# Reduction of a family of ideals

Tomasz Rodak

Abstract. In the paper we prove that there exists a simultaneous reduction of one-parameter family of  $m_n$ -primary ideals in the ring of germs of holomorphic functions. As a corollary we generalize the result of A. Płoski [\[6\]](#page-5-0) on the semicontinuity of the Łojasiewicz exponent in a multiplicity-constant deformation.

Mathematics Subject Classification (2010). Primary 14B07; Secondary 14C17, 13H15.

Keywords. Reduction of an ideal, Hilbert-Samuel multiplicity, Łojasiewicz exponent.

# 1. Introduction

Let R be a ring and I an ideal. We say that an ideal J is a *reduction of* I if it satisfies the following condition:

 $J \subset I$ , and for some  $r > 0$  we have  $I^{r+1} = J I^r$ .

The notion of reduction is closely related to the notions of *Hilbert-Samuel multiplicity* and *integral closure* of an ideal.

Recall that if  $(R, \mathfrak{m})$  is a Noetherian local ring of dimension n and I is an m-primary ideal of R, then the *Hilbert-Samuel multiplicity* of I is given by the formula

$$
e(I) = n! \lim_{k \to \infty} \frac{\text{length}_R R/I^k}{k^n}.
$$

For the multiplicity theory in local rings see for example [\[5\]](#page-5-1) or [\[2\]](#page-5-2).

Let I be an ideal in a ring R. An element  $x \in R$  is said to be *integral over* I if there exists an integer n and elements  $a_k \in I^k$ ,  $k = 1, \ldots, n$ , such that

$$
x^n + a_1 x^{n-1} + \dots + a_n = 0.
$$

This research was partially supported by the Polish OPUS Grant No 2012/07/B/ST1/03293.

The set of all elements of R that are integral over I is called the *integral closure of* I, and is denoted  $\overline{I}$ . If  $I = \overline{I}$  then I is called *integrally closed*. It is well known that  $\overline{I}$  is an ideal.

The relationship between the above notions is given in the following Theorem due to D. Rees:

<span id="page-1-1"></span>Theorem 1 (Rees, [\[2,](#page-5-2) Cor. 1.2.5, Thm. 11.3.1]). *Let* (R, m) *be a formally equidimensional Noetherian local ring and let*  $J \subset I$  *be two* m-*primary ideals. Then the following conditions are equivalent:*

- 1. J *is a reduction of* I*;*
- 2.  $e(I) = e(J)$ ;
- 3.  $\overline{I} = \overline{J}$ .

It is an important fact that a reduction of an ideal is often generated by a system of parameters. More precisely we have

<span id="page-1-2"></span>Theorem 2 ([\[5,](#page-5-1) Theorem 14.14]). *Let* (R, m) *be a* d*-dimensional Noetherian local ring, and suppose that*  $k = R/\mathfrak{m}$  *is an infinite field; let*  $I = (u_1, \ldots, u_s)$ *be an* m-primary ideal. Then there exist a finite number of polynomials  $D_{\alpha} \in$  $k[Z_{ij}; 1 \leq i \leq d, 1 \leq j \leq s], 1 \leq \alpha \leq \nu$  such that if  $y_i = \sum a_{ij} u_j$ ,  $i = 1, \ldots, d$ and at least one of  $D_{\alpha}(\overline{a}_{ii}; 1 \leq i \leq d, 1 \leq j \leq s) \neq 0$ , then the ideal  $(y_1, \ldots, y_d)R$  *is a reduction of* I and  $\{y_1, \ldots, y_d\}$  *is a system of parameters of* R*.*

Let  $(\mathcal{O}_n, \mathfrak{m}_n)$  be the ring of germs of holomorphic functions  $(\mathbb{C}^n, 0) \to \mathbb{C}$ . The aim of this note is to prove the following:

<span id="page-1-0"></span>**Theorem 3.** Let  $F = F_t(x) = F(x,t)$ :  $(\mathbb{C}^n \times \mathbb{C}, 0) \rightarrow (\mathbb{C}^m, 0)$  be a holomorphic *map. Assume that*  $(F_t)O_n$  *is an*  $\mathfrak{m}_n$ -primary ideal for all t. Then there exists *a complex linear map*  $\pi: \mathbb{C}^m \to \mathbb{C}^n$  *such that for all t the ideal*  $(\pi \circ F_t) \mathcal{O}_n$  *is a reduction of*  $(F_t) \mathcal{O}_n$ .

In the next section we get as a corollary that if the above family  $(F_t) \mathcal{O}_n$ is of constant multiplicity then the Łojasiewicz exponent in this family is a lower semicontinuos function of t. A. Płoski proved this result under additional restriction  $m = n$  but with space of parameters of arbitrary dimension.

The proof of Theorem [3](#page-1-0) is based on some geometric property of Hilbert-Samuel multiplicity, given in section 3.

#### 2. Semicontinuity of the Łojasiewicz exponent

Let (R, m) be a local ring and let I be an m-primary ideal. By the *Łojasiewicz exponent*  $\mathcal{L}(I)$  of I we define the infimum of

$$
\left\{\frac{p}{q}:\mathfrak{m}^p\subset \overline{I^q}\right\}.
$$

It was proved in [\[3\]](#page-5-3) that if  $F: (\mathbb{C}^n, 0) \to (\mathbb{C}^m, 0)$  is a holomorphic map with an isolated zero at the origin and  $I := (F) \mathcal{O}_n$ , then  $\mathcal{L}(I)$  is an optimal exponent  $\nu$  in the inequality

$$
|F(x)| \geqslant C |x|^{\nu},
$$

where C is some positive constant and x runs through sufficiently small neighbourhood of  $0 \in \mathbb{C}^n$ .

<span id="page-2-0"></span>Lemma 4. *Let* (R, m) *be a Noetherian local ring. If* I *is an* m*-primary ideal of* R and J is a reduction of I then  $\mathcal{L}(I) = \mathcal{L}(J)$ .

*Proof.* Obviously  $\mathcal{L}(I) \leq \mathcal{L}(J)$ . Assume that  $\mathfrak{m}^p \subset \overline{I^q}$ . Since J is a reduction of I, then also  $J^q$  is a reduction of  $I^q$  [\[2,](#page-5-2) Prop. 8.1.5]. Thus  $\overline{J^q} = \overline{I^q}$  by Theorem [1,](#page-1-1) which gives  $\mathfrak{m}^p \subset \overline{J^q}$ . This proves the inequality  $\mathcal{L}(J) \leq \mathcal{L}(I)$ and ends the proof.

**Corollary 5 (A. Płoski for**  $m = n$ , [\[6\]](#page-5-0)). Let  $F: (\mathbb{C}^n \times \mathbb{C}, 0) \to (\mathbb{C}^m, 0)$  be a *holomorphic map. Put*  $I_t := (F_t) \mathcal{O}_n$ . If the function  $t \mapsto e(I_t)$  is constant and finite then the function  $t \mapsto \mathcal{L}(I_t)$  is lower semicontinuos.

*Proof.* By Theorem [3](#page-1-0) there exists a linear map  $\pi: \mathbb{C}^m \to \mathbb{C}^n$  such that  $J_t :=$  $(\pi \circ F_t) \mathcal{O}_n$  is a reduction of  $I_t$  for all t. Thus  $\mathcal{L}(J_t) = \mathcal{L}(I_t)$  and  $e(J_t) = e(I_t)$ by Theorem [1](#page-1-1) and Lemma [4.](#page-2-0) Consequently  $t \mapsto e(J_t)$  is constant and finite and the assertion follows from the case  $m = n$  proved by A. Płoski.  $\Box$ 

# 3. Improper intersection multiplicity

Let I be an  $\mathfrak{m}_n$ -primary ideal of  $\mathcal{O}_n$  and let  $f_1, \ldots, f_m$  be its generators. We put  $f = (f_1, \ldots, f_m)$ . It is well known that if  $m = n$  then

$$
e(I) = \dim_{\mathbb{C}} \mathcal{O}_n/I.
$$

On the other hand, if  $m > n$  then we may define so-called *improper intersection multiplicity*  $i_0(I)$  of I as the improper intersection multiplicity  $i(\text{graph}f \cdot (\mathbb{C}^n \times \{0\});(0,0))$  of graph f and  $\mathbb{C}^n \times \{0\}$  at the point  $(0,0) \in$  $\mathbb{C}^n \times \mathbb{C}^m$  (see [\[1\]](#page-5-4)).

Let  $C_f$  be the (Whitney) tangent cone of the germ of the image of f at the origin. The following observation is due to S. Spodzieja.

<span id="page-2-1"></span>**Theorem 6** ([\[7\]](#page-5-5)). *The number*  $i_0(I)$  *is well defined. Moreover, if*  $\pi: \mathbb{C}^m \to \mathbb{C}^l$ *is a linear map such that* ker  $\pi \cap C_f = \{0\}$ , then the ideal J generated by  $\pi \circ f$  *is*  $\mathfrak{m}_n$ -primary and we have  $i_0(I) = i_0(J)$ *. If additionally*  $l = n$  *then*  $i_0(I) = e(J)$ .

**Corollary 7.** If I is an  $\mathfrak{m}_n$ -primary ideal in  $\mathcal{O}_n$ , then  $i_0(I) = e(I)$ .

*Proof.* Let  $I = (f_1, \ldots, f_m) \mathcal{O}_n$ . By Theorems [2](#page-1-2) and [6](#page-2-1) there exists linear combinations  $g_i = \sum a_{ij} f_j$ ,  $i = 1, ..., n$  such that  $J = (g_1, ..., g_n) \mathcal{O}_n$  is a reduction of I,  $\{g_1, \ldots, g_n\}$  is a system of parameters of  $\mathcal{O}_n$  and  $i_0(I)$  =  $i_0(J) = e(J)$ . From Theorem [1](#page-1-1) we get  $e(I) = e(J)$ . This ends the proof.  $\Box$ 

<span id="page-2-2"></span>**Corollary 8.** If  $\pi: \mathbb{C}^m \to \mathbb{C}^l$  is a linear map such that ker  $\pi \cap C_f = \{0\}$ , then *the ideal* J generated by  $\pi \circ f$  *is a reduction of* I.

*Proof.* We have  $J \subset I$  and  $e(J) = e(I)$ . This and Theorem [1](#page-1-1) give the  $\Box$ assertion.

# 4. Elementary blowing-up

Here we recall the notion of an elementary blowing-up after [\[4\]](#page-5-6).

Let  $U \subset \mathbb{C}^n$  be an open and connected neighbourhood of  $0 \in \mathbb{C}^n$ ; let  $f = (f_0, \ldots, f_m) \neq 0$  be a sequence of holomorphic functions on U. Put  $S = \{x \in U : f(x) = 0\}$  and

$$
E(f) = \{(x, u) \in U \times \mathbb{P}^m : f_i(x)u_j = f_j(x)u_i, i, j = 0, ..., m\},\
$$

where  $u = [u_0 : \cdots : u_m] \in \mathbb{P}^m$ .

Let Y be the closure of  $E(f) \setminus S$  in  $U \times \mathbb{P}^m$ . The natural projection

 $\pi: Y \to U$ 

is called the *(elementary)* blowing-up of U by means of  $f_0, \ldots, f_m$ . The analytic subset S is called a *centre of the blowing-up* and its inverse image  $\pi^{-1}(S) \subset Y$  is called the *exceptional set* of the blowing-up.

<span id="page-3-1"></span>Proposition 9. *Under above notations we have:*

- 1. *Y is an analytic subset of*  $U \times \mathbb{P}^m$ ;
- 2.  $\pi$  *is proper, its range is* U *and the restriction*  $\pi_{|Y \setminus \pi^{-1}(S)}$  *is a biholomorphism onto*  $U \setminus S$ *;*
- <span id="page-3-0"></span>3. Y *is irreducible;*
- 4. The exceptional set  $\pi^{-1}(S)$  is analytic in  $U \times \mathbb{P}^m$  and it is of pure  $dimension\ n-1.$

*Proof.* Although the above proposition is well known, we think that point [\(4\)](#page-3-0) is worth proving. Let us consider the analytic map

$$
F\colon U\times \mathbb{P}^m\ni (x,u)\mapsto (f(x),u)\in \mathbb{C}^{m+1}\times \mathbb{P}^m.
$$

Let  $y_0, \ldots, y_m$  be coordinates in  $\mathbb{C}^{m+1}$ . If we denote by  $\pi_{m+1} : \Pi_{m+1} \to \mathbb{C}^{m+1}$ the blowing-up of  $\mathbb{C}^{m+1}$  by means of  $y_0, \ldots, y_m$  then for the restriction  $\hat{f}$  =  $F<sub>Y</sub>$  we get the following commutative diagram of analytic maps:

$$
Y \xrightarrow{\widetilde{f}} \Pi_{m+1}
$$

$$
\downarrow \pi \qquad \qquad \downarrow \pi_{m+1}
$$

$$
U \xrightarrow{f} \mathbb{C}^{m+1}
$$

Take  $(x_0, u_0) \in \pi^{-1}(0)$ . Let  $\Omega \subset \Pi_{m+1}$  be a neighbourhood of  $(0, u_0)$ ,  $h: \Omega \to \mathbb{C}$  an analytic function such that

$$
\pi_{m+1}^{-1}(0) \cap \Omega = \{ (y, u) \in \Omega : h(y, u) = 0 \}.
$$

Let  $\widetilde{\Omega} \subset Y$  be a neighbourhood of  $(x_0, u_0)$  such that  $\widetilde{f}(\widetilde{\Omega}) \subset \Omega$ . Since  $\widetilde{f}^{-1}(\pi_{m+1}^{-1}(0)) = \pi^{-1}(S)$  we get

$$
\pi^{-1}(S) \cap \widetilde{\Omega} = \{ (x, u) \in \widetilde{\Omega} : h \circ \widetilde{f}(x, u) = 0 \}.
$$

Thus there exists a neighbourhood  $\Delta \subset U \times \mathbb{P}^m$  of  $(x_0, u_0)$  and an analytic set  $V \subset \Delta$  of pure dimension  $n + m - 1$  such that

$$
\pi^{-1}(S) \cap \Delta = V \cap Y \cap \Delta.
$$

This gives

$$
\dim_{(x_0, u_0)} \pi^{-1}(S) \geq \dim_{(x_0, u_0)} Y - 1 = n - 1.
$$

Since Y is irreducible and  $\pi^{-1}(S) \subsetneq Y$  we get that  $\dim_p \pi^{-1}(S) = n-1$ for any  $p \in \pi^{-1}(S)$ . This ends the proof.

### 5. Proof of Theorem [3](#page-1-0)

<span id="page-4-0"></span>**Lemma 10.** Let  $F: (\mathbb{C}^n \times \mathbb{C}, 0) \to (\mathbb{C}^{m+1}, 0), m \geq n$  be a holomorphic map. *Assume that* 0 *is an isolated point of*  $F_t^{-1}(0)$  *for*  $|t| < \delta$ . Then there exists  $\delta > \epsilon > 0$  and a complex line  $V \subset \mathbb{C}^{m+1}$ , such that  $V \cap C_{F_t} = \{0\}$  for  $|t| < \epsilon$ .

*Proof.* Let  $F: U \to \mathbb{C}^{m+1}$ , where  $U \subset \mathbb{C}^n \times \mathbb{C}$  is a connected neighbourhood of the origin. Put  $S = \{(z, t) \in U : F(z, t) = 0\}$  and let  $\pi : U \times \mathbb{P}^m \supset Y \to U$ be the elementary blowing-up of  $U$  by  $F$ . By Proposition [9](#page-3-1) its exceptional set  $E := \pi^{-1}(S)$  is an analytic set of pure dimension n. Let  $\mathcal E$  be a set of those irreducible components W of E for which origin in  $\mathbb{C}^{n+1}$  is an accumulation point of  $\pi(W) \cap (\{0\} \times \mathbb{C})$ . Then  $\mathcal E$  is finite. Denote by  $C_{F_t}$  the image of the cone  $C_{F_t}$  in  $\mathbb{P}^m$ . Observe that

$$
\{(0,t)\}\times \widetilde{C_{F_t}}\subset \bigcup \mathcal{E},\quad |t|<\delta.
$$

On the other hand for any  $W \in \mathcal{E}$  we have

 $\dim W \cap (\{0\} \times \mathbb{P}^m) \leqslant n - 1 < m.$ 

Thus there exists  $\epsilon > 0$  and an open set  $G \subset \mathbb{P}^m$  such that

$$
(\{(0,t)\}\times G)\cap | \mathbf{c}=\emptyset, \quad 0<|t|<\epsilon
$$

As a result if V is a line in  $\mathbb{C}^{m+1}$  corresponding to some point in G then  $V \cap C_{F_t} = \{0\}$  for  $0 < |t| < \epsilon$ . Since G is not a subset of  $C_{F_0}$  we get the  $\Box$ assertion.

*Proof of Theorem [3.](#page-1-0)* Induction on m. In the case  $m = n$  there is nothing to prove. Let us assume that the assertion is true for some  $m \geq n$  and let  $F: (\mathbb{C}^n \times \mathbb{C}, 0) \to (\mathbb{C}^{m+1}, 0)$  be a holomorphic map such that the ideals  $(F_t)$   $\mathcal{O}_n$  are  $\mathfrak{m}_n$ -primary. By Lemma [10](#page-4-0) there exists  $\epsilon > 0$  and a linear mapping  $\pi' : \mathbb{C}^{m+1} \to \mathbb{C}^m$  such that ker  $\pi' \cap C_{F_t} = \{0\}$  for  $|t| < \epsilon$ . Thus, by Corollary [8](#page-2-2) the ideal  $(\pi' \circ F_t) \mathcal{O}_n$  is a reduction of  $(F_t) \mathcal{O}_n$ . On the other hand, by induction hypothesis, there exists a linear map  $\pi'' : \mathbb{C}^m \to \mathbb{C}^n$  such that  $(\pi'' \circ \pi' \circ F_t) \mathcal{O}_n$  is a reduction of  $(\pi' \circ F_t) \mathcal{O}_n$  for small t. Thus if we put  $\pi := \pi'' \circ \pi'$  we get the assertion.
