## Abstract

In the era of data-driven decision-making, Long-Form Table Question Answering (LFTQA) is essential for integrating structured data with complex reasoning. Despite recent advancements in Large Language Models (LLMs) for LFTQA, evaluating their effectiveness remains a significant challenge. We introduce LFTQA-Eval, a meta-evaluation dataset comprising 2,988 human-annotated examples, to rigorously assess the efficacy of current automated metrics in assessing LLM-based LFTQA systems, with a focus on faithfulness and comprehensiveness. Our findings reveal that existing automatic metrics poorly correlate with human judgments and fail to consistently differentiate between factually accurate responses and those that are coherent but factually incorrect. Additionally, our in-depth examination of the limitations associated with automated evaluation methods provides essential insights for the improvement of LFTQA automated evaluation.

https://github.com/YukiiWWW/LfTQA-Eval

## 1 Introduction

In the current landscape where decisions are increasingly driven by data, the utility of tabular data provides a well-organized and efficient means of presenting data, which is essential for informed decision-making processes (Pasupat and Liang, 2015; Zhao et al., 2022a,b; Tang et al., 2024; Zhao et al., 2024a,b). Within this context, long-form table question answering (LFTQA) has emerged as a vibrant area of research, bridging the gap between structured data and the comprehensive insights required in real-world scenarios (Nan et al., 2022; Zhao et al., 2023a). As illustrated in Figure 1, given the complex question and numerous data points in a table, an LFTQA system must understand the relationships within the data and perform human-like reasoning over the tabular content to compose the paragraph-long answer.

Figure 1: An example of the Long-form Table Question Answering (LFTQA) task investigated in our work.

Recent studies highlight the exceptional performance of Large Language Models (LLMs) in LFTQA tasks (Zhao et al., 2023b; Chen, 2023; Ye et al., 2023). However, the reliable evaluation of LLM-based systems in this domain remains a relatively unexplored area. Unlike conventional text generation tasks, where automatic metrics such as BLEU and ROUGE can somewhat effectively gauge the fluency and surface-level coherence of the generated text, LFTQA demands a more nuanced assessment approach. These traditional metrics, primarily designed for shorter texts, often fall short in LFTQA where the answers not only need to be contextually rich and structurally complex but also deeply rooted in logical reasoning derived from the underlying tabular data. They struggle to evaluate the logical structure and reasoning accuracy essential for long-form responses, as they do not account for the correctness of data interpretation or the ability to maintain a coherent argument over extended narratives. This limitation significantly impacts their utility in scenarios where the decision-making process relies heavily on the ac-

*Proceedings of the 2024 Conference on Empirical Methods in Natural Language Processing*, pages 14696–14706

curate and logical processing of structured data, necessitating the development of new metrics that can more effectively measure these critical aspects.

Our research demonstrates that existing automatic metrics are inadequate in distinguishing between high-quality, factually accurate answers and those that are merely coherent. This discrepancy is alarming because developers might choose suboptimal systems for real-world applications if they rely solely on automatic metrics to compare and rank different LFTQA systems. To better investigate the automated evaluation methods for LFTQA tasks, we have constructed a meta-evaluation dataset named **LFTQA-Eval**, consisting of 2,988 human-annotated examples. Specifically, we gathered outputs from leading LLM-based systems on the FETAQA (Nan et al., 2022) and QTSUMM (Zhao et al., 2023a) datasets. We then benchmarked existing automatic evaluation metrics for these tasks, leveraging our collected human annotations across two distinct dimensions: faithfulness and comprehensiveness. Our experimental results demonstrate that all the examined automated metrics exhibit low correlations with human judgments, revealing their unreliability in determining the quality of LLM-generated answers and comparing different LLM-based systems. Moreover, we conducted an in-depth analysis of the failures associated with automated evaluation methods, supplemented by illustrative examples that provide valuable insights into potential areas for enhancement.

## 2 LFTQA-EVAL Construction

To better investigate the automated evaluation methods for LFTQA tasks, we have constructed a meta-evaluation dataset named LFTQA-Eval. The following subsections discuss the data collection methodology and annotation process.

### 2.1 Collecting LLM Output for LFTQA

We examine LFTQA automated evaluation methods on FETAQA and QTSUMM. Table 1 illustrates the basic data statistics of these two datasets.

- **FETAQA** (Nan et al., 2022) is designed for free-form table question answering, with answers averaging 18.9 words. It requires models to extract question-relevant information from the given table, and then aggregate and reason over this information to produce a coherent long-form answer.
- **QTSUMM** (Zhao et al., 2023a) requires models to perform reasoning and analysis akin to human thought processes on tables sourced from Wikipedia to produce paragraph-length answers. Compared to the FETAQA dataset, outputs in QTSUMM are longer, averaging 68.0 words.

| Property | FETAQA | QTSUMM |
|---|---|---|
| Table Source | Wikipedia | Wikipedia |
| Unique Tables | 1,942 | 424 |
| Avg. Rows per Table | 14.2 | 12.0 |
| Avg. Columns per Table | 5.7 | 6.7 |
| Avg. Table Title Length | 5.4 | 7.4 |
| Avg. Query Length | 14.0 | 22.3 |
| Avg. Summary Length | 23.3 | 67.8 |
| # QAs in Development Set | 1,001 | 1,052 |

Table 1: Basic statistics of the FETAQA and QTSUMM test sets used in our experiments.

**Collecting LLM Output** We collect output from eight popular LLMs using *zero-shot* prompting methods, including Llama-2&3-70B (Touvron et al., 2023), Qwen1.5-72B (Bai et al., 2023), Mistral-7B (Jiang et al., 2023a), DeepSeek-LLM-67B (DeepSeek, 2023), Gemma-7B (Team et al., 2024), OLMo-7B (Groeneveld et al., 2024), Yi-1.5-34B (01.AI, 2023), Phi-3-Medium (Abdin et al., 2024), and GPT-3.5-Turbo&4o (OpenAI, 2023). We use `chat` or `instruct` versions for each model. Additionally, we select the most recent, largest, and best-performing checkpoint available as of paper submission (i.e, June 15, 2024). We randomly sample 150 examples from the development sets of FETAQA and QTSUMM, and collect corresponding model outputs of these sampled examples. This results in a total of 2,988 examples within the final LFTQA-Eval benchmark (we exclude 12 empty model responses).

### 2.2 Evaluation Criteria

The automated evaluation of LFTQA tasks is challenging due to the unique features of LFTQA: 1) conducting intricate reasoning across multiple sources of information, and 2) ensuring factual accuracy while avoiding hallucination. To evaluate the reliability of automated evaluation methods for LFTQA, we collect human evaluation scores for each model output based on the the dimensions of **Faithfulness** and **Comprehensiveness**, respectively. Our preliminary study indicates that LLM-based systems exhibit the capability to generate texts that are both fluent and coherent, devoid of

spelling and grammatical errors. Therefore, we have excluded the evaluation of fluency and coherence from our analysis.

- **Faithfulness**: A good answer should be firmly rooted in the source table. It should consist of correct information from the table and precisely address the posed question, avoiding any inaccuracies or hallucinations.
- **Comprehensiveness**: A good answer should comprehensively include all relevant information from the tabular data that addresses the user's question, fully meeting their informational needs.

### 2.3 Collecting Human Evaluation Scores

We tasked annotators to evaluate answers using a *Likert scale* ranging from 1 to 5 for the criteria of *faithfulness* and *comprehensiveness*, individually. To ensure the high quality of annotations, we hired eight undergraduate students proficient in English. Before starting the annotations, each annotator completed a one-hour online training session and reviewed a guide detailing the task execution steps. The annotators were compensated at an approximate hourly rate of $10, aligned with the complexity and duration of the task. Each sample was independently evaluated by two different annotators to mitigate individual bias and variance in scoring. For each instance, we use the average of the two annotators' scores as the final human evaluation score. Instances of significant disagreement (a variance greater than 2 points) were re-evaluated by an additional annotator. We achieved substantial inter-annotator agreements, with Krippendorff's alpha for faithfulness- and comprehensiveness-level annotation at 0.738 and 0.714, respectively. This highlights the high-quality of LFTQA-Eval.

### 2.4 Collecting Automated Evaluation Scores

We examine following automatic metrics that are widely used in the LFTQA task, investigating their reliability in evaluating model performance:

- **BLEU** (Papineni et al., 2002) computes the geometric mean of the modified precision scores of the translated text and incorporates a brevity penalty factor. We use SacreBLEU (Post, 2018) for BLEU score calculation.
- **ROUGE** (Lin and Hovy, 2003) assesses the degree of lexical similarity between the generated text and the reference text. We employ F1 score for ROUGE-L.
- **METEOR** (Banerjee and Lavie, 2005) is developed to address the limitations of BLEU by introducing a method where alignment is established through the mapping of unigrams.
- **BERTScore** (Zhang et al., 2020) measures the similarity between the generated output and the reference text by utilizing contextualized token embeddings derived from a pre-trained model.
- **TAPAS-Acc** (Liu et al., 2022) assesses the faithfulness of table-to-text generation using TAPAS (Herzig et al., 2020) pretrained on the TabFact (Chen et al., 2020) dataset.
- **AutoACU** (Liu et al., 2023c) presents a reference-based automated evaluation system, utilizing atomic content units (ACUs) to gauge the similarity between text sequences.

We also adopt an LLM-based evaluation system, **G-Eval** (Liu et al., 2023a), to the LFTQA task. G-Eval employs LLMs using a chain-of-thought approach and the form-filling paradigm to assess the quality of generated text. We adopt the official prompt of evaluation instruction to assess the *faithfulness* and *comprehensiveness* of the generated answers, separately. The evaluation prompts used are presented in Appendix. We use the Llama-3.1-70B, GPT-4o-mini, and GPT-4o as the evaluators. For each model output collected in Section 2.1, we measure the scores of aforementioned metrics as automated evaluation scores.

### 2.5 Evaluating Automatic Evaluation Metrics

To evaluate the performance of automatic metrics, the human evaluation result on the same evaluation target is considered the gold standard, and metric performance is measured by the correlation between the human evaluation scores and automatic metric scores. Following previous work (Cohan and Goharian, 2016; Fabbri et al., 2021; Liu et al., 2023b), we calculate the correlation at the *instance*-level. Specifically, given $n$ QA examples and $m$ LFTQA systems, the human evaluation and an automatic metric result in two $n$-row, $m$-column score matrices $H$, $M$ respectively. The instance-level correlation can be computed as the average of sample-wise correlations as follows:

$$r_{\text{ins}}(H, M) = \frac{\sum_i \mathcal{C}(H_i, M_i)}{n}, \quad (1)$$

Where $H_i$ and $M_i$ represent the evaluation results for the $i$-th data sample, with $\mathcal{C}$ denoting a function that computes a correlation coefficient. In this

| | FeTaQA | | QTSumm | |
|---|---|---|---|---|
| Metric | Comp. | Faith. | Comp. | Faith. |
| BERT-Score | 0.052 | 0.041 | 0.085 | 0.072 |
| TAPAS-Acc | 0.064 | 0.008 | 0.022 | 0.076 |
| ROUGE | 0.104 | 0.206 | 0.186 | 0.124 |
| METEOR | 0.191 | 0.216 | 0.204 | 0.187 |
| AutoACU | 0.143 | 0.262 | 0.268 | 0.188 |
| BLEU | 0.293 | 0.415 | 0.425 | 0.341 |
| G-Eval$_{4o-mini}$ Faith. | 0.397 | 0.466 | 0.466 | 0.342 |
| G-Eval$_{4o-mini}$ Comp. | 0.381 | 0.486 | 0.508 | 0.359 |
| G-Eval$_{3.1-70B}$ Comp. | 0.424 | 0.521 | 0.543 | 0.426 |
| G-Eval$_{3.1-70B}$ Faith. | 0.435 | 0.534 | 0.545 | 0.433 |
| G-Eval$_{4o}$ Faith. | 0.470 | 0.628 | 0.633 | 0.470 |
| G-Eval$_{4o}$ Comp. | 0.500 | 0.650 | 0.662 | 0.493 |

Table 2: Results of *instance-level* Pearson correlations between automatic metrics and human judgments on FeTaQA and QTSumm datasets.

study, we employ Pearson correlation to measure the correlations between human and automated evaluation systems.

## 3 Experimental Results

### 3.1 Main Results

Table 2 illustrates the instance-level Kendall's tau correlation between automatic and human judgements. We can draw following two conclusions based on the results: **Existing automatic metrics fail in assessing the answers generated by LLM-based systems.** Table 2 reveals a general trend of low correlations across a range of metrics (e.g., BERT-Score, ROUGE, METEOR, and TAPAS-Acc), when evaluating individual LLM-generated responses. This indicates a widespread issue among current automatic metrics in measuring the faithfulness and comprehensive of LLM-generated answers, pointing to a systemic failure to align with human judgments at the instance level. **LLM-based metrics demonstrate a significant improvement over traditional automated metrics in terms of correlation with human evaluation.** G-Eval consistently achieves positive and high correlation scores, demonstrating the effectiveness of LLM-based metrics. Moreover, compared to Llama-3, GPT-4o yields higher scores, indicating that its evaluation results correspond more closely with human assessments. This superior performance reflects the enhanced evaluation capabilities of larger-size models in aligning with human judgment standards for the LFTQA task.

### 3.2 Case Study

To gain deeper insights into the failure cases of automated evaluation systems for LFTQA tasks, we conduct detailed human analyses by exploring scenarios where automated evaluations fall short. We identify three primary failure scenarios along with their underlying causes as follows:

**The Effect of Question** As we delve deeper into the examples, we observe that the clarity of the questions significantly impacts the quality of the generated answers. Ambiguous questions can lead the model to misinterpret the key elements, resulting in the retrieval of incorrect information from the tables. Furthermore, we discovered that some questions were subjective or open-ended, which led to a variety of perspectives and content in the answers. The information related to these questions may not be directly presented or elaborated in the given tables. Instead, it should be inferred and evaluated from external materials, requiring careful speculation and analysis. In contrast, both the ground truth and generated answers typically reflect only a subset of these potential viewpoints. Table 3 in Appendix presents detailed examples.

**The Effect of Ground Truth** Although ground truth is used as the standard reference in the evaluation process, it has certain issues that affect the quality of the assessment. Ground-truth answers often include extensive descriptive details, which can make them redundant and contain content irrelevant to the questions. Additionally, in some instances, the ground truth fails to provide the specific information requested in the question. This can lead to lower evaluation scores, even when the generated outputs are accurate. Table 4 in Appendix presents detailed examples.

**The Effect of Generated Answer** LLM-based models excel at incorporating additional, reasoning-intensive information that is not present in ground-truth answers. They generate direct, parallel structures in their responses, which align well with human expression in real-world applications. However, current automated metrics struggle to capture this supplementary information and concise structures, resulting in automated evaluation scores that are significantly lower than human scores. Table 5 in Appendix presents detailed examples.

## 4 Related Work

Table Question Answering (QA) challenges models to derive accurate answers from data presented in tables. This field is bifurcated into short-form QA (Pasupat and Liang, 2015; Zhong et al., 2017; Zhao et al., 2023c), which focuses on concise answers, and long-form QA (Nan et al., 2022; Zhao et al., 2023a), which demands the generation of paragraph-length responses that require advanced reasoning capabilities. Unlike short-form Table QA, where accuracy—the proportion of questions correctly answered—is the primary metric, the evaluation of LFTQA systems introduces unique challenges, particularly in ensuring the faithfulness and consistency of the generated responses to the underlying tabular data and posed questions. These responses must not only be accurate but also coherent and contextually relevant. In the era of LLMs (Zhao et al., 2023b; Chen, 2023; Ye et al., 2023), refining the automated evaluation methods to better capture the complexities of LFTQA remains a critical and ongoing area of research.

To evaluate automatic metric performance for text generation, several human evaluation benchmarks have been collected (Cohan and Goharian, 2016; Dhingra et al., 2019; Gabriel et al., 2021; Fabbri et al., 2021; Jiang et al., 2023b; Liu et al., 2024), comprising system-generated text and their human evaluation scores. The human evaluation result on the system-generated text is considered the gold standard, and metric performance is measured by the correlation between the human evaluation scores and automatic metric scores. To the best of our knowledge, we are the first to examine the automated evaluation methods for LFTQA research.

## 5 Conclusion

Our exploration into the evaluation of LLMs for LFTQA tasks reveals a significant gap between current automatic metrics and human judgment, particularly in assessing answer faithfulness and comprehensiveness. The insights from the LFTQA-Eval dataset highlight the need for more nuanced evaluation methods that align more closely with human evaluative standards. Addressing this discrepancy is essential for advancing the reliability of LFTQA systems and ensuring their practical utility in real-world scenarios.

## Limitations

Our analysis is limited to 2,988 examples for which we have collected. While a larger evaluation set would allow for more statistically significant conclusions, this would require a significantly greater allocation of time and resources. We encourage future research to adopt our protocol and expand the benchmark for further analysis.

**G-Eval for Evaluating Faithfulness**

**### Task Introduction**:
Given a complex question and a generated answer about a table, your task is to rate the answer's Faithfulness.

**### Evaluation Criteria:**
Faithfulness(1-5): A good answer should accurately and completely address the given question.It must be based entirely on the information provided and should not include any unfaithful or hallucinated content.

**### Evaluation Steps:**
1. Thoroughly review both the table and the question, ensuring a full understanding of the information they convey. Identify and analyze key points, critical data, and important details within the table that is relevant to the question.
2. Carefully examine the proposed answer, focusing on its faithfulness. Check for factual correctness and verify whether the answer reflects and aligns with the information presented in the table.
3. Evaluate the answer's faithfulness using a strict 1 to 5 rating scale, with 1 being the lowest and 5 the highest.

Figure 2: G-Eval for Evaluating the *faithfulness* of the LLM generated answer.

| Error Type | Example | Explanation |
|---|---|---|
| Question is ambiguous | **Question:** Who were the top three scorers for the 1961-62 Michigan Wolverines men's basketball team and how many points did they score? | It may take individual scores but is phrased in a way that could be interpreted as asking for a total score, potentially leading to the total score being treated as another player in the ranking. |
| Subjective issues | **Question:** How did the performance of Tom Brady in terms of passing yards during the Regular Season 2011 compare with other quarterbacks listed in 2011? | The subject of these questions might result in multiple reasonable interpretations and answers. For example, responses could pertain to Tom's scoring rate, passing rate, ball handling performance, etc., each in different ways. |
| Open-ended questions | **Question 1:** Summarize the basic information of the episode(s) written by Damon Lindelof. **Question 2:**Summarize the performance of Weekend Hussler in the Caulfield Guineas. | These questions involve various perspectives and require external information to be adequately addressed. For example, the first question might pertain to understanding the play, including plot trends, character development, and thematic elements in the episode. Different background knowledge and perspectives will result in varying answers. |

Table 3: Case studies on evaluation errors due to the effects of questions.

| Error Type | Example | Explanation |
|---|---|---|
| Redundancy in Ground Truth Answer | **Generated Answer:** The quantity of the aircraft models that were first introduced between the years 1980 and 1985 inclusive is 3 and their build years are 1978, 1979, and 1971. **Ground Truth Answer:**The number of aircraft models that were initially launched within the timeframe extending from the year 1980 up to and including the year 1985 amounts to a total of three distinct models. Specifically, the construction years for these models are identified as the years 1978, 1979, and 1971 respectively. | Ground truth answers tend to include additional details that may not directly contribute to answering the question in some cases while the generated answers are concise with all essential information. Based on the example provided, the ground truth answer offers a more comprehensive and detailed description of the launch times of the aircraft models. |
| Mismatch Between Question and Ground Truth Answer | **Generated Answer:** The track that has the lowest bpm on the Speed SFX series is 'Rhythm & Police (K.O.G G3 Mix)' and the track with the highest bpm on the Speed SFX series is the 'Mission: Impossible Theme'. **Ground Truth Answer:** The Speed SFX's lowest bpm is 175 on tracks 5, and the highest bpm is 195 on 20 in the Speed series. | The ground truth focuses on the BPM values without mentioning specific track names, which is the primary detail the question asks for. Conversely, the prediction accurately identifies the tracks by name, directly addressing the question. Therefore, the ground truth fails to provide the specific information that the question seeks. |

Table 4: Case studies on evaluation errors due to the effects of ground truth answers.

| Error Type | Example | Explanation |
|---|---|---|
| Inconsistency in LLM Output Length | **Generated Answer:** The HP LaserJet 4250 has a faster CPU speed of 460 MHz compared to the 4200's 300 MHz and its print speed is also higher at 43 pages per minute (PPM) compared to the 4200's 35 PPM, yet both printers come with a standard memory of 48 MB and can be expanded up to a maximum of 512 MB. **Ground Truth Answer:**The HP LaserJet 4200 and 4250 models, both in HP LaserJet 4000 series, have some same and different specifications. In same parts, both models come out in November 2002 and stop in June/November 20051. They have print resolution of 1200 DPI. Also, both printers can make the memory bigger, up to 512 MB. But, there are some different things between these two models. The LaserJet 4200 has 300 MHz CPU speed, but 4250 has faster 460 MHz CPU. Also, 4200 model can print 35 pages in one minute (PPM), but 4250 can print a little faster, 43 PPM". | The GT length is 68, while the LLM-generated length is 52.16. This indicates that the predicted output is significantly shorter than the actual answer. Generated responses tend to be concise and straightforward, focusing on delivering key points efficiently. In contrast, the actual answer provides more extensive information, with greater detail and elaboration. This difference highlights a tendency for automated responses to prioritize brevity. |
| Answers' Different Structures | **Generated Answer:** The quantity of the aircraft models that were first introduced between the years 1980 and 1985 inclusive is 3 and their build years are 1978, 1979, and 1971. **Ground Truth Answer:** Between the years 1980 to 1985 altogether, Agderfly added three airplane models to its fleet. In the year 1980, one Piper Chieftain made in 1978 was added, also one Piper Tomahawk was made in 1979 in the same year. The 1985 year, one Piper Seneca which was made in 1971. In total, during this time, Agderfly added three aircraft models whose combined quantity is four units. | Generated answers tend to be structured with parallel objects, while ground truth answers often utilize complex clauses to introduce related information thoroughly. In this example, the generated answer simply lists the years, while the ground truth introduces the information for each year in a single, comprehensive sentence. This discrepancy in structure can result in misalignment between automated predictions and the expected answers, impacting the accuracy of evaluations and interpretations. |

Table 5: Case studies on evaluation errors due to the effects of generated answers.

G-Eval for Evaluating Comprehensiveness

**### Task Introduction**:
Given a complex question and a generated answer about a table, your task is to rate the answer's Comprehensiveness.

**### Evaluation Criteria:**
Comprehensiveness(1-5): A good answer should provide all the necessary information to address the question comprehensively. Additionally, it should avoid including details that, while consistent with the tabular data, are irrelevant to the given question.

**### Evaluation Steps:**
1. Carefully review the table and the question, ensuring you understand the full scope of the information provided. Identify all relevant points and details necessary to answer the question comprehensively.
2. Analyze the proposed answer to determine if it covers all the key aspects and addresses the question fully. Check whether the answer omits any important information or includes unnecessary details.
3. Evaluate the answer's comprehensiveness using a 1 to 5 rating scale, where 1 indicates the least comprehensive and 5 indicates the most.

Figure 3: G-Eval for Evaluating the *Comprehensiveness* of the LLM generated answer.
