ABSTRACT

This report presents an analysis of the Ascent portion of the GT-5 flight. IGS system performance during the Ascent phase of the mission was near perfect. The results of the analysis indicate that the in-plane system navigation components were within 1σ of ideal performance. With the exception of Stage II guidance initiation, the maximum IGS pitch and yaw attitude errors seen during flight were less than 2.1° and 1° , respectively. The yaw attitude error signal anomaly which was observed in the flight at SECO +4 seconds was reproduced in the post-flight reconstruction. No other anomalies were noted.

I. Introduction

This report presents the results of the analysis of the performance of the on-board computer during the Ascent phase of the GT-5 flight.

The purpose of this study was to verify that no anomalies occurred in the computer or its program during the Prelaunch and Ascent phases of the flight. The study was made using the Operational Program interpretive simulation which executes a Gemini computer program tape (magnetic) on the 7090 DPS. The simulation uses fixed point arithmetic and Gemini computer word length. Also, several associated simulation runs were made using the FORTRAN model of the GDC Ascent mode. The implementation of the study is discussed in detail in Reference 1. The results obtained from the analysis of the GT-5 flight are discussed in the sections to follow.

II. Discussion of Ascent Flight Reconstruction

Appendix AA contains a tabulation of the DAS data obtained from the GT-5 flight. The data was obtained from one telemetry station and, therefore, has several discrete areas where data is incorrect or missing. However, the DAS parameter time histories are sufficiently complete to allow comparison with the flight reconstruction data which is included in graphical form in Appendix AB. The data presented in Appendix AB was derived using the GT-5 Operational Program as simulated on the 7090 DPS. This simulation performs all the Gemini arithmetic and logic operations in a manner identical to the GDC including fixed point arithmetic and parameter scaling. Additional details on the operation of this simulation as well as suggested improvements to the techniques used are described in Reference 1. These improvements have as yet not been implemented since authorization to do so has not been obtained.

The remainder of this section describes and explains the various data obtained from the flight and through mission reconstruction. It is divided into the following general areas of interest:

- A. Gimbal Angle and Attitude Error Behavior
- B. Position and Velocity Comparisons
- C. Platform Azimuth Alignment
- D. IGS Injection Conditions
- E. Navigation Accuracy
- F. IVAR and IVI Operation
- G. IGS Discretes and Lift-off Synchronization

II. A. Gimbal Angle and Attitude Error Behavior

Figures 1 through 3 present a comparison of the primary and back-up system attitude errors. Inspection of the IGS attitude errors from lift-off through SECO revealed no unusual or unexpected behavior. The yaw attitude error signal anomaly at SECO +4 seconds which was observed in the flight data was reproduced in the post flight reconstruction.

The differences noted in the Stage I pitch attitude error are believed due to pitch programmer error in the primary system and pitch program start time uncertainties in the back-up system. It is noted that the pitch attitude error signal increases to approximately $+1.1^\circ$ when Step I of the pitch program occurs. Evaluation of the telemetry data indicates that the IGS started its pitch program at approximately 22.8 seconds. This is .22 seconds before the programmed time of 23.04 seconds but within the anticipated range of $23.04 \pm .28$ seconds. Also, the DAS data indicates that at 24.15 seconds, the pitch gimbal angle read 90.036° . In the time interval from 22.82 to 24.15 seconds, the IGS would have computed the vehicle should pitch down to 89.06° , resulting in an error signal of $+1^\circ$, which agrees closely with the value of 1.1° recorded by the DAS.

At Stage II guidance initiation the IGS pitch attitude error reached a maximum of $+11.4^\circ$. This is considerably smaller than the maximum value of $+23^\circ$ seen on the GT-3 flight and smaller than the GT-4 flight where it reached $+14^\circ$. Thus the changes to the pitch program made for the GT-4 and GT-5 missions resulted in a significant improvement.

During Stage II operation, the IGS pitch attitude error signal remains less than one degree after the initial pitch down maneuver is completed at guidance initiate. Examination of Figure 1 will show that the IGS pitch attitude error signal deviates noticeably from the RGS signal near 223, 293 and 325 seconds. The first deviation at 223 seconds results when the final steering loss terms are included in the guidance computations at 110 seconds before shutdown.

The subsequent deviations directly reflect changes in the pitch attitude of the vehicle. This can readily be verified by examining Figure 14, which shows the pitch steering parameters obtained from the FORTRAN reconstruction run. This plot shows the pitch gimbal angle, θ_b , the computed value of vehicle pitch attitude with respect to local horizontal, β_{PM} , and the commanded value of vehicle thrust pitch attitude with respect to local horizontal β_{PN} . The difference between β_{PN} and β_{PM} is used in generating the IGS pitch attitude error signal. As expected, β_{PN} is approximately a monotonic decreasing function (the apparent noise on β_{PM} and β_{PN} results from the linear interpolation at DAS accelerometer data used in the reconstruction).

II. A. (Continued)

The quantity β_{PM} resembles the pitch gimbal angle quite closely although the effects of the rapidly increasing down range position is noticeable late in the flight. With reference to the IGS attitude error signal action beginning at 283 seconds, note that the pitch attitude rate of the vehicle changes at this point and the measured pitch attitude remains nearly constant. Since β_{PN} continues to decrease at a nearly constant rate, the IGS attitude error signal starts to increase positively (pitch down) and changes from approximately -75° at 283 seconds to $+4^\circ$ at 298 seconds. At this time, the vehicle pitches down more rapidly and the measured attitude decreases more rapidly than the commanded attitude. This causes the IGS error signal to decrease. At about 305 seconds, the two attitudes are decreasing at about the same rate and the IGS error signal remains relatively constant until about 320 seconds when the above described sequence of events is approximately duplicated. It is believed that the changes noted in the vehicle pitch attitude rate may be due to the filtering or smoothing used in the primary system which is controlling the vehicle.

The yaw attitude error signal seen in Figure 2 indicates good agreement between the IGS and RGS systems during Stage I operation. During Stage II the behavior of the yaw attitude error signals is very similar to that seen in earlier flights. The difference between the primary and back-up system attitude error in general is less than 1° . As SECO is approached it is noted that the IGS error is changing rapidly, increasing to near -1° just prior to SECO. This is evidently due to the out-of-plane velocity measured by the IGS which requires a yaw right correction by the launch vehicle to null the component.

The roll attitude error comparison provided in Figure 3 readily illustrates several perturbations which are affecting the roll orientation of the vehicle on the flight. The most obvious are the engine misalignments along the roll axis (note the change in roll error at staging) and the TARS roll gyro drift rates at high acceleration (note the change in IGS roll error between 100 and 150 seconds and 270 to 330 seconds). The affects are somewhat similar to or less than those seen on GT-3 and GT-4.

Inspection of the roll gimbal angle data indicate the vehicle rolled 12.78° during the roll program as compared to 12.867° which was desired.

II. A. (Continued)

Immediately following SECO the IGS pitch attitude error signal increases in the positive direction, going from $-.6^\circ$ to a maximum of about $+4^\circ$ near 343 seconds; then decreases to about -5° just before separation. This action reflects vehicle attitude changes during this period; the corresponding pitch gimbal angles at the referenced points are -13.4 , -8.9 and -18.4 . The yaw attitude of the vehicle also changes during this SECO- separation period. At SECO, the yaw gimbal is about $-.4^\circ$ and slowly changes to -4.4° at 345 seconds. It then slowly reverses and returns to -3.6° at about 352 seconds. The yaw attitude error signal changes to reflect the yaw attitude change for about the first four seconds after SECO, changing from $-.86^\circ$ to about -2.5° at about 336-337 seconds. It then abruptly changes to $-.65^\circ$ and remains near this value until the spacecraft attitude error signals are generated at SECO +20 seconds. A program error was found which caused this anomaly. In the Ascent fast loop the difference between measured and commanded yaw gimbal angles ($\Delta\psi$) is multiplied by the variable N22 (sine of roll gimbal angle) when transforming the attitude error signals from the platform frame to the GLV frame. The N22 quantity is computed once every slow loop until the SECO countdown is commenced. It was found that N22 is synonymous with the variable T_X which is used in other modes. At SECO plus approximately four seconds, the IVI routine is entered to display the velocity corrections for orbit adjustment (IVAR) and T_X is set equal to 100. Since T_X is scaled B17 and N22 is scaled B1, the net result is that the value used as N22 in the ascent fast loop becomes very small (.0015). When the measured yaw attitude error $\Delta\psi$ is multiplied by the "new" value of N22, the result is insignificant and yaw control is lost. During the flight, the yaw attitude error signal dropped to $-.65^\circ$, not zero, because the contribution of other terms (notably ψ_0') used in computing the GLV signal was not affected by the N22 problem. This program error has been corrected and a new tape generated for subsequent flights using MF6.

The attitude error signals generated for the spacecraft at SECO +20 seconds for the orbit adjustment (IVAR) are discussed in Section II-F, IVAR and IVI operation.

II. B. Position and Velocity Comparisons

Table 1 compares the in-flight DAS navigation data with similar data derived from mission reconstruction using the FORTRAN and Operational Program simulations. Inspection of this data indicates that a bit-for-bit comparison was not obtained in either reconstruction simulation, nor is it immediately obvious that one simulation provides a better reproduction of the flight than the other.

It should be noted that no DAS data was available for this flight from 45 to 60 seconds and from 72 to 86 seconds. The missing data was synthesized by interpolation using the data surrounding the vacant areas. This process was fairly successful, as can be noted by the small errors which are present at 98.028 seconds.

The largest position difference between the flight results and those obtained through reconstruction is seen in the Y component of the FORTRAN Run (183 feet at 359 seconds). Inspection will show that the FORTRAN result is within 13 feet of the Operational Program result. The major contributor to the 183 foot difference appears to be linear interpolation of data between DAS frames.

The reconstructed velocities are within 0.5 fps of the flight values. The velocity differences which exist at the end of the reconstruction are attributable to several factors. These are interpolation of missing data, linear interpolation of data between DAS data frames, differences caused by the fixed point vs. floating point arithmetic of the simulations and different navigation error growth characteristics between the FORTRAN and operational programs. These factors have been discussed in detail in previous post flight analysis reports. Since the velocity and position differences for this flight reconstruction are so small, a detailed analysis to precisely isolate the various error contributions did not seem warranted.

Flight - DAS Flight Data

Fortran - Fortran Flight Reconstruction Results

Op. Pgm. - Operational Program Flight Reconstruction Results

~~CONFIDENTIAL~~

II. C. Platform Azimuth Alignment

Reconstruction of the in-flight DAS data indicated that the platform roll gimbal angle at the time of platform release was almost within one quanta (.036°) of the value desired by the IGS. The value read by the GDC was 77.940 degrees (2165 quanta) and the commanded roll gimbal angle was 77.896 degrees.

The in-flight results indicated that both azimuth updates were received and properly used by the GDC. Table 2 lists the platform azimuth alignment values obtained from the flight reconstruction runs. The difference in misalignment estimates after the 140 second update is less than 6 sec and would contribute less than a 0.75 ft/sec out-of-plane velocity difference at SECO.

TABLE 2
PLATFORM AZIMUTH ALIGNMENT

<u>Time</u>	<u>Fortran Results (Degrees)</u>	<u>Operational Program Results (Degrees)</u>
Platform Release	+0.04574	+0.04329
105 seconds	-0.27458	-0.27052
145 seconds	-0.26636	-0.26470

Values of V_{ZG} received by the IGS via DCS from the Burroughs system were -319.5 at 105 seconds and -204.0 at 145 seconds.

Differences between the final Fortran and Operational Program results above is approximately 6 sec or equivalently a 0.75 ft/sec out-of-plane velocity error at SECO.

II. D. IGS Injection Conditions

Table 3 presents the IGS measured injection conditions obtained during the flight and those obtained from the post-flight reconstruction simulations. Column 4 of the table lists the IGS navigation errors as measured by STL. These errors have been combined with the X, Y, and Z velocity and position data from the flight, to derive the actual X, Y, and Z velocity and position achieved in the flight, which is given in Column 4. The insertion parameters quoted in Column 4 were computed from the corrected X, Y, Z data and should thus represent the actual insertion conditions achieved in the flight (V_1 may be in error by 1 to 2 FPS since the reconstruction value for platform misalignment had to be used in its computation). The indicated IGS navigation errors in terms of the insertion parameters are thus 2.7 FPS in total velocity, - 1.2 FPS in radial velocity, - 3.6 FPS in out-of-plane velocity and - 28 feet in altitude.

The IGS targeting quantities were biased to account for anticipated navigation errors of 1.8 FPS in X-velocity, 1.3 FPS in Y-velocity, and zero in Z-velocity. It is noted that the in-plane velocity errors realized exceeded the anticipated errors by .6 FPS in X and .7 FPS in Y-velocity and the out-of-plane velocity error was 3.2 FPS. It is concluded that had a switchover to the IGS been made early in the flight, the IGS would have achieved the desired insertion conditions within the specified tolerances. (The yaw attitude error signal anomaly at SECO +4 seconds would not have significantly affected the out-of-plane velocity since most of the cut-off impulse thrust had been realized when it occurred.)

~~CONFIDENTIAL~~

- (1) IGS parameters listed were obtained from in-flight DAS data.
 - (2) Out-of-plane velocity was calculated using platform misalignment obtained from flight reconstruction data.
 - (3) FORTRAN and Operational Program results were obtained from reconstruction of the flight using DAS accelerometer and gimbal angle data.
 - (4) IGS navigation data obtained from STL, error defined as IGS-tracking data.
 - (5) IGS flight values corrected for navigation errors.
- A-12 -

~~CONFIDENTIAL~~

II. E. Navigation Accuracy

Table 3 quotes the IGS velocity and position errors at SECO +20. As can be noted, the worst velocity error is seen along the Z-axis (perpendicular to the orbit plane). From the platform performance standpoint, this flight surpassed the accuracies obtained during Ascent on any previous flight. The in-plane component platform errors (X and Y-axis) were on the order of 2 FPS at SECO and the out-of-plane error was approximately 4 FPS. Thus, platform performance was within 1σ of nominal.

~~CONFIDENTIAL~~

II. F. IVAR and IVI Operation

The attached table lists the IVI and FDI readings following SECO +20 seconds. These readings were obtained from the post flight reconstruction simulation. The roll attitude error is initially saturated (unlimited value is 89°) indicating the spacecraft should be rolled upright. The yaw attitude error is also saturated (unlimited value -47°). This signal indicates yaw right and is large because the out-of-plane velocity to be gained is comparable to the in-plane velocity to be gained. The out-of-plane velocity is displayed on the Z meter while the spacecraft is rolled over. The pitch attitude error signal is -8° indicating pitch up is required. The astronaut begins to thrust forward at about 358 seconds and completes thrusting at about 366 seconds, gaining about 7 fps. The spacecraft is rolled upright starting at this time and reaches the heads-up position at about 379 seconds. At the completion of the separation maneuver, the IVI indicate a deficiency of 3 fps forward in-plane and a deficiency of 11 fps out-of-plane.

TABLE 4 - IVAR OPERATION

Time (sec)	IVI-X (fps)	IVI-Y (fps)	IVI-Z (fps)	$\Delta\theta_b$ (Deg)	$\Delta\psi_b$ (Deg)	$\Delta\phi_b$ (Deg)

II. G. IGS Discretes and Lift-off Synchronization

Detailed analysis of IGS time since lift-off, " t_{DAS} " and comparison with range time provides an estimate of lift-off synchronization (See Reference 1 Section IV.G). On this flight the analysis indicated the IGS was 20 ± 15 milliseconds late in the determination of lift-off. An error of 9 milliseconds is known to exist in a program constant used in lift-off determination (See IBM Report #65-554-0042, Reference 3). This error results in an apparent delay in IGS lift-off synchronization. Thus the synchronization accuracy obtained from this flight appears reasonable.

Table 5 presents a list of various discrete events issued or controlled by the IGS.

It was determined that the IGS SECO discrete was issued at a tDAS time of $333.234 \pm .003$ seconds. The tDAS time is lagging real time by 0.020 ± 0.015 seconds at lift-off but the analysis indicates that the clock is running fast at about 50 ppm. Therefore, at the time the SECO discrete is issued, about 0.017 seconds have been gained and the corrected time for delivery of the IGS SECO discrete is 333.237 ± 0.015 seconds after lift-off. A preliminary value quoted by Aerospace for RGS SECO time is 333.258 seconds.

Analysis of the IGS velocity data in the area near SECO provides an estimate of 93 ± 5 fps for the Stage II engine cutoff impulse.

TABLE 5 - IGS DISCRETE EVENTS

<u>Time (1) (sec)</u>	<u>Event</u>	<u>Comments</u>
-3.641 / -3.22	Platform Release	Based on reconstruction of the IGS position and velocity data in the time period prior to platform release through lift-off.
0	Lift-off	IGS lift-off sync was late by 20 ± 15 m seconds.
10.34	Roll Program Initiate	
20.284	Roll Program Termination	
22.802	Start Pitch Step 1	
88.03	Start Pitch Step 2	
104.72	Gain Change	
107.44	Receipt of First Update (Value -319.5 FPS)	Time quoted is DAS time in mode when update is seen on telemetry.
119.28	Start Pitch Step 3	
146.21	Receipt of Second Update (Value -204.0 FPS)	Time quoted is DAS time in mode when update is seen on telemetry.
167.97	Time Stage II Guidance Initiate	Time quoted is the time at which attitude error signals, generated by the IGS Stage II equations, are first sent to the autopilot.

(1) All times are quoted based on GDC clock readings. The times are not corrected for lift-off sync errors.

TABLE 5 (Continued)

<u>Time (sec)</u>	<u>Event</u>	<u>Comments</u>
333.237	IGS SECO (Uncertainty <u>+3.0 msec</u>)	Time quoted is based on the GDC clock reading just after the SECO discrete is issued. Lift-off time synchronization error and clock drift are accounted for in quoted time.
354.72 (1)	IVAR Initiation	Time is again quoted to reflect the time at which IVAR attitude errors are first displayed.

(1) All times are quoted based on GDC clock readings. The times are not corrected for lift-off sync errors.

III. Conclusions

The following conclusions are formed based on the analysis performed and documented in this report:

1. IGS system performance during the Ascent portion of this mission up to SECO + 4 seconds was near perfect. At that time the yaw attitude error signal anomaly appeared (See Section II-A). This was caused by a program error which has since been corrected. Other than this anomaly, no discrepancies were found.
2. IGS navigation errors at SECO + 20 were approximately + 2.4, + 2.0, and - 3.6 FPS on the X, Y, and Z-axes, respectively. This resulted in IGS errors of approximately 2.5 FPS in velocity magnitude and 3.6 FPS in the out-of-plane direction.
3. IMU performance was within 1 σ of nominal.
4. With the exception of the attitude errors seen at Stage II guidance initiation, the maximum IGS pitch and yaw attitude error seen during flight were less than 2.1° and 1° respectively.
5. IGS was successful in accepting airborne azimuth updates and reducing what could have been a potential 118 FPS out-of-plane velocity error to one less than 9 FPS. The calculated platform misalignment on this flight was on the order of -.26°.
6. IGS lift-off synchronization was established late by 20 ± 15 milliseconds.

IV. Recommendations

The analysis performed did not result in any recommendations in the GDC analytic equation area. Several recommendations were made as a result of the analysis of the GT-4 flight (Reference 2). These were as follows:

- 1) Sequence η_X , V_{ZG} , SF_X , SF_Y , SF_Z and time of IGS SECO by multiplexing the DAS word position now allotted to V_{ZG} .
- 2) Add IGS SECO discrete to Martin telemetry to be sampled at 400 cps rate.
- 3) Use "START COMP" pushbutton in Ascent mode to eliminate undesirable entry into the Ascent mode after Ascent guidance is completed.

Of these recommendations, the first has been implemented in Math Flow 7.

Reconstructed Navigation Data vs. Time	
Reconstructed Guidance Data vs. Time	

I. INTRODUCTION

This report presents the results of the reconstruction of the Gemini computer operation during GT-5 Re-entry. The purpose of the reconstruction was to verify that the computer navigated properly, and to explain certain anomalies observed in the telemetry guidance data.

The study was made using the operational program simulation, which executes a Gemini program on the 7090 Data Processing System in fixed point arithmetic and 26 bit word length. The accelerometer outputs and roll gimbal angle from the flight telemetry data were used as inputs to the program. In addition, the computation cycle time multiplexed with the flow tag on telemetry was used to allow accurate evaluation of split DAS frames.

The DCS quantities used in the reconstruction are shown for reference in Appendix BA. (Verification of these quantities was performed using readout of the computer memory made available shortly after the flight.) A printout of the entire reconstruction given in Appendix BB.

II. SUMMARY

A. The values of the six navigation parameters at three key times during Re-entry are shown in the following table: (R/C denotes reconstructed values, and T/M telemetry values)

End of Retro ($t = 1672.101$)

	<u>r_s</u>	<u>Φ</u>	<u>Θ_E</u>	<u>v_E</u>	<u>γ</u>	<u>ψ_E</u>
R/C	21,765,746 ft	17.962°	217.571°	23821.070 fps	- .914°	60.564°
T/M	21,765,719 ft	17.962°	217.572°	23821.160 fps	- .914°	60.565°

400,000 ft ($t = 2472.101$)

	<u>r_s</u>	<u>Φ</u>	<u>Θ_E</u>	<u>v_E</u>	<u>γ</u>	<u>ψ_E</u>
R/C	21,295,166 ft	32.626°	272.483°	24393.967 fps	- 1.666°	89.284°
T/M	21,295,043 ft	32.625°	272.484°	24394.175 fps	- 1.665°	89.285°

Termination of Guidance ($t = 2887.277$)

	<u>r_s</u>	<u>Φ</u>	<u>Θ_E</u>	<u>v_E</u>	<u>γ</u>	<u>ψ_E</u>
R/C	20,972,290 ft	29.636°	297.995°	1608.586 fps	- 35.059°	123.536°
T/M	20,972,083 ft	29.634°	297.997°	1609.097 fps	- 35.082°	123.536°

SUMMARY (Continued)

In addition, a complete listing of the reconstruction is given in Appendix B, so that agreement between the reconstructed navigation and the guidance quantities, and the corresponding telemetry quantities can be successfully demonstrated.

Analysis of the reconstructed data suggests two conclusions:

- (1) The Gemini computer used in the GT-5 mission navigated properly, and generated guidance commands consistent with the initial conditions and the navigated trajectory; and
- (2) Certain anomalies in the attitude error signals resulted from the erroneous initial condition input for the quantity ΔQ_R . These anomalies will now be described.

B. Anomalies in Guidance Data for Reconstructed Mission

- (1) Bank Command Anomaly -

IBM report #65-554-0071, "Effect of Erroneous ΔQ_R Input on GT-5 Re-entry", dated 3 September 1965 describes the conditions under which a divide overflow in the calculation of the quantity

$$\Delta R = \frac{R_N - R_P}{F_E(D)*R_P} \quad (1)$$

causes spurious bank commands to be calculated from the equation:

$$\cos \beta_1 = 0.5 + K_{B6} \Delta R + K_B (\Delta R)^2 \quad (2)$$

From the telemetry data, one can observe that the divide operation, prior to the overflow, was generating large negative values for ΔR which, upon being limited to -0.387 by the program, caused equation (2) to yield a value of

$$\cos \beta_1 = 0$$

whence

$$\beta_1 = 90^\circ$$

and therefore the magnitude of the bank angle was also 90° . The quantity ΔR , however, is scaled such that it can get

~~COPYRIGHTED MATERIAL~~

SUMMARY (Continued)

no larger than - 127.99---9. When the quotient exceeded that value, an overflow occurred in such a way that the sign bit was lost and a positive number resulted. This number consistently left ΔR at a value larger than 0.629 and thereby caused equation (2) to yield a value of

$$\cos \beta_1 = 1$$

whence

$$|\beta_c| = \beta_1 = 0^\circ.$$

Therefore, prior to the termination of guidance, the telemetry data shows commanded bank angles of 0° in spite of the fact that the down-range error obviously requires a zero lift command.

This same overflow occurred in the reconstruction during exactly the same computer cycle as the flight computer exhibited it. However, it did not produce the identical results because the Gemini simulator program sets the quotient to zero following a divide overflow; i.e., it sets

$$\Delta R = 0$$

whence

$$\cos \beta_1 = 0.5$$

and therefore

$$|\beta_c| = \beta_1 = 60^\circ.$$

The effect is seen in Appendix B as a string of 60° bank commands from a time-in-mode of 2849.620 seconds to the termination of closed-loop guidance.

(2) **Cross-Range Error Signal Anomaly -**

The reconstruction contained an anomaly in the cross-range error signal which was not seen in the digital telemetry, but which may have caused erratic needle behavior in the yaw channel of the ADG just prior to the termination of guidance. This anomaly was caused by a divide overflow in the calculation of the cross-range error

$$\Delta \psi_b = \frac{R_c}{C_{DB}}$$

SUMMARY (Continued)

This quotient is scaled so that it cannot exceed 127.99--9, which is more than adequate for a nominal mission, but under the conditions of the GT-5 Re-entry caused divide overflows: R_c exceeded - 130 n.m. while C_{DB} approached 1.0.

This fact is demonstrated in Appendix B under the column "DPSBO", which is the cross-range error $\Delta\Psi_b$ referred to above. From a time-in-mode of 2862.254 seconds until the termination of guidance, this quantity shows a value of zero in spite of the fact that the magnitude of R_c obviously requires a value of - 1.0. The value of zero again results from the fact that the Gemini simulator sets a quotient to zero following a divide overflow.

(3) Conclusions and Recommendations -

The reconstruction demonstrates that the Gemini computer navigated properly during the GT-5 mission, and generated guidance commands consistent with the initial conditions and navigated trajectory.

It is recommended that no action be taken regarding the divide overflows observed in the flight, since: (1) they resulted from an attempt to fly the computer to an unrealistic target; (2) no such problem can exist if the initial conditions are realistic; and (3) rescaling the quantities involved results in a degradation of performance under realistic conditions.

APPENDIX BB1. Reconstructed Navigation Data vs. Time -

Definition of Terms :

TDAS	$= t_{DAS}$: Computer time-in-mode
TT	$\square T_T$: Integration time
SFXP	$= SFX'$: Accumulated pulse sums, X platform axis
SFYP	$= SFY'$: Accumulated pulse sums, Y platform axis
SFZP	$= SFZ'$: Accumulated pulse sums, Z platform axis
RS	$= r_s$: S/C distance from earth center
PHI	$= \phi$: S/C latitude
THETA E	$= \Theta_E$: S/C earth-referenced longitude
VE	$= V_E$: S/C velocity relative to earth
GAMMA	$= \gamma$: S/C flight-path-angle
PSIE	$= \psi_E$: S/C earth-referenced heading

2. Reconstructed Guidance Data vs. Time -

Definition of Terms:

PHBI	$= \phi_b$: Roll gimbal angle
DTHBO	$= \Delta \theta_b$: Computer output to ADG pitch channel, converted to nautical miles
DPSBO	$= \Delta \psi_b$: Computer output to ADG yaw channel, converted to units of R_c/C_{DB}
DPHBO	$= \Delta \phi_b$: Computer output to ADG roll channel, converted to degrees
BA	$= B_A$: Actual bank angle
RD	$= R_N - R_P$: Down-range error
RC	$= R_C$: Cross-range error
BC	$= B_C$: Commanded bank angle
RP	$= R_P$: Predicted half-lift range
D	$= D$: Density-attitude parameter
PSIT	$= \psi_T$: S/C heading to target
RT	$= R_T$: Range to target
