Abstract

We demonstrated selective gas sensing with $MoS₂$ thin-film transistors using the change in the channel conductance, characteristic transient time and low-frequency current fluctuations as the sensing parameters. The back-gated $MoS₂$ thin-film field-effect transistors were fabricated on Si/SiO₂ substrates and intentionally aged for a month to verify reliability and achieve better current stability. The same devices with the channel covered by 10 nm of Al_2O_3 were used as reference samples. The exposure to ethanol, acetonitrile, toluene, chloroform, and methanol vapors results in drastic changes in the source-drain current. The current can increase or decrease by more than two-orders of magnitude depending on the analyte. The reference devices with coated channel did not show any response. It was established that transient time of the current change and the normalized spectral density of the low-frequency current fluctuations can be used as additional sensing parameters for selective gas detection with thin-film $MoS₂$ transistors.

Two-dimensional (2D) layered materials have attracted significant attention owing to their unusual electronic and optical properties [1-4]. Among these material systems, a semiconducting $MoS₂$ is one of the most promising [5-6]. Each layer of $MoS₂$ consists of one sub-layer of molybdenum sandwiched between two other sub-layers of sulfur in a trigonal prismatic arrangement [7]. A direct band gap of a single-layer MoS₂ is \sim 1.9 eV [8-9]. Single-layer and $few-layer MoS₂$ devices have been proposed for electronic, optoelectronic and energy applications [1-4, 10]. Recently, $MoS₂$ film-based field-effect transistors were tested for sensing NO and NO₂, other gases, and water vapor [11-16]. The sensing signal utilized in these experiments was the relative change in the resistance, $\Delta R/R$. The devices with 2D channels are natural candidates for sensor applications due to the ultimately high surface-to-volume ratio and widely tunable Fermi-level position.

In this letter we report on selective detection of ethanol, acetonitrile, toluene, chloroform, and methanol vapors with the $MoS₂$ thin-film field-effect transistors (TF-FETs). The devices were intentionally aged for over a month period to verify their suitability for practical applications. In addition to the relative change in the source-drain current, $\Delta I_D/I_D$, we used the normalized spectral density of the low-frequency current fluctuations, S_I/I_D^2 , and the characteristic transient time of the current as the sensing parameters (here I_D is the source-drain current). Our results show that the aged $MoS₂$ devices perform better as the sensors in terms of their current stability, sensitivity to the analyte and reduced contributions of metal contacts to the noise level. Comparison with the graphene FETs reveals significant differences in the effects of exposure to chemical vapors on $\Delta R/R$ and S_I/I_D^2 , suggesting differences in the physical mechanisms of lowfrequency current fluctuations [17-19].

Thin films of $MoS₂$ were mechanically exfoliated from bulk crystals and transferred onto $Si/SiO₂$ substrates following the standard approach [1]. The thickness H of the films ranged from bi-layer to a few layers. Micro-Raman spectroscopy (Renishaw InVia) confirmed the crystallinity and thickness of the $MoS₂$ flakes after exfoliation. The spectroscopy was performed in the backscattering configuration under λ =488-nm laser excitation using an optical microscope (Leica) with a $50\times$ objective. The excitation laser power was limited to less than 0.5 mW to avoid local heating. Figure 1 shows the schematic of $MoS₂ TF-FET$ (a) optical microscopy image

of a representative device (b) and Raman spectrum of the channel material (c). The observed Raman features at ~382.9 cm⁻¹ (E_{2g}^{1}) and ~406.0 cm⁻¹ (A_{1g}) are consistent with literature reports [20]. Analysis of the Raman spectrum indicates that this sample is 2-3 layer $MoS₂$ film. The thickness identification is based on the frequency difference, $\Delta\omega$, between the E_{2g}^1 and the A_{1g} peaks. The increase in the number of layers in $MoS₂$ films is accompanied by the red shift of the E_{2g}^{1} and blue shift of the A_{1g} peaks [20].

[Figure 1: Schematic, microscopy and Raman]

Devices with $MoS₂$ thin-film channels were fabricated using the electron beam lithography (LEO SUPRA 55) for patterning of the source and drain electrodes and the electron-beam evaporation (Temescal BJD-1800) for metal deposition. The $Si/SiO₂$ (300-nm) substrates were spin-coated (Headway SCE) and baked consecutively with two positive resists: first, methyl methacrylate (MMA) and then, polymethyl methacrylate (PMMA). The resulting TF-FETs consisted of $MoS₂$ thin-film channels with Ti/Au (10-nm / 100-nm) contacts. The heavily doped $Si/SiO₂$ wafer served as a back gate. The majority of the bi-layer and tri-layer thickness $MoS₂$ devices had a channel length, L, in the range from 1.3 μ m to 3.5 μ m, and the channel width, W, in the range from 1 μ m to 6 μ m. Some of the devices were covered with 10-nm Al₂O₃ layer to serve as the reference samples in control experiments.

It is known that that defective and doped graphene has the greater sensitivity for CO , NO , $NO₂$, and other gases [21]. The same can possibly be true for thin film $MoS₂$ devices. In particular, it has been shown that the high density of edge states enhances the sensitivity. Therefore aged, i.e. more defective devices can be more attractive for gas sensing applications. In the present work we found that aged $MoS₂ TF-FETs$ were more stable and had negligible contact contribution to the drain-to-source resistance. The aged $MoS₂$ devices were characterized by the on-to-off ratio of $\sim 10^4$, electron mobility $\mu \sim 0.5$ cm²/Vs and negligible contact resistance. The new, as fabricated, devices had mobility values in the range from 1 to 8 cm^2/Vs , which is typical for the back-gated MoS² TF-FETs [10, 22-23]. An estimate for the contact resistances was obtained by plotting the drain-to-source resistance, R_{DS} , vs. $1/(V_G - V_{TH})$, and extrapolating this dependence to zero. Figure 2 shows a representative transfer current-voltage (I-V) characteristic for the aged $MoS₂$

TF-FET used in this study. For comparison, typical I-Vs for a graphene device are also shown. Analyzing I-Vs for M_0S_2 thin films and graphene one can see possible implications for sensor operation: graphene device have much higher currents owing to graphene superb mobility while $MoS₂$ devices have better gating and on-off ration owing to $MoS₂$ band gap.

[Figure 2: Current – voltage characteristics of $MoS₂$ and graphene devices]

For testing the sensor operation, the vapors were produced by bubbling dry air through the respective solvents and diluting the gas flow with the dry air. The resulting concentrations were $~\sim$ 0.5 P/P_o, where P is the vapor pressure and P_o is the saturated vapor pressure. When the sample is exposed to the vapor, the vapor molecules, which attach the channel surface, create negative or positive charges at the MoS_2 surface (see Figure 1 (a)). The latter depletes or enhances the electron concentration in the channel depending on the vapor species. For testing $MoS₂ TF-FFSTs$ we selected three polar solvents: acetonitrile $(CH_3CN - polar$ aprotic), ethanol $(C_2H_5OH - polar$ protic), methanol (CH₃OH – polar protic); as well as two non-polar solvents: toluene (C₆H₅-CH₃) and chloroform $(CHCl₃)$.

Figure 3 shows the drain current as a function of time in $MoS₂ TF-FFT$ exposed to ethanol, methanol and acetonitrile, respectively (from top to bottom). For all chemical vapors, the measurements were conducted at the small drain-source voltage $V_D=0.1$ V. The high gate bias of $V_G=60$ V is explained by presence 300-nm thick SiO_2 layer in the back gate. One can see from Figure 3 that in all cases of polar solvents, the drain current increased upon exposure to the vapor and decreased after the vapor exposure was turned off. The results were reproducible for several switching on and off over in a month old $MoS₂ TF-FETs$ tested over a period of few days. The time constants, τ , for I_D increase and decrease were different for each examined analyte. Note that the current of the reference sample – the same device with the channel coated by Al_2O_3 – did not reveal any changes.

[Figure 3: I-Vs for polar solvents]

Figure 4 presents drain current as a function of time in $MoS₂ TF-FFT$ exposed to chloroform and toluene, respectively (from top to bottom). To better illustrate a large range of the current change, Figure 4 also shows the data for chloroform in a semi-logarithmic scale. The exposure to the vapors of non-polar solvents has an opposite effect on I_D . The drain current reduces by more than two-orders of magnitude, almost completely switching the device off. We found also that the response of the $MoS₂$ transistors to some vapors demonstrates a memory effect: current remains small or even continue to decrease after the vapor flow is switched off. The current (resistance) is completely restored after gate and voltage biases are set to zero. The τ values were different for each analyte. Although not shown, no changes in current were observed for the reference samples. It is important to note that the data presented in Figures 3 and 4 were for devices intentionally aged by a month. Initially, the aging study was performed to verify that $MoS₂ TF-$ FETs maintain their characteristic. Any practical sensor applications require that the FETs are operational for at least a month. Interestingly, we observed that the characteristics of the aged devices even improved in terms of their current stability and sensitivity.

[Figure 4: I-Vs for non-polar solvents]

We have recently demonstrated the use of the low-frequency current fluctuations of I_D in graphene devices as an additional sensing parameter [24-25]. Some gases induce bulges at characteristic frequencies in the spectral density of the low-frequency current fluctuations S_V/I_D^2 of graphene FETs or change its average value. In order to test the same approach for $MoS₂ TF$ -FETs we measured the low-frequency noise spectral density in $MoS₂ TF-FETs$ exposed to open air and chemical vapors. The details of our low-frequency measurements have been reported by us elsewhere [26]. Figure 5 shows S_1/I_D^2 of MoS₂ TF-FET for different vapors. Red lines show the noise spectra measured in open air with intervals of a few day. The change of the noise spectra was found only as a result of the exposure to the acetonitrile vapor (indicated by green lines). The inset in Figure 5 magnifies the low-frequency part of spectra indicating good noise spectra measurements reproducibility. One can see that $S_I/I_D^2 \propto 1/f$ (here f is the frequency)

without traces of bulges for all spectra including those measured under acetonitrile vapor. This is in a drastic contrast to graphene devices. In this sense, S_V/I_D^2 is a better sensing parameter for graphene rather than for few-layer $MoS₂$ films. However, the properly calibrated average level of S_I/I_D^2 can still be used for MoS₂ TF-FETs in combination with τ and $\Delta I_D/I_D$. Table I summarizes the data for examined chemical vapors including their type, dielectric constant ε and two sensing parameters. In addition to the relative current change, $\Delta I_D/I_D$, we also show the ratio of the drain current under gas exposure to the initial current before exposure, I_0 . The I_D/I_0 metric is illustrative for the situation when the drain current decreases. For comparison, the $\Delta I_D/I_D$ data for graphene FETs is also shown. As seen, the presence of the band gap in $MoS₂$, allows one to achieve a larger change in the current (orders of magnitude in some cases) than in graphene devices. For some vapors, it is possible to completely switch off $MoS₂$ by the gas. The latter makes $MoS₂$ very attractive for the gas sensing applications.

Vapor	Type	$\boldsymbol{\epsilon}$	$\tau(s)$	I_D/I_0	$\Delta I_D/I_D$ (%)	$\Delta I_D/I_D$ (%)
				MoS ₂ FET	MoS ₂ FET	Graphene FET
ethanol	polar protic	24.6	~ 35	3.778	$+300$	$-50*$
methanol	polar protic	33.0	~20	3.714	$+280$	$-40*$
acetonitrile	polar aprotic	37.5	~130	1.625	$+60$	$-35*$
chloroform	non-polar	4.81	$~1$ - 550	0.231	-75	$-25*$
toluene	non-polar	2.38	~1000	0.012	-98	$+15*$

Table I: Chemical Vapors and Sensing Parameters of MoS₂ TF-FET

*The data for graphene is after S. Rumyantsev, et al., Nano Letters, 12, 2294 (2012) [24].

Although the exact mechanism of vapor molecule interactions goes beyond the scope of this work and requires atomistic simulations, one can observe certain trends from data in Table I, and Figures 3 and 4. The characteristic time constants for current change under the exposure to polar molecules are much shorter than those for non-polar molecules. The vapors of non-polar solvents, characterized by small ε , induce current quenching in the thin $MoS₂$ channel. The vapors of polar solvents with much larger ε , on contrary increase the electrical current in $MoS₂$ channel likely via inducing additional charges. Indeed, considering that ε for a few-layer MoS₂ is around 4 [27], the polar molecules would create a much larger dielectric mismatch with $MoS₂$.

The absence of bulges in $MoS₂ TF-FETs$, which is in contract to graphene FETs, can be related to different mechanisms of low-frequency noise in these two material systems. We have previously shown that low-frequency noise in $MoS₂$ thin films is similar to that in conventional semiconductors and can be described well by McWhorter model, which assumes that the dominant noise contribution comes from the number of careers fluctuations [26]. Graphene, similar to metals, reveals noise response, which is does not comply with the McWhorter model [17-19, 28]. Although the low frequency noise mechanism in graphene is still under debates [19] it is clear now that it is different from that in $MoS₂$. The latter makes the response of noise to the gas exposure to be also different in these two materials.

In conclusion, we demonstrated selective gas sensing with $MoS₂ TF-FETS$ using the change in the channel current, characteristic transient time and low-frequency noise spectral density as the sensing parameters. The exposure to ethanol, acetonitrile, toluene, chloroform, and methanol vapors results in drastic changes in the source-drain current. The current can increase or decrease by more than two-orders of magnitude depending on the analyte type. The reference devices with coated channel did not show any response. Unlike graphene devices and thin-film $MoS₂$ transistors do not show characteristic bulges in the low-frequency current fluctuation spectra. The differences in the low-frequency noise response are likely related to differences in the noise mechanisms and require further study. The obtained results are important for practical applications of $MoS₂$ thin films and other van der Waals materials.

FIGURE CAPTIONS

Figure 1: Schematic of the $MoS₂$ thin-film sensor with the deposited molecules that create additional charge (upper panel). Optical microscopy image of a representative $MoS₂ TF-FET$ (middle panel). Raman spectrum of the MoS₂ thin-film channel showing the E_{2g}^1 and the A_{1g} peaks. The increase in the number of layers in $MoS₂$ films is accompanied by the red shift of the E_{2g}^1 and blue shift of the A_{1g} peaks. The energy difference, $\Delta\omega$, between E_{2g}^1 and the A_{1g} peaks indicates that the given sample is a tri-layer $MoS₂$ film.

Figure 2: Current-voltage characteristics of the aged $MoS₂ TF-FET$ used in the study. A typical graphene FET transfer characteristic is also shown for comparison in the same scale. Graphene reveals much higher current owing to superior electron mobility. $MoS₂ TF-FET$ is characterized by better on-off ratio owing to its energy band gap.

Figure 3: Drain-source current versus time in MoS₂ TF-FET exposed to the vapors of polar solvents: ethanol (upper panel), methanol (middle panel), and acetonitrile (lower panel). The data were taken at the same gate voltage $V_G=60$ V and drain voltage $V_D=0.1$ V for each case. The reference sample – the same device with the Al_2O_3 coated channel – has not revealed any variations in current as shown in the upper panel

Figure 4: Drain-source current versus time $MoS₂ TF-FET$ exposed to the vapors of non-polar solvents: chloroform (upper and middle panels) and toluene (lower panel). The data were taken at the same gate voltage $V_G=60$ V and drain voltage $V_D=0.1$ V for each case.

Figure 5: The normalized spectral density of the low-frequency source-drain current fluctuations measured for $MoS₂ TF-FFT$ in open air and under exposure to the vapors. The data were taken at the same gate voltage $V_G=60$ V and drain voltage $V_D=0.1$ V for each case. The spectral density of $MoS₂ TF-FET$ under vapor exposure reveals 1/f dependence without any traces of bulges unlike graphene FETs. The inset magnifies the low-frequency part of the spectra.
