Universal Sparse Superposition Codes with Spatial Coupling and GAMP Decoding

Jean Barbier^{†*}, Mohamad Dia[†], and Nicolas Macris[†]

Abstract

Sparse superposition codes, or sparse regression codes, constitute a new class of codes which was first introduced for communication over the additive white Gaussian noise (AWGN) channel. It has been shown that such codes are capacity-achieving over the AWGN channel under optimal maximum-likelihood decoding as well as under various efficient iterative decoding schemes equipped with power allocation or spatially coupled constructions. Here, we generalize the analysis of these codes to a much broader setting that includes all memoryless channels. We show, for a large class of memoryless channels, that spatial coupling allows an efficient decoder, based on the generalized approximate message-passing (GAMP) algorithm, to reach the potential (or Bayes optimal) threshold of the underlying (or uncoupled) code ensemble. Moreover, we argue that spatially coupled sparse superposition codes universally achieve capacity under GAMP decoding by showing, through analytical computations, that the error floor vanishes and the potential threshold tends to capacity as one of the code parameter goes to infinity. Furthermore, we provide a closed form formula for the algorithmic threshold of the underlying code ensemble in terms of a Fisher information. Relating an algorithmic threshold to a Fisher information has theoretical as well as practical importance. Our proof relies on the state evolution analysis and uses the potential method developed in the theory of low-density parity-check (LDPC) codes and compressed sensing.

I. INTRODUCTION

S PARSE superposition (SS) codes, or sparse regression codes, were first introduced by Barron and Joseph [1] for reliable communication over the additive white Gaussian noise (AWGN) channel. The SS codes were then proven to be capacity-achieving under adaptive successive decoding along with power allocation [2, 3]. Later on, the connection between SS codes and compressed sensing was made in [4]. The decoding of SS codes can be interpreted as an estimation of a sparse signal, with structured prior distribution, based on a relatively small number of noisy observations. Hence, the approximate message-passing (AMP) algorithm, originally developed for compressed sensing, was adapted in [4] to decode SS codes where it exhibited better finite-length performance than adaptive successive decoding. SS codes, with appropriate power allocation on the transmitted signal, were then proven to achieve capacity under AMP decoding [5]. Furthermore, the extension of the state evolution (SE) equations, originally developed to track the performance of AMP for compressed sensing [6], was proven to be exact for SS codes in [5].

The idea of *spatial coupling* was originaly introduced for low-density parity-check (LDPC) codes under the name of LDPC convolutional codes [7, 8]. Spatial coupling has been then successfully applied to various problems including error correcting codes [9], code division multiple access (CDMA) [10, 11], satisfiability [12], and compressed sensing [13–15]; where it has been shown to boost the performance under iterative algorithms. Recently, spatial coupling was applied to SS codes in [16, 17]. The construction of coding matrices for SS codes with local coupling and a proper termination was shown to considerably improve the performance. Moreover, practical Hadamard-based operators were used in [16] to encode SS codes, where they showed better finite-length performance than random operators under AMP decoding. The spatially coupled construction used in [16, 17] has many similarities with that introduced in the context of compressed sensing [18–20]. Empirical evidence shows that spatially coupled SS codes perform much better than power allocated ones and that they achieve capacity under AMP decoding without any need for power allocation. This motivated the initiation of their rigorous study [21] using the *potential method*, originally developed for the spatially coupled Curie-Weiss model [22, 23] and LDPC codes [24–26]. The phenomenon of *threshold saturation* for AWGN channels was shown in [21], i.e. the *potential threshold* that characterizes the performance of SS codes under the Bayes optimal minimum mean-square error (MMSE) decoder can be reached using spatial coupling and AMP decoding. Moreover, the potential threshold itself was shown to achieve capacity in the large input alphabet size limit.

Threshold saturation was first established in the context of spatially coupled LDPC codes for general binary input memoryless symmetric channels in [25, 27], and is recognized as the mechanism underpinning the excellent performance of such codes [28]. It is interesting that essentially the same phenomenon can be established for a coding system operating on a channel with *continuous inputs*. This result was a stepping-stone towards establishing that spatially coupled SS codes achieve capacity on the AWGN channel under AMP decoding [21]. Note that a similar (but different) potential to the one used in [21] has been introduced in the context of scalar compressed sensing [6, 26]. It is interesting that the potential method goes through for the present system involving a dense coding matrix and a fairly wide class of spatial couplings. Related results on the optimality of spatial coupling in compressed sensing [15] and on the threshold saturation of systems characterized by a 1-dimensional state evolution [26, 29] have been obtained by different approaches.

In the classical noisy compressed sensing problem, the AMP algorithm and the SE recursion tracking the algorithmic performance were derived for the AWGN channel [6, 30]. The extension of AMP to general memoryless (possibly non-linear) channels with arbitrary input and output distributions was introduced in [31] via the generalized approximate message-passing (GAMP) algorithm. Moreover, an extension of SE describing the exact behavior of GAMP was also provided in [31]. Later on, a full rigorous analysis proving the tractability of GAMP via SE was given in [20] (for the case of fully factorized prior). These encouraging results naturally led us to generalize the analysis of SS codes in [21] to a much broader setting that includes all memoryless channels and potentially any input signal model that factorizes over B-dimensional sections [32, 33]. Moreover, SS codes under GAMP decoding were recently proposed for an inverse source coding problem [34, 35].

In this work we prove that threshold saturation is a universal phenomenon for SS codes; i.e. we show that, for any memoryless channel, spatial coupling allows GAMP decoding to reach the potential threshold of the code ensemble (Section V Theorem 5.12 and Corollary 5.13). Moreover, we argue, through non-rigorous analytical computations, that spatially coupled SS codes universally achieve capacity under GAMP decoding by showing that the error floor vanishes and the potential threshold tends to capacity as one of the code's parameters (the section size, or input alphabet size, B) goes to infinity. Note that a fully rigorous statement about the capacity achieving property of SS codes still requires the following: i) a rigorous asymptotic

analysis in the large section size limit $B \to \infty$ (see Section VI), *ii*) the proof that state evolution tracks the performance of GAMP over general memoryless channels when the prior factorizes over *B*-dimensional sections (as opposed to the fully factorized case treated in [20]). Furthermore, we give a simple expression of the GAMP algorithmic threshold of the underlying code ensemble in terms of a Fisher information (Section VI). Although we focus on coding for the sake of coherence with our previous results, the framework and methods are very general and hold for a wide class of non-linear estimation problems with random linear mixing.

Our proof strategy uses a potential function, which is inspired from the statistical physics replica method. However, we stress that the proof *does not* rely on the replica method (which is not rigorous). Recently, it has been shown that the replica prediction is exact for generalized random linear estimation problems including compressed sensing and SS codes on general channels [36–40]. Hence, the potential threshold can be rigorously interpreted as the optimal threshold under MMSE decoding.

The paper is organized as follows. The code construction of the underlying and coupled ensembles are described in Section II. Section III reviews the GAMP algorithm, while Section IV presents the SE equations and potential function adapted to the present context. The GAMP thresholds of the underlying and coupled ensembles as well as the potential threshold are then given precise definitions. The essential steps for the proof of threshold saturation are presented in Section V. The connection between the potential threshold at infinite input alphabet size $B \to \infty$ and Shannon's capacity, as well as the closed form expression of the algorithmic threshold in terms of a Fisher information, are given in Section VI. Four different channel models are used to illustrate the results. Section VII is dedicated to conclusion and open challenges.

II. CODE ENSEMBLES

We first define the underlying and spatially coupled ensembles of SS codes for transmission over a generic memoryless channel. In the rest of the paper a subscript "un" indicates a quantity related to the underlying ensemble and a subscript "co" a quantity related to the spatially coupled ensemble. The probability law of a Gaussian random variable X with mean m and variance σ^2 is denoted $X \sim \mathcal{N}(m, \sigma^2)$ and the corresponding probability density function as $\mathcal{N}(x|m, \sigma^2)$.

A. The underlying ensemble

In the framework of SS codes, the *information word* or *message* is a vector made of L sections, $\mathbf{s} = [\mathbf{s}_1, \dots, \mathbf{s}_L]$. Each section \mathbf{s}_l , $l \in \{1, \dots, L\}$, is a B-dimensional vector with a single component equal to 1 and B - 1 components equal to 0. The non-zero component of each section can be set differently especially when schemes with power allocation are considered [2,3]. However, we will restrict ourselves to the binary case in this work where spatial coupling is used to achieve capacity instead of power allocation. We call B the section size (or alphabet size usually chosen to be a power of 2) and set N = LB. The message \mathbf{s} can be seen as a one-to-one mapping from an original message $\mathbf{u} \in \{0,1\}^{L \log_2(B)}$, where the position of the non-zero component in \mathbf{s}_l is specified by the binary representation of \mathbf{u}_l (i.e. \mathbf{s} is obtained from \mathbf{u} using a simple position modulation (PM) scheme). For example if B = 4 and L = 5, a valid message is $\mathbf{s} = [0001, 0010, 1000, 0100, 0010]$ which corresponds to $\mathbf{u} = [00, 01, 11, 10, 01]$. One can think of the information words as being defined for a B-ary alphabet with a constant power allocation for each symbol.

We consider random codes generated by a fixed *coding matrix* $\mathbf{F} \in \mathbb{R}^{M \times N}$ drawn from the ensemble of random matrices with i.i.d real Gaussian entries distributed as $\mathcal{N}(0, 1/L)$. The variance of the coding matrix entries is such that the *codeword* $\mathbf{Fs} \in \mathbb{R}^M$ has a normalized average power $\mathbb{E}[||\mathbf{Fs}||_2^2]/M = 1$. Note that the cardinality of this code is B^L and the length of the codeword is M. Hence, the (design) rate is defined as

$$R = \frac{L\log_2 B}{M} = \frac{N\log_2 B}{MB}.$$
(1)

The code is thus specified by (M, R, B) where R is the code rate, M the block length, B the section size.

Codewords are transmitted through a known memoryless channel W. This requires to map the codeword components $[\mathbf{Fs}]_{\mu} \in \mathbb{R}, \mu \in \{1, \dots, M\}$, onto the input alphabet of W. We call π this map and refer to Section VI for various examples. The concatenation of π and W can be seen as an *effective memoryless channel* P_{out} , such that

$$P_{\text{out}}(\mathbf{y}|\mathbf{Fs}) = \prod_{\mu=1}^{M} P_{\text{out}}(y_{\mu}|[\mathbf{Fs}]_{\mu}) := \prod_{\mu=1}^{M} W(y_{\mu}|\pi([\mathbf{Fs}]_{\mu})).$$
(2)

Note that one can look equivalently at π as a part of the channel model or as a part of the encoder. In the present framework, it is more convenient to work with the effective memoryless channel from which the receiver obtains the noisy channel observation **y**. However in the analysis of Section VI, the capacity of W is considered.

The decoding task is to recover **s** from channel observations **y** as depicted in Fig. 1. This can be interpreted as a compressed sensing problem with structured sparsity, due to the sectionwise structure of **s**, where **y** would be the compressed measurements. The rate R can be linked to the "measurement rate" α , used in the compressed sensing literature, by

$$\alpha = \frac{M}{N} = \frac{\log_2 B}{BR}.$$
(3)

Figure 1. The encoder/decoder block diagram of the SS codes under GAMP decoding over any memoryless channel W. The map π is needed when the capacity achieving input distribution of W is not Gaussian. The GAMP algorithm provides soft valued estimate \hat{s} of s in the MMSE sense. A simple hard decision (HD) mechanism is used to provide the binary decoded message \bar{s} by setting the most biased component in each section of \hat{s} to 1 and the others to 0. The original message \mathbf{u} and its decoded version $\bar{\mathbf{u}}$ can be easily recovered from s and \bar{s} respectively using PM modulator and demodulator as illustrated in Section II-A.

Figure 2. A spatially coupled coding matrix $\mathbf{F}^{co} \in \mathbb{R}^{M \times N}$ made of $\Gamma \times \Gamma$ blocks indexed by (r, c), each with N/Γ columns and $M/\Gamma = \alpha N/\Gamma$ rows where $\alpha = (\log_2 B)/BR$. The i.i.d elements in block (r, c) are distributed as $\mathcal{N}(0, J_{r,c}\Gamma/L)$. Away from the boundaries, in addition to the diagonal (in red), there are w forward and w backward coupling blocks. In this example, the design function g_w enforces a stronger backward coupling where the non-uniform variance across blocks is illustrated by the level of shading. Blocks are darker at the boundaries because the variances are larger so as to enforce the variance normalization $\sum_{c=1}^{\Gamma} J_{r,c} = 1 \forall r$. The yellow shape emphasizes variance symmetry.

Thus, the same algorithms and analysis used in compressed sensing theory like the GAMP algorithm and SE can be used in the present context. See [17] for more details on this interconnection.

B. The spatially coupled ensemble

We consider spatially coupled codes based on coding matrices $\mathbf{F}^{co} \in \mathbb{R}^{M \times N}$ as depicted in Fig. 2. A spatially coupled coding matrix \mathbf{F}^{co} is made of $\Gamma \times \Gamma$ blocks indexed by (r, c), each with N/Γ columns and $M/\Gamma = \alpha N/\Gamma$ rows. The structure of \mathbf{F}^{co} induces a natural decomposition of the message into Γ blocks, $\mathbf{s} = [\mathbf{s}_1, \dots, \mathbf{s}_{\Gamma}]$, where each block is made of L/Γ sections.¹ \mathbf{F}^{co} is constructed such that each block is coupled (except at the boundaries) with w forward blocks and w backward blocks, where w is the *coupling window*. The strength of the coupling is specified by the variance $J_{r,c}$ of each block (r, c). The entries inside each block (r, c) of \mathbf{F}^{co} are i.i.d. distributed as $\mathcal{N}(0, J_{r,c}\Gamma/L)$.² In order to impose homogeneous power over all the components of $\mathbf{F}^{co}\mathbf{s}$, we tune the (unscaled) block variances $J_{r,c}$ such that the following variance normalization condition holds for all $r \in \{1, \dots, \Gamma\}$

$$\sum_{c=1}^{\Gamma} J_{r,c} = 1.$$
 (4)

¹Of course N, M, L, Γ can always be chosen s.t $N/\Gamma, M/\Gamma, L/\Gamma$ are integers.

 $^{^{2}}$ In the uncoupled construction the variance scales as the inverse number of sections. In the coupled construction the variances within a block scales as the inverse number of sections within a block.

This normalization induces homogeneous average power over all codeword components, i.e. $M^{-1}||\mathbf{F}^{co}\mathbf{s}||_2^2 = 1$. There are various ways to construct the variance matrix J of the spatially coupled matrix such that (4) holds. For instance, one can pick $J_{r,c}$'s such that the coupling strength is uniform over the window. However, we will consider a more general construction in this work by using a *design function* g_w . The design function satisfies

$$\begin{cases} g_w(x) = 0 & \text{if } |x| > 1, \\ \underline{g} \le g_w(x) \le \overline{g} & \text{if } |x| \le 1, \end{cases}$$
(5)

where \bar{g} , \underline{g} are strictly positive constants independent of w. Moreover, g_w is assumed to be Lipschitz continuous on |x| < 1 with Lipschitz constant g_* independent of w. In particular

$$\left|g_w\left(\frac{k}{w}\right) - g_w\left(\frac{k'}{w}\right)\right| \le \frac{g_*}{w}|k - k'|,\tag{6}$$

for $k, k' \in \{-w, \ldots, w\}$. Furtheremore, we impose the following normalization

$$\frac{1}{2w+1}\sum_{k=-w}^{w}g_w(\frac{k}{w}) = 1.$$
(7)

The design function is then used to construct the variances such that (4) and (7) are satisfied. Hence, we choose

$$J_{r,c} = \gamma_r \frac{g_w((c-r)/w)}{2w+1} = \frac{g_w((c-r)/w)/(2w+1)}{\sum_{c=1}^{\Gamma} g_w((c-r)/w)/(2w+1)},$$
(8)

where γ_r is tuned to enforce (4). Note that, away from the boundaries, γ_r is a trivial term equal to 1. However, γ_r changes at the boundaries to compensate for the lower number of blocks being coupled (see Fig. 2 where darker colors were used at the boundaries to stress on this point). The following remarks will be used in the analysis. We always have $1 \le \gamma_r \le g^{-1}$ and

$$J_{r,c} \le (\bar{g}/g)(2w+1)^{-1}.$$
(9)

In the bulk (i.e. away from the boundaries), the following variance symmetry property holds for $k \in \{2w + 1, ..., \Gamma - 2w\}$

$$\sum_{r=1}^{\Gamma} J_{r,k} = \sum_{c=1}^{\Gamma} J_{k,c} = 1.$$
(10)

The ensemble of spatially coupled matrices is then parametrized by $(M, R, B, \Gamma, w, g_w)$. Note that the coupling induced by g_w is not necessarily symmetric, hence the present construction generalizes the ones in [24, 26, 29] which all require $g_w(-x) = g_w(x)$, while we do not. This relaxation may strongly improve the performances in practice [19].

One key element of spatially coupled codes is the *seed* introduced at the boundaries. We assume the sections in the first 4w and last 4w blocks of the message s to be known by the decoder (the choice of 4w blocks is convenient for the proofs and will become clear in Section V). This boundary condition can be interpreted as perfect side information that propagates inwards and boosts the performance. Note that one could also impose the seed differently by constructing a coding matrix with lower communication rate (higher measurement rate) at the boundaries [16–20]. The seed induces a rate loss in the *effective rate* of the code

$$R_{\rm eff} = R \left(1 - \frac{8w}{\Gamma} \right). \tag{11}$$

However, this loss vanishes as $L \to \infty$ and then $\Gamma \to \infty$ for any fixed R. As already mentioned, in addition to lower decoding error, the main advantage of coupled SS codes w.r.t power allocated ones is that they allow communication at high rate with a small section size B, while power allocated codes require a much larger B, which prevents communication of messages of practically relevant sizes [17]. Recently, the power allocated SS codes have been optimized in order to achieve better finite size performance [41].

III. GENERALIZED APPROXIMATE MESSAGE-PASSING ALGORITHM

The posterior distribution describing the statistical relationships in the decoding task is given by (in the following discussion \mathbf{F} denotes a generic coding matrix)

$$P(\mathbf{s}|\mathbf{y}, \mathbf{F}) = \frac{\prod_{l=1}^{L} p_0(\mathbf{s}_l) \prod_{\mu=1}^{M} P_{\text{out}}(y_{\mu}|[\mathbf{F}\mathbf{s}]_{\mu})}{\int d\mathbf{s} \prod_{l=1}^{L} p_0(\mathbf{s}_l) \prod_{\mu=1}^{M} P_{\text{out}}(y_{\mu}|[\mathbf{F}\mathbf{s}]_{\mu})}.$$
(12)

In the SS codes setting, the sections of the information word are uniformly distributed over all the possible *B*-dimensional vectors with a single non-zero component equal to 1. Hence, the prior of each section reads

$$p_0(\mathbf{s}_l) = \frac{1}{B} \sum_{i=1}^B \delta_{s_{li},1} \prod_{j \neq i}^{B-1} \delta_{s_{lj},0},$$
(13)

Figure 3. Left: Factor graph of the underlying ensemble showing the statistical relationships between the *B*-dimensional sections (circles) of the information word s given the known prior $p_0(s)$ (plain squares), the coding matrix F and the channel observation y (colored squares). The BP algorithm estimates s via iterative exchange of messages, along edges, between circle-nodes and square-nodes. Right: The GAMP algorithm simplifies the BP operations to a sequence of estimation problems from Gaussian noise. At the l^{th} section, $\hat{\mathbf{r}}_l$ is the output of an effective Gaussian channel of zero mean and covariance matrix diag($\boldsymbol{\tau}_l^r$).

where s_{li} is the i^{th} component of the l^{th} section (here $i \in \{1, ..., B\}$ and $l \in \{1, ..., L\}$). The posterior distribution (12) can be represented via a graphical model as shown in the l.h.s of Fig. 3. Therefore, it is natural to consider an iterative message-passing algorithm to perform the decoding. For a dense graphical model Belief Propagation (BP) is computationally prohibitive but can be simplified down to the AMP algorithm which has been successfully used in many applications, mainly in compressed sensing [6, 30]. The AMP algorithm uses efficient Gaussian (or quadratic) approximations of BP that "decouple" the vector-valued estimation problem into a sequence of scalar estimation problems under an *effective Gaussian noise* (r.h.s of Fig. 3). The sum-product version of AMP (originally used to perform MMSE estimation in compressed sensing with AWGN channel) was adapted in [4, 17] to SS codes by incorporating the structured *B*-dimensional prior distribution (13). The GAMP algorithm extends the approximations made in AMP to any memoryless channel [31]. Interestingly, the same Gaussian approximations on a dense graph remain valid under GAMP, even for a non-Gaussian channel, and the only difference appears in the computation of the effective Gaussian noise levels.

The GAMP algorithm was originally introduced to estimate signals with i.i.d components [31]. In the present context the message components are correlated through $p_0(\mathbf{s}_l)$, therefore we adapt GAMP to cover this vectorial setting. The steps of GAMP are shown in Algorithm 1 below. The " \circ 2" and " \circ – 1" symbols mean that the square and inverse operations are taken componentwise: $(\mathbf{F}^{\circ 2})_{\mu i} = F_{\mu i}^2$ and $(\mathbf{F}^{\circ -1})_{\mu i} = F_{\mu i}^{-1}$. All the derivatives in Algorithm 1 are also taken componentwise. The sum-product GAMP algorithm produces a sequence of the estimated posterior mean $\hat{\mathbf{s}}^{(t)}$ and the corresponding estimated posterior variance $\boldsymbol{\tau}^{s(t)}$. The dimensions of the various estimated vectors $\hat{\mathbf{s}}, \hat{\mathbf{r}}, \ldots$ and their corresponding variances $\boldsymbol{\tau}^s, \boldsymbol{\tau}^r, \ldots$ are given in Algorithm 1.

In this generalization to the vectorial setting of SS codes, only steps 12 and 13 of Algorithm 1 differ from the canonical GAMP algorithm in [31]. The function g_{in} depends on the input prior distibution and it is adapted from [31] to act on *B*-dimensional vectors. Due to the code construction, $g_{in}(\hat{\mathbf{r}}_l, \text{diag}(\boldsymbol{\tau}_l^r))$ can be interpreted as the MMSE estimator, or *denoiser*, of a given *B*-dimensional section \mathbf{s}_l sent through an effective Gaussian channel of zero mean and covariance matrix $\text{diag}(\boldsymbol{\tau}_l^r)$ where

$$\hat{\mathbf{r}}_l = \mathbf{s}_l + \boldsymbol{\xi}, \quad \boldsymbol{\xi} \sim \mathcal{N}(\mathbf{0}, \operatorname{diag}(\boldsymbol{\tau}_l^r)).$$
 (14)

Definition 3.1 (Denoiser): Formally, we define the denoiser acting sectionwise on each B-dimensional section of the message as follows

$$g_{\rm in}(\hat{\mathbf{r}}_l, {\rm diag}(\boldsymbol{\tau}_l^r)) := \mathbb{E}[\mathbf{S}_l \mid \hat{\mathbf{R}}_l = \hat{\mathbf{r}}_l] = \frac{\int d\mathbf{s}_l \, p_0(\mathbf{s}_l) \mathcal{N}(\hat{\mathbf{r}}_l | \mathbf{s}_l, {\rm diag}(\boldsymbol{\tau}_l^r)) \mathbf{s}_l}{\int d\mathbf{s}_l \, p_0(\mathbf{s}_l) \mathcal{N}(\hat{\mathbf{r}}_l | \mathbf{s}_l, {\rm diag}(\boldsymbol{\tau}_l^r))},$$
(15)

where $S_l \sim p_0(s_l)$. Plugging (13) yields the componentwise expression of the denoiser used in the GAMP algorithm for SS codes

$$[g_{in}(\hat{\mathbf{r}}_{l}, \operatorname{diag}(\boldsymbol{\tau}_{l}^{r}))]_{i} = \frac{\exp((2\hat{r}_{li} - 1)/(2\tau_{li}^{r}))}{\sum_{j=1}^{B} \exp((2\hat{r}_{lj} - 1)/(2\tau_{lj}^{r}))} \\ = \left[1 + \sum_{j \neq i}^{B} \exp\left((2\hat{r}_{lj} - 1)/(2\tau_{lj}^{r}) - (2\hat{r}_{li} - 1)/(2\tau_{li}^{r})\right)\right]^{-1},$$

where $i \in \{1, ..., B\}$.

Moreover, the componentwise product $\tau_l^r \circ \frac{\partial}{\partial \hat{\mathbf{r}}_l} g_{in}$ is the estimate of the posterior variance, which quantifies how "confident" GAMP is in its current iteration, and is given by

$$\boldsymbol{\tau}_{l}^{r} \circ \frac{\partial}{\partial \hat{\mathbf{r}}_{l}} g_{\text{in}}(\hat{\mathbf{r}}_{l}, \text{diag}(\boldsymbol{\tau}_{l}^{r})) \coloneqq \text{var}(\mathbf{S}_{l} \mid \hat{\mathbf{R}}_{l} = \hat{\mathbf{r}}_{l}) \\ = \mathbb{E}[\mathbf{S}_{l}^{\circ 2} \mid \hat{\mathbf{R}}_{l} = \hat{\mathbf{r}}_{l}] - (\mathbb{E}[\mathbf{S}_{l} \mid \hat{\mathbf{R}}_{l} = \hat{\mathbf{r}}_{l}])^{\circ 2},$$
(16)

where the expectation and the variance are induced from (14). As the message **s** in SS codes consists of only 0's and 1's, we have that $\mathbb{E}[\mathbf{S}_l^{\circ 2} | \hat{\mathbf{R}}_l = \hat{\mathbf{r}}_l] = \mathbb{E}[\mathbf{S}_l | \hat{\mathbf{R}}_l = \hat{\mathbf{r}}_l]$. Hence, the calculation of $\operatorname{var}(\mathbf{S}_l | \hat{\mathbf{R}}_l = \hat{\mathbf{r}}_l)$ is immediate using (13) which yields the following componentwise expression

$$[\boldsymbol{\tau}_l^r \circ \frac{\partial}{\partial \hat{\mathbf{r}}_l} g_{\text{in}}(\hat{\mathbf{r}}_l, \text{diag}(\boldsymbol{\tau}_l^r))]_i = [g_{\text{in}}(\hat{\mathbf{r}}_l, \text{diag}(\boldsymbol{\tau}_l^r))]_i - ([g_{\text{in}}(\hat{\mathbf{r}}_l, \text{diag}(\boldsymbol{\tau}_l^r))]_i)^2.$$

The function g_{out} of GAMP (see Algorithm 1) is acting componentwise and depends solely on the physical channel P_{out} . The general expression of g_{out} is given in Appendix I as well as examples for different communication channels. The function g_{out} can be interpreted as a *score function* of the parameter \hat{p} in the distribution of the random variable $Y \sim P_{out}(y \mid z)$ with $Z \sim \mathcal{N}(\hat{p}, \tau^p)$.

Note that the functions g_{in} and g_{out} can be seen heuristically as Gaussian (or quadratic) approximations of the sum-product loopy BP updates used in the MMSE estimation. The detailed interpretation of these functions, as well as that of the various parameters of the GAMP algorithm, is given in [31], which we omit here since it is lengthy and beyond the scope of this work.

The computational complexity of GAMP is dominated by the $O(MN) = O(L^2B\ln(B))$ matrix-vector multiplication. It can be reduced, for practical implementations, by using structured operators such as Fourier and Hadamard matrices [16, 33]. Fast Hadamard-based operators constructed as in [16], with random sub-sampled modes of the full Hadamard operator, allow to achieve a lower $O(L\ln(B)\ln(BL))$ decoding complexity and strongly reduce the memory need [17, 42]. Besides practical advantages, using structured operators can lead to a more robust finite-length performance [16]. However, random operators are mathematically more tractable and easier to analyse. Hence, we restrict ourselves in this work to random operators.

Decoding SS codes using iterative message-passing algorithm, such as GAMP, leads asymptotically in L to a sharp *phase* transition below Shannon's capacity. The decoder is therefore blocked at a certain threshold separating the "decodable" and "non-decodable" regions. Moreover, SS codes under message-passing decoding may exhibit, asymptotically in L and for any fixed alphabet size B, a non-negligible error floor³ in the decodable region (similarly to low-density generator-matrix codes [25]). Whenever the error floor exists, it can be made arbitrarily small by increasing B [16, 17].

IV. STATE EVOLUTION AND POTENTIAL FORMULATION

The asymptotic behavior of the AMP algorithm operating on dense graphs can be tracked by a simple recursion called state evolution (SE), similar to the density evolution (DE) for sparse graphs. The rigorous proof showing that SE tracks exactly the asymptotic performance of AMP and GAMP was given in [6, 20]. Moreover, the extension of the SE equation of AMP to SS

³In fact, the existence of an error floor depends on the communication channel being used. For example there is no error floor for the BEC and BSC (or any binary input channel) when $L \to \infty$ and any fixed B (see [33] for a proof in the BEC case) but there is one for the AWGN channel as long as B remains finite.

code settings, with *B*-dimensional structured prior distribution and power allocation, was proven to be exact in [5]. We believe that the methods of [5] and [20] can be extended to the present setting of spatially coupled SS codes and GAMP algorithm. This would prove that SE correctly tracks GAMP, a conjecture which is firmly supported by numerical simulations [33].

A. State evolution of the underlying system

SE tracks the performance of GAMP by computing the average asymptotic mean-square error (MSE) of the GAMP estimate $\hat{s}^{(t)}$ at each iteration t

$$\tilde{E}^{(t)} := \lim_{L \to \infty} \frac{1}{L} \sum_{l=1}^{L} \|\hat{\mathbf{s}}_{l}^{(t)} - \mathbf{s}_{l}\|_{2}^{2}.$$
(17)

It turns out that tracking the GAMP algorithm is equivalent to running a simple recursion that iteratively computes the MMSE of a single section sent through an *equivalent AWGN channel*. This equivalent channel is induced by the code construction and has an *effective* noise variance that depends solely on the physical channel $P_{out}(y|x)$. In order to formalize this, we first need some definitions.

Definition 4.1 (Effective noise): The effective noise variance $\Sigma^2(E)$, parametrized by $E \in [0, 1]$, is defined via the following relation

$$\Sigma^{-2}(E) := \frac{\mathbb{E}_{p|E}[\mathcal{F}(p|E)]}{R},$$

where the expectation $\mathbb{E}_{p|E}$ is w.r.t $\mathcal{N}(p|0, 1-E)$ and

$$\mathcal{F}(p|E) := \int dy f(y|p, E) (\partial_p \ln f(y|p, E))^2$$

is the Fisher information of the parameter p associated with the probability distribution of the random variable Y with density

$$f(y|p, E) := \int dx P_{\text{out}}(y|x) \mathcal{N}(x|p, E).$$

See Appendix I for explicit expressions for various communication channels. To get an intuition about this Fisher information, observe that in the AWGN channel, for example, the effective noise variance is directly related to the channel noise parameter with $\Sigma^2(E) = R(E + \operatorname{snr}^{-1})$, where snr is the signal-to-noise ratio. Intuitively speaking, the effective noise variance is tracking the denoising variance τ^r of the Algorithm 1.

We will need some regularity properties for the function $\Sigma(E)$ which boils down to mild assumptions on the channel transition probability $P_{\text{out}}(y|x)$.

Assumption 1 (Continuity and boundedness of $\Sigma(E)$): The channel transition probability $P_{out}(y|x)$ is such that $\Sigma(E)$ is a continuous and twice differentiable function of $E \in [0, 1]$.

Assumption 2 (Scaling of $\Sigma^{-2}(E)$ as $E \to 0$): The channel transition probability $P_{out}(y|x)$ is such that $\Sigma^{-2}(E)$ and its first two derivatives are bounded by a polynomial in E^{-1} . Formally, for a given channel there exist two constants C > 0 and $\beta > 0$ such that

$$\max\left(\Sigma^{-2}(E), \left|\frac{\partial\Sigma^{-2}(E)}{\partial E}\right|, \left|\frac{\partial^{2}\Sigma^{-2}(E)}{\partial E^{2}}\right|\right) \le \frac{C}{RE^{\beta}} \equiv \lambda(E)$$
(18)

for all $E \in [0, 1]$.

These assumptions will be needed in the proof of threshold saturation in Section V. In practice they can be checked on a case by case basis for each channel at hand. For the AWGN channel we have the analytic simple expression $\Sigma^2(E) = R(E + \operatorname{snr}^{-1})$ so the assumptions are obviously satisfied. One can also check them for the binary symmetric channel (BSC), binary erasure channel (BEC) and Z channel (ZC), using the tedious expressions for the Fisher information given in Table I in Appendix I. Fig. 4 illustrates $\Sigma^{-2}(E)$ and its derivatives for the BSC and BEC.

The following lemma (which is independent from the assumptions) will also be needed.

Lemma 4.2: $\Sigma^2(E)$ is non-negative and increasing with E. In particular $\Sigma^2(E) \leq \Sigma^2(1) < +\infty$.

Proof: Positivity of the Fisher information implies $\Sigma^2(E) \ge 0$. The proof that it is increasing is a straightforward application of the data processing inequality for Fisher information (e.g. Corollary 6 in [43]).

From now on, $\mathbf{S} \sim p_0(\mathbf{s})$ and $\mathbf{Z} \sim \mathcal{N}(\mathbf{0}, \mathbf{I}_B)$ are *B*-dimensional random vectors with corresponding expectations denoted $\mathbb{E}_{\mathbf{S},\mathbf{Z}}$, and $Z \sim \mathcal{N}(0, 1)$ with expectation denoted \mathbb{E}_Z .

Definition 4.3 (SE of the underlying system): The SE operator of the underlying system is the average MMSE of the equivalent channel

$$T_{\rm un}(E) := {\rm mmse}\big(\Sigma(E)\big) = \mathbb{E}_{\mathbf{S},\mathbf{Z}}\bigg[\sum_{i=1}^{B} \Big(\Big[g_{\rm in}\Big(\mathbf{S} + \frac{\mathbf{Z}\Sigma(E)}{\sqrt{\log_2 B}}, \frac{\mathbf{I}_B\,\Sigma^2(E)}{\log_2 B}\Big)\Big]_i - S_i\Big)^2\bigg],$$

Figure 4. $\Sigma^{-2}(E)$ and its first two derivatives in a semi-log scale for the BSC (left) and the BEC (right) with flip and erasure probabilities $\epsilon = 0.1$ and R = 0.2. Assumption 2 is satisfied with exponents $\beta = 1/2$ and 5/4. Furthermore, the effective noise variance of both channels is bounded with $\Sigma^{2}(E) < 1/2$. Note that the mapping $\pi([\mathbf{Fs}]_{\mu}) = \operatorname{sign}([\mathbf{Fs}]_{\mu})$ was used here.

where g_{in} is the denoiser given in Definition 3.1

$$\left[g_{\rm in}\left(\mathbf{s} + \frac{\mathbf{z}\Sigma}{\sqrt{\log_2 B}}, \frac{\mathbf{I}_B \Sigma^2}{\log_2 B}\right)\right]_i = \left[1 + \sum_{k \neq i}^B e^{(s_k - s_i)\log_2 B/\Sigma^2 + (z_k - z_i)\sqrt{\log_2 B}/\Sigma}\right]^{-1}.$$
(19)

The SE iteration tracking the performance of the GAMP decoder for the underlying system can be expressed as

$$E^{(t+1)} = T_{un}(E^{(t)}), \qquad t \ge 0$$

with the initialization $\tilde{E}^{(0)} = 1$.

Note for further use that (19) is a well defined continuous function of $\Sigma > 0$ (all other arguments being fixed). At $\Sigma = 0$ we define the function by its continuous extension which is obviously finite. Thus we will consider that g_{in} is continuous for $\Sigma \ge 0$.

After t iterations of the GAMP algorithm, the MSE tracked by SE is denoted by $T_{un}^{(t)}(\tilde{E}^{(0)})$. The monotonicity properties and the continuity of the SE operator, discussed in Section V-A, ensure that eventually all initial conditions converge to a fixed point. More specifically, the following limit exists

$$\lim_{t \to \infty} T_{un}^{(t)}(\tilde{E}^{(0)}) := T_{un}^{(\infty)}(\tilde{E}^{(0)}),$$
(20)

for all $\tilde{E}^{(0)} \in [0, 1]$ and satisfies

$$T_{\rm un}(T_{\rm un}^{(\infty)}(\tilde{E}^{(0)})) = T_{\rm un}^{(\infty)}(\tilde{E}^{(0)}).$$
⁽²¹⁾

Having introduced the SE iteration, the following definitions can be properly stated.

Definition 4.4 (MSE Floor): The MSE floor $E_{\rm f}$ is the fixed point reached from the initial condition of zero error,

$$E_{\rm f} = T_{\rm un}^{(\infty)}(0)$$

Note that for the channels where E = 0 is *not* a trivial fixed point of the SE at a finite section size B, the MSE floor E_f is *strictly positive*. For example, this is the case for the AWGN channel [4, 17]. However, one can show that for certain channels W there exists a *trivial* fixed point E = 0 of SE leading to *vanishing* MSE floor even at finite B. This is typically the case for binary input channels and has been proved explicitly for the BEC, BSC and Z channels [33]. For generality, we will always denote the MSE floor as E_f whether it is zero or not.

Definition 4.5 (Basin of attraction): For a fixed channel, the basin of attraction \mathcal{V}_0 to the MSE floor E_f is defined as

$$\mathcal{V}_0 := \left\{ E \in [0, 1] \, | \, T_{un}^{(\infty)}(E) = E_{f} \right\}$$

Note that for a given channel, the basin of attraction is a function of the rate as the T_{un} operator varies with the rate. **Definition** 4.6 (*Threshold of underlying ensemble*): The GAMP threshold of the underlying ensemble is defined as

$$R_{\rm un} := \sup\{R > 0 \,|\, T_{\rm un}^{(\infty)}(1) = E_{\rm f}\}.$$

For the present system, one can show that the only two possible fixed points are $T_{un}^{(\infty)}(0)$ and $T_{un}^{(\infty)}(1)$. For $R < R_{un}$, there is only one fixed point, namely the "good" one $T_{un}^{(\infty)}(1) = E_f$. Whenever E_f is non-zero, it will vanish as the section size B increases (see Section VI). Instead if $R > R_{un}$, the GAMP decoder is blocked by the "bad" fixed point $T_{un}^{(\infty)}(1) > E_f$. The "bad" fixed point does not vanish as B increases.

The GAMP algorithm "tries" to minimize the MSE. Thus the natural quantity being tracked by SE is the MSE. But one can also assess the performance of GAMP by looking at the section error rate (SER) (which is more natural for coding problems) after applying a hard decision (HD) thresholding on the decoder's output. The analytical relationship between MSE and the SER has been discussed in [4, 17] and one verifies that an MSE going to zero implies a SER going to zero.

B. State evolution of the coupled system

For a spatially coupled system, the performance of GAMP at each iteration t is described by an average *MSE vector* $[\tilde{E}_c^{(t)} \mid c \in \{1, ..., \Gamma\}]$ along the "spatial dimension" indexed by the blocks of the message with

$$\tilde{E}_{c}^{(t)} := \lim_{L \to \infty} \frac{\Gamma}{L} \sum_{l \in c} \|\hat{\mathbf{s}}_{l}^{(t)} - \mathbf{s}_{l}\|_{2}^{2}, \quad c \in \{4w + 1, \dots, \Gamma - 4w\},$$
(22)

where the sum $l \in c$ is over the set of indices of the L/Γ sections composing the c-th block of s. To reflect the seeding at the boundaries, we enforce the following *pinning condition* for all $c \in \{1, ..., 4w\} \cup \{\Gamma - 4w + 1, ..., \Gamma\}$

$$\tilde{E}_{c}^{(t)} = 0, \qquad t \ge 0,$$
(23)

where the message at these positions is assumed to be known to the decoder at all times.

It turns out that the following change of variables

$$E_r^{(t)} := \sum_{c=1}^{\Gamma} J_{r,c} \tilde{E}_c^{(t)}, \tag{24}$$

where $\mathbf{E} = [E_r | r \in \{1, ..., \Gamma\}]$ is called the *profile*, makes the problem mathematically more tractable for spatially coupled codes. The pinning condition implies

$$E_r^{(t)} = 0, \qquad t \ge 0,$$
 (25)

for all $r \in \mathcal{R} := \{1, \dots, 3w\} \cup \{\Gamma - 3w + 1, \dots, \Gamma\}.$

An important concept is that of *degradation* because it allows to compare different profiles.

Definition 4.7 (Degradation): A profile **E** is degraded (resp. strictly degraded) with respect to another one **G**, denoted as $\mathbf{E} \succeq \mathbf{G}$ (resp. $\mathbf{E} \succ \mathbf{G}$), if $E_r \ge G_r \forall r$ (resp. there exists some r such that the inequality is strict).

In order to define the SE of the spatially coupled system, we need first the following definition.

Definition 4.8 (*Per-block effective noise*): The per-block effective noise variance $\Sigma_c^2(\mathbf{E})$ is defined, for all $c \in \{1, \dots, \Gamma\}$, by

$$\Sigma_c^{-2}(\mathbf{E}) \coloneqq \sum_{r=1}^{\Gamma} \frac{J_{r,c}}{\Sigma^2(E_r)} = \sum_{r=1}^{\Gamma} \frac{J_{r,c}}{R} \mathbb{E}_{p|E_r}[\mathcal{F}(p|E_r)].$$

Definition 4.9 (SE of the coupled system): The vector valued coupled SE operator is defined componentwise for $t \ge 0$ as

$$E_r^{(t+1)} = [T_{\rm co}(\mathbf{E}^{(t)})]_r = \begin{cases} \sum_{c=1}^{\Gamma} J_{r,c} \mathbb{E}_{\mathbf{S},\mathbf{Z}} \Big[\sum_{i=1}^{B} \Big(g_{\rm in,i} \Big(\mathbf{S} + \frac{\mathbf{Z} \sum_c (\mathbf{E}^{(t)})}{\sqrt{\log_2 B}}, \frac{\Sigma_c^2 (\mathbf{E}^{(t)})}{\log_2 B} \Big) - S_i \Big)^2 \Big] & r \notin \mathcal{R}, \\ 0 & r \in \mathcal{R}. \end{cases}$$

Note that for $r \in \mathcal{R}$, the pinning condition $E_r^{(t)} = 0$ is enforced at all times. SE is initialized with $E_r^{(0)} = 1$ for $r \notin \mathcal{R}$. **Definition** 4.10 (Threshold of coupled ensemble): The GAMP threshold of the spatially coupled system is defined as

$$R_{\rm co} := \liminf_{w \to \infty} \liminf_{\Gamma \to \infty} \sup\{R > 0 \mid T_{\rm co}^{(\infty)}(\mathbf{1}) \preceq \mathbf{E}_{\rm f}\}$$

where 1 is the all ones vector and $\mathbf{E}_{f} := [E_{r} = E_{f} | r \in \{1, ..., \Gamma\}]$ is the *MSE floor profile* (recall E_{f} in Definition 4.4). The existence of the limit $T_{co}^{(\infty)}(1)$ is verified in Section V-A. Note that the degradation \leq holds with equality for the cases where $E_{f} = 0$.

For the noisy compressed sensing problem, the rigorous proof that SE tracks the performance of GAMP, on both the underlying and spatially coupled models, was already done in [20] by generalizing the work of [6]. For the SS codes, we assume that the same results hold.

Assumption 3 (Accuracy of state evolution): We assume that, at least for the channels under Assumption 1 and Assumption 2, the state evolution equation tracks the performance of GAMP on both the underlying and spatially coupled SS codes.

The proof of Assumption 3 is beyond the scope of this paper. It would follow from a generalization to any memoryless channel of the analysis done in [5], that accounts for the *B*-dimensional prior of the SS codes, or more generally from the analysis of the non-separable priors as recently done in [44,45]. Our assumption is, however, supported by numerical simulations [33] (see Fig. 5).

Figure 5. The GAMP performance over the binary erasure channel (BEC) with erasure probability $\epsilon = 0.1$. Left: SE tracking the GAMP decoder (MSE performance) at each iteration for three different rates with $L = 2^{11}$ and B = 4. Right: The potential threshold (Definition 4.13) as well as the GAMP thresholds of the underlying and coupled ensembles are shown as a function of B. R_{co} saturates R_{pot} as L, Γ and w go to infinity for all values of B. However, R_{un} maintains a gap to R_{pot} , and hence to channel capacity, for all values of B when $L \to \infty$. See [33] for further numerical simulations on various channels.

C. Potential formulation

The fixed point solutions of SE can be reformulated as stationary points of a *potential function*. This potential function can be obtained from the replica method [4] as shown in Appendix IV or by directly integrating the SE fixed point equations with the correct "integrating factor" as done in [26]. Our subsequent analysis does not depend on the means of obtaining the potential function which is here a mere mathematical tool.

Definition 4.11 (Potential function of underlying ensemble): The potential function of the underlying ensemble is given by

$$F_{\mathrm{un}}(E) := U_{\mathrm{un}}(E) - S_{\mathrm{un}}(\Sigma(E)),$$

with

$$\begin{split} U_{\mathrm{un}}(E) &:= -\frac{E}{2\ln(2)\Sigma^2(E)} - \frac{1}{R} \mathbb{E}_Z \Big[\int dy \, \phi(y|Z,E) \log_2 \phi(y|Z,E) \Big] \\ S_{\mathrm{un}}(\Sigma(E)) &:= \mathbb{E}_{\mathbf{S},\mathbf{Z}} \Big[\log_B \int d^B \mathbf{x} \, p_0(\mathbf{x}) \theta(\mathbf{x},\mathbf{S},\mathbf{Z},\Sigma(E)) \Big], \end{split}$$

where

$$\phi(y|z, E) := \int dx P_{\text{out}}(y|x) \mathcal{N}(x|z\sqrt{1-E}, E),$$

$$\theta(\mathbf{x}, \mathbf{s}, \mathbf{z}, \Sigma(E)) := \exp\left(-\frac{\|\mathbf{x} - (\mathbf{s} + \mathbf{z}\Sigma(E)/\sqrt{\log_2 B})\|_2^2}{2\Sigma^2(E)/\log_2 B}\right)$$

Replacing the prior distribution of SS codes (13) in the definition of $S_{un}(\Sigma(E))$, one gets

$$S_{\mathrm{un}}(\Sigma(E)) := \mathbb{E}_{\mathbf{Z}} \Big[\log_B \Big(1 + \sum_{i=2}^B e_i \big(\mathbf{Z}, \frac{\Sigma(E)}{\sqrt{\log_2 B}} \big) \Big) \Big]$$

where

$$e_i(\mathbf{z}, a) := \exp\left(\frac{z_i - z_1}{a} - \frac{1}{a^2}\right).$$

Definition 4.12 (Free energy gap): For a fixed channel, the free energy gap is

$$\Delta F_{\mathrm{un}} := \inf_{E \notin \mathcal{V}_0} (F_{\mathrm{un}}(E) - F_{\mathrm{un}}(E_{\mathrm{f}})),$$

with the convention that the infimum over the empty set is ∞ (i.e. when $R < R_{un}$). Note that for a given channel, the free energy gap is a function of the rate as both F_{un} and \mathcal{V}_0 vary with the rate.

Definition 4.13 (Potential threshold): The potential threshold is defined as

$$R_{\text{pot}} := \sup\{R > 0 \mid \Delta F_{\text{un}} > 0\}.$$

We give examples of potential functions for the BEC and the AWGN channel in Fig. 6 for B = 2. Because of Lemma 4.15 below, the minimum that is in the basin of attraction of E = 0 corresponds to the error floor E_f . We observe that there is a non-vanishing error floor for the AWGN channel but a vanishing one for the BEC. The latter situation is also the case for the BSC and Z channel.

Figure 6. The potential functions for the BEC with $\epsilon = 0.1$ (left) and the AWGN channel with snr = 100 (right), in both cases with B = 2. The black dots correspond to the global minima while the red dots correspond to the local minima preventing GAMP to decode (e.g. yellow curves). For a given rate (yellow curves), the black arrows indicate the free energy gap ΔF_{un} for each channel. The x-axis is given in the log scale to differentiate between the BEC where there is no error floor and the AWGN channel with non-negligible error floor.

Similarly to the underlying ensemble, one can define the potential function of the spatially coupled ensemble that is applied on a vector indexed by the spatial dimension.

Definition 4.14 (Potential function of spatially coupled ensemble): The potential function of the spatially coupled ensemble is given by

$$F_{\rm co}(\mathbf{E}) := U_{\rm co}(\mathbf{E}) - S_{\rm co}(\mathbf{E}) = \sum_{r=1}^{\Gamma} U_{\rm un}(E_r) - \sum_{c=1}^{\Gamma} S_{\rm un}(\Sigma_c(\mathbf{E})).$$

The following lemma links the potential and SE formulations.

Lemma 4.15: If $T_{un}(\mathring{E}) = \mathring{E}$, then $\frac{\partial F_{un}}{\partial E}|_{\mathring{E}} = 0$. Similarly for the spatially coupled system, if $[T_{co}(\mathring{E})]_r = \mathring{E}_r \ \forall \ r \in \mathcal{R}^c = \{3w + 1, \dots, \Gamma - 3w\}$ then $\frac{\partial F_{co}}{\partial E_r}|_{\mathring{E}} = 0 \ \forall \ r \in \mathcal{R}^c$.

Proof: See Appendix II.

We end this section by pointing out that the terms composing the potentials have natural interpretations in terms of effective channels. The term $\mathbb{E}_Z[\int dy \,\phi \log_2(\phi)]$ in $U_{un}(E)$ is minus the conditional entropy H(Y|Z) for the concatenation of the channels $\mathcal{N}(x|z\sqrt{1-E}, E)$ and $P_{\text{out}}(y|x)$ with a standardised input $Z \sim \mathcal{N}(0, 1)$. The term $S_{\text{un}}(\Sigma(E))$ is equal to minus the mutual information $I(\mathbf{S}; \mathbf{Y})/\log_2 B$ for the Gaussian channel $\mathcal{N}(\mathbf{y}|\mathbf{s}, \mathbf{I}_B \Sigma^2(E)/\log_2 B)$ and input distribution $p_0(\mathbf{s})$, up to a constant factor $-(2\ln 2)^{-1}$.

V. THRESHOLD SATURATION

We now prove threshold saturation for spatially coupled SS codes using methods from [26]. The main strategy is to assume a "bad" fixed point solution of the spatially coupled SE and to calculate the change in potential due to a small shift in two different ways: i) by second order Taylor expansion (Lemma 5.7 and Lemma 5.9), ii) by direct evaluation (Lemma 5.11). We then show by contradiction that as long as $R < R_{pot}$ the SE converges to the "good" fixed point (Theorem 5.12).

Our threshold saturation proof follows the lines of [26]. However, we consider a more general coupling construction. More specifically, we assume a general coupling strength which is not necessarily uniform or symmetric as in [26]. This relaxation could significantly improve the performance in practice [19]. Moreover, it is worth noting that carrying out step i) presents some technical difficulties when bounding the second-order Taylor expansion of the coupled state evolution which do not appear in [26]. This is due to the special form of the state evolution tracking the performance of the GAMP algorithm for SS codes over general channels.

In Section V-A we start by showing some essential properties of the spatially coupled SE operator.

A. Properties of the coupled system

Monotonicity properties of the SE operators T_{un} and T_{co} are key elements in the analysis.

Lemma 5.1: The SE operator of the coupled system maintains degradation in space, i.e. if $\mathbf{E} \succeq \mathbf{G}$, then $T_{co}(\mathbf{E}) \succeq T_{co}(\mathbf{G})$. This property is verified for T_{un} for a scalar error as well.

Proof: Combining Lemma 4.2 with the first equality in Definition 4.8 implies that if $\mathbf{E} \succeq \mathbf{G}$, then $\Sigma_c(\mathbf{E}) \ge \Sigma_c(\mathbf{G}) \forall c$. Now, the SE operator of Definition 4.9 can be interpreted as an average over the spatial dimension of local MMSE's. The local MMSE's for each position $c = 1, \dots, \Gamma$ are the ones of B-dimensional equivalent AWGN channels with noise $\xi \sim$

Figure 7. A non-symmetric error profile in a typical SE iteration. The solid line corresponds to the original spatially coupled system and the dashed line to the modified system. The error profile of the original system has a 0 plateau for all $r \leq 3w$ and it increases until r_{\max} where it reaches its maximum value $E_{\max} \in [0, 1]$. It flattens after r_{\max} then it decreases to reach 0 at $\Gamma - 3w + 1$ and remains null after. The non-symmetric shape of the double-sided wave in Fig. 7 emphasises that we are considering the generic case of non-symmetric coupling strength when designing spatially coupled matrices (see Section II). The error profile of the modified system (dashed line) starts with a plateau at $\bar{E}_{\rm f}$ for all $r \leq r_*$, where $r_* + 1$ is the first position s.t the original profile is at least $\overline{E}_{\mathbf{f}}$, and then matches that of the original system for all $r \in \{r_*, \dots, r_{\max}\}$. It then saturates to E_{\max} for all $r \ge r_{\max}$. Note that if $\mathbf{E} \preceq \overline{\mathbf{E}}_{\mathbf{f}}$ then $r_* = r_{max}$. By construction, the error profile of the modified system is non-decreasing and degraded with respect to that of the original system.

 $\mathcal{N}(\mathbf{0},\mathbf{I}_B \Sigma_c^2/\log_2 B)$. These are non-decreasing functions of Σ_c^2 : this is intuitively clear but we provide a justification based on an explicit formula for the derivative below. Thus $[T_{co}(\mathbf{E})]_r \ge [T_{co}(\mathbf{G})]_r \ \forall r$, which means $T_{co}(\mathbf{E}) \succeq T_{co}(\mathbf{G})$.

The derivative of the MMSE of the Gaussian channel with i.i.d noise $\mathcal{N}(\mathbf{0}, \mathbf{I}_B \Sigma^2)$ can be computed as

$$\frac{d \operatorname{mmse}(\Sigma)}{d(\Sigma^{-2})} = \frac{d}{d(\Sigma^{-2})} \mathbb{E}_{\mathbf{X},\mathbf{Y}} \left[\|\mathbf{X} - \mathbb{E}[\mathbf{X}|\mathbf{Y}]\|_2^2 \right] = -2\mathbb{E}_{\mathbf{X},\mathbf{Y}} \left[\|\mathbf{X} - \mathbb{E}[\mathbf{X}|\mathbf{Y}]\|_2^2 \operatorname{Var}[\mathbf{X}|\mathbf{Y}] \right].$$
(26)

This formula is valid for vector distributions $p_0(\mathbf{x})$, and in particular, for our B-dimensional sections. It confirms that T_{un} (resp. $[T_{co}]_r$) is a non-decreasing function of Σ (resp. Σ_c). In particular the local MMSE's for each position $c = 1, \dots, \Gamma$ in definition 4.9 are non-decreasing.

Corollary 5.2: The SE operator of the coupled system maintains degradation in time, i.e. $T_{co}(\mathbf{E}^{(t)}) \leq \mathbf{E}^{(t)}$ implies $T_{co}(\mathbf{E}^{(t+1)}) \leq \mathbf{E}^{(t+1)}$. Similarly, $T_{co}(\mathbf{E}^{(t)}) \succeq \mathbf{E}^{(t)}$ implies $T_{co}(\mathbf{E}^{(t+1)}) \succeq \mathbf{E}^{(t+1)}$. Furthermore, if we take the initial conditions $\mathbf{E}^{(0)} = \mathbf{1}$ (the all one-vector) or $\mathbf{E}^{(0)} = \mathbf{0}$ (the all zero-vector) the *limiting profile*

$$\lim_{t \to \infty} \mathbf{E}^{(t)} := T_{\rm co}^{(\infty)}(\mathbf{E}^{(0)}),\tag{27}$$

exists. Finally under Assumption 1 the limiting profile is a fixed point of T_{co} , i.e.,

$$T_{\rm co}(T_{\rm co}^{(\infty)}(\mathbf{E}^{(0)})) = T_{\rm co}^{(\infty)}(\mathbf{E}^{(0)}).$$
(28)

These properties are verified by T_{un} for the underlying system as well. *Proof:* First we note $T_{co}(\mathbf{E}^{(t)}) \leq \mathbf{E}^{(t)}$ means $\mathbf{E}^{(t+1)} \leq \mathbf{E}^{(t)}$ and thus by Lemma 5.1 $T_{co}(\mathbf{E}^{(t+1)}) \leq T_{co}(\mathbf{E}^{(t)})$ which means $T_{co}(\mathbf{E}^{(t+1)}) \leq \mathbf{E}^{(t+1)}$. The same argument shows that $T_{co}(\mathbf{E}^{(t)}) \geq \mathbf{E}^{(t)}$ implies $T_{co}(\mathbf{E}^{(t+1)}) \geq \mathbf{E}^{(t+1)}$. Let us show the existence of the limit (27) when we start with the initial condition $\mathbf{E}^{(0)} = \mathbf{1}$. This flat profile is maximal at every position thus after one iteration we necessarily have $\mathbf{E}^{(1)} \leq \mathbf{E}^{(0)}$. Applying t times the operator T_{co} we get $\mathbf{E}^{(t+1)} \leq \mathbf{E}^{(t)}$ which means $\mathbf{E}^{(t+1)} = \mathbf{E}^{(t)} = \mathbf{E}^{(t)}$. $E_r^{(t+1)} \le E_r^{(t)}$. Thus for every position we have a non-increasing sequence which is non-negative. Thus the sequence converges and $\lim_{t\to\infty} \mathbf{E}^{(t)} = T_{co}^{(\infty)}(\mathbf{1})$ exists. The same argument applies if we start from the initial condition $\mathbf{E}^{(0)} = \mathbf{0}$ (the limit may be different of course). To show the last statement (28) we argue that T_{co} is continuous with respect to E. We already noted after Definition 4.3 that the denoiser $[g_{in}]_i$ is a continuous function of $\Sigma \ge 0$. Clearly, the denoiser satisfies $0 \le [g_{in}]_i \le 1$ also, and so does the expression $([g_{in}]_i - s_i)^2$. A look at the Definition 4.9 of $[T_{co}(\mathbf{E})]_r$ thus shows, by Lebesgue's dominated convergence theorem, that $[T_{co}(\mathbf{E})]_r$ is jointly continuous in $\Sigma_c(\mathbf{E})$, $c = 1, \dots, \Gamma$. Thanks to Definition 4.8 and the Assumption 1 of continuity of $\Sigma(E)$, we conclude that T_{co} is a continuous function of **E**. **Corollary** 5.3: Starting from the error profile $\mathbf{E}^{(0)} = \mathbf{1}$ and due to the pinning condition, as the SE progresses the perfect

side information propagates inwards and the error profile adopts the shape of the solid line shown on Fig. 7 for every iteration t > 1: it is non-decreasing for $r \le r_{\max}$ and non-increasing for $r \ge r_{\max}$ for some value of $r_{\max} \in \{3w, \dots, \Gamma - 3w + 1\}$.

Proof: For a large enough Γ , the pinning condition (25) and the variance symmetry (10) ensure that in the first SE iteration $\Sigma_c^2(\mathbf{E}^{(0)} = \mathbf{1})$ satisfies the following ordering along the positions: i) it is non-decreasing for all $c \in \{1, \ldots, 4w + 1\}, ii)$ it is non-increasing for all $c \in \{\Gamma - 4w, \dots, \Gamma\}$, *iii*) it is constant elsewhere. Using the pinning condition again and the fact that the componentwise SE operator is non-decreasing in Σ_c^2 (see the proof of Lemma 5.1), one can show that after the first SE iteration the error profile $\mathbf{\hat{E}}^{(1)}$ must adopt the following ordering: i) it is non-decreasing for all $r \in \{1, \ldots, 5w + 1\}, ii\}$ it is non-increasing for all $r \in \{\Gamma - 5w, \dots, \Gamma\}$, *iii*) it is constant elsewhere. Repeating the same argument by recursion one deduces that a double-sided wave (solid line shown in Fig. 7) propagates inwards as the SE progresses.

Recall that state evolution is initialized with $\mathbf{E}^{(0)} = \mathbf{1}$. The iterations will eventually converge to a *fixed point profile*

$$\mathbf{E}^{(\infty)} := T_{\rm co}^{(\infty)}(\mathbf{1}). \tag{29}$$

The fixed point reached by SE may be the "good" MSE floor profile E_f or may be a "bad" profile which is strictly degraded with respect to E_f .

B. Proof of threshold saturation

The goal of this section is to arrive at a proof of the two main results, namely Theorem 5.12 and Corollary 5.13, both formulated at the end of the section. In this section we consider rates in the range $0 < R < R_{pot}$. Thus the gap given in Definition 4.12 is strictly positive and finite, i.e., $0 < \Delta F_{un} < +\infty$.

Definition 5.4 (The pseudo error floor): We fix $0 < \eta < 1$ (the reader may as well think of $\eta = 1/2$ in all subsequent arguments of this section). It can be shown that continuity of $\Sigma(E)$ (Assumption 1) implies that the potential function $F_{un}(E)$ is continuous for $E \in [0, 1]$. In particular it is continuous at the error floor E_f . Therefore we can find $\delta(\eta, B, R) > 0$ such that $|F_{un}(E) - F_{un}(E_f)| \le \eta \Delta F_{un}$ whenever $|E - E_f| \le \delta(\eta, B, R)$. Now we take any $0 < \epsilon < \delta(\eta, B, R)$ and set $\overline{E}_f = E_f + \epsilon$. We have in particular $|F_{un}(\overline{E}_f) - F_{un}(E_f)| \le \eta \Delta F_{un}$. This number \overline{E}_f , will serve as a "pseudo error floor" in the analysis.

Definition 5.5 (The modified system): The modified system is a modification of the SE iterations defined by applying two saturation constraints to the error profile of the original system at every iteration. First recall that the error profile of the original system has a 0 plateau for all $r \leq 3w$ and increases until r_{max} where it reaches its maximum value $E_{\text{max}} \in [0, 1]$. It flattens after r_{max} then it decreases to reach 0 at $\Gamma - 3w + 1$ and remains null after. Now take any $0 < \epsilon < \delta(\eta, B, R)$ and set $\overline{E}_{f} = E_{f} + \epsilon$ where E_{f} is the true error floor. At each iteration the profile of the modified system is defined by applying the following two saturation constraints: (i) the profile is set to the pseudo error floor \overline{E}_{f} for all $r \leq r_{*}$, where $r_{*} + 1$ is the first position s.t the original profile is at least \overline{E}_{f} ; (ii) the profile is set to E_{max} for all $r \geq r_{\text{max}}$. For $r \in \{r_{*}, \ldots, r_{\text{max}}\}$ the profiles of the modified and original systems are equal.

Figure 7 gives an illustration of this definition: the full line corresponds to the original system and the dashed one to the modified system. By construction, the error profile of the modified system is non-decreasing and degraded with respect to that of the original system. We note that when the error floor is non-vanishing (e.g. on the AWGN channel) we could take in the analysis $\bar{E}_{\rm f} = E_{\rm f} + \epsilon \rightarrow E_{\rm f}$ for fixed code parameters. However for zero error floor we need to have $\epsilon > 0$ in the analysis. For code parameters w and Γ large enough we can make ϵ arbitrarily small.

The fixed point profile of the modified system is degraded with respect to $\mathbf{E}^{(\infty)}$, thus the modified system serves as an upper bound in our proof. Note that the SE iterations of the modified system also satisfy the monotonicity properties of T_{co} (see Section V-A). Moreover, the modified system preserves the shape of the single-sided wave at all times. In the rest of this section we shall work with the modified system.

We now choose a proper shift of the saturated profile in Definition 5.6, and then evaluate the change in potential due to this shift in two different ways in Lemma 5.9 and Lemma 5.11. Theorem 5.12 and Corollary 5.13 will then be easy consequences. *Definition 5.6 (Shift operator):* The *shift operator* is defined pointwise as $[S(E)]_1 := \bar{E}_f$, $[S(E)]_r := E_{r-1}$.

Lemma 5.7: Let **E** be a fixed point profile of the modified system initialized with $\mathbf{E}^{(0)} = \mathbf{1}$. Then there exist $\hat{t} \in [0, 1]$ such that

$$F_{\rm co}(\mathbf{S}(\mathbf{E})) - F_{\rm co}(\mathbf{E}) = \frac{1}{2} \sum_{r,r'=1}^{\Gamma} \Delta E_r \Delta E_{r'} \left[\frac{\partial^2 F_{\rm co}}{\partial E_r \partial E_{r'}} \right]_{\hat{\mathbf{E}}}$$

where $\Delta E_r := E_r - E_{r-1}$ and $\hat{\mathbf{E}} := (1 - \hat{t})\mathbf{E} + \hat{t}\mathbf{S}(\mathbf{E})$. Note that \hat{t} depends in a non-trivial fashion on \mathbf{E} .

Proof: Consider $F_{co}(t) := F_{co}(\mathbf{E} + t(\mathbf{S}(\mathbf{E}) - \mathbf{E}))$ and note that $F_{co}(0) = F_{co}(\mathbf{E})$, $F_{co}(1) = F_{co}(\mathbf{S}(\mathbf{E}))$. Since $[\mathbf{S}(\mathbf{E})]_r = E_r + \Delta \mathbf{E}_r$ the mean value theorem yields

$$F_{\rm co}(\mathbf{S}(\mathbf{E})) - F_{\rm co}(\mathbf{E}) = -\sum_{r=1}^{\Gamma} \Delta E_r \left[\frac{\partial F_{\rm co}}{\partial E_r} \right]_{\mathbf{E}} + \frac{1}{2} \sum_{r,r'=1}^{\Gamma} \Delta E_r \Delta E_{r'} \left[\frac{\partial^2 F_{\rm co}}{\partial E_r \partial E_{r'}} \right]_{\hat{\mathbf{E}}},\tag{30}$$

for some suitable $\hat{t} \in [0, 1]$. By saturation of \mathbf{E} , $\Delta E_r = 0 \forall r \in \mathcal{B} := \{1, \dots, r_*\} \cup \{r_{\max} + 1, \dots, \Gamma\}$. Moreover for $r \notin \mathcal{B}$, $E_r = [T_{co}(\mathbf{E})]_r$, and thus by Lemma 4.15 the potential derivative cancels at these positions. Hence the first sum in the right hand side of (30) cancels.

Lemma 5.8: The fixed point profile of the modified system initialized with $\mathbf{E}^{(0)} = \mathbf{1}$ is *smooth*, meaning that ΔE_r satisfies the following

$$\begin{aligned} |\Delta E_r| &\leq \frac{g_* + \bar{g}}{wg} \exp(-c(B)\Sigma^{-2}(E_{r+w})) \\ &\leq \frac{g_* + \bar{g}}{wg}, \end{aligned}$$

where w is the coupling window and c(B) > 0 is a constant depending only on B; whereas g_* , \bar{g} and \underline{g} correspond to the design function defined in Section II-B.

Proof: $\Delta E_r = 0$ for all $r \in \mathcal{B}$. By construction of $\{J_{r,c}\}$ we have

$$J_{r,c} \le \frac{g_w((r-c)/w)}{\underline{g}(2w+1)},$$

Moreover from Definitions 4.8 and 4.9 of the coupled state evolution operator, the fact that mmse is an increasing function of the noise and Lemma 4.2, we have $mmse(\Sigma_c(\mathbf{E})) \leq mmse(\Sigma(E_{r+w}))$ for $c = r - w, \dots, r + w$. Thus using Lipschitz continuity of g_w , we have for all $r \notin \mathcal{B}$ that

$$|\Delta E_{r}| = \left| [T_{co}(\mathbf{E})]_{r} - [T_{co}(\mathbf{E})]_{r-1} \right| = \left| \sum_{c=1}^{\Gamma} (J_{r,c} - J_{r-1,c}) \operatorname{mmse}(\Sigma_{c}(\mathbf{E})) \right|$$

$$\leq \frac{\operatorname{mmse}(\Sigma(E_{r+w}))}{(2w+1)\underline{g}} \sum_{c=1}^{\Gamma} \left| g_{w} \left(\frac{r-c}{w} \right) - g_{w} \left(\frac{r-1-c}{w} \right) \right|$$

$$\leq \frac{\operatorname{mmse}(\Sigma(E_{r+w}))}{(2w+1)\underline{g}} \left(2w \frac{g_{*}}{w} + |g_{w}(1)| + |g_{w}(-1)| \right)$$

$$< \frac{\operatorname{mmse}(\Sigma(E_{r+w}))}{2w\underline{g}} \left(2g_{*} + 2\overline{g} \right)$$

$$\leq \frac{g_{*} + \overline{g}}{w\underline{g}} \exp(-c(B)\Sigma^{-2}(E_{r+w})). \tag{31}$$

The last inequality is obtained by knowing that for an equivalent AWGN channel of variance Σ^2 and under *discrete prior*, mmse(Σ) $\leq \exp(-c\Sigma^{-2})$ where c is some positive number that depends on the prior (see e.g. Appendix D of [37] for an explicit proof). Here the prior is uniform over sections so this number depends only on B.

Lemma 5.9: Let **E** be a fixed point profile of the modified system initialized with $\mathbf{E}^{(0)} = \mathbf{1}$. Then the coupled potential verifies

$$\frac{1}{2} \Big| \sum_{r,r'=1}^{\Gamma} \Delta E_r \Delta E_{r'} \left[\frac{\partial^2 F_{\rm co}}{\partial E_r \partial E_{r'}} \right]_{\hat{\mathbf{E}}} \Big| < \frac{K(B, \bar{g}, \underline{g}, g_*)}{(E_{\rm f} + \epsilon)^{2\beta} Rw}.$$

where $K(B, \bar{g}, g, g_*) > 0$. In particular, the RHS is $\mathcal{O}(w^{-1})$.

Proof: First remark that a fixed point of the modified system satisfies $\mathbf{E} \succeq \mathbf{E}_{f}$. For $\mathbf{E} = \mathbf{E}_{f}$ the result is immediate since $\Delta E_{r} = 0$. It remains to prove this lemma for \mathbf{E} a fixed point of the modified system such that $\mathbf{E} \succ \mathbf{E}_{f}$. In Appendix III we prove that

$$\left[\frac{\partial^2 F_{\rm co}}{\partial E_r \partial E_{r'}}\right]_{\hat{\mathbf{E}}} \le \delta_{r,r'} \frac{K_1(B, \bar{g}, \underline{g})}{(E_{\rm f} + \epsilon)R} + 1_{|r-r'| \le 2w+1} \frac{K_2(B, \bar{g}, \underline{g})}{(E_{\rm f} + \epsilon)^{2\beta} R(2w+1)}$$
(32)

for some finite positive $K_1(B, \bar{g}, \underline{g})$ and $K_2(B, \bar{g}, \underline{g})$ independent of w and Γ . Since $\Delta E_r \ge 0$, using the triangle inequality we get

$$\begin{split} \frac{1}{2} \Big| \sum_{r,r'=1}^{\Gamma} \Delta E_r \Delta E_{r'} \left[\frac{\partial^2 F_{\text{co}}}{\partial E_r \partial E_{r'}} \right]_{\hat{\mathbf{E}}} \Big| &\leq \frac{K_1(B,\bar{g},\underline{g})}{2(E_{\text{f}}+\epsilon)R} \sum_{r=1}^{\Gamma} \Delta E_r^2 + \frac{K_2(B,\bar{g},\underline{g})}{2(E_{\text{f}}+\epsilon)^{2\beta}R(2w+1)} \sum_{r=1}^{\Gamma} \Delta E_r \sum_{r'=r-w}^{r+w} \Delta E_{r'} \\ &\leq \frac{K_1(B,\bar{g},\underline{g})}{2(E_{\text{f}}+\epsilon)R} \max_{r'} \Delta E_{r'} \sum_{r=r_*+1}^{r_{\max}} \Delta E_r + \frac{K_2(B,\bar{g},\underline{g})}{2(E_{\text{f}}+\epsilon)^{2\beta}R} \max_{r'} \Delta E_{r'} \sum_{r=r_*+1}^{r_{\max}} \Delta E_r \\ &\leq \frac{K_1(B,\bar{g},\underline{g},g_*)}{2(E_{\text{f}}+\epsilon)Rw} + \frac{K_2'(B,\bar{g},\underline{g},g_*)}{2(E_{\text{f}}+\epsilon)^{2\beta}Rw}. \end{split}$$

To get the last inequality we used Lemma 5.8 and $\sum_{r=r_*+1}^{r_{\text{max}}} \Delta E_r = E_{\text{max}} - E_{r_*+1} < 1$. Finally, one can find $K(B, \bar{g}, \underline{g}, g_*) > 0$ such that the last estimate is smaller than $K(B, \bar{g}, \underline{g}, g_*) > 0$

$$\frac{\overline{R(D,g,\underline{g},g_*)}}{(E_{\rm f}+\epsilon)^{2\beta}Rw}$$

The change in potential due to the shift can be also computed by direct evaluation as shown in the following lemmas.

Lemma 5.10: Let **E** be a fixed point profile of the modified system initialized with $\mathbf{E}^{(0)} = \mathbf{1}$. If $\mathbf{E} \succ \bar{\mathbf{E}}_{f}$, then E_{max} cannot be in the basin of attraction to the MSE floor, i.e., $E_{max} \notin \mathcal{V}_0$.

Proof: Knowing that $\mathbf{E} \succ \bar{\mathbf{E}}_{f}$ and also that \mathbf{E} is non-decreasing implies $\bar{E}_{f} < E_{max}$. Moreover, we have that

$$E_{\max} = [T_{co}(\mathbf{E})]_{r_{\max}} = \sum_{c=1}^{\Gamma} J_{r_{\max,c}} \operatorname{mmse}(\Sigma_c(\mathbf{E})) \le \sum_{c=1}^{\Gamma} J_{r_{\max,c}} \operatorname{mmse}(\Sigma(E_{\max})) \le T_{un}(E_{\max}),$$
(33)

where the first inequality follows from the fact that $\Sigma_c(\mathbf{E}) \leq \Sigma(E_{\max})$ due to the variance symmetry (10) at r_{\max} and the fact that \mathbf{E} is non-decreasing. The second inequality follows from the variance normalization (4). Applying the monotonicity of T_{un} on (33) yields

$$E_{\rm f} < \bar{E}_{\rm f} < E_{\rm max} \le T_{\rm un}^{(\infty)}(E_{\rm max}),\tag{34}$$

which implies that $E_{\max} \notin \mathcal{V}_0$.

Lemma 5.11: Let $0 < \eta < 1$ fixed and $\bar{E}_{f} = E_{f} + \epsilon$ with any $0 < \epsilon < \delta(\eta, B, R)$ where $\delta(\eta, B, R)$ has been constructed in Definition 5.4. Let $\mathbf{E} \succ \bar{\mathbf{E}}_{f}$ be a fixed point profile of the modified system initialized with $\mathbf{E}^{(0)} = \mathbf{1}$. Then \mathbf{E} satisfies

$$F_{\rm co}(\mathbf{S}(\mathbf{E})) - F_{\rm co}(\mathbf{E}) \leq -(1-\eta)\Delta F_{\rm un},$$

where ΔF_{un} is the free energy gap of the underlying system given in Definition 4.12.

Proof: The contribution of the change in the "energy" term is a perfect telescoping sum:

$$U_{\rm co}(\mathbf{S}(\mathbf{E})) - U_{\rm co}(\mathbf{E}) = U_{\rm un}(\bar{E}_{\rm f}) - U_{\rm un}(E_{\rm max}). \tag{35}$$

We now deal with the contribution of the change in the "entropy" term. Using the properties of the construction of $J_{r,c}$ we notice that for all $c \in \{2w + 1, ..., \Gamma - 2w - 1\}$

$$\Sigma_{c+1}^{-2}(\mathbf{S}(\mathbf{E})) = \sum_{r=c+1-w}^{c+1+w} \frac{J_{r,c+1}}{\Sigma^2(E_{r-1})} = \sum_{r=c-w}^{c+w} \frac{J_{r+1,c+1}}{\Sigma^2(E_r)} = \sum_{r=c-w}^{c+w} \frac{J_{r,c}}{\Sigma^2(E_r)} = \Sigma_c^{-2}(\mathbf{E})$$
(36)

which yields

$$S_{\rm co}(\mathbf{E}) - S_{\rm co}(\mathbf{S}(\mathbf{E})) = S_{\rm un}(\Sigma_{\Gamma-2w}(\mathbf{E})) - S_{\rm un}(\Sigma_{2w+1}(\mathbf{S}(\mathbf{E}))) - \sum_{c \in \mathcal{S}} [S_{\rm un}(\Sigma_c(\mathbf{S}(\mathbf{E}))) - S_{\rm un}(\Sigma_c(\mathbf{E}))],$$
(37)

where $S := \{1, ..., 2w\} \cup \{\Gamma - 2w + 1, ..., \Gamma\}$. By the saturation of the modified system, **E** possesses the following property

$$[\mathbf{S}(\mathbf{E})]_r = [\mathbf{E}]_r \quad \text{for all} \quad r \in \{1, \dots, r_*\} \cup \{r_{\max} + 1, \dots, \Gamma\}.$$
(38)

Hence, $\Sigma_c(\mathbf{S}(\mathbf{E})) = \Sigma_c(\mathbf{E})$ for all $c \in S$ and thus the sum in (37) cancels. Furthermore, one can show, using the saturation of \mathbf{E} and the variance symmetry (10), that $\Sigma_{2w+1}(\mathbf{S}(\mathbf{E})) = \Sigma(\bar{E}_f)$. The same arguments and the fact that $r_{\max} \leq \Gamma - 3w$ for $\mathbf{E} \succ \bar{\mathbf{E}}_f$ lead to $\Sigma_{\Gamma-2w}(\mathbf{E}) = \Sigma(E_{\max})$. Hence, (37) yields

$$S_{\rm co}(\mathbf{E}) - S_{\rm co}(\mathbf{S}(\mathbf{E})) = S_{\rm un}(\Sigma(E_{\rm max})) - S_{\rm un}(\Sigma(\bar{E}_{\rm f})).$$
(39)

Combining (35) with (39) gives

$$F_{\rm co}(\mathbf{S}(\mathbf{E})) - F_{\rm co}(\mathbf{E}) = -(F_{\rm un}(E_{\rm max}) - F_{\rm un}(E_{\rm f}))$$

= -(F_{\rm un}(E_{\rm max}) - F_{\rm un}(E_{\rm f})) + (F_{\rm un}(\bar{E}_{\rm f}) - F_{\rm un}(E_{\rm f})).

Using the definition of the free energy gap (Definition 4.12), the fact that $E_{\max} \notin \mathcal{V}_0$ (Lemma 5.10), and $F_{un}(\bar{E}_f) - F_{un}(E_f) \le \eta \Delta F_{un}$ we find

$$F_{\rm co}(\mathbf{S}(\mathbf{E})) - F_{\rm co}(\mathbf{E}) \le -(1-\eta)\Delta F_{\rm un}.$$

Using Lemmas 5.7, 5.9, 5.11 we now prove threshold saturation.

Theorem 5.12: Let $0 < \eta < 1$ fixed and $\overline{E}_{f} = E_{f} + \epsilon$ with any $0 < \epsilon < \delta(\eta, B, R)$ where $\delta(\eta, B, R)$ has been constructed in Definition 5.4. Fix

$$R < R_{\text{pot}} \quad \text{and} \quad w > \frac{K(B, \bar{g}, \underline{g}, g_*)}{(E_{\text{f}} + \epsilon)^{2\beta} R(1 - \eta) \Delta F_{\text{un}}}$$
(40)

Then the fixed point profile $E^{(\infty)}$ of the coupled SE must satisfy $E^{(\infty)} \preceq \bar{E}_f.$

Proof: Assume that, under these hypotheses, the fixed point profile of the modified system initialized with $\mathbf{E}^{(0)} = \mathbf{1}$ is such that $\mathbf{E} \succ \bar{\mathbf{E}}_{f}$. On one hand by Lemma 5.11 we have for $R < R_{pot}$ a positive ΔF_{un} and

$$|F_{\rm co}(\mathbf{E}) - F_{\rm co}(\mathbf{S}(\mathbf{E}))| \ge (1 - \eta)\Delta F_{\rm un}.$$

On the other hand by Lemmas 5.7 and 5.9

$$|F_{\rm co}(\mathbf{E}) - F_{\rm co}(\mathbf{S}(\mathbf{E}))| \le \frac{K(B, \bar{g}, \underline{g}, g_*)}{(E_{\rm f} + \epsilon)^{2\beta} R w}$$

Figure 8. The potential threshold v.s the alphabet size B for the BEC with erasure probability $\epsilon = 0.1$.

Thus we get

$$w \le \frac{K(B, \bar{g}, \underline{g}, g_*)}{(E_{\mathrm{f}} + \epsilon)^{2\beta} R(1 - \eta) \Delta F_{\mathrm{u}}}$$

which is a contradiction. Hence, $\mathbf{E} \preceq \bar{\mathbf{E}}_{\mathrm{f}}$. Since $\mathbf{E} \succeq \mathbf{E}^{(\infty)}$ we have $\mathbf{E}^{(\infty)} \preceq \bar{\mathbf{E}}_{\mathrm{f}}$.

The most important consequence of this theorem is a statement on the GAMP threshold,

Corollary 5.13: By first taking $\Gamma \to \infty$ and then $w \to \infty$, the GAMP threshold of the coupled ensemble satisfies $R_{\rm co} \ge R_{\rm pot}$. This result follows from Theorem 5.12 and Definition 4.10. Once the limit $w \to +\infty$ is taken we can send $\epsilon \to 0$ and the pseudo error floor tends to the true error floor $\bar{E}_{\rm f} \to E_{\rm f}$.

C. Discussion

Corollary 5.13 says that the GAMP threshold for the coupled codes saturates the potential threshold in the limit $w \to +\infty$. It is in fact not possible to have the strict inequality $R_{\rm co} > R_{\rm pot}$, so in fact equality holds, but the proof would require a separate argument that we omit here because it is not so informative. Besides, this equality is not needed in order to argue that sparse superposition codes universally achieve capacity under GAMP decoding when $B \to +\infty$. Indeed we have necessarily $R_{\rm co} < C$ and we show in Section VI, using non-rigorous asymptotic computations, that $\lim_{B\to\infty} R_{\rm pot} = C$. Thus $\lim_{B\to\infty} R_{\rm co} = C$.

We emphasize that Theorem 5.12 and Corollary 5.13 hold for a large class of estimation problems with random linear mixing [31]. Both the SE and potential formulations of Section IV as well as the proof given in the present section are not restricted to SS codes. Indeed all the definitions and results are obtained for any memoryless channel P_{out} and can be generalized for any factorizable (over *B*-dimensional sections) prior of the message (or signal) **s**.

Theorem 5.12 states that for w large enough the state evolution iterations will drive the MSE profile below some pseudo error floor $\bar{E}_{\rm f} = E_{\rm f} + \epsilon$. This is then enough information to deduce that the threshold saturation phenomenon happens in the limit where $w \to +\infty$ (and note we do not expect full threshold saturation, i.e., $R_{\rm co} \to R_{\rm pot}$ for finite w). However, it is worth pointing out that the condition (40) in Theorem 5.12 on the size of the coupling window is most probably *not* optimal. We conjecture that a better bound should hold where $w > C/\Delta F_{\rm un}$ for some C > 0 which does *not* diverge when $E_{\rm f} + \epsilon \to 0$. The appearance of the error floor in the denominator can be traced back to inequality (32) whose derivation is detailed in Appendix III. One possible way to cancel this divergence would be to obtain a better bound on ΔE_r than the one given by (31). More precisely if E_{r+w} can be replaced by E_r then the proof of Lemma 5.9 and Theorem 5.12 would give a more resonable lower bound for w. Carrying out this program presents technical difficulties in the analysis of coupled state evolution which we have not overcome in this work. The present difficulties do not appear in the analysis of spatially coupled LDPC codes [25].

VI. LARGE ALPHABET SIZE ANALYSIS AND CONNECTION WITH SHANNON'S CAPACITY

We now show, through non-rigorous analytical computations, that as the alphabet size B increases, the potential threshold of SS codes approaches Shannon's capacity $R_{\text{pot}}^{\infty} := \lim_{B\to\infty} R_{\text{pot}} = C$ (Fig. 8), and also that $\lim_{B\to\infty} E_{\text{f}} = 0$. These are "static" or "information theoretic" properties of the code independent of the decoding algorithm. Nevertheless this result has an algorithmic consequence. The threshold saturation established in Corollary 5.13 for spatially coupled SS codes suggests that optimal decoding can actually be performed using the GAMP decoder, i.e. $\lim_{B\to\infty} R_{\text{co}} = C$, because $R_{\text{pot}} \leq R_{\text{co}} \leq C$.

The potential of the underlying system contains all the information about R_{pot} and R_{un} . Hence, we proceed by computing the potential in the large B regime,

$$\varphi_{\rm un}(E) := \lim_{B \to \infty} F_{\rm un}(E). \tag{41}$$

Figure 9. The large alphabet potential $\varphi_{un}(E)$ (42) as a function of the error parameter E for the BSC (left) and AWGN (right) channels with $\epsilon = 0.1$ and snr = 10 respectively. $\varphi_{un}(E)$ is scaled such that $\varphi_{un}(0) = 0$. For R below the "asymptotic" GAMP threshold R_{un}^{∞} , there is a unique minimum at E = 0 while just above R_{un}^{∞} , this minimum coexists with a local one at E = 1. At the optimal threshold of the code, that coincides with the Shannon capacity, the two minima are equal. Then, for R > C the minimum at E = 1 becomes the global one, and thus decoding is impossible.

The limit (41) was heuristically computed in [17, 46] for the AWGN channel. Extending this computation to the present setting, one obtains

$$\varphi_{\rm un}(E) = U_{\rm un}(E) - \max\left(0, 1 - \frac{1}{2\ln(2)\Sigma^2(E)}\right). \tag{42}$$

The extension from the AWGN case is straightforward, the $U_{un}(E)$ term in $F_{un}(E)$ is independent of B while the $S_{un}(\Sigma(E))$ term remains the same. The difference is only in the computation of the effective noise $\Sigma(E)$, which is independent of B. We note that (42) is not a trivial asymptotic calculation because the "entropy" term $S_{un}(\Sigma(E))$ involves a B-dimensional integral (see Definition 4.11). Since $B \to \infty$, this amounts to compute a "partition function" (or equivalently solve a non-linear estimation problem where the signal has one non-zero component). We have not attempted to make this asymptotic computation rigorous but we expect that such computation could be made rigorous using the recent work [36–40].

The analysis of (42) for $E \in [0, 1]$ leads to the following

Claim 1: For a fixed rate R and $E \in [0, 1]$, the only possible local minima of $\varphi_{un}(E)$ are at E = 0 and E = 1. Furthermore, for $E' \in \{E \in [0, 1] \mid 2\ln(2)\Sigma^2(E) < 1\}$ the minimum is at E' = 0 and for $E' \in \{E \in [0, 1] \mid 2\ln(2)\Sigma^2(E) > 1\}$ the minimum is at E' = 1.

Note that this result was rigorously proven for the AWGN channel in [17] and then verified for several memoryless channels in [32]. A fully rigorous analysis of the function $\varphi_{un}(E)$ would be lengthy; we thus only claim the result here, which is confirmed by numerical analysis.

The existence of a minimum at E = 0 means that the error floor $E_{\rm f}$, if it exists, vanishes as B increases (Fig. 9). Moreover, if $\Sigma^2(E) < (2\ln(2))^{-1} \forall E \in [0,1]$, which corresponds to the region $R < (2\ln(2))^{-1} \mathbb{E}_{p|1}[\mathcal{F}(p|1)]$, then $\varphi_{\rm un}(E)$ has a unique minimum at E = 0. Similarly if $\Sigma^2(E) > (2\ln 2)^{-1} \forall E \in [0,1]$, corresponding to $R > (2\ln(2))^{-1} \mathbb{E}_{p|0}[\mathcal{F}(p|0)]$, then $\varphi_{\rm un}(E)$ has a unique minimum at E = 1. For *intermediate rates* both minima exist.

Therefore, we identify the algorithmic GAMP threshold, when $B \to +\infty$, as the smallest rate such that a second minimum appears,

$$R_{\rm un}^{\infty} := \lim_{B \to \infty} R_{\rm un} = \frac{\mathbb{E}_{p|1}[\mathcal{F}(p|1)]}{2\ln(2)} = \frac{\mathcal{F}(0|1)}{2\ln(2)}.$$
(43)

Recall R_{pot} is defined by the point where ΔF_{un} switches sign (Definition 4.13). Thus R_{pot}^{∞} can be obtained by equating the two minima of $\varphi_{\text{un}}(E)$. The potential (42) takes the following values at the two minimizers

$$\begin{aligned} \varphi_{\mathrm{un}}(0) &= -\frac{1}{R} \mathbb{E}_z \left[\int dy \, \phi(y|z,0) \log_2\left(\phi(y|z,0)\right) \right], \\ \varphi_{\mathrm{un}}(1) &= -\frac{1}{R} \mathbb{E}_z \left[\int dy \, \phi(y|z,1) \log_2\left(\phi(y|z,1)\right) \right] - 1 \end{aligned}$$

where $\phi(y|z, E)$ is given in Definition 4.11. Then, setting $\varphi_{un}(1) = \varphi_{un}(0)$ yields

$$R_{\text{pot}}^{\infty} = -\int \int dz dy \mathcal{N}(z|0,1) P_{\text{out}}(y|z) \log_2 \left(\int d\tilde{z} \mathcal{N}(\tilde{z}|0,1) P_{\text{out}}(y|\tilde{z}) \right) + \int \int dz dy \mathcal{N}(z|0,1) P_{\text{out}}(y|z) \log_2 \left(P_{\text{out}}(y|z) \right).$$
(44)

We will now recognize that this expression is the Shannon capacity of W for a proper choice of the map π .

Let \mathcal{A} and \mathcal{B} be the input and output alphabet of W respectively, where $\mathcal{A}, \mathcal{B} \subseteq \mathbb{R}$ have discrete or continuous supports. Call \mathcal{P} the capacity-achieving input distribution associated with W. Choose $\pi : \mathbb{R} \to \mathcal{A}$ such that i) $P_{\text{out}}(y|z) = W(y|\pi(z))$ and ii) if $Z \sim \mathcal{N}(0,1)$, then $\pi(Z) \sim \mathcal{P}$. This map converts a standard Gaussian random variable Z onto a channel-input random variable $\pi(Z) = A$ with capacity-achieving distribution $\mathcal{P}(a)$. Recall that π can be viewed equivalently as part of the code or of the channel.

Now using the relation

$$\int dz \mathcal{N}(z|0,1) P_{\text{out}}(y|z) = \int dz \mathcal{N}(z|0,1) W(y|\pi(z)) = \int da \mathcal{P}(a) W(y|a),$$

(44) can be expressed equivalently as

$$R_{\text{pot}}^{\infty} = -\int \int dy da \mathcal{P}(a) W(y|a) \log_2 \left(\int d\tilde{a} \mathcal{P}(\tilde{a}) W(y|\tilde{a}) \right) + \int \int dy da \mathcal{P}(a) W(y|a) \log_2 \left(W(y|a) \right).$$
(45)

The first term in (45) is nothing but the Shannon entropy H(Y) of the channel output-distribution. The second term eaquals minus the conditional entropy H(Y|A) of the channel-output distribution given the input $A = \pi(Z)$ with capacity-achieving distribution. Thus, R_{pot}^{∞} is the Shannon capacity of W. Combining this result with Corollary 5.13, we can argue that spatially coupled SS codes allow to communicate reliably up to Shannon's capacity over any memoryless channel under low complexity GAMP decoding.

An essential question remains on how to find the proper map π for a given memoryless channel. In the case of discrete input memoryless symmetric channels, Shannon's capacity can be attained by inducing a uniform input distribution $\mathcal{P} = \mathcal{U}_{\mathcal{A}}$. Let us call q the cardinality of $\mathcal{A} = \{a_1, \ldots, a_q\}$. In this case the mapping π is simply $\pi(z) = a_i$ if $z \in]z_{(i-1)/q}, z_{i/q}]$, where $z_{i/q}$ is the *i*th q-quantile⁴ of the Gaussian distribution, with $z_0 = -\infty, z_1 = \infty$. For asymmetric channels, one can use some standard methods such as Gallager's mapping or more advanced ones [47] that introduce bias in the channel-input distribution in order to match the capacity-achieving one. We now illustrate these findings for various channels as depicted in Fig. 10 and Fig. 11.

A. AWGN channel

We start showing that our results for the AWGN channel [21] are a special case of the present general framework. No map π is required and the Shannon capacity is directly obtained from (44) because the capacity-achieving input distribution for the AWGN channel is Gaussian. Thus, by replacing $P_{\text{out}}(y|z) = \mathcal{N}(y|z, 1/\text{snr})$ in (44), one recovers the Shannon capacity $R_{\text{pot}}^{\infty} = \frac{1}{2}\log_2(1 + \text{snr})$. Furthermore, from (43) one obtains the following algorithmic threshold as $B \to \infty$

$$R_{\rm un}^{\infty} = \frac{1}{2\ln(2)(1+{\rm snr}^{-1})}.$$
(46)

B. Binary symmetric channel

The BSC with flip probability⁵ ϵ has transition probability $W(y|a) = (1-\epsilon)\delta(y-a) + \epsilon\delta(y+a)$, where $\mathcal{A} = \mathcal{B} = \{-1, 1\}$. The proper map is $\pi(z) = \operatorname{sign}(z)$. For $Z \sim \mathcal{N}(0, 1)$, this map induces uniform input distribution $\mathcal{U}_{\mathcal{A}} = 1/2$. So by replacing W and $\mathcal{U}_{\mathcal{A}}$ in (45), or equivalently $P_{\operatorname{out}}(y|z) = (1-\epsilon)\delta(y-\pi(z)) + \epsilon\delta(y+\pi(z))$ into (44), one obtains the Shannon capacity of the BSC channel $R_{\operatorname{pot}}^{\infty} = 1 - h_2(\epsilon)$ where h_2 is the binary entropy function. Using (43) this map also gives the algorithmic threshold

$$R_{\rm un}^{\infty} = \frac{(1 - 2\epsilon)^2}{\pi \ln(2)}.$$
(47)

C. Binary erasure channel

Note that the BEC is also symmetric. Therefore, the same mapping $\pi(z) = \operatorname{sign}(z)$ is used and leads to the Shannon capacity $R_{\text{pot}}^{\infty} = 1 - \epsilon$, where ϵ is the erasure probability. Moreover, from (43) the algorithmic threshold for the BEC when $B \to \infty$ is

$$R_{\rm un}^{\infty} = \frac{1-\epsilon}{\pi\ln(2)}.\tag{48}$$

⁴With $z_{i/q} = Q^{-1}(1 - i/q)$, where $Q^{-1}(\cdot)$ is the inverse of the Gaussian Q-function defined by $Q(x) = \int_x^{+\infty} dt \, \frac{e^{-\frac{t^2}{2}}}{\sqrt{2\pi}}$. ⁵With a slight abuse of notation, we use ϵ here as a channel parameter. Not to confuse with ϵ of Section V (Definition 5.4).

Figure 10. The capacities and GAMP thresholds in the infinite alphabet limits for the BSC (left) and AWGN (right) channels.

D. Z channel

The Z channel is the "most asymmetric" discrete channel. It has binary input and output $\mathcal{A} = \mathcal{B} = \{-1, 1\}$ with transition probability $W(y|a) = \delta(a-1)\delta(y-a) + \delta(a+1)[(1-\epsilon)\delta(y-a) + \epsilon\delta(y+a)]$, where ϵ is the flip probability of the -1 input. The map $\pi(z) = \text{sign}(z)$ leads to the symmetric capacity of the Z channel

$$R_{\rm pot}^{\infty}\left(\frac{1}{2}\right) = C\left(\frac{1}{2}\right) = h_2((1-\epsilon)/2) - h_2(\epsilon)/2,\tag{49}$$

where $C(\frac{1}{2})$ denotes the symmetric capacity, in other words the input-output mutual information when the input is uniformly distributed with $\mathcal{U}_{\mathcal{A}} = 1/2$. Under the same map $\pi(z)$, one obtains the following algorithmic threshold in the limit $B \to +\infty$

$$R_{\rm un}^{\infty}(\frac{1}{2}) = \frac{1-\epsilon}{\pi \ln(2)(1+\epsilon)}.$$
(50)

Note that the expression of $R_{\text{pot}}^{\infty}(\frac{1}{2})$ differs from Shannon's capacity. However, one can introduce bias in the input distribution and hence match the capacity-achieving one. To do so, the proper map defined in terms of the Q-function⁶ is $\pi(z) = \text{sign}(z - Q^{-1}(p_1))$, where p_1 is the induced input probability of the bit 1.

By optimizing over p_1 , one can obtain Shannon's capacity of the Z channel

$$R_{\text{pot}}^{\infty}(p_1^*) = C(p_1^*) = h_2((1-p_1^*)(1-\epsilon)) - (1-p_1^*)h_2(\epsilon),$$
(51)

with

$$p_1^* = 1 - \left[(1 - \epsilon)(1 + 2^{h_2(\epsilon)/(1 - \epsilon)}) \right]^{-1}.$$
(52)

Using this optimal map, one obtains the following algorithmic threshold as depicted in Fig. 11

$$R_{\rm un}^{\infty}(p_1^*) = \frac{(1-\epsilon) \left(e^{-[Q^{-1}(p_1^*)]^2/2}\right)^2}{4\pi \ln(2)(1-p_1^*)((1-p_1^*)\epsilon + p_1^*)}.$$
(53)

VII. CONCLUSION AND OPEN CHALLENGES

In this work, we argue that spatially coupled SS codes universally achieve capacity over any memoryless channel under GAMP decoding. In particular, we prove that spatial coupling allows the algorithmic GAMP performance to saturate the potential threshold of the underlying code ensemble. Moreover, we show by analytical calculation that the potential threshold tends to capacity and the error floor vanishes in the proper limit. The approach taken in this work relies on the SE analysis and the application of the potential method.

We end up pointing out some open problems. In order to have a fully rigorous capacity achieving scheme over any memoryless channel, using spatially coupled SS codes and GAMP decoding, it must be shown that SE tracks the asymptotic performance of GAMP for the *B*-dimensional prior. We conjecture that this is indeed the case. The proof is beyond the scope of this work and would follow by extending the analysis of [6, 20] to the SS codes setting as done in [5] for AMP. Moreover, a rigorous proof of the asymptotic alphabet size analysis of Section VI is also needed.

⁶Here
$$Q(x) = \int_{x}^{+\infty} dt \; \frac{e^{-\frac{t^2}{2}}}{\sqrt{2\pi}}.$$

Figure 11. Capacity and GAMP threshold of the Z channel in the infinite alphabet limits. $C(p_1^*)$ and $R_{un}^{\infty}(p_1^*)$ are the values under capacity-achieving input distribution, whereas $C(\frac{1}{2})$ and $R_{un}^{\infty}(\frac{1}{2})$ are the values under uniform distribution.

It is also desirable to consider practical coding schemes using Hadamard-based operators or, more generally, row-orthogonal matrices. Another important point is to estimate at what rate the error floor vanishes as *B* increases (when it exists e.g., in the AWGN channel). Finally, finite size effects should be considered in order to assess the practical performance of these codes, a direction which was recently pursued for power allocated codes in [41], [48] and [49].

ACKNOWLEDGMENT

The authors would like to thank Florent Krzakala, Christophe Schülke and Rüdiger Urbanke for helpful discussions and Erdem Bıyık for numerical implementation of the GAMP algorithm. The work of Jean Barbier and Mohamad Dia is supported by the Swiss national Foundation Grant no 200021-156672.

APPENDIX I

THE OUTPUT FUNCTION IN THE GAMP ALGORITHM

The GAMP algorithm was introduced for general estimation with random linear mixing in [31]. The extension to the present context of SS codes with *B*-dimensional prior was given in Section III of this paper. On a dense graphical model, an important notion of equivalent AWGN channel is used to simplify the BP messages. This notion is due to the linear mixing and it is independent of the physical channel. The physical channel P_{out} is reflected in the computation of the equivalent AWGN channel's parameter through the function $g_{out}(\mathbf{p}, \mathbf{y}, \tau)$. This function is acting componentwise and can be interpreted as a *score function* of the parameter p_i associated with the distribution of Y_i . The general expression is

$$[g_{\text{out}}(\mathbf{p}, \mathbf{y}, \boldsymbol{\tau})]_{i} = (\mathbb{E}[z_{i}|p_{i}, y_{i}, \tau_{i}] - p_{i})/\tau_{i}$$
$$= \frac{\int dz_{i}P_{\text{out}}(y_{i}|z_{i})\mathcal{N}(z_{i}|p_{i}, \tau_{i})(z_{i} - p_{i})/\tau_{i}}{\int dz_{i}P_{\text{out}}(y_{i}|z_{i})\mathcal{N}(z_{i}|p_{i}, \tau_{i})},$$
(54)

where $Z_i \sim \mathcal{N}(p_i, \tau_i)$. This expression is also equal to $\partial_{p_i} \ln f(y_i | p_i, \tau_i)$ where f is the function occurring in Definition 4.1 of the Fisher information.

In Table I⁷ we give the explicit expressions for various channels as well as their derivatives used in the GAMP algorithm of Section III (where snr is the signal-to-noise ratio of the AWGN channel, ϵ the erasure or flip probability of the BSC, BEC and ZC). The expressions of the Fisher information used in SE of Section IV are given as well. These involve the Gaussian error function $\operatorname{erf}(x) = \frac{\sqrt{2}}{\pi} \int_0^x dt \, e^{-t^2}$ and its complement $\operatorname{erfc}(x) = 1 - \operatorname{erf}(x)$. Note that, for the sake of simplicity, all the expressions for the binary input channels of Table I (BSC, BEC and ZC) are given using the map $\pi(z) = \operatorname{sign}(z)$. This map leads to a sub-optimal performance for the asymetric Z channel. The optimal map would require a bias in the input distribution as explained in Section VI-D.

APPENDIX II

STATE EVOLUTION AND POTENTIAL FUNCTION

In this appendix we prove Lemma 4.15. Namely, we show that the stationarity condition $\partial F_{un}/\partial E = 0$ for the potential function in Definition 4.11 implies the state evolution equation in Definition 4.3. We present a detailed derivation for the underlying uncoupled system. The proof of Lemma 4.15 for the coupled system follows exactly the same steps.

Table I The expressions for $g_{\mathrm{out}}, -\frac{\partial}{\partial \mathbf{p}}g_{\mathrm{out}}$ and $\mathcal{F}.$

The calculation is best done by looking at F_{un} as a function of E and $\Sigma(E)^{-2}$, so that

$$\frac{dF_{\rm un}}{dE} = -\frac{1}{2\ln(2)\Sigma(E)^2} - \frac{1}{R}\frac{\partial}{\partial E}\mathbb{E}_Z\left[\int dy\,\phi(y|Z,E)\log_2\phi(y|Z,E)\right] \\
-\left\{\frac{E}{2\ln(2)} + \frac{\partial}{\partial\Sigma(E)^{-2}}\mathbb{E}_{\mathbf{S},\mathbf{Z}}\left[\log_B\int d^B\mathbf{x}\,p_0(\mathbf{x})\theta(\mathbf{x},\mathbf{S},\mathbf{Z},\Sigma(E))\right]\right\}\frac{d}{dE}\Sigma(E)^{-2}.$$
(55)

We first look at the derivative of the bracket $\{\cdots\}$ with respect to Σ^{-2} . In the next few lines the following notation is used for the "Gibbs" average

$$\langle A(\mathbf{x}) \rangle_{\text{den}} = \frac{\int d^B \mathbf{x} \, A(\mathbf{x}) p_0(\mathbf{x}) \theta(\mathbf{x}, \mathbf{S}, \mathbf{Z}, \Sigma(E))}{\int d^B \mathbf{x} \, p_0(\mathbf{x}) \theta(\mathbf{x}, \mathbf{S}, \mathbf{Z}, \Sigma(E))}$$

Using the explicit expression of $\theta(\mathbf{x}, \mathbf{S}, \mathbf{Z}, \Sigma(E))$ we have

$$\begin{split} \frac{\partial}{\partial \Sigma(E)^{-2}} \mathbb{E}_{\mathbf{S},\mathbf{Z}} \Big[\log_B \int d^B \mathbf{x} \, p_0(\mathbf{x}) \theta(\mathbf{x}, \mathbf{S}, \mathbf{Z}, \Sigma(E)) \Big] \\ &= \frac{\partial}{\partial \Sigma(E)^{-2}} \mathbb{E}_{\mathbf{S},\mathbf{Z}} \Big[\log_B \int d^B \mathbf{x} \, p_0(\mathbf{x}) e^{-\frac{1}{2} \left(\|\mathbf{x} - \mathbf{S}\|^2 \Sigma(E)^{-2} \frac{\ln B}{\ln 2} - 2\mathbf{Z} \cdot (\mathbf{x} - \mathbf{S}) \Sigma(E)^{-1} \sqrt{\frac{\ln B}{\ln 2}} + \|Z\|^2 \right)} \Big] \\ &= -\frac{1}{2 \ln 2} \mathbb{E}_{\mathbf{S},\mathbf{Z}} \Big[\langle \|\mathbf{x} - \mathbf{S}\|^2 \rangle_{den} \Big] + \frac{1}{2} \mathbb{E}_{\mathbf{S},\mathbf{Z}} \Big[\mathbf{z} \cdot \langle \mathbf{x} - \mathbf{S} \rangle_{den} \Big] \frac{\Sigma(E)}{\sqrt{(\ln B)(\ln 2)}} \\ &= -\frac{1}{2 \ln 2} \mathbb{E}_{\mathbf{S},\mathbf{Z}} \Big[\langle \|\mathbf{x} - \mathbf{S}\|^2 \rangle_{den} \Big] + \frac{1}{2} \mathbb{E}_{\mathbf{S},\mathbf{Z}} \Big[\nabla_{\mathbf{Z}} \cdot \langle \mathbf{x} - \mathbf{S} \rangle_{den} \Big] \frac{\Sigma(E)}{\sqrt{(\ln B)(\ln 2)}} \\ &= -\frac{1}{2 \ln 2} \mathbb{E}_{\mathbf{S},\mathbf{Z}} \Big[\langle \|\mathbf{x} - \mathbf{S}\|^2 \rangle_{den} \Big] + \frac{1}{2 \ln 2} \mathbb{E}_{\mathbf{S},\mathbf{Z}} \Big[\langle \|\mathbf{x} - \mathbf{S}\|^2 \rangle_{den} \Big] - \frac{1}{2 \ln 2} \mathbb{E}_{\mathbf{S},\mathbf{Z}} \Big[\|\langle \mathbf{x} - \mathbf{S} \rangle_{den} \|^2 \Big] \\ &= -\frac{1}{2 \ln 2} \mathbb{E}_{\mathbf{S},\mathbf{Z}} \Big[\langle \|\mathbf{x} - \mathbf{S}\|^2 \rangle_{den} - \mathbf{S} \|^2 \Big] \\ &= -\frac{1}{2 \ln 2} \mathbb{E}_{\mathbf{S},\mathbf{Z}} \Big[\|\langle \mathbf{x} \rangle_{den} - \mathbf{S} \|^2 \Big] \\ &= -\frac{1}{2 \ln 2} \mathbb{E}_{\mathbf{S},\mathbf{Z}} \Big[\|\langle \mathbf{x} \rangle_{den} - \mathbf{S} \|^2 \Big] \\ &= -\frac{1}{2 \ln 2} \mathbb{E}_{\mathbf{S},\mathbf{Z}} \Big[\|\langle \mathbf{x} \rangle_{den} - \mathbf{S} \|^2 \Big] \\ &= -\frac{1}{2 \ln 2} \mathbb{E}_{\mathbf{S},\mathbf{Z}} \Big[\|\langle \mathbf{x} \rangle_{den} - \mathbf{S} \|^2 \Big] \\ &= -\frac{1}{2 \ln 2} \mathbb{E}_{\mathbf{S},\mathbf{Z}} \Big[\|\langle \mathbf{x} \rangle_{den} - \mathbf{S} \|^2 \Big] \\ &= -\frac{1}{2 \ln 2} \mathbb{E}_{\mathbf{S},\mathbf{Z}} \Big[\|\langle \mathbf{x} \rangle_{den} - \mathbf{S} \|^2 \Big] \\ &= -\frac{1}{2 \ln 2} \mathbb{E}_{\mathbf{S},\mathbf{Z}} \Big[\|\langle \mathbf{x} \rangle_{den} - \mathbf{S} \|^2 \Big] \\ &= -\frac{1}{2 \ln 2} \mathbb{E}_{\mathbf{S},\mathbf{Z}} \Big[\|\langle \mathbf{x} \rangle_{den} - \mathbf{S} \|^2 \Big]$$

We show below that

$$\frac{1}{\Sigma(E)^2} = -\frac{2}{R} \frac{\partial}{\partial E} \mathbb{E}_Z \left[\int dy \,\phi(y|Z, E) \ln \phi(y|Z, E) \right]$$
(56)

so that (55) becomes

$$\frac{dF_{\rm un}}{dE} = \left\{ {\rm mmse}(\Sigma(E)) - E \right\} \frac{1}{2\ln 2} \frac{d}{dE} \Sigma(E)^{-2}$$
(57)

which obviously shows that $dF_{un}/dE = 0$ implies the SE equation $E = T_{un}(E)$. We point out as a side remark that this is the correct "integrating factor" which allows to recover the potential function from the SE equation.

It remains to derive (56). We will start from the derivative with respect to E in (56) and show that this relation can be transformed into Definition 4.1, namely

$$\frac{1}{\Sigma(E)^2} = \frac{1}{R} \int dp \, \frac{e^{-\frac{p^2}{2(1-E)}}}{\sqrt{2\pi(1-E)}} \int dy f(y|p,E) (\partial_p \ln f(y|p,E))^2 \tag{58}$$

where

$$f(y|p,E) = \int dx P_{\text{out}}(y|x) \frac{e^{-\frac{(x-p)^2}{2E}}}{\sqrt{2\pi E}}.$$
(59)

We first note that $\phi(y|z, E) = f(y|z\sqrt{1-E}, E)$ so the derivative w.r.t E on the right hand side of (56) becomes

$$\frac{\partial}{\partial E} \mathbb{E}_{Z} \left[\int dy \,\phi(y|Z,E) \ln \phi(y|Z,E) \right] = \frac{\partial}{\partial E} \int dz \, \frac{e^{-\frac{z^{2}}{2}}}{\sqrt{2\pi}} \int dy \, f(y|z\sqrt{1-E},E) \ln f(y|z\sqrt{1-E},E) \\ = \int dz \, \frac{e^{-\frac{z^{2}}{2}}}{\sqrt{2\pi}} \int dy \, (1+\ln f(y|z\sqrt{1-E},E)) \partial_{E} f(y|z\sqrt{1-E},E).$$
(60)

An exercise in differentiation of Gaussians shows⁸

$$\partial_E \left\{ \frac{e^{-\frac{(x-z\sqrt{1-E})^2}{2E}}}{\sqrt{2\pi E}} \right\} = \frac{e^{\frac{z^2}{2}}}{2(1-E)} \partial_z \left\{ e^{-\frac{z^2}{2}} \partial_z \left\{ \frac{e^{-\frac{(x-z\sqrt{1-E})^2}{2E}}}{\sqrt{2\pi E}} \right\} \right\}.$$

Thus from (59)

$$\partial_E f(y|z\sqrt{1-E}, E) = \frac{e^{\frac{z^2}{2}}}{2(1-E)} \partial_z \left\{ e^{-\frac{z^2}{2}} \partial_z f(y|z\sqrt{1-E}, E) \right\}$$

and (60) becomes

$$\begin{split} \frac{\partial}{\partial E} \mathbb{E}_{Z} \Big[\int dy \, \phi(y|Z,E) \ln \phi(y|Z,E) \Big] &= \frac{1}{2(1-E)} \int dz \, \int dy \, (1+\ln f(y|z\sqrt{1-E},E)) \\ &\times \partial_{z} \Big\{ \frac{e^{-\frac{z^{2}}{2}}}{\sqrt{2\pi}} \partial_{z} f(y|z\sqrt{1-E},E) \Big\} \\ &= -\frac{1}{2(1-E)} \int dz \, \frac{e^{-\frac{z^{2}}{2}}}{\sqrt{2\pi}} \int dy \, \frac{\left(\partial_{z} f(y|z\sqrt{1-E},E)\right)^{2}}{f(y|z\sqrt{1-E},E)} \\ &= -\frac{1}{2} \int dz \, \frac{e^{-\frac{z^{2}}{2(1-E)}}}{\sqrt{2\pi(1-E)}} \int dy \, \frac{\left(\partial_{z} f(y|z,E)\right)^{2}}{f(y|z,E)} \\ &= -\frac{1}{2} \int dz \, \frac{e^{-\frac{z^{2}}{2(1-E)}}}{\sqrt{2\pi(1-E)}} \int dy \, f(y|z,E) \left(\partial_{z} \ln f(y|z,E)\right)^{2}. \end{split}$$

This result explicitly shows that (56) and (58) are equivalent as announced.

APPENDIX III

BOUNDS ON THE SECOND DERIVATIVE OF THE POTENTIAL FUNCTION

In this appendix, we provide an upper bound on the second derivative

$$\begin{bmatrix} \frac{\partial^2 F_{\rm co}}{\partial E_r \partial E_{r'}} \end{bmatrix}_{\hat{\mathbf{E}}} = \begin{bmatrix} \frac{\partial^2}{\partial E_r \partial E_{r'}} \sum_{r=1}^{\Gamma} U_{\rm un}(E_r) \end{bmatrix}_{\hat{\mathbf{E}}} - \frac{\partial^2}{\partial E_r \partial E_{r'}} \begin{bmatrix} \sum_{c=1}^{\Gamma} S_{\rm un}(\Sigma_c(\mathbf{E})) \end{bmatrix}_{\hat{\mathbf{E}}} \\ = \delta_{r,r'} \begin{bmatrix} \frac{\partial^2 U_{\rm un}(E_r)}{\partial E_r^2} \end{bmatrix}_{\hat{\mathbf{E}}} - \sum_{c=1}^{\Gamma} \begin{bmatrix} \frac{\partial^2 S_{\rm un}(\Sigma_c(\mathbf{E}))}{\partial E_r \partial E_{r'}} \end{bmatrix}_{\hat{\mathbf{E}}}$$
(61)

of the potential function needed in the proof of Lemma 5.9. We first perform the analysis for general memoryless channels satisfying our two Assumptions 1, 2. We then briefly show how to improve the estimate in the special case of the AWGN because of the non vanishing error floor.

⁸We thank Christophe Schülke for pointing out this trick.

A. General channel

Energy term: Using relation (56) of Appendix II one obtains for the first derivative of the energy term

$$\frac{\partial U_{\rm un}(E_r)}{\partial E_r} = -\frac{E_r}{2\ln 2} \frac{\partial \Sigma^{-2}}{\partial E_r}$$

Differentiating once more

$$\frac{\partial^2 U_{\rm un}(E_r)}{\partial E_r^2} = -\frac{1}{2\ln 2} \frac{\partial \Sigma^{-2}}{\partial E_r} - \frac{E_r}{2\ln 2} \frac{\partial^2 \Sigma^{-2}}{\partial E_r^2}.$$

Using Assumption 2 we immediately get

$$\frac{\partial^2 U_{\mathrm{un}}(E_r)}{\partial E_r^2} \leq \frac{C}{2(\ln 2)RE_r^\beta} + \frac{CE_r}{2(\ln 2)RE_r^\beta}$$

Now recall that in the proof of Lemma 5.9 we have $\hat{E}_r > \bar{E}_f = E_f + \epsilon$ where E_f is the (true) error floor and $\epsilon > 0$. Therefore

$$\left[\frac{\partial^2 U_{\rm un}}{\partial E_r^2}\right]_{\hat{\mathbf{E}}} \leq \frac{C}{2(\ln 2)R(E_{\rm f}+\epsilon)^{\beta}} + \frac{C(E_{\rm f}+\epsilon)}{2(\ln 2)R(E_{\rm f}+\epsilon)^{\beta}} \\ \leq \frac{C(2+\epsilon)}{2(\ln 2)R(E_{\rm f}+\epsilon)^{\beta}}.$$
(62)

Of course this is the worse possible bound and is valid all the way up to the left boundary of the *modified* system. As one moves towards the right of the spatially coupled system one could use bigger values for E_r and tigthen the bound. This however is not needed to prove Lemma 5.9 as long as $\epsilon > 0$.

Entropy term: For the second derivative of the "entropy" term we first apply the chain rule

$$\begin{split} \frac{\partial^2 S_{\mathrm{un}}(\Sigma_c(\mathbf{E}))}{\partial E_r \partial E_{r'}} &= \frac{\partial}{\partial E_{r'}} \Big(\frac{\partial S_{\mathrm{un}}}{\partial \Sigma_c^{-2}} \frac{\partial \Sigma_c^{-2}}{\partial E_r} \Big) \\ &= \frac{\partial^2 S_{\mathrm{un}}}{\partial (\Sigma_c^{-2})^2} \frac{\partial \Sigma_c^{-2}}{\partial E_r} \frac{\partial \Sigma_c^{-2}}{\partial E_{r'}} + \frac{\partial S_{\mathrm{un}}}{\partial \Sigma_c^{-2}} \frac{\partial^2 \Sigma_c^{-2}}{\partial E_r \partial E_{r'}} \\ &= J_{r,c} J_{r',c} \frac{\partial^2 S_{\mathrm{un}}}{\partial (\Sigma_c^{-2})^2} \frac{\partial \Sigma^{-2}}{\partial E_r} \frac{\partial \Sigma^{-2}}{\partial E_{r'}} + \delta_{rr'} J_{r,c} \frac{\partial S_{\mathrm{un}}}{\partial \Sigma_c^{-2}} \frac{\partial^2 \Sigma^{-2}}{\partial E_r^2}, \end{split}$$

where to get the last line we used

$$\frac{\partial \Sigma_c^{-2}}{\partial E_r} = J_{r,c} \frac{\partial \Sigma^{-2}}{\partial E_r} \mathbf{1}_{c-w \le r \le c+w}, \qquad \frac{\partial^2 \Sigma_c^{-2}}{\partial E_r \partial E_{r'}} = \delta_{rr'} J_{r,c} \frac{\partial^2 \Sigma^{-2}}{\partial E_r^2} \mathbf{1}_{c-w \le r \le c+w}$$

which follow directly from the definition of $\Sigma_c^{-2}(\mathbf{E})$. Recall that by construction $J_{r,c}/\Gamma \leq (\bar{g}/\underline{g})(2w+1)^{-1}$. Recall also Assumption 2. We thus have

$$\left|\frac{\partial^{2} S_{\mathrm{un}}(\Sigma_{c}(\mathbf{E}))}{\partial E_{r} \partial E_{r'}}\right| \leq \frac{\bar{g}^{2}}{\underline{g}^{2} (2w+1)^{2}} \left|\frac{\partial^{2} S_{\mathrm{un}}}{\partial (\Sigma_{c}^{-2})^{2}}\right| \left|\frac{\partial \Sigma^{-2}}{\partial E_{r}}\right| \left|\frac{\partial \Sigma^{-2}}{\partial E_{r'}}\right| \mathbf{1}_{c-w \leq r \leq c+w} \mathbf{1}_{c-w \leq r' \leq c+w} + \frac{\delta_{rr'} \bar{g}}{\underline{g} (2w+1)} \left|\frac{\partial S_{\mathrm{un}}}{\partial \Sigma_{c}^{-2}}\right| \left|\frac{\partial^{2} \Sigma^{-2}}{\partial E_{r}^{2}}\right| \mathbf{1}_{c-w \leq r \leq c+w} \leq \frac{\bar{g}^{2} C^{2}}{\underline{g}^{2} (2w+1)^{2} R^{2} E_{r}^{\beta} E_{r'}^{\beta}} \left|\frac{\partial^{2} S_{\mathrm{un}}}{\partial (\Sigma_{c}^{-2})^{2}}\right| \mathbf{1}_{c-w \leq r \leq c+w} \mathbf{1}_{c-w \leq r' \leq c+w} + \frac{\delta_{rr'} \bar{g} C}{\underline{g} (2w+1) R E^{\beta}} \left|\frac{\partial S_{\mathrm{un}}}{\partial \Sigma_{c}^{-2}}\right| \mathbf{1}_{c-w \leq r \leq c+w}$$
(63)

The next step is to compute and estimate the partial derivatives of S_{un} in this expression. Using Definition 4.11 we find (this involves differentiating under integral signs which can be justified by the ensuing bounds)

$$\frac{\partial S_{\text{un}}}{\partial \Sigma_c^{-2}} = \sum_{i=2}^B \mathbb{E}_{\mathbf{Z}} \left[\left(\frac{(Z_i - Z_1) \Sigma_c}{2\sqrt{\ln 2 \ln B}} - \frac{1}{\ln 2} \right) \frac{e_i}{1 + \sum_{j=2}^B e_j} \right]$$
(64)

$$\frac{\partial^2 S_{\rm un}}{\partial (\Sigma_c^{-2})^2} = (\ln B) \sum_{i=2}^B \mathbb{E}_{\mathbf{Z}} \Big[\Big(\Big(\frac{(Z_i - Z_1) \Sigma_c}{2\sqrt{\ln 2 \ln B}} - \frac{1}{\ln 2} \Big)^2 - \frac{(Z_i - Z_1) \Sigma_c^3}{2\sqrt{\ln 2 \ln B}} \Big) \frac{e_i}{1 + \sum_{j=2}^B e_j} - (\ln B) \sum_{i,j=2}^B \Big(\frac{(Z_i - Z_1) \Sigma_c}{2\sqrt{\ln 2 \ln B}} - \frac{1}{\ln 2} \Big) \Big(\frac{(Z_j - Z_1) \Sigma_c}{2\sqrt{\ln 2 \ln B}} - \frac{1}{\ln 2} \Big) \frac{e_i e_j}{(1 + \sum_{j=2}^B e_j)^2} \Big], \tag{65}$$

Since $e_i \ge 0$ we have for $2 \le i \le n$

$$\frac{e_i}{1 + \sum_{j=2}^B e_j} \le 1$$

which easily implies the following bounds for (64) and (65)

$$\left|\frac{\partial S_{\mathrm{un}}}{\partial \Sigma_c^{-2}}\right| \le (B-1) \left(\frac{\Sigma_c}{\sqrt{\pi \ln 2 \ln B}} + \frac{1}{\ln 2}\right)$$
$$\le C_1(B) + C_2(B)\Sigma_c \tag{66}$$

$$\begin{aligned} \frac{\partial S_{\rm un}}{\partial \Sigma_c^{-2}} &| \le (\ln B)(B-1) \Big(\frac{\Sigma_c^2}{2\ln 2\ln B} + \frac{1}{(\ln 2)^2} + \frac{2\Sigma_c}{\ln 2\sqrt{\pi\ln 2\ln B}} \Big) + (B-1) \frac{\Sigma_c^3}{\sqrt{\pi\ln 2\ln B}} \\ &+ (\ln B)(B-1)^2 \Big(\frac{(\frac{2\sqrt{3}}{\pi} + \frac{1}{3})\Sigma_c^2}{4\ln 2\ln B} + \frac{1}{(\ln 2)^2} + \frac{2\Sigma_c}{\ln 2\sqrt{\pi\ln 2\ln B}} \Big) \\ &\le C_3(B) + C_4(B)\Sigma_c + C_5(B)\Sigma_c^2 + C_6(B)\Sigma_c^3. \end{aligned}$$
(67)

where $C_i(B)$, $i = 1, \dots, 6$ are constants that depend only on B. Furthermore from the definition of $\Sigma_c(\mathbf{E})$ and Assumption 1 we remark that $\Sigma_c(\mathbf{E}) \leq \sup_{E \in [0,1]} \Sigma(E) = \Sigma(1)$ so in the bounds (66), (67) we can replace Σ_c by $\Sigma(1)$. Then using these two bounds the estimate (63) becomes

$$\begin{split} \left| \frac{\partial^2 S_{\mathrm{un}}(\Sigma_c(\mathbf{E}))}{\partial E_r \partial E_{r'}} \right| &\leq \frac{\bar{g}^2 C^2}{\underline{g}^2 (2w+1)^2 R^2 E_r^\beta E_{r'}^\beta} \Big(C_3(B) + C_4(B) \Sigma(1) + C_5(B) \Sigma^2(1) + C_6(B) \Sigma^3(1) \Big) \\ &\times \mathbf{1}_{c-w \leq r \leq c+w} \mathbf{1}_{c-w \leq r' \leq c+w} \\ &+ \frac{\delta_{rr'} \bar{g} C}{\underline{g} (2w+1) R E_r^\beta} \Big(C_1(B) + C_2(B) \Sigma(1) \Big) \mathbf{1}_{c-w \leq r \leq c+w} \end{split}$$

Since

$$1_{c-w \le r \le c+w} 1_{c-w \le r' \le c+w} \le 1_{r-w \le c \le r+w} 1_{|r-r'| \le 2w+1} \quad \text{and} \quad 1_{c-w \le r \le c+w} = 1_{r-w \le c \le r+w} 1_{|r-r'| \le 2w+1}$$

when we sum over c we get

$$\begin{split} \sum_{c=1}^{\Gamma} \frac{\partial^2 S_{\mathrm{un}}(\Sigma_c(\mathbf{E}))}{\partial E_r \partial E_{r'}} \leq & \frac{\bar{g}^2 C^2}{\underline{g}^2 R^2 (2w+1) E_r^{\beta} E_{r'}^{\beta}} \Big(C_3(B) + C_4(B) \Sigma(1) + C_5(B) \Sigma^2(1) + C_6(B) \Sigma^3(1) \Big) \mathbf{1}_{|r-r'| \leq 2w+1} \\ & + \frac{\delta_{rr'} \bar{g} C}{g R E_r^{\beta}} \Big(C_1(B) + C_2(B) \Sigma(1) \Big) \end{split}$$

Finally using again $\hat{E}_r \geq \bar{E}_{\rm f} = E_{\rm f} + \epsilon$ we obtain

$$\left[\sum_{c=1}^{1} \frac{\partial^{2} S_{\mathrm{un}}(\Sigma_{c}(\mathbf{E}))}{\partial E_{r} \partial E_{r'}}\right]_{\hat{\mathbf{E}}} \leq \frac{\bar{g}^{2} C^{2}}{\underline{g}^{2} R^{2} (2w+1) (E_{\mathrm{f}}+\epsilon)^{2\beta}} \times \left(C_{3}(B) + C_{4}(B) \Sigma(1) + C_{5}(B) \Sigma^{2}(1) + C_{6}(B) \Sigma^{3}(1)\right) \mathbf{1}_{|r-r'| \leq 2w+1} + \frac{\delta_{rr'} \bar{g} C}{\underline{g} R (E_{\mathrm{f}}+\epsilon)^{\beta}} \left(C_{1}(B) + C_{2}(B) \Sigma(1)\right)$$
(68)

Final bound: Putting (61), (62) and (68) together the triangle inequality implies the important result

$$\left[\frac{\partial^2 F_{\rm co}}{\partial E_r \partial E_{r'}}\right]_{\hat{\mathbf{E}}} \le \delta_{r,r'} \frac{K_1(B,\bar{g},\underline{g})}{(E_{\rm f}+\epsilon)R} + 1_{|r-r'| \le 2w+1} \frac{K_2(B,\bar{g},\underline{g})}{(E_{\rm f}+\epsilon)^{2\beta}R(2w+1)} \tag{69}$$

for some finite positive $K_1(B, \bar{g}, g)$ and $K_2(B, \bar{g}, g)$ independent of w and Γ .

B. AWGN Channel

For the AWGN channel we have an explicit expression for the effective noise, $\Sigma(E)^2 = (\operatorname{snr}^{-1} + E)R$ which implies

$$\begin{cases} \Sigma^{2}(E_{r}) \leq R(\operatorname{snr}^{-1}+1) \\ \frac{\partial \Sigma^{-2}}{\partial E_{r}} \leq \frac{\operatorname{snr}^{2}}{R} \\ \frac{\partial^{2} \Sigma^{-2}}{\partial E_{r}^{2}} \leq \frac{\operatorname{snr}^{3}}{R}. \end{cases}$$
(70)

Then using these bounds at the appropriate places in the previous analysis we get

$$\left[\frac{\partial^2 F_{\rm co}}{\partial E_r \partial E_{r'}}\right]_{\hat{\mathbf{E}}} \le \delta_{r,r'} K_1'(B,\bar{g},\underline{g}) {\rm snr}^2 + 1_{|r-r'| \le 2w+1} \frac{K_2'(B,\bar{g},\underline{g}) {\rm snr}^4}{2w+1}$$
(71)

for new constants $K'_1(B, \bar{g}, \underline{g})$, $K'_2(B, \bar{g}, \underline{g})$ (independent of w, Γ). We can see that the qualitative behaviour of the bound when $\operatorname{snr} \to +\infty$ is the same than in the case of vanishing error floor $E_f = 0$ and $\epsilon \to 0$.

APPENDIX IV

POTENTIAL FUNCTION AND REPLICA CALCULATION

The potential functions of the uncoupled and coupled systems, used in this paper, can be viewed as a mathematical tool and we are not really concerned how they are found. However in practice it is important to have a more or less systematic method which allows to write down "good" potential functions. There are essentially two ways. One is to "integrate" the SE equations as done in [26] by using an appropriate "integrating factor". With this method there is some amount of guess involved. For example in the present problem it is not entirely obvious that the correct integrating factor is directly related to the Fisher information (as equation (57) in Appendix II shows). The other way is to perform a formal and brute force replica or cavity calculation of the free energy which is then given as a variational expression involving the potential function. The disadvantage of such a calculation is that it is painful and maybe also that it is formal, but the advantage is that it is quite systematic. For completeness we give the replica calculation. We stress that the results of the paper do *not* rest on this formal calculation and the reader can entirely skip it.

We treat the prototypical case of a spatially coupled compressed-sensing like system where the signal has *scalar* components x_i , $i = 1, \dots, N$ iid distributed according to a general prior $p_0(x)$. The calculation is exactly the same for signals whose components are *B*-dimensional with arbitray priors and sparse superposition codes fall in this class. The integration symbol $\mathcal{D}v$ is used for $dv e^{-\frac{v^2}{2}}$.

The spatially coupled matrix is made of $\Gamma \times \Gamma$ blocks, each with N/Γ columns and $\alpha N/\Gamma$ rows for the blocks part of the r^{th} block-row. The entries inside the block (r, c) are i.i.d. with distribution $\mathcal{N}(0, J_{r,c}\Gamma/N)$. Furthermore, we enforce the per block-row variance normalization $\sum_{c=1}^{\Gamma} J_{r,c} = 1 \forall r$. We use the notation \mathbf{x}^0 for the signal and define $z_{\mu}^a := \sum_{c=1}^{\Gamma} \sum_{i \in c}^{N/\Gamma} F_{\mu i} x_i^a$ where the matrix structure is made explicit.

The posterior distribution is given by the Bayes rule

$$P(\mathbf{x}|\mathbf{y}) = Z(\mathbf{y})^{-1} \prod_{i=1}^{N} p_0(x_i) \prod_{\mu=1}^{M} P_{\text{out}}(y_{\mu}|z_{\mu})$$

where $Z(\mathbf{y}) = P(\mathbf{y})$ is the observation dependent normalization, or partition function. The (coupled) free energy F_{co} will be calculated using the replica trick in one of its many incarnations

$$F_{\rm co} := -\lim_{N \to \infty} \lim_{n \to 0} \frac{\partial}{\partial n} \frac{\ln(\mathbb{E}[Z(\mathbf{y})^n])}{N},\tag{72}$$

where \mathbb{E} denotes expectation with respect to the observation $\mathbf{y}(\mathbf{F})$ which depend on the measurement matrix realization (that will be always implicit). We thus need to compute the n^{th} moment of the partition function. For the moment, we consider $n \in \mathbb{N}$ despite that we will let $n \to 0$ at the end.

 $Z(\mathbf{y})^n$ can be interpreted as the partition function of *n* i.i.d. systems, the replicas $a = 1, \dots, n$, each generated independently from the posterior $P(\mathbf{x}|\mathbf{y})$

$$Z(\mathbf{y})^{n} = \int \prod_{a=1}^{n} \left[d\mathbf{x}^{a} \prod_{i=1}^{N} p_{0}(x_{i}^{a}) \prod_{\mu=1}^{M} P_{\text{out}}(y_{\mu}|z_{\mu}^{a}) \right],$$
(73)

$$\mathbb{E}[Z(\mathbf{y})^n] = \mathbb{E}_{\mathbf{F}} \int d\mathbf{y} Z(\mathbf{y})^n P(\mathbf{y}) = \mathbb{E}_{\mathbf{F}} \int d\mathbf{y} Z(\mathbf{y})^{n+1} = \mathbb{E}_{\mathbf{F}} \int d\mathbf{y} \prod_{a=0}^n \left[d\mathbf{x}^a \prod_{i=1}^N p_0(x_i^a) \prod_{\mu=1}^M P_{\text{out}}(y_\mu | z_\mu^a) \right],$$
(74)

where the last equality is implied by $P(\mathbf{y}) = Z(\mathbf{y})$. This last point is valid only in the Bayes optimal setting and is known to induce a remarkable set of consequences, among which the correctness of the replica symmetric predictions.

The **F** and \mathbf{x}^a r.v being i.i.d., we can treat z^a_{μ} as a Gaussian random variable by the central limit theorem. Let us compute their distribution. As **F** has zero mean, z^a_{μ} has zero mean also. Its covariance matrix $\tilde{q}_{r_{\mu}}$ depends on the block-row index $r_{\mu} \in \{1, \dots, \Gamma\}$ to which the μ^{th} measurement index belongs. Similarly, $c_i \in \{1, \dots, \Gamma\}$ is the block-column index to which the *i*th column belongs. We have

$$\tilde{q}_{r_{\mu}}^{ab} = \mathbb{E}_{\mathbf{F}}[z_{\mu}^{a} z_{\mu}^{b}] = \sum_{c,c'=1}^{\Gamma,\Gamma} \sum_{i\in c,j\in c'}^{N/\Gamma,N/\Gamma} \mathbb{E}_{\mathbf{F}}[F_{\mu i}F_{\mu j}] x_{i}^{a} x_{j}^{b} = \sum_{c}^{\Gamma} \frac{J_{r_{\mu},c}}{N} \sum_{i\in c}^{N/\Gamma} x_{i}^{a} x_{i}^{b},$$
(75)

because $\mathbb{E}_{\mathbf{F}}[F_{\mu i}F_{\mu j}] = \delta_{ij}J_{r_{\mu},c_i}/N$ in the present spatial coupling construction. We introduce the macroscopic replica overlap matrix, that takes into account the block structure in the signal induced by the matrix structure. Let

$$q_c^{ab} := \frac{\Gamma}{N} \sum_{i \in c}^{N/\Gamma} x_i^a x_i^b \ \forall \ a, b \in \{0, \cdots, n\}.$$

$$(76)$$

Then (75) becomes $\tilde{q}_r^{ab} = \sum_{c=1}^{\Gamma} J_{r,c} q_c^{ab}$. We now introduce the replica symmetric ansatz. According to this ansatz, the overlap should not depend on the replica index $q_c^{ab} = q_c \ \forall \ a \neq b, \ q_c^{aa} = Q_c \ \forall \ a.$ This implies

$$\tilde{q}_{r}^{ab} = \tilde{q}_{r} = \sum_{c=1}^{\Gamma} J_{r,c} q_{c} \ \forall \ a \neq b, \ \tilde{q}_{r}^{aa} = \tilde{Q}_{r} = \sum_{c=1}^{\Gamma} J_{r,c} Q_{c} \ \forall \ a.$$
(77)

Using the variance normalization $Q_c = \tilde{Q}_r$. Then, one can show that in Bayes optimal inference we have furthermore $Q_c = \tilde{Q}_r = \mathbb{E}[S^2] \ \forall \ c, r \in \{1, \dots, \Gamma\}$, where $\mathbb{E}[s^2] = \int ds p_0(s) s^2$. In the physics litterature this is often called a "Nishimori identity".

Thus the self overlap Q_c is fixed and the condition (76) for a = b does not need to be enforced. On the other hand, the cross overlap for $a \neq b$ is unknown and so we must keep $\{q_c\}$ as variables. Define a distribution of replicated variables at fixed overlap matrices $\{\boldsymbol{q}_c, c \in \{1, \cdots, \Gamma\}\}$

$$P(\{\mathbf{x}^{a}\}|\{\mathbf{q}_{c}\}) := \frac{1}{\Xi(\{\mathbf{q}_{c}\})} \prod_{a=0}^{n} \left[\prod_{i=1}^{N} p_{0}(x_{i}^{a}) \prod_{c=1}^{\Gamma} \prod_{b(78)$$

where $\Xi(\{q_c\})$ is the associated normalization. The role of the $2i\pi$ appearing in the delta function is purely formal and will become clear later on. Plugging this expression inside (74) we get

$$\mathbb{E}[Z(\mathbf{y})^n] = \mathbb{E}_{\mathbf{F}} \int d\mathbf{y} \prod_{c=1}^{\Gamma} d\mathbf{q}_c P(\{\mathbf{x}^a\} | \{\mathbf{q}_c\}) \Xi(\{\mathbf{q}_c\}) \prod_{a=0}^{n} \left[d\mathbf{x}^a \prod_{r=1}^{\Gamma} \prod_{\mu \in r}^{\alpha N/\Gamma} P_{\text{out}}(y_\mu | z_\mu^a) \right]$$
(79)

$$= \int \prod_{c=1}^{\Gamma} d\boldsymbol{q}_{c} \Xi(\{\boldsymbol{q}_{c}\}) \int d\boldsymbol{y} P(\{\boldsymbol{z}^{a}\}|\{\boldsymbol{q}_{c}\}) \prod_{a=0}^{n} \left[d\boldsymbol{z}^{a} \prod_{r=1}^{\Gamma} \prod_{\mu \in r}^{\alpha N/\Gamma} P_{\text{out}}(y_{\mu}|z_{\mu}^{a}) \right].$$
(80)

The second equality is obtained after noticing that the integrand in (79) depends on $\{x_i^a\}$ only through $\{z_{\mu}^a\}$, this allows to replace the integration on $\{x_i^a\}$ by an integration on $\{z_{\mu}^a\}$. As already explained, by the central limit theorem

$$P(\{\mathbf{z}^{a}\}|\{\mathbf{q}_{c}\}) = \prod_{\mu=1}^{M} \mathcal{N}(\mathbf{z}_{\mu}|0, \tilde{\mathbf{q}}_{r_{\mu}}) = \prod_{r=1}^{\Gamma} \prod_{\mu \in r}^{\alpha N/\Gamma} \mathcal{N}(\mathbf{z}_{\mu}|0, \tilde{\mathbf{q}}_{r})$$
$$= \prod_{r=1}^{\Gamma} \left[(2\pi)^{n+1} \det(\tilde{\mathbf{q}}_{r}) \right]^{-\frac{\alpha N}{2\Gamma}} \prod_{\mu \in r}^{\alpha N/\Gamma} e^{-\frac{1}{2} \sum_{a,b=0}^{n,n} z_{\mu}^{a} [\tilde{\mathbf{q}}_{r}^{-1}]_{ab} z_{\mu}^{b}}.$$
(81)

This is a product of multivariate centered Gaussian distributions, where $\mathbf{z}_{\mu} := [z_{\mu}^{a}, a \in \{0, \dots, n\}], \mathbf{z}^{a} := [z_{\mu}^{a}, \mu \in \{1, \dots, M\}].$ Recall \tilde{q}_r is a function of $\{q_c\}$. Let

$$\mathbb{E}[Z(\mathbf{y})^n] = \int \prod_{c=1}^{\Gamma} d\boldsymbol{q}_c \exp\left[N\left(f(\{\boldsymbol{q}_c\}) + g(\{\boldsymbol{q}_c\})\right)\right],\tag{82}$$

$$f(\lbrace \boldsymbol{q}_c \rbrace) := \frac{1}{N} \ln \left[\Xi(\lbrace \boldsymbol{q}_c \rbrace) \right], \tag{83}$$

$$g(\{\boldsymbol{q}_{c}\}) \coloneqq \frac{1}{N} \ln \left[\int d\boldsymbol{y} P(\{\boldsymbol{z}^{a}\} | \{\boldsymbol{q}_{c}\}) \prod_{a=0}^{n} \left[d\boldsymbol{z}^{a} \prod_{r=1}^{\Gamma} \prod_{\mu \in r}^{\alpha N/\Gamma} P_{\text{out}}(y_{\mu} | \boldsymbol{z}_{\mu}^{a}) \right] \right].$$
(84)

Now we perform a saddle point estimation. This requires to take the limit $N \to \infty$ limit before letting $n \to 0$, and we assume without justification that the final result does not depend on the order of limits n and N. This gives for the free energy, using (72)

$$F_{\rm co} = -\lim_{n \to 0} \frac{\partial}{\partial n} \mathop{\rm extr}_{\{q_c\}} \left(f(\{\boldsymbol{q}_c\}) + g(\{\boldsymbol{q}_c\}) \right) = -\mathop{\rm extr}_{\{q_c\}} \left(\lim_{n \to 0} \frac{\partial f(\{\boldsymbol{q}_c\})}{\partial n} + \lim_{n \to 0} \frac{\partial g(\{\boldsymbol{q}_c\})}{\partial n} \right). \tag{85}$$

Now the replica symmetric ansatz allows to simplify g since $P(\{\mathbf{z}^a\}|\{\mathbf{q}_c\})$ becomes

$$P(\{\mathbf{z}^{a}\}|\{\mathbf{q}_{c}\}) = \prod_{r=1}^{\Gamma} \left[(2\pi)^{n+1} \det(\tilde{\mathbf{q}}_{r}) \right]^{-\frac{\alpha N}{2\Gamma}} \prod_{\mu \in r}^{\alpha N/\Gamma} e^{-\frac{C_{1,r}}{2} \sum_{a=0}^{n} (z_{\mu}^{a})^{2} - \frac{C_{2,r}}{2} \sum_{a=0, b \neq a}^{n,n} z_{\mu}^{a} z_{\mu}^{b}},$$
(86)

where $C_{1,r}$ and $C_{2,r}$ depend on \tilde{q}_r and $\mathbb{E}[s^2]$ as they are obtained from the matrix inversion \tilde{q}_r^{-1} . Thanks to the simple structure of \tilde{q}_r under the replica symmetric ansatz, one can easily show that

$$C_{1,r} = \frac{\mathbb{E}[s^2] + (n-2)\tilde{q}_r}{\mathbb{E}[s^2](\mathbb{E}[s^2] + (n-2)\tilde{q}_r) + (1-n)\tilde{q}_r^2} \xrightarrow[n \to 0]{} \frac{\mathbb{E}[s^2] - 2\tilde{q}_r}{(\mathbb{E}[s^2] - \tilde{q}_r)^2},$$
(87)

$$C_{2,r} = -\frac{\tilde{q}_r}{\mathbb{E}[s^2](\mathbb{E}[s^2] + (n-2)\tilde{q}_r) + (1-n)\tilde{q}_r^2} \xrightarrow[n \to 0]{} -\frac{\tilde{q}_r}{(\mathbb{E}[s^2] - \tilde{q}_r)^2}.$$
(88)

The replicated variables $\{\mathbf{z}^a\}$ are correlated through $P(\{\mathbf{z}^a\}|\{\mathbf{q}_c\})$. In order to simplify g, we decorrelate them by linearizing the exponent of $P(\{\mathbf{z}^a\}|\{\mathbf{q}_c\})$ using the Gaussian transformation formula for a given K > 0

$$e^{\frac{K}{2}\sum_{a=0,b\neq a}^{n,n} z_{\mu}^{a} z_{\mu}^{b}} = \int \mathcal{D}\xi_{\mu} e^{\xi_{\mu}\sqrt{K}\sum_{a=0}^{n} z_{\mu}^{a} - \frac{K}{2}\sum_{a=0}^{n} (z_{\mu}^{a})^{2}},$$
(89)

i.e. the previously correlated $\{z_{\mu}^{a}, a \in \{0, ..., n\}\}$ are now i.i.d. Gaussian variables, but that all interact with a common random Gaussian effective field ξ_{μ} . Using this with $K = -C_{2,r}$ as we know that $C_{2,r} \leq 0$, the integration in g can now be performed starting from (84)

$$g(\{\boldsymbol{q}_{c}\}) = \frac{1}{N} \ln \left[\prod_{r=1}^{\Gamma} \prod_{\mu \in r}^{\alpha N/\Gamma} \int \mathcal{D}\xi_{\mu} dy_{\mu} \left(\int dz_{\mu} \mathcal{N}\left(z_{\mu} \middle| m(\xi_{\mu}, \tilde{q}_{r}), V(\mathbb{E}[s^{2}], \tilde{q}_{r}) \right) P_{\text{out}}(y_{\mu} | z_{\mu}) \right)^{n+1} \right]$$
(90)

$$= \frac{1}{\Gamma} \sum_{r=1}^{\Gamma} \alpha \ln \left[\int \mathcal{D}\xi dy \left(\int dz \, \mathcal{N}\left(z \Big| m(\xi, \tilde{q}_r), V(\mathbb{E}[s^2], \tilde{q}_r) \right) P_{\text{out}}(y|z) \right)^{n+1} \right]$$
(91)

$$= \frac{1}{\Gamma} \sum_{r=1}^{\Gamma} \alpha \ln \left[\int \mathcal{D}\xi dy \left(\int \mathcal{D}z \, P_{\text{out}} \left(y \Big| m(\xi, \tilde{q}_r) + z \sqrt{V(\mathbb{E}[s^2], \tilde{q}_r)} \right) \right)^{n+1} \right].$$
(92)

As assumed, g does no depend on N. Let us compute $m(\xi_{\mu}, \tilde{q}_r), V(\mathbb{E}[s^2], \tilde{q}_r)$. Combining (86) with (89), we get that for a $\mu \in r$ and up to a normalization, $z_{\mu} \sim \exp(-z_{\mu}^2(C_{1,r} - C_{2,r})/2 + z_{\mu}\xi_{\mu}\sqrt{-C_{2,r}})$ which becomes using the $n \to 0$ limit of (87), (88) $z_{\mu} \sim \mathcal{N}(z_{\mu}|\xi_{\mu}\sqrt{q_r}, \mathbb{E}[s^2] - \tilde{q}_r) \exp(\xi_{\mu}^2 \tilde{q}_r/[2(\mathbb{E}[s^2] - \tilde{q}_r)])$. Normalizing $P(z_{\mu})$, the term $\exp(\xi_{\mu}^2 \tilde{q}_r/[2(\mathbb{E}[s^2] - \tilde{q}_r)])$ disappears being independent of z_{μ} and thus $P(z_{\mu}) = \mathcal{N}(z_{\mu}|\xi_{\mu}\sqrt{q_r}, \mathbb{E}[s^2] - \tilde{q}_r)$. Thus $m(\xi_{\mu}, \tilde{q}_r) = \xi_{\mu}\sqrt{q_r}, V(\mathbb{E}[s^2], \tilde{q}_r) = \mathbb{E}[s^2] - \tilde{q}_r$. Now performing the $\lim_{n\to 0} \partial_n$ operation and using the identity

$$\lim_{n \to 0} \frac{\partial}{\partial n} \ln \left[\int du X(u)^{n+1} \right] = \frac{\int du X(u) \ln(X(u))}{\int dv X(v)},\tag{93}$$

we directly obtain

$$\lim_{n \to 0} \frac{\partial g(\{\boldsymbol{q}_c\})}{\partial n} = \sum_{r=1}^{\Gamma} \frac{\alpha}{\Gamma} \int \mathcal{D}\xi dy \mathcal{D}\hat{z} P_{\text{out}}\left(y \Big| \xi \sqrt{\tilde{q}_r} + \hat{z} \sqrt{\mathbb{E}[s^2] - \tilde{q}_r}\right) \ln\left[\int \mathcal{D}z P_{\text{out}}\left(y \Big| \xi \sqrt{\tilde{q}_r} + z \sqrt{\mathbb{E}[s^2] - \tilde{q}_r}\right)\right], \quad (94)$$

where we used the normalization $\int dy du P_{\text{out}}(y|u) \mathcal{N}(u|a, b) = 1$, such that the denominator in (93) sums to one. Let us now deal with $f(\{q_c\})$. We will use the following representation of the delta function $\delta(x) = \int_{\mathbb{R}} d\hat{q} \exp(2i\pi \hat{q}x) \Leftrightarrow \delta(x/(2i\pi)) = \int_{\mathbb{R}} d\hat{q} \exp(\hat{q}x)$ where \hat{q} can be interpreted as an auxiliary external field.⁹

⁹We now understand that the presence of the $2i\pi$ in (78) is thus just a trick to make the integral real.

We assume the replica symmetric ansatz for the auxiliary fields similarly as for the overlap matrix $\hat{q}_c^{ab} = -\hat{q}_c \forall a, b \neq a$. The minus sign is just introduced for convenience. Using again the Gaussian transformation formula, we get

$$f(\{\boldsymbol{q}_{c}\}) = \frac{1}{N} \ln \left[\prod_{c=1}^{\Gamma} \int d\hat{q}_{c} \prod_{a=0}^{n} \prod_{k\in c}^{N/\Gamma} \left[p_{0}(x_{k}^{a}) dx_{k}^{a} \right] e^{-\hat{q}_{c} \sum_{a=0,b

$$= \frac{1}{N} \sum_{c=1}^{\Gamma} \ln \left[\int d\hat{q}_{c} e^{-\frac{N(n+1)n}{2\Gamma} \hat{q}_{c} q_{c}} \left(\int \prod_{a=0}^{n} \left[dx^{a} p_{0}(x^{a}) \right] e^{\frac{\hat{q}_{c}}{2} \sum_{a=0,b\neq a}^{n,n} x^{a} x^{b}} \right)^{\frac{N}{\Gamma}} \right]$$

$$= \frac{1}{N} \sum_{c=1}^{\Gamma} \ln \left[\int d\hat{q}_{c} e^{-\frac{N(n+1)n}{2\Gamma} \hat{q}_{c} q_{c}} \left(\int \mathcal{D}\xi \prod_{a=0}^{n} \left[dx^{a} p_{0}(x^{a}) \right] e^{-\frac{\hat{q}_{c}}{2} \sum_{a=0}^{n} (x^{a})^{2} + \xi \sqrt{\hat{q}_{c}} \sum_{a=0}^{n} x^{a}} \right)^{\frac{N}{\Gamma}} \right]$$

$$= \frac{1}{\Gamma} \sum_{c=1}^{\Gamma} \exp\left(-\frac{(n+1)n}{2} \hat{q}_{c} q_{c} + \ln \left[\int \mathcal{D}\xi \left(\int dx p_{0}(x) e^{-\frac{\hat{q}_{c}}{2} x^{2} + \xi \sqrt{\hat{q}_{c}} x} \right)^{n+1} \right] \right), \tag{95}$$$$

where we have assumed that we can treat \hat{q}_c as a positive variable for the Gaussian transformation transform. This will be verified a posteriori at the end of the computation. The saddle point method employed for the estimation of the integral over the auxiliary fields is justified similarly as before, as the $N \to \infty$ as already been assumed. Finally, using again (93), we obtain

$$\lim_{n \to 0} \frac{\partial f(\{\boldsymbol{q}_c\})}{\partial n} = \frac{1}{\Gamma} \sum_{c=1}^{\Gamma} \operatorname{extr}_{\hat{q}_c} \left(-\frac{\hat{q}_c q_c}{2} + \int \mathcal{D}\xi ds p_0(s) e^{-\frac{\hat{q}_c}{2}s^2 + \xi\sqrt{\hat{q}_c}s} \ln\left[\int dx p_0(x) e^{-\frac{\hat{q}_c}{2}x^2 + \xi\sqrt{\hat{q}_c}s} \right] \right).$$
(96)

Using (85), (94) and this last expression, we get a first version of the replica formula for the free energy

$$\Gamma F_{co} = \underset{\{q_c, \hat{q}_c\}}{\operatorname{extr}} \left\{ -\sum_{r=1}^{\Gamma} \alpha \int \mathcal{D}\xi dy \mathcal{D}\hat{z} P_{\text{out}} \left(y \left| \xi \sqrt{\tilde{q}_r} + \hat{z} \sqrt{\mathbb{E}[s^2] - \tilde{q}_r} \right) \ln \left[\int \mathcal{D}z P_{\text{out}} \left(y \left| \xi \sqrt{\tilde{q}_r} + z \sqrt{\mathbb{E}[s^2] - \tilde{q}_r} \right) \right] + \sum_{c=1}^{\Gamma} \left(\frac{\hat{q}_c q_c}{2} - \int \mathcal{D}\xi ds p_0(s) e^{-\frac{\hat{q}_c}{2}s^2 + \xi \sqrt{\tilde{q}_c}s} \ln \left[\int dx p_0(x) e^{-\frac{\hat{q}_c}{2}x^2 + \xi \sqrt{\tilde{q}_c}x} \right] \right) \right\}.$$

$$(97)$$

Recall that in this expression $\tilde{q}_r = \sum_{c=1}^{\Gamma} J_{r,c} q_c$.

To make contact with the potential function introduced in this paper we still have to partially solve the extremization problem and reduce (97) to a variational problem over one variable. Differentiating the function of $\{q_c, \hat{q}_c\}$ in (97) with respect to q_c and setting the derivative to zero we find

$$\hat{q}_c = 2\sum_{r=1}^{\Gamma} J_{r,c} \alpha \,\partial_{\tilde{q}_r} \left(\int dy \mathcal{D}t f(y|t\sqrt{\tilde{q}_r}, \mathbb{E}[s^2] - \tilde{q}_r) \ln\left[f(y|t\sqrt{\tilde{q}_r}, \mathbb{E}[s^2] - \tilde{q}_r) \right] \right),\tag{98}$$

where

$$f(y|\mu,\sigma^2) := \int dx \mathcal{N}(x|\mu,\sigma^2) P_{\text{out}}(y|x) = \int \mathcal{D}x P_{\text{out}}(y|x\sigma+\mu).$$
(99)

One can show the following identity (this has already been shown and used in Appendix II)

$$\partial_{\tilde{q}_r} f(y|t\sqrt{\tilde{q}_r}, \mathbb{E}[s^2] - \tilde{q}_r) = \frac{e^{\frac{t^2}{2}}}{2\tilde{q}_r} \partial_t \left(e^{-\frac{t^2}{2}} \partial_t \left(f(y|t\sqrt{\tilde{q}_r}, \mathbb{E}[s^2] - \tilde{q}_r) \right) \right).$$
(100)

Hence, (98) can be rewritten as

$$\begin{aligned} \hat{q}_{c} &= 2\sum_{r=1}^{\Gamma} J_{r,c} \alpha \int dy \mathcal{D}t \left(1 + \ln \left[f_{\text{out}}(y | t \sqrt{\tilde{q}_{r}}, \mathbb{E}[s^{2}] - \tilde{q}_{r}) \right] \right) \partial_{\tilde{q}_{r}} f_{\text{out}}(y | t \sqrt{\tilde{q}_{r}}, \mathbb{E}[s^{2}] - \tilde{q}_{r}) \\ &= -\sum_{r=1}^{\Gamma} J_{r,c} \frac{\alpha}{\tilde{q}_{r}} \int dy dt \frac{1}{\sqrt{2\pi}} \left(1 + \ln \left[f_{\text{out}}(y | t \sqrt{\tilde{q}_{r}}, \mathbb{E}[s^{2}] - \tilde{q}_{r}) \right] \right) \partial_{t} \left(e^{\frac{-t^{2}}{2}} \partial_{t} \left(f_{\text{out}}(y | t \sqrt{\tilde{q}_{r}}, \mathbb{E}[s^{2}] - \tilde{q}_{r}) \right) \right) \\ &= \sum_{r=1}^{\Gamma} J_{r,c} \frac{\alpha}{\tilde{q}_{r}} \int dy \mathcal{D}t \frac{\left(\partial_{t} f_{\text{out}}(y | t \sqrt{\tilde{q}_{r}}, \mathbb{E}[s^{2}] - \tilde{q}_{r}) \right)^{2}}{f_{\text{out}}(y | t \sqrt{\tilde{q}_{r}}, \mathbb{E}[s^{2}] - \tilde{q}_{r})} \\ &= \sum_{r=1}^{\Gamma} J_{r,c} \alpha \int dy dp dz \frac{\exp\left(-\frac{p^{2}}{2\tilde{q}_{r}}\right)}{\sqrt{2\pi}\tilde{q}_{r}} f(y | p, \mathbb{E}[s^{2}] - \tilde{q}_{r}) \left(\partial_{p} \ln f(y | p, \mathbb{E}[s^{2}] - \tilde{q}_{r}) \right)^{2} \\ &= \sum_{r=1}^{\Gamma} J_{r,c} \alpha \mathbb{E}_{p | \tilde{q}_{r}} [\mathcal{F}(p | \mathbb{E}(s^{2}) - \tilde{q}_{r})]. \end{aligned}$$

The final step consists in replacing the stationarity condition (101) in (97). First we remark

$$\sum_{c=1}^{\Gamma} \frac{\hat{q}_c q_c}{2} = \frac{1}{2} \sum_{r=1}^{\Gamma} \sum_{c=1}^{\Gamma} J_{r,c} q_c \alpha \mathbb{E}_{p|\tilde{q}_r} [\mathcal{F}(p|\mathbb{E}(s^2) - \tilde{q}_r)]$$
$$= \frac{1}{2} \sum_{r=1}^{\Gamma} \tilde{q}_r \alpha \mathbb{E}_{p|\tilde{q}_r} [\mathcal{F}(p|\mathbb{E}(s^2) - \tilde{q}_r)]$$
$$= \frac{1}{2} \sum_{r=1}^{\Gamma} \tilde{q}_r \Sigma^{-2} (\mathbb{E}(s^2) - \tilde{q}_r)$$
(102)

where in the last line we have set

$$\Sigma^{-2}(\mathbb{E}(s^2) - \tilde{q}_r) = \alpha \mathbb{E}_{p|\tilde{q}_r}[\mathcal{F}(p|\mathbb{E}(s^2) - \tilde{q}_r)].$$
(103)

We also set

$$\Sigma_c^{-2}(\{\tilde{q}_r\}) = \sum_{r=1}^{\Gamma} J_{r,c} \alpha \mathbb{E}_{p|\tilde{q}_r} [\mathcal{F}(p|\mathbb{E}(s^2) - \tilde{q}_r)]$$
(104)

so that $\hat{q}_c = \sum_c^{-2} (\{\tilde{q}_r\})$. Then (97) becomes

$$\exp_{\{\tilde{q}_r\}} \left\{ -\sum_{r=1}^{\Gamma} \left(\alpha \int \mathcal{D}\xi dy \mathcal{D}\hat{z} \, P_{\text{out}}\left(y \left| \xi \sqrt{\tilde{q}_r} + \hat{z} \sqrt{\mathbb{E}[s^2] - \tilde{q}_r} \right) \ln \left[\int \mathcal{D}z \, P_{\text{out}}\left(y \left| \xi \sqrt{\tilde{q}_r} + z \sqrt{\mathbb{E}[s^2] - \tilde{q}_r} \right) \right] + \frac{1}{2} \tilde{q}_r \Sigma^{-2}(\tilde{q}_r) \right) - \sum_{c=1}^{\Gamma} \left(\int \mathcal{D}\xi ds p_0(s) e^{-\frac{\Sigma_c^{-2}(\{\tilde{q}_r\})}{2}s^2 + \xi \sqrt{\Sigma_c^{-2}(\{\tilde{q}_r\})s}} \ln \left[\int dx p_0(x) e^{-\frac{\tilde{q}_c}{2}x^2 + \xi \sqrt{\Sigma_c^{-2}(\{\tilde{q}_r\})x}} \right] \right) \right\}. \quad (105)$$

The (courageous) reader can now compare with Definitions (4.14) and (4.11). The sum over r yields an "internal energy" contribution $\sum_{r} U_{un}(E_r)$ and the sum over c an "entropic" contribution $\sum_{c} S_{un}(\Sigma_c(\mathbf{E}))$. To adapt the formula to sparse superposition codes one must replace all scalars by *B*-dimensional vectors, replace $E[s^2] \rightarrow 1$, $\alpha \rightarrow 1/R$ and set $\tilde{q}_r \rightarrow E[s^2] - E_r = 1 - E_r$.
