

THE p -ADIC ORDER OF POWER SUMS, THE ERDŐS–MOSER EQUATION, AND BERNOULLI NUMBERS

JONATHAN SONOW AND EMMANUEL TSUKERMAN

ABSTRACT. The *Erdős–Moser equation* is a Diophantine equation proposed more than 60 years ago which remains unresolved to this day. In this paper, we consider the problem in terms of divisibility of power sums and in terms of certain Egyptian fraction equations. As a consequence, we show that solutions must satisfy strong divisibility properties and a restrictive Egyptian fraction equation. Our studies lead us to results on the Bernoulli numbers and allow us to motivate Moser’s original approach to the problem.

1. INTRODUCTION

For $m \in \mathbb{N}$ and $n \in \mathbb{Z}$, define the *power sum*

$$S_n(m) := \sum_{j=1}^m j^n = 1^n + 2^n + \cdots + m^n$$

and set $S_n(0) := 0$. The *Erdős–Moser equation* is the Diophantine equation

$$(1) \quad S_n(m) = (m+1)^n.$$

Erdős and Moser [24] conjectured that the only solution is the trivial solution $1 + 2 = 3$, that is, $(m, n) = (2, 1)$. See Moree’s surveys “A top hat for Moser’s four mathemagical rabbits” [23] and [21], as well as Guy’s discussion in [12, Section D7].

The *generalized Erdős–Moser equation* is the Diophantine equation

$$(2) \quad S_n(m) = a(m+1)^n.$$

Moree [20] conjectured that the only solution is the trivial solution

$$1 + 2 + 3 + \cdots + 2a = a(2a + 1),$$

that is, $(m, n) = (2a, 1)$.

In this paper, we consider the equations from two angles: as problems on the divisibility of power sums and as problems on Egyptian fraction equations. In the final two sections, we consider implications of our results to the Bernoulli numbers, and motivate Moser’s “mathemagical rabbits.”

2. MAIN RESULTS

For $q \in \mathbb{Z}$ and prime p , the p -adic order of q is the exponent $v_p(q)$ of the highest power of p that divides q :

$$v_p : \mathbb{Z} \rightarrow \mathbb{N} \cup \{0, \infty\}, \quad v_p(q) := \sup_{p^d | q} d.$$

We note that the domain of definition of v_p can be extended to the p -adic integers $\mathbb{Z}_p \supset \mathbb{Z}$ by considering the digits of the base p expansion.

We also define a map

$$V_p : \mathbb{Z}_p \rightarrow \mathbb{N} \cup \{0, \infty\}, \quad V_p(m) := v_p(m - \lfloor \frac{m}{p} \rfloor) + 1.$$

This function can be interpreted as follows: $V_p(m)$ counts the number of equal p -digits at the end of the base p expansion of $m \in \mathbb{Z}_p$. That is, if we write m in base p as

$$m = \dots a_k \dots a_1 a_0 p = \sum_{i=0}^{\infty} a_i p^i,$$

and let

$$h = \sup\{i \in \mathbb{N} \cup \{0\} : a_i = a_j \ \forall 0 \leq j \leq i\},$$

then $V_p(m) = h + 1$.

Theorem 4. *Let p be an odd prime and let m be a positive integer.*

(i). *In case $m \equiv 0$ or $-1 \pmod{p}$, we have*

$$v_p(S_n(m)) \begin{cases} = v_p(S_{p-1}(m)) = V_p(m) - 1 & \text{if } p-1 \mid n, \\ \geq V_p(m) & \text{if } p-1 \nmid n. \end{cases}$$

(ii). *In case $m \equiv \frac{p-1}{2} \pmod{p}$, we have*

$$v_p(S_n(m)) \begin{cases} = v_p(S_{p-1}(m)) = V_p(m) - 1 & \text{if } n \text{ is even,} \\ \geq V_p(m) & \text{if } n \text{ is odd.} \end{cases}$$

As a result, we prove:

Theorem 6. *Let p be an odd prime.*

(i). *In the generalized Erdős–Moser equation, if $p \mid m+1$, then $p-1 \nmid n$.*

(ii). *In the Erdős–Moser equation, if $p \mid m$, then $p-1 \mid n$ and $p^2 \mid m+p$. Also, if $p \mid m - \frac{p-1}{2}$, then $p-1 \mid n$ and $m \equiv -(p + \frac{1}{2}) \pmod{p^2}$.*

Next we consider Egyptian fraction equations of the following form. For a given positive integer n , we seek an integer d so that the congruence

$$(3) \quad \sum_{p|n} \frac{1}{p} + \frac{d}{n} \equiv 1 \pmod{1}$$

holds. Integers n for which $d \equiv \pm 1 \pmod{n}$ are closely related to Giuga numbers and primary pseudoperfect numbers. Moreover, d as a function of n can be seen as an arithmetic derivative of n and is related to the arithmetic derivative considered in [3, 8, 27]. By studying these equations, we prove:

Theorem 12. *Let (m, n) be a nontrivial solution to the Erdős–Moser equation.*

(i). *The pair $(n, d) = (m - 1, 2^n - 1 - X)$ satisfies congruence (3), where*

$$X := \sum_{\substack{p|m-1, \\ p-1 \nmid n}} \frac{m-1}{p}.$$

(ii). *If $p \mid m - 1$, then $n = p - 1 + k \cdot \text{ord}_p(2)$ for some $k \geq 0$.*

(iii). *Given $p \mid m - 1$, if $p^e \mid m - 1$ with $e \geq 1$, then $p^{e-1} \mid 2^n - 1$.*

(iv). *Given $p \mid m - 1$, if $p - 1 \mid n$ and $p^e \mid 2^n - 1$ with $e \geq 1$, then $p^{e+1} \mid m - 1$; in particular, $p^2 \mid m - 1$.*

As an application, combining this with the result of [21] that $3^5 \mid n$, we see that if (m, n) is a solution of the Erdős–Moser equation with $m \equiv 1 \pmod{3}$, then in fact $m \equiv 1 \pmod{3^7}$.

3. POWER SUMS

In all the formulas of this paper, *the letter p denotes a prime number*, unless “integer p ” is specified.

For $m \in \mathbb{N}$ and $n \in \mathbb{Z}$, define the *power sum*

$$S_n(m) := \sum_{j=1}^m j^n = 1^n + 2^n + \cdots + m^n$$

and set $S_n(0) := 0$. Fixing a prime p , we define the *restricted power sum* $S_n^*(0) := 0$ and

$$S_n^*(m) = S_n^*(m, p) := \sum_{\substack{j=1, \\ (j,p)=1}}^m j^n,$$

obtained from $S_n(m)$ by removing the terms j^n with j divisible by p . (Compare [10, equation (2.1)].) For example, $S_n(p) - p^n = S_n(p - 1) = S_n^*(p - 1) = S_n^*(p)$ and, by induction on $d \in \mathbb{N}$,

$$(4) \quad S_n(p^d) = S_n^*(p^d) + p^n S_n^*(p^{d-1}) + p^{2n} S_n^*(p^{d-2}) + \cdots + p^{dn} S_n^*(p^0).$$

We now prove the linearity of certain restricted and unrestricted power sums upon reduction modulo prime powers.

Lemma 1. *If p is a prime, $d, q \in \mathbb{N}$, $N \in \mathbb{Z}$, $m_1 \in p^d \mathbb{N} \cup \{0\}$, and $m_2 \in \mathbb{N} \cup \{0\}$, then*

$$S_n^*(qm_1 + m_2) \equiv qS_n^*(m_1) + S_n^*(m_2) \pmod{p^d}.$$

Furthermore, the congruence also holds with all S_n^ replaced by the unrestricted sum S_n .*

Proof. Note first that

$$S_n^*(qp^d) = \sum_{\substack{k=1, \\ (k,p)=1}}^{p^d q} k^n = \sum_{j=0}^{q-1} \sum_{\substack{k=1, \\ (k,p)=1}}^{p^d} (p^d j + k)^n \equiv q \sum_{\substack{k=1, \\ (k,p)=1}}^{p^d} k^n \equiv qS_n^*(p^d) \pmod{p^d}.$$

Since $m_1 \in p^d\mathbb{N} \cup \{0\}$, we therefore have

$$\begin{aligned} S_n^*(qm_1 + m_2) &= \sum_{\substack{k=1, \\ (k,p)=1}}^{qm_1+m_2} k^n = \sum_{\substack{k=1, \\ (k,p)=1}}^{qm_1} k^n + \sum_{\substack{j=1, \\ (j,p)=1}}^{m_2} (qm_1 + j)^n \\ &\equiv qS_n^*(m_1) + S_n^*(m_2) \pmod{p^d}, \end{aligned}$$

as desired. The proof in the unrestricted case is similar. \square

Theorem 1. *Let p be an odd prime, and assume $d, q \in \mathbb{N}$ and $n \in \mathbb{Z}$. Then*

$$S_n^*(p^dq) \equiv \begin{cases} -p^{d-1}q \pmod{p^d} & \text{if } p-1 \mid n, \\ 0 \pmod{p^d} & \text{if } p-1 \nmid n. \end{cases}$$

Proof. By Lemma 1, it suffices to prove the theorem in the special case where $q = 1$. Let $\phi(n)$ denote Euler's totient function. Since

$$S_0^*(p^d) = \phi(p^d) = p^{d-1}(p-1) \equiv -p^{d-1} \pmod{p^d}$$

and $p-1 \mid 0$, the result holds when $n = 0$.

Now assume $n \neq 0$. As $d > 0$ and p is an odd prime, p^d has a primitive root g . Then g has multiplicative order $\phi(p^d)$ modulo p^d , and $g^n \neq 1$. Hence $S_n^*(p^d)$ is congruent to

$$S_n^*(p^d) = \sum_{\substack{j=1, \\ (j,p)=1}}^{p^d} j^n \equiv \sum_{i=0}^{\phi(p^d)-1} (g^i)^n \equiv \sum_{i=0}^{\phi(p^d)-1} (g^n)^i \equiv \frac{g^{n\phi(p^d)} - 1}{g^n - 1} \pmod{p^d}.$$

We now consider the case $n > 0$. If $p-1 \mid n$, then Fermat's Little Theorem implies $g^n = 1 + kp$, for some $k > 0$. Hence

$$S_n^*(p^d) \equiv \frac{(1+kp)^{\phi(p^d)} - 1}{(1+kp) - 1} \equiv \frac{\phi(p^d)kp + \binom{\phi(p^d)}{2}(kp)^2 + \cdots + (kp)^{\phi(p^d)}}{kp} \equiv \phi(p^d) \pmod{p^d}.$$

Thus $S_n^*(p^d) \equiv -p^{d-1} \pmod{p^d}$, as desired. This proves the result when $p-1 \mid n$.

If $p-1 \nmid n$, then a fortiori $\phi(p^d) \nmid n$, and so $g^n \not\equiv 1 \pmod{p}$. As $g^{\phi(p^d)} \equiv 1 \pmod{p^d}$,

$$S_n^*(p^d) \equiv \frac{g^{n\phi(p^d)} - 1}{g^n - 1} \equiv 0 \pmod{p^d}.$$

This proves the result when $p-1 \nmid n$, and the proof of the case $n > 0$ is complete.

The case $n < 0$ follows, because another primitive root of p^d is $g^{\phi(p^d)-1} \equiv g^{-1} \pmod{p^d}$, and so $S_n^*(p^d) \equiv S_{-n}^*(p^d) \pmod{p^d}$. This completes the proof of the theorem. \square

In the following application of Theorem 1, the case $d = q = 1$ is classical. (For a recent elementary proof of that case, as well as a survey of other proofs and applications of it, see [16].)

Corollary 2. *Let p be an odd prime and $n, d, q \in \mathbb{N}$. Then*

$$1^n + 2^n + \cdots + (p^dq)^n \equiv \begin{cases} -p^{d-1}q \pmod{p^d} & \text{if } p-1 \mid n, \\ 0 \pmod{p^d} & \text{if } p-1 \nmid n. \end{cases}$$

In particular, $S_n(p^dq) \equiv 0 \pmod{p}$ if $d > 1$ or $p > n + 1$.

Proof. By the linearity of Lemma 1, it suffices to prove the result when $q = 1$. In case $n = 1$, then $p - 1 \nmid n$ and $S_n(p^d) = p^d(p^d + 1)/2 \equiv 0 \pmod{p^d}$, verifying this case. For $n > 1$, we reduce both sides of equation (4) modulo p^d , then apply Theorem 1 to each term on the right-hand side, obtaining $S_n(p^d) \equiv S_n^*(p^d) \pmod{p^d}$. The corollary follows. \square

For example, taking $q = p$ gives

$$S_n(p^{d+1}) \equiv 0 \pmod{p^d},$$

whether or not $p - 1$ divides n . For instance, $S_2(9) = 285 \equiv 0 \pmod{3}$ and $S_1(9) = 45 \equiv 0 \pmod{3}$.

On the other hand, taking $q = 1$ and replacing d with $d + 1$ in Corollary 2 gives

$$p - 1 \mid n \implies S_n(p^{d+1}) \not\equiv 0 \pmod{p^{d+1}}.$$

For example, $S_2(9) = 285 \not\equiv 0 \pmod{9}$.

Corollary 3. For $n \in \mathbb{N}$,

$$\text{prime } p \geq n + 2 \implies \frac{1}{1^n} + \frac{1}{2^n} + \cdots + \frac{1}{(p-1)^n} \equiv 0 \pmod{p}.$$

Proof. The sum is $S_{-n}(p-1) = S_{-n}^*(p)$, and the formula follows from Theorem 1 by replacing n with $-n$ and setting $d = q = 1$. \square

Taking $n = 1$, the congruence $S_{-1}(p-1) \equiv 0$ actually holds modulo p^2 , if $p \geq 5$, by *Wolstenholme's theorem* [29, 18].

The following theorem provides us with additional information about the divisibility of power sums.

Proposition 4. Given integers $p, q \geq 1, n \geq 0$, and $d \geq c \geq 0$, set $\delta = d - c$. Then

$$S_n(p^d q) = p^\delta q S_n(p^c) + \sum_{k=1}^n \binom{n}{k} p^{ck} (S_k(p^\delta q) - (p^\delta q)^k) S_{n-k}(p^c).$$

Proof. We have

$$\begin{aligned} S_n(p^d q) &= \sum_{j=0}^{p^\delta q - 1} \sum_{i=1}^{p^c} (jp^c + i)^n = \sum_{j=0}^{p^\delta q - 1} \sum_{i=1}^{p^c} \left(i^n + \sum_{k=1}^n \binom{n}{k} (jp^c)^k i^{n-k} \right) \\ &= \sum_{j=0}^{p^\delta q - 1} \sum_{i=1}^{p^c} i^n + \sum_{k=1}^n \binom{n}{k} p^{ck} \sum_{j=0}^{p^\delta q - 1} j^k \sum_{i=1}^{p^c} i^{n-k}. \end{aligned}$$

Using $\sum_{j=0}^{p^\delta q - 1} j^k = S_k(p^\delta q) - (p^\delta q)^k$, the desired formula follows. \square

Corollary 5. For any prime $p \geq 5$ and integer $n \geq 0$, the following congruence holds:

$$S_n(p^2) \equiv p S_n(p) + p n S_{n-1}(p) (S_1(p) - p) \pmod{p^3}.$$

Proof. If $n = 0$ or 1 , it is easy to verify the congruence. Now, assume that $n \geq 2$ and set $d = 2$ and $c = 1$ in Theorem 4. Then

$$\begin{aligned} S_n(p^2) &= p S_n(p) + \sum_{k=1}^n \binom{n}{k} p^k (S_k(p) - p^k) S_{n-k}(p) \\ &\equiv p S_n p + n p (S_1(p) - p) S_{n-1}(p) + \binom{n}{2} p^2 (S_2(p) - p^2) S_{n-2}(p) \pmod{p^3}. \end{aligned}$$

Since $p \geq 5$ implies that $S_2(p)$ is divisible by p , the proof is complete. \square

Corollary 5 fails with $p = 3$. Indeed, take $n = 1$. Then $S_n(p^2) = S_1(9) = 45$, whereas $pS_n(p) + pnS_{n-1}(p)(S_1(p) - p)$ equals

$$3S_1(3) + 3S_2(3)(S_1(3) - 3) = 18 + 3 \cdot 14(6 - 3) = 144 \not\equiv 45 \pmod{3^3}.$$

Recall that *Pascal's identity* is

$$(5) \quad \sum_{k=0}^{n-1} \binom{n}{k} S_k(a) = (a+1)^n - 1,$$

valid for $a \geq 0$ and $n \geq 1$ (see, e.g., [16]). Here is an analog for even exponents.

Theorem 2 (A Pascal identity for even exponents). *For any integer $a \geq 0$ and even $n \geq 2$,*

$$\sum_{k=0}^{(n-2)/2} \binom{n}{2k} S_{2k}(a) = \frac{1}{2} ((a+1)^n - (a^n + 1)).$$

Proof. Since n is even, the Binomial Theorem gives

$$\begin{aligned} S_n(a+1) + S_n(a-1) - 1 &= \sum_{j=1}^a ((1+j)^n + (1-j)^n) = \sum_{j=1}^a \sum_{k=0}^n \binom{n}{k} j^k (1 + (-1)^k) \\ &= 2 \sum_{j=1}^a \sum_{k=0}^{n/2} \binom{n}{2k} j^{2k} = 2 \sum_{k=0}^{n/2} \binom{n}{2k} \sum_{j=1}^a j^{2k}. \end{aligned}$$

Using $S_n(m) = \sum_{j=1}^m j^n = S_n(m-1) + m^n$, we can write this as

$$2S_n(a) + (a+1)^n - a^n - 1 = 2 \sum_{k=0}^{n/2} \binom{n}{2k} S_{2k}(a).$$

As $n \geq 2$, subtracting $2S_n(a)$ from both sides and then dividing by 2 yields the desired formula. \square

For an application of Pascal's identity to Bernoulli numbers, see Section 5.

Theorem 3. *Let p be an odd prime and let m and n be positive integers.*

(i). *For some integer $d \geq 1$, we can write*

$$m = qp^d + r \frac{p^d - 1}{p - 1} = qp^d + rp^{d-1} + rp^{d-2} + \cdots + rp^0,$$

where $r \in \{0, 1, \dots, p-1\}$ and $0 \leq q \not\equiv r \pmod{p}$.

(ii). *In case $m \equiv 0 \pmod{p}$, we have*

$$S_n(m) \equiv \begin{cases} -p^{d-1}q \pmod{p^d} & \text{if } p-1 \mid n, \\ 0 \pmod{p^d} & \text{if } p-1 \nmid n. \end{cases}$$

(iii). *In case $m \equiv -1 \pmod{p}$, we have*

$$S_n(m) \equiv \begin{cases} -p^{d-1}(q+1) \pmod{p^d} & \text{if } p-1 \mid n, \\ 0 \pmod{p^d} & \text{if } p-1 \nmid n. \end{cases}$$

(iv). In case $m \equiv \frac{p-1}{2} \pmod{p}$, we have

$$S_n(m) \equiv \begin{cases} -p^{d-1} \left(q + \frac{1}{2} \right) & \pmod{p^d} \quad \text{if } p-1 \mid n, \\ 0 & \pmod{p^d} \quad \text{if } p-1 \nmid n \text{ and } n \text{ is even.} \end{cases}$$

Proof. Since $m > 0$, we can write it in base p as $m = a_k a_{k-1} \dots a_d a_{d-1} \dots a_1 a_0$ with a leading zero $a_k = 0$, all $a_i \in \{0, 1, \dots, p-1\}$, and $r := a_0 = a_1 = \dots = a_{d-1} \neq a_d$, where $d \geq 1$. Then $m = qp^d + r \frac{p^d-1}{p-1}$, where $0 \leq q = \sum_{i=0}^{k-d} a_{d+i} p^i \equiv a_d \not\equiv r \equiv m \pmod{p}$, proving (i).

If $m \equiv 0 \pmod{p}$, then $r = 0$. Hence $m = p^d q$, and Corollary 2 implies (ii).

Reducing binomials of the form $(qp^d + j)^n$ modulo p^d shows that

$$S_n(m) = S_n \left(qp^d + r \frac{p^d-1}{p-1} \right) \equiv S_n(qp^d) + S_n \left(r \frac{p^d-1}{p-1} \right) \pmod{p^d},$$

and Corollary 2 computes the term $S_n(qp^d)$ modulo p^d . It remains to compute the last term modulo p^d in case $m \equiv -1$ or $\frac{p-1}{2} \pmod{p}$.

If $m \equiv -1 \pmod{p}$, then $r = p-1$. Now,

$$S_n \left(r \frac{p^d-1}{p-1} \right) = S_n(p^d - 1) = S_n(p^d) - p^{dn} \equiv S_n(p^d) \pmod{p^d},$$

and another application of Corollary 2 yields (iii).

Finally, if $m \equiv \frac{p-1}{2} \pmod{p}$, then $r = \frac{p-1}{2}$ and

$$S_n \left(r \frac{p^d-1}{p-1} \right) = S_n \left(\frac{p^d-1}{2} \right).$$

To compute the latter modulo p^d when n is even, we write

$$S_n(p^d - 1) = \sum_{k=1}^{(p^d-1)/2} (k^n + (p^d - k)^n) \equiv 2S_n \left(\frac{p^d-1}{2} \right) \pmod{p^d}.$$

Since $S_n(p^d - 1) \equiv S_n(p^d) \pmod{p^d}$, we get

$$n \text{ even} \implies S_n \left(\frac{p^d-1}{2} \right) \equiv \frac{1}{2} S_n(p^d) \pmod{p^d},$$

and a final application of Corollary 2 gives (iv). \square

Definition 1. For $q \in \mathbb{Z}$ and prime p , the p -adic order of q is the exponent $v_p(q)$ of the highest power of p that divides q :

$$v_p : \mathbb{Z} \rightarrow \mathbb{N} \cup \{0, \infty\}, \quad v_p(q) := \sup_{p^d | q} d.$$

The function $v_p(\cdot)$ is totally additive: $v_p(x \cdot y) = v_p(x) + v_p(y)$ for any x and y . Note that $v_p(q) \in \mathbb{N} \cup \{0\}$ for $q \neq 0$, and $v_p(0) = \infty$.

For the next result, we will find it useful to write a positive integer m in a certain nice form which allows us to determine the least d for which $S_n(m) \pmod{p^d}$ is not zero for n divisible by $p-1$. More generally, we let m lie in the p -adic integers \mathbb{Z}_p and note that v_p can be defined on \mathbb{Z}_p by considering the digits of the base p expansion.

Definition 2. Define a map $V_p : \mathbb{Z}_p \rightarrow \mathbb{N} \cup \{0, \infty\}$ by

$$V_p(m) := v_p(m - \lfloor \frac{m}{p} \rfloor) + 1.$$

This function can be interpreted as follows: $V_p(m)$ counts the number of equal p -digits at the end of the base p expansion of $m \in \mathbb{Z}_p$.

Lemma 6. Write $m \in \mathbb{Z}_p$ in base p as

$$m = \dots a_k \dots a_1 a_0 = \sum_{i=0}^{\infty} a_i p^i,$$

with $a_i \in \{0, 1, \dots, p-1\}$ for each i . Let

$$h = \sup\{i \in \mathbb{N} \cup \{0\} : a_i = a_j \ \forall 0 \leq j \leq i\}.$$

Then $V_p(m) = h + 1$.

Proof. Indeed,

$$m - \lfloor \frac{m}{p} \rfloor = \sum_{i=0}^{\infty} a_i p^i - \sum_{i=0}^{\infty} a_{i+1} p^i.$$

If $h = \infty$ then the result follows. Assume then that h is finite. For each of the indices $i = 1, 2, \dots, h-1$, we have $a_i = a_{i+1}$. For the index $i = h$, by assumption $a_h \neq a_{h+1}$. Therefore $v_p(m - \lfloor \frac{m}{p} \rfloor) = h$. \square

A few comments regarding V_p are in order. From Lemma 6, we see that $V_p(m) = \infty$ exactly when all base p digits of m are the same. The values of $m \in \mathbb{Z}_p$ for which this occurs are

$$m = -\frac{r}{p-1} = \dots rrrr_p = \sum_{i=0}^{\infty} r p^i$$

for $r \in \{0, 1, \dots, p-1\}$. In particular, this is the case for $m = -1, 0$, and $-\frac{1}{2}$ when p is odd.

Let $V_p(m) = d$. Then, as in Theorem 3, we may write $m = qp^d + a_0 \sum_{k=0}^{d-1} p^k$ with $0 \leq q \not\equiv a_0 \pmod{p}$.

Remark 7. If $m \equiv -1 \pmod{p}$, then the equalities $V_p(m) = V_p(m+1) = v_p(m+1)$ hold. Indeed, write m in base p as

$$m = \dots a_h (p-1)(p-1) \dots (p-1)_p,$$

with $a_h \neq p-1$ so that $V_p(m) = h$. Notice that $a_h \neq p-1$ implies $v_p(m+1) = h$ because $m+1 = \dots a_{h+1}(a_h+1)00 \dots 0_p$, since $a_h < p-1$. Thus $V_p(m) = V_p(m+1) = v_p(m+1)$.

Theorem 4. Let p be an odd prime and let m be a positive integer.

(i). In case $m \equiv 0$ or $-1 \pmod{p}$, we have

$$v_p(S_n(m)) \begin{cases} = v_p(S_{p-1}(m)) = V_p(m) - 1 & \text{if } p-1 \mid n, \\ \geq V_p(m) & \text{if } p-1 \nmid n. \end{cases}$$

(ii). In case $m \equiv \frac{p-1}{2} \pmod{p}$, we have

$$v_p(S_n(m)) \begin{cases} = v_p(S_{p-1}(m)) = V_p(m) - 1 & \text{if } n \text{ is even,} \\ \geq V_p(m) & \text{if } n \text{ is odd.} \end{cases}$$

Proof. This follows immediately from Theorem 3. \square

As an example, take $p = 3$ and $m = 1222_3$ in base 3. In particular, there are three copies of 2 at the end, so we know that $V_3(m) = 3$. By Theorem 4, for any even n ,

$$v_3(S_n(m)) = v_3(S_2(m)) = V_3(m) - 1 = 2.$$

As $m = 53$, this agrees with the fact that $S_2(53) = 53 \cdot 54(2 \cdot 53 + 1)/6 = 51039 = 3^2 \cdot 53 \cdot 107$.

We note that Theorem 4 is tight. Indeed, take $p = 5$ and $n = 8$, so that $p - 1 \mid n$. Besides $m \equiv 0, (p - 1)/2, p - 1 \pmod{p}$, consider the remaining two congruence classes, namely $m \equiv 1, 3 \pmod{5}$. First, take $m = 6 \equiv 1 \pmod{5}$. We then have $S_4(6) = 2275 \equiv 0 \pmod{25}$, whereas $S_8(6) = 2142595 \equiv 20 \pmod{25}$. Now take $m = 18 \equiv 3 \pmod{5}$. Then $S_4(18) = 432345 \equiv 20 \pmod{25}$, whereas $S_8(18) = 27957167625 \equiv 0 \pmod{25}$. Thus in both cases $v_p(S_n(m)) \neq v_p(S_{p-1}(m))$.

As an application, we obtain a simple proof of the following classical result.

Corollary 8. *For even n , the polynomial in $\mathbb{Q}[x]$ interpolating $S_n(x)$ is divisible by the product $x(x + 1)(2x + 1)$.*

Proof. Fix an odd prime p . First, consider the sequence $x_i = p^i$, for $i = 1, 2, \dots$. We have $v_p(x_i) = i$, so that $x_i \rightarrow 0$ p -adically. On the other hand, $v_p(S_n(x_i)) \geq V_p(x_i) - 1 = i - 1$ by Theorem 4. Therefore $S_n(x_i) \rightarrow 0$ p -adically. By continuity, $x = 0$ is a root of $S_n(x)$.

Similarly, consider the sequence $x_i = \sum_{j=0}^i (p - 1)p^j$, for $i = 1, 2, \dots$. This sequence converges p -adically to -1 . Theorem 4 gives $v_p(S_n(x_i)) \geq V_p(x_i) - 1 = i - 1$. Therefore, $x = -1$ is a root of $S_n(x)$.

Finally, the sequence $x_i = \sum_{j=0}^i \frac{p-1}{2} p^j$, which converges p -adically to $-1/2$, shows that $x = -1/2$ is a root of $S_n(x)$. \square

The next result gives two special cases of Theorem 4.

Corollary 9. *Let m and n be positive integers.*

(i). *The 3-adic order of $S_{2n}(m)$ equals*

$$v_3(S_{2n}(m)) = v_3(m(m + 1)(2m + 1)/3) = V_3(m) - 1.$$

(ii). *If $m \equiv 0, 2$, or $4 \pmod{5}$, then the 5-adic order of $S_{4n}(m)$ equals*

$$v_5(S_{4n}(m)) = v_5(m(m + 1)(2m + 1)(3m^2 + 3m - 1)/5) = V_5(m) - 1.$$

Proof. Take $p = 3$ and 5 in Theorem 4, and use the formulas $S_2(m) = m(m + 1)(2m + 1)/6$ and $S_4(m) = m(m + 1)(2m + 1)(3m^2 + 3m - 1)/30$, respectively. \square

We recall an analogous result for the prime 2. (The result is not used in this paper.)

Theorem 5 (MacMillan and Sondow [17]). *For any positive integers m and n , the 2-adic order of $S_n(m)$ equals*

$$v_2(S_n(m)) = \begin{cases} v_2(m(m + 1)/2) & \text{if } n = 1 \text{ or } n \text{ is even,} \\ 2v_2(m(m + 1)/2) & \text{if } n \geq 3 \text{ is odd.} \end{cases}$$

As an application of our results to the the Erdős–Moser equation, we have the following theorem. Part (i) is due to Moree [20, Proposition 9].

Theorem 6. *Let p be an odd prime.*

(i). *In the generalized Erdős–Moser equation, if $p \mid m + 1$, then $p - 1 \nmid n$.*

(ii). *In the Erdős–Moser equation, if $p \mid m$, then $p - 1 \mid n$ and $p^2 \mid m + p$. Also, if $p \mid m - \frac{p-1}{2}$, then $p - 1 \mid n$ and $m \equiv -(p + \frac{1}{2}) \pmod{p^2}$.*

Proof. (i). Assume that $m \equiv -1 \pmod{p}$. Then by Remark 7 we have $V_p(m) = v_p(m + 1)$. If $p - 1 \mid n$, then using Theorem 4 and applying v_p to both sides of equation (2) gives

$$V_p(m) - 1 = v_p(S_n(m)) = v_p(a) + nv_p(m + 1) = v_p(a) + nV_p(m),$$

contradicting $v_p \geq 0$ and $V_p \geq 0$. Therefore $p - 1 \nmid n$.

(ii). If $p \mid m$, write $m = p^d q$, with $d > 0$ and $p \nmid q$. Reducing both sides of (1) modulo p^d , we deduce that $S_n(m) \equiv 1 \pmod{p^d}$. Hence, by Theorem 3, we must have $p - 1 \mid n$ and

$$S_n(m) \equiv -p^{d-1}q \pmod{p^d}.$$

Thus $-\frac{m}{p} = -p^{d-1}q \equiv 1 \pmod{p^d}$. Since $d \geq 1$, this implies $m \equiv -p \pmod{p^2}$.

If $m \equiv \frac{p-1}{2} \pmod{p}$, write $m = a_d p^d + \frac{p^d-1}{2}$. Reducing both sides of (1) modulo p^d , we see that

$$S_n(m) \equiv \left(\frac{p^d+1}{2}\right)^n \pmod{p^d}.$$

By Theorem 3, we see that $p - 1 \mid n$ and

$$-p^{d-1}(a_d + 2^{-1}) \equiv \left(\frac{p^d+1}{2}\right)^n \equiv (2^{-1})^n \pmod{p^d}.$$

Hence $d = 1$. Using the fact that the multiplicative order of any element of $(\mathbb{Z}/p\mathbb{Z})^*$ divides $p - 1$, we obtain $a_d \equiv -1 - 2^{-1} \pmod{p}$. Therefore $m \equiv -p - 2^{-1} \pmod{p^2}$. \square

Theorem 7. (i). *Any non-trivial solution of the generalized Erdős–Moser equation must have $m \equiv 0$ or $4 \pmod{6}$. Furthermore, if $m \equiv 4 \pmod{5}$, then $n \equiv 2 \pmod{4}$.*

(ii). *Any non-trivial solution of the Erdős–Moser equation must have $m \equiv 6$ or $10 \pmod{18}$.*

Proof. (i). By [20, 24] (see also [17]), any non-trivial solution of (2) has $m \equiv n \equiv 0 \pmod{2}$. Since n is even, Theorem 6 part (i) implies $m \not\equiv 2 \pmod{3}$. Hence $m \equiv 0$ or $4 \pmod{6}$, proving the first part of (i). The second part follows from Corollary 9 part (ii).

(ii). Since n is even, we can apply Corollary 9 part (i) to equation (1), yielding

$$v_3(m(m+1)(2m+1)) - 1 = nv_3(m+1),$$

that is,

$$v_3(m) + v_3(2m+1) = 1 + (n-1)v_3(m+1).$$

It follows that $m \equiv 1, 3, 6$, or $7 \pmod{9}$.

According to [23, Equations 6, 10, 12, 13], in any solution (m, n) of the Erdős–Moser equation, m , $\frac{m+2}{2}$, $2m+1$, and $2m+3$ are all square-free. Also, Moree [21, Theorem 1], whose m is our $m+1$, showed that our $m \equiv 0 \pmod{2}$. The condition that $2m+3$ is square-free eliminates the case $m \equiv 3 \pmod{9}$. In the case $m \equiv 7 \pmod{9}$, the Chinese Remainder Theorem would imply $m \equiv 34 \pmod{72}$, contradicting the square-freeness of

$$\frac{m+2}{2} \equiv 18 \pmod{36}.$$

Therefore $m \equiv 1$ or $6 \pmod{9}$. Since m is even, it follows that $m \equiv 6$ or $10 \pmod{18}$. \square

4. EGYPTIAN FRACTION EQUATIONS

Fix a positive integer n . The congruence

$$(6) \quad \sum_{p|n} \frac{1}{p} + \frac{d}{n} \equiv 1 \pmod{1}$$

is equivalent to the congruence

$$(7) \quad d \equiv - \sum_{p|n} \frac{n}{p} \pmod{n}.$$

In particular, there are always integer solutions d .

Definition 3. We denote one solution of (6) by

$$(8) \quad d(n) := - \sum_{p|n} \frac{n}{p}.$$

If n is composite and $d(n) \equiv -1 \pmod{n}$, then n is called a *Giuga number*.

In other words, a *Giuga number* is a composite number n satisfying the *Egyptian fraction condition*

$$\sum_{p|n} \frac{1}{p} - \frac{1}{n} \in \mathbb{N}.$$

All known Giuga numbers n in fact satisfy the *Egyptian fraction equation*

$$\sum_{p|n} \frac{1}{p} - \frac{1}{n} = 1,$$

which holds if and only if $d(n) = -1 - n$. In that case, we call n a *strong Giuga number*. The first few (strong) Giuga numbers are [4], [19], [25, Sequence A007850]

$$n = 30, 858, 1722, 66198, 2214408306, 24423128562, 432749205173838, \dots$$

Definition 4. If $n > 1$ and $d(n) = 1 - n$, then n is called a *primary pseudoperfect number*.

Equivalently, Butske, Jaje, and Mayernik [6] *define a primary pseudoperfect number to be a solution $n > 1$ to the Egyptian fraction equation*

$$\sum_{p|n} \frac{1}{p} + \frac{1}{n} = 1.$$

It follows from Definition 3 that *if $d(n) \equiv \pm 1 \pmod{n}$, then n is square-free*. In particular, *all Giuga and primary pseudoperfect numbers are square-free*.

The primary pseudoperfect numbers with $k \leq 8$ (distinct) prime factors are [6, Table 1], [25, Sequence A054377]

$$n_k = 2, 6, 42, 1806, 47058, 2214502422, 52495396602, 8490421583559688410706771261086.$$

Each n_k has exactly k (distinct) prime factors, $k = 1, 2, 3, 4, 5, 6, 7, 8$. Moreover, the n_k are the only known solutions to the congruence $d(n) \equiv 1 \pmod{n}$.

In some cases the next result can be used to generate new Giuga and primary pseudoperfect numbers from given ones. Part (i) is from [28] and part (iii) is a special case of Brenton and Hill [5, Proposition 12] (see also [6, Lemma 4.1]).

Theorem 8. (i). *Assume $n + 1$ is an odd prime. Then n is a primary pseudoperfect number if and only if $n(n + 1)$ is also a primary pseudoperfect number.*

(ii). *Assume $n - 1$ is a prime. Then n is a primary pseudoperfect number if and only if $n(n - 1)$ is a strong Giuga number.*

(iii). *Assume $n^2 + 1 = FG$, where $n + F$ and $n + G$ are prime. Then n is a primary pseudoperfect number if and only if $n(n + F)(n + G)$ is also a primary pseudoperfect number.*

(iv). *Assume $n^2 - 1 = FG$, where $n + F$ and $n + G$ are prime. Then n is a primary pseudoperfect number if and only if $n(n + F)(n + G)$ is a strong Giuga number.*

Proof. In the proof of (i), (ii), take all \pm signs to be $+$, or all to be $-$, and likewise in the proof of (iii), (iv).

(i), (ii). We can write

$$\sum_{p|n} \frac{1}{p} + \frac{1}{n} = \sum_{p|n} \frac{1}{p} + \frac{1}{n \pm 1} + \left(\frac{1}{n} - \frac{1}{n \pm 1} \right) = \sum_{p|n(n \pm 1)} \frac{1}{p} \pm \frac{1}{n(n \pm 1)},$$

as $n \pm 1$ is prime. This implies (i) and (ii).

(iii), (iv). Since $n^2 \pm 1 = f^2$ has no solutions in positive integers, the primes $n + F$ and $n + G$ are distinct. Setting $M := n(n + F)(n + G)$, we therefore have

$$\begin{aligned} \sum_{p|M} \frac{1}{p} \pm \frac{1}{M} &= \sum_{p|n} \frac{1}{p} + \frac{1}{n + F} + \frac{1}{n + G} \pm \frac{1}{M} = \sum_{p|n} \frac{1}{p} + \frac{n(n + F) + n(n + G) \pm 1}{M} \\ &= \sum_{p|n} \frac{1}{p} + \frac{1}{n}, \end{aligned}$$

because $n^2 \pm 1 = FG$ implies $n(n + F) + n(n + G) \pm 1 = (n + F)(n + G)$. This proves (iii) and (iv). \square

Example 1. For examples of (i), let n be one of the four primary pseudoperfect numbers

$$2, \quad 6 = 2 \cdot 3, \quad 42 = 2 \cdot 3 \cdot 7, \quad 47058 = 2 \cdot 3 \cdot 11 \cdot 23 \cdot 31.$$

Then the primes $n + 1 = 3, 7, 43, 47059$ yield the primary pseudoperfect numbers

$$n(n + 1) = 6, 42, 1806, 2214502422$$

For (ii), if $n = 6, 42$, or 47058 , then $n - 1 = 5, 41$, or 47057 is prime, and the products

$$n(n - 1) = 30, 1722, 2214408306$$

are strong Giuga numbers.

Notice here the three pairs of twin primes

$$(n - 1, n + 1) = (5, 7), (41, 43), (47057, 47059).$$

Is this more than just a coincidence? In other words:

Question 1. Let $n > 2$ be a primary pseudoperfect number. Is $n - 1$ prime if and only if $n + 1$ is prime? Equivalently (by Theorem 8), is $n(n - 1)$ a strong Giuga number if and only if $n(n + 1)$ is a primary pseudoperfect number?

Example 2. The only known example of Theorem 8 part (iii) begins with the primary pseudoperfect number

$$n_6 = 2214502422 = 2 \cdot 3 \cdot 11 \cdot 23 \cdot 31 \cdot 47059.$$

Factoring

$$n_6^2 + 1 = 4904020977043866085 = 2839805 \cdot 1726886521097 =: F^+ \cdot G^+$$

leads to the primes $n_6 + F^+$ and $n_6 + G^+$ and then to the largest known primary pseudoperfect number

$$\begin{aligned} n_8 &= n_6(n_6 + F^+)(n_6 + G^+) = 2 \cdot 3 \cdot 11 \cdot 23 \cdot 31 \cdot 47059 \cdot 2217342227 \cdot 1729101023519 \\ &= 8490421583559688410706771261086. \end{aligned}$$

The number n_6 also provides an example of (iv). Namely, the factorization

$$n_6^2 - 1 = 4904020977043866083 = 45193927 \cdot 108510618629 =: F^- \cdot G^-$$

yields the primes $n_6 + F^-$ and $n_6 + G^-$ and hence the strong Giuga number

$$\begin{aligned} n_6(n_6 + F^-)(n_6 + G^-) &= 2 \cdot 3 \cdot 11 \cdot 23 \cdot 31 \cdot 47059 \cdot 2259696349 \cdot 110725121051 \\ &= 554079914617070801288578559178. \end{aligned}$$

Another example of (iv) begins with n_8 and ends with the largest known (strong) Giuga number

$$\begin{aligned} &2 \cdot 3 \cdot 11 \cdot 23 \cdot 31 \cdot 47059 \cdot 2217342227 \cdot 1729101023519 \cdot 58254480569119734123 \cdot 8491659218261819498490029296021 \\ &= 4200017949707747062038711509670656632404195753751630609228764416142557211582098432545190323474818541298976556403, \end{aligned}$$

discovered by R. Girgensohn [4].

Proposition 10. *An ordered pair (n, d) is a solution to the congruence (6) if and only if*

$$(9) \quad p \mid n \implies d \equiv -\frac{n}{p} \pmod{p^{v_p(n)}}.$$

In that case, let p be a prime factor of n and $e \in \mathbb{N}$. Then p^e divides n if and only if p^{e-1} divides d . In particular, n is square-free if and only if n and d are coprime.

Proof. If (n, d) is a solution, then (7) reduced modulo $p^{v_p(n)}$ implies (9). The converse follows from the Chinese Remainder Theorem, and we infer the proposition. \square

The next theorem gives three properties of the function $n \mapsto d(n)$. The first is a power rule. The second shows that the function $n \mapsto d(n)$ satisfies Leibnitz's product rule, but only on coprime integers; in other words, it is "Leibnitzian," but not "totally Leibnitzian." The third is an analog of the quotient rule.

Theorem 9. (i). *For $k, n \in \mathbb{N}$, we have $d(n^k) = n^{k-1}d(n)$.*

(ii). *Given $M, n \in \mathbb{N}$, denote their greatest common divisor by $G := \gcd(M, n)$ and their least common multiple by $L := \text{lcm}(M, n)$. Then*

$$d(Mn) = Md(n) + nd(M) - Ld(G).$$

In particular,

$$\gcd(M, n) = 1 \implies d(Mn) = Md(n) + nd(M).$$

(iii). *Let a and b be positive integers with $b \mid a$. Set $\gamma := \gcd(b, a/b)$. Then*

$$d\left(\frac{a}{b}\right) = \frac{bd(a) - ad(b)}{b^2} + \frac{a/b}{\gamma}d(\gamma).$$

In particular, when $\gamma = 1$ we have the standard quotient rule.

Proof. (i). By Definition 3,

$$d(n^k) = - \sum_{p|n^k} \frac{n^k}{p} = -n^{k-1} \sum_{p|n} \frac{n}{p} = n^{k-1}d(n).$$

(ii). Since $G = \gcd(M, n)$,

$$\sum_{p|Mn} \frac{1}{p} = \sum_{p|M} \frac{1}{p} + \sum_{p|n} \frac{1}{p} - \sum_{p|G} \frac{1}{p}.$$

Multiplying through by $-Mn$, we write the result as

$$d(Mn) = - \sum_{p|Mn} \frac{Mn}{p} = -n \sum_{p|M} \frac{M}{p} - M \sum_{p|n} \frac{n}{p} + \frac{Mn}{G} \sum_{p|G} \frac{G}{p}.$$

Since $L = Mn/G$, the first conclusion follows. If $G = 1$, then $\sum_{p|G} \frac{1}{p} = 0$, and we get the product rule.

(iii). By part (ii),

$$d(a) = d\left(b\frac{a}{b}\right) = \frac{a}{b}d(b) + bd\left(\frac{a}{b}\right) - \frac{a}{\gamma}d(\gamma).$$

Dividing by b and solving for $d(\frac{a}{b})$ yields (iii). \square

For a prime p , Definition 3 gives

$$(10) \quad d(p) = -\frac{p}{p} = -1$$

On the other hand, the *arithmetic derivative* [3, 8, 27] of p is defined as $p' = 1$, and that of a product ab is defined as $(ab)' = ab' + ba'$. (Also, $0' := 1' := 0$.) Thus, for square-free $n > 1$, both $d(n)$ and the arithmetic derivative n' can be calculated by applying Leibnitz's product rule to the prime factorization of n . Therefore,

$$(11) \quad n > 1 \text{ square-free} \implies d(n) = -n'.$$

In 2010 Lava [2, p. 129] conjectured that Giuga numbers are the solutions of the differential equation $n' = n + 1$. Grau and Oller-Marcén [11] proved in 2011 that Giuga numbers are the solutions of the differential equation $n' = an + 1$, with $a \in \mathbb{N}$.

The following result shows that if k and n are Giuga numbers or primes, then the product kn cannot be a Giuga number, and that the product of two primary pseudoperfect numbers cannot be another one. (In contrast, the product of a primary pseudoperfect number and a prime can be either a primary pseudoperfect number, e.g., $6 \cdot 7 = 42$, or a Giuga number, e.g., $6 \cdot 5 = 30$, or neither, e.g., $6 \cdot 11 = 66$ —compare Theorem 8.)

Theorem 10. *The product of two integers each of which is either a Giuga number or a prime is never a Giuga number, and the product of two primary pseudoperfect numbers is never a primary pseudoperfect number.*

Proof. We show more generally that, if $M > 1$ and $n > 1$ are coprime integers satisfying $d(M) \equiv \epsilon \pmod{M}$ and $d(n) \equiv \epsilon \pmod{n}$, where $\epsilon = \pm 1$, then $d(Mn) \not\equiv \epsilon \pmod{Mn}$. Indeed, Theorem 9 part (ii) gives

$$d(Mn) = Md(n) + nd(M) \equiv \epsilon(M + n) \pmod{Mn}$$

and it follows that the congruence $d(Mn) \equiv \epsilon \pmod{Mn}$ holds only if $M = 1$ or $n = 1$, a contradiction. \square

Proposition 11. *Given a positive integer n , let P be the set of its distinct prime divisors, and let Q and R be subsets of P satisfying $Q \cup R = P$ and $Q \cap R = \emptyset$. Suppose that (n, d_Q) and (n, d_R) satisfy the congruences*

$$\sum_{p \in Q} \frac{1}{p} + \frac{d_Q}{n} \equiv 1 \equiv \sum_{p \in R} \frac{1}{p} + \frac{d_R}{n} \pmod{1}.$$

Then d_Q and d_R are related by $d_Q + d_R = d$, where (n, d) is a solution to congruence (6).

Proof. We have

$$d = d_Q + d_R \equiv - \sum_{p \in Q} \frac{n}{p} - \sum_{p \in R} \frac{n}{p} \equiv - \sum_{p \in P} \frac{n}{p} \equiv - \sum_{p|n} \frac{n}{p} \pmod{n}$$

and the result follows. \square

An interesting variation on the Egyptian fraction equation (6) is obtained by replacing the integers in the definition with polynomials having integer coefficients. Let $n(x) = p_1(x)p_2(x) \cdots p_m(x) \in \mathbb{Z}[x]$, with $p_i(x) \in \mathbb{Z}[x]$ primitive and irreducible in $\mathbb{Q}[x]$ for each i . From now on, we will assume that polynomials denoted by $p(x)$ are prime in this sense. We seek $d(x) \in \mathbb{Z}[x]$ such that

$$(12) \quad \sum_{p(x)|n(x)} \frac{1}{p(x)} + \frac{d(x)}{n(x)} \equiv 1 \pmod{1}.$$

As before, solutions are given by

$$d(x) \equiv - \sum_{p(x)|n(x)} \frac{n(x)}{p(x)} \pmod{n(x)}.$$

Example 3. Take $n(x) = p_1(x)p_2(x)p_3(x)$, where the polynomials $p_1(x) = x$, $p_2(x) = -2x+1$ and $p_3(x) = -2x-1$ are prime. Then

$$\frac{1}{x} + \frac{1}{-2x+1} + \frac{1}{-2x-1} + \frac{d(x)}{x(-2x+1)(-2x-1)} = \frac{-1+d(x)}{x(-2x+1)(-2x-1)}.$$

Consequently, $d(x) \equiv 1 \pmod{n(x)}$ is a solution to (12). Thus, taking $x = p$ for some prime $p \in \mathbb{Z}$, if $-2p+1$ and $-2p-1$ are also prime, then $n(p)$ satisfies an equation akin to that of a primary pseudoperfect number, although the primes may be negative. For instance, we may take $p = 19$, $-2p+1 = -37$ and $-2p-1 = -39$ to conclude that the number $27417 = 19 \times -37 \times -39$ is almost primary pseudoperfect:

$$\frac{1}{19} + \frac{1}{-37} + \frac{1}{-39} + \frac{1}{27417} = 0.$$

To prove the square-freeness of m , $\frac{m+2}{2}$, $2m+1$, and $2m+3$, Moser [24] showed that if (m, n) is a solution of the Erdős–Moser equation, then $(m, 1)$, $(m+2, 2)$, $(2m+1, 2)$ and $(2m+3, 4)$ are solutions (n, d) to the congruence (6). We now aim to find an additional solution of the form $(n, d) = (m-1, x)$.

We employ the *Carlitz-von Staudt Theorem* [7, Theorem 4], as corrected by Moree [23, Theorem 3].

Theorem 11 (Carlitz-von Staudt). *Let n and m be positive integers. Then*

$$S_n(m) \equiv \begin{cases} -\sum_{\substack{p|m+1, \\ p-1|n}} \frac{m+1}{p} \pmod{m+1} & \text{if } n \text{ is even,} \\ 0 \pmod{m(m+1)/2} & \text{if } n \text{ is odd.} \end{cases}$$

Proof of the first case. When n is even, apply Corollary 2 to each factor $p^{v_p(m+1)}$ of $m+1$ and use the Chinese Remainder Theorem. \square

Theorem 12. *Let (m, n) be a nontrivial solution to the Erdős–Moser equation.*

(i). *Let*

$$X := \sum_{\substack{p|m-1, \\ p-1|n}} \frac{m-1}{p}.$$

The pair $(n, d) = (m-1, 2^n - 1 - X)$ satisfies congruence (6).

(ii). *If $p \mid m-1$, then $n = p-1 + k \cdot \text{ord}_p(2)$ for some $k \geq 0$.*

(iii). *Given $p \mid m-1$, if $p^e \mid m-1$ with $e \geq 1$, then $p^{e-1} \mid 2^n - 1$.*

(iv). *Given $p \mid m-1$, if $p-1 \mid n$ and $p^e \mid 2^n - 1$ with $e \geq 1$, then $p^{e+1} \mid m-1$; in particular, $p^2 \mid m-1$.*

Proof. (i). Rearranging the Erdős–Moser equation, we have

$$S_n(m-2) = (m+1)^n - m^n - (m-1)^n \equiv 2^n - 1 \pmod{m-1}.$$

As in the proof of Theorem 7, the hypothesis implies n is even. Hence, by the Carlitz-von Staudt Theorem,

$$-\sum_{\substack{\ell|m-1, \\ \ell-1|n}} \frac{m-1}{\ell} \equiv 2^n - 1 \pmod{m-1},$$

where ℓ denotes a prime. By Proposition 11, this proves (i).

(ii). If $p \mid m-1$, but $p-1 \nmid n$, then reducing both sides modulo p yields $2^n \equiv 1 \pmod{p}$, so that n is a multiple of $\text{ord}_p(2)$. Recall that $\text{ord}_p(2) \mid p-1$. It follows that if $p \mid m-1$, then n is a multiple of $\text{ord}_p(2)$.

We now show that $n \geq p-1$. We refer to [22, Lemma 6], a result of Moser, which states that $3n \geq 2m$. This implies that $n \geq p-1$ and proves (ii).

(iii). By Proposition 10,

$$p^e \mid m-1 \implies p^{e-1} \mid 2^n - 1 - X.$$

Since $X \equiv 0 \pmod{p^{e-1}}$, result (iii) follows.

(iv). Finally, assume that $p-1 \mid n$. We proceed by induction on $e \geq 1$. For the base case $e=1$, since $p-1 \mid n$ and $p \mid m-1$, we have $2^n - 1 - X \equiv 0 \pmod{p}$. By Proposition 10, the base case follows. Now assume (iv) for $e \geq 1$. Then since $m-1 \equiv 0 \pmod{p^e}$ and $p-1 \mid n$, we get $2^n - 1 - X \equiv 0 \pmod{p^e}$. By Proposition 10, the induction is complete. \square

Corollary 12. *If (m, n) is a solution of the Erdős–Moser equation with $m \equiv 1 \pmod{3}$, then in fact $m \equiv 1 \pmod{3^7}$.*

Proof. It is known [21] that n is divisible by $2^8 \cdot 3^5$. Therefore $\phi(3^6) \mid n$, and it follows that $2^n - 1 \equiv 0 \pmod{3^6}$. Now Theorem 12 part (iv) implies $3^7 \mid m-1$. \square

5. BERNOULLI NUMBERS

In this section, we apply some of the results of previous sections to study the *Bernoulli numbers* $B_0, B_1, B_2, B_3, B_4, \dots = 1, -1/2, 1/6, 0, -1/30, \dots$

Corollary 13. *For $n \geq 1$ and every positive integer $m \leq n$, we have the relation*

$$\sum_{k=m-1}^{n-1} (-1)^k \binom{n}{k} \binom{k+1}{m} \frac{B_{k+1-m}}{k+1} = (-1)^{m+1} \binom{n}{m}.$$

Proof. By *Bernoulli's formula* (see, e.g., Conway and Guy [9, pp. 106–109]), the polynomial

$$(13) \quad P_n(x) := \frac{1}{n+1} \sum_{j=0}^n (-1)^j \binom{n+1}{j} B_j x^{n+1-j}$$

satisfies

$$(14) \quad S_n(a) = P_n(a)$$

for any positive integers n and a . Substituting this into Pascal's identity (5), we expand the right-hand side and get

$$\sum_{k=0}^{n-1} \binom{n}{k} \frac{1}{k+1} \sum_{j=0}^k (-1)^j \binom{k+1}{j} B_j a^{k+1-j} = \sum_{m=1}^n \binom{n}{m} a^m.$$

Setting $n = k + 1 - j$, we can write this as

$$\sum_{k=0}^{n-1} \sum_{n=1}^{k+1} (-1)^{k+1-n} \binom{n}{k} \binom{k+1}{n} \frac{B_{k+1-n}}{k+1} a^n = \sum_{m=1}^n \binom{n}{m} a^m.$$

Since this holds for all $a > 0$, we may equate coefficients when $n = m$, and the desired formula follows. \square

In particular, the case $m = 1$ is

$$\sum_{k=0}^{n-1} (-1)^k \binom{n}{k} B_k = n.$$

Since $B_1 = -1/2$ and $B_{2n+1} = 0$ for $n > 0$, this case is equivalent to

$$(15) \quad \sum_{k=0}^{n-1} \binom{n}{k} B_k = 0,$$

which is the standard recursion for the Bernoulli numbers. Thus, Corollary 13 is a generalization of this recursion.

As a numerical example, take $n = 8$ and $m = 3$:

$$\begin{aligned} \sum_{k=2}^6 (-1)^k \binom{8}{k} \binom{k+1}{3} \frac{B_{k-2}}{k+1} &= \frac{28}{3} B_0 - 56 B_1 + 140 B_2 - \frac{560}{3} B_3 + 140 B_4 \\ &= \frac{28}{3} + 28 + \frac{70}{3} - 0 - \frac{14}{3} = 56 = \binom{8}{3}, \end{aligned}$$

as predicted.

Corollary 14. *Let $n \geq 2$ be even and let $m < n$ be a positive integer. Then*

$$\sum_{k=\lceil (m-1)/2 \rceil}^{(n-2)/2} \binom{n}{2k} \binom{2k+1}{m} \frac{B_{2k+1-m}}{2k+1} = (-1)^{m+1} \frac{1}{2} \binom{n}{m},$$

where $\lceil \cdot \rceil$ denotes the ceiling function.

Proof. We follow the steps in the previous proof, except that instead of Pascal's identity we use its analog for even exponents, Theorem 2. Details are omitted. \square

For example, again take $n = 8$ and $m = 3$:

$$\begin{aligned} \sum_{k=1}^3 \binom{8}{2k} \binom{2k+1}{3} \frac{B_{2k-2}}{2k+1} &= \frac{28}{3} B_0 + 140 B_2 + 140 B_4 \\ &= \frac{28}{3} + \frac{70}{3} - \frac{14}{3} = 28 = \frac{1}{2} \binom{8}{3}, \end{aligned}$$

also as predicted.

Comparing the numerical examples for Corollaries 13 and 14, one sees that Corollary 14 follows from Corollary 13, together with the standard recursion (15) solved for B_1 .

Let us now adopt Kellner's notation [14] and write the Bernoulli numbers as

$$B_k = \frac{n_k}{D_k}$$

in lowest terms with $D_k > 0$. Thus,

$$\frac{n_0}{D_0} = \frac{1}{1}, \frac{n_1}{D_1} = \frac{-1}{2}, \frac{n_3}{D_3} = \frac{n_5}{D_5} = \frac{n_7}{D_7} = \frac{n_9}{D_9} = \cdots = \frac{0}{1},$$

and

$$\frac{n_{2n}}{D_{2n}} = \frac{1}{6}, \frac{-1}{30}, \frac{1}{42}, \frac{-1}{30}, \frac{5}{66}, \frac{-691}{2730}, \frac{7}{6}, \frac{-3617}{510}, \frac{43867}{798}, \frac{-174611}{330}, \frac{854513}{138}, \frac{-236364091}{2730}, \dots,$$

for $n = 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, \dots$, respectively.

Recall that the *von Staudt-Clausen Theorem* states that, for $n \geq 1$,

$$(16) \quad \sum_{p-1|2n} \frac{1}{p} + B_{2n} \equiv 1 \pmod{1}.$$

As a consequence, the denominator of B_{2n} is the square-free number $D_{2n} = \prod_{p-1|2n} p$. Then multiplying (16) by D_{2n} gives

$$n_{2n} \equiv - \sum_{p|D_{2n}} \frac{D_{2n}}{p} \pmod{D_{2n}}.$$

It now follows from the definition of $d(n)$ in (8) that *the numerator of B_{2n} satisfies*

$$n_{2n} \equiv d(D_{2n}) \pmod{D_{2n}}.$$

Theorem 13. *Let n and k be positive integers. For the difference $B_{2nk} - B_{2n}$,*

(i). *the denominator equals*

$$\text{denom}(B_{2nk} - B_{2n}) = \frac{D_{2nk}}{D_{2n}} \in \mathbb{N},$$

(ii). and the numerator satisfies the congruence

$$\text{numer}(B_{2nk} - B_{2n}) \equiv d(\text{denom}(B_{2nk} - B_{2n})) \pmod{\text{denom}(B_{2nk} - B_{2n})}.$$

Proof. (i). For any $m \in \mathbb{N}$, the von Staudt-Clausen Theorem gives $B_{2m} = A_m - \sum_{p-1|2m} \frac{1}{p}$, where $A_m \in \mathbb{Z}$. Hence

$$(17) \quad B_{2nk} - B_{2n} = A_{nk} - A_n - \left(\sum_{p-1|2nk} \frac{1}{p} - \sum_{p-1|2n} \frac{1}{p} \right) = A_{nk} - A_n - \sum_{\substack{p-1|2nk, \\ p-1 \nmid 2n}} \frac{1}{p}.$$

Therefore,

$$\text{denom}(B_{2nk} - B_{2n}) = \prod_{\substack{p-1|2nk, \\ p-1 \nmid 2n}} p = \frac{\prod_{p-1|2nk} p}{\prod_{p-1|2n} p} = \frac{D_{2nk}}{D_{2n}} \in \mathbb{N}.$$

(ii). Writing $\frac{P}{Q} := B_{2nk} - B_{2n}$, we have, by part (i) and equation (17),

$$\sum_{p|Q} \frac{1}{p} + \frac{P}{Q} = \sum_{\substack{p-1|2nk, \\ p-1 \nmid 2n}} \frac{1}{p} + \frac{P}{Q} \equiv 1 \pmod{1}.$$

Since $d(Q) = -\sum_{p|Q} \frac{Q}{p}$, we obtain $P \equiv d(Q) \pmod{Q}$, proving (ii). \square

For example, taking $n = 1$ and $k = 12$, we have

$$B_{24} - B_2 = \frac{-236364091}{2730} - \frac{1}{6} = \frac{-39394091}{455}.$$

From Theorem 9 part (ii) and equation (10), we compute that d of the denominator equals

$$d(455) = d(5 \cdot 7 \cdot 13) = -5 \cdot 7 - 5 \cdot 13 - 7 \cdot 13 = -191.$$

These calculations agree with (i) and (ii), which in this example state that

$$\text{denom}(B_{24} - B_2) = \frac{D_{24}}{D_2} = \frac{2730}{6} = 455$$

and that $-39394091 \equiv d(455) \pmod{455}$.

Here is a result due to Agoh [1] (see also [4, pp. 41, 49] and [13]).

Theorem 14 (Agoh). *The following statements about a positive integer n are equivalent:*

(i). $p \mid \left(\frac{n}{p} - 1\right)$, for each prime factor p of n .

(ii). $S_{n-1}(n-1) \equiv -1 \pmod{n}$.

(iii). $nB_{n-1} \equiv -1 \pmod{n}$.

We prove a related result, using a theorem of Kellner.

Theorem 15. (i). *Let n and d be positive integers, with n square-free. Then $p \mid \left(\frac{n}{p} + d\right)$, for each prime factor p of n , if and only if $S_{\phi(n)}(n) \equiv d \pmod{n}$.*

(ii). *For any positive integer n , we have the congruence*

$$S_{\phi(n)}(n) \equiv nB_{\phi(n)} \pmod{n}.$$

Proof. (i). The statement holds for $n = 1$. Now take $n > 2$, let p be a prime factor of n , and set $n = pq$. Then using Lemma 1 we have

$$\sum_{j=1}^n j^{\phi(n)} \equiv q \sum_{j=1}^p j^{\phi(n)} \equiv q \sum_{j=1}^{p-1} j^{\phi(n)} \pmod{p}.$$

Since n is square-free, $\gcd(p, q) = 1$ and so $\phi(n) = \phi(p)\phi(q)$. Thus $\phi(n)$ is divisible by $\phi(p) = p - 1$, and hence by Fermat's little theorem,

$$q \sum_{j=1}^{p-1} j^{\phi(n)} \equiv q(p-1) \equiv -q \pmod{p}.$$

As $q = n/p$, we get

$$(18) \quad \text{prime } p \mid n \implies \sum_{j=1}^n j^{\phi(n)} \equiv -\frac{n}{p} \pmod{p}.$$

To prove (i), assume first that $p \mid (\frac{n}{p} + d)$ for all primes $p \mid n$, so that $-\frac{n}{p} \equiv d \pmod{p}$. Together with (18) and the square-freeness of n , this implies that $\sum_{j=1}^n j^{\phi(n)} \equiv d \pmod{n}$. Conversely, if the latter holds, then (18) yields $-\frac{n}{p} \equiv d \pmod{p}$. This proves (i).

(ii). It is easy to see that (ii) holds if $n = 1$ or 2 . Now take $n \geq 3$ and recall that then $\phi(n)$ is even. For any $n, m \in \mathbb{N}$ with n even, Kellner [13, Theorem 1.2] proved that

$$S_n(m) \equiv (m+1)B_n \pmod{m+1}.$$

Setting $n = \phi(n)$ and $m = n - 1$, part (ii) follows. \square

When $n > 3$ is prime, we can improve part (ii) to a supercongruence.

Theorem 16. *If $p > 3$ is prime, then*

$$S_{p-1}(p) \equiv pB_{p-1} \pmod{p^3}.$$

Proof. Bernoulli's formula (14) gives $S_{p-1}(p-1) = P_{p-1}(p-1)$. For prime $p > 3$, the von Staudt-Clausen Theorem (16) implies that $P_{p-1}(p-1) \equiv pB_{p-1} \pmod{p^3}$ (for details, see the proof of [26, Theorem 1], where $P_{p-1}(p-1)$ is written symbolically as $(B+p)^p/p$). As $S_{p-1}(p) \equiv S_{p-1}(p-1) \pmod{p^3}$, this proves the theorem. \square

6. MOSER'S MATHEMATICAL RABBITS

In this section, we reveal some of the magic behind Moser's "mathematical rabbits" [23]. In particular, we give a hint as to why one could expect $m, \frac{m+2}{2}, 2m+1$, and $2m+3$ to be square-free. Consider the generalized Erdős–Moser equation:

$$S_n(m) = a(m+1)^n \iff (a+1)S_n(m) = aS_n(m+1).$$

Let $P_n(x) \in \mathbb{Q}[x]$ denote the polynomial interpolating S_n in (13). Then

$$(a+1)P_n(m) = aP_n(m+1).$$

Let $L_n \in \mathbb{Q}$ satisfy the conditions that

$$L_n P_n(x) \in \mathbb{Z}[x]$$

and that the greatest common divisor of the coefficients of $L_n P_n(x)$ is 1. Set $Q_n(x) := L_n P_n(x)$. Then

$$(a+1)Q_n(m) = aQ_n(m+1).$$

On the other hand, it is known that $P_n(x)$ is given by (13). For $j = 1, 2, \dots, n$, let

$$R_j = R_j(n) := \frac{D_j}{\gcd(D_j, \binom{n+1}{j})} \in \mathbb{N}.$$

Then

$$L_n = (n+1)\text{lcm}(R_1, R_2, \dots, R_n)$$

and we obtain

$$Q_n(x) = \text{lcm}(R_1, R_2, \dots, R_n) \sum_{j=0}^n (-1)^j \binom{n+1}{j} B_j x^{n+1-j}.$$

We now focus on the Erdős–Moser equation, when $a = 1$ and n is even, i.e., a counterexample to the Erdős–Moser conjecture:

$$2Q_n(m) = Q_n(m+1).$$

In this case, Corollary 8 implies $m(m+1)(2m+1)$ divides $Q_n(m)$, and $(m+1)(m+2)(2m+3)$ divides $Q_n(m+1)$. Note the appearance of the numbers $m, m+2, 2m+1, 2m+3$ as divisors—these are the same numbers that appear in Moser’s trick.

Consider $Q_n(m+1)$ modulo m :

$$\begin{aligned} 0 &\equiv Q_n(m+1) = \text{lcm}(R_1, R_2, \dots, R_n) \sum_{j=0}^n (-1)^j \binom{n+1}{j} B_j (m+1)^{n+1-j} \pmod{m} \\ &\equiv \text{lcm}(R_1, R_2, \dots, R_n) \sum_{j=0}^n (-1)^j \binom{n+1}{j} B_j = (n+1)\text{lcm}(R_1, R_2, \dots, R_n) = L. \end{aligned}$$

Therefore m divides L . The denominators of Bernoulli numbers are square-free, so we almost obtain another proof of the square-freeness of m .

Acknowledgments. The authors are very grateful to Wadim Zudilin for many helpful suggestions on the terminology and exposition of the first half of the paper.
