Abstract

The AdS/CFT conjecture offers the possibility of a quantum description for a black hole in terms of a CFT. This has led to the study of general AdS^3 type black holes with a view to constructing an explicit toy quantum black hole model. Such a CFT description would be characterized by its central charge and the dimensions of its primary fields. Recently the expression for the central charges (C_L, C_R) of the CFT dual to the warped AdS^3 have been determined using asymptotic symmetry arguments. The central charges depend, as expected, on the warping factor. We show that topological arguments, used by Witten to constrain central charges for the BTZ black hole, can be generalized to deal with the warped AdS^3 case. Topology constrains the warped factor to be rational numbers while quasinormal modes are conjectured to give the dimensions of primary fields. We find that in the limit when warping is large or when it takes special rational values the system tends to Witten's conjectured unique CFT's with central charges that are multiples of 24.

The possibility of constructing a complete quantum theory of gravity for the 3D BTZ was attempted by Witten [1]. The approach used the AdS/CFT correspondence and constructed the quantum theory of gravity as a CFT which had holomorphic factorization and central charges given by the pair $(24k_1, 24k_2)$ where $k_1, k_2 \in \mathbb{Z}$. For $k_1 = k_2 = 1$, the corresponding CFT was conjectured to be unique. Subsequent work suggested that a pure 3D quantum gravity theory might not be physically sensible [2].

Recently a generalization of the BTZ black hole, the warped AdS^3 black hole, arose in the context of topologically massive gravity [3, 4, 5, 6]. Using analogies suggested by the BTZ black hole [7, 8], the central charges C_L, C_R of the holomorphic and anti-holomorphic dual CFT's of the warped AdS^3 black holes were first conjectured in [9] and later these conjectured forms of C_L and C_R shown to follow from a study of the asymptotic symmetry of the warped AdS^3 black hole[10, 11]. The central charges were found to respect the gravitational anomaly constraint.

In view of these results we study if there are topological restriction on the central charge for the warped AdS^3 black hole, following the analysis of [9]. We note that the warped AdS_3 system has vector type excitations present and hence is not a pure gravity theory. Following the analysis of Witten [1] we find that topology restricts warping to rational numbers and that surprisingly for large warping the associated CFT tends to a pure gravity theory. This follows from the observation that in this limit the central charges for the associated CFT's are integral multiples of 24. Such CFT's, were conjectured by Witten [1] to be unique to represent pure gravity theories. We next observe that, following the treatment in [12, 13], that the conformal weights of the associated CFT's for the warped AdS^3 can also be determined from their quasinormal modes[14, 15, 16, 17]. Thus the associated dual CFT's are completely determined in terms of the warping factor and the quasinormal modes of the warped AdS^3 black hole.

The action for topologically massive gravity in three dimensions in terms of two Chern-Simons gauge theories is given by

$$S_{EH} = \frac{K_L + K_R}{2}(I_{CS}(A_L) - I_{CS}(A_R)) \quad (1)$$

and the gravitational Chern-Simons action has the form

$$S_{GCS} = \frac{K_L - K_R}{2}(I_{CS}(A_L) + I_{CS}(A_R)), \quad (2)$$

where I_{CS} is the Chern-Simon action given by

$$I_{CS}(A) = \frac{1}{4\pi} \int d^3x \operatorname{tr} \left(A \wedge dA + \frac{2}{3} A \wedge A \wedge A \right). \quad (3)$$

The allowed values of the coupling constants K_L, K_R get restrictions, if the gauge group is $SO(2, 1) \times SO(2, 1)$. The BTZ black hole has the symmetry under $SL(2, R) \times SL(2, R)$. Witten's idea was to think of $SL(2, R)$ as a double cover of the $SO(2, 1)$ [1]. From the fact that $SO(2, 1)$ has a compact $SO(2)$ subgroup in it, topological considerations restrict K_L, K_R values. We would like to investigate if Witten's restrictions are relevant for the warped AdS^3 black hole.

Consider the the action

$$S = \frac{1}{16\pi G} \int d^3x \sqrt{-g} (R + \frac{2}{l^2}) + \frac{l}{96\pi G\nu} \int d^3x \sqrt{-g} \epsilon^{\mu\nu\lambda} \Gamma_{\mu\sigma}^{\rho} \left(\partial_{\lambda} \Gamma_{\rho\lambda}^{\sigma} + \frac{2}{3} \Gamma_{\nu\beta}^{\sigma} \Gamma_{\lambda\rho}^{\beta} \right) \quad (4)$$

describing topologically massive gravity in three dimension. Here the warping factor $\nu = \mu l/3$ where μ is the mass and $\epsilon^{\mu\nu\lambda} = +1/\sqrt{-g}$. The second term in the above is the gravitational Chern-Simon term $-I_{GCS}$. The warped black hole with $U(1) \times SL(2, R)$ symmetry is a classical

solution to the above action which goes to warped AdS^3 asymptotically [9]. The warping was done by constructing a fibration of AdS^3 as $R \times SL(2, R)$. The resulting spacetime still has a constant negative curvature as AdS^3 but have a very different metric.

In order to get topological constraints we follow Witten[1] and replace $SL(2, R)$ by $SO(2, 1)$ and rewrite the above action in Eqn.(4) as a $SO(2, 1)$ gauge theory. We find that the action can be written as the sum of two Chern Simons terms of opposite chirality. This immediately allows us to use the topological ideas of Witten. We introduce $A_L = \omega - *e/l$, $A_R = \omega + *e/l$ where $*e = \epsilon^{abc}e_c$ is a two index object in $SO(2, 1)$ and ω is the spin connection. Using these A_L and A_R in Eqns.(1,2), we find

$$\frac{1}{\pi l} \int d^3x \sqrt{-g} (R + \frac{2}{l^2}) = -\frac{1}{\pi l} \int d^3x \text{tr} *e (d\omega \wedge \omega) - \frac{l}{3\pi l^3} \int d^3x \text{tr} (*e \wedge *e \wedge *e). \quad (5)$$

The gravitational Chern-Simons action I_{GCS} can be written in terms of spin connection ω alone as $\int \text{tr} (1/2\pi)(\omega \wedge d\omega + (1/3\pi)\omega \wedge \omega \wedge \omega)$.

Thus the action for warped, topologically massive gravity given is Eqn.(4) can be expressed in terms of the Chern-Simons action for the gauge fields A_L and A_R as

$$S = S_{EH} + S_{GCS} \quad (6)$$

where S_{EH} and S_{GCS} are given in Eqns.(1,2). Comparing the coefficients of the above action with that in Eqn. (4), we get

$$\frac{K_L + K_R}{2\pi l} = \frac{1}{16\pi G} \quad (7)$$

$$\frac{K_L - K_R}{4\pi l} = \frac{1}{94\pi G\nu}, \quad (8)$$

which gives

$$\frac{l}{G\nu} = 24(K_L - K_R). \quad (9)$$

Exploiting the fact that the action in Eqn.(6) is expressed in terms of the Chern-Simons theory, Witten used the topological arguments to conclude that

$$K_L \in Z/2, \quad K_L - K_R \in Z. \quad (10)$$

Here the fact that $SL(2, R)$ is double cover of $SO(2, 1)$ is used. The constraints in Eqn.(10) along with Eqns.(7,8) imply

$$\frac{l}{G\nu} = 24n \quad (11)$$

$$\frac{l}{8G} = \frac{m}{2}, \quad n, m \in Z. \quad (12)$$

From the above we also get $\nu = m/6n$. Thus topology forces the warping factor to be a rational number.

Warped AdS^3 black hole which is asymptotic to warped AdS^3 is free of naked closed time like curves and other pathologies arise as solution to the warped, topologically massive gravity

with $\nu^2 > 1$ [18, 19]. Note that although the generic structure of warped AdS^3 black hole is very different and have reduced symmetry compared to the unwarped case, the topological constraints of Witten which are independent of metric are still relevant.

We now turn to the explicit forms of C_L and C_R obtained in [9] which are

$$C_L = \frac{4\nu l}{G(\nu^2 + 3)} \quad (13)$$

$$C_R = \frac{(5\nu^2 + 3)l}{G\nu(\nu^2 + 3)}. \quad (14)$$

These results were confirmed using different approaches in [10, 11]. Furthermore, these central charges also obey

$$C_L - C_R = -\frac{l}{G\nu}, \quad (15)$$

which matched the diffeomorphism anomaly[21].

Using Eqns.(11) in Eqn.(15) we find

$$C_L - C_R = -24n, \quad n \in Z \quad (16)$$

which agrees with the requirement of modular invariance that the difference between the left and right moving ground state energies must be an integer. Substituting Eqn.(11) in Eqn.(15) and using Eqns.(13,14), we find

$$C_L = 24n \left(\frac{4\nu^2}{\nu^2 + 3} \right), \quad (17)$$

$$C_R = 24n \left(1 + \frac{4\nu^2}{\nu^2 + 3} \right). \quad (18)$$

There are several observations one can make about Eqns. (17) and (18). Note that for the usual BTZ black hole in 3d gravity, Witten argued that the central charges of the left and right moving sectors must be of the form $(24k_1, 24k_2)$ with k_1, k_2 integers. The CFT with a central charge $24k$ with $k = 1$ was constructed by Frenkel, Lepowsky and Meurman [22] and conjectured to be unique. Witten suggested that this unique CFT with an associated Monster Group symmetry was the quantum theory of the BTZ black hole. He further conjectured that such unique CFT's should also exist for $k > 1$ [1]. We note that the warped AdS_3 black hole central charges tend to multiples of 24 in the limit of large warping or for special values. This means that in these cases the black hole system tends to a conjectured pure gravity theory with a unique CFT description. In these cases the central charges are of the form $(24k_1, 24k_2)$, which is precisely the case considered by Witten. The special values for the warping factor for which this happens are:

$$\nu^2 = \frac{3k_1}{4k_2 - 5k_1}. \quad (19)$$

We also note that when $\nu^2 \gg 1$, for a fixed n ,

$$(C_L, C_R) \rightarrow (24n_1, 24n_2), \quad n_1 = 4n, \quad n_2 = 5n. \quad (20)$$

The large n_1, n_2 limit which we need to make contact with these values for central charges is expected to describe classical black hole. This is so as it is only for large ‘quantum charges’ that the quantum system is expected to have a classical description. In this limit all the thermodynamics quantities, S, T_L, T_R become large and classical. In general, the central charges do not have the $(24k_1, 24k_2)$ structure, for warped topologically massive gravity. However in these cases the central charges are still determined to be rational multiples of 24 with associated primary fields, whose dimension can be read off from the quasinormal modes that have been determined. It would be of interest to exploit this quantum information to carry out dynamical calculations.

Abstract

The AdS/CFT conjecture offers the possibility of a quantum description for a black hole in terms of a CFT. This has led to the study of general AdS^3 type black holes with a view to constructing an explicit toy quantum black hole model. Such a CFT description would be characterized by its central charge and the dimensions of its primary fields. Recently the expression for the central charges (C_L, C_R) of the CFT dual to the warped AdS^3 have been determined using asymptotic symmetry arguments. The central charges depend, as expected, on the warping factor. We show that topological arguments, used by Witten to constrain central charges for the BTZ black hole, can be generalized to deal with the warped AdS^3 case. Topology constrains the warped factor to be rational numbers while quasinormal modes are conjectured to give the dimensions of primary fields. We find that in the limit when warping is large or when it takes special rational values the system tends to Witten's conjectured unique CFT's with central charges that are multiples of 24.

Recently a generalization of the BTZ black hole, the warped AdS^3 black hole, arose in the context of topologically massive gravity [3, 4, 5, 6]. Using analogies suggested by the BTZ black hole [7, 8], the central charges C_L, C_R of the holomorphic and anti-holomorphic dual CFT's of the warped AdS^3 black holes were first conjectured in [9] and later these conjectured forms of C_L and C_R shown to follow from a study of the asymptotic symmetry of the warped AdS^3 black hole [10, 11, 12, 13]. The central charges were found to respect the gravitational anomaly constraint.

In view of these results we study if there are topological restriction on the central charge for the warped AdS^3 black hole, following the analysis of [9]. We note that the warped AdS_3 system has vector type excitations present and hence is not a pure gravity theory. Following the analysis of Witten [1] we find that topology restricts warping to rational numbers and that surprisingly for large warping the associated CFT tends to a pure gravity theory. This follows from the observation that in this limit the central charges for the associated CFT's are integral multiples of 24. Such CFT's, were conjectured by Witten [1] to be unique to represent pure gravity theories. We next observe that, following the treatment in [14, 15], that the conformal weights of the associated CFT's for the warped AdS^3 can also be determined from their quasinormal modes [16, 17, 18, 19]. Thus the associated dual CFT's are completely determined in terms of the warping factor and the quasinormal modes of the warped AdS^3 black hole.

The action for topologically massive gravity in three dimensions in terms of two Chern-Simons gauge theories is given by

$$S_{EH} = \frac{K_L + K_R}{2} (I_{CS}(A_L) - I_{CS}(A_R)) \quad (1)$$

and the gravitational Chern-Simons action has the form

$$S_{GCS} = \frac{K_L - K_R}{2} (I_{CS}(A_L) + I_{CS}(A_R)), \quad (2)$$

where I_{CS} is the Chern-Simon action given by

$$I_{CS}(A) = \frac{1}{4\pi} \int d^3x \operatorname{tr} \left(A \wedge dA + \frac{2}{3} A \wedge A \wedge A \right). \quad (3)$$

The allowed values of the coupling constants K_L, K_R get restrictions, if the gauge group is $SO(2, 1) \times SO(2, 1)$. The BTZ black hole has the symmetry under $SL(2, R) \times SL(2, R)$. Witten's idea was to think of $SL(2, R)$ as a double cover of the $SO(2, 1)$ [1]. From the fact that $SO(2, 1)$ has a compact $SO(2)$ subgroup in it, topological considerations restrict K_L, K_R values. We would like to investigate if Witten's restrictions are relevant for the warped AdS^3 black hole.

Consider the the action

$$S = \frac{1}{16\pi G} \int d^3x \sqrt{-g} \left(R + \frac{2}{l^2} \right) + \frac{l}{96\pi G\nu} \int d^3x \sqrt{-g} \epsilon^{\mu\nu\lambda} \Gamma_{\mu\sigma}^\rho \left(\partial_\lambda \Gamma_{\rho\lambda}^\sigma + \frac{2}{3} \Gamma_{\nu\beta}^\sigma \Gamma_{\lambda\rho}^\beta \right) \quad (4)$$

describing topologically massive gravity in three dimension. Here the warping factor $\nu = \mu l/3$ where μ is the mass and $\epsilon^{\mu\nu\lambda} = +1/\sqrt{-g}$. The second term in the above is the gravitational

Chern-Simon term $-I_{GCS}$. The warped black hole with $U(1) \times SL(2, R)$ symmetry is a classical solution to the above action which goes to warped AdS^3 asymptotically [9]. The warping was done by constructing a fibration of AdS^3 as $R \times SL(2, R)$. The resulting spacetime still has a constant negative curvature as AdS^3 but have a very different metric.

In order to get topological constraints we follow Witten[1] and replace $SL(2, R)$ by $SO(2, 1)$ and rewrite the above action in Eqn.(4) as a $SO(2, 1)$ gauge theory. We find that the action can be written as the sum of two Chern Simon terms of opposite chirality. This immediately allows us to use the topological ideas of Witten. We introduce $A_L = \omega - *e/l$, $A_R = \omega + *e/l$ where $*e = \epsilon^{abc}e_c$ is a two index object in $SO(2, 1)$ and ω is the spin connection. Using these A_L and A_R in Eqns.(1,2), we find

$$\frac{1}{\pi l} \int d^3x \sqrt{-g} (R + \frac{2}{l^2}) = -\frac{1}{\pi l} \int d^3x \text{tr}^*e (d\omega \wedge \omega) - \frac{l}{3\pi l^3} \int d^3x \text{tr}(*e \wedge *e \wedge *e). \quad (5)$$

The gravitational Chern-Simon action I_{GCS} can be written in terms of spin connection ω alone as $\int \text{tr} (1/2\pi)(\omega \wedge d\omega + (1/3\pi)\omega \wedge \omega \wedge \omega)$.

Thus the action for warped, topologically massive gravity given in Eqn.(4) can be expressed in terms of the Chern-Simon action for the gauge fields A_L and A_R as

$$S = S_{EH} + S_{GCS} \quad (6)$$

where S_{EH} and S_{GCS} are given in Eqns.(1,2). Comparing the coefficients of the above action with that in Eqn. (4), we get

$$\frac{K_L + K_R}{2\pi l} = \frac{1}{16\pi G} \quad (7)$$

$$\frac{K_L - K_R}{4\pi l} = \frac{1}{94\pi G\nu}, \quad (8)$$

which gives

$$\frac{l}{G\nu} = 24(K_L - K_R). \quad (9)$$

Exploiting the fact that the action in Eqn.(6) is expressed in terms of the Chern-Simons theory, Witten used the topological arguments to conclude that

$$K_L \in Z/2, \quad K_L - K_R \in Z. \quad (10)$$

Here the fact that $SL(2, R)$ is double cover of $SO(2, 1)$ is used. The constraints in Eqn.(10) along with Eqns.(7,8) imply

$$\frac{l}{G\nu} = 24n \quad (11)$$

$$\frac{l}{8G} = \frac{m}{2}, \quad n, m \in Z. \quad (12)$$

From the above we also get $\nu = m/6n$. Thus topology forces the warping factor to be a rational number.

Warped AdS^3 black hole which is asymptotic to warped AdS^3 is free of naked closed time like curves and other pathologies arise as solution to the warped, topologically massive gravity with $\nu^2 > 1$ [20, 21]. Note that although the generic structure of warped AdS^3 black hole is very different and have reduced symmetry compared to the unwarped case, the topological constraints of Witten which are independent of metric are still relevant.

We now turn to the explicit forms of C_L and C_R obtained in [9] which are

$$C_L = \frac{4\nu l}{G(\nu^2 + 3)} \quad (13)$$

$$C_R = \frac{(5\nu^2 + 3)l}{G\nu(\nu^2 + 3)}. \quad (14)$$

These results were confirmed using different approaches in [12, 13]. Furthermore, these central charges also obey

$$C_L - C_R = -\frac{l}{G\nu}, \quad (15)$$

which matched the diffeomorphism anomaly[23].

Using Eqns.(11) in Eqn.(15) we find

$$C_L - C_R = -24n, \quad n \in Z \quad (16)$$

which agrees with the requirement of modular invariance that the difference between the left and right moving ground state energies must be an integer. Substituting Eqn.(11) in Eqn.(15) and using Eqns.(13,14), we find

$$C_L = 24n \left(\frac{4\nu^2}{\nu^2 + 3} \right), \quad (17)$$

$$C_R = 24n \left(1 + \frac{4\nu^2}{\nu^2 + 3} \right). \quad (18)$$

There are several observations one can make about Eqns. (17) and (18). Note that for the usual BTZ black hole in 3d gravity, Witten argued that the central charges of the left and right moving sectors must be of the form $(24k_1, 24k_2)$ with k_1, k_2 integers. The CFT with a central charge $24k$ with $k = 1$ was constructed by Frenkel, Lepowsky and Meurman [24] and conjectured to be unique. Witten suggested that this unique CFT with an associated Monster Group symmetry was the quantum theory of the BTZ black hole. He further conjectured that such unique CFT's should also exist for $k > 1$ [1]. We note that the warped AdS_3 black hole central charges tend to multiples of 24 in the limit of large warping or for special values. This means that in these cases the black hole system tends to a conjectured pure gravity theory with a unique CFT description. In these cases the central charges are of the form $(24k_1, 24k_2)$, which is precisely the case considered by Witten. The special values for the warping factor for which this happens are:

$$\nu^2 = \frac{3k_1}{4k_2 - 5k_1}. \quad (19)$$

We also note that when $\nu^2 \gg 1$, for a fixed n ,

$$(C_L, C_R) \rightarrow (24n_1, 24n_2), \quad n_1 = 4n, \quad n_2 = 5n. \quad (20)$$

The large n_1, n_2 limit which we need to make contact with these values for central charges is expected to describe classical black hole. This is so as it is only for large ‘quantum charges’ that the quantum system is expected to have a classical description. In this limit all the thermodynamics quantities, S, T_L, T_R become large and classical. In general, the central charges do not have the $(24k_1, 24k_2)$ structure, for warped topologically massive gravity. However in these cases the central charges are still determined to be rational multiples of 24 with associated primary fields, whose dimension can be read off from the quasinormal modes that have been determined. It would be of interest to exploit this quantum information to carry out dynamical calculations.
