

# Portfolio Theory and Risk Analysis Using Coefficient of Variation: An Alternative to the Modern Portfolio Theory

Julius O. Campeciño

Michigan State University, East Lansing, MI

## Abstract

We provided proof here that coefficient of variation (CV) is a direct measure of risk using an equation that has been derived here for the first time. We also presented a method to generate a stock CV based on return that strongly correlates with stock price performance. Consequently, we found that the price growths of stocks with low but positive CV are approximately exponential which explains our finding here that the total return of US domestic stocks within  $0 \leq CV \leq 1$  between Dec 2008 – Dec 2018 averaged at around 475% and outperformed the average total return of stocks within  $CV > 1$  and  $CV > 4$  by 144% and 2000%, respectively. From these observations, we posit that minimizing portfolio CV does not only minimize risk but also maximizes return. Minimizing risk by minimizing the standard deviation of return (volatility) as espoused by the Modern Portfolio Theory only resulted in a meager average total return of 15%, and the low-risk (low volatility) portfolio outperformed the high-risk portfolio by only 25%. These observations suggest that CV is a more reliable measure of risk than volatility.

## I. Introduction

The 1950s saw the development of the mean-variance analysis also known as the Modern Portfolio Theory (MPT) which is still used today for optimizing security return while minimizing risk (Markowitz 1952). The method described standard deviation (and variance) of return as the measure of risk which can be mathematically defined for a portfolio with  $n$  securities as:

$$\sigma_p^2 = \sum_{i=1}^n w_i^2 \sigma_i^2 + \sum_{i=1}^n \sum_{j=1}^n 2w_i w_j \rho_{i,j} \sigma_i \sigma_j \quad j \neq i \quad Eq.1$$

where  $\sigma_i^2$  and  $\sigma_p^2$  are the variances for security  $i$  and portfolio  $p$ , respectively, while  $w_i$  is the proportion of the asset allocated to each security, and  $\rho_{i,j}$  is the correlation of returns between securities  $i$  and  $j$ . While MPT is a model that produced innumerable investment successes and nurtured better investing practices, it fails to accurately model risk in the financial markets (Chen 2016). It had been argued that instead of measuring risk in terms of variance, risk should be measured only based on the probability of investment losses (Kim, Kim, and Fabozzi 2015; Keppler 1990). About 20 years later, Miller *et al.* developed a different method for risk analysis by introducing the use of coefficient of variation as a *relative measure of risk* (Miller and Karson 1977). In their method, the coefficient of variation (CV) of one security is compared to the CV of another security using a test statistic to determine if the CV of the two securities differ significantly. The test statistic is complex which may not be accessible by many ordinary investors and are, admittedly, only good when the number of securities ( $n$ ) is  $n \geq 10$  and  $CV \leq 0.67$  for a

one-sided alternative hypothesis, *i.e.*,  $H_0: CV_1 = CV_2$  versus  $H_a: CV_1 \neq CV_2$  (Feltz and Miller 1996), but such CV is rarely achieved in securities, especially in stock market (see Appendix). This limitation is in addition to the fact that such test is inaccurate when the data include negative values (Miller and Karson 1977) which, unfortunately, is common in financial securities' rate of return. In fact, Miller *et al.* used historical share prices instead of historical returns perhaps to avoid the inclusion of data with negative values and further assumed that the prices under consideration were taken from a normal population (Miller and Karson 1977). However, such assumption may be often incorrect as it is well known that share prices have a log-normal distribution (Antoniou *et al.* 2004; Rosenkrantz 2003).

This manuscript focuses on stock securities and describes an approach that generates stock CVs based on return that are strongly correlated to share price performance. CV can also be used to estimate the probability of the occurrence of negative return, herein defined as risk, using an equation that is described here for the first time. We found here that stocks with low but positive CV (low risk) have price growths that are approximately exponential and significantly outperform stocks with high or negative CV (high-risk). The method of selecting stocks using CV based on return as presented herein is mathematically simpler but more robust and reliable than the mean-variance analysis and test statistic.

## II. Deriving risk from the probability density function

The probability density function,  $f_X$ , is a function that describes a normal distribution and is given by:

$$f_X(x) = \frac{1}{\sigma\sqrt{2\pi}} e^{-\frac{(x-\mu)^2}{2\sigma^2}} \quad Eq. 3$$

where  $\mu$ ,  $\sigma$ , and  $\sigma^2$  are the mean, standard deviation, and variance (Naghattini 2017). In finance,  $\mu$  can be the average return of a security, and the distribution of returns has been theoretically and empirically proven to be normal (Fama 1965; Samuelson 2016). With  $\mu$  as the average return, the mean-variance analysis (also known as Modern Portfolio Theory or MPT) then defined  $\sigma$  (and  $\sigma^2$ ) as the measure of risk. To illustrate why standard deviation is an inaccurate measure of risk, consider the theoretical normal distribution of returns of portfolios A and B shown in Figure 1.

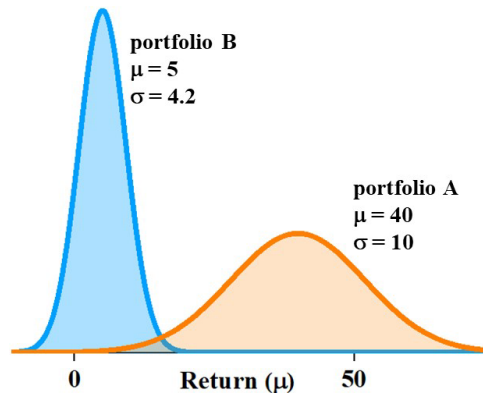

Figure 1. Theoretical normal distribution of returns of portfolios A and B.

Portfolio A has the larger standard deviation, and therefore should be the riskier portfolio according to MPT. However, the distribution of its return is well within the positive domain, suggesting that this portfolio had not incurred any losses. In contrast, portfolio B has the smaller standard deviation, and this portfolio should have the lower risk according to MPT. However, it is obvious that portfolio B incurred losses (some return fall below zero, Figure 1) and should, therefore, be the riskier portfolio. This example and the similar illustrations previously described (Kim, Kim, and Fabozzi 2015) demonstrate that risk should be defined only as the probability of incurring negative return. This probability is the area under a normal distribution curve in which the return fall below zero. This area is defined by the probability density function evaluated at  $(-\infty, 0]$  shown as follows,

$$\text{probability of negative return (risk)} = \int_{-\infty}^0 \frac{1}{\sigma\sqrt{2\pi}} e^{-\frac{(x-\mu)^2}{2\sigma^2}} dx \quad \text{Eq. 4}$$

Equation 4 transforms into an error function (Weisstein 2002; Burkardt 2014; Marsaglia 2004) shown as follows:

$$\text{probability of negative returns (risk)} = \frac{1}{2} \left[ 1 + \text{erf} \left( \frac{-\mu}{\sigma\sqrt{2}} \right) \right] \quad \text{Eq. 5}$$

which can be rewritten as:

$$\Phi_R = \frac{1}{2} \left[ 1 + \text{erf} \left( \frac{-1}{CV\sqrt{2}} \right) \right] \times 100\% \quad \text{Eq. 6}$$

where  $\Phi_R$  is the % probability of occurrence of negative return (risk) and  $CV = \frac{\sigma}{\mu}$ . This equation reveals for the first time the direct relationship between coefficient of variation and risk. In contrast to using CV as *relative risk* as espoused by Miller *et al.*, equation 6 is straight forward and the error function (erf) can be easily accessed in most spreadsheets, calculators, and graphing softwares.

### III. $\Phi_R$ describes practical market phenomena

Insights from equation 6 can be derived by plotting risk ( $\Phi_R$ ) against standard deviation or volatility ( $\sigma$ ) for various returns ( $\mu$ ) (Figure 2). The plot suggests that as volatility ( $\sigma$ ) increases, risk ( $\Phi_R$ ) approaches but never cross 50%. This observation is interesting because it suggests that so long as the average return ( $\mu$ ) is positive, the odds of profiting from an investment is better than the odds of losing. Also apparent from the plot is the inverse relationship between risk ( $\Phi_R$ ) and return (blue arrow) which suggests that for the same volatility, assets with lower returns are riskier. Furthermore, it is apparent from the plot that for the same risk (red arrow), assets with higher returns tend to be more volatile, *e.g.*, stocks vs bonds. Overall, these observations point to the fact that equation 6 has basis from the reality of the financial market.

Interestingly, there exists a region for each return where a nonzero volatility carries zero risk. This region turns out to be within  $0 \leq CV \leq 0.25$  regardless of the magnitude of the return (figure 2). The existence of this risk-free region suggests that volatility is not a risk-factor when its magnitude is no more than 0.25 of the return, highlighting the argument that volatility cannot be the true measures of risk.

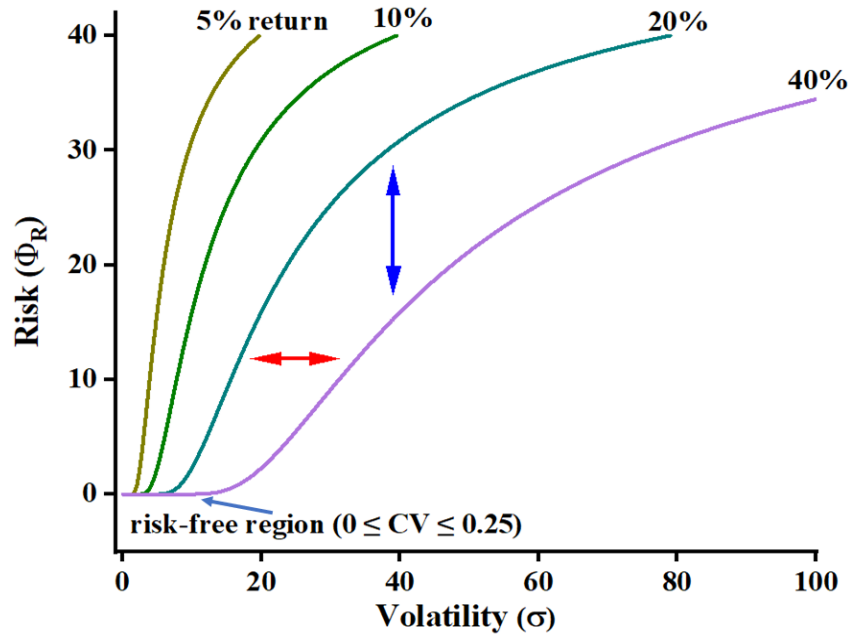

Figure 2. Plot of risk vs standard deviation for select returns.

#### IV. CV derived from monthly annual returns is strongly correlated to stock performance

This section presents for the first time the strong but inverse correlation between CV and stock performance when CV is determined from annual returns calculated for each month of the period of interest. For lack of a better description, we shall call it as monthly annual return and is simply described as follows:

$$\frac{\text{month's closing price} - \text{closing price of the same month a year ago}}{\text{closing price of the same month a year ago}} \times 100\% \quad \text{Eq. 7}$$

It can be readily shown that if CV calculation only includes annual returns based on, for example, end-of-year closing prices (Figure 3A), price fluctuations from the intervening months are unaccounted for and often lead to a weak correlation between CV and stock performance. However, when a CV is derived from monthly annual returns (Figure 3B), most of the price fluctuations are accounted for and, therefore, should lead to a strong but inverse correlation between CV and stock performance - this manner of CV calculation is akin to integral calculus. To illustrate this idea, we evaluated ~3000 US domestic stock securities and calculated their CVs based on end-of-year vs monthly annual returns between Dec 2008 – Dec 2018 (see Appendix).

Tickers (some may be valid only up to 2020) were included in the table which the reader may use for a quick verification using, for example, Yahoo!/Google Finance. For securities with no tickers, PERMNOs were provided which can be used to retrieve historical share prices from the Center for Research in Security Prices (CRSP). Indeed, we found that CVs derived from annual returns based only on end-of-the-year closing prices have weaker correlation with stock performance. For example, WRB stock (Figure 4A) appears to be riskier compared to BMRN stock (Figure 4B) by comparison of their CVs based on end-of-year closing prices. However, it is apparent from the historical share prices of these two stocks that the WRB share price growth was more consistent than that of BMRN. Reconciliation of the seemingly disconnect between CV and stock performance appears to be remediated by using monthly annual returns (compare CVs based on annual monthly returns in Figure 4). The reader is invited to verify this claim by comparing CV and performance of the stocks listed in the Appendix using Yahoo!/Google Finance as described above.

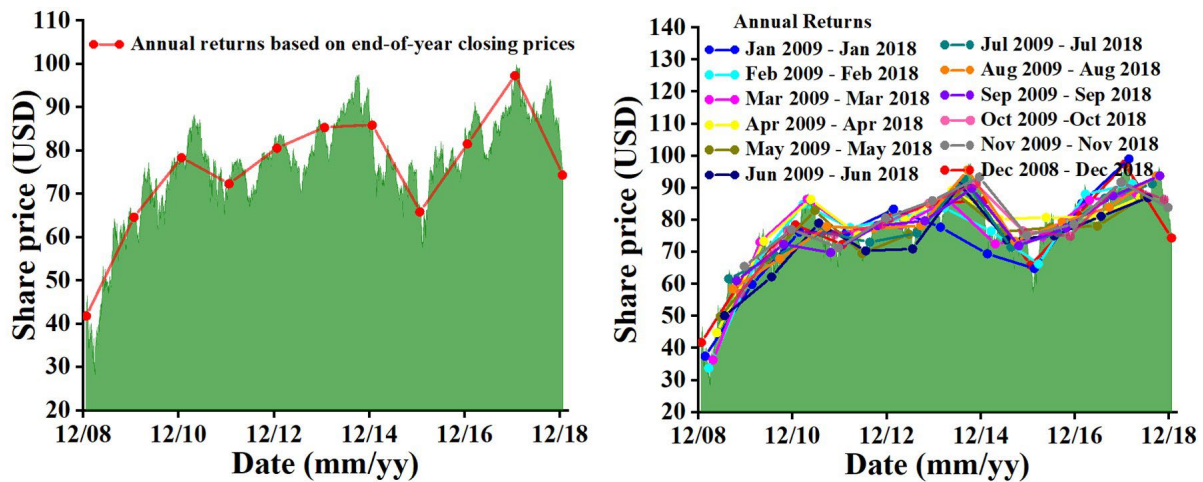

Figure 3. A. End of year annual returns. B. Monthly annual returns.

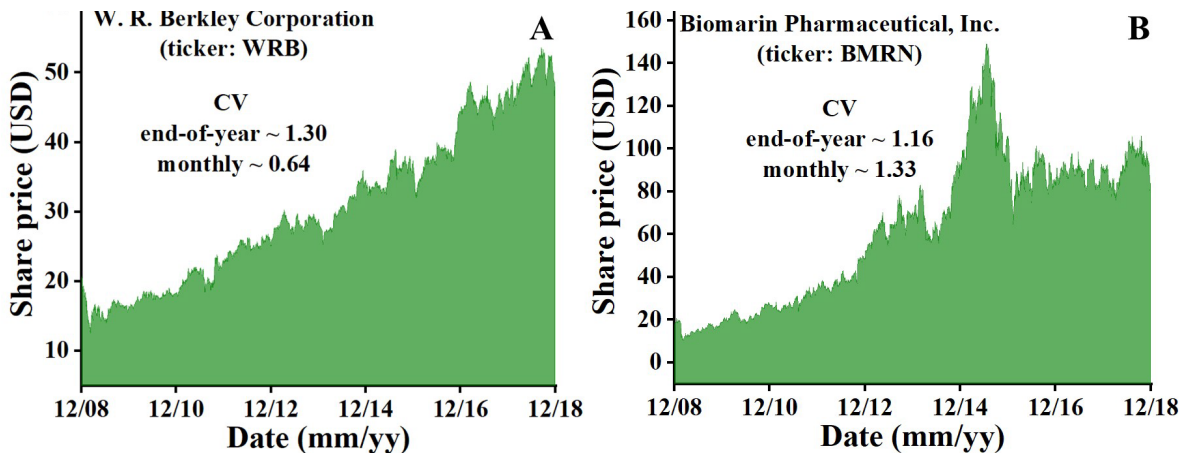

Figure 4. Comparison of WRB and BMRN end-of-year and monthly CVs and their correlation to historical share prices.

## V. Price of stocks with low but positive CV grow exponentially

Examination of the relationship between CV (see Appendix) and price growth (via Yahoo!/Google Finance) revealed that the price growth of stocks with low but positive CVs are approximately exponential (at least between 2008 to 2018). Then, gradual flattening or appearance of large peaks and valleys occur as CV increases or a decline in price growth as CV becomes negative. This observation suggests that stocks with low but positive CVs should outperform stocks with high or negative CVs. In fact, by calculating the total return between Dec 2008 – Dec 2018 for each stock, *i.e.*,

$$\text{total return} = \frac{\text{Dec 2018 price} - \text{Dec 2008 price}}{\text{Dec 2008 price}} \times 100\% \quad \text{Eq. 8}$$

we found that stocks within  $0 \leq CV \leq 1$  have an average total return of 475% compared to 195% and -25% average total return for stocks within  $CV > 1$  and  $CV > 4$ , respectively (see Appendix and figure 5A). Stocks within  $0 \leq CV \leq 1$ , dominated stocks within  $CV > 1$  &  $CV > 4$  by 144% and 2000%, respectively. It is noticeable from figure 5A that stocks within  $1 \leq CV \leq 4$  appears to be still profitable. However, it needs to be pointed out that most of the stocks within this range already deviate from the exponential price growth. Previously, Baker *et al.* and many others (Baker and Haugen 2012; Haugen and Heins 1975; Haugen and Baker 1991; Jagannathan and Ma 2003) also found that low-risk (low volatility) equities/portfolios outperform high-risk (high volatility) equities/portfolios. However, when minimizing risk by minimizing volatility, the low-risk portfolio only has an average total return of no more than 15%, and dominated the high-risk portfolio by 25% only (Baker and Haugen 2012). These results are rather meager compared to the numbers generated when using CV, suggesting yet again that CV may be the better measure of risk than volatility. Also, we can show that only an exponential growth can possibly achieve zero risk. Assuming  $\text{price} = ce^{a+bt}$ , where a, b, c are positive constants and  $t$  is the number of invested years,

$$\begin{aligned} \text{risk-free annual return} &= \frac{ce^{a+2b} - ce^{a+b}}{ce^{a+b}} \times 100\% = \frac{ce^{a+3b} - ce^{a+2b}}{ce^{a+2b}} \times 100 \\ &= \frac{ce^{a+b(t+1)} - ce^{a+bt}}{ce^{a+bt}} \times 100 \quad \text{Eq. 9} \end{aligned}$$

which can be simplified to

$$\text{risk-free annual return} = (e^b - 1) \times 100\% \quad \text{Eq. 10}$$

and with plots of selected risk-free price growth presented in figure 5B-D. Theoretically, the risk-free return has no limit, but the question is: what distinguishes a high yield risk-free stock from a stock in a bubble? In theory, the return of a risk-free stock is constant with respect to time. In practice, the return randomly fluctuates around a mean value (figure 6 A-B). For a stock in a bubble, however, the return is either trending up during bubble formation or trending down during bubble rupture (figure 6 C-D).

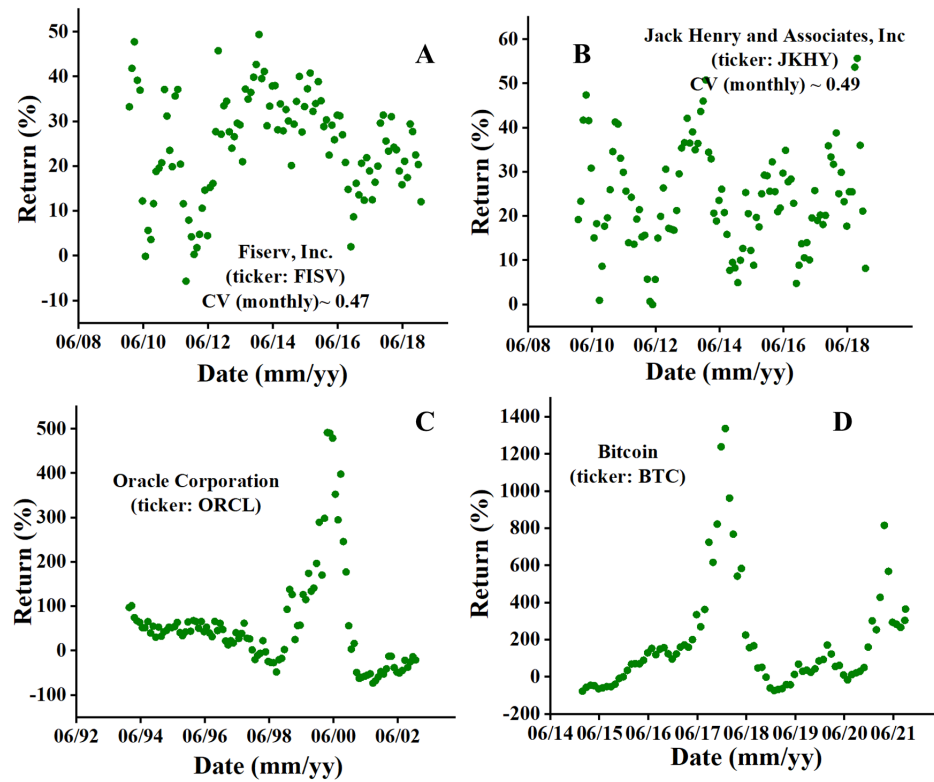

Figure 6. A-B. Stocks with normal growth. C-D. Assets in a bubble.

## VI. CV allows calculation of risk along the efficient frontier

Building a portfolio has been a practice for decades to mitigate the risk of untoward price declines, and this idea was mathematically embodied in MPT and gave rise to a very popular investment tool known as the efficient frontier (Fabozzi, Markowitz, and Gupta 2008; Markowitz 1952). MPT suggests that for any group of securities, there exists a set of portfolios offering the highest expected return for any given risk (defined in MPT as  $\sigma$ ). These portfolios lie along the upper half of a curve (see sample curves in Figure 7) that is said to be the efficient frontier (Fabozzi, Markowitz, and Gupta 2008; Markowitz 1952). Portfolios that lie to the left of the efficient frontier are considered to have lower risks but also offer lower returns, whereas portfolios that lie to the right of the efficient frontier are considered to have higher risks but also deliver higher returns. Portfolios that lie below the curve are said to be suboptimal (Fabozzi, Markowitz, and Gupta 2008; Markowitz 1952).

We examined  $\Phi_R$  along the efficient curve of a two-security portfolio (Table 1) previously described (Templeton 2013). The relationship of portfolio expected return ( $\mu_p$ ), standard deviation ( $\sigma_p$ ), and coefficient of variation ( $CV_p$ ) is described as follows:

$$CV_p = \frac{\sigma_p}{\mu_p} = \frac{\sqrt{(\sum_{i=1}^n w_i^2 \sigma_i^2 + \sum_{i=1}^n \sum_{j=1}^n 2w_i w_j \rho_{i,j} \sigma_i \sigma_j \quad j \neq i)}}{\sum_{i=1}^n w_i \mu_i} \quad Eq. 11$$

For a two-security portfolio, equation 11 is reduced to

$$CV_p = \frac{\sigma_p}{\mu_p} = \frac{\sqrt{[w_1^2 \sigma_1^2 + (1 - w_1)^2 \sigma_2^2 + 2w_1(1 - w_1)\rho\sigma_1\sigma_2]}}{w_1\mu_1 + (1 - w_1)\mu_2} \quad Eq. 12$$

where  $w_1$  and  $(1 - w_1)$  are the proportions of the asset allocated to securities 1 and 2, respectively. The frontiers with correlation  $\rho = -1, 0$ , and  $1$  were constructed and described in Figure 7.

Table 1. Theoretical securities described in (Templeton 2013).

	security A	security B

Figure 7. Calculation of CV and  $\Phi_R$  along the efficient frontier. Encircled points in each figure correspond to the data of the same highlight color found in each table.

Indeed, we observe from the efficient frontier with  $\rho = -1$  (Figure 7) that lower  $\sigma_p$  is associated with lower  $\Phi_R$  and vice versa, and this relationship is maintained even for the efficient frontier with  $\rho = 0$ . However at  $\rho = 0$ , comparison of  $\mu_p$  and risk (CV or  $\Phi_R$ ) between any two portfolios becomes an important consideration. For example, the portfolio that has an expected return  $\mu_p = 6.4$  has  $\Phi_R \sim 23\%$ , while the portfolio with an expected return  $\mu_p = 12$  has  $\Phi_R \sim 27\%$ . The expected return almost doubled but there is only a slight increase in  $\Phi_R$ , suggesting that the portfolio with  $\mu_p = 12$  may be the more efficient of the two portfolios. Even more surprising is the fact that the relationship between  $\sigma_p$  and  $\Phi_R$  is reversed for the efficient frontier with  $\rho = 1$ , *i.e.*, lower  $\sigma_p$  corresponds to higher  $\Phi_R$ , and vice versa. These analyses revealed that the direct relationship between  $\sigma_p$  and  $\Phi_R$  along the efficient frontier may only hold true for portfolios that have negative overall correlation. However, the reader is invited to verify that even at slightly negative correlation (*e.g.*,  $\rho = -0.3$ ),  $CV_p$  remains an important consideration. Interestingly, it had been found that inter- and intra-assets are likely to be positively correlated even for assets from diversified international origin (Hunter and Coggin 1990; Van Landschoot

2007; Chernih, Vanduffel, and Henrard 2006; Newell and Peng 2008), indicating that  $CV_p$  calculation may be the more superior tool than the efficient frontier. Judging from the observations from this and the previous section, we can posit that to maximize portfolio return, one only needs to minimize portfolio CV.

## VII. Conclusion

In addition to presenting a method for generating CV that strongly correlates with stock performance, we also presented here for the first time a mathematical equation that allows us to calculate risk using CV. This equation perfectly describes known market phenomena which provides confidence for its practical application in risk analysis. The equation suggests that stocks with high return are not necessarily risky. In fact, any stock with high return can be a risk-free if its volatility is no more than 25% of its return. This observation appears to contradict the notion that volatility is a measure of risk as proposed in the mean-variance analysis. Finally, we found that stocks with low but positive CV of up to 1.00 have approximately exponential price growths, and that these stocks appear to be outperforming stocks with high CV (high risk) by hundreds and even thousands of percent as opposed to only tens of percent when minimizing risk by minimizing volatility. Along with the empirical data from previous studies, it appears that the low risk/high return may indeed be the true risk/return correlation in the equity market, which appears to contradict the notion of high risk/high return in modern finance as espoused by the Modern Portfolio Theory. Consequently, it appears that in building a portfolio, one must minimize CV to maximize returns, but it needs to be borne in mind that CV comparison must be done only within an asset class as previously illustrated (Haugen and Heins 1975; Baker and Haugen 2012).

## VIII. Methodology

The historical and raw monthly share prices of US domestic stocks between December 2018 to December 2019 were downloaded from the Center for Research in Security Prices database which is available at Wharton Research Data Services. The prices were adjusted to reflect stock splits, repurchases, etc. by dividing the raw prices with the corresponding cumulative factor (CFACPR) also downloaded from the same database. Only stocks that have the complete historical monthly closing prices within the aforementioned period were included in the calculation. Bitcoin historical monthly closing prices were downloaded from [www.investing.com](http://www.investing.com). All plots were generated using OriginPro 2021 (OriginLab®).
