(Dated: September 29, 2018)

The second Fourier component v_2 of the azimuthal anisotropy with respect to the reaction plane was measured for direct photons at midrapidity and transverse momentum (p_T) of 1–13 GeV/c in Au+Au collisions at $\sqrt{s_{NN}} = 200$ GeV. Previous measurements of this quantity for hadrons with $p_T < 6$ GeV/c indicate that the medium behaves like a nearly perfect fluid, while for $p_T > 6$ GeV/c a reduced anisotropy is interpreted in terms of a path-length dependence for parton energy loss. In this measurement with the PHENIX detector at the Relativistic Heavy Ion Collider we find that for $p_T > 4$ GeV/c the anisotropy for direct photons is consistent with zero, as expected if the dominant source of direct photons is initial hard scattering. However, in the $p_T < 4$ GeV/c region dominated by thermal photons, we find a substantial direct photon v_2 comparable to that of hadrons, whereas model calculations for thermal photons in this kinematic region significantly underpredict the observed v_2 .

PACS numbers: 25.75.Dw

Direct photons are produced in various processes during the entire space-time history of relativistic heavy ion collisions and, due to their small coupling, can leave the collision region without appreciable further interaction. This makes them a sensitive and direct probe of all stages of the collision, including initial hard scattering, formation and evolution of the strongly interacting partonic medium, its transition to hadronic matter, and final decoupling [1, 2]. The transverse momentum (p_T) ranges populated by various production mechanisms overlap. However, azimuthal asymmetries tied to the event-byevent collision geometry provide useful additional information and a means to distinguish between sources of direct photons. In this paper we consider the second Fourier component $(v_2, \text{ often referred to as elliptic flow})$ of the event-by-event photon distribution in azimuth with respect to the reaction plane for minimum bias and selected centralities in Au+Au collisions.

At higher p_T (> 4 GeV/c) there are four fundamental sources of direct photons, characterized by different v_2 [2, 3]. Photons from initial hard scattering (predominantly from $qg \rightarrow q\gamma$ "gluon Compton scattering") are isotropic and so $v_2 = 0$. Jet fragmentation photons have positive v_2 since the energy loss of the originating parton is smaller in the reaction plane [4]. Jet-conversion photons where a hard scattered quark interacts with a thermal gluon in the medium and converts into a photon with almost equal p_T have negative v_2 [3], because the average pathlength of the parton in the medium (proportional to the conversion probability) is larger out of the reaction plane than within. Finally, Bremsstrahlung photons are also emitted preferentially in the direction where the medium is thicker, leading to a negative v_2 [3]. Note that in this picture the azimuthal asymmetry of high p_T photon production – while expressed in terms of v_2 - reflects the pure geometry of the medium, not its dynamics: it depends on the pathlength, not on the boost from the hydrodynamic pressure gradients.

The picture is quite different in the low p_T range $(1 < p_T < 4 \text{ GeV}/c)$ dominated by thermal photons, as first measured in [5], where bulk dynamics (expansion) plays an important role since it influences both the rate and azimuthal asymmetries of photon production [3, 6]. It is now established that collectivity – which already exists in the partonic phase (strongly interacting Quark-Gluon Plasma, sQGP) – persists after transition into the hadronic phase and the resulting azimuthal asymmetries in particle production can be described by near-ideal hydrodynamics. The expectation is that thermal radiation from both the sQGP and the hadronic phase will inherit the collective motion of the medium, i.e. will have a bona fide elliptic flow, positive v_2 at low p_T [7]. The low p_T behavior of direct photon v_2 puts constraints on the viscosity of the sQGP [6].

The PHENIX experiment has published the invariant yield as a function of p_T for direct photons both via real photons and internal conversions of nearly real virtual photons [5, 8]. In the $1 < p_T < 4 \text{ GeV}/c$ region, a substantial excess of direct photons was observed relative to scaling of p+p yields and has been interpreted in terms of thermal photon emission from the hot medium. An early attempt to infer v_2 of direct photons from a π^0 and inclusive photon v_2 measurement performed in a limited p_T range has been published in [9]. In this Letter we present measurements by the PHENIX experiment [10] of v_2 of π^0 and inclusive photons in a much extended transverse momentum (p_T) range (up to 13 GeV/c) in $\sqrt{s_{_{NN}}} = 200 \text{ GeV} \text{Au}+\text{Au} \text{ collisions.}$ Also, at low p_T the fraction R_{γ} of direct over inclusive photons is now measured with much higher precision [5] than before [8], therefore, for the first time a meaningful extraction of the direct photon v_2 itself is possible.

Data were taken in the 2007 run of the Relativistic Heavy Ion Collider at Brookhaven National Laboratory. The analyzed sample includes ~ 3.0×10^9 minimum bias Au+Au collisions. Events were triggered by the Beam-Beam Counters (BBC), as described in [11], which comprise two arrays of Čerenkov counters covering $3.1 < |\eta| < 3.9$ and 2π in azimuth in both beam directions (North and South). Event centrality was determined by the charge sum in the BBC.

The event-by-event reaction plane (RP) has been determined by two detectors, the first being the BBC itself. The RP resolution (effectively a dilution factor with which the observed v_2 is normalized to obtain the true v_2) is defined as $\sigma_{\rm RP} = \langle \cos[2(\Psi^{\rm true} - \Psi^{\rm RP})] \rangle$ and it is established by comparing event-by-event the RPs obtained separately in the North and South detectors. The resolution is highest in the 20-30% centrality bin where it reaches a value of 0.4. For the 2007 data taking period, a dedicated reaction plane detector (RXN) [12] was installed covering $1.0 < |\eta| < 2.8$ and the full azimuth. The RXN is a highly segmented lead-scintillator sampling detector providing much better measurement ($\sigma_{\rm RP} \sim 0.7$) than the BBC, but it is closer to the central $|\eta| < 0.35$ pseudorapidity region where v_2 is measured, making it more sensitive to jet bias in those (rare) events where a high p_T particle is observed. The 0.7/0.4 = 1.75 improvement on the reaction plane resolution results is a 1.75-fold improvement on point-by-point uncertainty.

Inclusive photons were measured in the PHENIX electromagnetic calorimeter [13]. Particles were identified (PID) and hadrons were rejected by a shower shape cut and a veto on charged particles using the Pad Chambers [14]. The remaining sample is collected for each p_T range in histograms binned according to $\Phi - \Psi^{\rm RP}$ where $\Psi^{\rm RP}$ is the azimuth of the event-by-event reaction plane and established independently by the BBC and RXN. These distributions are then fit for each p_T range with $N_0 \left[1 + 2 v_2 \cos\{2(\Phi - \Psi^{\rm RP})\}\right]$ to extract the raw $v_2^{\gamma, \rm meas}$ coefficient for inclusive photons. As a cross-check of the fit value, another $v_2^{\gamma,\text{meas}}$ is also calculated from the average cosine of the particles with respect to the reaction plane. While the PID eliminates virtually all hadrons above 6 GeV deposited energy (which might come from hadrons of any p_T above 6 GeV/c), a significant fraction of hadrons (up to 20% below 2 GeV deposited energy) survive the photon identification cuts. Since hadrons are known to have a large v_2 value, the observed v_2^{obs} of inclusive photons is obtained after correcting for hadrons as

$$v_2^{\gamma,\text{obs}} = \frac{v_2^{\gamma,\text{meas}} - (N^{\text{hadr}}/N^{\text{meas}})v_2^{\text{hadr}}}{1 - N^{\text{hadr}}/N^{\text{meas}}},$$

where v_2^{hadr} is the elliptic flow of hadrons and $N^{\text{hadr}}/N^{\text{meas}}$ is the fraction of hadrons in the sample surviving the PID cuts, as estimated from GEANT simulations (20% at 2 GeV, 10% at 4 GeV and negligible

above 6 GeV deposited energy). Finally the true $v_2^{\gamma,\text{inc}}$ for inclusive photons is obtained by dividing by the reaction plane resolution $v_2^{\gamma,\text{inc}} = v_2^{\gamma,\text{obs}}/\sigma_{\text{RP}}$.

A large fraction of inclusive photons comes from hadron decays, predominantly from π^0 (~80%) and η (~15%), with a small fraction coming from ρ, ω and η' decays, but only the $\pi^0 v_2$ is directly measured. The measurement of neutral pions and their v_2 is described in detail in [4, 15]. We assume that η, ω , etc. follow the same KE_T scaling observed in hadrons [16] where $KE_T = m_T - m$, Thus, $v_2^{\text{hadr}}(p_T)$ can be calculated for all hadrons from $v_2^{\pi^0}(p_T)$. For this we assume m_T -scaling of hadron p_T spectra and establish a "hadron cocktail" using the measured yield ratios, similar to the one in [5]. This cocktail is the input of a Monte Carlo simulation to calculate the total $v_2^{\gamma,\text{bg}}$ due to photons from hadron decays. The direct photon $v_2^{\gamma,\text{dir}}$ is then obtained using the $R_{\gamma}(p_T)$ "direct photon excess ratio" as

$$v_2^{\gamma, \text{dir}} = \frac{R_\gamma(p_T)v_2^{\gamma, \text{inc}} - v_2^{\gamma, \text{bg}}}{R_\gamma(p_T) - 1}$$

where $R_{\gamma}(p_T) = N^{\text{inc}}(p_T)/N^{bg}(p_T)$ with $N^{\text{inc}} = N^{\text{meas}} - N^{\text{hadr}}$, the number of inclusive photons, while $N^{bg}(p_T)$ is the number of photons attributed to hadron decay. Values of $R_{\gamma}(p_T)$ above 5 GeV/*c* are taken from the real photon measurement with the PHENIX electromagnetic calorimeter [8], and below that from the more accurate, but p_T -range limited internal conversion measurement of direct photons [5].

TABLE I: Systematic uncertainties $(\delta x/x)$ contributing to the direct photon $v_2^{\gamma,\text{dir}}$ measurement for minimum-bias collisions over two p_T ranges.

Contributing	Source	p_T range		Type
via		1-3 ${\rm GeV}/c$	10-16 ${\rm GeV}/c$	
$v_2^{\gamma, \text{inc}}$	remaining hadrons	2.2%	N/A	В
	v_2 extraction method	0.4%	0.6%	В
0				
$v_{2}^{\pi^{0}}$	particle ID	3.7%	6.0%	В
	normalization	0.4%	7.2%	В
	shower merging	N/A	4.0%	В
$\operatorname{subtraction}$	R_γ	3.1%	22%	В
common	reaction plane	6.3%	6.3%	\mathbf{C}

Sources of systematic uncertainties for representative p_T values are listed in Table I along with their characterization: type A means point-by-point uncertainties which are uncorrelated with p_T , type B means uncertainties that are correlated (with p_T) and type C is the overall normalization uncertainty, moving all points by the same fraction up or down. Since the v_2 measurement is a relative one (the azimuthal anisotropy is fit without the need to know the absolute normalization), the π^0 and

FIG. 1: (Color online) (a,b,c) v_2 in minimum bias collisions, using two different reaction plane detectors: (solid black circles) BBC and (solid red squares) RXN for (a) π^0 , (b) inclusive photon, and (c) direct photon. (d) direct photon fraction R_{γ} for (solid black circles) virtual photons [5] and (open blue squares) real photons [8] and (e) ratio of direct photon to π^0 v_2 for (solid black circles) BBC and (solid red squares) RXN. The vertical error bars on each data point indicate statistical uncertainties and shaded (gray and cyan) and hatched (red) areas around the data points indicate sizes of systematic uncertainties.

inclusive photon v_2 measurements are largely immune to energy scale uncertainties which are typically the dominant source of uncertainty in an absolute (invariant yield) measurement. The uncertainties on v_2 are dominated by the common uncertainty on determining $\sigma_{\rm RP}$ and by uncertainties on particle identification. Uncertainties from absolute yields enter indirectly via the hadron cocktail (normalization) and more directly at higher p_T (where the real photon measurement is used) by the $R_{\gamma}(p_T)$ needed to establish the direct photon v_2 . Note that due to the way $v_2^{\gamma, \rm dir}$ is calculated, once R_{γ} is large, its relative error contributes to the error on $v_2^{\gamma, \rm dir}$ less and less.

Figure 1 shows steps of the analysis using the minimum bias sample, as well as the differences between results obtained with BBC and RXN. The first v_2 of π^0 and inclusive photons $(v_2^{\pi^0}, v_2^{\gamma,inc})$ are measured, as described above (panels (a) and (b)). Then, using the $v_2^{\gamma,bg}$ of photons from hadronic decays and the R_{γ} direct photon excess ratio, we derive the $v_2^{\gamma,dir}$ of direct photons (panel (c)). Panel (d) shows the $R_{\gamma}(p_T)$ values from the direct photon invariant yield measurements using internal conversion [5] and real [8] photons, with their respective uncertainties. Panel (e) shows the ratio of $v_2^{\gamma,dir}/v_2^{\pi^0}$. We observe substantial direct photon flow in the low p_T region (c), commensurate with the hadron flow itself (e). However, in contrast to hadrons, the direct photon v_2 rapidly decreases with p_T ; and starting with 5 GeV/*c* and above, it is consistent with zero (c). The rapid transition from high direct photon flow at 3 GeV/*c* to zero flow at 5 GeV/*c* is also demonstrated on panel (e), since the $\pi^0 v_2$ changes little in this region [4].

FIG. 2: (Color online) (a,c,e) Centrality dependence of v_2 for (solid black circles) π^0 , (solid red squares) inclusive photons, and (b,d,f) (solid black circles) direct photons measured with the BBC detector for (a,b) minimum bias (c,d) 0-20% centrality, and (e,f) 20-40% centrality. For (b,d,f) the direct photon fraction is taken from [5] up to 4 GeV/c and from [8] for higher p_T . The vertical error bars on each data point indicate statistical uncertainties and the shaded (gray) and hatched (red) areas around the data points indicate sizes of systematic uncertainties.

A major issue in any azimuthal asymmetry measurement is the potential bias from where in pseudorapidity the (event-by-event) reaction plane is measured. At low p_T - where multiplicities are high and particle production is dominated by the bulk with genuine hydrodynamic behavior – there is no difference between the flow derived with BBC and RXN. However, at higher p_T we observe that the v_2 values using BBC and RXN diverge, particularly for π^0 (panel (a) in Fig. 1), less for inclusive photons. For direct photons (panel (c)) the two results are apparently consistent within their *total* errors, including the error $\delta R_{\gamma}/R_{\gamma}$ (see Table I) but it should be noted that R_{γ} is a common correction factor in the v_2 measurements with both reaction plane detectors.

Event substructure not related to bulk properties and expansion – most notably jets – can bias the reaction plane measurement, particularly at higher p_T and lower multiplicity. Observation of a high p_T particle practically guarantees the presence of a jet, which in turn modifies the event structure over a large η range. The bias on the true event plane (with the bulk as its origin) is stronger if the overall multiplicity is small and if the η gap between the central arm (where v_2 is measured) and the reaction plane detector is reduced. The bias in Fig. 1 is largest for π^0 , since high p_T hadrons are always jet fragments. Inclusive photons are a mixture of hadron decay photons, inheriting the bias seen in π^0 and the mostly unbiased direct photons, therefore, the difference between BBC and RXN is smaller. Finally, the bias is smallest (but nonzero) for direct photons, of which only a relatively small fraction (jet fragmentation photons) exhibit bias.

Figure 2 shows v_2 for minimum bias and two centralities as a function of transverse momentum for π^0 , inclusive and direct photons. For reaction plane determination the BBC is used because it is farthest from midrapidity where v_2 is measured. Despite the fact that there is a significant direct (thermal) photon yield at low p_T [5], the π^0 and inclusive photon v_2 is virtually identical there. Note that the surprisingly large inclusive photon v_2 is confirmed by the (so far preliminary) results with a completely different analysis technique [17]. For direct photons at low p_T we observe a pronounced positive v_2 signal, increasing with decreasing centrality and comparable to the π^0 flow, but then rapidly going toward zero at 5-6 GeV/c. Qualitatively this shape agrees with the prediction for very early thermalization times, 0.2-0.4 fm/c in [18], 0.2 fm/c and vanishing viscosity in [7], but both models severely underestimate the magnitude of the v_2 . The model in [19] combines somewhat later thermalization time (0.6 fm/c) with partial chemical equilibrium in the hadronic phase, reproducing the shape, but missing the magnitude of the observed v_2 at low p_T . While such large direct photon v_2 in principle could be attributed to a dominant production mechanism at the later stage when bulk flow is already developed, simultaneously explaining the large values of v_2 at $\sim 2 \text{ GeV}/c$ and its vanishing above 5 GeV/c remains a challenge to current theories.

Figure 3 shows the high p_T integrated v_2 ($p_T > 6 \text{ GeV}/c$) for π^0 and photons (inclusive and direct) as a function of centrality. The low N_{part} behavior is strongly influenced by the location in pseudorapidity of the reaction plane detector. The $\pi^0 v_2$ is comparable to other hadrons and is higher than the inclusive photon v_2 , which is diluted by direct photons. The two direct photon v_2 measurements (panel (c)) are consistent with zero (and each other) at all centralities within their total system-

FIG. 3: High p_T ($p_T > 6 \text{ GeV}/c$) integrated v_2 vs N_{part} for (a) π^0 , (b) inclusive photon, and (c) direct photon. Results are shown with both reaction plane detectors: (solid black circles) BBC and (solid red squares) RXN. Each point represents a 10% wide centrality bin from 60–0%. The vertical error bars on each data point indicate statistical uncertainties and the shaded (gray) and hatched (red) areas around the data points indicate sizes of systematic uncertainties.

atic errors. While zero v_2 would be expected if initial hard scattering is the dominant (sole considered) source of photons, it should be pointed out that the typical contribution from jet-conversion only would be $v_2 \sim -0.02$ and from fragmentation $v_2 \leq 0.01$ weighted with the fraction of photons coming from these specific processes [3, 7]. Currently the experiment is not sensitive to their negative/positive contributions to v_2 .

In conclusion, PHENIX has measured v_2 of π^0 , inclusive and direct photons in the $1 < p_T < 13 \text{ GeV}/c$ range for minimum bias and selected centralities in $\sqrt{s_{NN}} = 200 \text{ GeV Au}+\text{Au}$ collisions. At higher p_T (> 6 GeV/c) the direct photon v_2 is consistent with zero at all centralities, as expected if the dominant source of photon production is initial hard scattering. However, the experimental uncertainties are currently about a factor of 2 higher than the predicted (small) positive and negative contributions from fragmentation and jet conversion photons, respectively. In the thermal region ($p_T < 4 \text{ GeV}/c$), a positive direct photon v_2 is observed which is comparable in magnitude to the $\pi^0 v_2$ and consistent with early thermalization times and low viscosity, but its magnitude is much larger than current theories predict.

We thank the staff of the Collider-Accelerator and Physics Departments at Brookhaven National Laboratory and the staff of the other PHENIX participating institutions for their vital contributions. We acknowledge support from the Office of Nuclear Physics in the Office of Science of the Department of Energy, the National Science Foundation, Abilene Christian University Research Council, Research Foundation of SUNY, and Dean of the College of Arts and Sciences, Vanderbilt University (U.S.A), Ministry of Education, Culture, Sports, Science, and Technology and the Japan Society for the Promotion of Science (Japan), Conselho Nacional de Desenvolvimento Científico e Tecnológico and Fundação de Amparo à Pesquisa do Estado de São Paulo (Brazil), Natural Science Foundation of China (P.
