Elliptic Gauss Sums and Hecke L-values at s = 1

Dedicated to Professor Tomio Kubota

Tetsuya Asai*

Introduction

It seems that some retro-fashioned but still fascinating formulas lead us to consider the *elliptic Gauss sum*. The classical formulas concerned are the following :

$$\frac{1}{2}\sum_{k=1}^{p-1} \left(\frac{k}{p}\right) \cot \frac{\pi k}{p} = h(-p)\sqrt{p} \quad \text{and} \quad \frac{1}{2}\sum_{k=1}^{p-1} \left(\frac{k}{p}\right) \sec \frac{2\pi k}{p} = h(-p)\sqrt{p},$$

where $p \ (> 3)$ is a rational prime such that $p \equiv 3 \pmod{4}$ and $p \equiv 1 \pmod{4}$, respectively; $(\frac{k}{p})$ is the Legendre symbol and h(-p) is the class number of the quadratic field $\mathbf{Q}(\sqrt{-p})$. The formulas are apparently related to the Dirichlet *L*-values at s = 1.

To get a typical elliptic Gauss sum, we have only to replace the Legendre symbol by the cubic or the quartic residue character, and the trigonometric function by a suitable elliptic function. The notion of elliptic Gauss sum was first introduced by G. Eisenstein for a concern of higher reciprocity laws, but since then it has been regarded seemingly as a minor object of study. (cf. [L], p.311)

We shall here try to reconsider it. Especially, we treat the problem of *rationality of* the coefficient, so we call, of the elliptic Gauss sum, which is an analogy of the coefficient h(-p) in the above classical case. A typical example is as follows.

Let sl(u) be the lemniscatic sine of Gauss so that $sl((1-i)\varpi u)$ is an elliptic function with the period lattice $\mathbf{Z}[i]$, where $\varpi = 2 \int_0^1 \frac{dx}{\sqrt{1-x^4}}$. Let π be a primary prime in $\mathbf{Z}[i]$; $\pi \equiv 1 \pmod{(1+i)^3}$ and assume $p = \pi \overline{\pi} \equiv 13 \pmod{16}$. We consider the sum

$$\mathcal{G}_{\boldsymbol{\pi}} = \frac{1}{4} \sum_{\nu \in (\mathcal{O}/(\boldsymbol{\pi}))^{\times}} \left(\frac{\nu}{\boldsymbol{\pi}}\right)_{4} \operatorname{sl}((1-i)\boldsymbol{\varpi}\,\nu/\boldsymbol{\pi}).$$

It is not difficult to see that it is expressible as $\mathcal{G}_{\pi} = \alpha_{\pi}(\sqrt[4]{-\pi})^3$ by an integer α_{π} in $\mathbf{Z}[i]$. We can, furthermore, find remarkable facts by some experimental observation of the exact value α_{π} after having chosen the *canonical quartic root* $\tilde{\pi} = \sqrt[4]{-\pi}$. Namely,

 $\mathcal{G}_{\pi} = \alpha_{\pi} \widetilde{\pi}^3$ with a rational integer α_{π} ; the magnitude of which is rather small. This is not so trivial, but we can now prove the rationality. It proceeds as follows.

Let $\tilde{\chi}_{\pi}$ be the Hecke character of weight one induced by the quartic residue character to the modulus π . As is well known, the associated Hecke *L*-series $L(s, \tilde{\chi}_{\pi})$ has the functional equation. We have in particular the *central value equation* $L(1, \tilde{\chi}_{\pi}) = C(\tilde{\chi}_{\pi}) \overline{L(1, \tilde{\chi}_{\pi})}$ at s = 1; the constant $C(\tilde{\chi}_{\pi})$ is the so-called *root number*. Then it will be first shown that the value of $L(1, \tilde{\chi}_{\pi})$ is expressed by the elliptic Gauss sum \mathcal{G}_{π} .

^{*}apeiros@thn.ne.jp / Department of Mathematics, Shizuoka University (retired)

Secondly, it will be seen the root number $C(\tilde{\chi}_{\pi})$ coincides with the classical quartic Gauss sum $G_4(\pi)$ in this case, and fortunately the explicit formula of the value is known owing to Cassels-Matthews. Finally, the accordant expression of $\tilde{\pi}$ and $G_4(\pi)$ combined with the central value equation proves immediatly the fact $\alpha_{\pi} = \bar{\alpha}_{\pi}$, that is, the coefficient α_{π} of \mathcal{G}_{π} is a rational integer. As a corollary we shall obtain a new formula on the value $L(1, \tilde{\chi}_{\pi})$. It also should be remarked that we shall bring out a better understanding of Matthews' formula by considering together with the elliptic Gauss sum.

On the other hand, Mr. Naruo Kanou has observed these coefficients α_{π} for many primes by computer. According to his result, it holds $-49 \leq \alpha_{\pi} \leq 49$ for 35, 432 primes in the interval $13 \leq p \leq 3999949$. At present, however, the reason is not completely clarified, so we shall not touch on this topic of the small magnitude, while some persons say that α_{π}^2 might closely relate to the order of a certain Tate-Shafarevich group.

In this paper, we describe detail of the proof, mainly of rationality of the coefficient. There are two cases : the cubic character case and the quartic one. Although the idea is common and most of discussion goes in parallel, we would like to treat the two cases separately in the parts I and II to avoid possible confusion and complication. Since the same notations appear with each different meaning, we hope the reader would read carefully and also he would tolerate some redundant and overlapped description.

Acknowledgements

I am deeply grateful to Prof. Yoshikazu Baba, who called my attention to a theorem of heptagon, which has made a beginning of the study. Special thanks are due to my younger friends for their constant support, and the task has never been completed without the collaboration with them. Especially, Naruo Kanou has first made and provided a big table of the coefficients, which still appeals and waits for better elucidation; Yoshihiro Ônishi himself has discovered the congruence between the coefficients of elliptic Gauss sums and the generalized Hurwitz numbers, which has brought me a great inspiration and encouragement; Yoshinori Mizuno has suggested accurately to use the doubly periodic but non-analytic function in computation of Hecke Lvalues, and I followed him fully in this point. While it was not till a week after the meeting at Kyoto that I completed the proof by using the functional equation, Mr. Seidai Yasuda became independently aware of the same idea just after my meeting talk. He tenderly informed me of this after my realization. I thank him for this and permitting my own publication.

I. The Cubic Character Case

Let ρ be the cubic root of unity $e^{2\pi i/3}$. Throughout the part **I**, the field $\mathbf{Q}(\rho)$ and the ring $\mathbf{Z}[\rho]$ are abbreviated to F and \mathcal{O} , respectively. The set \mathcal{O} or its constant multiple appears also as a period lattice for elliptic functions. We use the notations as well : $W = \{\pm 1, \pm \rho, \pm \overline{\rho}\}, W' = \{1, \rho, \overline{\rho}\}.$

I.1. Special elliptic functions with complex multiplication

1.1. We shall define some special functions which play the leading role in our argument. We denote by ϖ_1 the real period given by

$$\varpi_1 \doteq \int_0^1 \frac{dx}{\sqrt[3]{(1-x^3)^2}} = \sqrt[3]{2} \int_0^1 \frac{dx}{\sqrt{1-x^3}} = 1.76663875\cdots$$

and let $\wp(u)$ denote Weierstrass' \wp with the period lattice $\varpi_1 \mathcal{O}$, so that $\wp'^2 = 4\wp^3 - 27$. Then it is obvious $\wp(\varpi_1 u)$ and $\wp'(\varpi_1 u)$ are elliptic functions of the period \mathcal{O} . Further, we can get another doubly periodic function by a slight modification of Weierstrass' ζ :

Definition. The non-analytic but doubly periodic function Z(u) is defined by

$$\mathsf{Z}(u) \doteq \zeta(\varpi_1 u) - \frac{2\pi}{\sqrt{3}\,\varpi_1}\,\overline{u},\tag{I.1}$$

where $\zeta(u)$ is Weierstrass' ζ to the period $\varpi_1 \mathcal{O}$. Double periodicity of Z(u) relative to \mathcal{O} is easily verified by a usual formula of ζ .

The addition formula of Z, that follows immediately from one of ζ , is useful :

$$\mathsf{Z}(u+v) = \mathsf{Z}(u) + \mathsf{Z}(v) + \frac{1}{2} \frac{\wp'(\varpi_1 u) - \wp'(\varpi_1 v)}{\wp(\varpi_1 u) - \wp(\varpi_1 v)}.$$
 (I.2)

The significance of the following two functions will be clear later when we see that they are closely related to some Hecke's L-values at s = 1. In fact, they are the corresponding functions with the lemniscatic sine and cosine of the quartic case. Anyway we shall find that these functions are automatically introduced by the associated Hecke L-series.

Definition. The elliptic functions $\varphi(u)$ and $\psi(u)$ to the period \mathcal{O} are defined by

$$\varphi(u) \doteq \frac{1}{3} \left\{ \mathsf{Z}\left(u - \frac{1}{3}\right) + \overline{\rho} \,\mathsf{Z}\left(u - \frac{\rho}{3}\right) + \rho \,\mathsf{Z}\left(u - \frac{\overline{\rho}}{3}\right) \right\},\tag{I.3}$$

$$\psi(u) \doteq -\frac{1}{3} \left\{ \mathsf{Z}\left(u - \frac{1}{3}\right) + \rho \,\mathsf{Z}\left(u - \frac{\rho}{3}\right) + \overline{\rho} \,\mathsf{Z}\left(u - \frac{\overline{\rho}}{3}\right) \right\}. \tag{I.4}$$

From the addition formula (I.2) we can easily derive the following expressions.

$$\varphi(u) = \frac{6\,\wp(\varpi_1 u)}{9 + \wp'(\varpi_1 u)}, \quad \psi(u) = \frac{9 - \wp'(\varpi_1 u)}{9 + \wp'(\varpi_1 u)}. \tag{I.5}$$

We need also the following formula.

$$\varphi(u)^{-1} + \varphi(-u)^{-1} = \frac{3}{\wp(\varpi_1 u)} = \frac{1}{\sqrt{-3}} \left\{ \mathsf{Z}\left(u - \frac{1}{\sqrt{-3}}\right) - \mathsf{Z}\left(u + \frac{1}{\sqrt{-3}}\right) \right\}.$$
 (I.6)

It seems that these functions are highly basic in the theory of elliptic functions relative to the lattice \mathcal{O} , especially in the theory of complex multiplication. We here list some fundamental properties of these functions, which are easily derived from the definitions and by usual theory of elliptic functions. Sometimes we need further properties, including the addition and multiplication formulas, which, however, we shall collect in the end of the part (Appendix I.2) for descriptive simplicity.

$$\begin{aligned} \operatorname{div}(\varphi) &= (0) + ((1-\rho)/3) + ((\rho-1)/3) - (1/3) - (\rho/3) - (\overline{\rho}/3), \\ \operatorname{div}(\psi) &= (-1/3) + (-\rho/3) + (-\overline{\rho}/3) - (1/3) - (\rho/3) - (\overline{\rho}/3), \\ \mathsf{Z}(\rho u) &= \overline{\rho} \,\mathsf{Z}(u), \quad \varphi(\rho \, u) &= \rho \,\varphi(u), \quad \psi(\rho \, u) &= \psi(u), \\ \mathsf{Z}(-u) &= -\mathsf{Z}(u), \quad \varphi(-u) &= -\varphi(u) \,\psi(u)^{-1}, \quad \psi(-u) &= \psi(u)^{-1}, \\ \psi(u) &= \varphi(-u - 1/3), \quad \varphi(u)^{-1} &= \varphi(-u + 1/3), \\ \varphi'(u) &= -3\overline{\omega}_1 \,\psi(u)^2, \quad \psi'(u) &= 3\overline{\omega}_1 \,\varphi(u)^2, \quad \varphi(u)^3 + \psi(u)^3 &= 1. \end{aligned}$$

1.2. Let π be a complex prime in $\mathcal{O} = \mathbf{Z}[\rho]$ so that $p = \pi \overline{\pi} \equiv 1 \pmod{3}$, and we assume also $\pi \equiv 1 \pmod{3}$. Then we have $(\mathcal{O}/(\pi))^{\times} \cong (\mathbf{Z}/p\mathbf{Z})^{\times}$. We often abbreviate as $\nu \pmod{\pi}$ in such a case when ν runs over $(\mathcal{O}/(\pi))^{\times}$.

Class field or complex multiplication theory tells us that such a division value $\varphi(1/\pi)$ or $\psi(1/\pi)$ generates an abelian extension field of $F = \mathbf{Q}(\rho)$. Namely, we have

Lemma I.1. Let $L = F(\varphi(1/\pi))$ and $L_1 = F(\psi(1/\pi))$. One has

- (i) L/F is a cyclic extension of degree p-1, and L_1 is a subfield; $[L:L_1] = 3$.
- (ii) $\operatorname{Gal}(L/F) \cong (\mathcal{O}/(\pi))^{\times}$ by corresponding σ_{μ} to μ , and it holds $\varphi(\nu/\pi)^{\sigma_{\mu}} = \varphi(\mu\nu/\pi)$, $\psi(\nu/\pi)^{\sigma_{\mu}} = \psi(\mu\nu/\pi)$ for arbitrary $\mu, \nu \in (\mathcal{O}/(\pi))^{\times}$.
- (iii) $\varphi(1/\pi)$, $\psi(1/\pi)$ are algebraic integers, and particularly $\psi(1/\pi)$ is a unit.
- (iv) The prime ideal $(\boldsymbol{\pi})$ splits completely in $L : (\boldsymbol{\pi}) = \mathfrak{P}^{p-1}$ where $\mathfrak{P} = (\varphi(1/\boldsymbol{\pi}))$.

In fact, L and L_1 are called the ray class fields of the conductors (3π) and $(\sqrt{-3\pi})$, respectively. We omit a proof, but in the appendix we give a brief comment on the complex multiplication formula which is crucial for the theory of division values. For a general consultation and a background we can refer to [L]. We here only give some numerical examples.

Example 1. In each case tabulated below, we have the π -multiplication formula :

$$\varphi(\boldsymbol{\pi} \, u) = \varphi(u) \cdot \frac{U(\varphi(u))}{R(\varphi(u))}, \quad R(x) = x^{p-1} \, U(x^{-1}).$$

We can also verify

$$U(x) = \prod_{\nu \pmod{\pi}}' (x - \varphi(\nu/\pi)), \quad V(x)^3 = \prod_{\nu \pmod{\pi}}' (x - \psi(\nu/\pi)),$$
$$x U(x) - R(x) = (x - 1) V(x)^3.$$

Furthermore it is easy to check

$$U(x), V(x) \in \mathcal{O}[x], \quad U(x) \equiv x^{p-1} \pmod{(\pi)}, \quad U(0) = \pi, \quad V(0) = 1.$$

In fact, U(x) and V(x) are the minimal polynomials of $\varphi(1/\pi)$ and $\psi(1/\pi)$, respectively.

| p | π | U(x) |
|----|------------|--|
| 7 | $1+3\rho$ | $x^6 - \pi x^3 + \pi$ |
| 13 | $4+3\rho$ | $x^{12} + (1+3 ho) \pi x^9 - 3 ho \pi x^6 - 2\pi x^3 + \pi$ |
| 19 | $-2+3\rho$ | $x^{18} - 3\rho \pi x^{15} - (3 - 9\rho) \pi x^{12} + (5 - 12\rho) \pi x^9 + 6\rho \pi x^6 - 3\pi x^3 + \pi$ |
| p | π | V(x) |
| 7 | $1+3\rho$ | $x^2 + \rho x + 1$ |
| 13 | $4+3\rho$ | $x^{4} - (1 + \rho) x^{3} - (1 + 2\rho) x^{2} - (1 + \rho) x + 1$ |
| 19 | $-2+3\rho$ | $x^{6} + (1 - \rho) x^{5} + (1 + 2\rho) x^{4} - x^{3} + (1 + 2\rho) x^{2} + (1 - \rho) x + 1$ |

Remark. As for the division value $Z(1/\pi)$, we can prove the following. (cf. II.1)

$$L = F(\varphi(1/\pi)) = F(\mathsf{Z}(1/\pi)), \quad \mathsf{Z}(\nu/\pi)^{\sigma_{\mu}} = \mathsf{Z}(\mu\nu/\pi) \quad (\mu, \nu \in (\mathcal{O}/(\pi))^{\times})$$

I.2. L-series for Hecke characters of weight one

2.1. In this section we recall some fundamental facts about the topic, which will give a basis and a framework of our whole discussion.

Let $\tilde{\chi}$ denote a Hecke character of weight one relative to the modulus $(\beta) \subset \mathcal{O}$, so that it is a multiplicative function on the ideal group of \mathcal{O} of the following form :

$$\widetilde{\chi}((\nu)) = \chi_1(\nu)\overline{\nu}, \quad \chi_1 : (\mathcal{O}/(\beta))^{\times} \to \mathbf{C}^{\times}, \quad \chi_1(\varepsilon) = \varepsilon \quad (\varepsilon \in W),$$

where χ_1 is an ordinary residue class character to the modulus (β), and (β) is called the coductor of $\tilde{\chi}$ if χ_1 is a primitive character to the modulus (β).

It is well known the associated L-series has the analytic continuation and satisfies the functional equation.

We here follow Weil's argument and his notation.

$$L(s, \ \widetilde{\chi}) = \sum_{\mathfrak{a}} \widetilde{\chi}(\mathfrak{a}) N \mathfrak{a}^{-s} = \frac{1}{6} \sum_{\nu \in \mathcal{O}} \chi_1(\nu) \overline{\nu} |\nu|^{-2s}$$
$$= \frac{1}{6} \sum_{\lambda \pmod{\beta}} \chi_1(\lambda) \sum_{\mu \in \mathcal{O}} (\overline{\lambda} + \overline{\mu}\overline{\beta}) |\lambda + \mu\beta|^{-2s}.$$

Therefore we have

$$L(s, \ \widetilde{\chi}) = \beta^{-1} |\beta|^{2-2s} \cdot \frac{1}{6} \sum_{\lambda \pmod{\beta}} \chi_1(\lambda) K_1(\lambda/\beta, \ 0, \ s).$$
(I.7)

Here the function K_1 is defined for $\operatorname{Re} s > 3/2$ as follows, and it is analytically continued to the whole s-plane and satisfies the own functional equation : (cf. [W], VIII)

$$K_{1}(u, u_{0}, s) = \sum_{\mu \in \mathcal{O}} e^{\frac{2\pi}{\sqrt{3}} (\overline{u}_{0}\mu - u_{0}\overline{\mu})} (\overline{u} + \overline{\mu}) |u + \mu|^{-2s},$$
$$\left(\frac{2\pi}{\sqrt{3}}\right)^{-s} \Gamma(s) K_{1}(u, u_{0}, s) = e^{\frac{2\pi}{\sqrt{3}} (\overline{u}_{0}u - u_{0}\overline{u})} \left(\frac{2\pi}{\sqrt{3}}\right)^{s-2} \Gamma(2 - s) K_{1}(u_{0}, u, 2 - s).$$

If (β) is the conductor of $\tilde{\chi}$, we can apply a usual computation of Gauss sum, and thus we obtain the functional equation of Hecke *L*-series in this case :

$$\Lambda(s, \ \widetilde{\chi}) = C(\widetilde{\chi}) \Lambda(2-s, \ \overline{\widetilde{\chi}}),$$

where $\Lambda(s, \ \widetilde{\chi}) = \left(\frac{2\pi}{\sqrt{3 \cdot N(\beta)}}\right)^{-s} \Gamma(s) L(s, \ \widetilde{\chi}),$
and $C(\widetilde{\chi}) = -\rho \beta^{-1} \sum_{\lambda \pmod{\beta}} \chi_1(\lambda) e^{2\pi i S(\lambda/\beta)}.$

In the above we use the following abbreviation :

$$S(\lambda) = a \text{ for } \lambda = a + b\overline{\rho} \ (a, b \in \mathbf{Q}), \text{ i.e. } 2\pi i S(\lambda) = \frac{2}{\sqrt{3}}\pi \left(\lambda \rho - \overline{\lambda}\overline{\rho}\right).$$

In particular we have a simple equality of Hecke L-values at s = 1, which we call the central value equation, and the constant $C(\tilde{\chi})$ is called the root number :

Lemma I.2. Let $\tilde{\chi}$ be a Hecke character of weight 1 with the conductor (β). Then

$$L(1, \ \widetilde{\chi}) = C(\widetilde{\chi}) \, \overline{L(1, \ \widetilde{\chi})}, \tag{I.8}$$

where
$$C(\tilde{\chi}) = -\rho \beta^{-1} \sum_{\lambda \pmod{\beta}} \chi_1(\lambda) e^{2\pi i S(\lambda/\beta)}.$$
 (I.9)

Remark. $L(1, \overline{\widetilde{\chi}}) = \overline{L(1, \widetilde{\chi})}.$

2.2. On the other hand, we can notice that the value $L(1, \tilde{\chi})$ relates to some elliptic functions. As is remarked in [W] (VIII, §14) or in others, the following is valid.

$$E_1^*(u) \doteq K_1(u, 0, 1) = \varpi_1 \zeta(\varpi_1 u) - \frac{2\pi}{\sqrt{3}} \overline{u}$$

By the definition (I.1) the right-hand side is nothing but our function $\varpi_1 Z(u)$. Combining this and the equation (I.7) at s = 1, we obtain the following formula.

Lemma I.3. Under the same condition of the preceding Lemma, it holds

$$L(1, \ \widetilde{\chi}) = \frac{\varpi_1}{6\beta} \sum_{\lambda \pmod{\beta}} \chi_1(\lambda) \,\mathsf{Z}(\lambda/\beta).$$
(I.10)

As we shall later discuss, the sum appeared in the right-hand of (I.10) is a prototype of *elliptic Gauss sum*. When a Hecke character $\tilde{\chi}$ is given in a suitably explicit form, we may evaluate both the elliptic Gauss sum and the root number more explicitly, and the central values equation will give some relation between the two. In particular, from the value of the elliptic Gauss sum, if non-vanishing, we can know the value of the root number. This is the case of our cubic characters, that is the point of this report.

Example 2. The following is probably the simplest case and the derived formula $L(1, \tilde{\chi}_0) = \frac{\varpi_1}{3}$ may be compared with the classical formula : $1 - \frac{1}{3} + \frac{1}{5} - \frac{1}{7} + \cdots = \frac{\pi}{4}$.

The conductor is the ideal (3). The Hecke character $\tilde{\chi}_0 \mod (3)$ is given as follows:

$$\widetilde{\chi}_0((\nu)) \doteq \chi_0(\nu) \overline{\nu}$$
, where $\chi_0 : (\mathcal{O}/(3))^{\times} \cong W$ is the natural isomorphism.

Then we can evaluate the *L*-value at s = 1 directly by (I.10) :

$$L(1, \ \widetilde{\chi}_0) = \frac{\overline{\omega}_1}{18} \sum_{\varepsilon \in W} \varepsilon \operatorname{\mathsf{Z}}(\varepsilon/3) = \frac{\overline{\omega}_1}{3} \operatorname{\mathsf{Z}}(1/3) = \frac{\overline{\omega}_1}{3},$$

because Z(1/3) = 1 by usual theory of elliptic functions. Also we can easily check $C(\tilde{\chi}_0) = -\frac{\rho}{3} \sum_{\varepsilon \in W} \varepsilon e^{2\pi i S(\varepsilon/3)} = 1$ as is expected.

I.3. Elliptic Gauss sums for cubic characters

3.1. Let π be a primary prime in \mathcal{O} ; namely $\pi \equiv 1 \pmod{3}$. Let χ_{π} be the cubic residue character to the modulus π ; the notation will be fixed throughout the part \mathbf{I} :

$$\chi_{\boldsymbol{\pi}}(\nu) = \left(\frac{\nu}{\boldsymbol{\pi}}\right)_{3} : \chi_{\boldsymbol{\pi}}(\nu)^{3} = 1 \text{ and } \chi_{\boldsymbol{\pi}}(\nu) \equiv \nu^{(p-1)/3} \pmod{\boldsymbol{\pi}} \quad (\nu \in (\mathcal{O}/(\boldsymbol{\pi}))^{\times}).$$

Let f(u) be a certain elliptic function with the periods \mathcal{O} , which we specify below. **Definition.** The following is called an *elliptic Gauss sum*.

$$\mathcal{G}_{\boldsymbol{\pi}}(\chi_{\boldsymbol{\pi}}, f) \doteq \frac{1}{3} \sum_{\nu \pmod{\boldsymbol{\pi}}} \chi_{\boldsymbol{\pi}}(\nu) f(\nu/\boldsymbol{\pi}).$$
(I.11)

In the part I, we deal with the elliptic Gauss sums $\mathcal{G}_{\pi}(\chi_{\pi}, \varphi)$, $\mathcal{G}_{\pi}(\chi_{\pi}, \varphi^{-1})$ and $\mathcal{G}_{\pi}(\chi_{\pi}, \psi)$ only, where $\varphi(u)$ and $\psi(u)$ are the special elliptic functions defined by (I.3), (I.4). So we understand that f(u) denotes an arbitrary one of these functions $\varphi(u), \varphi(u)^{-1}$ and $\psi(u)$ in the subsequence. In these cases, unless "the parity condition", so we call, $\chi_{\pi}(\rho\nu) f(\rho\nu/\pi) = \chi_{\pi}(\nu) f(\nu/\pi)$ is satisfied, $\mathcal{G}_{\pi}(\chi_{\pi}, f)$ vanishes trivially. Since $\varphi(\rho u) = \rho \varphi(u), \ \psi(\rho u) = \psi(u)$ and $\chi_{\pi}(\rho) = \rho^{(p-1)/3}$, we can easily check that $\mathcal{G}_{\pi}(\chi_{\pi}, f)$ is not trivial in the following only three cases. The parity condition, however, is not sufficient for non-vanishing of the elliptic Gauss sum as we shall see later.

The elliptic Gauss sums which we shall consider are the followings :

- (a) $\mathfrak{G}_{\pi}(\chi_{\pi}, \varphi)$ in the case $p = \pi \overline{\pi} \equiv 7 \pmod{18}$,
- (b) $\mathcal{G}_{\pi}(\chi_{\pi}, \varphi^{-1})$ in the case $p = \pi \overline{\pi} \equiv 13 \pmod{18}$,
- (c) $\mathfrak{G}_{\pi}(\chi_{\pi}, \psi)$ in the case $p = \pi \overline{\pi} \equiv 1 \pmod{18}$.

As noted in Lemma I.1, the division values $\varphi(\nu/\pi), \psi(\nu/\pi)$ are algebraic integers in $L = F(\varphi(1/\pi))$, and $\operatorname{Gal}(L/F) \cong (\mathcal{O}/(\pi))^{\times}$, hence we can immediately see the following.

$$\mathfrak{G}_{\boldsymbol{\pi}}(\chi_{\boldsymbol{\pi}}, f)^{\sigma_{\mu}} = \overline{\chi}_{\boldsymbol{\pi}}(\mu) \,\mathfrak{G}_{\boldsymbol{\pi}}(\chi_{\boldsymbol{\pi}}, f) \quad (\mu \in (\mathcal{O}/(\boldsymbol{\pi}))^{\times})$$
(I.12)

In particular, $\mathfrak{G}_{\pi}(\chi_{\pi}, f)^3$ is an element of F, and furthermore we have

Lemma I.4. $\mathfrak{G}_{\pi}(\chi_{\pi}, f)^3$ is an algebraic integer in \mathcal{O} .

Proof. We show only the integrity of $\mathfrak{G}_{\pi}(\chi_{\pi}, \varphi^{-1})^3$. Since $\varphi(1/\pi) \varphi(\nu/\pi)^{-1}$ is a unit, $\mathfrak{P}^3(\mathfrak{G}_{\pi}(\chi_{\pi}, \varphi^{-1})^3)$ is an integral ideal, where $\mathfrak{P} = (\varphi(1/\pi))$. On the other hand, $(\pi) = \mathfrak{P}^{p-1}$ and $p-1 \ge 12$, hence $(\mathfrak{G}_{\pi}(\chi_{\pi}, \varphi^{-1})^3)$ must be integral by itself.

Lemma I.5. $\mathfrak{G}_{\pi}(\chi_{\pi}, \varphi)^3 \equiv 1 \pmod{\sqrt{-3}}, \quad \mathfrak{G}_{\pi}(\chi_{\pi}, \varphi^{-1})^3 \equiv -1 \pmod{\sqrt{-3}}$ and $\mathfrak{G}_{\pi}(\chi_{\pi}, \psi)^3 \equiv 0 \pmod{\sqrt{-3}}, \quad if \ p = \pi \overline{\pi} \equiv 7 \pmod{18}, \ p = \pi \overline{\pi} \equiv 13 \pmod{18}$ and $p = \pi \overline{\pi} \equiv 1 \pmod{18}, \quad respectively.$

Proof. First, we quote the $\sqrt{-3}$ multiplication formula of $\varphi(u)$ (cf. Appendix I.2) :

$$\varphi(\sqrt{-3}\,u) = \frac{\sqrt{-3}\,\varphi(u)\,\psi(u)}{1+\overline{\rho}\,\varphi(u)^3}.$$

Put $u = \nu/\pi$, then we know $\mathfrak{P} = (\varphi(\nu/\pi)) = (\varphi(\sqrt{-3}\nu/\pi))$ and $\psi(\nu/\pi)$ is a unit. Hence an ideal equality $(\varphi(\nu/\pi)^3 + \rho) = (\sqrt{-3})$ holds. Therefore we have

$$\varphi(\nu/\pi)^3 \equiv -1 \pmod{\sqrt{-3}}.$$
 (I.13)

Next, let S be an arbitrary third set of $(\mathcal{O}/(\pi))^{\times}$, namely, $(\mathcal{O}/(\pi))^{\times} = S \cup \rho S \cup \overline{\rho} S$. By virtue of the parity condition, we have $\mathcal{G}_{\pi}(\chi_{\pi}, f) = \sum_{\nu \in S} \chi_{\pi}(\nu) f(\nu/\pi)$. So we obtain

$$\mathcal{G}_{\boldsymbol{\pi}}(\chi_{\boldsymbol{\pi}},\,\varphi)^3 \equiv \sum_{\nu \in S} \varphi(\nu/\boldsymbol{\pi})^3 \equiv \frac{p-1}{3} \cdot (-1) \equiv 1 \pmod{\sqrt{-3}}.$$

For other cases of $\mathfrak{G}_{\pi}(\chi_{\pi}, \varphi^{-1})$ and $\mathfrak{G}_{\pi}(\chi_{\pi}, \psi)$, the same argument holds by using

$$\boldsymbol{\pi} \cdot \varphi(\nu/\boldsymbol{\pi})^{-3} \equiv -1 \pmod{\sqrt{-3}}$$
 and $\psi(\nu/\boldsymbol{\pi})^3 \equiv -1 \pmod{\sqrt{-3}}$,

instead of (I.13), respectively. Thus we complete the proof of Lemma I.5.

3.2. Obviously from (I.12), the value $\mathcal{G}_{\pi}(\chi_{\pi}, f)$ belongs to the cubic extension over F. So it is necessary to give an suitable cubic root of π for the precise investigation of the value of $\mathcal{G}_{\pi}(\chi_{\pi}, f)$.

Let S be an arbitrary third set of $(\mathcal{O}/(\pi))^{\times}$. Let $\gamma(S)$ be the cubic root of unity such that $\gamma(S) \equiv -\prod_{\nu \in S} \nu \mod (\pi)$. (cf. [M1], (1.6))

Definition. The following is called the *canonical cubic root* of π .

$$\widetilde{\boldsymbol{\pi}} \doteq \gamma(S)^{-1} \prod_{\nu \in S} \varphi(\nu/\boldsymbol{\pi}).$$
(I.14)

Because of the property $\varphi(\rho u) = \rho \varphi(u)$, $\tilde{\pi}$ is independent of the choice of S, and also we can easily show the following by the theory of complex multiplication. (cf. Appendix)

$$\widetilde{\boldsymbol{\pi}}^3 = \prod_{\nu \, (ext{mod} \, \boldsymbol{\pi})}' arphi(
u/oldsymbol{\pi}) = oldsymbol{\pi}.$$

The following is a fundamental property of the cubic residue symbol :

$$\widetilde{\pi}^{\sigma_{\mu}} = \chi_{\pi}(\mu) \widetilde{\pi}, \quad (\mu \in (\mathcal{O}/(\pi))^{\times})$$
 (I.15)

which is also easily verified in view of $\gamma(\mu S) = \chi_{\pi}(\mu) \gamma(S)$.

Definition. The following is called the *coefficient* of the elliptic Gauss sum $\mathcal{G}_{\pi}(\chi_{\pi}, f)$.

$$\alpha_{\boldsymbol{\pi}} \doteq \widetilde{\boldsymbol{\pi}}^{-2} \, \mathcal{G}_{\boldsymbol{\pi}}(\chi_{\boldsymbol{\pi}}, f). \tag{I.16}$$

Theorem I.1. Let $\tilde{\pi}$ be the canonical cubic root of π . Then the elliptic Gauss sum is expressible as follows:

$$\mathcal{G}_{\boldsymbol{\pi}}(\boldsymbol{\chi}_{\boldsymbol{\pi}},\,f) = \alpha_{\boldsymbol{\pi}}\,\widetilde{\boldsymbol{\pi}}^2,$$

where the coefficient α_{π} is an algebraic integer in \mathcal{O} . Futher, it holds

$$\alpha_{\pi} \equiv \begin{cases}
1 \pmod{\sqrt{-3}} & \text{if } p = \pi \,\overline{\pi} \equiv 7 \pmod{18}, \\
-1 \pmod{\sqrt{-3}} & \text{if } p = \pi \,\overline{\pi} \equiv 13 \pmod{18}, \\
0 \pmod{\sqrt{-3}} & \text{if } p = \pi \,\overline{\pi} \equiv 1 \pmod{18}.
\end{cases}$$
(I.17)

Proof. By the definition of the coefficient α_{π} and by virtue of the properties (I.12) and (I.15), $\alpha_{\pi}^{\sigma_{\mu}} = \alpha_{\pi}$ ($\mu \in (\mathcal{O}/(\pi))^{\times}$), and hence $\alpha_{\pi} \in F$. For the integrity, we can check it similarly to the proof of Lemma I.4 : $\alpha_{\pi} \tilde{\pi}^2$ is an algebraic integer, while $\pi = \tilde{\pi}^3$ is a prime in \mathcal{O} ; it means α_{π} itself is already an integer. The latter part of Theorem I.1 is immediately observed by Lemma I.5.

Remark. When $p \equiv 7$ or 13 (mod 18), we can take $S = \ker \chi_{\pi}$ as a typical third set of $(\mathcal{O}/(\pi))^{\times}$; namely, S is the subgroup consisting of all cubic residues mod π . This choice has some advantages. Particularly, it is valid

$$\mathfrak{G}_{\boldsymbol{\pi}}(\chi_{\boldsymbol{\pi}}, f) = \sum_{\nu \in S} f(\nu/\boldsymbol{\pi}), \quad \gamma(S) = 1, \quad \widetilde{\boldsymbol{\pi}} = \prod_{\nu \in S} \varphi(\nu/\boldsymbol{\pi}).$$

Example 3. Consider the case of $\pi = 4 + 3\rho$ (p = 13), and we shall show $\alpha_{\pi} = -\overline{\rho}$. Take $S = \ker \chi_{\pi}$. Then $S = \{\pm 1, \pm 5\} = \{1, -1, 1 - \overline{\rho}, -2\overline{\rho}\}$, and so we have

$$\widetilde{\boldsymbol{\pi}} = \prod_{\nu \in S} \varphi(\nu/\boldsymbol{\pi}) = \varphi(1/\boldsymbol{\pi}) \, \varphi(-1/\boldsymbol{\pi}) \, \varphi((1-\overline{\rho})/\boldsymbol{\pi}) \, \varphi(-2\overline{\rho}/\boldsymbol{\pi})$$

By using suitable multiplication formulas (cf. Appendix) we can compute the right-hand to the following form :

$$\widetilde{\boldsymbol{\pi}} = \frac{(\rho - \overline{\rho}) \, \varphi(1/\boldsymbol{\pi})^4 \, (\varphi(1/\boldsymbol{\pi})^3 - 1)}{(1 + \rho \, \varphi(1/\boldsymbol{\pi})^3)(1 - 2 \, \varphi(1/\boldsymbol{\pi})^3)}.$$

Therefore $\varphi(1/\pi)$ is a solution of the following equaition.

$$(1+2\rho) x^7 + 2\rho \,\widetilde{\pi} \, x^6 - 2(1+2\rho) \, x^4 + (2-\rho) \,\widetilde{\pi} \, x^3 - \widetilde{\pi} = 0.$$

The equation is decomposed as follows.

$$((1+2\rho)x^3+2\,\widetilde{\pi}\,x^2+\overline{\rho}\,\widetilde{\pi}^2\,x-1)(x^4-2\overline{\rho}\,\widetilde{\pi}\,x^3-(1-\rho)\,\widetilde{\pi}^2\,x^2+\overline{\rho}\,\widetilde{\pi}^3\,x+\widetilde{\pi})=0.$$

The second factor must be the minimal polynomial of $\varphi(1/\pi)$ over $F(\tilde{\pi}) = \mathbf{Q}(\rho, \sqrt[3]{\pi})$. So $\varphi(\nu/\pi)^{-1}$ ($\nu \in S$) are the four roots of the reciprocal equation.

$$x^{4} + \overline{\rho}\,\widetilde{\boldsymbol{\pi}}^{2}\,x^{3} - (1-\rho)\,\widetilde{\boldsymbol{\pi}}\,x^{2} - 2\overline{\rho}\,x + \widetilde{\boldsymbol{\pi}}^{-1} = 0.$$

Comparing the second coefficient, we have

$$\mathcal{G}_{\boldsymbol{\pi}}(\chi_{\boldsymbol{\pi}}, \, \varphi^{-1}) = \sum_{\nu \in S} \varphi(\nu/\boldsymbol{\pi})^{-1} = -\overline{\rho} \, \widetilde{\boldsymbol{\pi}}^2 \quad \therefore \quad \alpha_{\boldsymbol{\pi}} = -\overline{\rho},$$

which satisfies certainly $\alpha_{\pi} \equiv -1 \pmod{\sqrt{-3}}$.

In general, it seems pretty hard to compute the value of the coefficient α_{π} by hand. Some examples by computor are given in the table Appendix I.1.

I.4. The cubic Hecke characters and *L*-values at s = 1

4.1. We introduce a Hecke character $\tilde{\chi}_{\pi}$ induced by the cubic residue character χ_{π} . As mentioned before, it is of the form $\tilde{\chi}_{\pi}((\nu)) = \chi_1(\nu)\overline{\nu}$ with a residue class character χ_1 . For the purpose we first modify the character χ_{π} into χ_1 satisfying $\chi_1(-\rho) = -\rho$. After the preparation of supplementary characters χ_0 and χ'_0 , we shall treat the three cases separately in view of $\chi_{\pi}(-\rho) = \rho^{(p-1)/3}$.

Let χ_0 be the character of $(\mathcal{O}/(3))^{\times}$ defined by

$$\chi_0(\nu) \doteq \varepsilon \text{ for } \nu \equiv \varepsilon \pmod{3}, \ \varepsilon \in W = \{\pm 1, \pm \rho, \pm \overline{\rho}\}.$$

We here should notice that χ_0 gives the natural isomorphism $(\mathcal{O}/(3))^{\times} \cong W$.

Let χ'_0 be the character of $(\mathcal{O}/(\sqrt{-3}))^{\times}$ defined by

$$\chi'_0(\nu) \doteq \delta \text{ for } \nu \equiv \delta \pmod{\sqrt{-3}}, \ \delta \in \{\pm 1\}.$$

We also should notice that χ'_0 gives the natural isomorphism $(\mathcal{O}/(\sqrt{-3}))^{\times} \cong \{\pm 1\}$.

Definition. For each primary prime π in \mathcal{O} , the Hecke character $\tilde{\chi}_{\pi}$ is defined and fixed throughout the part I as follows :

$$\widetilde{\chi}_{\boldsymbol{\pi}}((\nu)) \doteq \chi_1(\nu) \overline{\nu}, \quad \chi_1 \doteq \begin{cases} \chi_{\boldsymbol{\pi}} \cdot \overline{\chi}_0 & \text{for } p = \boldsymbol{\pi} \,\overline{\boldsymbol{\pi}} \equiv 7 \pmod{18}, \\ \chi_{\boldsymbol{\pi}} \cdot \chi'_0 & \text{for } p = \boldsymbol{\pi} \,\overline{\boldsymbol{\pi}} \equiv 13 \pmod{18}, \\ \chi_{\boldsymbol{\pi}} \cdot \chi_0 & \text{for } p = \boldsymbol{\pi} \,\overline{\boldsymbol{\pi}} \equiv 1 \pmod{18}. \end{cases}$$
(I.18)

For later use, we present a list of the circumstance of each case.

(a) The case $p = \pi \overline{\pi} \equiv 7 \pmod{18}$.

$$(\mathcal{O}/(\beta))^{\times} \cong (\mathcal{O}/(\pi))^{\times} \times W$$
 by λ to $(\kappa, \varepsilon) : \lambda \equiv 3\kappa + \pi \varepsilon \pmod{\beta}$. (I.19)

The conductor of $\widetilde{\chi}_{\pi}$ is (β) where $\beta = 3\pi$, and we have $\chi_1(\lambda) = \chi_{\pi}(3) \chi_{\pi}(\kappa) \overline{\varepsilon}$.

(b) The case $p = \pi \overline{\pi} \equiv 13 \pmod{18}$.

 $(\mathcal{O}/(\beta))^{\times} \cong (\mathcal{O}/(\pi))^{\times} \times \{\pm 1\}$ by λ to $(\kappa, \delta) : \lambda \equiv \sqrt{-3}\kappa + \pi \delta \pmod{\beta}$. (I.20)

The conductor of $\tilde{\chi}_{\pi}$ is (β) where $\beta = \sqrt{-3}\pi$, and we have $\chi_1(\lambda) = \overline{\chi}_{\pi}(3) \chi_{\pi}(\kappa) \delta$. (c) The case $p = \pi \overline{\pi} \equiv 1 \pmod{18}$.

$$(\mathcal{O}/(\beta))^{\times} \cong (\mathcal{O}/(\pi))^{\times} \times W$$
 by λ to $(\kappa, \varepsilon) : \lambda \equiv 3\kappa + \pi \varepsilon \pmod{\beta}$. (I.21)

The conductor of $\tilde{\chi}_{\pi}$ is (β) where $\beta = 3 \pi$, and we have $\chi_1(\lambda) = \chi_{\pi}(3) \chi_{\pi}(\kappa) \varepsilon$.

4.2. We are now ready to evaluate the value of the associated *L*-series, especially at s = 1, and we show that $L(1, \tilde{\chi}_{\pi})$ is expressed by the corresponding elliptic Gauss sum.

Theorem I.2. Let $\widetilde{\chi}_{\pi}$ be the Hecke character for π . Then

$$\varpi_{1}^{-1} L(1, \widetilde{\chi}_{\pi}) = \begin{cases} -\chi_{\pi}(3) \, \pi^{-1} \, \mathcal{G}_{\pi}(\chi_{\pi}, \varphi) & \text{if } p = \pi \, \overline{\pi} \equiv 7 \pmod{18}, \\ -\overline{\chi}_{\pi}(3) \, \pi^{-1} \, \mathcal{G}_{\pi}(\chi_{\pi}, \varphi^{-1}) & \text{if } p = \pi \, \overline{\pi} \equiv 13 \pmod{18}, \\ \chi_{\pi}(3) \, \pi^{-1} \, \mathcal{G}_{\pi}(\chi_{\pi}, \psi) & \text{if } p = \pi \, \overline{\pi} \equiv 1 \pmod{18}. \end{cases}$$
(I.22)

Proof. We follow the formula (I.10) of Lemma I.3, and refer to (I.19), (I.20) and (I.21).

(a) The case $p = \pi \overline{\pi} \equiv 7 \pmod{18}$. In view of (I.19), we have

$$L(1, \ \widetilde{\chi}_{\pi}) = \frac{\varpi_{1}}{6\beta} \cdot \sum_{\lambda \pmod{\beta}} \chi_{1}(\lambda) \operatorname{Z}(\lambda/\beta)$$

$$= \frac{\varpi_{1}}{18\pi} \chi_{\pi}(3) \cdot \sum_{\kappa \pmod{\pi}} \chi_{\pi}(\kappa) \sum_{\varepsilon \in W} \overline{\varepsilon} \operatorname{Z}(\kappa/\pi + \varepsilon/3)$$

$$= -\frac{\chi_{\pi}(3) \varpi_{1}}{6 \cdot \pi} \cdot \sum_{\kappa \pmod{\pi}} \chi_{\pi}(\kappa) \left\{ \varphi(\kappa/\pi) + \varphi(-\kappa/\pi) \right\}$$

$$= -\frac{\chi_{\pi}(3) \varpi_{1}}{\pi} \cdot \frac{1}{3} \sum_{\kappa \pmod{\pi}} \chi_{\pi}(\kappa) \varphi(\kappa/\pi),$$

by the definition (I.3).

(b) The case $p = \pi \overline{\pi} \equiv 13 \pmod{18}$. In view of (I.20), we have

$$L(1, \ \widetilde{\chi}_{\pi}) = \frac{\varpi_1}{6\sqrt{-3}\pi} \overline{\chi}_{\pi}(3) \cdot \sum_{\kappa \pmod{\pi}} \chi_{\pi}(\kappa) \sum_{\delta=\pm 1} \delta \operatorname{Z}(\kappa/\pi + \delta/\sqrt{-3})$$
$$= -\frac{\overline{\chi}_{\pi}(3) \varpi_1}{6 \cdot \pi} \cdot \sum_{\kappa \pmod{\pi}} \chi_{\pi}(\kappa) \left\{ \varphi(\kappa/\pi)^{-1} + \varphi(-\kappa/\pi)^{-1} \right\}$$
$$= -\frac{\overline{\chi}_{\pi}(3) \varpi_1}{\pi} \cdot \frac{1}{3} \sum_{\kappa \pmod{\pi}} \chi_{\pi}(\kappa) \varphi(\kappa/\pi)^{-1},$$

by the formula (I.6).

(c) The case $p = \pi \overline{\pi} \equiv 1 \pmod{18}$. In view of (I.21), we have

$$L(1, \ \widetilde{\chi}_{\pi}) = \frac{\varpi_1}{18 \, \pi} \, \chi_{\pi}(3) \cdot \sum_{\kappa \pmod{\pi}} \chi_{\pi}(\kappa) \sum_{\varepsilon \in W} \varepsilon \, \mathsf{Z}(\kappa/\pi + \varepsilon/3)$$
$$= \frac{\chi_{\pi}(3) \, \varpi_1}{6 \cdot \pi} \cdot \sum_{\kappa \pmod{\pi}} \chi_{\pi}(\kappa) \left\{ \psi(\kappa/\pi) + \psi(-\kappa/\pi) \right\}$$
$$= \frac{\chi_{\pi}(3) \, \varpi_1}{\pi} \cdot \frac{1}{3} \sum_{\kappa \pmod{\pi}} \chi_{\pi}(\kappa) \, \psi(\kappa/\pi),$$

by the definition (I.4). Thus the proof of Theorem I.2 is finished.

It may be noteworthy that the special elliptic functions $\varphi(u), \varphi(u)^{-1}$ and $\psi(u)$ appear naturally and automatically in these *L*-series ; consequently the associated *L*-series would introduce those elliptic functions the division values of which generate some abelian extensions of the field *F*.

I.5. The explicit formula of the root number $C(\tilde{\chi}_{\pi})$

5.1. We require an important formula about the classical cubic Gauss sum. Let π be a primary prime in \mathcal{O} ; $\pi \equiv 1 \pmod{3}$, and set $p = \pi \overline{\pi}$ as before. The cubic Gauss sum, often called the Kummer sum, is defined and is denoted by

$$G_3(\boldsymbol{\pi}) \doteq \sum_{r \, (\text{mod } p)} \chi_{\boldsymbol{\pi}}(r) \, e^{2\pi i r/p} = \sum_{r=1}^{p-1} \left(\frac{r}{\boldsymbol{\pi}}\right)_3 \, e^{2\pi i r/p}. \tag{I.23}$$

Also we here should recall our definition of the canonical cubic root $\widetilde{\pi}$ of π :

$$\widetilde{\pi} = \gamma(S)^{-1} \prod_{\nu \in S} \varphi(\nu/\pi) \text{ where } \gamma(S)^3 = 1 \text{ and } \gamma(S) \equiv -\prod_{\nu \in S} \nu \pmod{\pi},$$

where S is an arbitrary third set of modulus $(\boldsymbol{\pi})$; $(\mathcal{O}/(\boldsymbol{\pi}))^{\times} = S \cup \rho S \cup \overline{\rho} S$.

Lemma I.6. (G_3 -formula)

$$G_3(\boldsymbol{\pi}) = -\chi_{\boldsymbol{\pi}}(3) \,\widetilde{\boldsymbol{\pi}}^2 \,\overline{\boldsymbol{\pi}}.\tag{I.24}$$

Proof. This is only a slight modification of the celebrated Cassels-Matthews formula. They use the lattice $\theta \mathcal{O}$ instead of our $\varpi_1 \mathcal{O}$, where $\theta = \sqrt{3} \varpi_1 = 3.05990807 \cdots$. Let $\wp_1(u)$ denote Weierstrass' \wp with the period lattice $\theta \mathcal{O}$. Hence the relation $\wp(\varpi_1 u) = 3 \wp_1(\theta u)$ holds, so that $\wp'_1(u)^2 = 4 \wp_1(u)^3 - 1$. Their formula states

Formula (Cassel-Matthews, [M1], Th.1)

$$G_3(\pi) = -\gamma(S)^{-1} \,\pi \, p^{1/3} \,\prod_{\nu \in S} \wp_1(\theta \,\nu/\pi).$$
(I.25)

We shall show the formula (I.24) from (I.25). Indeed it will be seen they are equivalent. First, by using the following two identities : the latter being the $\sqrt{-3}$ multiplication,

$$\varphi(u) = \frac{6\,\wp_1(\theta\,u)}{\sqrt{3}(\wp_1'(\theta\,u) + \sqrt{3})} \quad and \quad \wp_1(\sqrt{-3}\,u) = -\frac{\wp_1'(u)^2 - 3}{12\,\wp_1(u)^2},$$

we have

$$\varphi(u)^{-1}\varphi(-u)^{-1} = \wp_1(\sqrt{-3}\,\theta\,u).$$

Next, substitute $u = \nu/\pi$ and make the product over $\nu \in S$, then we have

$$\prod_{\nu \in S} \varphi(\nu/\pi)^{-1} \cdot \prod_{\nu \in -S} \varphi(\nu/\pi)^{-1} = \prod_{\nu \in \sqrt{-3}S} \wp_1(\theta \, \nu/\pi).$$

Finally, multiply the factor $\gamma(S)^{-1}$ to the both sides and notice such properties as below, then we can see that Cassels-Matthews' formula easily turns to our formula (I.24).

In fact, on the one hand $\gamma(S)^{-1} = \gamma(S)^2 = \gamma(S) \cdot \gamma(-S)$, and on the other hand $\gamma(S)^{-1} = \chi_{\pi}(\sqrt{-3}) \gamma(\sqrt{-3}S)^{-1} = \overline{\chi}_{\pi}(3) \gamma(\sqrt{-3}S)^{-1}$.

Remark. As is immediately observed by G_3 -formula, $G_3(\pi)^3 = -\pi^2 \overline{\pi}$ holds.

5.2. We are now ready to give the value of the root number $C(\tilde{\chi}_{\pi})$ explicitly.

Theorem I.3. Let $\tilde{\chi}_{\pi}$ be the Hecke character for π . Then

$$C(\widetilde{\chi}_{\pi}) = \begin{cases} \chi_{\pi}(3) \, \widetilde{\pi}^{-1} \overline{\widetilde{\pi}} & \text{if } p = \pi \, \overline{\pi} \equiv 7 \pmod{18}, \\ \overline{\chi}_{\pi}(3) \, \widetilde{\pi}^{-1} \overline{\widetilde{\pi}} & \text{if } p = \pi \, \overline{\pi} \equiv 13 \pmod{18}, \\ -\chi_{\pi}(3) \, \widetilde{\pi}^{-1} \overline{\widetilde{\pi}} & \text{if } p = \pi \, \overline{\pi} \equiv 1 \pmod{18}. \end{cases}$$
(I.26)

Proof. As a preparation we shall evaluate some simple Gauss sums. The first three are easily verified by direct calculation :

$$g(\chi_0) \doteq \sum_{\varepsilon \in W} \varepsilon \, e^{2\pi i S(\varepsilon/3)} = -3\overline{\rho}, \quad g(\overline{\chi}_0) \doteq \sum_{\varepsilon \in W} \overline{\varepsilon} \, e^{2\pi i S(\varepsilon/3)} = 3\,\rho$$

and
$$g(\chi_0') \doteq \sum_{\delta = \pm 1} \delta \, e^{2\pi i S(\delta/\sqrt{-3})} = \sqrt{-3}.$$
 (I.27)

The next sum is nothing but the cubic Gauss sum :

$$g(\chi_{\boldsymbol{\pi}}) \doteq \sum_{\kappa \pmod{\boldsymbol{\pi}}} \chi_{\boldsymbol{\pi}}(\kappa) e^{2\pi i S(\kappa/\boldsymbol{\pi})} = -\overline{\chi}_{\boldsymbol{\pi}}(\rho) \,\widetilde{\boldsymbol{\pi}}^2 \,\overline{\widetilde{\boldsymbol{\pi}}}.$$
 (I.28)

In fact, we first replace the sum over $\kappa \pmod{\pi}$ by one over $r \pmod{p}$, and then, by using $S(r \overline{\pi}/p) = ar/p$ where $\pi = a + b\rho$ $(a, b \in \mathbb{Z})$, we can calculate as follows :

$$g(\chi_{\boldsymbol{\pi}}) = \sum_{r \pmod{p}} \chi_{\boldsymbol{\pi}}(r) \, e^{2\pi i S(r \, \overline{\boldsymbol{\pi}}/p)} = \sum_{r \pmod{p}} \chi_{\boldsymbol{\pi}}(r) \, e^{2\pi i ar/p} = \overline{\chi}_{\boldsymbol{\pi}}(a) \, G_3(\boldsymbol{\pi}).$$

Further, since we know $\overline{\chi}_{\pi}(a) = \chi_{\pi}(1-\rho)$ (cf. [IR] Chap. 9, Exerc. 24, 26.), it follows $\overline{\chi}_{\pi}(a) = \overline{\chi}_{\pi}(\rho) \overline{\chi}_{\pi}(3)$. Finally, by applying G_3 -formula, we can obtain (I.28).

We now follow the formula (I.9) of the root number in Lemma I.2, and we treat the three cases separately as in 4.1, especially in view of (I.19), (I.20) and (I.21).

(a) The case $p = \pi \overline{\pi} \equiv 7 \pmod{18}$.

Since $\beta = 3\pi$, $\lambda \equiv 3\kappa + \pi \varepsilon \pmod{\beta}$ and $\chi_1(\lambda) = \chi_{\pi}(3) \chi_{\pi}(\kappa) \overline{\varepsilon}$, we have

$$C(\widetilde{\chi}_{\boldsymbol{\pi}}) = -\rho \,\beta^{-1} \sum_{\lambda \pmod{\beta}} \chi_1(\lambda) \, e^{2\pi i \, S(\lambda/\beta)}$$
$$= -\rho \, (\boldsymbol{\pi} \cdot 3)^{-1} \chi_{\boldsymbol{\pi}}(3) \, g(\overline{\chi}_0) \, g(\chi_{\boldsymbol{\pi}}) = \chi_{\boldsymbol{\pi}}(3) \, \widetilde{\boldsymbol{\pi}}^{-1} \overline{\widetilde{\boldsymbol{\pi}}}.$$

(b) The case $p = \pi \overline{\pi} \equiv 13 \pmod{18}$.

Since $\beta = \sqrt{-3} \pi$, $\lambda \equiv \sqrt{-3} \kappa + \pi \delta \pmod{\beta}$ and $\chi_1(\lambda) = \overline{\chi}_{\pi}(3) \chi_{\pi}(\kappa) \delta$, we have

$$C(\widetilde{\chi}_{\pi}) = -\rho \left(\sqrt{-3} \,\pi\right)^{-1} \cdot \chi_{\pi}(\sqrt{-3}) \cdot g(\chi'_{0}) \,g(\chi_{\pi}) = \overline{\chi}_{\pi}(3) \,\widetilde{\pi}^{-1} \overline{\widetilde{\pi}}.$$

(c) The case $p = \pi \overline{\pi} \equiv 1 \pmod{18}$.

Since $\beta = 3\pi$, $\lambda \equiv 3\kappa + \pi \varepsilon \pmod{\beta}$ and $\chi_1(\lambda) = \chi_{\pi}(3) \chi_{\pi}(\kappa) \varepsilon$, we have

$$C(\widetilde{\chi}_{\boldsymbol{\pi}}) = -\rho \left(\boldsymbol{\pi} \cdot \boldsymbol{3}\right)^{-1} \cdot \chi_{\boldsymbol{\pi}}(\boldsymbol{3}) \cdot g(\chi_0) g(\chi_{\boldsymbol{\pi}}) = -\chi_{\boldsymbol{\pi}}(\boldsymbol{3}) \, \widetilde{\boldsymbol{\pi}}^{-1} \, \overline{\widetilde{\boldsymbol{\pi}}}.$$

These complete the proof of Theorem I.3.

I.6. Rationality of the elliptic Gauss sum coefficient

6.1. In Theorem I.1 we have seen that each coefficient α_{π} is an algebraic integer in \mathcal{O} . Now we can mention about their **Q**-rationality. More precisely, the coefficient itself is not always rational, but it will be seen that the essential factor of this is certainly a rational integer. The next is our main theorem of the part **I**.

Theorem I.4. For a primary prime π in \mathcal{O} there exists a rational integer a_{π} , and the coefficient α_{π} of the elliptic Gauss sum is expressed by a_{π} as follows.

$$\alpha_{\pi} = \begin{cases} \chi_{\pi}(3) a_{\pi} & and & a_{\pi} \equiv 1 \pmod{3} & if \quad p = \pi \,\overline{\pi} \equiv 7 \pmod{18}, \\ \overline{\chi}_{\pi}(3) a_{\pi} & and & a_{\pi} \equiv -1 \pmod{3} & if \quad p = \pi \,\overline{\pi} \equiv 13 \pmod{18}, \\ \chi_{\pi}(3) a_{\pi} \sqrt{-3} & if \quad p = \pi \,\overline{\pi} \equiv 1 \pmod{18}. \end{cases}$$
(I.29)

Proof. By the theorems I.1, I.2 and I.3 we know already both the explicit values of $L(1, \tilde{\chi}_{\pi})$ and $C(\tilde{\chi}_{\pi})$. To prove Theorem I.4, we have only to substitute them for the both sides of the central value equation (I.8) of Lemma I.2. There are three cases :

(a) The case $p = \pi \overline{\pi} \equiv 7 \pmod{18}$. In this case we have

$$\varpi_1^{-1} L(1, \widetilde{\chi}_{\pi}) = -\chi_{\pi}(3) \widetilde{\pi}^{-1} \alpha_{\pi} \text{ and } C(\widetilde{\chi}_{\pi}) = \chi_{\pi}(3) \widetilde{\pi}^{-1} \overline{\widetilde{\pi}}.$$

Hence from the central value equation $L(1, \tilde{\chi}_{\pi}) = C(\tilde{\chi}_{\pi}) \overline{L(1, \tilde{\chi}_{\pi})}$, we can deduce

$$-\chi_{\boldsymbol{\pi}}(3)\,\widetilde{\boldsymbol{\pi}}^{-1}\,\alpha_{\boldsymbol{\pi}} = \chi_{\boldsymbol{\pi}}(3)\,\widetilde{\boldsymbol{\pi}}^{-1}\,\overline{\widetilde{\boldsymbol{\pi}}}\cdot(-1)\,\overline{\chi}_{\boldsymbol{\pi}}(3)\,\overline{\widetilde{\boldsymbol{\pi}}}^{-1}\,\overline{\alpha_{\boldsymbol{\pi}}}\quad \therefore\quad \alpha_{\boldsymbol{\pi}} = \overline{\chi}_{\boldsymbol{\pi}}(3)\,\overline{\alpha_{\boldsymbol{\pi}}}.$$

This means $\overline{\chi}_{\pi}(3) \alpha_{\pi} = \chi_{\pi}(3) \overline{\alpha_{\pi}} \in \mathcal{O} \cap \mathbf{R}$, which we may denote by a_{π} , so that

$$\alpha_{\boldsymbol{\pi}} = \chi_{\boldsymbol{\pi}}(3) a_{\boldsymbol{\pi}}$$
 where $a_{\boldsymbol{\pi}} \in \mathbf{Z}$ and $a_{\boldsymbol{\pi}} \equiv 1 \pmod{3}$.

The last congruence follows from Theorem I.1.

(b) The case $p = \pi \overline{\pi} \equiv 13 \pmod{18}$. Since we have

$$\overline{\omega}_1^{-1} L(1, \widetilde{\chi}_{\pi}) = -\overline{\chi}_{\pi}(3) \, \widetilde{\pi}^{-1} \, \alpha_{\pi} \quad \text{and} \quad C(\widetilde{\chi}_{\pi}) = \overline{\chi}_{\pi}(3) \, \widetilde{\pi}^{-1} \, \overline{\widetilde{\pi}},$$

we can deduce quite similarly to the above

$$\alpha_{\pi} = \overline{\chi}_{\pi}(3) a_{\pi}$$
 where $a_{\pi} \in \mathbb{Z}$ and $a_{\pi} \equiv -1 \pmod{3}$.

(c) The case $p = \pi \overline{\pi} \equiv 1 \pmod{18}$. We know in this case

$$\varpi_1^{-1} L(1, \widetilde{\chi}_{\pi}) = \chi_{\pi}(3) \widetilde{\pi}^{-1} \alpha_{\pi} \text{ and } C(\widetilde{\chi}_{\pi}) = -\chi_{\pi}(3) \widetilde{\pi}^{-1} \overline{\widetilde{\pi}},$$

so that we have $\overline{\chi}_{\pi}(3) \alpha_{\pi} = -\chi_{\pi}(3) \overline{\alpha_{\pi}}$, which means

$$\alpha_{\pi} = \chi_{\pi}(3) a_{\pi} \sqrt{-3}$$
 with some $a_{\pi} \in \mathbb{Z}$.

Thus the proof is completed.

Example 4. We follow Example 3, where we evaluated the coefficient of the elliptic Gauss sum $\mathcal{G}_{\pi}(\chi_{\pi}, \varphi^{-1})$: $\alpha_{\pi} = -\overline{\rho}$ in the case $\pi = 4 + 3\rho$, p = 13. Since we find $\chi_{\pi}(3) = \rho$ in this case, we can represent this as $\alpha_{\pi} = -\overline{\rho} = \overline{\chi}_{\pi}(3) \cdot (-1)$, thus we get $a_{\pi} = -1$, which satisfies obviously the expected congruence $a_{\pi} \equiv -1 \pmod{3}$. Other examples by computor are given in the table in Appendix I.1.

Remark. By tracing the process of the proof we can observe a remarkable fact. Under the theorems I.1, I.2 and I.3, the assertions of Theorem I.4 and Lemma I.6 (G_3 -formula) are equivalent to each other. Therefore if the rationality of the elliptic Gauss sum coefficient could be independently proved beforehand, we can get Cassels-Matthews' formula as a corollary. It might be a natural proof of G_3 -formula.

6.2. The substance of Theorem I.4 can be stated by the language of Hecke *L*-values. The following may be simply regarded as a precise form of Damerell's general result in a very special case. At the same time, however, it shows that there is a direct relation between the values $L(1, \tilde{\chi}_{\pi})$ and $G_3(\pi)$, especially between their arguments.

Theorem I.5. Let a_{π} be a rational integer as given in Theorem I.4.

$$\varpi_1^{-1} L(1, \, \widetilde{\chi}_{\pi}) = \begin{cases} p^{1/3} \, G_3(\pi)^{-1} \, a_{\pi} & \text{if} \quad p = \pi \, \overline{\pi} \equiv 7 \text{ or } 13 \pmod{18}, \\ -p^{1/3} \, \sqrt{-3} \, G_3(\pi)^{-1} \, a_{\pi} & \text{if} \quad p = \pi \, \overline{\pi} \equiv 1 \pmod{18}. \end{cases}$$
(I.30)

Proof. Combining Theorems I.1–I.4 and G_3 -formula, it can be easily verified.

Corollary I.1. $L(1, \tilde{\chi}_{\pi}) \neq 0$ if $p = \pi \overline{\pi} \equiv 7 \text{ or } 13 \pmod{18}$.

Proof. Because $a_{\pi} \equiv \pm 1 \pmod{3}$ in these cases.

Remark. On the other hand, we can observe that $L(1, \tilde{\chi}_{\pi})$ happens often to vanish in the case $p = \pi \overline{\pi} \equiv 1 \pmod{18}$. For examples it is the case for each prime as follows :

 $p = 73, 271, 307, 523, 577, 919, 1531, 1549, 1783, 2179, 2287, 2971, 3079, 3529, \ldots$, while any reason or any rule is not known yet.

For convenience' and interest's sake, we append a table and a brief list of formulas.

Appendix I.1.

A small table of the coefficients of elliptic Gauss sums is given. In the table, the coefficient α_{π} is expressed as $\alpha_{\pi} = a_{\pi} \cdot \chi_{\pi}(3), a_{\pi} \cdot \overline{\chi}_{\pi}(3), a_{\pi} \cdot \chi_{\pi}(3) \cdot \sqrt{-3}$, for the case $p \equiv 7 \pmod{18}, p \equiv 13 \pmod{18}, p \equiv 1 \pmod{18}$, respectively. We can observe that the size of a_{π} is remarkably small. The computation was made by UBASIC.

Appendix I.2.

Addition and multiplication formulas of the functions $\varphi(u)$ and $\psi(u)$ are selected. Proofs are omitted, while a brief comment on the general complex multiplication formula is given. Those formulas listed without proof might be less familiar in comparison with the lemniscatic function case. It, however, is not difficult to obtain them. For example, we first deduce the expressions of $\wp(\varpi_1 u)$ and $\wp'(\varpi_1 u)$ in $\varphi(u), \psi(u)$ from (I.5), and substitute them into an ordinary addition formula of \wp , \wp' , e.g. the determinant formula, to derive the addition formula of φ , ψ , and so forth. For a general survey, one may refer to the book [L]. While the lemniscatic case is mainly treated there, the cubic case proceeds quite analogously.

Appendix I.2. Formulas of special elliptic functions (cf. §I.1)

Addition Formula

$$\varphi(u+v) = \frac{\varphi(u)^2 \,\psi(v) - \varphi(v)^2 \,\psi(u)}{\varphi(u) \,\psi(v)^2 - \varphi(v) \,\psi(u)^2} = \frac{\varphi(v) + \varphi(u) \,\psi(u) \,\psi(v)^2}{\psi(u) + \varphi(u)^2 \,\varphi(v) \,\psi(v)} \tag{1}$$

$$\psi(u+v) = \frac{\varphi(u)\,\psi(u) - \varphi(v)\,\psi(v)}{\varphi(u)\,\psi(v)^2 - \varphi(v)\,\psi(u)^2} = \frac{\psi(u)^2\,\psi(v) - \varphi(u)\,\varphi(v)^2}{\psi(u) + \varphi(u)^2\,\varphi(v)\,\psi(v)} \tag{2}$$

$$\varphi(u-v) = \frac{\varphi(u)^2 \psi(v) - \varphi(v)^2 \psi(u)}{\varphi(u) + \varphi(v) \psi(v) \psi(u)^2} = \frac{\varphi(u) \psi(u) - \varphi(v) \psi(v)}{\psi(u) \psi(v)^2 - \varphi(u)^2 \varphi(v)}$$
(3)

$$\psi(u-v) = \frac{\psi(u)^2 \,\psi(v) - \varphi(u) \,\varphi(v)^2}{\psi(u) \,\psi(v)^2 - \varphi(u)^2 \,\varphi(v)} = \frac{\varphi(v) + \varphi(u) \,\psi(u) \,\psi(v)^2}{\varphi(u) + \varphi(v) \,\psi(v) \,\psi(u)^2} \tag{4}$$

Multiplication Formula

$$\varphi(\rho u) = \rho \varphi(u), \quad \psi(\rho u) = \psi(u), \quad \mathsf{Z}(\rho u) = \overline{\rho} \mathsf{Z}(u) \tag{5}$$

$$\varphi(-u) = -\varphi(u)\,\psi(u)^{-1}, \quad \psi(-u) = \psi(u)^{-1}, \quad \mathsf{Z}(-u) = -\mathsf{Z}(u) \tag{6}$$

$$\varphi(-2u) = \varphi(u) \cdot \frac{\varphi(u) - 2}{1 - 2\varphi(u)^3}, \quad \psi(-2u) = \psi(u) \cdot \frac{\psi(u) - 2}{1 - 2\psi(u)^3}$$
(7)

$$\varphi(\sqrt{-3}\,u) = \frac{\sqrt{-3}\,\varphi(u)\psi(u)}{1+\overline{\rho}\,\varphi(u)^3}, \quad \psi(\sqrt{-3}\,u) = \frac{\rho+\psi(u)^3}{1+\rho\,\psi(u)^3} \tag{8}$$

$$\mathsf{Z}((1-\rho)\,u) = (1-\overline{\rho})\,\mathsf{Z}(u) + (1-\overline{\rho})\big\{\varphi(u)^{-1} - \varphi(-u)^{-1}\big\}$$
(9)

Primary Prime Multiplication : $p = \pi \overline{\pi}, \pi \equiv 1 \pmod{3}$

$$\varphi(\boldsymbol{\pi}\,\boldsymbol{u}) = \varphi(\boldsymbol{u}) \prod_{\nu \,(\text{mod}\,\boldsymbol{\pi})}' \varphi(\boldsymbol{u} + \nu/\boldsymbol{\pi}), \quad \psi(\boldsymbol{\pi}\,\boldsymbol{u}) = \psi(\boldsymbol{u}) \prod_{\nu \,(\text{mod}\,\boldsymbol{\pi})}' \psi(\boldsymbol{u} + \nu/\boldsymbol{\pi}) \tag{10}$$

$$\varphi(\boldsymbol{\pi}\,\boldsymbol{u}) = \varphi(\boldsymbol{u}) \cdot \frac{U(\varphi(\boldsymbol{u}))}{R(\varphi(\boldsymbol{u}))}, \quad \psi(\boldsymbol{\pi}\,\boldsymbol{u}) = \psi(\boldsymbol{u}) \cdot \frac{U(\psi(\boldsymbol{u}))}{R(\psi(\boldsymbol{u}))} \tag{11}$$

$$U(x) = \prod_{\nu \pmod{\pi}} (x - \varphi(\nu/\pi)), \quad R(x) = x^{p-1} U(x^{-1})$$
(12)

$$U(x) \in \mathcal{O}[x], \quad U(x) \equiv x^{p-1} \pmod{\pi}, \quad U(0) = \pi$$
 (13)

Proof of (10), (11): By comparing the divisors we have (10). By using the first form of (1),

$$\prod_{\varepsilon \in W'} \varphi(u + \varepsilon v) = \frac{\psi(v)^3 \left(\varphi(u)^3 - \varphi(-v)^3\right)}{1 - \varphi(u)^3 \varphi(v)^3}, \quad \prod_{\varepsilon \in W'} \varphi(u - \varepsilon v) = \frac{\varphi(u)^3 - \varphi(v)^3}{\psi(v)^3 \left(1 - \varphi(u)^3 \varphi(-v)^3\right)}.$$

$$\therefore \quad \prod_{\varepsilon \in W} \varphi(u + \varepsilon v) = \frac{\left(\varphi(u)^3 - \varphi(-v)^3\right) \left(\varphi(u)^3 - \varphi(v)^3\right)}{\left(1 - \varphi(u)^3 \varphi(v)^3\right) \left(1 - \varphi(u)^3 \varphi(-v)^3\right)} = \prod_{\varepsilon \in W} \frac{\varphi(u) - \varphi(\varepsilon v)}{1 - \varphi(u) \varphi(\varepsilon v)}.$$

This combined with (10) leads to (11) as follows there U is an arbitrary 1 ast mod $-$

This combined with (10) leads to (11) as follows; here U is an arbitrary $\frac{1}{6}$ -set mod π .

$$\frac{\varphi(\pi u)}{\varphi(u)} = \prod_{\nu \in U} \prod_{\varepsilon \in W} \varphi(u + \varepsilon \nu/\pi) = \prod_{\nu \in U} \prod_{\varepsilon \in W} \frac{\varphi(u) - \varphi(\varepsilon \nu/\pi)}{1 - \varphi(\varepsilon \nu/\pi) \varphi(u)} = \prod_{\nu \pmod{\pi}} \frac{\varphi(u) - \varphi(\nu/\pi)}{1 - \varphi(\nu/\pi) \varphi(u)}.$$

II. The Quartic Character Case

Throughout the part II, the field $\mathbf{Q}(i)$ and the ring $\mathbf{Z}[i]$ are abbreviated to F and \mathcal{O} , respectively. The unit group is denoted by $W = \{\pm 1, \pm i\}$. The set \mathcal{O} or its constant multiple appears also as a period lattice for elliptic functions. Though we don't treat the octic case, we shall come on a scene to need the eighth root of unity $\zeta_8 = e^{2\pi i/8}$ and so it is not strange to meet $\sqrt{2} = (1-i) \zeta_8$ or $i\sqrt{2} = (1+i) \zeta_8$ in some formulas.

II.1. Special elliptic functions with complex multiplication

1.1. We shall define some special functions which play the leading role in our argument. Let $\wp(u)$ denote the Weierstrass function respect to the period lattice $\varpi \mathcal{O}$ so that $\wp'(u)^2 = 4\wp(u)^3 - 4\wp(u)$; the real period ϖ is given by

$$\varpi \doteq 2 \int_0^1 \frac{dx}{\sqrt{1 - x^4}} = 2.62205755 \cdots$$

It is obvious $\wp(\varpi u)$ and $\wp'(\varpi u)$ are elliptic functions of periods \mathcal{O} . Further, we can get another doubly periodic function by a slight modification of Weierstrass' ζ of $\varpi \mathcal{O}$: **Definition.** The non-analytic but doubly periodic function Z(u) is defined by

$$\mathsf{Z}(u) \doteq \zeta(\varpi u) - \frac{\pi}{\varpi} \overline{u},\tag{II.1}$$

Double periodicity of Z relative to \mathcal{O} is easily verified by a usual formula of ζ . The addition formula of Z, that follows immediately from one of ζ , is useful :

$$\mathsf{Z}(u+v) = \mathsf{Z}(u) + \mathsf{Z}(v) + \frac{1}{2} \frac{\wp'(\varpi u) - \wp'(\varpi v)}{\wp(\varpi u) - \wp(\varpi v)}.$$

In particular, such a function $\sum_{k=1}^{r} c_k Z(u + \gamma_k)$ is an elliptic function if $\sum_{k=1}^{r} c_k = 0$.

The following two functions are specially important, really which are nothing but the old lemniscatic sine and cosine functions of Gauss.

Definition. The elliptic functions $\varphi(u)$ and $\psi(u)$ to the period \mathcal{O} are defined by

$$\varphi(u) \doteq -\frac{1-i}{2} \left\{ \mathsf{Z}\left(u-\frac{1}{2}\right) - \mathsf{Z}\left(u-\frac{i}{2}\right) \right\},\tag{II.2}$$

$$\psi(u) \doteq -\frac{1-i}{2} \left\{ \mathsf{Z}\left(u - \frac{1-i}{4}\right) - \mathsf{Z}\left(u + \frac{1-i}{4}\right) \right\}.$$
(II.3)

From the addition formula of Z(u) we can easily derive the other expressions :

$$\varphi(u) = -2(1-i) \cdot \frac{\wp(\varpi u)}{\wp'(\varpi u)}, \quad \psi(u) = \frac{\wp(\varpi u) + i}{\wp(\varpi u) - i}.$$
 (II.4)

We need also the following formula.

$$\varphi(u)^{-1} = \frac{1+i}{2} \left\{ \mathsf{Z}(u) - \mathsf{Z}\left(u - \frac{1+i}{2}\right) \right\}.$$
 (II.5)

Here are some basic properties of these functions, which are all classical or easily deduced from the definitions and by usual theory of elliptic functions.

$$\begin{aligned} \operatorname{div}(\varphi) &= (0) + ((1+i)/2) - (1/2) - (i/2), \\ \operatorname{div}(\psi) &= ((1+i)/4) + (-(1+i)/4) - ((1-i)/4) - (-(1-i)/4), \\ \mathsf{Z}(iu) &= -i \operatorname{\mathsf{Z}}(u), \quad \varphi(iu) &= i \varphi(u), \quad \psi(iu) &= \psi(u)^{-1}, \\ \psi(u) &= \varphi(u + (1+i)/4), \quad \varphi(u)^{-1} &= -i \varphi(u + 1/2), \\ \varphi'(u) &= (1-i) \varpi \, \psi(u) \, (1 + \varphi(u)^2), \quad \psi'(u) &= -(1-i) \varpi \, \varphi(u) \, (1 + \psi(u)^2), \\ \varphi(u)^2 \psi(u)^2 + \varphi(u)^2 + \psi(u)^2 &= 1. \end{aligned}$$

In particular $(((1-i)\varpi)^{-1}\varphi'(u))^2 = 1 - \varphi(u)^4$ holds, and so we can ascertain that $\varphi(u) = \operatorname{sl}((1-i)\varpi u)$ and $\psi(u) = \operatorname{cl}((1-i)\varpi u)$ by Gauss' lemniscatic sine and cosine.

We can refer to the survey monograph [L] by F. Lemmermeyer for further general facts and some background of these elliptic functions.

1.2. Let $\boldsymbol{\pi}$ be a complex prime in \mathcal{O} so that $p = \boldsymbol{\pi} \overline{\boldsymbol{\pi}} \equiv 1 \pmod{4}$, and we assume also $\boldsymbol{\pi}$ is primary : $\boldsymbol{\pi} \equiv 1 \pmod{(1+i)^3}$. Then we have $(\mathcal{O}/(\boldsymbol{\pi}))^{\times} \cong (\mathbf{Z}/p\mathbf{Z})^{\times}$. We often abbreviate like as $\nu \pmod{\boldsymbol{\pi}}$ in such a case when ν runs over $(\mathcal{O}/(\boldsymbol{\pi}))^{\times}$.

It is well known that such a division value $\varphi(1/\pi)$ or $\psi(1/\pi)$ generates an abelian extension of the imaginary quadratic field $F = \mathbf{Q}(i)$. In fact,

Lemma II.1. Let $L = F(\varphi(1/\pi))$ and $L_1 = F(\psi(1/\pi))$. One has

- (i) L/F is a cyclic extension of degree p-1, and L_1 is a subfield of $[L:L_1] = 2$.
- (ii) Gal $(L/F) \cong (\mathcal{O}/(\pi))^{\times}$ by corresponding σ_{μ} to μ , and it holds $\varphi(\nu/\pi)^{\sigma_{\mu}} = \varphi(\mu\nu/\pi)$, $\psi(\nu/\pi)^{\sigma_{\mu}} = \psi(\mu\nu/\pi)$ for arbitrary $\mu, \nu \in (\mathcal{O}/(\pi))^{\times}$.
- (iii) $\varphi(1/\pi)$, $\psi(1/\pi)$ are algebraic integers, and particularly $\psi(1/\pi)$ is a unit.
- (iv) The prime ideal (π) splits completely in L: (π) = \mathfrak{P}^{p-1} where $\mathfrak{P} = (\varphi(1/\pi))$.

L and L_1 are called the ray class fields of the conductors $((1+i)^3\pi)$ and $((1+i)^2\pi)$, respectively. The proof is omitted, but it may be found mostly in [L]. We only give some numerical examples in the end of this section.

The following is a minor property of division values and perhaps classically known, but it is important for us and hence we state it as a lemma with a brief proof :

Lemma II.2. For arbitrary $\mu, \nu \in (\mathcal{O}/(\pi))^{\times}$,

$$\varphi(\mu/\pi)\,\varphi(\nu/\pi) \equiv 1 \pmod{(1+i)}.\tag{II.6}$$

Proof. Recall the (1+i)-multiplication formula of $\varphi(u) : \varphi((1+i)u) = (1+i)\varphi(u)\psi(u) \cdot (1-\varphi(u)^2)^{-1}$. Substituting $u = \nu/\pi$ and cancelling by \mathfrak{P} , we obtain an ideal equality $(1-\varphi(\nu/\pi)^2) = (1+i)$, which implies (II.6) of the case $\mu = \nu$. For the other case, it suffices to show the following.

$$\varphi(\mu/\pi) \equiv \varphi(\nu/\pi) \pmod{(1+i)}$$

To prove this, we may assume $\nu = 1$. Let λ be a primary prime such that $\lambda \equiv \mu \pmod{\pi}$. Then the complex multiplication formula (cf. Example 1) says : $\varphi(\lambda u) = \varphi(u) U(\varphi(u)) R(\varphi(u))^{-1}$, where U(x), R(x) are the polynomials of x^4 reciprocal to each other over $\mathbf{Z}[i]$, so that U(1) = R(1). Combining this with the fact $\varphi(1/\pi)^2 \equiv 1 \pmod{(1+i)}$ by (II.6), we can deduce $\varphi(\lambda/\pi) \equiv \varphi(1/\pi) \pmod{(1+i)}$.

As for the division value $Z(1/\pi)$, we have

Lemma II.3. The value $Z(1/\pi)$ generates the same extension L. Namely,

$$L = F(\varphi(1/\pi)) = F(\mathsf{Z}(1/\pi)) \quad and \quad \mathsf{Z}(\nu/\pi)^{\sigma_{\mu}} = \mathsf{Z}(\mu\nu/\pi) \quad (\mu, \nu \in (\mathcal{O}/(\pi))^{\times}).$$

Proof. The following is obtained by substituting v = iu in the addition formula of Z.

$$Z((1+i)u) = (1-i) Z(u) + i \varphi(u)^{-1}.$$
 (II.7)

Using formula (II.7) repeatedly and in view of $(1+i)^{p-1} \equiv 1 \pmod{\pi}$, we have

$$(1 - (-4)^{(p-1)/4}) \operatorname{Z}(\nu/\pi) = i \sum_{k=1}^{p-1} (1-i)^{p-1-k} \varphi((1+i)^{k-1}\nu/\pi)^{-1}.$$

Now it is easy to see the assertion of Lemma II.3.

Example 5. In each case tabulated below, we have the π -multiplication formula :

$$\begin{split} \varphi(\boldsymbol{\pi} \, u) &= \varphi(u) \cdot \frac{U(\varphi(u))}{R(\varphi(u))}, \quad R(x) = x^{p-1} \, U(x^{-1}), \\ U(x) &= \prod_{\nu \pmod{\boldsymbol{\pi}}}' (x - \varphi(\nu/\boldsymbol{\pi})), \quad V(x)^2 = \prod_{\nu \pmod{\boldsymbol{\pi}}}' (x - \psi(\nu/\boldsymbol{\pi})), \\ where \qquad x \, U(x) - R(x) = (x - 1) \, V(x)^2. \end{split}$$

Furthermore it is easy to check

$$U(x), V(x) \in \mathcal{O}[x], \quad U(x) \equiv x^{p-1} \pmod{(\pi)}, \quad U(0) = \pi, \quad V(0) = 1.$$

In fact, U(x) and V(x) are the minimal polynomials of $\varphi(1/\pi)$ and $\psi(1/\pi)$, respectively.

| p | π | U(x) |
|------------------|----------------------------|---|
| 5 | -1 + 2i | $x^4 + \pi$ |
| 13 | 3+2i | $x^{12} - (1 - 4i) \pi x^8 + (1 - 2i) \pi x^4 + \pi$ |
| 17 | 1+4i | $x^{16} - (4+4i) \pi x^{12} + (6+4i) \pi x^8 - (4-4i) \pi x^4 + \pi$ |
| n | _ | V(m) |
| p | П | V(x) |
| $\frac{p}{5}$ | $\frac{\pi}{-1+2i}$ | $\frac{V(x)}{x^2 + (1-i)x + 1}$ |
| $\frac{p}{5}$ 13 | $\frac{\pi}{-1+2i}$ $3+2i$ | $\frac{v(x)}{x^{2} + (1 - i)x + 1}$ $x^{6} - (1 + i)x^{5} - (1 + 2i)x^{4} - 4ix^{3} - (1 + 2i)x^{2} - (1 + i)x + 1$ |

II.2. *L*-series for Hecke characters of weight one

2.1. Let $\tilde{\chi}$ denote a Hecke character of weight 1 relative to the modulus $(\beta) \subset \mathcal{O}$, namely it is a multiplicative function on the ideal group of \mathcal{O} of the following form :

$$\widetilde{\chi}((\nu)) = \chi_1(\nu)\overline{\nu}, \quad \chi_1 : (\mathcal{O}/(\beta))^{\times} \to \mathbf{C}^{\times}, \quad \chi_1(\varepsilon) = \varepsilon \quad (\varepsilon \in W),$$

where χ_1 is an ordinary residue class character to the modulus (β), and (β) is called the coductor of $\tilde{\chi}$ if χ_1 is a primitive character to the modulus (β).

It is well known the associated *L*-series has the analytic continuation and satisfies a functional equation. We follow Weil's argument and his notation.

$$L(s, \ \widetilde{\chi}) = \sum_{\mathfrak{a}} \widetilde{\chi}(\mathfrak{a}) N \mathfrak{a}^{-s} = \frac{1}{4} \sum_{\nu \in \mathcal{O}} \chi_1(\nu) \overline{\nu} |\nu|^{-2s}$$
$$= \frac{1}{4} \sum_{\lambda \pmod{\beta}} \chi_1(\lambda) \sum_{\mu \in \mathcal{O}} (\overline{\lambda} + \overline{\mu}\overline{\beta}) |\lambda + \mu\beta|^{-2s}$$
$$\therefore L(s, \ \widetilde{\chi}) = \beta^{-1} |\beta|^{2-2s} \cdot \frac{1}{4} \sum_{\lambda \pmod{\beta}} \chi_1(\lambda) K_1(\lambda/\beta, \ 0, \ s)$$
(II.8)

Here the function K_1 is defined for $\operatorname{Re} s > 3/2$ as follows, and it is analytically continued to the whole s-plane and satisfies the own functional equation : (cf. [W], VIII)

$$K_1(u, u_0, s) = \sum_{\mu \in \mathcal{O}} e^{\pi (\overline{u}_0 \mu - u_0 \overline{\mu})} (\overline{u} + \overline{\mu}) |u + \mu|^{-2s},$$

$$\pi^{-s} \Gamma(s) K_1(u, u_0, s) = e^{\pi (\overline{u}_0 u - u_0 \overline{u})} \pi^{s-2} \Gamma(2 - s) K_1(u_0, u, 2 - s).$$

When (β) is the conductor of $\tilde{\chi}$, a usual computation of Gauss sum works. From this combined with the above, the functional equation of Hecke *L*-series is derived :

$$\Lambda(s, \ \widetilde{\chi}) = C(\widetilde{\chi}) \Lambda(2-s, \ \overline{\widetilde{\chi}}),$$

where $\Lambda(s, \ \widetilde{\chi}) = \left(\frac{2\pi}{\sqrt{4 \cdot N(\beta)}}\right)^{-s} \Gamma(s) L(s, \ \widetilde{\chi}),$

and
$$C(\tilde{\chi}) = -i\beta^{-1} \sum_{\lambda \pmod{\beta}} \chi_1(\lambda) e^{2\pi i \operatorname{Re}(\lambda/\beta)}$$
.

In particular, we have a simple equality of Hecke L-values at s = 1:

Lemma II.4. Let $\tilde{\chi}$ be a Hecke character of weight 1 with the conductor (β). Then

$$L(1, \ \widetilde{\chi}) = C(\widetilde{\chi}) \, \overline{L(1, \ \widetilde{\chi})}, \tag{II.9}$$

where
$$C(\widetilde{\chi}) = -i\beta^{-1} \sum_{\lambda \pmod{\beta}} \chi_1(\lambda) e^{2\pi i \operatorname{Re}(\lambda/\beta)}.$$
 (II.10)

Remark. $L(1, \overline{\widetilde{\chi}}) = \overline{L(1, \widetilde{\chi})}.$

We call (II.9) the central value equation, and the constant $C(\tilde{\chi})$ the root number.

2.2. On the other hand, we can notice that the value $L(1, \tilde{\chi})$ relates to some elliptic functions. As is remarked in [W] (VIII, §14) or in others, the following is valid.

$$E_1^*(u) \doteq K_1(u, 0, 1) = \varpi \zeta(\varpi u) - \pi \overline{u}.$$

By the definition (II.1) the right-hand side is nothing but our function $\varpi Z(u)$. Combining this with the equation (II.8) at s = 1, we obtain the following formula :

Lemma II.5. Let $\tilde{\chi}$ be a Hecke character of weight 1 with the conductor (β). Then

$$\overline{\omega}^{-1} L(1, \ \widetilde{\chi}) = \frac{1}{4\beta} \sum_{\lambda \pmod{\beta}} \chi_1(\lambda) \,\mathsf{Z}(\lambda/\beta).$$
(II.11)

Example 6. The following is probably the simplest case and the derived formula $L(1, \tilde{\chi}_0) = \frac{\overline{\omega}}{4}$ may be compared with the classical formula : $1 - \frac{1}{3} + \frac{1}{5} - \frac{1}{7} + \cdots = \frac{\pi}{4}$.

The Hecke character $\widetilde{\chi}_0$ of the conductor $(1+i)^3$ is given as follows :

$$\widetilde{\chi}_0((\nu)) \doteq \chi_0(\nu) \overline{\nu}, \text{ where } \chi_0 : (\mathcal{O}/(1+i)^3)^{\times} \cong W \text{ is the natural isomorphism}$$

Then we can evaluate the *L*-value at s = 1 directly by (II.11) :

$$\varpi^{-1} L(1, \ \widetilde{\chi}_0) = \frac{1}{4(1+i)^3} \sum_{\varepsilon \in W} \varepsilon \operatorname{Z}(-(1+i)\varepsilon/4) = \frac{1+i}{4} \operatorname{Z}((1+i)/4) = \frac{1}{4}$$

Also we can easily check $C(\widetilde{\chi}_0) = -i (1+i)^{-3} \sum_{\varepsilon \in W} \varepsilon e^{2\pi i \operatorname{Re}(-(1+i)\varepsilon/4)} = 1$ as is expected.

II.3. Elliptic Gauss sums for quartic characters

3.1. Let π be a primary prime in \mathcal{O} ; $\pi \equiv 1 \pmod{(1+i)^3}$. Let χ_{π} be the quartic residue character to the modulus (π) and the notation will be fixed throughout :

Let f(u) be a doubly periodic function of the period \mathcal{O} , which we specify below. **Definition.** The following is called an *elliptic Gauss sum*.

$$\mathcal{G}_{\boldsymbol{\pi}}(\chi_{\boldsymbol{\pi}}, f) \doteq \frac{1}{4} \sum_{\nu \pmod{\boldsymbol{\pi}}} \chi_{\boldsymbol{\pi}}(\nu) f(\nu/\boldsymbol{\pi}).$$
(II.12)

In the part II, we deal with the three types of elliptic Gauss sums $\mathcal{G}_{\pi}(\chi_{\pi}, \varphi)$, $\mathcal{G}_{\pi}(\chi_{\pi}, \mathbf{Z})$, $\mathcal{G}_{\pi}(\chi_{\pi}, \psi)$, and one more $\mathcal{G}_{\pi}(\chi_{\pi}, \varphi^{-1})$ for a supplementary use. So we understand that f(u) denotes one of these functions $\varphi(u)$, $\mathsf{Z}(u)$, $\psi(u)$, and $\varphi(u)^{-1}$ in the subsequence. In these cases, if "the parity condition" is not satisfied, $\mathcal{G}_{\pi}(\chi_{\pi}, f)$ vanishes trivially. Since $\varphi(iu) = i \varphi(u)$, $\mathsf{Z}(iu) = -i \mathsf{Z}(u)$, $\psi(-u) = \psi(u)$ and $\chi_{\pi}(i) = i^{(p-1)/4}$, we can easily check that $\mathcal{G}_{\pi}(\chi_{\pi}, f)$ is not trivial only in the following cases. The parity condition, however, is not sufficient for non-vanishing of the elliptic Gauss sum as we shall see later.

The elliptic Gauss sums that we shall consider are the following :

- (a) $\mathfrak{G}_{\boldsymbol{\pi}}(\chi_{\boldsymbol{\pi}}, \varphi)$ for the case $p = \boldsymbol{\pi} \, \overline{\boldsymbol{\pi}} \equiv 13 \pmod{16}$,
- (b) $\mathfrak{G}_{\pi}(\chi_{\pi}, \mathsf{Z}), \ \mathfrak{G}_{\pi}(\chi_{\pi}, \varphi^{-1})$ for the case $p = \pi \overline{\pi} \equiv 5 \pmod{16}$ and p > 5,
- (c) $\mathfrak{G}_{\boldsymbol{\pi}}(\chi_{\boldsymbol{\pi}}, \psi)$ for the case $p = \boldsymbol{\pi} \, \overline{\boldsymbol{\pi}} \equiv 1 \pmod{8}$.

As noted in Lemma II.1 and Lemma II.3, $\mathfrak{G}_{\pi}(\chi_{\pi}, f) \in L$ and $f(\mu\nu/\pi) = f(\nu/\pi)^{\sigma_{\mu}}$ are valid, and hence we can immediately deduce the property of Lagrange's resolvent :

$$\mathfrak{G}_{\boldsymbol{\pi}}(\chi_{\boldsymbol{\pi}}, f)^{\sigma_{\mu}} = \overline{\chi}_{\boldsymbol{\pi}}(\mu) \,\mathfrak{G}_{\boldsymbol{\pi}}(\chi_{\boldsymbol{\pi}}, f) \quad (\mu \in (\mathcal{O}/(\boldsymbol{\pi}))^{\times})$$
(II.13)

In particular, $\mathcal{G}_{\pi}(\chi_{\pi}, f)^4$ is an element of F, and furthermore we have

Lemma II.6. $\mathfrak{G}_{\pi}(\chi_{\pi}, f)^4$ is an algebraic integer in \mathcal{O} for each $f = \varphi, \varphi^{-1}$ and ψ .

Proof. We must show the algebraic integrity of $\mathfrak{G}_{\pi}(\chi_{\pi}, f)$ for each case. Let S be an arbitrary quarter subset mod (π) , namely $(\mathcal{O}/(\pi))^{\times} = S \cup -S \cup i S \cup -i S$ by definition.

(a) The case $p = \pi \overline{\pi} \equiv 13 \pmod{16}$. We have $\mathcal{G}_{\pi}(\chi_{\pi}, \varphi) = \sum_{\nu \in S} \chi_{\pi}(\nu) \varphi(\nu/\pi)$. Since $\varphi(\nu/\pi)$'s are algebraic integers, the integrity is obvious in this case.

(b) The case $p = \pi \overline{\pi} \equiv 5 \pmod{16}$, p > 5. We have $\mathcal{G}_{\pi}(\chi_{\pi}, \varphi^{-1}) = \sum_{\nu \in S} \chi_{\pi}(\nu) \varphi(\nu/\pi)^{-1}$. Since $\varphi(1/\pi) \cdot \varphi(\nu/\pi)^{-1}$ is a unit, $\mathfrak{P}^{4}(\mathcal{G}_{\pi}(\chi_{\pi}, \varphi^{-1})^{4})$ is an integral ideal, where $\mathfrak{P} = (\varphi(1/\pi))$. On the other hand, $(\pi) = \mathfrak{P}^{p-1}$ and p-1 > 4, and hence $(\mathcal{G}_{\pi}(\chi_{\pi}, \varphi^{-1})^{4})$ is already integral. We need the condition p > 5 in this case ; in fact $\mathcal{G}_{\pi}(\chi_{\pi}, \varphi^{-1})^{4} = -\pi^{-1} \notin \mathcal{O}$ in the case $\pi = -1 + 2i \quad (p = 5)$. (c) The case $p = \pi \overline{\pi} \equiv 1 \pmod{8}$.

First of all we have $\mathcal{G}_{\pi}(\chi_{\pi}, \psi) = \frac{1}{2} \sum_{\nu \in S} \chi_{\pi}(\nu) \{ \psi(\nu/\pi) + \chi_{\pi}(i) \psi(i\nu/\pi) \}$. We must show the summation of the right side is divisible by 2 = (1 - i)(1 + i). Note $\chi_{\pi}(i) = \pm 1$. By using (1 + i)-multiplication formula of $\varphi(u)$, it is easy to verify

$$\psi(u) - \psi(iu) = -(1-i)\,\varphi((1+i)\,u)\,\varphi(u), \quad \psi(u) + \psi(iu) = (1-i)\,\varphi((1+i)\,u)\,\varphi(u)^{-1}.$$

By Lemma II.2, $\varphi((1+i)\nu/\pi)\varphi(\nu/\pi) \equiv \varphi((1+i)\nu/\pi)\varphi(\nu/\pi)^{-1} \equiv 1 \pmod{(1+i)}$ holds. Thus $\sum_{\nu \in S} \chi_{\pi}(\nu) \varphi((1+i)\nu/\pi) \varphi(\nu/\pi)^{\pm 1} \equiv \sum_{\nu \in S} 1 \equiv (p-1)/4 \equiv 0 \pmod{(1+i)}$, which implies the integrity of $\mathcal{G}_{\pi}(\chi_{\pi}, \psi)$. Thus the proof of Lemma II.6 is completed.

As a matter of fact, it is also valid

Claim (Z) : $\mathfrak{G}_{\pi}(\chi_{\pi}, \mathbb{Z})^4$ is an algebraic integer in \mathcal{O} .

Although the proof is a bit indirect and will be completed after Theorem II.4, we shall often assume the claim for convenience' sake. We here only prepare the following.

Lemma II.7. One has

$$((1+i) - i \overline{\chi}_{\pi}(1+i)) \mathcal{G}_{\pi}(\chi_{\pi}, \mathsf{Z}) = \mathcal{G}_{\pi}(\chi_{\pi}, \varphi^{-1}).$$
(II.14)

Proof. This is immediately derived from the addition formula (II.7) of Z(u).

Lemma II.8. We have $\mathfrak{G}_{\pi}(\chi_{\pi}, \varphi)^4 \equiv 1 \pmod{2}$ and $\mathfrak{G}_{\pi}(\chi_{\pi}, \varphi^{-1})^4 \equiv 1 \pmod{2}$, for $p = \pi \overline{\pi} \equiv 13 \pmod{16}$ and $p = \pi \overline{\pi} \equiv 5 \pmod{16}$, respectively.

Proof. By Lemma II.2 we can deduce $\varphi(\nu/\pi)^4 \equiv 1 \pmod{(1+i)^2}$. Hence we obtain

$$\mathcal{G}_{\boldsymbol{\pi}}(\chi_{\boldsymbol{\pi}},\,\varphi)^4 \equiv \sum_{\nu \in S} \varphi(\nu/\boldsymbol{\pi})^4 \equiv (p-1)/4 \equiv 1 \pmod{2}.$$

Similarly, using $\pi \varphi(\nu/\pi)^{-4} \equiv 1 \pmod{2}$, we can prove $\mathfrak{G}_{\pi}(\chi_{\pi}, \varphi^{-1})^4 \equiv 1 \pmod{2}$.

3.2. Obviously from (II.13), the value $\mathcal{G}_{\pi}(\chi_{\pi}, f)$ belongs to the quartic extension field over F. So it is convenient to give a suitable quartic root of $-\pi$ or π for the precise investigation of the value of $\mathcal{G}_{\pi}(\chi_{\pi}, f)$. We shall even define "the canonical quartic root" of $-\pi$. Let S be an arbitrary quarter subset of $(\mathcal{O}/(\pi))^{\times}$; hence $(\mathcal{O}/(\pi))^{\times} = \bigcup_{\varepsilon \in W} \varepsilon S$. First of all, we notice the following two equations :

$$\prod_{\nu \in S} \nu^4 \equiv \chi_{\boldsymbol{\pi}}(-1) \cdot (p-1)! \equiv -\chi_{\boldsymbol{\pi}}(-1) \pmod{\boldsymbol{\pi}},$$
$$\prod_{\nu \in S} \varphi(\nu/\boldsymbol{\pi})^4 = \chi_{\boldsymbol{\pi}}(-1) \prod_{\nu \in (\mathcal{O}/(\boldsymbol{\pi}))^{\times}} \varphi(\nu/\boldsymbol{\pi}) = \chi_{\boldsymbol{\pi}}(-1)\boldsymbol{\pi}.$$

By the first equation we can define a quartic or octic root of unity according to each S as follows. In the case $p \equiv 5 \pmod{8}$, i.e. $\chi_{\pi}(-1) = -1$, we put and denote by $\gamma(S)$ the quartic root of unity determined by the property $\gamma(S) \equiv \prod_{\nu \in S} \nu \pmod{\pi}$. In the case

 $p \equiv 1 \pmod{8}$, i.e. $\chi_{\pi}(-1) = 1$, the prime π is decomposable in $\mathbb{Z}[\zeta_8]$. Let Π be a prime once chosen and fixed such that $\pi = \Pi \Pi'$ in $\mathbb{Z}[\zeta_8]$. We denote by $\gamma(S)$ the quartic root of -1 such that $\gamma(S) \equiv \prod_{\nu \in S} \nu \pmod{(\Pi)}$. Note $\gamma(S) \notin W$, but $\zeta_8 \gamma(S) \in W$ in this case. Unfortunately $\gamma(S)$ depends on either choice of (Π) , and the sign will be changed when another (Π') is chosen, that is, only $\gamma(S)^2$ is an invariant of π and S. We should also remark that $\gamma(S)^2 \equiv \prod_{\nu \in S} \nu^2 \pmod{(\pi)}$ is valid for both cases.

Definition. The following is called the *canonical quartic root* of $-\pi$.

$$\widetilde{\boldsymbol{\pi}} \doteq \gamma(S)^{-1} \prod_{\nu \in S} \varphi(\nu/\boldsymbol{\pi}).$$
(II.15)

We have $\tilde{\pi}^4 = -\pi$, and $\tilde{\pi}$ is independent of the choice of S because of the property $\varphi(iu) = i\varphi(u)$. As is remarked in the above, there is an ambiguity of the sign of $\tilde{\pi}$ in the case $p \equiv 1 \pmod{8}$. Also we should remark that $\tilde{\pi} \notin L = F(\varphi(1/\pi))$ but $\zeta_8 \tilde{\pi} \in L$, and $(\zeta_8 \tilde{\pi})^4 = \pi$ in the case $p \equiv 1 \pmod{8}$, while $\tilde{\pi} \in L$ holds in the case $p \equiv 5 \pmod{8}$.

Remark. In the case $p \equiv 5 \pmod{8}$, we can take $S = \ker \chi_{\pi}$ as a quarter subset of $(\mathcal{O}/(\pi))^{\times}$; then S is the subgroup consisting of all quartic residues mod (π) . This choice has some advantages. Particularly, it is valid

$$\mathcal{G}_{\boldsymbol{\pi}}(\chi_{\boldsymbol{\pi}}, f) = \sum_{\nu \in S} f(\nu/\boldsymbol{\pi}), \quad \gamma(S) = 1, \quad \widetilde{\boldsymbol{\pi}} = \prod_{\nu \in S} \varphi(\nu/\boldsymbol{\pi})$$

The following is a fundamental property of the quartic residue symbol, which is also directly verified in view of $\gamma(\mu S) = \chi_{\pi}(\mu) \gamma(S)$.

$$\widetilde{\boldsymbol{\pi}}^{\sigma_{\mu}} = \chi_{\boldsymbol{\pi}}(\mu) \, \widetilde{\boldsymbol{\pi}}, \quad (\mu \in (\mathcal{O}/(\boldsymbol{\pi}))^{\times})$$
 (II.16)

where we mean $\widetilde{\pi}^{\sigma_{\mu}} = \zeta_8^{-1} (\zeta_8 \widetilde{\pi})^{\sigma_{\mu}}$ in the strict meaning when $p \equiv 1 \pmod{8}$.

Definition. The following is called the *coefficient* of the elliptic Gauss sum $\mathcal{G}_{\pi}(\chi_{\pi}, f)$.

$$\alpha_{\boldsymbol{\pi}} \doteq \widetilde{\boldsymbol{\pi}}^{-3} \, \mathcal{G}_{\boldsymbol{\pi}}(\chi_{\boldsymbol{\pi}}, f). \tag{II.17}$$

Theorem II.1. The elliptic Gauss sum is expressible as follows :

$$\mathfrak{G}_{\boldsymbol{\pi}}(\chi_{\boldsymbol{\pi}},\,f)=\alpha_{\boldsymbol{\pi}}\,\widetilde{\boldsymbol{\pi}}^3,$$

where the coefficient α_{π} is an algebraic integer in \mathcal{O} or in $\zeta_8 \mathcal{O}$, for $p \equiv 5 \pmod{8}$ or $p \equiv 1 \pmod{8}$, respectively. Further, one has

$$\alpha_{\boldsymbol{\pi}} \equiv 1 \pmod{(1+i)} \quad if \ p = \boldsymbol{\pi} \, \overline{\boldsymbol{\pi}} \equiv 5 \pmod{8}. \tag{II.18}$$

Proof. By the definition and by virtue of (II.13) and (II.16), we have $\alpha_{\pi}^{\sigma_{\mu}} = \alpha_{\pi}$ for an arbitrary $\mu \in (\mathcal{O}/(\pi))^{\times}$, and hence $\alpha_{\pi} \in F$. For the integrity, we can check it in similar manner to the proof (b) of Lemma II.6. We here assume that Claim (Z) is valid. Suppose first $p \equiv 5 \pmod{8}$, p > 5, then $\alpha_{\pi} \tilde{\pi}^3$ is an algebraic integer, though $\pi = -\tilde{\pi}^4$ is a prime in \mathcal{O} ; it means α_{π} itself is already an integer. In the case $p \equiv 1 \pmod{8}$ we need some modification, but the essence is the very same. The last assertion of Theorem II.1 is immediately deduced from the lemmas II.7 and II.8.

Example 7. This example is based on an idea of Y. Ônishi. Consider the case $\pi = 3 + 2i$ (p = 13), and we shall show $\alpha_{\pi} = 1$. Take $S = \ker \chi_{\pi}$. Then $S = \{1, 3, 9\} = \{1, -2i, 1-i\}$, and so we have

$$\widetilde{\pi} = \prod_{\nu \in S} \varphi(\nu/\pi) = \varphi(1/\pi) \,\varphi(-2i/\pi) \,\varphi((1-i)/\pi) = \frac{(-2-2i) \,\varphi(1/\pi)^3}{1 + \varphi(1/\pi)^4},$$

by using suitable multiplication formulas. Since $-2 - 2i = 1 - \pi = 1 + \tilde{\pi}^4$, $\varphi(1/\pi)$ is a solution of the following equation.

$$\widetilde{\boldsymbol{\pi}} \, x^4 - (1 + \widetilde{\boldsymbol{\pi}}^4) \, x^3 + \widetilde{\boldsymbol{\pi}} = 0.$$

The equation is decomposed as follows.

$$(\widetilde{\boldsymbol{\pi}} x - 1)(x^3 - \widetilde{\boldsymbol{\pi}}^3 x^2 - \widetilde{\boldsymbol{\pi}}^2 x - \widetilde{\boldsymbol{\pi}}) = 0.$$

The second factor must be the minimal polynomial of $\varphi(1/\pi)$ over $F(\tilde{\pi})$, and hence the sum of the three roots $\varphi(\nu/\pi)$ ($\nu \in S$) is $\tilde{\pi}^3$, namely,

$$\mathfrak{G}_{\boldsymbol{\pi}}(\chi_{\boldsymbol{\pi}},\,\varphi) = \sum_{\nu\in S} \varphi(\nu/\boldsymbol{\pi}) = \widetilde{\boldsymbol{\pi}}^3.$$

In general, it seems pretty hard to compute the value of the coefficient α_{π} by hand. More examples by computor will be given in the table in Appendix II.

II.4. The quartic Hecke characters and L-values at s = 1

4.1. We introduce a Hecke character $\tilde{\chi}_{\pi}$ induced by the quartic residue character χ_{π} . As mentioned before, it is of the form $\tilde{\chi}_{\pi}((\nu)) = \chi_1(\nu)\overline{\nu}$ with a residue class character χ_1 . For the purpose we first modify the character χ_{π} into χ_1 satisfying $\chi_1(i) = i$. After the preparation of supplementary simple characters χ_0 and χ'_0 , we shall treat the four cases separately in view of $\chi_{\pi}(i) = i^{(p-1)/4}$.

Let χ_0 be the character with conductor $(1+i)^3$ that gives the natural isomorphism $(\mathcal{O}/(1+i)^3)^{\times} \cong W$, namely,

$$\chi_0(\nu) \doteq \varepsilon \text{ for } \nu \equiv \varepsilon \pmod{(1+i)^3}, \ \varepsilon \in W = \{\pm 1, \pm i\}.$$

Let χ'_0 be the character with conductor $(1+i)^2$ that gives the natural isomorphism $(\mathcal{O}/(1+i)^2)^{\times} = (\mathcal{O}/(2))^{\times} \cong \{\pm 1\}$, namely,

$$\chi'_0(\nu) \doteq \delta^2 \text{ for } \nu \equiv \delta \pmod{(1+i)^2}, \ \delta \in \{1, i\}.$$

Let $\boldsymbol{\pi}$ be a primary prime in \mathcal{O} ; $\boldsymbol{\pi} \equiv 1 \pmod{(1+i)^3}$ and let $\chi_{\boldsymbol{\pi}}$ be the quartic residue character to the modulus $(\boldsymbol{\pi})$.

Definition. For each π , the Hecke character $\tilde{\chi}_{\pi}$ is fixed throughout as follows.

$$\widetilde{\chi}_{\boldsymbol{\pi}}((\nu)) \doteq \chi_1(\nu) \,\overline{\nu}, \quad \chi_1 \doteq \begin{cases} \chi_{\boldsymbol{\pi}} \cdot \chi'_0 & \text{for } p = \boldsymbol{\pi} \,\overline{\boldsymbol{\pi}} \equiv 13 \pmod{16}, \\ \chi_{\boldsymbol{\pi}} & \text{for } p = \boldsymbol{\pi} \,\overline{\boldsymbol{\pi}} \equiv 5 \pmod{16}, \\ \chi_{\boldsymbol{\pi}} \cdot \chi_0 & \text{for } p = \boldsymbol{\pi} \,\overline{\boldsymbol{\pi}} \equiv 1 \pmod{16}, \\ \chi_{\boldsymbol{\pi}} \cdot \overline{\chi}_0 & \text{for } p = \boldsymbol{\pi} \,\overline{\boldsymbol{\pi}} \equiv 9 \pmod{16}. \end{cases}$$
(II.19)

For later use, we summarize these circumstances as a brief list :

(a) The case $p = \pi \overline{\pi} \equiv 13 \pmod{16}$. The conductor of $\tilde{\chi}_{\pi}$ is $(\beta) = (2\pi)$. $(\mathcal{O}/(\beta))^{\times} \cong (\mathcal{O}/(\pi))^{\times} \times \{\pm 1\}$ by λ to $(\kappa, \ \delta^2)$: $\lambda \equiv 2\kappa + \pi \delta \pmod{\beta}$; (II.20) $\chi_1(\lambda) = \chi_{\pi}(2) \chi_{\pi}(\kappa) \delta^2$.

(b) The case
$$p = \pi \overline{\pi} \equiv 5 \pmod{16}$$
. The conductor of $\widetilde{\chi}_{\pi}$ is $(\beta) = (\pi)$.
 $(\mathcal{O}/(\beta))^{\times} \cong (\mathcal{O}/(\pi))^{\times}$ by $\lambda \equiv \kappa \pmod{\beta}$; $\chi_1(\lambda) = \chi_{\pi}(\kappa)$. (II.21)

(c) The case
$$p = \pi \overline{\pi} \equiv 1 \pmod{8}$$
. The conductor of $\widetilde{\chi}_{\pi}$ is $(\beta) = ((1+i)^3 \pi)$.
 $(\mathcal{O}/(\beta))^{\times} \cong (\mathcal{O}/(\pi))^{\times} \times W$ by λ to $(\kappa, \varepsilon) : \lambda \equiv (1+i)^3 \kappa + \pi \varepsilon \pmod{\beta}$;
 $\chi_1(\lambda) = \begin{cases} \overline{\chi}_{\pi}(1+i) \chi_{\pi}(\kappa) \varepsilon & (p \equiv 1 \pmod{16}), \\ \overline{\chi}_{\pi}(1+i) \chi_{\pi}(\kappa) \overline{\varepsilon} & (p \equiv 9 \pmod{16}). \end{cases}$
(II.22)

4.2. Now we can evaluate the value of the associated *L*-series, especially at s = 1, and we shall show that $L(1, \tilde{\chi}_{\pi})$ is expressed by the corresponding elliptic Gauss sum.

Theorem II.2. Let $\tilde{\chi}_{\pi}$ be the Hecke character for a primary prime π . Then

$$\varpi^{-1} L(1, \tilde{\chi}_{\pi}) = \begin{cases} -\frac{1+i}{2} \chi_{\pi}(2) \pi^{-1} \mathcal{G}_{\pi}(\chi_{\pi}, \varphi) & \text{if } p = \pi \,\overline{\pi} \equiv 13 \pmod{16}, \\ \pi^{-1} \mathcal{G}_{\pi}(\chi_{\pi}, \mathbb{Z}) & \text{if } p = \pi \,\overline{\pi} \equiv 5 \pmod{16}, \\ \overline{\chi}_{\pi}(1+i) \,\pi^{-1} \mathcal{G}_{\pi}(\chi_{\pi}, \psi) & \text{if } p = \pi \,\overline{\pi} \equiv 1 \pmod{16}, \\ -\overline{\chi}_{\pi}(1+i) \,\pi^{-1} \mathcal{G}_{\pi}(\chi_{\pi}, \psi) & \text{if } p = \pi \,\overline{\pi} \equiv 9 \pmod{16}. \end{cases}$$
(II.23)

Proof. We follow the formula (II.11) of Lemma II.5.

(a) The case $p = \pi \overline{\pi} \equiv 13 \pmod{16}$. In view of (II.20), we have

$$\varpi^{-1} L(1, \ \widetilde{\chi}_{\pi}) = \frac{1}{4\beta} \cdot \sum_{\lambda \pmod{\beta}} \chi_{1}(\lambda) \operatorname{Z}(\lambda/\beta)$$

$$= \frac{1}{8\pi} \chi_{\pi}(2) \cdot \sum_{\kappa \pmod{\pi}} \chi_{\pi}(\kappa) \sum_{\delta=1,i} \delta^{2} \operatorname{Z}(\kappa/\pi + \delta/2)$$

$$= -\frac{1+i}{2} \cdot \frac{\chi_{\pi}(2)}{\pi} \cdot \frac{1}{4} \sum_{\kappa \pmod{\pi}} \chi_{\pi}(\kappa) \varphi(\kappa/\pi),$$

since $\sum_{\delta=1,i} \delta^2 \mathsf{Z}(u+\delta/2) = -(1+i)\varphi(u)$ by the definition (II.2).

(b) The case $p = \pi \overline{\pi} \equiv 5 \pmod{16}$. In view of (II.21), we obtain directly

$$\varpi^{-1} L(1, \ \widetilde{\chi}_{\boldsymbol{\pi}}) = \frac{1}{\boldsymbol{\pi}} \cdot \frac{1}{4} \sum_{\kappa \pmod{\boldsymbol{\pi}}} \chi_{\boldsymbol{\pi}}(\kappa) \, \mathsf{Z}(\kappa/\boldsymbol{\pi}).$$

(c) The case $p = \pi \overline{\pi} \equiv 1 \pmod{16}$. In view of (II.22), we have

$$\varpi^{-1} L(1, \ \widetilde{\chi}_{\boldsymbol{\pi}}) = -\frac{1+i}{16} \cdot \frac{\overline{\chi}_{\boldsymbol{\pi}}(1+i)}{\boldsymbol{\pi}} \sum_{\kappa \pmod{\boldsymbol{\pi}}} \chi_{\boldsymbol{\pi}}(\kappa) \sum_{\varepsilon \in W} \varepsilon \operatorname{\mathsf{Z}}(\kappa/\boldsymbol{\pi} - \varepsilon(1+i)/4)$$
$$= \frac{\overline{\chi}_{\boldsymbol{\pi}}(1+i)}{\boldsymbol{\pi}} \cdot \frac{1}{4} \sum_{\kappa \pmod{\boldsymbol{\pi}}} \chi_{\boldsymbol{\pi}}(\kappa) \psi(\kappa/\boldsymbol{\pi}),$$

since $\sum_{\varepsilon \in W} \varepsilon Z(u - \varepsilon(1+i)/4) = -(1-i)\{\psi(u) + \psi(iu)\}$ by the definition (II.3).

(c') The case $p = \pi \overline{\pi} \equiv 9 \pmod{16}$. In view of (II.22), we have

$$\varpi^{-1} L(1, \ \widetilde{\chi}_{\pi}) = -\frac{1+i}{16} \cdot \frac{\overline{\chi}_{\pi}(1+i)}{\pi} \sum_{\kappa \pmod{\pi}} \chi_{\pi}(\kappa) \sum_{\varepsilon \in W} \overline{\varepsilon} \, \mathbb{Z}(\kappa/\pi - \varepsilon(1+i)/4)$$
$$= -\frac{\overline{\chi}_{\pi}(1+i)}{\pi} \cdot \frac{1}{4} \sum_{\kappa \pmod{\pi}} \chi_{\pi}(\kappa) \, \psi(\kappa/\pi),$$

since $\sum_{\varepsilon \in W} \overline{\varepsilon} \mathsf{Z}(u - \varepsilon(1+i)/4) = (1-i)\{\psi(u) - \psi(iu)\}$ also by the definition (II.3).

Thus we have completed the proof of Theorem II.2.

II.5. The explicit formula of the root number $C(\tilde{\chi}_{\pi})$

5.1. We require an important formula about the classical quartic Gauss sum. Let π be a primary prime in \mathcal{O} and set $p = \pi \overline{\pi}$. The quartic residue character χ_{π} may be considered as a character on $(\mathbf{Z}/p\mathbf{Z})^{\times}$. Then the quartic Gauss sum is defined by

$$G_4(\boldsymbol{\pi}) \doteq \sum_{r=1}^{p-1} \chi_{\boldsymbol{\pi}}(r) e^{2\pi i r/p}.$$
 (II.24)

Also we here should recall the definition (II.15) of the canonical quartic root $\tilde{\pi}$ of $-\pi$.

Lemma II.9. (G_4 -formula)

$$G_4(\boldsymbol{\pi}) = \chi_{\boldsymbol{\pi}}(-2)\,\widetilde{\boldsymbol{\pi}}^3\,\overline{\widetilde{\boldsymbol{\pi}}} \tag{II.25}$$

Remark. As an immediate consequence we have a famous formula (cf. [I-R], Prop.9.10.1): $G_4(\pi)^2 = -\chi_{\pi}(-1) \pi \sqrt{p}$, and also we obtain $G_4(\pi)^4 = \pi^3 \overline{\pi}$. The ambiguity of the definition of $\widetilde{\pi}$ does not matter, for the right side of our G_4 -formula depends only on $\widetilde{\pi}^2$. *Proof.* This is only a slight modification of the celebrated formula of Matthews. He used the lattice $\theta \mathcal{O}$ instead of our $\varpi \mathcal{O}$, where $\theta = \sqrt{2} \varpi = 3.70814935 \cdots$. Let $\wp_1(u)$ denote Weierstrass' \wp with the period lattice $\theta \mathcal{O}$. Hence the relation $\wp(\varpi u) = 2 \wp_1(\theta u)$ holds, so that $\wp'_1(u)^2 = 4 \wp_1(u)^3 - \wp_1(u)$; further we have

$$\varphi(u) = \mathrm{sl}((1-i)\,\varpi\,u) = -2\,(1-i)\,\frac{\wp(\varpi\,u)}{\wp'(\varpi\,u)} = -\sqrt{2}\,(1-i)\,\frac{\wp_1(\theta\,u)}{\wp_1'(\theta\,u)} = \zeta_8^{-1}\,T(\theta\,u),$$

where $T(u) = -2 \wp_1(u) \wp'_1(u)^{-1}$ after his notation. Matthews' formula states Formula ([M2], esp. p.51)

$$G_4(\boldsymbol{\pi}) = -\beta(\boldsymbol{\pi}) \,\chi_{\boldsymbol{\pi}}(2i) \prod_{r \in N} T(\theta \, r/\boldsymbol{\pi}) \cdot p^{1/4}, \tag{II.26}$$

where $N = \{1, 2, \dots, (p-1)/2\}$, and the constant $\beta(\boldsymbol{\pi})$ is uniquely determined by the conditions $\beta(\boldsymbol{\pi}) \equiv \prod_{r \in N} r \pmod{\boldsymbol{\pi}}$ and $\beta(\boldsymbol{\pi})^2 = -1$.

Now we can derive the formula (II.25) from (II.26); indeed they are equivalent. We first note that since N is a half subset mod $(\boldsymbol{\pi})$, there is a quarter subset S_0 such that $N = S_0 \cup iS_0$. Then $\beta(\boldsymbol{\pi}) \equiv \prod_{r \in N} r \equiv \chi_{\boldsymbol{\pi}}(i) \prod_{r \in S_0} r^2 \pmod{(\boldsymbol{\pi})}$; namely, $\beta(\boldsymbol{\pi}) = \chi_{\boldsymbol{\pi}}(i) \gamma(S_0)^2$. Also we can observe $\gamma(S_0)^4 = -\chi_{\boldsymbol{\pi}}(-1)$. Hence we have

$$G_{4}(\boldsymbol{\pi}) = -\chi_{\boldsymbol{\pi}}(-2) \gamma(S_{0})^{2} \prod_{r \in N} \{\zeta_{8} \varphi(r/\boldsymbol{\pi})\} \cdot p^{1/4}$$

$$= -\chi_{\boldsymbol{\pi}}(-2) \gamma(S_{0})^{4} \chi_{\boldsymbol{\pi}}(-1) \cdot \gamma(S_{0})^{-2} \prod_{\nu \in S_{0}} \varphi(\nu/\boldsymbol{\pi})^{2} \cdot p^{1/4} = \chi_{\boldsymbol{\pi}}(-2) \widetilde{\boldsymbol{\pi}}^{3} \overline{\widetilde{\boldsymbol{\pi}}}.$$

This finishes the proof of G_4 -formula.

5.2. We are now ready to give the explicit value of the root number $C(\tilde{\chi}_{\pi})$.

Theorem II.3. Let $\tilde{\chi}_{\pi}$ be the Hecke character for a primary prime π . Then

$$C(\widetilde{\chi}_{\pi}) = \begin{cases} -i\,\widetilde{\pi}^{-1}\,\overline{\widetilde{\pi}} & \text{if } p = \pi\,\overline{\pi} \equiv 13 \pmod{16}, \\ i\,\chi_{\pi}(2)\,\widetilde{\pi}^{-1}\,\overline{\widetilde{\pi}} & \text{if } p = \pi\,\overline{\pi} \equiv 5 \pmod{16}, \\ -\overline{\chi}_{\pi}(1+i)\,\widetilde{\pi}^{-1}\,\overline{\widetilde{\pi}} & \text{if } p = \pi\,\overline{\pi} \equiv 1 \pmod{16}, \\ -i\,\chi_{\pi}(1+i)\,\widetilde{\pi}^{-1}\,\overline{\widetilde{\pi}} & \text{if } p = \pi\,\overline{\pi} \equiv 9 \pmod{16}. \end{cases}$$
(II.27)

Proof. We first evaluate some simple Gauss sums. The first three are easily verified by direct calculation :

$$g(\chi_0) \doteq \sum_{\varepsilon \in W} \varepsilon \, e^{2\pi i \operatorname{Re}(\varepsilon/(1+i)^3)} = -2 - 2i, \quad g(\overline{\chi}_0) \doteq \sum_{\varepsilon \in W} \overline{\varepsilon} \, e^{2\pi i \operatorname{Re}(\varepsilon/(1+i)^3)} = 2 - 2i$$

and
$$g(\chi_0') \doteq \sum_{\delta=1, i} \delta^2 \, e^{2\pi i \operatorname{Re}(\delta/2)} = -2.$$
 (II.28)

The next sum is essentially nothing but the quartic Gauss sum :

$$g(\chi_{\boldsymbol{\pi}}) \doteq \sum_{\kappa \pmod{\boldsymbol{\pi}}} \chi_{\boldsymbol{\pi}}(\kappa) e^{2\pi i \operatorname{Re}(\kappa/\boldsymbol{\pi})} = \chi_{\boldsymbol{\pi}}(-2) \,\widetilde{\boldsymbol{\pi}}^3 \,\overline{\widetilde{\boldsymbol{\pi}}} \cdot \begin{cases} 1 & \text{if } p \equiv 13, 1 \pmod{16} \\ -1 & \text{if } p \equiv 5, 9 \pmod{16} \end{cases}$$
(II.29)

In fact, we first replace the sum over $\kappa \pmod{\pi}$ by one over $r \pmod{p}$, and then, by using $\operatorname{Re}(r \overline{\pi}/p) = ar/p$ where $\pi = a + bi$ $(a, b \in \mathbb{Z})$, we can calculate as follows :

$$g(\chi_{\boldsymbol{\pi}}) = \sum_{r \pmod{p}} \chi_{\boldsymbol{\pi}}(r) e^{2\pi i \operatorname{Re}(r \,\overline{\boldsymbol{\pi}}/p)} = \sum_{r \pmod{p}} \chi_{\boldsymbol{\pi}}(r) e^{2\pi i ar/p} = \overline{\chi}_{\boldsymbol{\pi}}(a) G_4(\boldsymbol{\pi}).$$

Furthermore, we know $\overline{\chi}_{\pi}(a) = 1$ or -1 for $p \equiv 13, 1$ or 5, 9 (mod 16), respectively (cf. [IR] Chap. 9, Exerc. 34), and finally, by applying G_4 -formula we have (II.29).

We return to the proof of Theorem II.3. Using the formula (II.10) of Lemma II.4 :

$$C(\widetilde{\chi}_{\pi}) = -i\,\beta^{-1}\,\sum_{\lambda \,(\mathrm{mod}\,\beta)}\,\chi_1(\lambda)\,e^{2\pi i\,\mathrm{Re}(\lambda/\beta)},$$

we treat each of the four cases according to the definition of χ_1 , especially in view of (II.20), (II.21) and (II.22). Thus we can easily obtain

(a) The case $p = \pi \overline{\pi} \equiv 13 \pmod{16}$.

$$C(\widetilde{\chi}_{\boldsymbol{\pi}}) = -i \, 2^{-1} \, \boldsymbol{\pi}^{-1} \, \chi_{\boldsymbol{\pi}}(2) \, g(\chi'_0) \, g(\chi_{\boldsymbol{\pi}}) = -i \, \widetilde{\boldsymbol{\pi}}^{-1} \, \overline{\widetilde{\boldsymbol{\pi}}}.$$

(b) The case $p = \pi \overline{\pi} \equiv 5 \pmod{16}$.

$$C(\widetilde{\chi}_{\boldsymbol{\pi}}) = -i\,\boldsymbol{\pi}^{-1}\,g(\chi_{\boldsymbol{\pi}}) = i\,\chi_{\boldsymbol{\pi}}(2)\cdot\widetilde{\boldsymbol{\pi}}^{-1}\,\overline{\widetilde{\boldsymbol{\pi}}}.$$

(c) The case $p = \pi \overline{\pi} \equiv 1 \pmod{16}$.

$$C(\widetilde{\chi}_{\boldsymbol{\pi}}) = -i \, (1+i)^{-3} \, \boldsymbol{\pi}^{-1} \, \overline{\chi}_{\boldsymbol{\pi}}(1+i) \, g(\chi_0) \, g(\chi_{\boldsymbol{\pi}}) = -\chi_{\boldsymbol{\pi}}(1+i) \, \widetilde{\boldsymbol{\pi}}^{-1} \, \overline{\widetilde{\boldsymbol{\pi}}}.$$

(c') The case $p = \pi \overline{\pi} \equiv 9 \pmod{16}$.

$$C(\widetilde{\chi}_{\boldsymbol{\pi}}) = -i\,(1+i)^{-3}\,\boldsymbol{\pi}^{-1}\,\overline{\chi}_{\boldsymbol{\pi}}(1+i)\,g(\overline{\chi}_0)\,g(\chi_{\boldsymbol{\pi}}) = -i\,\chi_{\boldsymbol{\pi}}(1+i)\,\widetilde{\boldsymbol{\pi}}^{-1}\,\overline{\widetilde{\boldsymbol{\pi}}}.$$

These complete the proof of Theorem II.3.

II.6. Rationality of the elliptic Gauss sum coefficient

6.1. Now we can mention about the rationality of the coefficients of elliptic Gauss sums. More precisely, the coefficient itself is not always rational but it will be seen that the essential factor of this is certainly a rational integer. In other words, we shall extract a rational integer factor from the elliptic Gauss sum, i.e. from the Hecke *L*-value at s = 1, which seems also the most important part in respect of arithmetical nature. The following theorem, together with corollaries, is the main result of the part **II**.

Theorem II.4. Let α_{π} be the coefficient of the elliptic Gauss sum (II.17). Then

$$\alpha_{\boldsymbol{\pi}} = \begin{cases}
\overline{\alpha}_{\boldsymbol{\pi}} & \text{if } p = \boldsymbol{\pi} \,\overline{\boldsymbol{\pi}} \equiv 13 \pmod{16}, \\
i \,\chi_{\boldsymbol{\pi}}(2) \,\overline{\alpha}_{\boldsymbol{\pi}} & \text{if } p = \boldsymbol{\pi} \,\overline{\boldsymbol{\pi}} \equiv 5 \pmod{16}, \\
-\overline{\chi}_{\boldsymbol{\pi}}(1+i) \,\overline{\alpha}_{\boldsymbol{\pi}} & \text{if } p = \boldsymbol{\pi} \,\overline{\boldsymbol{\pi}} \equiv 1 \pmod{16}, \\
-i \,\overline{\chi}_{\boldsymbol{\pi}}(1+i) \,\overline{\alpha}_{\boldsymbol{\pi}} & \text{if } p = \boldsymbol{\pi} \,\overline{\boldsymbol{\pi}} \equiv 9 \pmod{16}.
\end{cases} (II.30)$$

Proof. By the theorems II.1, II.2 and II.3 we have already known both the explicit values of $L(1, \tilde{\chi}_{\pi})$ and $C(\tilde{\chi}_{\pi})$. To prove Theorem II.4, we have only to substitute them for the both sides of the central value equation : $L(1, \tilde{\chi}_{\pi}) = C(\tilde{\chi}_{\pi}) \overline{L(1, \tilde{\chi}_{\pi})}$ (cf. Lemma II.4). For example, suppose that $p = \pi \overline{\pi} \equiv 13 \pmod{16}$. In this case we have

$$\varpi^{-1} L(1, \widetilde{\chi}_{\pi}) = \frac{1+i}{2} \chi_{\pi}(2) \widetilde{\pi}^{-1} \alpha_{\pi} \quad \text{and} \quad C(\widetilde{\chi}_{\pi}) = -i \widetilde{\pi}^{-1} \overline{\widetilde{\pi}},$$

and hence the central value equation implies $\chi_{\pi}(2) \alpha_{\pi} = -\overline{\chi}_{\pi}(2) \overline{\alpha}_{\pi}$. This immediately proves $\alpha_{\pi} = \overline{\alpha}_{\pi}$ since $\chi_{\pi}(2)^2 = \chi_{\pi}(i)^2 = -1$. In other cases, the argument is quite similar, so we omit the details. Thus the proof is finished.

Before stating the corollaries of Theorem II.4, we give a proof of the integrity of $\mathcal{G}_{\pi}(\chi_{\pi}, \mathsf{Z})$, which has been postponed until now.

Proof of Claim (Z). Assume that $p = \pi \overline{\pi} \equiv 5 \pmod{16}$ and $\mathfrak{G}_{\pi}(\chi_{\pi}, \mathsf{Z}) = \alpha_{\pi} \widetilde{\pi}^3$. We know $\alpha_{\pi} \in F$. Further, Theorem II.4 shows $\overline{\chi}_{\pi}(1+i) \alpha_{\pi} = \chi_{\pi}(1+i) \overline{\alpha}_{\pi}$, and hence $\alpha_{\pi} = \chi_{\pi}(1+i) a_{\pi}$ for some $a_{\pi} \in \mathbf{Q}$. On the other hand, by Lemma II.7 and the subsequent discussions, we know $((1+i) - i \overline{\chi}_{\pi}(1+i)) \alpha_{\pi} \in \mathcal{O}$. Namely, $a_{\pi}, -(1+2i) a_{\pi}, -a_{\pi}$ or $(1-2i) a_{\pi}$ is algebraic integer in \mathcal{O} , when $\chi_{\pi}(1+i) = 1, -1, i$ or -i, accordingly. This means that $a_{\pi} \in \mathbf{Z}$ holds already. Thus the proof of Claim (Z) is completed.

Corollary II.1. Suppose that $p = \pi \overline{\pi} \equiv 5 \pmod{8}$. There exists a rational integer a_{π} such that $a_{\pi} \equiv 1 \pmod{2}$, and the coefficient α_{π} of the elliptic Gauss sum is expressed by a_{π} as follows. In particular, $|\alpha_{\pi}|^2 = a_{\pi}^2$.

$$\alpha_{\boldsymbol{\pi}} = \begin{cases} a_{\boldsymbol{\pi}} & \text{if } p = \boldsymbol{\pi} \, \overline{\boldsymbol{\pi}} \equiv 13 \pmod{16}, \\ a_{\boldsymbol{\pi}} \, \chi_{\boldsymbol{\pi}}(1+i) & \text{if } p = \boldsymbol{\pi} \, \overline{\boldsymbol{\pi}} \equiv 5 \pmod{16}. \end{cases}$$
(II.31)

Proof. We can derive the integrity of the coefficient α_{π} from Theorem II.1, and the rationality from Theorem II.4. The property $a_{\pi} \equiv 1 \pmod{2}$ follows from $\alpha_{\pi} \equiv 1 \pmod{(1+i)}$ in Theorem II.1.

Corollary II.2. Suppose that $p = \pi \overline{\pi} \equiv 1 \pmod{8}$. There exists a rational integer a_{π} , and the coefficient α_{π} of the elliptic Gauss sum is expressed by a_{π} as follows. In

particular, $|\alpha_{\pi}|^2 = 2 a_{\pi}^2$ or $|\alpha_{\pi}|^2 = a_{\pi}^2$ according as $\chi_{\pi}(2) = 1$ or $\chi_{\pi}(2) = -1$.

$$\alpha_{\pi} = \begin{cases}
a_{\pi} \cdot i \sqrt{2} & \text{if } \chi_{\pi}(1+i) = 1, \\
a_{\pi} \cdot \sqrt{2} & \text{if } \chi_{\pi}(1+i) = -1, \\
a_{\pi} \cdot \zeta_{8} & \text{if } \chi_{\pi}(1+i) = i, \\
a_{\pi} \cdot i \zeta_{8} & \text{if } \chi_{\pi}(1+i) = -i, \\
\alpha_{\pi} \cdot \zeta_{8} & \text{if } \chi_{\pi}(1+i) = -1, \\
a_{\pi} \cdot \zeta_{8} & \text{if } \chi_{\pi}(1+i) = -1, \\
a_{\pi} \cdot i \sqrt{2} & \text{if } \chi_{\pi}(1+i) = i, \\
a_{\pi} \cdot \sqrt{2} & \text{if } \chi_{\pi}(1+i) = -i, \\
\end{cases} \text{ and } p \equiv 9 \pmod{16}. \quad (\text{II.33})$$

Proof. In this case we have $\alpha_{\pi} \in \zeta_8 \mathcal{O}$, which combined with the rationality relation (II.30) will immediately give an explicit form of the coefficient. For example, consider the case of $p \equiv 1 \pmod{16}$ and $\chi_{\pi}(1+i) = 1$. Put $\alpha_{\pi} = (c+di)\zeta_8$ with $c, d \in \mathbb{Z}$. By (II.30) we see $\alpha_{\pi} = -\overline{\alpha}_{\pi}$, and hence c + di = i(c - di), which means c = d. Namely, we have $\alpha_{\pi} = c(1+i)\zeta_8 = a_{\pi} \cdot i\sqrt{2}$ by putting $a_{\pi} = c$. We omit the details for other seven cases.

6.2. The substance of Theorem II.4 and the corollaries can be stated by the language of Hecke *L*-values in various ways. The following is one of them. It shows that there is a close relation between the values of Hecke's $L(1, \tilde{\chi}_{\pi})$ and the quartic Gauss sum $G_4(\pi)$, especially between their arguments. Roughly speaking, the argument of $L(1, \tilde{\chi}_{\pi})$ is parallel to one of $\tilde{\pi}^{-1}$, and the argument of $G_4(\pi)$ is parallel to one of $\tilde{\pi}^2$. Hence by eliminating the factors of $\tilde{\pi}$ from their formulas, the result can be obtained.

Theorem II.5. Let a_{π} $(p = \pi \overline{\pi})$ be a rational integer given in Corollary II.1 or II.2.

$$\varpi^{-2} L(1, \tilde{\chi}_{\pi})^{2} = \begin{cases} 2^{-1} i \chi_{\pi}(2) p^{1/4} a_{\pi}^{2} \cdot G_{4}(\pi)^{-1} & \text{if} \quad p \equiv 13 \pmod{16}, \\ i p^{1/4} a_{\pi}^{2} \cdot G_{4}(\pi)^{-1} & \text{if} \quad p \equiv 5 \pmod{16}, \\ -2 \overline{\chi}_{\pi}(1+i) p^{1/4} a_{\pi}^{2} \cdot G_{4}(\pi)^{-1} & \text{if} \quad p \equiv 1 \pmod{16}, \ \chi_{\pi}(2) = 1, \\ -\overline{\chi}_{\pi}(1+i) p^{1/4} a_{\pi}^{2} \cdot G_{4}(\pi)^{-1} & \text{if} \quad p \equiv 1 \pmod{16}, \ \chi_{\pi}(2) = -1, \\ 2 i \overline{\chi}_{\pi}(1+i) p^{1/4} a_{\pi}^{2} \cdot G_{4}(\pi)^{-1} & \text{if} \quad p \equiv 9 \pmod{16}, \ \chi_{\pi}(2) = 1, \\ i \overline{\chi}_{\pi}(1+i) p^{1/4} a_{\pi}^{2} \cdot G_{4}(\pi)^{-1} & \text{if} \quad p \equiv 9 \pmod{16}, \ \chi_{\pi}(2) = -1. \end{cases}$$

Proof. Consider the case $p = \pi \overline{\pi} \equiv 13 \pmod{16}$. By Theorems II.1 and II.2, we have $\overline{\omega}^{-1}L(1, \widetilde{\chi}_{\pi}) = 2^{-1}(1+i)\chi_{\pi}(2)\alpha_{\pi}\widetilde{\pi}^{-1}$. Theorem II.4 shows $\alpha_{\pi}^2 = a_{\pi}^2$. These combined with G_4 -formula : $G_4(\pi) = -\chi_{\pi}(2)\widetilde{\pi}^2 p^{1/4}$ implies the result. We omit the similar discussions for other cases. Obviously the formula for $|L(1, \widetilde{\chi}_{\pi})|^2$ is very simple.

Corollary II.3. $L(1, \tilde{\chi}_{\pi}) \neq 0$ if $p = \pi \overline{\pi} \equiv 5 \pmod{8}$.

Proof. Because $|\alpha_{\pi}|^2 = a_{\pi}^2 \equiv 1 \pmod{2}$.

Remark. The case $p = \pi \overline{\pi} \equiv 1 \pmod{8}$. According to some observation it is plausible that $a_{\pi} \equiv 1 \pmod{2}$ and so $L(1, \tilde{\chi}_{\pi})$ never vanishes if $p \equiv 1 \pmod{16}$ and $\chi_{\pi}(1+i) \neq 1$, or if $p \equiv 9 \pmod{16}$ and $\chi_{\pi}(1+i) \neq -i$. On the other hand, we can observe that $L(1, \tilde{\chi}_{\pi})$ happens to vanish very often in the contrary cases. For examples it seems $L(1, \tilde{\chi}_{\pi}) = 0$ holds for each prime as follows :

 $p = 113, 257, 593, 1201, 1217, 2129, 2593, \dots, \quad (p \equiv 1 \pmod{16}), \quad \chi_{\pi}(1+i) = 1),$ $p = 89, 601, 1097, 1193, 1433, 1481, 1721, \dots, \quad (p \equiv 9 \pmod{16}), \quad \chi_{\pi}(1+i) = -i).$

Appendix II.

For convenience' and interest's sake, we append a small table of the coefficients of elliptic Gauss sums in the following pages. The computation and the table was made by using UBASIC.

In the table (1), (2), the coefficient is given as $\alpha_{\pi} = a_{\pi}$ or $\alpha_{\pi} = a_{\pi} \cdot (\chi_{\pi}(1+i))$, for the case $p \equiv 13 \pmod{16}$ or $p \equiv 5 \pmod{16}$, respectively. (cf. Corollary II.1)

For the case of $p \equiv 1 \pmod{8}$, we need to add a few remarks. In this case, as was mentioned before, there is an ambiguity caused by the choice of Π or Π' in defining the quartic root $\tilde{\pi}$ of $-\pi$. In our computation, we take the quarter subset S_0 such as $S_0 \cup i S_0 = \{1, 2, \ldots, (p-1)/2\}$. And we set $\gamma(S_0) = \zeta_8$ or $\overline{\zeta_8}$ when $\gamma(S_0)^2 \equiv i$ or -i(mod π), respectively. This means that we have chosen an appropriate Π for temporary convenience. Anyway in the case $p \equiv 1 \pmod{8}$, only the quantity α_{π}^2 has an invariant meaning. In the table (3), (4), we can see and check that the value of the coefficient is exactly in conformity with the statement of Corollary II.2.

It is very notable that the magnitude of a_{π} seems to be remarkable small. In fact, thanks to Mr. Naruo Kanou's computation by PARI/GP, we know

$$-49 \le a_{\pi} \le 49$$
 for $13 \le p \le 3999949$, $p \equiv 13 \pmod{16}$,
 $-43 \le a_{\pi} \le 47$ for $37 \le p \le 3999893$, $p \equiv 5 \pmod{16}$.
