AI-Powered Energy algorithmic Trading: Integrating Hidden Markov Models with Neural Networks

Tiago Monteiro

NOVA School of Science and Technology

tca.monteiro@campus.fct.unl.pt

ABSTRACT

In quantitative finance, machine-learning methods are essential for alpha generation. This study introduces a novel approach that combines Hidden Markov Models (HMM) and neural networks integrated with Black-Litterman portfolio optimization. The approach was tested during the COVID period (2019-2022), where it achieved an 83% return with a Sharpe ratio of 0.77. Two risk models were incorporated to enhance risk management, particularly during the volatile periods. The methodology was implemented on the QuantConnect platform, which was chosen for its robust framework and experimental reproducibility. The system is designed to predict future price movements and includes a three-year warm-up period to ensure the proper functioning of the algorithm. It focuses on highly liquid, large-cap energy stocks to ensure stable and predictable performance, while also accounting for broker payments. The dual-model alpha system utilizes log returns to select the optimal state based on historical performance. It combines state predictions with neural network outputs derived from historical data to generate trading signals. This study provides an in-depth examination of the trading system's architecture, data pre-processing, training, and performance. The full code and backtesting data are available under QuantConnect's terms.

Word count: 3,939 words, excluding references.

Keywords: Hidden Markov Models, Neural Networks, Algorithmic Trading, AI Models, Energy Sector **Stocks**

Funding Statement: This study did not receive any funding. This study was conducted independently by Tiago Monteiro.

Ethical Compliance: This study did not involve human participants or personal data; therefore, ethical compliance with institutional and national research standards was not required.

Conflict of Interest Declaration: The author declares no conflict of interest with any organization or entity related to the subject matter or materials discussed in this manuscript. The author paid access to QuantConnect independently and had no financial ties with the service or its providers.

Author Contributions: Tiago Monteiro independently designed, implemented, and analyzed the research and wrote the manuscript.

1 PLAIN LANGUAGE SUMMARY

This study introduces a novel algorithmic trading method for the energy sector by integrating Hidden Markov Models (HMMs) with neural networks to enhance stock price predictions and generate profitable signals. HMMs identify market conditions like bull or bear markets, while neural networks detect complex data patterns. Tested during the volatile COVID-19 period (2019-2022), the model achieved an 83% return on investment with a Sharpe ratio of 0.77, showing strong performance even in uncertain conditions.

The study contributes to quantitative finance by demonstrating that combining different models can improve prediction accuracy. Trading signals are generated when both HMMs and neural networks agree, minimizing errors. The strategy was tested on the QuantConnect platform, known for its extensive data access and reliable back-testing, ensuring the system's reproducibility and reliability.

2 INTRODUCTION

Algorithmic trading profoundly influences financial markets by enabling the rapid and precise execution of trading strategies beyond human capability.[1] Machine learning integration has further revolutionized this field by, providing advanced techniques for pattern recognition and predictive modeling.[2]

QuantConnect, chosen for this study, offers extensive data access, powerful back-testing, and a robust algorithmic trading framework. This simplifies the development, testing, and deployment of trading strategies, making them ideal for this study. The comprehensive environment also ensures result replication, which is crucial for validating the complex trading algorithms.

This study introduces a novel methodology that fuses the HMM and neural networks to create a dual-model alpha generation system. The aim is to leverage the HMM's ability to capture temporal dependencies and market regimes, along with the capability of neural networks to learn intricate patterns from historical price data.[3][4] The strategy uses Black-Litterman portfolio optimization combined with two risk management models, integrated with a dual-model alpha system.

The system employs a low-frequency buying strategy that is activated by converging signals from various AI models. A buy decision is made only when different model signals align, trade timing is refined, and broker payment considerations are incorporated to enhance the trading efficiency and cost-effectiveness.

The primary objective is to develop an adaptable trading strategy that predicts price fluctuations and optimizes trading decisions. The results indicate the potential of this unified approach, with the algorithm achieving a 83% return and a Sharpe ratio of 0.77 during the COVID period (2019-2022)

3 BACKGROUND

HMMs, deep learning, and multi-model AI are crucial for optimizing algorithmic trading strategies. HMMs models systems with partially observable states, whereas deep learning utilizes neural networks to capture complex patterns. Multi-model AI integrates various machine learning models to improve robustness and accuracy.[5]

The application of HMMs in financial markets has evolved from simple regime-switching models to advanced volatility modeling methods.[6] Deep learning has progressed from basic neural networks to sophisticated architectures, such as LSTM, CNN, and transformer-based models.[7] Multi-model AI, employing ensemble methods, surpasses single ML algorithms in terms of robustness.[8] These theories form the basis for advanced trading strategies. HMMs provide insights into market regimes and volatility, deep learning models predict price movements, and multi-model AI enhances the overall robustness and predictive performance.

3.1 Previous Research

Previous research has highlighted the utility of HMMs in identifying market regimes and in volatility modeling. In addition, deep learning techniques have shown potential for time-series forecasting and sentiment analysis.[9] Multi-model AI approaches, such as stacking and boosting, have improved prediction accuracy across various fields.[10] HMM studies often use regime-switching models and probabilistic analysis, whereas deep learning focuses on neural network architectures and training methods. Multi-model AI research combines different algorithms through ensemble techniques to leverage their unique strengths.

3.2 Challenges

Despite their advantages, HMMs face challenges in capturing the market complexity. Simple HMMs may not accurately interpret market dynamics because of their inability to capture both immediate and extended trends.[11] Deep learning models capture nonlinear relationships but require substantial data and computational resources. Although they often outperform traditional methods, their benefits can be modest and context-dependent, especially when data are limited or computational costs are high.[12] Multi-model AI approaches offer enhanced robustness and predictive performance but are more complex to implement.[13] Variability in data, methods, and implementation can lead to inconsistencies and reliability issues, complicating the reproduction.[14]

3.3 Research Gaps and Future Directions

Researchers often overlook the benefits of HMMs, deep learning, and multi-model AI in trading strategies owing to the lack of standardized frameworks for strategy standardization and data pre-processing. This absence complicates the creation of single and multi-model systems.[15] Bridging these gaps is essential to develop robust trading strategies capable of navigating complex financial markets. Future studies should explore integrating techniques to capture both linear and nonlinear market behavior, and investigate the impact of real-time market conditions on model performance.[16]

3.4 Tools and Hypotheses

QuantConnect facilitates advanced trading by supporting multi-model deployment using the LEAN opensource engine. It standardizes data and algorithm development, enhancing efficiency and reproducibility, while addressing current limitations.^[17]

The development of the hypotheses depends on incorporating HMM, deep learning, and multi-model AI to optimize algorithmic trading strategies. A comprehensive literature review clarifies each approach's advantages and limitations, forming the following research questions: How does integrating HMM, deep learning, and multi-model AI affect the effectiveness of algorithmic trading strategies? What computational challenges do this integration present, and how can they be mitigated? How does the unified model perform under market conditions compared with the S&P 500, a standard benchmark for evaluating equity trading algorithms?

These hypotheses and research questions aim to develop an adaptive trading strategy that addresses the identified research gaps and leverages HMM, deep learning, and multi-model AI strengths.

4 METHODOLOGY

Figure 1: Workflow of Algorithmic Trading System

This section explains how a dual-model system for generating trading signals is created using the HMM and neural networks. The QuantConnect platform was used in this project because it provides extensive market data and supports strategy development, testing, and deployment. Since 2013, it has been refined through over two million algorithms, ensuring reproducibility and transparency.[18] QuantConnect's strong backtesting features help to verify that trading strategies are valid and reliable.

However, QuantConnect has some limitations, such as data availability, which might lead to missing market scenarios required for training deep learning models. Future studies can use distributed computing to address these limitations. This study covers aspects such as the model design, data management, training, signal generation, and portfolio strategies, as illustrated in Figure 1.. A transparent and reproducible approach was used to confirm the reliability and effectiveness of the system.

Full code and backtesting data are available and licensed under the QuantConnect terms.

4.1 Universe Selection

This study used a dynamic universe with two filters to select tradable securities. The first filter evaluates liquidity through the dollar volume by selecting stocks with the highest total traded value to ensure high liquidity. The second filter focuses on energy sector stocks based on market capitalization, and identifies the top 20 companies in this sector. Larger companies typically exhibit more stable and predictable performance, beneficial for analysis.[19] This straightforward dynamic universe ensures robustness and clarity, making it efficient, easy to implement, and adaptable. Prioritizing liquidity and market capitalization forms a solid foundation for advanced models to operate effectively without unnecessary complexity.[20]

4.2 Alpha Generation

4.2.1 Model Architecture

The system employs the fusion of an HMM and a neural network based on PyTorch to examine the historical price data, generate trading insights, and facilitate their implementation.

4.2.1.1 Hidden Markov Model

Figure 2: HMM Architecture for Simulating Stock Price Fluctuations

The HMM is a stochastic framework for simulating stock price fluctuations (Figure 2). Trained by log returns, it identifies the underlying market conditions and predicts future states, providing a probabilitybased system for potential price changes. The model consists of five components, balancing complexity and performance, chosen through empirical analysis of historical price data and market regime clustering. The five hidden states represent various market conditions such as bull, bear, and transitional phases, offering a comprehensive market view. To enhance flexibility and accuracy, the HMM uses a "full" covariance type, allowing each state its own covariance matrix to improve data fitting. The model was run for up to 10 iterations during fitting to ensure convergence while maintaining computational efficiency. The best state for prediction was selected based on the historical mean return, allowing the model to choose the state most likely to indicate favorable market conditions.

The HMM can overfit past data, affecting the prediction accuracy owing to abrupt market changes. Future research should explore regularization techniques and hybrid models that combine HMM with unsupervised machine learning to better detect hidden patterns and navigate market transitions.

4.2.1.2 PyTorch-Based Neural Network

Figure 3: Neural Network Architecture for Detecting Complex Patterns in Historical Price Data

The neural network aims to detect complex patterns in the historical price data, as shown in Figure 3. Its architecture includes input, hidden, and output layers using ReLU for nonlinearity. The aim was to forecast future price levels using recent trend patterns, which were achieved by training with the Adam optimizer and mean squared error loss function on historical price sequences.

The input size is five, corresponding to the historical price steps used as features. The first hidden layer transforms these five features into 10 using ReLU activation. The next two hidden layers maintained ten features with ReLU activation. The fourth hidden layer reduces the feature size to five, and the output layer condenses them into a single predicted value. This structure gradually reduced the dimensionality of the final prediction. The hyperparameters involved a learning rate of 0.001 to ensure a stable convergence. The mean squared error loss function minimizes the difference between the predicted and actual values, making it suitable for regression tasks. The Adam optimizer adapts the learning rate for each parameter to enhance the convergence speed.[21] The model was trained for five epochs to balance the training time and risk of overfitting, making it practical for real-time applications.

Neural networks can encounter challenges in terms of hyperparameter tuning and overfitting. Addressing these challenges can be facilitated by cross-validation and automated hyperparameter optimization.

4.2.2 Data Management

Effective data management is crucial for optimizing the model forecasting performance. The algorithm uses a rolling window to update the historical price data and enhance model accuracy by training the latest information. Data integrity was ensured through validation, adding only trade bars with valid closing prices, and using QuantConnect's infrastructure for data consistency. Feature extraction involves the use of log returns for the HMM and differences in closing prices for the neural network to ensure that the models have timely data for predictions. Regular retraining and error handling ensured reliable insights across market conditions.

4.2.3 Models Training

HMM training uses a Gaussian HMM with multiple components to capture diverse market regimes, recognize and adapt to various market patterns, and enhance the predictive capabilities. Neural network training occurs in mini-batches over multiple epochs and involves forward propagation, loss calculation, backpropagation, and parameter updates. This iterative process enables the network to learn from data, refine parameters, and improve accuracy. A three-year preparation period provides historical data to help models recognize patterns and understand market dynamics before making predictions.

Cross-validation and regularization techniques are essential for preventing overfitting and underfitting. Incorporating validation metrics and evaluation methods further enhances model performance assessment.

4.2.4 Insight Generation

The dual-model system generates trading insights by integrating predictions from both the HMM and Neural Network. The HMM provides statistical predictions of price direction based on historical patterns, whereas the Neural Network uses deep learning to analyze sequences of closing prices for trends.

A trading signal is generated by combining these predictions; for example, a buy signal occurs when both models predict upward movements, and a sell signal is triggered if both agree on a downward trend. If there was no consensus, insights were considered flat.

Potential conflicts between model predictions can be mitigated using ensemble techniques, such as stacking, weighted voting, and gradient boosting, which enhance prediction accuracy and resilience by leveraging the strengths of each model.

4.3 Portfolio Construction

Effective portfolio construction is crucial for the success of the algorithm. The Black-Litterman model was chosen for its innovative approach, combining expected returns and risk. Created by Fischer Black and Robert Litterman, this model merges investor views with market equilibrium for better asset allocation.[22] It offers more stable and realistic outcomes by integrating subjective insights with objective data and creating a flexible portfolio strategy.[23]

This model increases algorithm modularity, separating alpha generation from portfolio management. Unlike signal-based portfolio construction, it reduces the probability of inaccurate signals, preventing inefficient management and delays in achieving the optimal Sharpe ratio. The Black–Litterman model improves system stability and reliability by clearly dividing alpha generation and portfolio management. It directs alpha model insights into risk management and execution models, enables the early detection of flawed predictions, and minimizes unnecessary trades and risks.

4.4 Risk management and execution models

This study integrates two risk management models to enhance portfolio robustness. The selected models are the Maximum Drawdown Percent per security and the trailing-stop risk management model. The maximum drawdown percentage per security model sets a maximum allowable drawdown for each security, ensuring protection against substantial declines in value. This model protects investor capital by automatically exiting positions with excessive losses, thereby ensuring disciplined risk controls.

The trailing-stop model dynamically adjusts stop-loss levels to capture gains and protect against losses and locking in profits in trending markets. These risk management models, combined with the lean engine's execution model, ensure timely trade execution and capitalize on market opportunities. This approach supports robust prediction models and effective asset allocation, balancing the alpha generation with disciplined risk management.

5 RESULTS AND DISCUSSION

5.1 Key Statistics

Key statistics	Values
Runtime Days	1096
Drawdown	17.1%
Portefolio Turnover	3.29%
Probabilistic SR (Sharpe Ratio):	30%
CAGR (Compounded Annual Growth Rate):	22.2%
Capacity (USD)	\$10M
Sortino Ratio	0.6
Information Ratio	-0.1

Table 1: Key trading metrics

This table presents the essential metrics used to evaluate the performance and risk of an investment portfolio. It covers "Runtime Days" over a period of 1096 days to assess performance sustainability and volatility. The "Drawdown" indicates a maximum loss from peak to trough of 17.1%, reflecting the risk of potential declines. A "Portfolio Turnover" of 3.29% signifies trading frequency, with lower figures suggesting a more passive management strategy aimed at minimizing transaction costs.

Risk-adjusted performance was assessed using several ratios, as summarized in Table 1.The "Probabilistic SR (Sharpe Ratio)" at 41% quantifies returns relative to risk, with higher ratios denoting more efficient risk management. The "CAGR (Compounded Annual Growth Rate)" stands at 22.2%, indicating a strong average growth rate beneficial for long-term investment strategies. Meanwhile, a "Sortino Ratio" of 0.6 highlights performance concerning downside risk, where values above 1 are preferred.

Further details include the "Capacity (USD)" at \$10 million, which represents the optimal investment level for strategy sustainability and achieving target returns. The "Information Ratio" of -0.1 indicates that the portfolio's performance is almost equal to the benchmark S&P 500, which typically seeks values above 1 to indicate superior risk-adjusted performance.

5.2 Detailed Trading Metrics

Detailed Trading Metrics	Values
Total Orders	40
Average Win	7.70%
Average Loss	$-3.29%$
Start Equity	\$100 000
End Equity	\$182761.12
Sharpe Ratio	0.77
Loss Rate	40%
Win Rate	60%
Profit-Loss Ratio	2.34
Alpha	0.13
Beta	0.175
Annual Standard Deviation	0.21
Annual Variance	0.044
Tracking Error	0.256
Treynor Ratio	0.924
Total Interactive Brokers Fees	\$971.62

Table 2: Detailed Trading Metrics

The metrics evaluate trading outcomes over a specified period, revealing a relatively low frequency, with only 40 trades. An average win rate of 7.70% and an average loss of -3.29%, with a 60% success rate, highlight the effectiveness of the strategy. The initial equity of \$100,000 increased to \$182,761.12, indicating substantial gain. A Sharpe Ratio of 0.77 demonstrates a risk-return trade-off.

An Alpha of 0.13 suggests modest active returns, and a beta of 0.175 indicates lower market volatility than broader indices, as detailed in Table 2. An annual standard deviation of 0.21 and a variance of 0.044 quantified the return variability. A tracking error of 0.256 indicates how the portfolio's returns deviate from the benchmark, whereas a Treynor Ratio of 0.951 indicates good risk-adjusted returns. Fees amounting to \$971.62, are relatively small compared to growth in equity.

These data indicate a robust trading strategy that can effectively manage risk. Optimizing hyperparameters and effectively pre-processing data can enhance model performance, reduce training time, and improve results. Extensive Monte Carlo simulations are necessary to ensure model reliability. This highlights the importance of rigorous data analysis and strategy refinement in trading, leading to more efficient performance and maximizing return on investments

5.3 Cummulative returns

The "Cumulative Returns" chart illustrates the performance comparison of a backtested investment strategy against a benchmark from January 2019 to January 2022. The x-axis represents the timeline, marked in months, while the y-axis quantifies cumulative returns in percentage terms. The backtested strategy is depicted by a light blue line, whereas the benchmark (presumed to be the S&P 500) is shown in gray.

Throughout the observation period, the strategy generally aligns closely with the benchmark, indicating a strong market correlation. Notably, the strategy outperformed the benchmark at specific points, such as during the onset of the COVID-19 pandemic in May 2020 and September 2021, as illustrated in Figure 4. These surges suggest effective strategy adjustments in response to market volatility.

Despite some instances of notable growth, the strategy often mirrors the benchmark's movements, highlighting its dependence on broader market trends rather than consistently outperforming it. During the COVID-19 crisis, the strategy demonstrated resilience, maintaining its value better than the benchmark and taking advantage of the recovery phase, which is indicative of adept risk management and opportunity utilization.

5.4 Advantages of the Approach

Utilizing the HMM alongside neural networks offers significant advantages for predictive modeling in financial markets. HMMs capture temporal dependencies crucial for sequential data like stock prices, while neural networks excel in recognizing complex patterns and relationships.[24][25] By combining these approaches, a more comprehensive and accurate prediction model is achieved, leveraging the strengths of both methodologies. This hybrid approach enhances the robustness by reducing the biases inherent in any single model, resulting in more reliable trading signals. Risk management strategies also play a crucial role in safeguarding against potential losses and improving the overall portfolio stability. The adaptability gained from merging HMMs and neural networks is essential for maintaining a high performance across different market conditions.

~

5.5 Future Research Directions

Future research should explore various approaches to enhance dual-model methodology by combining HMMs and neural networks.

5.5.1 Wavelet Transform for Enhanced Market Pattern Recognition

One potential approach is to apply a wavelet transform to the pre-processing data. Wavelet transform captures both time and frequency domain information, improving the ability of the model to recognize patterns in price data is crucial to ensuring its effectiveness.[26] This is crucial as it accounts for the dynamic nature of the market, making it more effective than static methods such as Pearson's correlation coefficient.

5.5.2 Monte Carlo Simulations for Model Generalizability

The use of extensive Monte Carlo simulations across diverse temporal frames is another avenue of research. These simulations help analyse the generalizability of the model, evaluating its reliability and identifying instances of overfitting or incorrect market predictions.[27] This ensures the stability and utility of the algorithmic trading system in a real trading context.

5.5.3 Hyperparameter Tuning and Ensemble methods

Employing diverse neural network architectures through automated hyperparameter fine-tuning can enhance forecasting capabilities by finding the optimal architecture for a specific dataset.[28] Additionally, incorporating an ensemble machine learning method for HMM and neural network systems can enable the model to adapt dynamically to market fluctuations, improving overall alpha generation performance.[29]

5.5.4 Diversifying Equities for Growth and Stability

Increasing sector diversification is essential to enhance portfolio resilience. For example, incorporating the 25 largest stocks from high-potential sectors such as technology, biomedicine, pharmaceuticals, and energy can enhance diversification and access growth opportunities. This approach helps mitigate sector-specific risks, leverages the strengths of each sector, and potentially leads to more stable returns.

5.6 QuantConnect for Reproducibility

Quantconnect was chosen for its comprehensive framework and user-friendly design, which simplified research replication. Its extensive access to data, including both historical and real-time market information, guarantees precise training and testing of the model.

The integrated lean open-source algorithmic trading framework allows the implementation and testing of complex strategies, accelerating the development and validation of innovative models. This platform enhances research replicability, enabling other researchers and practitioners to validate and extend the findings, which is essential for the reliability and advancement of scientific research.

6 CONCLUSION

The integration of the HMM and neural networks in a dual-model approach has shown significant success in enhancing the accuracy and resilience of trading signals. During the COVID period (2019-2022), the dual-model system achieved an 83% return and a Sharpe ratio of 0.77, highlighting its practical potential. A three-year preparation period provides historical data to help models recognize patterns and understand market dynamics before making predictions. However, replicating these outcomes in complex financial markets is challenging. These results suggest that combining the HMM and neural networks can strengthen algorithmic trading by generating more precise and reliable signals. Additionally, integration of multiple risk models improves the robustness of the system.

This study underscores the benefits of combining HMMs and neural networks for signal trading. Future research could explore wavelet transform pre-processing, extensive Monte Carlo simulations, and adaptive machine learning methods to further improve model performance. Using QuantConnect can enhance the reproducibility of results.
