0=\frac{\partial}{\partial t}\left(e^{-a t} \tilde{f}(t, \infty)\right)+(Q(1)-\lambda)\left(e^{-a t} \tilde{f}(t, \infty)\right)+\lambda \sup _{\zeta \in \mathbb{R}}\left(e^{-a t} \tilde{f}(t, \zeta)\left(\frac{1-\epsilon}{1-\underline{\epsilon}(\zeta)}\right)^{1-\gamma}\right) \tag{A.11}
\end{equation*}
$$

We can treat $\lim _{z \rightarrow-\infty} e^{-a t} \tilde{f}(t, z)$ by the same way and obtain

$$
\begin{equation*}
0=\frac{\partial}{\partial t}\left(e^{-a t} \tilde{f}(t,-\infty)\right)+(Q(0)-\lambda)\left(e^{-a t} \tilde{f}(t,-\infty)\right)+\lambda \sup _{\zeta \in \mathbb{R}}\left(e^{-a t} \tilde{f}(t, \zeta)\left(\frac{1}{1+\bar{\epsilon} h(\zeta)}\right)^{1-\gamma}\right) \tag{A.12}
\end{equation*}
$$

We set $v(t, x):=e^{-a t} \tilde{f}\left(t, h^{-1}(x)\right)$ for $(t, x) \in[0, T] \times[0,1]$. The PDE for $\tilde{f}$ in A.10 implies that $v$ satisfies (3.2) for $(t, x) \in[0, T) \times(0,1)$. We check (ii) by A.11) and A.12). To check (iii), since $\tilde{f} \in C^{1+\frac{\alpha}{2}, 2+\alpha}([0, T] \times \mathbb{R})$, it is enough to observe that for $z=h^{-1}(x)$,

$$
\begin{aligned}
& v_{t}(t, x)=e^{-a t}\left(\tilde{f}_{t}(t, z)-a \tilde{f}(t, z)\right), \\
& x(1-x) v_{x}(t, x)=e^{-a t} \tilde{f}_{z}(t, z), \\
& x^{2}(1-x)^{2} v_{x x}(t, x)=e^{-a t}\left(\tilde{f}_{z z}(t, z)-(1-2 x) \tilde{f}_{z}(t, z)\right) .
\end{aligned}
$$

## Appendix B. Preliminary analysis for Section 5

This appendix is devoted to presenting and proving preliminary asymptotic results used in the proof of the lemmas in Section 5. As in Section 5, we set $\epsilon=\bar{\epsilon}=\underline{\epsilon} \in(0,1)$ and assume that $y_{M} \in(0,1)$. Recall that $A_{s, t}, Y_{s}^{(t, x)}$ and $Z_{s}^{(t, x)}$ are defined in 4.8).
Lemma B.1. Let $C>0$ be a generic constant independent of $(t, s, x, \lambda) \in[0, T] \times[t, T] \times(0,1) \times$ $[1, \infty)$ that may differ line by line.
(i) For nonnegative integers $n, m, k, l$,

$$
\left|\mathbb{E}\left[\left(\frac{\partial^{m} Z_{s}^{(t, x)}}{\partial x^{m}}\right)^{k}\left(\frac{\partial^{n} Y_{s}^{(t, x)}}{\partial x^{n}}\right)^{l}\right]\right| \leq C(s-t)+\left\{\begin{array}{lc}
0, & m \geq 1 \text { or } n \geq 2  \tag{B.1}\\
x^{l}, & m=0 \text { and } n=0 \\
1, & m=0 \text { and } n=1
\end{array}\right.
$$

In particular,

$$
\begin{equation*}
\mathbb{E}\left[\left|Z_{s}^{(t, x)}\right|\right] \leq 1+C(s-t), \quad \mathbb{E}\left[\left|\frac{\partial^{2} Z_{s}^{(t, x)}}{\partial x^{2}}\right|\right] \leq C(s-t), \quad \mathbb{E}\left[\left|\frac{\partial Z_{s}^{(t, x)}}{\partial x}\right|\right] \leq C \sqrt{s-t} . \tag{B.2}
\end{equation*}
$$

(ii) Let $n \in \mathbb{N}$ and $F:[0, T] \times(0,1) \rightarrow \mathbb{R}$. Suppose that $y \mapsto F(t, y)$ is piecewise continuous for each $t \in[0, T]$ and $\sup _{(t, y) \in[0, T] \times(0,1)}\left|(y(1-y))^{n-1} F(t, y)\right|=C_{F}<\infty$. Then,

$$
\begin{equation*}
\left|\frac{\partial}{\partial x}\left(\int_{t}^{T} \lambda e^{-\lambda(s-t)} \mathbb{E}\left[Z_{s}^{(t, x)}\left(\frac{\partial Y_{s}^{(t, x)}}{\partial x}\right)^{n} F\left(s, Y_{s}^{(t, x)}\right)\right] d s\right)\right| \leq \frac{C \cdot C_{F} \sqrt{\lambda}}{(x(1-x))^{n}} \tag{B.3}
\end{equation*}
$$

(iii) Let $F:(0,1) \rightarrow \mathbb{R}$ be a continuous function. Suppose that $F^{\prime}$ is continuous on $(0,1), F^{\prime \prime}$ is continuous on $(0,1)$ except finitely many points, the left and right limits of $F^{\prime \prime}$ exist at the discontinuous points and

$$
\begin{equation*}
\underset{y \in(0,1)}{\operatorname{ess} \sup }\left(|F(y)|+\left|y(1-y) F^{\prime}(y)\right|+\left|y^{2}(1-y)^{2} F^{\prime \prime}(y)\right|\right)<\infty . \tag{B.4}
\end{equation*}
$$

Then, the derivative below exists and

$$
\begin{align*}
& \left|\frac{\partial}{\partial t} \mathbb{E}\left[\frac{\partial Z_{s}^{(t, x)}}{\partial x} F\left(Y_{s}^{(t, x)}\right)\right]\right| \leq C\left(\left|\left(y_{M}-x\right) F(x)\right|+\left|x(1-x) F^{\prime}(x)\right|\right)+C(s-t),  \tag{B.5}\\
& \left|\mathbb{E}\left[\frac{\partial Z_{s}^{(t, x)}}{\partial x} F\left(Y_{s}^{(t, x)}\right)\right]\right| \leq C\left(\left|\left(y_{M}-x\right) F(x)\right|+\left|x(1-x) F^{\prime}(x)\right|\right)(s-t)+C(s-t)^{2} . \tag{B.6}
\end{align*}
$$

Proof. Throughout this proof, $C>0$ is a generic constant independent of $(t, s, x, \lambda) \in[0, T] \times$ $[t, T] \times(0,1) \times[1, \infty)$ that may differ line by line.
(i) To obtain (B.1), we apply Ito's lemma to $\left(\frac{\partial^{m} Z_{s}^{(t, x)}}{\partial x^{m}}\right)^{k}\left(\frac{\partial^{n} Y_{Y^{(t, x)}}^{\partial x^{n}}}{}\right)^{l}$ using the expression in (4.13) and the SDE for $A_{s}^{(t, x)}$ in 4.10), then we apply the inequalities in (4.14).

Since $Z_{s}^{(t, x)}>0$, we obtain the first inequality in (B.2) by (B.1) (with $m=n=0, k=1$ and $l=0$ ). The expression in (4.13) and (B.1) (with $m=2, k=1$ and $l=0$ ) imply

$$
\mathbb{E}\left[\left|\frac{\partial^{2} Z_{s}^{(t, x)}}{\partial x^{2}}\right|\right]=\operatorname{sgn}(\gamma-1) \cdot \mathbb{E}\left[\frac{\partial^{2} Z_{Z}^{(t, x)}}{\partial x^{2}}\right] \leq C(s-t)
$$

Hölder's inequality and (B.1) (with $m=1, k=2$ and $l=0$ ) produce the last inequality in (B.2).
(ii) The probability density function $\varphi(y ; s-t, x)$ of $Y_{s}^{(t, x)}$ is calculated as

$$
\begin{align*}
\varphi(y ; s-t, x) & :=\frac{\partial}{\partial y} \mathbb{P}\left(Y_{s}^{(t, x)} \leq y\right)=\frac{\exp \left(-\frac{1}{2 \sigma^{2}(s-t)}\left(\left(\frac{\sigma^{2}}{2}-\mu\right)(s-t)+\ln \left(\frac{y(1-x)}{(1-y) x}\right)\right)^{2}\right)}{\sigma y(1-y) \sqrt{2 \pi(s-t)}}  \tag{B.7}\\
\Longrightarrow \quad \varphi_{x}(y ; s-t, x) & =\varphi(y ; s-t, x) \cdot \frac{1}{\sigma^{2} x(1-x)}\left(\frac{\sigma^{2}}{2}-\mu+\frac{1}{s-t} \ln \left(\frac{y(1-x)}{(1-y) x}\right)\right) .
\end{align*}
$$

We use the expression above to obtain

$$
\begin{align*}
& \int_{0}^{1}\left|\frac{\partial}{\partial x}\left(\left(\frac{1-x}{1-y}\right)^{1-\gamma}\left(\frac{y(1-y)}{x(1-x)}\right)^{n} F(s, y) \varphi(y ; s-t, x)\right)\right| d y \\
& =\int_{0}^{1}\left(\frac{1-x}{1-y}\right)^{1-\gamma}\left(\frac{y(1-y)}{x(1-x)}\right)^{n}|F(s, y)| \\
& \cdot\left|\frac{1}{\sigma^{2} x(1-x)}\left(\frac{\sigma^{2}}{2}-\mu+\frac{1}{s-t} \ln \left(\frac{y(1-x)}{(1-y) x}\right)\right)-\frac{n(1-2 x)+x(1-\gamma)}{x(1-x)}\right| \cdot \varphi(y ; s-t, x) d y \\
& =\frac{1}{(x(1-x))^{n}} \mathbb{E}\left[Z_{s}^{(t, x)} \frac{\partial Y_{s}^{(t, x)}}{\partial x}\left(Y_{s}^{(t, x)}\left(1-Y_{s}^{(t, x)}\right)\right)^{n-1}\left|F\left(s, Y_{s}^{(t, x)}\right)\right| \cdot\left|\frac{B_{s}-B_{t}}{\sigma(s-t)}-n-x(1-\gamma-2 n)\right|\right] \\
& \leq \frac{C \cdot C_{F}}{(x(1-x))^{n} \sqrt{s-t}}, \tag{B.8}
\end{align*}
$$

where the inequality is due to (B.1) and Hölder's inequality. This implies that

$$
\begin{aligned}
& \int_{0}^{1} \frac{\partial}{\partial x}\left(\left(\frac{1-x}{1-y}\right)^{1-\gamma}\left(\frac{y(1-y)}{x(1-x)}\right)^{n} F(s, y) \varphi(y ; s-t, x)\right) d y \\
& =\frac{1}{(x(1-x))^{n}} \mathbb{E}\left[Z_{s}^{(t, x)} \frac{\partial Y_{s}^{(t, x)}}{\partial x}\left(Y_{s}^{(t, x)}\left(1-Y_{s}^{(t, x)}\right)\right)^{n-1} F\left(s, Y_{s}^{(t, x)}\right)\left(\frac{B_{s}-B_{t}}{\sigma(s-t)}-n-x(1-\gamma-2 n)\right)\right]
\end{aligned}
$$

is well-defined and continuous in $x$. Therefore, together with the estimate (B.8), we validate the interchange of integration and differentiation below:

$$
\begin{aligned}
& \left|\frac{\partial}{\partial x}\left(\int_{t}^{T} \lambda e^{-\lambda(s-t)} \mathbb{E}\left[Z_{s}^{(t, x)}\left(\frac{\partial Y_{s}^{(t, x)}}{\partial x}\right)^{n} F\left(s, Y_{s}^{(t, x)}\right)\right] d s\right)\right| \\
& =\left|\int_{t}^{T} \lambda e^{-\lambda(s-t)} \int_{0}^{1} \frac{\partial}{\partial x}\left(\left(\frac{1-x}{1-y}\right)^{1-\gamma}\left(\frac{y(1-y)}{x(1-x)}\right)^{n} F(s, y) \varphi(y ; s-t, x)\right) d y d s\right| \leq \frac{C \cdot C_{F} \sqrt{\lambda}}{(x(1-x))^{n}},
\end{aligned}
$$

where the inequality is due to (B.8) and Lemma F.3. Especially, when $n=1$, we have

$$
\begin{align*}
& \frac{\partial}{\partial x}\left(\int_{t}^{T} \lambda e^{-\lambda(s-t)} \mathbb{E}\left[Z_{s}^{(t, x)} \frac{\partial Y_{s}^{(t, x)}}{\partial x} F\left(s, Y_{s}^{(t, x)}\right)\right] d s\right) \\
& =\frac{1}{x(1-x)} \int_{t}^{T} \lambda e^{-\lambda(s-t)} \mathbb{E}\left[Z_{s}^{(t, x)} \frac{\partial Y_{s}^{(t, x)}}{\partial x} F\left(s, Y_{s}^{(t, x)}\right)\left(\frac{B_{s}-B_{t}}{\sigma(s-t)}-1+x(1+\gamma)\right)\right] d s . \tag{B.9}
\end{align*}
$$

(iii) By 4.13), we have $\frac{\partial Z_{s}^{(t, x)}}{\partial x} F\left(Y_{s}^{(t, x)}\right)=f\left(A_{s, t}\right)$ with $f(a):=(1-\gamma)(a-1)(x a+1-x)^{-\gamma} F\left(\frac{x a}{x a+1-x}\right)$. The conditions for $F$ allow us to apply Ito's lemma (see 6.24 Problem in p. 215 of [29]) and obtain

$$
f\left(A_{s-t, 0}\right)=\int_{0}^{s-t} g\left(A_{u, 0}\right) d u+\int_{0}^{s-t} f^{\prime}\left(A_{u, 0}\right) \sigma A_{u, 0} d B_{u}
$$

where $g(a):=f^{\prime}(a) \mu a+\frac{1}{2} f^{\prime \prime}(a) \sigma^{2} a^{2}$. The inequalities in (4.14) and (B.4) imply that the stochastic integral term above is a square integrable martingale. Therefore,

$$
\mathbb{E}\left[\frac{\partial Z_{s}^{(t, x)}}{\partial x} F\left(Y_{s}^{(t, x)}\right)\right]=\mathbb{E}\left[f\left(A_{s, t}\right)\right]=\mathbb{E}\left[f\left(A_{s-t, 0}\right)\right]=\int_{0}^{s-t} \mathbb{E}\left[g\left(A_{u, 0}\right)\right] d u
$$

We differentiate above with respect to $t$, apply Ito's lemma and use the inequalities in 4.14), then

$$
\begin{equation*}
\left|\frac{\partial}{\partial t} \mathbb{E}\left[\frac{\partial Z^{(t, x)}}{\partial x} F\left(Y_{s}^{(t, x)}\right)\right]\right|=\left|\mathbb{E}\left[g\left(A_{s-t, 0}\right)\right]\right| \leq|g(1)|+C(s-t) . \tag{B.10}
\end{equation*}
$$

Since $g(1)=\gamma(1-\gamma) \sigma^{2}\left(y_{M}-x\right) F(x)+(1-\gamma) \sigma^{2} x(1-x) F^{\prime}(x)$, B.10) implies B.5) and B.6.
Recall Notation 5.2 (ii) and (iii). When $\epsilon=0$ and $\lambda=\infty$, the value function is $v^{0}(t)$ in (5.4) and optimal fraction is $y_{M}=\frac{\mu}{\gamma \sigma^{2}}$. When $\epsilon=0$ and $\lambda<\infty$, we denote the value function as $v^{S O, \lambda}(t, x)$ and optimal fraction as $\hat{y}^{S O, \lambda}(t)$. Similarly, we denote $L^{S O, \lambda}(t, x):=\left.L(t, x)\right|_{\epsilon=0}$, where $L$ is defined in (4.15). Observe that

$$
\begin{equation*}
\hat{y}^{S O, \lambda}(t)=\left.\underline{y}(t)\right|_{\epsilon=0}=\left.\bar{y}(t)\right|_{\epsilon=0} \quad \text { and } \quad L^{S O, \lambda}(t, x)=v^{S O, \lambda}\left(t, \hat{y}^{S O, \lambda}(t)\right) \quad \text { for all } x \in[0,1] . \tag{B.11}
\end{equation*}
$$

The following results can be found in [34]: there is a constant $C>0$ independent of $(t, \lambda) \in$ $[0, T) \times[1, \infty)$ such that

$$
\begin{align*}
& \left|\hat{y}^{S O, \lambda}(t)-y_{M}\right| \leq \frac{C}{\lambda},  \tag{B.12}\\
& \left|v^{S O, \lambda}\left(t, \hat{y}^{S O, \lambda}(t)\right)-v^{0}(t)\right| \leq \frac{C}{\lambda},  \tag{B.13}\\
& \lim _{\lambda \rightarrow \infty} \frac{\lambda\left(v^{0}(t)-v^{S O, \lambda}\left(t, y_{M}\right)\right)}{1-\gamma}=\frac{\gamma \sigma^{4} y_{M}^{2}\left(1-y_{M}\right)^{2}}{2} \cdot e^{Q\left(y_{M}\right)(T-t)}(T-t) . \tag{B.14}
\end{align*}
$$

For the later analysis, we provide more estimates in this direction.
Lemma B. 2 (Asymptotics for $\epsilon=0$ case). The functions $v^{S O, \lambda}(t, x), v_{x}^{S O, \lambda}(t, x), v_{x x}^{S O, \lambda}(t, x)$ obtained by substitution $\epsilon=0$ can be continuously extended to $x=0$ and $x=1$. There exist positive constants $C, \underline{C}, \bar{C}$ independent of $(t, x, \lambda) \in[0, T] \times(0,1) \times[1, \infty)$ such that

$$
\begin{align*}
& \left|\frac{\partial^{n}}{\partial x^{n}} v^{S O, \lambda}(t, x)\right| \leq \frac{C}{\lambda} \quad \text { for } \quad n \in \mathbb{N}  \tag{B.15}\\
& \underline{C} \cdot \min \{1, \lambda(T-t)\} \leq-\frac{\lambda v_{x x}^{S O, \lambda}(t, x)}{1-\gamma} \leq \bar{C} \cdot \min \{1, \lambda(T-t)\} \tag{B.16}
\end{align*}
$$

Furthermore, for $(t, x) \in[0, T) \times(0,1)$,

$$
\begin{equation*}
\lim _{\lambda \rightarrow \infty} \frac{\lambda v_{x x}^{S O, \lambda}(t, x)}{1-\gamma}=-\gamma \sigma^{2} v^{0}(t) \tag{B.17}
\end{equation*}
$$

Proof. Throughout this proof, $C>0$ is a generic constant independent of $(t, x, \lambda) \in[0, T) \times(0,1) \times$ $[1, \infty)$ that may differ line by line. Using (B.11), the representation in 4.16) for $\epsilon=0$ becomes

$$
\begin{equation*}
v^{S O, \lambda}(t, x)=e^{-\lambda(T-t)} \mathbb{E}\left[Z_{T}^{(t, x)}\right]+\lambda \int_{t}^{T} e^{-\lambda(s-t)} v^{S O, \lambda}\left(s, \hat{y}^{S O, \lambda}(s)\right) \mathbb{E}\left[Z_{s}^{(t, x)}\right] d s \tag{B.18}
\end{equation*}
$$

We take derivative with respect to $x$ above. Using Lemma 4.3 and the dominated convergence theorem, we put the derivative inside of the integrals: for $n \in \mathbb{N}$,

$$
\begin{equation*}
\frac{\partial^{n}}{\partial x^{n}} v^{S O, \lambda}(t, x)=e^{-\lambda(T-t)} \mathbb{E}\left[\frac{\partial^{n} Z_{T}^{(t, x)}}{\partial x^{n}}\right]+\lambda \int_{t}^{T} e^{-\lambda(s-t)} v^{S O, \lambda}\left(s, \hat{y}^{S O, \lambda}(s)\right) \mathbb{E}\left[\frac{\partial^{n} Z_{s}^{(t, x)}}{\partial x^{n}}\right] d s \tag{B.19}
\end{equation*}
$$

The above equality, Lemma 4.3 , 4.13 and the dominated convergence theorem enable us to conclude that $v^{S O, \lambda}(t, x), v_{x}^{S O, \lambda}(t, x), v_{x x}^{S O, \lambda}(t, x)$ can be continuously extended to $x=0$ and $x=1$.

Observe that

$$
\begin{aligned}
& x e^{-x} \leq \min \{1, x\} \quad \text { and } \quad 0 \leq 1-e^{-x}-x e^{-x} \leq \min \{1, x\} \quad \text { for } \quad x \geq 0 \\
& x e^{-x} \geq \frac{x}{e} \quad \text { for } \quad 0 \leq x \leq 1, \quad 1-e^{-x}-x e^{-x} \geq 1-\frac{2}{e}>0 \quad \text { for } \quad x \geq 1
\end{aligned}
$$

By the above inequalities, for positive constants $c_{1}$ and $c_{2}$, we can find positive constants $\underline{c}$ and $\bar{c}$ such that

$$
\begin{equation*}
\underline{c} \cdot \min \{1, x\} \leq c_{1} x e^{-x}+c_{2}\left(1-e^{-x}-x e^{-x}\right) \leq \bar{c} \cdot \min \{1, x\} \quad \text { for } \quad x \geq 0 \tag{B.20}
\end{equation*}
$$

We apply (B.1) to (B.19) and obtain

$$
\left|\frac{\partial^{n}}{\partial x^{n}} v^{S O, \lambda}(t, x)\right| \leq C(T-t) e^{-\lambda(T-t)}+C \lambda \int_{t}^{T} e^{-\lambda(s-t)}(s-t) d s \leq \frac{C}{\lambda}
$$

where the second inequality is due to B.20). Thus, we conclude (B.15).
The expressions in 4.8 and 4.13 imply

$$
\begin{aligned}
& \min \left\{A_{s, t}^{-1-\gamma}, 1\right\} \leq\left(x A_{s, t}+1-x\right)^{-1-\gamma} \leq \max \left\{A_{s, t}^{-1-\gamma}, 1\right\} \quad \text { for } \quad 0 \leq x \leq 1 \\
& \lim _{s \downarrow t} \mathbb{E}\left[\min \left\{A_{s, t}^{-1-\gamma}, 1\right\}\left(\frac{A_{s, t}-1}{\sqrt{s-t}}\right)^{2}\right]=\lim _{s \downarrow t} \mathbb{E}\left[\max \left\{A_{s, t}^{-1-\gamma}, 1\right\}\left(\frac{A_{s, t}-1}{\sqrt{s-t}}\right)^{2}\right]=\sigma^{2}>0 \\
& -\frac{1}{(1-\gamma)(s-t)} \mathbb{E}\left[\frac{\partial^{2} Z_{s}^{(t, x)}}{\partial x^{2}}\right]=\gamma \mathbb{E}\left[\left(x A_{s, t}+1-x\right)^{-1-\gamma}\left(\frac{A_{s, t}-1}{\sqrt{s-t}}\right)^{2}\right]
\end{aligned}
$$

We combine the above inequalities, limits and expression to conclude that

$$
\begin{equation*}
\lim _{s \downarrow t}\left(-\frac{1}{(1-\gamma)(s-t)} \mathbb{E}\left[\frac{\partial^{2} Z_{s}^{(t, x)}}{\partial x^{2}}\right]\right)=\gamma \sigma^{2}>0 \tag{B.21}
\end{equation*}
$$

and there exist positive constants $\underline{c}$ and $\bar{c}$ independent of $(t, s, x, \lambda)$ such that

$$
\begin{equation*}
\underline{c} \leq-\frac{1}{(1-\gamma)(s-t)} \mathbb{E}\left[\frac{\partial^{2} Z_{s}^{(t, x)}}{\partial x^{2}}\right] \leq \bar{c} \tag{B.22}
\end{equation*}
$$

From $(\mathrm{B} .19$ for $n=2$, we obtain the following expression:

$$
\begin{aligned}
-\frac{\lambda v_{x x}^{S O, \lambda}(t, x)}{1-\gamma}= & \lambda(T-t) e^{-\lambda(T-t)} \cdot\left(-\frac{1}{(1-\gamma)(T-t)} \mathbb{E}\left[\frac{\partial^{2} Z_{T}^{(t, x)}}{\partial x^{2}}\right]\right) \\
& +\lambda^{2} \int_{t}^{T} e^{-\lambda(s-t)}(s-t) \cdot v^{S O, \lambda}\left(s, \hat{y}^{S O, \lambda}(s)\right) \cdot\left(-\frac{1}{(1-\gamma)(s-t)} \mathbb{E}\left[\frac{\partial^{2} Z_{s}^{(t, x)}}{\partial x^{2}}\right]\right) d s
\end{aligned}
$$

We apply the inequalities in Lemma 3.3 (ii), B.20 and $\overline{B .22}$ to the above expression to conclude B.16). Finally, in the above expression, we substitute $u=\lambda(s-t)$ and let $\lambda \rightarrow \infty$ :

$$
\begin{aligned}
\lim _{\lambda \rightarrow \infty}-\frac{\lambda v_{x x}^{S O, \lambda}(t, x)}{1-\gamma} & =\lim _{\lambda \rightarrow \infty} \int_{0}^{\lambda(T-t)} e^{-u} u \cdot v^{S O, \lambda}\left(\frac{u}{\lambda}+t, \hat{y}^{S O, \lambda}\left(\frac{u}{\lambda}+t\right)\right) \cdot\left(-\frac{1}{(1-\gamma) \frac{u}{\lambda}} \mathbb{E}\left[\frac{\partial^{2} Z_{u}^{(t, x)}(\lambda+t}{\partial x^{2}}\right]\right) d u \\
& =\int_{0}^{\infty} e^{-u} u d u \cdot v^{0}(t) \cdot \gamma \sigma^{2}=\gamma \sigma^{2} v^{0}(t)
\end{aligned}
$$

where the second equality is due to $(\mathrm{B} .13),(\mathrm{B} .21),(\mathrm{B} .22)$ and the dominated convergence theorem.

Lemma B. 3 (Estimates of $v^{\epsilon}, v_{x}^{\epsilon}, v_{x x}^{\epsilon}$ and $v_{x x x}^{\epsilon}$ ). Let Assumption 5.1 hold. Let $C>0$ be a generic constant independent of $(t, s, x, \epsilon) \in[0, T) \times[t, T) \times(0,1) \times(0,1)$ (also independent of $\lambda$ due to relation $\left.\lambda=c \epsilon^{-\frac{2}{3}}\right)$ that may differ line by line. Then, the followings hold:

$$
\begin{align*}
& x(1-x)\left|v_{x x}^{\epsilon}(t, x)-v_{x x}^{S O, \lambda}(t, x)\right| \leq C \epsilon^{\frac{2}{3}}  \tag{B.23}\\
& \left|v_{x}^{\epsilon}(t, x)-v_{x}^{S O, \lambda}(t, x)\right| \leq C \epsilon  \tag{B.24}\\
& \left|v^{\epsilon}(t, x)-v^{S O, \lambda}(t, x)\right| \leq C \epsilon^{\frac{2}{3}}  \tag{B.25}\\
& -\frac{v_{x x}^{\epsilon}(t, x)}{1-\gamma} \geq C\left(\epsilon^{\frac{2}{3}}-\epsilon\right) \min \{\lambda(T-t), 1\}  \tag{B.26}\\
& x^{2}(1-x)^{2}\left|v_{x x x}^{\epsilon}(t, x)-v_{x x x}^{S O, \lambda}(t, x)\right| \leq C \epsilon^{\frac{1}{3}} \tag{B.27}
\end{align*}
$$

where $v_{x x x}^{\epsilon}(t, x)$ exists and is continuous in $(t, x) \in[0, T) \times(0,1)$.
Proof. For convenience, let $g^{\epsilon}:[0,1]^{2} \rightarrow \mathbb{R}$ be

$$
\begin{equation*}
g^{\epsilon}(x, y):=\left(\left(\frac{1+\epsilon x}{1+\epsilon y}\right)^{1-\gamma}-1\right) 1_{\{y>x\}}+\left(\left(\frac{1-\epsilon x}{1-\epsilon y}\right)^{1-\gamma}-1\right) 1_{\{y<x\}} \tag{B.28}
\end{equation*}
$$

Then, the mean value theorem (consider $\epsilon$ as a variable) produces

$$
\begin{equation*}
\left|g^{\epsilon}(x, y)\right| \leq C|x-y| \epsilon \quad \text { for } \quad x, y \in[0,1] \tag{B.29}
\end{equation*}
$$

From the expression of $L$ in 4.19 , we obtain

$$
\begin{align*}
\left|L^{\epsilon}(t, x)-L^{S O, \lambda}(t, x)\right| & \leq \sup _{y \in[0,1]}\left|v^{\epsilon}(t, y) g^{\epsilon}(x, y)\right|+\sup _{y \in[0,1]}\left|v^{\epsilon}(t, y)-v^{S O, \lambda}(t, y)\right| \\
& \leq C \epsilon+\sup _{y \in[0,1]}\left|v^{\epsilon}(t, y)-v^{S O, \lambda}(t, y)\right| \tag{B.30}
\end{align*}
$$

where the second inequality is due to (3.18) and (B.29). The above inequality and 4.16) produce

$$
\left|v^{\epsilon}(t, x)-v^{S O, \lambda}(t, x)\right|=\left|\lambda \int_{t}^{T} e^{-\lambda(s-t)} \mathbb{E}\left[Z_{s}^{(t, x)}\left(L^{\epsilon}\left(s, Y_{s}^{(t, x)}\right)-L^{S O, \lambda}\left(s, Y_{s}^{(t, x)}\right)\right)\right] d s\right|
$$

$$
\begin{align*}
& \leq \lambda \int_{t}^{T} e^{-\lambda(s-t)} \mathbb{E}\left[Z_{s}^{(t, x)}\right]\left(C \epsilon+\sup _{y \in[0,1]}\left|v^{\epsilon}(s, y)-v^{S O, \lambda}(s, y)\right|\right) d s \\
& \leq \lambda \int_{t}^{T} e^{(C-\lambda)(s-t)}\left(C \epsilon+\sup _{y \in[0,1]}\left|v^{\epsilon}(s, y)-v^{S O, \lambda}(s, y)\right|\right) d s \tag{B.31}
\end{align*}
$$

where the last inequality is due to $\mathbb{E}\left[Z_{s}^{(t, x)}\right] \leq 1+C(s-t) \leq e^{C(s-t)}$ by (B.1). For convenience, we define $f(t):=e^{(C-\lambda) t} \sup _{y \in[0,1]}\left|v^{\epsilon}(t, y)-v^{S O, \lambda}(t, y)\right|$. Then, inequality B.31 can be written as

$$
f(t) \leq C \epsilon \int_{t}^{T} \lambda e^{(C-\lambda) s} d s+\int_{t}^{T} \lambda f(s) d s
$$

Since $f$ is measurable due to Lemma F.2, we apply Gronwall's inequality (see Lemma F.1) to obtain

$$
\begin{aligned}
f(t) & \leq C \epsilon \int_{t}^{T} \lambda e^{(C-\lambda) s} d s+\int_{t}^{T}\left(C \epsilon \int_{s}^{T} \lambda e^{(C-\lambda) u} d u\right) \lambda e^{\lambda(s-t)} d s \\
& =\frac{C \epsilon \lambda}{\lambda-C} \cdot\left(e^{(C-\lambda) t}-e^{(C-\lambda) T}\right)+\frac{C \epsilon \lambda e^{-\lambda t}}{\lambda-C} \cdot\left(\frac{\lambda\left(e^{C T}-e^{C t}\right)}{C}-e^{C T}\left(1-e^{-\lambda(T-t)}\right)\right)
\end{aligned}
$$

We apply $\lambda=c \epsilon^{-\frac{2}{3}}$ to the above inequality and conclude that

$$
\begin{equation*}
\sup _{y \in[0,1]}\left|v^{\epsilon}(t, y)-v^{S O, \lambda}(t, y)\right|=e^{(\lambda-C) t} f(t) \leq C \epsilon^{\frac{1}{3}} \tag{B.32}
\end{equation*}
$$

Notice that $(\bar{B} .25)$ is not obtained yet.
Since the value function $V$ in (3.1) should decrease in $\epsilon$, we have $\frac{v^{\epsilon}(t, x)}{1-\gamma} \leq \frac{v^{S O, \lambda}(t, x)}{1-\gamma}$. Therefore, the expression of $L$ in (4.19), together with (B.30) and (B.32), implies that

$$
\begin{equation*}
-C \epsilon^{\frac{1}{3}} \leq \frac{L^{\epsilon}(t, x)-L^{S O, \lambda}(t, x)}{1-\gamma} \leq 0 \tag{B.33}
\end{equation*}
$$

(Proof of B.23))
We take derivative with respect to $x$ in 4.18, and put the derivative inside of the expectation (Lemma 4.3, $\|L\|_{\infty}<\infty$ and 4.22 allow us to do this) to obtain the following expression:

$$
\begin{align*}
v_{x x}^{\epsilon}(t, x)= & e^{-\lambda(T-t)} \mathbb{E}\left[\frac{\partial^{2} Z_{T}^{(t, x)}}{\partial x^{2}}\right]+\lambda \int_{t}^{T} e^{-\lambda(s-t)} \mathbb{E}\left[\frac{\partial^{2} Z_{s}^{(t, x)}}{\partial x^{2}} L^{\epsilon}\left(s, Y_{s}^{(t, x)}\right)+\frac{\partial Z_{s}^{(t, x)}}{\partial x} L_{x}^{\epsilon}\left(s, Y_{s}^{(t, x)}\right) \frac{\partial Y_{s}^{(t, x)}}{\partial x}\right] d s \\
& +\frac{\partial}{\partial x}\left(\lambda \int_{t}^{T} e^{-\lambda(s-t)} \mathbb{E}\left[Z_{s}^{(t, x)} L_{x}^{\epsilon}\left(s, Y_{s}^{(t, x)}\right) \frac{\partial Y_{s}^{(t, x)}}{\partial x}\right] d s\right) \tag{B.34}
\end{align*}
$$

This implies that

$$
\begin{aligned}
\left|v_{x x}^{\epsilon}(t, x)-v_{x x}^{S O, \lambda}(t, x)\right| \leq & \left|\lambda \int_{t}^{T} e^{-\lambda(s-t)} \mathbb{E}\left[\frac{\partial^{2} Z_{s}^{(t, x)}}{\partial x^{2}}\left(L^{\epsilon}\left(s, Y_{s}^{(t, x)}\right)-L^{S O, \lambda}\left(s, Y_{s}^{(t, x)}\right)\right)\right] d s\right| \\
& +\left|\lambda \int_{t}^{T} e^{-\lambda(s-t)} \mathbb{E}\left[\frac{\partial Z_{s}^{(t, x)}}{\partial x} L_{x}^{\epsilon}\left(s, Y_{s}^{(t, x)}\right) \frac{\partial Y_{s}^{(t, x)}}{\partial x}\right] d s\right| \\
& +\left|\frac{\partial}{\partial x}\left(\lambda \int_{t}^{T} e^{-\lambda(s-t)} \mathbb{E}\left[Z_{s}^{(t, x)} L_{x}^{\epsilon}\left(s, Y_{s}^{(t, x)}\right) \frac{\partial Y_{s}^{(t, x)}}{\partial x}\right] d s\right)\right|
\end{aligned}
$$

In the right side of the above inequality, the first term is bounded by $C \lambda \int_{t}^{T} e^{-\lambda(s-t)} \epsilon^{\frac{1}{3}}(s-t) d s$ due to $(\overline{\mathrm{B} .2})$ and $(\overline{\mathrm{B} .33})$, the second term is bounded by $C \lambda \int_{t}^{T} e^{-\lambda(s-t)} \epsilon d s$ due to Lemma 4.3 and (4.22) and the third term is bounded by $\frac{C}{x(1-x)} \epsilon^{\frac{2}{3}}$ due to Lemma B.1 (ii) (with $n=1$ and $F=L_{x}^{\epsilon}$ ) and 4.22 . These bounds and $\lambda=c \epsilon^{-\frac{2}{3}}$ produce (B.23).
(Proof of B.24)
The expression of $L_{x}$ in 4.17 implies that $L_{x}^{\epsilon}(t, x)$ is continuously differentiable with respect to $x$, except $x=\underline{y}^{\epsilon}(t)$ and $x=\bar{y}^{\epsilon}(t)$. To be specific,

$$
L_{x x}^{\epsilon}(t, x)= \begin{cases}-\frac{\gamma(1-\gamma) \epsilon^{2} v^{\epsilon}\left(t, \underline{y}^{\epsilon}(t)\right)}{(1+\epsilon x)^{2}}\left(\frac{1+\epsilon x}{1+\epsilon \underline{y}^{\epsilon}(t)}\right)^{1-\gamma} & \text { if } \quad x \in\left(0, \underline{y}^{\epsilon}(t)\right)  \tag{B.35}\\ v_{x x}^{\epsilon}(t, x) & \text { if } \quad x \in\left(\underline{y}^{\epsilon}(t), \bar{y}^{\epsilon}(t)\right) \\ -\frac{\gamma(1-\gamma) \epsilon^{2} v^{\epsilon}\left(t, \bar{y}^{\epsilon}(t)\right)}{(1-\epsilon x)^{2}}\left(\frac{1-\epsilon x}{1-\epsilon \bar{y}^{\epsilon}(t)}\right)^{1-\gamma} & \text { if } \quad x \in\left(\bar{y}^{\epsilon}(t), 1\right)\end{cases}
$$

Lemma 3.3 (i), B.15 and B.23 imply

$$
\begin{equation*}
-\frac{C \epsilon^{\frac{2}{3}}}{x(1-x)} \leq \frac{v_{x x}^{\epsilon}(t, x)}{1-\gamma} \leq 0 \tag{B.36}
\end{equation*}
$$

We combine Lemma 3.3 (ii), B.35) and $\bar{B} .36$ to obtain

$$
\begin{equation*}
-\frac{C \epsilon^{\frac{2}{3}}}{x(1-x)} \leq \frac{L_{x x}^{\epsilon}(t, x)}{1-\gamma} \leq 0 \tag{B.37}
\end{equation*}
$$

To apply Lemma B.1 (iii), we set $F(y)=L^{\epsilon}(s, y)-L^{S O, \lambda}(s, y)$ and observe that $F^{\prime}(y)=L_{x}^{\epsilon}(s, y)$ and $F^{\prime \prime}(y)=L_{x x}^{\epsilon}(s, y)$ except $y \in\left\{\underline{y}^{\epsilon}(s), \bar{y}^{\epsilon}(s)\right\}$. We check that (B.4) is satisfied due to (3.18), (4.22) and (B.37). Therefore, Lemma B.1 (iii) is applicable and (B.6), together with (B.33), (4.22) and (B.37), produces

$$
\begin{equation*}
\left|\mathbb{E}\left[\frac{\partial Z_{s}^{(t, x)}}{\partial x}\left(L^{\epsilon}\left(s, Y_{s}^{(t, x)}\right)-L^{S O, \lambda}\left(s, Y_{s}^{(t, x)}\right)\right)\right]\right| \leq C\left(\epsilon^{\frac{1}{3}}+\epsilon\right)(s-t)+C(s-t)^{2} \tag{B.38}
\end{equation*}
$$

We use the stochastic representation 4.18 to obtain

$$
\begin{aligned}
\left|v_{x}^{\epsilon}(t, x)-v_{x}^{S O, \lambda}(t, x)\right| \leq & \left|\lambda \int_{t}^{T} e^{-\lambda(s-t)} \mathbb{E}\left[\frac{\partial Z_{s}^{(t, x)}}{\partial x}\left(L^{\epsilon}\left(s, Y_{s}^{(t, x)}\right)-L^{S O, \lambda}\left(s, Y_{s}^{(t, x)}\right)\right)\right] d s\right| \\
& +\left|\lambda \int_{t}^{T} e^{-\lambda(s-t)} \mathbb{E}\left[Z_{s}^{(t, x)} L_{x}^{\epsilon}\left(s, Y_{s}^{(t, x)}\right) \frac{\partial Y_{s}^{(t, x)}}{\partial x}\right] d s\right|
\end{aligned}
$$

The first term in the right-hand side is bounded by $C \lambda \int_{t}^{T} e^{-\lambda(s-t)}\left(\left(\epsilon^{\frac{1}{3}}+\epsilon\right)(s-t)+(s-t)^{2}\right) d s$ due to (B.38) and the second term is bounded by $C \lambda \int_{t}^{T} e^{-\lambda(s-t)} \epsilon d s$ due to Lemma 4.3 and 4.22). These bounds and $\lambda=c \epsilon^{-\frac{2}{3}}$ produce $(\overline{\mathrm{B} .24})$.
(Proof of (B.25))
Using (B.11) and (B.33), we obtain

$$
\begin{align*}
0 & \leq \frac{1}{1-\gamma}\left(L^{S O, \lambda}\left(s, Y_{s}^{\left(t, \hat{y}^{S O, \lambda}(t)\right)}\right)-L^{\epsilon}\left(s, Y_{s}^{\left(t, \hat{y}^{S O, \lambda}(t)\right)}\right)\right) \\
& =\frac{1}{1-\gamma}\left(v^{S O, \lambda}\left(s, \hat{y}^{S O, \lambda}(s)\right)-L^{\epsilon}\left(s, Y_{s}^{\left(t, \hat{y}^{S O, \lambda}(t)\right)}\right)\right) \\
& \leq \frac{1}{1-\gamma}\left(v^{S O, \lambda}\left(s, \hat{y}^{S O, \lambda}(s)\right)-v^{\epsilon}\left(s, \hat{y}^{S O, \lambda}(s)\right)-v^{\epsilon}\left(s, \hat{y}^{S O, \lambda}(s)\right) g^{\epsilon}\left(Y_{s}^{\left(t, \hat{y}^{S O, \lambda}(t)\right)}, \hat{y}^{S O, \lambda}(s)\right)\right) \\
& \leq C \epsilon\left|Y_{s}^{\left(t, \hat{y}^{S O, \lambda}(t)\right)}-\hat{y}^{S O, \lambda}(s)\right|+\frac{v^{S O, \lambda}\left(s, \hat{y}^{S O, \lambda}(s)\right)-v^{\epsilon}\left(s, \hat{y}^{S O, \lambda}(s)\right)}{1-\gamma} \\
& \leq C \epsilon\left(\left|Y_{s}^{\left(t, \hat{y}^{S O, \lambda}(t)\right)}-\hat{y}^{S O, \lambda}(t)\right|+\frac{1}{\lambda}\right)+\frac{v^{S O, \lambda}\left(s, \hat{y}^{S O, \lambda}(s)\right)-v^{\epsilon}\left(s, \hat{y}^{S O, \lambda}(s)\right)}{1-\gamma} \tag{B.39}
\end{align*}
$$

where the second inequality is due to $(4.19)$ and $(\mathrm{B} .28)$, the third inequality is due to (B.29) and the last inequality is due to B .12 .

By the same way as we prove Lemma B.1 (i), we can check that $\mathbb{E}\left[\left(Y_{s}^{(t, x)}-x\right)^{2}\right] \leq C(s-t)$. Hence, by Lemma B.1 (i) and Hölder's inequality, we produce

$$
\begin{equation*}
\mathbb{E}\left[Z_{s}^{(t, x)} \cdot\left|Y_{s}^{(t, x)}-x\right|\right] \leq \sqrt{(1+C(s-t)) C(s-t)} \leq C e^{C(s-t)} \sqrt{s-t} \tag{B.40}
\end{equation*}
$$

The stochastic representation in (4.16) produces

$$
\begin{aligned}
0 \leq & \frac{1}{1-\gamma}\left(v^{S O, \lambda}\left(t, \hat{y}^{S O, \lambda}(t)\right)-v^{\epsilon}\left(t, \hat{y}^{S O, \lambda}(t)\right)\right) \\
= & \lambda \int_{t}^{T} e^{-\lambda(s-t)} \mathbb{E}\left[Z_{s}^{\left(t, \hat{y}^{S O, \lambda}(t)\right)} \frac{1}{1-\gamma}\left(L^{S O, \lambda}\left(s, Y_{s}^{\left(t, \hat{y}^{S O, \lambda}(t)\right)}\right)-L^{\epsilon}\left(s, Y_{s}^{\left(t, \hat{y}^{S O, \lambda}(t)\right)}\right)\right)\right] d s \\
\leq & \lambda \int_{t}^{T} e^{-\lambda(s-t)} \mathbb{E}\left[Z_{s}^{\left(t, \hat{y}^{S O, \lambda}(t)\right)} C \epsilon\left(\left|Y_{s}^{\left(t, \hat{y}^{S O, \lambda}(t)\right)}-\hat{y}^{S O, \lambda}(t)\right|+\frac{1}{\lambda}\right)\right] d s \\
& +\lambda \int_{t}^{T} e^{-\lambda(s-t)} \mathbb{E}\left[Z_{s}^{\left(t, \hat{y}^{S O, \lambda}(t)\right)}\right] \frac{v^{S O, \lambda}\left(s, \hat{y}^{S O, \lambda}(s)\right)-v^{\epsilon}\left(s, \hat{y}^{S O, \lambda}(s)\right)}{1-\gamma} d s \\
\leq & C \lambda \int_{t}^{T} e^{(C-\lambda)(s-t)}\left(\epsilon\left(\sqrt{s-t}+\frac{1}{\lambda}\right)+\frac{v^{S O, \lambda\left(s, \hat{y}^{S O, \lambda}(s)\right)-v^{\epsilon}\left(s, \hat{y}^{S O, \lambda}(s)\right)}}{1-\gamma}\right) d s,
\end{aligned}
$$

where the first and second inequalities are due to $(\overline{B .39)}$ and the last inequality is due to $(\bar{B} .40)$ and (4.3). Since the map $t \mapsto v^{S O, \lambda}\left(t, \hat{y}^{S O, \lambda}(t)\right)-v^{\epsilon}\left(t, \hat{y}^{S O}, \lambda(t)\right)$ is measurable due to Lemma F.2, by the same way as we treated B.31), we apply Gronwall's inequality (see Lemma F.1), Lemma F. 3 and $\lambda=c \epsilon^{-\frac{2}{3}}$ to the above inequality to obtain

$$
\left|v^{S O, \lambda}\left(t, \hat{y}^{S O, \lambda}(t)\right)-v^{\epsilon}\left(t, \hat{y}^{S O, \lambda}(t)\right)\right| \leq C \epsilon^{\frac{2}{3}}
$$

The above inequality and (B.24) produce (B.25): for $(t, x) \in[0, T) \times(0,1)$,

$$
\left|v^{\epsilon}(t, x)-v^{S O, \lambda}(t, x)\right|=\left.\left|v^{\epsilon}(t, \zeta)-v^{S O, \lambda}(t, \zeta)+\int_{\zeta}^{x}\left(v_{x}^{\epsilon}(t, z)-v_{x}^{S O, \lambda}(t, z)\right) d z\right|\right|_{\zeta=\hat{y} S O, \lambda(t)} \leq C \epsilon^{\frac{2}{3}}
$$

(Proof of B.26)
By (B.30) and (B.25), we have

$$
\begin{equation*}
\left|L^{\epsilon}(t, x)-L^{S O, \lambda}(t, x)\right| \leq C \epsilon^{\frac{2}{3}} \tag{B.41}
\end{equation*}
$$

Since $\mathbb{P}\left(Y_{s}^{(t, x)} \notin\left\{\underline{y}^{\epsilon}(s), \bar{y}^{\epsilon}(s)\right\}\right)=1$ for $t<s$, Lemma 4.3 and (B.37) and the continuity of $x \mapsto$ $L_{x}^{\epsilon}(t, x)$ allow us to put the derivative inside of the expectation in (B.34):

$$
\begin{align*}
v_{x x}^{\epsilon}(t, x)= & \lambda \int_{t}^{T} e^{-\lambda(s-t)} \mathbb{E}\left[\frac{\partial^{2} Z_{s}^{(t, x)}}{\partial x^{2}} L^{\epsilon}\left(s, Y_{s}^{(t, x)}\right)+\left(2 \frac{\partial Z_{s}^{(t, x)}}{\partial x} \frac{\partial Y_{s}^{(t, x)}}{\partial x}+Z_{s}^{(t, x)} \frac{\partial^{2} Y_{s}^{(t, x)}}{\partial x^{2}}\right) L_{x}^{\epsilon}\left(s, Y_{s}^{(t, x)}\right)\right] d s \\
& +e^{-\lambda(T-t)} \mathbb{E}\left[\frac{\partial^{2} Z_{T}^{(t, x)}}{\partial x^{2}}\right]+\lambda \int_{t}^{T} e^{-\lambda(s-t)} \mathbb{E}\left[Z_{s}^{(t, x)} L_{x x}^{\epsilon}\left(s, Y_{s}^{(t, x)}\right)\left(\frac{\partial Y_{s}^{(t, x)}}{\partial x}\right)^{2}\right] d s . \tag{B.42}
\end{align*}
$$

The above expression produces the following equality:

$$
\begin{align*}
\frac{v_{x x}^{\epsilon}(t, x)-v_{x x}^{S O, \lambda}(t, x)}{1-\gamma}= & \lambda \int_{t}^{T} e^{-\lambda(s-t)} \mathbb{E}\left[Z_{s}^{(t, x)} \frac{L_{x x}^{\epsilon}\left(s, Y_{s}^{(t, x)}\right)}{1-\gamma}\left(\frac{\partial Y_{y^{(t, x)}}^{\partial x}}{\partial x}\right)^{2}\right] d s \\
& +\lambda \int_{t}^{T} e^{-\lambda(s-t)} \mathbb{E}\left[\frac{\partial^{2} Z_{s}^{(t, x)}}{\partial x^{2}} \frac{L^{\epsilon}\left(s, Y_{s}^{(t, x)}\right)-L^{S O, \lambda}\left(s, Y_{s}^{(t, x)}\right)}{1-\gamma}\right] d s \\
& +\lambda \int_{t}^{T} e^{-\lambda(s-t)} \mathbb{E}\left[\left(2 \frac{\partial Z_{s}^{(t, x)}}{\partial x} \frac{\partial Y_{s}^{(t, x)}}{\partial x}+Z_{s}^{(t, x)} \frac{\partial^{2} Y_{s}^{(t, x)}}{\partial x^{2}}\right) \frac{L_{x}^{\epsilon}\left(s, Y_{s}^{(t, x)}\right)}{1-\gamma}\right] d s \tag{B.43}
\end{align*}
$$

In the right-hand side of the above equality, the first term is bounded above by 0 due to ( $\bar{B} .37$ ), the second term is bounded above by $C \lambda \int_{t}^{T} e^{-\lambda(s-t)} \epsilon^{\frac{2}{3}}(s-t) d s$ due to (B.2) and B.41) and the third term is bounded above by $C \lambda \int_{t}^{T} e^{-\lambda(s-t)} \epsilon d s$ due to and 4.22) and Lemma 4.3. These bounds and $\lambda=c \epsilon^{-\frac{2}{3}}$, together with $1-e^{-\lambda(T-t)} \leq \min \{\lambda(T-t), 1\}$, produce

$$
-\frac{v_{x x}^{\epsilon}(t, x)}{1-\gamma} \geq-\frac{v_{x x}^{S O}, \lambda}{}(t, x)-C \epsilon \min \{\lambda(T-t), 1\}
$$

We combine the above inequality and (B.16) to conclude B.26).
(Proof of B.27)
By the same way as we obtain (B.34), we take derivative with respect to $x$ in (B.42):

$$
\begin{gathered}
v_{x x x}^{\epsilon}(t, x)=e^{-\lambda(T-t)} \mathbb{E}\left[\frac{\partial^{3} Z_{T}^{(t, x)}}{\partial x^{3}}\right]+\frac{\partial}{\partial x}\left(\lambda \int_{t}^{T} e^{-\lambda(s-t)} \mathbb{E}\left[Z_{s}^{(t, x)} L_{x x}^{\epsilon}\left(s, Y_{s}^{(t, x)}\right)\left(\frac{\partial Y_{s}^{(t, x)}}{\partial x}\right)^{2}\right] d s\right) \\
+\lambda \int_{t}^{T} e^{-\lambda(s-t)} \mathbb{E}\left[\frac{\partial^{3} Z_{s}^{(t, x)}}{\partial x^{3}} L^{\epsilon}\left(s, Y_{s}^{(t, x)}\right)+\left(2 \frac{\partial Z_{s}^{(t, x)}}{\partial x} \frac{\partial Y_{s}^{(t, x)}}{\partial x}+Z_{s}^{(t, x)} \frac{\partial^{2} Y_{s}^{(t, x)}}{\partial x^{2}}\right) L_{x x}^{\epsilon}\left(s, Y_{s}^{(t, x)}\right) \frac{\partial Y_{s}^{(t, x)}}{\partial x}\right. \\
\left.+\left(3 \frac{\partial^{2} Z_{s}^{(t, x)}}{\partial x^{2}} \frac{\partial Y_{s}^{(t, x)}}{\partial x}+3 \frac{\partial Z_{s}^{(t, x)}}{\partial x} \frac{\partial^{2} Y_{s}^{(t, x)}}{\partial x^{2}}+Z_{s}^{(t, x)} \frac{\partial^{3} Y_{s}^{(t, x)}}{\partial x^{3}}\right) L_{x}^{\epsilon}\left(s, Y_{s}^{(t, x)}\right)\right] d s .
\end{gathered}
$$

This implies that

$$
\begin{aligned}
\left|v_{x x x}^{\epsilon}(t, x)-v_{x x x}^{S O, \lambda}(t, x)\right| \leq & \left|\frac{\partial}{\partial x}\left(\lambda \int_{t}^{T} e^{-\lambda(s-t)} \mathbb{E}\left[Z_{s}^{(t, x)} L_{x x}^{\epsilon}\left(s, Y_{s}^{(t, x)}\right)\left(\frac{\partial Y_{s}^{(t, x)}}{\partial x}\right)^{2}\right] d s\right)\right| \\
+\mid \lambda & \int_{t}^{T} e^{-\lambda(s-t)} \mathbb{E}\left[\frac{\partial^{3} Z_{s}^{(t, x)}}{\partial x^{3}}\left(L^{\epsilon}\left(s, Y_{s}^{(t, x)}\right)-L^{S O, \lambda}\left(s, Y_{s}^{(t, x)}\right)\right)\right. \\
& +\left(2 \frac{\partial Z_{s}^{(t, x)}}{\partial x} \frac{\partial Y_{s}^{(t, x)}}{\partial x}+Z_{s}^{(t, x)} \frac{\partial^{2} Y_{s}^{(t, x)}}{\partial x^{2}}\right) L_{x x}^{\epsilon}\left(s, Y_{s}^{(t, x)}\right) \frac{\partial Y_{s}^{(t, x)}}{\partial x} \\
& \left.+\left(3 \frac{\partial^{2} Z_{s}^{(t, x)}}{\partial x^{2}} \frac{\partial Y_{s}^{(t, x)}}{\partial x}+3 \frac{\partial Z_{s}^{(t, x)}}{\partial x} \frac{\partial^{2} Y_{s}^{(t, x)}}{\partial x^{2}}+Z_{s}^{(t, x)} \frac{\partial^{3} Y_{s}^{(t, x)}}{\partial x^{3}}\right) L_{x}^{\epsilon}\left(s, Y_{s}^{(t, x)}\right)\right] d s \mid .
\end{aligned}
$$

In the right-hand side of the above inequality, the first integral is bounded by $\frac{C \epsilon^{\frac{2}{3}} \sqrt{\lambda}}{x^{2}(1-x)^{2}}$ due to Lemma B. 1 (ii) (with $n=2$ and $F=L_{x x}^{\epsilon}$ ) and B.37) and the second integral is bounded by $C \lambda \int_{t}^{T} e^{-\lambda(s-t)}\left(\epsilon^{\frac{2}{3}}+\frac{1}{x(1-x)} \epsilon^{\frac{2}{3}}+\epsilon\right) d s$ due to Lemma 4.3. (B.41), B.37) and 4.22. These bounds and $\lambda=c \epsilon^{-\frac{2}{3}}$ produce (B.27).
Lemma B.4. Let Assumption 5.1 hold. Let $C>0$ be a generic constant independent of $(t, s, x, \epsilon) \in$ $[0, T) \times[t, T) \times(0,1) \times(0,1)$ (also independent of $\lambda$ due to relation $\lambda=c \epsilon^{-\frac{2}{3}}$ ) that may differ line by line. Recall that $\underline{t}^{\epsilon}$ and $\bar{t}^{\epsilon}$ appear in (6.1).
(i) $v_{x t}^{\epsilon}(t, x)=v_{t x}^{\epsilon}(t, x)$ exist and are continuous in $(t, x) \in[0, T) \times(0,1)$. Furthermore,

$$
\begin{equation*}
\left|v_{t}^{\epsilon}(t, x)\right| \leq C, \quad\left|v_{x t}^{\epsilon}(t, x)\right| \leq C \tag{B.44}
\end{equation*}
$$

(ii) There exists $\epsilon_{0}>0$ such that for $\epsilon \in\left(0, \epsilon_{0}\right]$ and $t \in\left[0, \min \left\{\underline{t}^{\epsilon}, \bar{t}^{\epsilon}\right\}\right)$,

$$
\begin{equation*}
\underline{y}_{t}^{\epsilon}(t):=\frac{\partial y^{\epsilon}(t)}{\partial t}=\frac{\frac{v_{x t}^{\epsilon}\left(t, y^{\epsilon}(t)\right)}{1-\gamma}-\frac{\epsilon v_{t}^{\epsilon}\left(t, y^{\epsilon}(t)\right)}{1+\epsilon \underline{y}^{\epsilon}(t)}}{-\frac{v_{x x}^{\epsilon}\left(t, \underline{y}^{\epsilon}(t)\right)}{1-\gamma}-\frac{\left.\gamma \epsilon^{2} v^{\epsilon}\left(t, \underline{y}^{\epsilon}(t)\right)\right)}{\left(1+\epsilon \underline{y}^{\epsilon}(t)\right)^{2}}} \quad \bar{y}_{t}^{\epsilon}(t):=\frac{\partial \bar{y}^{\epsilon}(t)}{\partial t}=\frac{\frac{v_{x t}^{\epsilon}\left(t, \bar{y}^{\epsilon}(t)\right)}{1-\gamma}+\frac{\epsilon v_{t}^{\epsilon}\left(t, \bar{y}^{\epsilon}(t)\right)}{11-\epsilon \bar{y}^{\epsilon}(t)}}{-\frac{v_{x x}^{\epsilon}\left(t, \bar{y}^{\epsilon}(t)\right)}{1-\gamma}-\frac{\gamma \epsilon^{2} v^{\epsilon}\left(t, \bar{y}^{\epsilon}(t)\right)}{\left(1-\epsilon \overline{y^{\epsilon}}(t)\right)^{2}}} . \tag{B.45}
\end{equation*}
$$

Obviously, $\underline{y}_{t}^{\epsilon}(t)=0$ for $t \in\left(\underline{t}^{\epsilon}, T\right)$ and $\bar{y}_{t}^{\epsilon}(t)=0$ for $t \in\left(\bar{t}^{\epsilon}, T\right)$.
(iii) Recall that $L^{\epsilon}$ appears in 4.15). For $\epsilon \in\left(0, \epsilon_{0}\right]$ with $\epsilon_{0}$ in (ii) and $t \in[0, T) \backslash\left\{\underline{t}^{\epsilon}, \bar{t}^{\epsilon}\right\}$,

$$
\begin{align*}
& L_{t}^{\epsilon}(t, x)=\left\{\begin{array}{lll}
v_{t}^{\epsilon}\left(t, \underline{y}^{\epsilon}(t)\right)\left(\frac{1+\epsilon x}{1+\epsilon \underline{y}^{\epsilon}(t)}\right)^{1-\gamma} & \text { if } & x \in\left(0, \underline{y}^{\epsilon}(t)\right) \\
v_{t}^{\epsilon}(t, x) & \text { if } & x \in\left(\underline{y}^{\epsilon}(t), \bar{y}^{\epsilon}(t)\right) \\
v_{t}^{\epsilon}\left(t, \bar{y}^{\epsilon}(t)\right)\left(\frac{1-\epsilon x}{1-\epsilon \bar{y}^{\epsilon}(t)}\right)^{1-\gamma} & \text { if } & x \in\left(\bar{y}^{\epsilon}(t), 1\right)
\end{array}\right.  \tag{B.46}\\
& L_{x t}^{\epsilon}(t, x)=\left\{\begin{array}{lll}
\frac{\epsilon(1-\gamma) v_{t}^{\epsilon}\left(t, \underline{y}^{\epsilon}(t)\right)}{1+\epsilon x}\left(\frac{1+\epsilon x}{1+\epsilon \underline{y}^{\epsilon}(t)}\right)^{1-\gamma} & \text { if } & x \in\left(0, \underline{y}^{\epsilon}(t)\right) \\
v_{x t}^{\epsilon}(t, x) & \text { if } & x \in\left(\underline{y}^{\epsilon}(t), \bar{y}^{\epsilon}(t)\right) \\
-\frac{\epsilon(1-\gamma) v_{t}^{\epsilon}\left(t, \bar{y}^{\epsilon}(t)\right)}{1-\epsilon x}\left(\frac{1-\epsilon x}{1-\epsilon \bar{y}^{\epsilon}(t)}\right)^{1-\gamma} & \text { if } & x \in\left(\bar{y}^{\epsilon}(t), 1\right)
\end{array}\right.  \tag{B.47}\\
& \left|L_{t}^{\epsilon}(t, x)\right| \leq C, \quad\left|L_{x t}^{\epsilon}(t, x)\right| \leq C \quad \text { for } \quad x \in(0,1) . \tag{B.48}
\end{align*}
$$

(iv) For $(t, x, \epsilon) \in[0, T) \times(0,1) \times\left(0, \epsilon_{0}\right]$ with $\epsilon_{0}$ in (ii),

$$
\begin{align*}
& \left|v_{x t}^{\epsilon}(t, x)-\lambda \int_{t}^{T} e^{-\lambda(s-t)} \mathbb{E}\left[Z_{s}^{(t, x)} \frac{\partial Y_{s}^{(t, x)}}{\partial x} v_{x t}^{\epsilon}\left(s, Y_{s}^{(t, x)}\right) \cdot 1_{\left\{\underline{y}^{\epsilon}(s)<Y_{s}^{(t, x)}<\bar{y}^{\epsilon}(s)\right\}}\right] d s\right| \\
& \leq C\left(e^{-\lambda(T-t)}+\epsilon^{\frac{2}{3}}\right) . \tag{B.49}
\end{align*}
$$

Proof. (i) Lemma B.3, (5.4), (B.13) and (B.15) imply that for $(t, x) \in[0, T) \times(0,1)$,

$$
\left\{\begin{array}{l}
\left|v^{\epsilon}(t, x)\right| \leq C, \quad\left|v_{x}^{\epsilon}(t, x)\right| \leq C \epsilon^{\frac{2}{3}}  \tag{B.50}\\
\left|x(1-x) v_{x x}^{\epsilon}(t, x)\right| \leq C \epsilon^{\frac{2}{3}}, \quad\left|x^{2}(1-x)^{2} v_{x x x}^{\epsilon}(t, x)\right| \leq C \epsilon^{\frac{1}{3}}
\end{array}\right.
$$

Since $L^{\epsilon}(t, x)=v^{\epsilon}(t, x)$ for $x \in\left[\underline{y}^{\epsilon}(t), \bar{y}^{\epsilon}(t)\right]$, the mean value theorem and the bounds of $L_{x}^{\epsilon}$ and $v_{x}^{\epsilon}$ in (4.22) and B.50) imply

$$
\begin{equation*}
\left|L^{\epsilon}(t, x)-v^{\epsilon}(t, x)\right| \leq C \epsilon^{\frac{2}{3}} \quad \text { for } \quad(t, x) \in[0, T) \times(0,1) . \tag{B.51}
\end{equation*}
$$

By (B.11), B.41) and B.13), we observe that for $(t, x) \in[0, T) \times(0,1)$,

$$
\begin{equation*}
\left|L^{\epsilon}(t, x)-v^{0}(t)\right|=\left|L^{\epsilon}(t, x)-L^{S O, \lambda}(t, x)+v^{S O, \lambda}\left(t, \hat{y}^{S O, \lambda}(t)\right)-v^{0}(t)\right| \leq C \epsilon^{\frac{2}{3}} . \tag{B.52}
\end{equation*}
$$

Let $f^{\epsilon}:[0, T) \times(0,1) \rightarrow \mathbb{R}$ be defined as

$$
\begin{equation*}
f^{\epsilon}(t, x):=x(1-x)\left(\mu-\gamma \sigma^{2} x\right) v_{x}^{\epsilon}(t, x)+\frac{\sigma^{2} x^{2}(1-x)^{2}}{2} v_{x x}^{\epsilon}(t, x)+\lambda\left(L^{\epsilon}(t, x)-v^{\epsilon}(t, x)\right) . \tag{B.53}
\end{equation*}
$$

Then, (B.50), (B.51) and 4.22) imply that for $(t, x) \in[0, T) \times(0,1)$,

$$
\begin{equation*}
\left|f^{\epsilon}(t, x)\right| \leq C, \quad\left|f_{x}^{\epsilon}(t, x)\right| \leq C \tag{B.54}
\end{equation*}
$$

From (3.2) and B.53), we obtain the bound of $v_{t}^{\epsilon}$ in (B.44): for $(t, x) \in[0, T) \times(0,1)$,

$$
\begin{equation*}
\left|v_{t}^{\epsilon}(t, x)\right|=\left|-Q(x) v^{\epsilon}(t, x)-f^{\epsilon}(t, x)\right| \leq C \tag{B.55}
\end{equation*}
$$

where the inequality is due to (B.50) and (B.54).
Using (B.53), we rewrite (3.2) as

$$
\begin{align*}
0 & =\frac{\partial}{\partial t}\left(e^{Q(x) t} v^{\epsilon}(t, x)\right)+e^{Q(x) t} f^{\epsilon}(t, x) \quad \text { with } \quad v^{\epsilon}(T, x)=1 \\
& \Longrightarrow \quad v^{\epsilon}(t, x)=e^{Q(x)(T-t)}+\int_{t}^{T} e^{Q(x)(s-t)} f^{\epsilon}(s, x) d s . \tag{B.56}
\end{align*}
$$

We differentiate B.56 with respect to $t$ and $x(x$ and $t$, respectively) to obtain

$$
\begin{equation*}
v_{x t}^{\epsilon}(t, x)=v_{t x}^{\epsilon}(t, x)=-Q(x) v_{x}^{\epsilon}(t, x)-Q^{\prime}(x) v^{\epsilon}(t, x)-f_{x}^{\epsilon}(t, x), \tag{B.57}
\end{equation*}
$$

where the differentiations are justified by the bounds in (B.50) and (B.54). The above expression shows the continuity of $v_{x t}^{\epsilon}$ and the boundedness of $v_{x t}^{\epsilon}$ in (B.44) due to (B.50) and (B.54).
(ii) We prove the result for $\underline{y}_{t}^{\epsilon}(t)\left(\bar{y}_{t}^{\epsilon}(t)\right.$ case can be treated by the same way). Observe that

$$
\frac{\lim }{\epsilon \downarrow 0} \inf _{t \in\left[0, \underline{t}^{\epsilon}\right)}\left(-\frac{\lambda v_{x x}^{\epsilon}\left(t, \underline{y}^{\epsilon}(t)\right)}{1-\gamma}-\frac{\gamma \epsilon^{2} \lambda v^{\epsilon}\left(t, \underline{y}^{\epsilon}(t)\right)}{\left(1+\epsilon \underline{y}^{\epsilon}(t)\right)^{2}}\right) / \epsilon^{\frac{1}{3}} \geq \underline{\lim }_{\epsilon \downarrow 0} \inf _{t \in[0, T-\underline{C} \epsilon)}-\frac{\lambda v_{x x}^{\epsilon}\left(t, \underline{y}^{\epsilon}(t)\right)}{(1-\gamma) \epsilon^{\frac{1}{3}}} \geq C>0
$$

where the first inequality is due to Lemma 6.1 and 3.18 and the second inequality is due to (B.26). The above observation implies that there exists $\epsilon_{0}>0$ such that

$$
\begin{equation*}
-\frac{v_{x x}^{\epsilon}\left(t, \underline{y}^{\epsilon}(t)\right)}{1-\gamma}-\frac{\gamma \epsilon^{2} v^{\epsilon}\left(t, \underline{y}^{\epsilon}(t)\right)}{\left(1+\epsilon \underline{\underline{y}}^{\epsilon}(t)\right)^{2}} \geq C \epsilon>0 \quad \text { for } \quad(t, \epsilon) \in\left[0, \underline{t}^{\epsilon}\right) \times\left(0, \epsilon_{0}\right] \tag{B.58}
\end{equation*}
$$

By Lemma 4.1, we have $\frac{v_{x}^{\epsilon}\left(t, \underline{y}^{\epsilon}(t)\right)}{1-\gamma}=\frac{\epsilon v^{\epsilon}\left(t, \underline{y}^{\epsilon}(t)\right)}{1+\epsilon \underline{y}^{\epsilon}(t)}$ for $t \in\left[0, \underline{t}^{\epsilon}\right)$. For $(t, \epsilon) \in\left[0, \underline{t}^{\epsilon}\right) \times\left(0, \epsilon_{0}\right]$, we apply the implicit function theorem to this equality (justified by (B.58)) and conclude that $\underline{y}_{t}^{\epsilon}(t)$ exists and is as in B.45).
(iii) We differentiate (4.15) and (4.17) with respect to $t$ and apply (B.45), then we obtain (B.46) and $(\overline{\mathrm{B} .47})^{4}$ These expressions and ( $\overline{\mathrm{B} .44}$ ) imply (B.48).
(iv) As before, in this part of the proof, one can justify the interchanges of differentiations and integrations using suitable bounds such as Lemma B.1 (i) and B.48).

Since $\lim _{t \uparrow T} \underline{y}^{\epsilon}(t)=0$ and $\lim _{t \uparrow T} \bar{y}^{\epsilon}(t)=1$, 4.15, 4.17), $v^{\epsilon}(T, x)=1$ and $v_{x}^{\epsilon}(T, x)=0$ imply

$$
\begin{equation*}
\lim _{t \uparrow T} L^{\epsilon}(t, x)=1, \quad \lim _{t \uparrow T} L_{x}^{\epsilon}(t, x)=0 \tag{B.59}
\end{equation*}
$$

Since $\left(Z_{s}^{(t, x)}, Y_{s}^{(t, x)}\right)$ and $\left(Z_{s-t}^{(0, x)}, Y_{s-t}^{(0, x)}\right)$ have the same probability distribution, we have

$$
\lambda \int_{t}^{T} e^{-\lambda(s-t)} \mathbb{E}\left[Z_{s}^{(t, x)} \frac{\partial Y_{s}^{(t, x)}}{\partial x} L_{x}^{\epsilon}\left(s, Y_{s}^{(t, x)}\right)\right] d s=\lambda \int_{0}^{T-t} e^{-\lambda u} \mathbb{E}\left[Z_{u}^{(0, x)} \frac{\partial Y_{u}^{(0, x)}}{\partial x} L_{x}^{\epsilon}\left(t+u, Y_{u}^{(0, x)}\right)\right] d u
$$

We differentiate above with respect to $t$, then B.59 and the continuity of $t \mapsto L_{x}^{\epsilon}(t, x)$ imply

$$
\begin{align*}
& \frac{\partial}{\partial t}\left(\lambda \int_{t}^{T} e^{-\lambda(s-t)} \mathbb{E}\left[Z_{s}^{(t, x)} \frac{\partial Y_{s}^{(t, x)}}{\partial x} L_{x}^{\epsilon}\left(s, Y_{s}^{(t, x)}\right)\right] d s\right) \\
& =\lambda \int_{0}^{T-t} e^{-\lambda u} \mathbb{E}\left[Z_{u}^{(0, x)} \frac{\partial Y_{u}^{(0, x)}}{\partial x} L_{x t}^{\epsilon}\left(t+u, Y_{u}^{(0, x)}\right)\right] d u \\
& =\lambda \int_{t}^{T} e^{-\lambda(s-t)} \mathbb{E}\left[Z_{s}^{(t, x)} \frac{\partial Y_{s}^{(t, x)}}{\partial x} L_{x t}^{\epsilon}\left(s, Y_{s}^{(t, x)}\right)\right] d s \tag{B.60}
\end{align*}
$$

We differentiate 4.18 with respect to $t$ and obtain

$$
\begin{align*}
v_{x t}^{\epsilon}(t, x)= & \lambda e^{-\lambda(T-t)} \mathbb{E}\left[\frac{\partial Z_{T}^{(t, x)}}{\partial x}\right]+e^{-\lambda(T-t)} \frac{\partial}{\partial t} \mathbb{E}\left[\frac{\partial Z_{T}^{(t, x)}}{\partial x}\right] \\
& +\frac{\partial}{\partial t}\left(\lambda \int_{t}^{T} e^{-\lambda(s-t)} \mathbb{E}\left[Z_{s}^{(t, x)} \frac{\partial Y_{s}^{(t, x)}}{\partial x} L_{x}^{\epsilon}\left(s, Y_{s}^{(t, x)}\right)+\frac{\partial Z_{s}^{(t, x)}}{\partial x} L^{\epsilon}\left(s, Y_{s}^{(t, x)}\right)\right] d s\right) \\
= & e^{-\lambda(T-t)} \frac{\partial}{\partial t} \mathbb{E}\left[\frac{\partial Z_{T}^{(t, x)}}{\partial x}\right]+\lambda \int_{t}^{T} e^{-\lambda(s-t)} \mathbb{E}\left[Z_{s}^{(t, x)} \frac{\partial Y_{s}^{(t, x)}}{\partial x} L_{x t}^{\epsilon}\left(s, Y_{s}^{(t, x)}\right)\right] d s \\
& +\frac{\partial}{\partial t}\left(\lambda \int_{t}^{T} e^{-\lambda(s-t)} \mathbb{E}\left[\frac{\partial Z_{s}^{(t, x)}}{\partial x} L^{\epsilon}\left(s, Y_{s}^{(t, x)}\right)\right] d s\right)+\lambda e^{-\lambda(T-t)} \mathbb{E}\left[\frac{\partial Z_{T}^{(t, x)}}{\partial x}\right] \tag{B.61}
\end{align*}
$$

[^3]where the second equality is due to $\overline{\mathrm{B} .60}$. Using $\frac{\partial Z_{t}^{(t, x)}}{\partial x}=0$, we obtain
\[

$$
\begin{align*}
& \left|\frac{\partial}{\partial t}\left(\lambda \int_{t}^{T} e^{-\lambda(s-t)} \mathbb{E}\left[\frac{\partial Z_{s}^{(t, x)}}{\partial x}\left(L^{\epsilon}\left(s, Y_{s}^{(t, x)}\right)-v^{0}(s)\right)\right] d s\right)\right| \\
& =\left\lvert\, \lambda^{2} \int_{t}^{T} e^{-\lambda(s-t)} \mathbb{E}\left[\frac{\partial Z_{s}^{(t, x)}}{\partial x}\left(L^{\epsilon}\left(s, Y_{s}^{(t, x)}\right)-v^{0}(s)\right)\right] d s\right. \\
& \left.\quad+\lambda \int_{t}^{T} e^{-\lambda(s-t)} \frac{\partial}{\partial t} \mathbb{E}\left[\frac{\partial Z_{s}^{(t, x)}}{\partial x}\left(L^{\epsilon}\left(s, Y_{s}^{(t, x)}\right)-v^{0}(s)\right)\right] d s \right\rvert\, \\
& \leq C \lambda^{2} \int_{t}^{T} e^{-\lambda(s-t)}\left(\epsilon^{\frac{2}{3}}(s-t)+(s-t)^{2}\right) d s+C \lambda \int_{t}^{T} e^{-\lambda(s-t)}\left(\epsilon^{\frac{2}{3}}+s-t\right) d s \leq C \epsilon^{\frac{2}{3}} \tag{B.62}
\end{align*}
$$
\]

where the first inequality is due to Lemma B. 1 (iii) (with $F(y)=L^{\epsilon}(s, y)-v^{0}(s)$ ), (B.52) and (4.22) and the second inequality is due to Lemma F. 3 and $\lambda=c \epsilon^{-\frac{2}{3}}$. Similarly,

$$
\begin{align*}
& \left|\frac{\partial}{\partial t}\left(\lambda \int_{t}^{T} e^{-\lambda(s-t)} \mathbb{E}\left[\frac{\partial Z_{s}^{(t, x)}}{\partial x} v^{0}(s)\right] d s\right)+\lambda e^{-\lambda(T-t)} \mathbb{E}\left[\frac{\partial Z_{T}^{(t, x)}}{\partial x}\right]\right| \\
& =\left|\frac{\partial}{\partial t}\left(\lambda \int_{0}^{T-t} e^{-\lambda u} \mathbb{E}\left[\frac{\partial Z_{u}^{(0, x)}}{\partial x} v^{0}(u+t)\right] d u\right)+\lambda e^{-\lambda(T-t)} \mathbb{E}\left[\frac{\partial Z_{T-t}^{(0, x)}}{\partial x}\right]\right| \\
& =\left|-\lambda \int_{0}^{T-t} e^{-\lambda u} Q\left(y_{M}\right) v^{0}(u+t) \mathbb{E}\left[\frac{\partial Z_{u}^{(0, x)}}{\partial x}\right] d u\right| \\
& \leq C \lambda \int_{0}^{T-t} e^{-\lambda u} u d u \leq C \epsilon^{\frac{2}{3}} \tag{B.63}
\end{align*}
$$

where the second equality is due to (5.4), the first inequality is due to Lemma B. 1 (i) and the last inequality is due to $\lambda=c \epsilon^{-\frac{2}{3}}$. Combining (B.61), (B.62), and (B.63), we obtain

$$
\begin{align*}
& \left|v_{x t}^{\epsilon}(t, x)-\lambda \int_{t}^{T} e^{-\lambda(s-t)} \mathbb{E}\left[Z_{s}^{(t, x)} \frac{\partial Y_{S}^{(t, x)}}{\partial x} L_{x t}^{\epsilon}\left(s, Y_{s}^{(t, x)}\right)\right] d s\right| \\
& =\left|e^{-\lambda(T-t)} \frac{\partial}{\partial t} \mathbb{E}\left[\frac{\partial Z_{T}^{(t, x)}}{\partial x}\right]+\frac{\partial}{\partial t}\left(\lambda \int_{t}^{T} e^{-\lambda(s-t)} \mathbb{E}\left[\frac{\partial Z_{s}^{(t, x)}}{\partial x} L^{\epsilon}\left(s, Y_{s}^{(t, x)}\right)\right] d s\right)+\lambda e^{-\lambda(T-t)} \mathbb{E}\left[\frac{\partial Z_{T}^{(t, x)}}{\partial x}\right]\right| \\
& \leq C\left(e^{-\lambda(T-t)}+\epsilon^{\frac{2}{3}}\right) \tag{B.64}
\end{align*}
$$

where the boundedness of $\frac{\partial}{\partial t} \mathbb{E}\left[\frac{\partial Z_{T}^{(t, x)}}{\partial x}\right]$ is due to Lemma B.1 (iii) (with $F(y)=1$ ). The expression of $L_{x t}^{\epsilon}$ in (B.47) and the bounds in Lemma B.1 (i) and (B.44) imply

$$
\left|\lambda \int_{t}^{T} e^{-\lambda(s-t)} \mathbb{E}\left[Z_{s}^{(t, x)} \frac{\partial Y_{s}^{(t, x)}}{\partial x}\left(L_{x t}^{\epsilon}\left(s, Y_{s}^{(t, x)}\right)-v_{x t}^{\epsilon}\left(s, Y_{s}^{(t, x)}\right) \cdot 1_{\left\{\underline{y}^{\epsilon}(s)<Y_{s}^{(t, x)}<\bar{y}^{\epsilon}(s)\right\}}\right)\right] d s\right| \leq C \epsilon .
$$

Finally, we conclude the desired result by the above inequality and B.64).

## Appendix C. Proof of Lemma 6.2

Throughout this proof, $C, C_{1}, C_{2}>0$ are generic constants independent of $(t, s, x, \epsilon) \in[0, T) \times$ $[t, T) \times(0,1) \times(0,1)$ (also independent of $\lambda$ due to relation $\lambda=c \epsilon^{-\frac{2}{3}}$ ) that may differ line by line.
(i) By Lemma 4.1 and B.11, we have $v_{x}^{S O, \lambda}\left(t, \hat{y}^{S O, \lambda}(t)\right)=0$. By the mean value theorem,

$$
\left|v_{x}^{S O, \lambda}\left(t, \underline{\epsilon}^{\epsilon}(t)\right)\right|=\left|v_{x}^{S O, \lambda}\left(t, \underline{y}^{\epsilon}(t)\right)-v_{x}^{S O, \lambda}\left(t, \hat{y}^{S O, \lambda}(t)\right)\right| \geq \inf _{y \in(0,1)}\left|v_{x x}^{S O, \lambda}(t, y)\right| \cdot\left|\underline{y}^{\epsilon}(t)-\hat{y}^{S O, \lambda}(t)\right|
$$

$$
\begin{equation*}
\geq C \frac{\min \{1, \lambda(T-t)\}}{\lambda} \cdot\left|\underline{y}^{\epsilon}(t)-\hat{y}^{S O, \lambda}(t)\right|, \tag{C.1}
\end{equation*}
$$

where the last inequality is due to (B.16). By Lemma 4.1 (iii) and (B.24), we obtain

$$
\begin{equation*}
\left|v_{x}^{S O, \lambda}\left(t, \underline{y}^{\epsilon}(t)\right)\right| \leq\left|v_{x}^{\epsilon}\left(t, \underline{y}^{\epsilon}(t)\right)-v_{x}^{S O, \lambda}\left(t, \underline{y}^{\epsilon}(t)\right)\right|+\left|v_{x}^{\epsilon}\left(t, \underline{y}^{\epsilon}(t)\right)\right| \leq C \epsilon . \tag{C.2}
\end{equation*}
$$

We combine (B.12), (C.1) and (C.2) to obtain

$$
\left|\underline{y}^{\epsilon}(t)-y_{M}\right| \leq \frac{C \epsilon^{\frac{1}{3}}}{\min \{1, \lambda(T-t)\}} .
$$

By the same way, we obtain the other inequalities in (6.2).
(ii) Let $t \in[0, T)$ be fixed. Since $\min \{1, \lambda(T-t)\}=1$ for small enough $\epsilon$, the inequalities in (6.2) and $0<y_{M}<1$ imply that

$$
\begin{equation*}
0<\varliminf_{\epsilon \downarrow 0} \underline{y}^{\epsilon}(t) \leq \varlimsup_{\epsilon \downarrow 0} \bar{y}^{\epsilon}(t)<1 . \tag{C.3}
\end{equation*}
$$

By the mean value theorem, there exists $x^{\epsilon} \in\left[\underline{y}^{\epsilon}(t), \bar{y}^{\epsilon}(t)\right]$ such that for small enough $\epsilon$,

$$
\begin{equation*}
v_{x x}^{\epsilon}\left(t, x^{\epsilon}\right)\left(\bar{y}^{\epsilon}(t)-\underline{y}^{\epsilon}(t)\right)=v_{x}^{\epsilon}\left(t, \bar{y}^{\epsilon}(t)\right)-v_{x}^{\epsilon}\left(t, \underline{y}^{\epsilon}(t)\right)=-\frac{\epsilon(1-\gamma) v^{\epsilon}\left(t, \bar{y}^{\epsilon}(t)\right)}{1-\epsilon \bar{y}^{\epsilon}(t)}-\frac{\epsilon(1-\gamma))^{\epsilon}\left(t, y^{\epsilon}(t)\right)}{1+\epsilon \underline{y}^{\epsilon}(t)}, \tag{C.4}
\end{equation*}
$$

where the second equality is due to (C.3) and Lemma 4.1. We observe that (B.36) and (C.3) imply $\underline{l i m}_{\epsilon \downarrow 0} \frac{-(1-\gamma)}{v_{x x}^{\epsilon}\left(t, x^{\epsilon}\right)} \epsilon^{\frac{2}{3}}>0$. Therefore, (C.4) and (3.18) produce

$$
\frac{\lim }{\epsilon \downarrow 0} \frac{\bar{y}^{\epsilon}(t)-\underline{y}^{\epsilon}(t)}{\epsilon^{\frac{1}{3}}}=\underline{\lim } \frac{-(1-\gamma)}{\epsilon \downarrow 0} \frac{v^{\frac{2}{\epsilon}}}{v_{x x}\left(t, x^{\epsilon}\right)} \epsilon^{\frac{2}{3}}\left(\frac{v^{\epsilon}\left(t, \bar{y}^{\epsilon}(t)\right)}{1-\epsilon \bar{y}^{\epsilon}(t)}+\frac{v^{\epsilon}\left(t, \underline{y}^{\epsilon}(t)\right)}{1+\epsilon \underline{y}^{\epsilon}(t)}\right)>0 .
$$

(iii) Considering Lemma 4.1 (i), it is enough to show that

$$
\varlimsup_{\epsilon \downarrow 0} \sup _{t \in[0, T)}\left(\frac{v_{x}^{\epsilon}\left(t, y_{M}\right)}{\epsilon(1-\gamma)}-\frac{v^{\epsilon}\left(t, y_{M}\right)}{1+\epsilon y_{M}}\right)<0 \quad \text { and } \quad \lim _{\epsilon \downarrow 0} \inf _{t \in[0, T)}\left(\frac{v_{x}^{\epsilon}\left(t, y_{M}\right)}{\epsilon(1-\gamma)}+\frac{v^{\epsilon}\left(t, y_{M}\right)}{1-\epsilon y_{M}}\right)>0 .
$$

We prove the first inequality above. The other inequality can be proved by the same way.
By (6.2), we have

$$
\begin{equation*}
\left|\bar{y}^{\epsilon}(s)-y_{M}\right| \leq C \epsilon^{\frac{1}{3}} \quad \text { for } \quad 0 \leq s \leq T-\frac{1}{\lambda} . \tag{C.5}
\end{equation*}
$$

The expression of $Y_{s}^{(t, x)}$ in 4.8) implies that

$$
\begin{align*}
\mathbb{P}\left(Y_{s}^{\left(t, y_{M}\right)} \geq \bar{y}^{\epsilon}(s)\right) & =\mathbb{P}\left(B_{s}-B_{t} \geq\left(\frac{\sigma}{2}-\frac{\mu}{\sigma}\right)(s-t)+\frac{1}{\sigma} \ln \left(\frac{\bar{y}^{\epsilon}(s)\left(1-y_{M}\right)}{y_{M}\left(1-\bar{y}^{\epsilon}(s)\right)}\right)\right) \\
& \geq \mathbb{P}\left(B_{1} \geq C\left(1+\frac{1}{\sqrt{s-t}} \epsilon^{\frac{1}{3}}\right)\right) \quad \text { for } \quad t<s \leq T-\frac{1}{\lambda}, \tag{C.6}
\end{align*}
$$

where the inequality is due to (C.5) and the mean value theorem. By the same way as we prove (B.1), we check that for $t \leq s$,

$$
\begin{align*}
\left.\mathbb{E}\left[\left|Z_{s}^{(t, x)} \frac{\partial Y_{s}^{(t, x)}}{\partial x}-1\right|\right]\right|_{x=y_{M}} & \leq C \sqrt{s-t}  \tag{C.7}\\
\left.\mathbb{E}\left[\left|Z_{s}^{(t, x)}\left(\frac{\partial Y_{s}^{(t, x)}}{\partial x}-1\right)\right|\right]\right|_{x=y_{M}} & \leq C \sqrt{s-t} \tag{C.8}
\end{align*}
$$

By (3.18) and Lemma 4.1 (i), for $x>\underline{y}^{\epsilon}(t)$,

$$
\begin{equation*}
\frac{v_{x}^{\epsilon}(t, x)}{\epsilon(1-\gamma)}-\frac{v^{\epsilon}(t, x)}{1+\epsilon y_{M}} \leq \frac{v^{\epsilon}(t, x)}{1+\epsilon x}-\frac{v^{\epsilon}(t, x)}{1+\epsilon y_{M}} \leq C \epsilon . \tag{C.9}
\end{equation*}
$$

From the expression of $L$ in 4.15) and $L_{x}$ in 4.17), we obtain

$$
\frac{L_{x}^{\epsilon}(t, x)}{\epsilon(1-\gamma)}-\frac{L^{\epsilon}(t, x)}{1+\epsilon y_{M}}=\frac{\epsilon\left(y_{M}-x\right) v^{\epsilon}\left(t, y^{\epsilon}(t)\right)}{(1+\epsilon x)\left(1+\epsilon y_{M}\right)}\left(\frac{1+\epsilon x}{1+\epsilon \underline{y}^{\epsilon}(t)}\right)^{1-\gamma} 1_{\left\{x \leq \underline{y}^{\epsilon}(t)\right\}}+\left(\frac{v_{x}^{\epsilon}(t, x)}{\epsilon(1-\gamma)}-\frac{v^{\epsilon}(t, x)}{1+\epsilon y_{M}}\right) 1_{\left\{x \in\left(\underline{y}^{\epsilon}(t), \bar{y}^{\epsilon}(t)\right)\right\}}
$$

$$
\begin{align*}
& -\frac{\left(2+\epsilon\left(y_{M}-x\right)\right) v^{\epsilon}\left(t, \bar{y}^{\epsilon}(t)\right)}{(1-\epsilon x)\left(1+\epsilon y_{M}\right)}\left(\frac{1-\epsilon x}{1-\epsilon \bar{y}^{\epsilon}(t)}\right)^{1-\gamma} 1_{\left\{x \geq \bar{y}^{\epsilon}(t)\right\}} \\
\leq & C_{1} \epsilon-C_{2} 1_{\left\{x \geq \bar{y}^{\epsilon}(t)\right\}} \tag{C.10}
\end{align*}
$$

where the inequality is due to (3.18) and C.9). Since $Z_{s}^{(t, x)} \frac{\partial Y_{s}^{(t, x)}}{\partial x}>0$, C.7 and C.10 imply

$$
\begin{align*}
& \left.\mathbb{E}\left[Z_{s}^{(t, x)} \frac{\partial Y_{s}^{(t, x)}}{\partial x}\left(\frac{L_{x}^{\epsilon}\left(s, Y_{s}^{(t, x)}\right)}{\epsilon(1-\gamma)}-\frac{L^{\epsilon}\left(s, Y_{s}^{(t, x)}\right)}{1+\epsilon x}\right)\right]\right|_{x=y_{M}} \\
& \leq\left.\mathbb{E}\left[\left(Z_{s}^{(t, x)} \frac{\partial Y_{s}^{(t, x)}}{\partial x}-1\right)\left(C_{1} \epsilon-C_{2} 1_{\left\{Y_{s}^{(t, x)} \geq \bar{y}^{\epsilon}(s)\right\}}\right)\right]\right|_{x=y_{M}}+\mathbb{E}\left[C_{1} \epsilon-C_{2} 1_{\left\{Y_{s}^{\left(t, y_{M}\right)} \geq \bar{y}^{\epsilon}(s)\right\}}\right] \\
& \leq C_{1}(\sqrt{s-t}+\epsilon)-C_{2} \mathbb{P}\left(Y_{s}^{\left(t, y_{M}\right)} \geq \bar{y}^{\epsilon}(s)\right) \quad \text { for } \quad t \leq s \leq T \tag{C.11}
\end{align*}
$$

By (C.11) and Lemma F.3, we have

$$
\begin{align*}
& \left.\lambda \int_{t}^{T} e^{-\lambda(s-t)} \mathbb{E}\left[Z_{s}^{(t, x)} \frac{\partial Y_{s}^{(t, x)}}{\partial x}\left(\frac{L_{x}^{\epsilon}\left(s, Y_{s}^{(t, x)}\right)}{\epsilon(1-\gamma)}-\frac{L^{\epsilon}\left(s, Y_{s}^{(t, x)}\right)}{1+\epsilon x}\right)\right] d s\right|_{x=y_{M}} \\
& \leq C_{1} \epsilon^{\frac{1}{3}}-C_{2} \lambda \int_{t}^{T} e^{-\lambda(s-t)} \mathbb{P}\left(Y_{s}^{\left(t, y_{M}\right)} \geq \bar{y}^{\epsilon}(s)\right) d s \\
& \leq C_{1} \epsilon^{\frac{1}{3}}-C_{2} \int_{0}^{(\lambda(T-t)-1)^{+}} e^{-u} \int_{C\left(1+\frac{1}{\sqrt{u}}\right)}^{\infty} \frac{e^{-\frac{z^{2}}{2}}}{\sqrt{2 \pi}} d z d u \tag{C.12}
\end{align*}
$$

where the last inequality is due to (C.6) and the substitution $u=\lambda(s-t)$.
Lemma B.1 (iii) (with $F(y)=1$ and $F(y)=L^{\epsilon}(s, y)$, respectively) and 4.22 produce

$$
\begin{align*}
& \left|\mathbb{E}\left[\frac{\partial Z_{s}^{(t, x)}}{\partial x}\right]\right|_{x=y_{M}} \leq C(s-t)^{2}  \tag{C.13}\\
& \left|\mathbb{E}\left[\frac{\partial Z_{s}^{(t, x)}}{\partial x} L^{\epsilon}\left(s, Y_{s}^{(t, x)}\right)\right]\right|_{x=y_{M}} \leq C\left(\epsilon(s-t)+(s-t)^{2}\right) \tag{C.14}
\end{align*}
$$

By the same way as we prove (B.1), we check that $\mathbb{E}\left[Z_{T}^{(t, x)}\right] \geq 1-C(T-t)$. Then (C.13) produces

$$
\begin{align*}
\left.e^{-\lambda(T-t)} \mathbb{E}\left[\frac{1}{\epsilon(1-\gamma)} \frac{\partial Z_{T}^{(t, x)}}{\partial x}-\frac{Z_{T}^{(t, x)}}{1+\epsilon x}\right]\right|_{x=y_{M}} & \leq C_{1} e^{-\lambda(T-t)} \cdot \frac{(T-t)^{2}}{\epsilon}-e^{-\lambda(T-t)}\left(1-C_{2}(T-t)\right) \\
& \leq C \epsilon^{\frac{1}{3}}-e^{-\lambda(T-t)} \tag{C.15}
\end{align*}
$$

where the last inequality is due to $\sup _{t \geq 0} t^{n} e^{-t}<\infty$ for $n=1,2$. By (C.14, (C.8) and Lemma F.3.

$$
\begin{align*}
& \left.\lambda \int_{t}^{T} e^{-\lambda(s-t)} \mathbb{E}\left[\frac{\partial Z_{s}^{(t, x)}}{\partial x} \frac{L^{\epsilon}\left(s, Y_{s}^{(t, x)}\right)}{\epsilon(1-\gamma)}\right] d s\right|_{x=y_{M}} \leq C \lambda \int_{t}^{T} e^{-\lambda(s-t)}\left((s-t)+\frac{1}{\epsilon}(s-t)^{2}\right) \leq C \epsilon^{\frac{1}{3}}  \tag{C.16}\\
& \left.\lambda \int_{t}^{T} e^{-\lambda(s-t)} \mathbb{E}\left[Z_{s}^{(t, x)}\left(\frac{\partial Y_{s}^{(t, x)}}{\partial x}-1\right) \frac{L^{\epsilon}\left(s, Y_{s}^{(t, x)}\right)}{1+\epsilon x}\right] d s\right|_{x=y_{M}} \leq C \lambda \int_{t}^{T} e^{-\lambda(s-t)} \sqrt{s-t} \leq C \epsilon^{\frac{1}{3}}
\end{align*}
$$

The representation of $v$ in 4.16 and $v_{x}$ in 4.18 produce

$$
\begin{aligned}
\frac{v_{x}^{\epsilon}(t, x)}{\epsilon(1-\gamma)}-\frac{v^{\epsilon}(t, x)}{1+\epsilon x}= & e^{-\lambda(T-t)} \mathbb{E}\left[\frac{1}{\epsilon(1-\gamma)} \frac{\partial Z_{T}^{(t, x)}}{\partial x}-\frac{Z_{T}^{(t, x)}}{1+\epsilon x}\right]+\lambda \int_{t}^{T} e^{-\lambda(s-t)} \mathbb{E}\left[\frac{\partial Z_{s}^{(t, x)}}{\partial x} \frac{L^{\epsilon}\left(s, Y_{s}^{(t, x)}\right)}{\epsilon(1-\gamma)}\right] d s \\
& +\lambda \int_{t}^{T} e^{-\lambda(s-t)} \mathbb{E}\left[Z_{s}^{(t, x)} \frac{\partial Y_{s}^{(t, x)}}{\partial x}\left(\frac{L_{x}^{\epsilon}\left(s, Y_{s}^{(t, x)}\right)}{\epsilon(1-\gamma)}-\frac{L^{\epsilon}\left(s, Y_{s}^{(t, x)}\right)}{1+\epsilon x}\right)\right] d s \\
& +\lambda \int_{t}^{T} e^{-\lambda(s-t)} \mathbb{E}\left[Z_{s}^{(t, x)}\left(\frac{\partial Y_{s}^{(t, x)}}{\partial x}-1\right) \frac{L^{\epsilon}\left(s, Y_{s}^{(t, x)}\right)}{1+\epsilon x}\right] d s
\end{aligned}
$$

We substitute $x=y_{M}$ above and apply (C.12), (C.15) and (C.16) to obtain

$$
\begin{aligned}
\varlimsup_{\epsilon \downarrow 0} \sup _{t \in[0, T)}\left(\frac{v_{x}^{\epsilon}\left(t, y_{M}\right)}{\epsilon(1-\gamma)}-\frac{v^{\epsilon}\left(t, y_{M}\right)}{1+\epsilon y_{M}}\right) & \leq C \varlimsup_{\epsilon \downarrow 0} \sup _{t \in[0, T)}\left(-e^{-\lambda(T-t)}-\int_{0}^{(\lambda(T-t)-1)^{+}} e^{-u} \int_{C_{2}\left(1+\frac{1}{\sqrt{u}}\right)}^{\infty} \frac{e^{-\frac{z^{2}}{2}}}{\sqrt{2 \pi}} d z d u\right) \\
& \leq C \sup _{a \in[0, \infty)}\left(-e^{-a}-\int_{0}^{(a-1)^{+}} e^{-u} \int_{\left.C_{2}\left(1+\frac{1}{\sqrt{u}}\right)^{\frac{e^{-\frac{z^{2}}{2}}}{\sqrt{2 \pi}}} d z d u\right)<0 .} .\right.
\end{aligned}
$$

## Appendix D. Proof of Lemma 6.3

Throughout this proof, $C>0$ is a generic constant independent of $(t, s, x, \epsilon) \in[0, T) \times[t, T) \times$ $(0,1) \times(0,1)$ (also independent of $\lambda$ due to relation $\lambda=c \epsilon^{-\frac{2}{3}}$ ) that may differ line by line.
(i) We obtain (6.3) by Lemma 4.1 (iii) and (3.18). We combine (B.13), (B.15) and (B.25) to obtain (6.4). To check (6.5), we rewrite (3.2) using (5.4) as

$$
\begin{equation*}
v_{t}^{\epsilon}(t, x)-v_{t}^{0}(t)=Q\left(y_{M}\right)\left(v^{0}(t)-v^{\epsilon}(t, x)\right)+\frac{\gamma(1-\gamma) \sigma^{2}}{2}\left(x-y_{M}\right)^{2} v^{\epsilon}(t, x)-f^{\epsilon}(t, x), \tag{D.1}
\end{equation*}
$$

where $f^{\epsilon}$ is defined in (B.53). Since $L^{\epsilon}(t, x)=v^{\epsilon}(t, x)$ for $x \in\left[\underline{y}^{\epsilon}(t), \bar{y}^{\epsilon}(t)\right]$, 6.3) and (B.36) imply that $\left|f^{\epsilon}(t, x)\right| \leq C \epsilon^{\frac{2}{3}}$ for $x \in\left[\underline{y}^{\epsilon}(t), \bar{y}^{\epsilon}(t)\right]$. We apply this inequality, (6.4), (6.2) and (3.18) to (D.1) and conclude 6.5).
(ii) For $x_{1}, x_{2} \in\left[y^{\epsilon}(t), \bar{y}^{\epsilon}(t)\right]$, the mean value theorem and (6.3) imply $\left|v^{\epsilon}\left(t, x_{1}\right)-v^{\epsilon}\left(t, x_{2}\right)\right| \leq C \epsilon$. Then we conclude (6.6).

Since $v_{t x}^{\epsilon}$ is continuous by Lemma B.4 (i), the mean value theorem and (6.2) imply

$$
\left|v_{t}^{\epsilon}\left(t, x_{1}\right)-v_{t}^{\epsilon}\left(t, x_{2}\right)\right| \leq \sup _{x \in\left[\underline{y}^{\epsilon}(t), \bar{y}^{\epsilon}(t)\right]}\left|v_{t x}^{\epsilon}(t, x)\right| \cdot \frac{C_{\epsilon}^{\frac{1}{3}}}{\min \{1, \lambda(T-t)\}} \quad \text { for } \quad x_{1}, x_{2} \in\left[\underline{y}^{\epsilon}(t), \bar{y}^{\epsilon}(t)\right] .
$$

The above inequality and the following lemma produce (6.7).
Lemma D.1. Let Assumption 5.1 hold. Let $\epsilon_{0}>0$ be as in Lemma B. 4 (ii). For $\alpha \in(0,1)$, there exists a positive constant $C$ independent of $(t, x, \epsilon) \in[0, T) \times(0,1) \times\left(0, \epsilon_{0}\right]$ such that

$$
\begin{equation*}
\left|v_{x t}^{\epsilon}(t, x)\right| \leq C\left(\epsilon^{\frac{2}{3}}+e^{-\alpha \lambda(T-t)}\right) . \tag{D.2}
\end{equation*}
$$

Proof. By (B.53), (B.50) and (4.22), we have $\left|f_{x}^{\epsilon}(t, x)\right| \leq C \epsilon^{\frac{1}{3}}$. We apply this inequality, (6.2) and (B.50) to the expression in B.57) to obtain

$$
\begin{equation*}
\left|v_{x t}^{\epsilon}(t, x) \cdot 1_{\left\{\underline{y}^{\epsilon}(t)<x<\bar{y}^{\epsilon}(t)\right\}}\right| \leq C \epsilon^{\frac{1}{3}} \quad \text { for } \quad(t, x, \epsilon) \in\left[0, T-\frac{1}{\lambda}\right] \times(0,1) \times(0,1) . \tag{D.3}
\end{equation*}
$$

By (C.7), D.3) and Lemma F.3, we have

$$
\begin{align*}
& \left|\lambda \int_{t}^{\left(T-\frac{1}{\lambda}\right) \vee t} e^{-\lambda(s-t)} \mathbb{E}\left[\left(Z_{s}^{(t, x)} \frac{\partial Y_{s}^{(t, x)}}{\partial x}-1\right) v_{x t}^{\epsilon}\left(s, Y_{s}^{(t, x)}\right) \cdot 1_{\left\{\underline{y}^{\epsilon}(s)<Y_{s}^{(t, x)}<\bar{y}^{\epsilon}(s)\right\}}\right] d s\right| \\
& \leq C \lambda \int_{t}^{\left(T-\frac{1}{\lambda}\right) \vee t} e^{-\lambda(s-t)} \sqrt{s-t} \epsilon^{\frac{1}{3}} d s \leq C \epsilon^{\frac{2}{3}} . \tag{D.4}
\end{align*}
$$

Since $\lambda \int_{T-\frac{1}{\lambda}}^{T} e^{-\lambda(s-t)} d s \leq C e^{-\lambda(T-t)}$, Lemma B. 1 (i) and B.44) produce

$$
\begin{equation*}
\lambda \int_{T-\frac{1}{\lambda}}^{T} e^{-\lambda(s-t)} \mathbb{E}\left[\left|Z_{s}^{(t, x)} \frac{\partial Y_{s}^{(t, x)}}{\partial x} v_{x t}^{\epsilon}\left(s, Y_{s}^{(t, x)}\right) \cdot 1_{\left\{\underline{y}^{\epsilon}(s)<Y_{s}^{(t, x)}<\bar{y}^{\epsilon}(s)\right\}}\right|\right] d s \leq C e^{-\lambda(T-t)} . \tag{D.5}
\end{equation*}
$$

We combine Lemma B.4 (iv), (D.4) and (D.5) to conclude that for $(t, x, \epsilon) \in[0, T) \times(0,1) \times\left(0, \epsilon_{0}\right]$,

$$
\left|v_{x t}^{\epsilon}(t, x)\right| \leq C\left(e^{-\lambda(T-t)}+\epsilon^{\frac{2}{3}}\right)+\lambda \int_{t}^{\left(T-\frac{1}{\lambda}\right) v t} e^{-\lambda(s-t)} \mathbb{E}\left[\left|v_{x t}^{\epsilon}\left(s, Y_{s}^{(t, x)}\right)\right| \cdot 1_{\left\{\underline{y}^{\epsilon}(s)<Y_{s}^{(t, x)}<\bar{y}^{\epsilon}(s)\right\}}\right] d s
$$

For $\alpha \in(0,1)$, let $k^{\epsilon}(\alpha):=\sup _{(t, x) \in[0, T) \times(0,1)} \frac{\left|v_{x t}^{\epsilon}(t, x)\right|}{e^{-\alpha \lambda(T-t)}+\epsilon^{\frac{2}{3}}}$. Then, the above inequality implies

$$
\begin{align*}
\frac{\left|v_{x t}^{\epsilon}(t, x)\right|}{e^{-\alpha \lambda(T-t)}+\epsilon^{\frac{2}{3}}} & \leq C+\lambda \int_{t}^{\left(T-\frac{1}{\lambda}\right) \vee t} e^{-\lambda(s-t)} \frac{e^{-\alpha \lambda(T-s)}+\epsilon^{\frac{2}{3}}}{e^{-\alpha \lambda(T-t)}+\epsilon^{\frac{2}{3}}} k^{\epsilon}(\alpha) \mathbb{E}\left[1_{\left\{\underline{y}^{\epsilon}(s)<Y_{s}^{(t, x)}<\bar{y}^{\epsilon}(s)\right\}}\right] d s \\
& \leq C+k^{\epsilon}(\alpha) \lambda \int_{t}^{\left(T-\frac{1}{\lambda}\right) \vee t} e^{-(1-\alpha) \lambda(s-t)} \mathbb{E}\left[1_{\left\{\underline{y}^{\epsilon}(s)<Y_{s}^{(t, x)}<\bar{y}^{\epsilon}(s)\right\}}\right] d s . \tag{D.6}
\end{align*}
$$

Observe that for $t<s<\left(T-\frac{1}{\lambda}\right) \vee t$, the definition of $Y_{s}^{(t, x)}$ in 4.8) produces

$$
\begin{align*}
& \mathbb{P}\left(\underline{y}^{\epsilon}(s)<Y_{s}^{(t, x)}<\bar{y}^{\epsilon}(s)\right) \\
& =\mathbb{P}\left(\ln \left(\frac{(1-x) \underline{y}^{\epsilon}(s)}{x\left(1-\underline{y}^{\epsilon}(s)\right)}\right)-\left(\mu-\frac{\sigma^{2}}{2}\right)(s-t)<\sigma\left(B_{s}-B_{t}\right)<\ln \left(\frac{(1-x) \bar{y}^{\epsilon}(s)}{x\left(1-\bar{y}^{\epsilon}(s)\right)}\right)-\left(\mu-\frac{\sigma^{2}}{2}\right)(s-t)\right) \\
& \leq \mathbb{P}\left(-C \epsilon^{\frac{1}{3}}<B_{s}-B_{t}<C \epsilon^{\frac{1}{3}}\right)=\mathbb{P}\left(-\frac{C \epsilon^{\frac{1}{3}}}{\sqrt{s-t}}<B_{1}<\frac{C \epsilon^{\frac{1}{3}}}{\sqrt{s-t}}\right), \tag{D.7}
\end{align*}
$$

where the inequality is due to $\mathbb{P}\left(a<B_{s}-B_{t}<b\right) \leq \mathbb{P}\left(-\frac{b-a}{2}<B_{s}-B_{t}<\frac{b-a}{2}\right)$ for $a<b$, 6.2) and the mean value theorem. Then, D.7) with the substitution $u=\lambda(s-t)$ produces

$$
\lambda \int_{t}^{\left(T-\frac{1}{\lambda}\right) \vee t} e^{-(1-\alpha) \lambda(s-t)} \mathbb{E}\left[1_{\left\{\underline{y}^{\epsilon}(s)<Y_{s}^{(t, x)}<\bar{y}^{\epsilon}(s)\right\}}\right] d s \leq C_{\alpha}:=\int_{0}^{\infty} e^{-(1-\alpha) u} \mathbb{P}\left(-\frac{C}{\sqrt{u}}<B_{1}<\frac{C}{\sqrt{u}}\right) d u .
$$

Since the constant $C_{\alpha}$ above does not depend on $t, x, \epsilon$ and $C_{\alpha}<1$, D.6) implies $k^{\epsilon}(\alpha) \leq \frac{C}{1-C_{\alpha}}$.

## Appendix E. Proof of Lemma 6.4

Throughout this appendix, $C>0$ is a generic constant independent of $(t, s, x, \epsilon) \in[0, T) \times[t, T) \times$ $(0,1) \times(0,1)$ (also independent of $\lambda$ due to relation $\lambda=c \epsilon^{-\frac{2}{3}}$ ) that may differ line by line. First, we prove the following lemma.

Lemma E.1. Let Assumption 5.1 hold. Let $\epsilon_{0}>0$ be as in Lemma B.4 (ii) and $\alpha \in(0,1)$. Then, there exists $\epsilon_{00} \in\left(0, \epsilon_{0}\right]$ such that

$$
\begin{align*}
& x(1-x)\left|v_{x x t}^{\epsilon}(t, x)\right| \leq C\left(\epsilon^{\frac{1}{3}}+\sqrt{\lambda} e^{-\alpha \lambda(T-t)}\right) \quad \text { for } \quad(t, x, \epsilon) \in[0, T) \times(0,1) \times\left(0, \epsilon_{0}\right],  \tag{E.1}\\
& \left|\underline{y}_{t}^{\epsilon}(t)\right|,\left|\bar{y}_{t}^{\epsilon}(t)\right| \leq C \quad \text { for } \quad(t, \epsilon) \in\left[0, T-\epsilon^{\frac{1}{3}}\right] \times\left(0, \epsilon_{00}\right] . \tag{E.2}
\end{align*}
$$

Proof. Using (B.9) with $F=L_{x}^{\epsilon}$, we rewrite (B.34) as

$$
\begin{align*}
& v_{x x}^{\epsilon}(t, x)=e^{-\lambda(T-t)} \mathbb{E}\left[\frac{\partial^{2} Z_{T}^{(t, x)}}{\partial x^{2}}\right]+\lambda \int_{t}^{T} e^{-\lambda(s-t)} \mathbb{E}\left[\frac{\partial^{2} Z^{(t, x)}}{x^{2}} L^{\epsilon}\left(s, Y_{s}^{(t, x)}\right)\right] d s \\
& \quad+\lambda \int_{t}^{T} e^{-\lambda(s-t)} \mathbb{E}\left[\left(\frac{1}{x(1-x)} Z_{s}^{(t, x)} \frac{\partial Y_{s}^{(t, x)}}{\partial x}\left(\frac{B_{s}-B_{t}}{\sigma(s-t)}-1+x(1+\gamma)\right)+\frac{\partial Z_{s}^{(t, x)}}{\partial x} \frac{\partial Y_{s}^{(t, x)}}{\partial x}\right) L_{x}^{\epsilon}\left(s, Y_{s}^{(t, x)}\right)\right] d s \\
& =e^{-\lambda(T-t)} \mathbb{E}\left[\frac{\partial^{2} Z_{T}^{(0, x)}}{\partial x^{2}}\right]+\lambda \int_{0}^{T-t} e^{-\lambda u} \mathbb{E}\left[\frac{\partial^{2} Z_{u}^{(0, x)}}{\partial x^{2}} L^{\epsilon}\left(u+t, Y_{u}^{(0, x)}\right)\right] d u \\
& \quad+\lambda \int_{0}^{T-t} e^{-\lambda u} \mathbb{E}\left[\left(\frac{\frac{B_{u}}{\sigma u}-1+x(1+\gamma)}{x(1-x)} Z_{u}^{(0, x)} \frac{\partial Y_{u}^{(0, x)}}{\partial x}+\frac{\partial Z_{u}^{(0, x)}}{\partial x} \frac{\partial Y_{u}^{(0, x)}}{\partial x}\right) L_{x}^{\epsilon}\left(u+t, Y_{u}^{(0, x)}\right)\right] d u \tag{E.3}
\end{align*}
$$

because $\left(Z_{s}^{(t, x)}, Y_{s}^{(t, x)}, B_{s}-B_{t}\right)$ and $\left(Z_{s-t}^{(0, x)}, Y_{s-t}^{(0, x)}, B_{s-t}\right)$ have the same distribution. By the same way as in the proof of Lemma B.1 (iii), we can check that

$$
\begin{equation*}
\left|\frac{\partial}{\partial t} \mathbb{E}\left[\frac{\partial^{2} Z_{T}^{(t, x)}}{\partial x^{2}}\right]\right| \leq C . \tag{E.4}
\end{equation*}
$$

We observe that ( $\bar{B} .59$ ) and the inequalities in (B.48), (B.2) and (E.4) produce

$$
\begin{align*}
& \left|\frac{\partial}{\partial t}\left(\lambda \int_{0}^{T-t} e^{-\lambda u} \mathbb{E}\left[\frac{\partial^{2} Z_{u}^{(0, x)}}{\partial x^{2}} L^{\epsilon}\left(u+t, Y_{u}^{(0, x)}\right)\right] d u+e^{-\lambda(T-t)} \mathbb{E}\left[\frac{\partial^{2} Z_{T-t}^{(0, x)}}{\partial x^{2}}\right]\right)\right| \\
& =\left|\lambda \int_{0}^{T-t} e^{-\lambda u} \mathbb{E}\left[\frac{\partial^{2} Z_{u}^{(0, x)}}{\partial x^{2}} L_{t}^{\epsilon}\left(u+t, Y_{u}^{(0, x)}\right)\right] d u+e^{-\lambda(T-t)} \frac{\partial}{\partial t} \mathbb{E}\left[\frac{\partial^{2} Z_{T}^{(t, x)}}{\partial x^{2}}\right]\right| \\
& \leq C\left(\lambda \int_{0}^{T-t} e^{-\lambda u} u d u+e^{-\lambda(T-t)}\right) \leq C\left(\epsilon^{\frac{2}{3}}+e^{-\lambda(T-t)}\right) . \tag{E.5}
\end{align*}
$$

The expression of $L_{x t}^{\epsilon}$ in (B.47) and the bound in (D.2) imply

$$
\begin{equation*}
\left|L_{x t}^{\epsilon}(t, x)\right| \leq C\left(\epsilon^{\frac{2}{3}}+e^{-\alpha \lambda(T-t)}\right) \tag{E.6}
\end{equation*}
$$

Using (B.59) again, we obtain

$$
\begin{align*}
& \left|\frac{\partial}{\partial t}\left(\lambda \int_{0}^{T-t} e^{-\lambda u} \mathbb{E}\left[\left(\frac{\frac{B_{u}}{\sigma u}-1+x(1+\gamma)}{x(1-x)} Z_{u}^{(0, x)} \frac{\partial Y_{u}^{(0, x)}}{\partial x}+\frac{\partial Z_{u}^{(0, x)}}{\partial x} \frac{\partial Y_{u}^{(0, x)}}{\partial x}\right) L_{x}^{\epsilon}\left(u+t, Y_{u}^{(0, x)}\right)\right] d u\right)\right| \\
& =\left|\lambda \int_{0}^{T-t} e^{-\lambda u} \mathbb{E}\left[\left(\frac{\frac{B u}{\sigma u}-1+x(1+\gamma)}{x(1-x)} Z_{u}^{(0, x)} \frac{\partial Y_{u}^{(0, x)}}{\partial x}+\frac{\partial Z_{u}^{(0, x)}}{\partial x} \frac{\partial Y_{u}^{(0, x)}}{\partial x}\right) L_{x t}^{\epsilon}\left(u+t, Y_{u}^{(0, x)}\right)\right] d u\right| \\
& \leq C \frac{1}{x(1-x)} \lambda \int_{0}^{T-t} e^{-\lambda u}\left(1+\frac{1}{\sqrt{u}}\right)\left(\epsilon^{\frac{2}{3}}+e^{-\alpha \lambda(T-t-u)}\right) d u \leq C \frac{1}{x(1-x)}\left(\epsilon^{\frac{1}{3}}+\sqrt{\lambda} e^{-\alpha \lambda(T-t)}\right), \tag{E.7}
\end{align*}
$$

where the first inequality is due to Lemma B.1 (i) and E.6) and the second inequality is due to Lemma F. 3 and $\lambda=c \epsilon^{-\frac{2}{3}}$. We combine (E.3), (E.5) and E.7) to conclude (E.1).

The bounds in $(\overline{\mathrm{B} .44}),(\overline{\mathrm{D} .22}),\left(\overline{\mathrm{B} .26)}\right.$ and (3.18) imply that there exists $\epsilon_{00} \in\left(0, \epsilon_{0}\right]$ such that for $(t, \epsilon) \in\left[0, T-\epsilon^{\frac{1}{3}}\right] \times\left(0, \epsilon_{00}\right]$,

$$
\begin{equation*}
\left|\frac{v_{x t}^{\epsilon}\left(t, \underline{y}^{\epsilon}(t)\right)}{1-\gamma}-\frac{\epsilon v_{t}^{\epsilon}\left(t, \underline{y}^{\epsilon}(t)\right)}{1+\epsilon \underline{y}^{\epsilon}(t)}\right| \leq C \epsilon^{\frac{2}{3}}, \quad-\frac{v_{x x}^{\epsilon}\left(t, \underline{y}^{\epsilon}(t)\right)}{1-\gamma}-\frac{\gamma \epsilon^{2} v^{\epsilon}\left(t, y^{\epsilon}(t)\right)}{\left(1+\epsilon \underline{y}^{\epsilon}(t)\right)^{2}} \geq C \epsilon^{\frac{2}{3}} . \tag{E.8}
\end{equation*}
$$

The above inequalities and (B.45) produce the inequality for $\underline{y}_{t}^{\epsilon}(t)$ in (E.2). The inequality for $\bar{y}_{t}^{\epsilon}(t)$ can be checked by the same way.

Now we prove Lemma 6.4 By the mean value theorem and B.15), we have

$$
\left|\frac{\lambda\left(v_{x x}^{S O, \lambda}\left(t, x_{\epsilon}\right)-v_{x x}^{S O, \lambda}\left(t, y_{M}\right)\right)}{1-\gamma}\right| \leq C\left|x_{\epsilon}-y_{M}\right| \xrightarrow{\epsilon \downarrow 0} 0,
$$

where the convergence is due to (6.2). The above inequality and (B.17) imply

$$
\begin{equation*}
\lim _{\epsilon \downarrow 0} \frac{\lambda v_{x x}^{S O, \lambda}\left(t, x_{\epsilon}\right)}{1-\gamma}=-\gamma \sigma^{2} v^{0}(t) . \tag{E.9}
\end{equation*}
$$

Direct computations using (4.8) and the definition of $G^{\epsilon}$ produce

$$
\begin{aligned}
& \lambda^{2} \int_{t}^{T} e^{-\lambda(s-t)} \mathbb{E}\left[Z_{s}^{(t, x)}\left(\frac{\partial Y_{s}^{(t, x)}}{\partial x}\right)^{2} \frac{v_{x x}^{\epsilon}\left(s, Y_{s}^{(t, x)}\right)}{1-\gamma} \cdot 1_{\left\{\underline{y}^{\epsilon}(s)<Y_{s}^{(t, x)}<\bar{y}^{\epsilon}(s)\right\}}\right] d s \\
& =\frac{\lambda}{x^{2}(1-x)^{1+\gamma}} \int_{t}^{T} e^{-\lambda(s-t)} \mathbb{E}\left[\left(Y_{s}^{(t, x)}\right)^{2}\left(1-Y_{s}^{(t, x)}\right)^{1+\gamma} \frac{\lambda v_{x x}^{\epsilon}\left(s, Y_{s}^{(t, x)}\right)}{1-\gamma} \cdot 1_{\left\{\underline{y}^{\epsilon}(s)<Y_{s}^{(t, x)}<\bar{y}^{\epsilon}(s)\right\}}\right] d s
\end{aligned}
$$

$$
\begin{equation*}
=\frac{\lambda}{x^{2}(1-x)^{1+\gamma}} \int_{t}^{T} e^{-\lambda(s-t)} \int_{\underline{y}^{\epsilon}(s)}^{\bar{y}^{\epsilon}(s)} G^{\epsilon}(s, y) \varphi(y ; s-t, x) d y d s \tag{E.10}
\end{equation*}
$$

In (B.43), we apply B.35 and follow the same procedure after B.43) to obtain

$$
\left|\frac{\lambda v_{x x}^{\epsilon}(t, x)-\lambda v_{x x}^{S O, \lambda}(t, x)}{1-\gamma}-\lambda^{2} \int_{t}^{T} e^{-\lambda(s-t)} \mathbb{E}\left[Z_{s}^{(t, x)}\left(\frac{\partial Y_{s}^{(t, x)}}{\partial x}\right)^{2} \frac{v_{x x}^{\epsilon}\left(s, Y_{s}^{(t, x)}\right)}{1-\gamma} \cdot 1_{\left\{\underline{y}^{\epsilon}(s)<Y_{s}^{(t, x)}<\bar{y}^{\epsilon}(s)\right\}}\right] d s\right| \leq C \epsilon^{\frac{1}{3}}
$$

We combine (E.9), E.10 and the above inequality to conclude that

$$
G^{\epsilon}\left(t, x_{\epsilon}\right)+y_{M}^{2}\left(1-y_{M}\right)^{1+\gamma} \gamma \sigma^{2} v^{0}(t)-\lambda \int_{t}^{T} e^{-\lambda(s-t)} \int_{\underline{y}^{\epsilon}(s)}^{\bar{y}^{\epsilon}(s)} G^{\epsilon}(s, y) \varphi\left(y ; s-t, x_{\epsilon}\right) d y d s \xrightarrow{\epsilon \downarrow 0} 0
$$

Therefore, to complete the proof, it is enough to prove the following:

$$
\begin{align*}
\lambda & \int_{t}^{T} e^{-\lambda(s-t)} \int_{\underline{y}^{\epsilon}(s)}^{\bar{y}^{\epsilon}(s)} G^{\epsilon}(s, y) \varphi\left(y ; s-t, x_{\epsilon}\right) d y d s \\
& -\int_{\underline{z}^{\epsilon}(t)}^{\bar{z}^{\epsilon}(t)} G^{\epsilon}(t, h(z)) \frac{\sqrt{2 \lambda}}{2 \sigma} e^{-\frac{\sqrt{2 \lambda}}{\sigma}\left|z-z_{\epsilon}\right|} d z \xrightarrow{\epsilon \downarrow 0} 0 . \tag{E.11}
\end{align*}
$$

By (6.2), there exists $\epsilon_{00}^{\prime} \in\left(0, \epsilon_{00}\right]$ such that $\frac{1}{x_{\epsilon}\left(1-x_{\epsilon}\right)} \leq C$ for $(t, \epsilon) \in\left[0, T-\frac{1}{\lambda}\right] \times\left(0, \epsilon_{00}^{\prime}\right]$. Then the form of $\varphi$ in B.7) implies

$$
\begin{equation*}
0 \leq \varphi\left(y ; s-t, x_{\epsilon}\right) \leq \frac{C}{\sqrt{s-t}} \quad \text { for } \quad(s, y, \epsilon) \in\left(t, T-\frac{1}{\lambda}\right] \times(0,1) \times\left(0, \epsilon_{00}^{\prime}\right] \tag{E.12}
\end{equation*}
$$

The mean value theorem, E.2, B.50 and E.12 imply that for $(s, \epsilon) \in\left(t, T-\epsilon^{\frac{1}{3}}\right) \times\left(0, \epsilon_{00}^{\prime}\right]$,

$$
\begin{equation*}
\left|\int_{\underline{y}^{\epsilon}(s)}^{\bar{y}^{\epsilon}(s)} G^{\epsilon}(s, y) \varphi\left(y ; s-t, x_{\epsilon}\right) d y-\int_{\underline{y}^{\epsilon}(t)}^{\bar{y}^{\epsilon}(t)} G^{\epsilon}(s, y) \varphi\left(y ; s-t, x_{\epsilon}\right) d y\right| \leq C \sqrt{s-t} \tag{E.13}
\end{equation*}
$$

The mean value theorem and (E.1) imply that for $(s, \epsilon) \in\left(t, T-\epsilon^{\frac{1}{3}}\right) \times\left(0, \epsilon_{0}\right]$,

$$
\begin{align*}
& \left|\int_{\underline{y}^{\epsilon}(t)}^{\bar{y}^{\epsilon}(t)} G^{\epsilon}(s, y) \varphi\left(y ; s-t, x_{\epsilon}\right) d y-\int_{\underline{y}^{\epsilon}(t)}^{\bar{y}^{\epsilon}(t)} G^{\epsilon}(t, y) \varphi\left(y ; s-t, x_{\epsilon}\right) d y\right| \\
& =\left|\int_{\underline{y}^{\epsilon}(t)}^{\bar{y}^{\epsilon}(t)} \lambda y(1-y)^{\gamma} \cdot \frac{y(1-y)\left(v_{x x}^{\epsilon}(s, y)-v_{x x}^{\epsilon}(t, y)\right)}{1-\gamma} \varphi\left(y ; s-t, x_{\epsilon}\right) d y\right| \\
& \leq C \lambda\left(\epsilon^{\frac{1}{3}}+\sqrt{\lambda} e^{-\alpha \lambda(T-s)}\right)(s-t) \cdot \mathbb{P}\left(\underline{y}^{\epsilon}(t)<Y_{s}^{\left(t, x_{\epsilon}\right)}<\bar{y}^{\epsilon}(t)\right) \\
& \leq C\left(\sqrt{\lambda}+\lambda^{\frac{3}{2}} e^{-\alpha \lambda(T-s)}\right)(s-t) \tag{E.14}
\end{align*}
$$

We combine (E.13 and E.14 to obtain

$$
\begin{align*}
& \left|\lambda \int_{t}^{T} e^{-\lambda(s-t)}\left(\int_{\underline{y}^{\epsilon}(s)}^{\overline{\bar{y}^{\epsilon}(s)}} G^{\epsilon}(s, y) \varphi\left(y ; s-t, x_{\epsilon}\right) d y-\int_{\underline{y}^{\epsilon}(t)}^{\bar{y}^{\epsilon}(t)} G^{\epsilon}(t, y) \varphi\left(y ; s-t, x_{\epsilon}\right) d y\right) d s\right| \\
& \leq C \lambda \int_{t}^{T} e^{-\lambda(s-t)}\left(\sqrt{s-t}+\left(\sqrt{\lambda}+\lambda^{\frac{3}{2}} e^{-\alpha \lambda(T-s)}\right)(s-t)\right) d s \xrightarrow{\epsilon \downarrow 0} 0 \tag{E.15}
\end{align*}
$$

where the convergence can be checked using Lemma F.3 and $\lambda=c \epsilon^{-\frac{2}{3}}$. Observe that

$$
\left|\lambda \int_{t}^{\infty} e^{-\lambda(s-t)} \int_{\underline{y}^{\epsilon}(t)}^{\bar{y}^{\epsilon}(t)} G^{\epsilon}(t, y)\left(\varphi\left(y ; s-t, x_{\epsilon}\right)-\frac{1}{\sigma y(1-y) \sqrt{2 \pi(s-t)}} \exp \left(-\frac{\left(\ln \left(\frac{y\left(1-x_{\epsilon}\right)}{(1-y) x_{\epsilon}}\right)\right)^{2}}{2 \sigma^{2}(s-t)}\right)\right) d y d s\right|
$$

$$
\begin{equation*}
\leq C \int_{0}^{\infty} e^{-u} \int_{-\infty}^{\infty}\left|\frac{\exp \left(-\frac{\left(z+\left(\frac{\sigma^{2}}{2}-\mu\right) \sqrt{\frac{u}{\lambda}}\right)^{2}}{2 \sigma^{2}}\right)-\exp \left(-\frac{z^{2}}{2 \sigma^{2}}\right)}{\sigma \sqrt{2 \pi}}\right| d z d s \xrightarrow{\epsilon \downarrow 0} 0 \tag{E.16}
\end{equation*}
$$

where the inequality is due to the boundedness of $G^{\epsilon}$ and the substitution $z=\frac{h^{-1}(y)-h^{-1}\left(x_{\epsilon}\right)}{\sqrt{s-t}}$ and $u=\lambda(s-t)$ and the convergence is due to the dominated convergence theorem. The boundedness of $G^{\epsilon}$ also implies

$$
\begin{equation*}
\left|\lambda \int_{T}^{\infty} e^{-\lambda(s-t)} \int_{\underline{y}^{\epsilon}(t)}^{\bar{y}^{\epsilon}(t)} G^{\epsilon}(t, y) \varphi\left(y ; s-t, x_{\epsilon}\right) d y d s\right| \leq C e^{-\lambda(T-t)} \xrightarrow{\epsilon \downarrow 0} 0 . \tag{E.17}
\end{equation*}
$$

We substitute $z=h^{-1}(y)$ and $u=\sqrt{\lambda(s-t)}$, then use Fubini's theorem below:

$$
\begin{align*}
& \lambda \int_{t}^{\infty} e^{-\lambda(s-t)} \int_{\underline{y}^{\epsilon}(t)}^{\bar{y}^{\epsilon}(t)} G^{\epsilon}(t, y) \frac{1}{\sigma y(1-y) \sqrt{2 \pi(s-t)}} \exp \left(-\frac{\left(\ln \left(\frac{y\left(1-x_{\epsilon}\right)}{(1-y) x_{\epsilon}}\right)\right)^{2}}{2 \sigma^{2}(s-t)}\right) d y d s \\
& =\int_{\underline{z}^{\epsilon}(t)}^{\bar{z}^{\epsilon}(t)} G^{\epsilon}(t, h(z)) \int_{0}^{\infty} \frac{\sqrt{2 \lambda}}{\sigma \sqrt{\pi}} \exp \left(-u^{2}-\frac{\lambda\left(z-z_{\epsilon}\right)^{2}}{2 \sigma^{2} u^{2}}\right) d u d z \\
& =\int_{\underline{z}^{\epsilon}(t)}^{\bar{z}^{\epsilon}(t)} G^{\epsilon}(t, h(z)) \frac{\sqrt{2 \lambda}}{2 \sigma} e^{-\frac{\sqrt{2 \lambda}}{\sigma}\left|z-z_{\epsilon}\right|} d z, \tag{E.18}
\end{align*}
$$

where the last equality is due to the observation that for $k>0$,

$$
e^{-u^{2}-\frac{k}{u^{2}}}=\frac{d}{d u}\left(\frac{e^{-2 \sqrt{k}}}{2} \int_{\frac{\sqrt{k}}{u}-u}^{\infty} e^{-\zeta^{2}} d \zeta-\frac{e^{2 \sqrt{k}}}{2} \int_{\frac{\sqrt{k}}{u}+u}^{\infty} e^{-\zeta^{2}} d \zeta\right) \quad \Longrightarrow \quad \int_{0}^{\infty} e^{-u^{2}-\frac{k}{u^{2}}} d u=\frac{\sqrt{\pi}}{2} e^{-2 \sqrt{k}} .
$$

Finally, we combine E.15 , E.16, E.17) and E.18 to conclude E.11).

## Appendix F. Additional lemmas

Lemma F. 1 (Gronwall's lemma). Let $\alpha, \beta, f:[0, T] \rightarrow \mathbb{R}$ be measurable and $\beta \geq 0$. Assume that

$$
\int_{0}^{T}|f(t)| \beta(t) d t<\infty \quad \text { and } \quad f(t) \leq \alpha(t)+\int_{t}^{T} \beta(s) f(s) d s \quad \text { for } \quad t \in[0, T] .
$$

Then, $f$ satisfies the following inequality: for $t \in[0, T]$,

$$
\begin{equation*}
f(t) \leq \alpha(t)+\int_{t}^{T} \alpha(s) \beta(s) e^{\int_{t}^{s} \beta(r) d r} d s \tag{F.1}
\end{equation*}
$$

Lemma F.2. Let $F:[0, T] \times[0,1]^{2} \rightarrow \mathbb{R}$ be continuous. We define $f:[0, T] \times[0,1] \rightarrow[0,1]$ as

$$
\begin{equation*}
f(t, x):=\max \{z: z \in \underset{y \in[0,1]}{\operatorname{argmax}} F(t, x, y)\}, \tag{F.2}
\end{equation*}
$$

then $f$ is upper semicontinuous (which is obviously Borel-measurable).
Proof. This is Lemma D. 1 in [21].
Lemma F.3. There is a constant $C_{\alpha}$ independent of $t \in[0, T), \lambda \in[1, \infty)$ such that

$$
\lambda \int_{t}^{T} e^{-\lambda(s-t)}(s-t)^{\alpha} d s \leq \begin{cases}C_{\alpha} \lambda^{-\alpha} \min \{1, \lambda(T-t)\} & \text { if } \alpha \geq 0  \tag{F.3}\\ C_{\alpha} \lambda^{-\alpha} & \text { if } \alpha \in(-1,0)\end{cases}
$$

Proof. Simple change of variable implies

$$
\lambda \int_{t}^{T} e^{-\lambda(s-t)}(s-t)^{\alpha} d s=\lambda^{-\alpha} \int_{0}^{\lambda(T-t)} e^{-u} u^{\alpha} d u \leq \begin{cases}C_{\alpha} \lambda^{-\alpha} \min \{1, \lambda(T-t)\} & \text { if } \alpha \geq 0 \\ C_{\alpha} \lambda^{-\alpha} & \text { if } \alpha \in(-1,0)\end{cases}
$$

where we use the fact that $\int_{0}^{\infty} e^{-u} u^{\alpha} d u<\infty$ for $\alpha>-1$ and $e^{-u} u^{\alpha} \leq 1$ for $\alpha \geq 0$ and $u \leq 1$.
