(Dated: July 9, 2018)

We analyze different factors which influence the negative refraction in solids and multi-atom molecules. We find that this negative refraction is significantly influenced by simultaneous multielectron transitions with the same transition frequency and dipole redistribution over different eigenstates. We show that these simultaneous multi-electron transitions and enhanced transition dipole broaden the bandwidth of the negative refraction by at least one order of magnitude. This work provides additional connection between metamaterials and Möbius strips.

Introduction.–– Metamaterials with negative refraction [\[1–](#page-5-2)[7\]](#page-5-3) have attracted broad interest because of its potential applications, including perfect lenses [\[2\]](#page-5-4), fingerprint identification in forensic science [\[8\]](#page-5-5), simulating condensed matter phenomena and reversed Doppler effect [\[9,](#page-5-6) [10\]](#page-5-7), controlling light's polarization [\[11,](#page-5-8) [12\]](#page-5-9), and electromagnetic cloaking [\[13,](#page-5-10) [14\]](#page-5-11). In order to realize metamaterials, a number of routes have been proposed, including (molecular) split-ring resonators [\[3,](#page-5-12) [15,](#page-5-13) [16\]](#page-5-14), chiral routes [\[17,](#page-5-15) [18\]](#page-5-16), hyperbolic dispersion [\[19–](#page-5-17)[22\]](#page-5-18), dark-state mechanism [\[7,](#page-5-19) [8,](#page-5-20) [25,](#page-5-21) [26\]](#page-6-0), and topological routes [\[6,](#page-6-1) [27–](#page-6-2)[29\]](#page-6-3). However, none of these can effectively overcome the difficulty of realizing broad-band negative refraction.

In multi-atom molecules and solids, there are generally more than one electron which can respond to applied electromagnetic fields. In previous investigations [\[6–](#page-6-1)[8,](#page-5-5) [8–](#page-5-20)[10,](#page-6-4) [16,](#page-5-14) [31,](#page-6-5) [33,](#page-6-6) [35,](#page-6-7) [36\]](#page-6-8), only transitions for a single electron were considered. Because each atom contributes a π -electron to the molecule, there are N π -electrons in a molecule with N atoms. Thus, there would be N possible transitions for the π -electrons in the molecule. Since two or more transitions can effectively overlap with each other, it would be reasonable to expect a broadened bandwidth of the negative refraction by simultaneous multi-electron transitions. On the other hand, Möbius molecules with nontrivial topology have been successfully synthesized [\[37–](#page-6-9)[40\]](#page-6-10) and proposed to realize, e.g., metamaterials [\[6,](#page-6-1) [28,](#page-6-11) [41\]](#page-6-12), quantum devices [\[42–](#page-6-13)[44\]](#page-6-14), dual-mode resonators and bandpass filters [\[45\]](#page-6-15), topological insulators [\[46\]](#page-6-16), molecular knots and engines [\[47\]](#page-6-17), and artificial light harvesting [\[48,](#page-6-18) [49\]](#page-6-19). As a concrete example for demonstrating the above principle, here we consider multi-electron transitions in a double-ring Möbius molecule $[6, 44]$ $[6, 44]$ $[6, 44]$ with $2N \pi$ -electrons. Every energy level could be filled with two electrons of different spins, due to Pauli's exclusion principle. Because the lower energy level has a higher probability to be filled with electrons, half of the N energy levels with lower energy can be filled with electrons. Furthermore, electrons can transit from an occupied energy level to an unoccupied energy level. Because multi-electrons can be involved in the transitions of nearby frequencies, the bandwidth of the negative refraction would be *significantly broadened* compared to previous findings $[6-10]$ $[6-10]$, as illustrated in Fig. [1.](#page-2-0)

Generally, it is difficult to fabricate metamaterials, as most of these require producing a huge number of splitring resonators. Also, the size of a resonator in classical metamaterials is of the order of the wavelength of the electromagnetic field [\[3,](#page-6-20) [4\]](#page-6-21). However, since in a molecular medium the electromagnetic response results from quantum transitions, the size of a molecule for quantum metamaterials can be intrinsically smaller by 2–3 orders of magnitude than the size of a resonator for classical metamaterials. Furthermore, metamaterials consisting of molecules are crystal of such molecules and thus can be easily fabricated by crystallization.

Simultaneous Multi-Electron Transitions.—The electric displacement field \vec{D} and magnetic induction \vec{B} can be written as $[3, 4]$ $[3, 4]$ $[3, 4]$

$$
\vec{D} = \varepsilon_0 \vec{E} + \vec{P} = \varepsilon_0 \overleftrightarrow{\varepsilon_r} \vec{E},\tag{1}
$$

$$
\vec{B} = \mu_0(\vec{H} + \vec{M}) = \mu_0 \overleftrightarrow{\mu_r} \vec{H}, \qquad (2)
$$

where \vec{E} is the applied electric field, \vec{P} is the polarization, ε_0 and $\varepsilon_0 \leftrightarrow$ are, respectively, the permittivity of the vacuum and medium, \vec{H} is the applied magnetic field, \vec{M} is the magnetization, μ_0 and $\mu_0 \overleftrightarrow{\mu_r}$ are, respectively, the permeability of the vacuum and medium. Under the dipole approximation, according to linear response theory [\[1\]](#page-6-22), the relative permittivity and permeability are given by $[6, 8, 16, 22, 53]$ $[6, 8, 16, 22, 53]$ $[6, 8, 16, 22, 53]$ $[6, 8, 16, 22, 53]$ $[6, 8, 16, 22, 53]$ $[6, 8, 16, 22, 53]$ $[6, 8, 16, 22, 53]$ $[6, 8, 16, 22, 53]$ $[6, 8, 16, 22, 53]$

$$
\overleftrightarrow{\varepsilon_r} = 1 - \sum_{i \neq f} \frac{\overrightarrow{d}_{if} \overrightarrow{d}_{fi}}{n_i \hbar \varepsilon_0 v_0} \text{Re}\left(\frac{1}{\omega - \Delta_{fi} + i\gamma}\right),\tag{3}
$$

$$
\overleftrightarrow{\mu_r} = 1 - \sum_{i \neq f} \frac{\mu_0 \vec{m}_{if} \vec{m}_{fi}}{n_i \hbar v_0} \text{Re}\left(\frac{1}{\omega - \Delta_{fi} + i\gamma}\right),\tag{4}
$$

where \vec{d}_{if} (\vec{m}_{if}) is the transition electric (magnetic) dipole between the initial state $|i\rangle$ and the final state $|f\rangle$ with level spacing $\hbar \Delta_{fi}$, n_i^{-1} is the number of electrons occupying the initial state, ω is the frequency of the applied electromagnetic field, h is the Planck constant, and v_0 is the volume of the molecule. In obtaining Eqs. [\(39,](#page-8-0)[40\)](#page-8-1), we assume that all molecules are identical, and every molecule responds equally to the applied electromagnetic field. Due to the response of the molecules, the actual electromagnetic field inside the medium is different from that in the vacuum. However, it can be proven by Lorentzian local field theory that both the center and bandwidth of the negative refraction will not be modified significantly [\[6–](#page-6-1)[8,](#page-5-20) [22\]](#page-5-18). Furthermore, the dipole-dipole interaction between molecules can be omitted as long as it is smaller than either the decoherence rate of the molecular excited states $[54, 55]$ $[54, 55]$ $[54, 55]$ or the static disorder $[56]$.

As a specific case, we consider a Möbius molecule with double rings consisting of 2N carbon atoms [\[39\]](#page-6-27), as shown in Fig. [1.](#page-2-0) The jth atomic position of ring a (b) is \vec{R}_{j+} (\vec{R}_{j-}) with

$$
\vec{R}_{j\pm} = \left(R \pm W \sin \frac{\varphi_j}{2}\right) \cos \varphi_j \hat{e}_x \pm W \cos \frac{\varphi_j}{2} \hat{e}_z \n+ \left(R \pm W \sin \frac{\varphi_j}{2}\right) \sin \varphi_j \hat{e}_y,
$$
\n(5)

where the radius and width of the Möbius molecule are, respectively, R and $2W$, with W the radius of the carbon atom, $\varphi_j = j\delta$, and $\delta = 2\pi/N$. According to the Hückel molecular orbital theory [\[5\]](#page-6-28), the Hamiltonian of the Möbius molecule for the single electron is [\[6,](#page-6-1) [44\]](#page-6-14)

$$
H = \sum_{j=0}^{N-1} \left[A_j^{\dagger} M A_j - \xi \left(A_j^{\dagger} A_{j+1} + \text{h.c.} \right) \right], \tag{6}
$$

where $A_j = (a_j, b_j)^T$ with a_j (b_j) the annihilation operator at the jth site of ring a (b),

$$
M = \begin{bmatrix} \epsilon & -V \\ -V & -\epsilon \end{bmatrix},\tag{7}
$$

 ϵ is the on-site energy difference between the two rings, and V (ξ) is the inter-ring (intra-ring) resonant integral. Because of the Möbius boundary condition, the last atom of each ring is linked to the first atom of the other ring, i.e., $a_0 = b_N$, and $b_0 = a_N$.

The Möbius boundary condition can be canceled by a local unitary transformation, i.e., $B_j \equiv (c_{j\uparrow}, c_{j\downarrow})^T = U_j A_j$, $B_N = B_0$, where $c_{i\sigma}$ is the annihilation operator of an electron at jth atomic site with σ pseudo-spin label,

$$
U_j = \frac{1}{\sqrt{2}} \begin{bmatrix} e^{-i\varphi_j/2} & -e^{-i\varphi_j/2} \\ 1 & 1 \end{bmatrix}.
$$
 (8)

Therefore, the Hamiltonian with periodic boundary condition can be rewritten as

$$
H = \sum_{j=0}^{N-1} \left[B_j^{\dagger} V \sigma_z B_j - \xi \left(B_j^{\dagger} Q B_{j+1} + \text{h.c.} \right) \right],\tag{9}
$$

where

$$
Q = \begin{bmatrix} e^{i\delta/2} & 0\\ 0 & 1 \end{bmatrix}.
$$
 (10)

By using the Fourier transform, $B_j = \sum_k e^{-ikj} C_k$, the Hamiltonian of the Möbius molecule is diagonalized as

$$
H = C_k^{\dagger} E_k C_k,\tag{11}
$$

Figure 1: Schematic illustration of broad-band negative refraction induced by simultaneous multi-electron transitions. Dashed curves are for single-electron transitions, while the solid curve provides the overall simultaneous contribution. Inset: Top view of a Möbius molecule with $N = 12$ carbon atoms in each ring. The adjacent atoms are linked with covalent bonds.

where $C_k = (c_{k\uparrow}, c_{k\downarrow})^T$ with

$$
c_{k\uparrow} = \frac{1}{\sqrt{2N}} \sum_{j=0}^{N-1} e^{-i(k-\delta/2)j} \left(a_j^{\dagger} - b_j^{\dagger} \right),\tag{12}
$$

$$
c_{k\downarrow} = \frac{1}{\sqrt{2N}} \sum_{j=0}^{N-1} e^{-ikj} \left(a_j^{\dagger} + b_j^{\dagger} \right),\tag{13}
$$

$$
E_k = \begin{bmatrix} E_{k\uparrow} & 0\\ 0 & E_{k\downarrow} \end{bmatrix} \tag{14}
$$

with $E_{k\uparrow} = V - 2\xi \cos(k - \frac{\delta}{2})$ and $E_{k\downarrow} = -V - 2\xi \cos k$ the eigenenergies of the upper and lower bands, respectively.

Selection Rules for Transitions.—In Eqs. [\(39,](#page-8-0)[40\)](#page-8-1), we apply linear response theory to rewrite the relative permittivity and permeability in terms of the transition matrix elements of the electric and magnetic dipoles, i.e., \vec{d}_{if} and \vec{m}_{if} . According to Eqs. [\(39](#page-8-0)[,40\)](#page-8-1), we would expect negative permittivity and permeability close to the transition frequencies $\Delta_{fi} = (E_f - E_i)/\hbar$. The selection rules of transitions are explicitly provided by the matrix elements of the electric and magnetic dipoles [\[53\]](#page-6-23).

Using the dipole approximation, the interaction Hamiltonian with the electric field is written as [\[3,](#page-6-20) [4\]](#page-6-21)

$$
H'_E = -\vec{d} \cdot \vec{E_0} \cos \omega t,\tag{15}
$$

where the molecule is subject to an electric field with amplitude $\vec{E}_0 = (E_0^x, E_0^y, E_0^z)$ and frequency ω . The electric-dipole-induced transition is allowed if the corresponding matrix element is nonzero. By using the relation $\langle \phi_{js} | \vec{r} | \phi_{j's'} \rangle = \vec{R}_{js} \delta_{jj'} \delta_{ss'}$ [\[5\]](#page-6-28) and the rotating-wave approximation [\[2,](#page-6-29) [59\]](#page-6-30), the selection rules for the electric-dipoleinduced transitions are summarized as

$$
|k,\downarrow\rangle \stackrel{x,y,z}{\rightleftharpoons} |k,\uparrow\rangle, \tag{16a}
$$

$$
|k, \downarrow\rangle \stackrel{x,y}{\rightleftharpoons} |k+2\delta, \uparrow\rangle, \tag{16b}
$$

$$
|k,\downarrow\rangle \stackrel{x,y,z}{\rightleftharpoons} |k+\delta,\uparrow\rangle, \tag{16c}
$$

$$
|k,\downarrow\rangle \stackrel{x,y}{\rightleftharpoons} |k-\delta,\uparrow\rangle,\tag{16d}
$$

where the superscripts over the arrows indicate the polarization of the electric field. Under the dipole approximation, the interaction Hamiltonian with the magnetic field is written as [\[3,](#page-6-20) [4\]](#page-6-21)

$$
H'_B = -\vec{m} \cdot \vec{B}_0 \cos \omega t,\tag{17}
$$

Figure 2: Selection rules for transitions in a Möbius molecule. The curve marked with circles (squares) represents the upper (lower) energy band. The red circles and blue squares are the levels occupied by two π electrons with spin up and down, while the empty symbols are unoccupied. The green squares are occupied by one π electron. The curves connecting two bands indicate the selection rules for transitions. Hereafter, we choose the following parameters: $\gamma^{-1} = 4$ ns [\[6\]](#page-6-1), $V = \xi = 3.6$ eV [\[60\]](#page-6-31), $W = 0.077$ nm [\[40\]](#page-6-10), and $R = NW/\pi$.

Figure 3: Relative permittivity ε_r (blue dotted curve) and permeability μ_r (green curve) of a Möbius molecule versus the detuning $\Delta\omega$. Here we only show the lowest eigenvalue.

where $\vec{B}_0 = (B_0^x, B_0^y, B_0^z)$. A straightforward calculation shows [\[53\]](#page-6-23) that the selection rules for the magnetic-dipoleinduced transitions are the same as Eq. [\(16\)](#page-2-1). The transitions allowed by both electric and magnetic dipole couplings are depicted in Fig. [2,](#page-3-0) in combination with initial and final conditions. Because a transition can take place from the highest occupied molecular orbital (HOMO), denoted by solid symbols, to the lowest unoccupied molecular orbital (LUMO), denoted by empty symbols.

Broad-Band Negative Refraction.––In order to investigate the effects of simultaneous multi-electron transitions on the negative refraction, we explore the relative permittivity and permeability for different detunings $\Delta \omega = \omega - \Delta_{fi}$. In Eq. [\(14\)](#page-2-2), the lower-band $E_{k,\downarrow}$ is symmetric with respect to $k = 0$, while the upper-band $E_{k,\uparrow}$ is symmetric with respect to $k = \delta/2$. The following four pairs of transitions possess the same transition frequencies, respectively: $|k, \downarrow\rangle \leftrightarrows |k, \uparrow\rangle$ and $|-k,\downarrow\rangle \leftrightarrows |-k+\delta,\uparrow\rangle$, denoted by the green curves in Fig [2;](#page-3-0) $|k,\downarrow\rangle \leftrightarrows |k+\delta,\uparrow\rangle$ and $|-k,\downarrow\rangle \leftrightarrows |-k,\uparrow\rangle$, denoted by the magenta curves; $|k, \downarrow\rangle \leftrightarrows |k - \delta, \uparrow\rangle$ and $| -k, \downarrow\rangle \leftrightarrows | -k + 2\delta, \uparrow\rangle$, denoted by the black curves; $|k, \downarrow\rangle \leftrightarrows |k + 2\delta, \uparrow\rangle$ and $|-k, \downarrow\rangle \leftrightarrows |-k-\delta, \uparrow\rangle$, denoted by the blue curves, which also fulfill the selection rules [\(16\)](#page-2-1) for the transitions in Möbius molecules.

In Fig. [3,](#page-3-1) we show the widest bandwidth for the negative refraction which corresponds to the transitions labeled by the thick green curves in Fig. [2.](#page-3-0) The bandwidth of the negative refraction is 80 μ eV, which is about 20 times that of Ref. [\[6\]](#page-6-1). To explore the underlying broadening mechanism, we investigate the relevant contributions from all

Figure 4: Effects of simultaneous multi-electron transitions and enhanced transition dipole on the relative permeability of a Möbius molecule. The green circles is for $\left|-\frac{\pi}{2},\downarrow\right\rangle \rightleftarrows \left|-\frac{\pi}{3},\uparrow\right\rangle$, and the black curve are for $\left|\frac{\pi}{2},\downarrow\right\rangle \rightleftarrows \left|\frac{\pi}{2},\uparrow\right\rangle$, and the red dotted curve sums up the two resonant transitions.

simultaneous transitions. Generally, the magnetic response is much smaller than the electric response. Therefore, the bandwidth of the negative refraction is mainly determined by bandwidth of the negative permeability. In Fig. [4,](#page-4-0) we investigate the effect of simultaneous transitions on the negative refraction by the relative permeability. At the transition frequency, there are two degenerate transitions, denoted by the thick green curves in Fig. [2.](#page-3-0) One is from the initial state $\left|-\frac{\pi}{2},\downarrow\right\rangle$ to the final state $\left|-\frac{\pi}{3},\uparrow\right\rangle$, denoted by the green circles in Fig. [4.](#page-4-0) The other transition is from $\left|\frac{\pi}{2},\downarrow\right\rangle$ to $\left|\frac{\pi}{2},\uparrow\right\rangle$, denoted by the black curve. The summation of the two transitions, denoted by the red dotted curve, is nearly the same as that of all contributions.

The bandwidth of the negative refraction is determined by the zeros of the lowest eigenvalue of \hat{h}_r^r [\[53\]](#page-6-23), i.e.,

$$
\mu_r^1 = 1 - \sum_{k \in \text{HOMO}} \sum_{k' \in \text{LUMO}} 2\alpha_{k,k'}^2 \eta_{k,k'}' = 0,\tag{18}
$$

where $\eta'_{k,k'}$ is of the same form for different transitions but with a different central frequency. Among four possible $\alpha_{k,k'}$'s, the maximum of $\alpha_{k,k}$ and $\alpha_{k,k+\delta}$ are generally larger than those of $\alpha_{k,k-\delta}$ and $\alpha_{k,k+2\delta}$ [\[53\]](#page-6-23). Assuming that $\varepsilon = V$, we have

$$
\alpha_{\frac{\pi}{2},\frac{\pi}{2}} \simeq \frac{RV}{\hbar c} \left(1 + 2 \sin \frac{3\delta}{4} \right) \simeq \frac{7RV}{4\hbar c},\tag{19}
$$

$$
\alpha_{-\frac{\pi}{2},-\frac{\pi}{3}} \simeq \frac{RV}{\hbar c} \left(1 + 2\sin\frac{3\delta}{4} \right) \simeq \frac{7RV}{4\hbar c}.\tag{20}
$$

In Ref. [\[6\]](#page-6-1), negative refraction was considered for the single transition $|0, \downarrow\rangle \rightleftarrows |0, \uparrow\rangle$ with

$$
\alpha_{0,0} \simeq \frac{RV}{\hbar c} \left(1 - 2\sin\frac{\delta}{2}\sin\frac{3\delta}{4} \right) \simeq \frac{13RV}{16\hbar c}.\tag{21}
$$

Since $\alpha_{\frac{\pi}{2},\frac{\pi}{2}}^2 = \alpha_{-\frac{\pi}{2},-\frac{\pi}{3}}^2 \simeq 5\alpha_{0,0}^2$, the transition dipoles have been enlarged by a factor of $\sqrt{5}$. Furthermore, there are four simultaneous transitions with the same transition frequency, i.e., $\left|\frac{\pi}{2},\downarrow\right\rangle \rightleftarrows \left|\frac{\pi}{2},\uparrow\right\rangle$ and $\left|-\frac{\pi}{2},\downarrow\right\rangle \rightleftarrows \left|-\frac{\pi}{3},\uparrow\right\rangle$ with two different electronic spins, the bandwidth of the negative refraction is about 20 times of our previous observation in Ref. [\[6\]](#page-6-1). Compared to other discoveries, our proposed bandwidth is about: 10^5 times that of Refs. [\[7,](#page-5-19) [8\]](#page-5-20), 4×10^5 times that of Ref. [\[9\]](#page-6-32), and 121 times that of Ref. [\[10\]](#page-6-4).

Conclusions.––We explore the possibility of broadening negative refraction by simultaneous multi-electron transitions. As a specific example, we calculate the optical properties of Möbius molecules based on the Hückel molecular orbital method and linear response theory. The simultaneous multi-electron transitions provide parallel contributions to the overlapping negative refraction. Furthermore, in each transition, the negative refraction is significantly broadened by the enhanced transition dipole. As a result of these two broadening effects, the bandwidth for the negative refraction is larger than the previous discoveries in Refs. [\[7,](#page-5-19) [10\]](#page-6-4) by at least two orders of magnitude. Therefore, we clearly show that the contributions of multi-electron transitions and enhanced transition dipoles can lead to a large broadening of the negative-index interval. Moreover, as metamaterials consisting of Möbius molecules are based

on quantum transitions, their size is smaller by 2–3 orders of magnitude than in classical metamaterials. Instead of producing a huge number of split-ring resonators, metamaterials of Möbius molecules are chemically synthesized and self-assembled by crystallization. In conclusion, this work provides a possible route for broad-band negative refractive-index of metamaterials.

I. MULTI-ELECTRON TRANSITIONS IN MÖBIUS RING

As shown in the main text, the single-electron Hamiltonian of a Möbius molecule

$$
H = \sum_{j=0}^{N-1} \left[A_j^{\dagger} M A_j - \xi \left(A_j^{\dagger} A_{j+1} + \text{h.c.} \right) \right]
$$
 (22)

can be diagonalized as

$$
H = C_k^{\dagger} E_k C_k,\tag{23}
$$

where the eigenstates are

$$
|k,\uparrow\rangle = \frac{1}{\sqrt{2N}} \sum_{j=0}^{N-1} \exp\left[-i\left(k - \frac{\delta}{2}\right)j\right] \left(a_j^{\dagger} - b_j^{\dagger}\right)|v\rangle, \ |k,\downarrow\rangle = \frac{1}{\sqrt{2N}} \sum_{j=0}^{N-1} \exp(-ikj) \left(a_j^{\dagger} + b_j^{\dagger}\right)|v\rangle, \tag{24}
$$

with $|v\rangle$ the vacuum state. The corresponding eigenenergies are, respectively, $E_{k\uparrow} = V - 2\xi \cos(k - \delta/2)$ and $E_{k\downarrow} =$ $-V - 2\xi \cos k$.

In order to simulate the electromagnetic response of the Möbius medium in the presence of applied fields, we employ linear-response theory [\[1\]](#page-6-22) to calculate the electric permittivity and magnetic permeability. When there is an electric field applied on the Möbius molecule, the molecule is polarized as

$$
\langle \vec{d} \rangle = \int \frac{d\omega}{2\pi} S(\omega) \vec{E}(\omega) e^{-i\omega t}, \qquad (25)
$$

where

$$
\vec{E}(\omega) = \int_{-\infty}^{\infty} dt \ \vec{E}(t)e^{i\omega t}
$$
\n(26)

is the Fourier transform of the time-dependent electric field with amplitude \vec{E}_0 and frequency ω

$$
\vec{E}(t) = \vec{E}_0 \cos \omega t,\tag{27}
$$

$$
S(\omega) = -J(\omega) - J^*(-\omega). \tag{28}
$$

Here, the dipole-dipole correlation function reads

$$
J(\omega) = -i \int_0^\infty dt \, \text{Tr} \left[\vec{d}(t) \vec{d\rho}(0) \right] e^{i\omega t},\tag{29}
$$

where the initial state of the molecule is $\rho(0) = \sum_i n_i^{-1} |i\rangle\langle i|$ with $\sum_i n_i^{-1} = 2N$ the total number of π -electrons. Particularly, we obtain that $n_i = 1$ when $|i\rangle = |k, \overline{\downarrow}\rangle$ for $\left(-\frac{\pi}{2} \leq k \leq \frac{\pi}{2}\right)$, denoted by the blue solid squares in Fig. 2 of the main text, or $|i\rangle = |k,\uparrow\rangle$ for $(-\frac{\pi}{6} \leq k \leq \frac{\pi}{3})$, denoted by the red solid circles in Fig. 2 of the main text; $n_i = 2$ when $|i\rangle = |\pm \frac{2\pi}{3}, \downarrow\rangle$, denoted by the green squares in Fig. 2 of the main text.

The electric dipole in the Heisenberg picture is

$$
\vec{d}(t) = \exp(iH^{\dagger}t/\hbar) \vec{d} \exp(-iHt/\hbar).
$$
\n(30)

Because the Fourier transform of the electric field is

$$
\vec{E}(\omega_1) = \pi \vec{E}_0[\delta(\omega_1 + \omega) + \delta(\omega_1 - \omega)],\tag{31}
$$

the molecular electric dipole in the presence of an applied electric field is

$$
\langle \vec{d} \rangle = \int \frac{d\omega_1}{2\pi} S(\omega_1) e^{-i\omega_1 t} \pi \vec{E}_0 [\delta(\omega_1 + \omega) + \delta(\omega_1 - \omega)] = -\vec{E}_0 \text{Re} \left\{ [J(\omega) + J^*(-\omega)] e^{-i\omega t} \right\},\tag{32}
$$

where

$$
J(\omega) = -i \int_0^{\infty} dt \, e^{i\omega t} \sum_i \frac{1}{n_i} \langle i | \vec{d}(t) \vec{d} | i \rangle = -i \int_0^{\infty} dt \, e^{i\omega t} \sum_i \frac{1}{n_i} \langle i | e^{iH^\dagger t/\hbar} \vec{de}^{-iHt/\hbar} \vec{d} | i \rangle = \sum_{i,f} \frac{\vec{d}_{if} \vec{d}_{fi}}{n_i(\omega - \Delta_{fi} + i\gamma)}.
$$
 (33)

Here, in the sum, the final state should be different from the initial state, and

$$
\langle i|H|i\rangle = E_i - \frac{i}{2}\gamma \tag{34}
$$

with $-i\gamma/2$ being phenomenologically introduced for the decay of the excited state. In Eq. [\(33\)](#page-8-2), $\Delta_{fi} = (E_f - E_i)/\hbar$ is the transition frequency between the initial state $|i\rangle$ and the final state $|f\rangle$. Therefore, the molecular electric dipole can be rewritten as

$$
\langle \vec{d} \rangle = -\sum_{i,f} \frac{\vec{E}_0}{2n_i} \left\{ \left[\left(\frac{\vec{d}_{if} \vec{d}_{fi}}{\omega - \Delta_{fi} + i\gamma} - \frac{\vec{d}_{if} \vec{d}_{fi}}{\omega + \Delta_{fi} + i\gamma} \right) e^{-i\omega t} + \left(\frac{\vec{d}_{if} \vec{d}_{fi}}{\omega - \Delta_{fi} - i\gamma} - \frac{\vec{d}_{if} \vec{d}_{fi}}{\omega + \Delta_{fi} - i\gamma} \right) e^{i\omega t} \right] \right\}.
$$
 (35)

Because of the rotating-wave approximation [\[2\]](#page-6-29), the second and third terms of the above equation can be ignored as

$$
\langle \vec{d} \rangle \approx -\sum_{i,f} \frac{\vec{E}_0}{2n_i} \left(\frac{\vec{d}_{if} \vec{d}_{fi} e^{-i\omega t}}{\omega - \Delta_{fi} + i\gamma} + \frac{\vec{d}_{if} \vec{d}_{fi} e^{i\omega t}}{\omega - \Delta_{fi} - i\gamma} \right) \approx -\sum_{i,f} \text{Re} \left[\frac{\vec{d}_{if} \vec{d}_{fi} \cdot \vec{E}(t)}{n_i \hbar (\omega - \Delta_{fi} + i\gamma)} \right]. \tag{36}
$$

Assuming that all molecules are identical, the polarization density reads

$$
\vec{P} = \frac{\langle \vec{d} \rangle}{\hbar v_0},\tag{37}
$$

where $v_0 \simeq 2\pi (R + W)^2 W$ is the volume of the molecule.

Because the electric displacement field is [\[3,](#page-6-20) [4\]](#page-6-21)

$$
\vec{D} = \varepsilon_0 \vec{E} + \vec{P} = \varepsilon_0 \overleftrightarrow{\varepsilon_r} \vec{E},\tag{38}
$$

the relative permittivity is explicitly given as

$$
\overleftrightarrow{\varepsilon_r} = 1 - \sum_{i,f} \frac{\overrightarrow{d}_{if} \overrightarrow{d}_{fi}}{n_i \hbar \varepsilon_0 v_0} \text{Re}\left(\frac{1}{\omega - \Delta_{fi} + i\gamma}\right). \tag{39}
$$

In a similar way, the relative permeability is calculated as

$$
\overleftrightarrow{\mu_r} = 1 - \sum_{i,f} \frac{\mu_0 \vec{m}_{if} \vec{m}_{fi}}{n_i \hbar v_0} \text{Re}\left(\frac{1}{\omega - \Delta_{fi} + i\gamma}\right). \tag{40}
$$

II. SELECTION RULES FOR TRANSITIONS

In the previous section, we apply linear response theory to rewrite the relative permittivity and permeability in terms of the transition matrix elements of the electric and magnetic dipole, i.e., d_{if} and \vec{m}_{if} . According to Eqs. [\(39,](#page-8-0)[40\)](#page-8-1), we would expect the negative permittivity and permeability to be close to the transition frequency Δ_{fi} . Hereafter, the selection rules of transitions are explicitly provided by calculating the matrix elements of the electric and magnetic dipole.

Under the dipole approximation, the interaction Hamiltonian with the electric field is written as $[3, 4]$ $[3, 4]$ $[3, 4]$

$$
H'_{E} = -\vec{d} \cdot \vec{E_0} \cos \omega t. \tag{41}
$$

The electric-dipole-induced transition is allowed if the corresponding matrix element is nonzero. By using the relation $\langle \phi_{js} | \vec{r} | \phi_{j's'} \rangle = \vec{R}_{js} \delta_{jj'} \delta_{ss'}$ [\[5\]](#page-6-28), the non-vanishing matrix elements are explicitly listed as

$$
\langle 0|C_{k\uparrow}^{\dagger}H_{E}^{'}C_{k\downarrow}|0\rangle = \left(i\frac{E_{0}^{(x)}}{4} + \frac{E_{0}^{(y)}}{4} + \frac{E_{0}^{(z)}}{2}\right)eW\cos\omega t,\tag{42a}
$$

$$
\langle 0 | C_{k\downarrow}^{\dagger} H_{E}^{\prime} C_{k\uparrow} | 0 \rangle = \left(-i \frac{E_{0}^{(x)}}{4} + \frac{E_{0}^{(y)}}{4} + \frac{E_{0}^{(z)}}{2} \right) eW \cos \omega t, \tag{42b}
$$

$$
\langle 0| C_{k\uparrow}^{\dagger} H_E C_{k+\delta,\uparrow} |0\rangle = \left(\frac{E_0^{(x)}}{2} - i\frac{E_0^{(y)}}{2}\right) eR \cos\omega t, \tag{42c}
$$

$$
\langle 0| C_{k\uparrow}^{\dagger} H_{E}^{'} C_{k+\delta,\downarrow} |0\rangle = \left(-i\frac{E_{0}^{(x)}}{4} - \frac{E_{0}^{(y)}}{4} \right) eW \cos\omega t, \tag{42d}
$$

$$
\langle 0| C_{k\downarrow}^\dagger H_E C_{k+\delta,\uparrow} |0\rangle = \left(i \frac{E_0^{(x)}}{4} + \frac{E_0^{(y)}}{4} + \frac{E_0^{(z)}}{2} \right) eW \cos \omega t, \tag{42e}
$$

$$
\langle 0| C_{k\downarrow}^{\dagger} H_E C_{k+\delta,\downarrow} |0\rangle = \left(\frac{E_0^{(x)}}{2} - i\frac{E_0^{(y)}}{2}\right) eR \cos\omega t, \tag{42f}
$$

$$
\langle 0|C_{k\uparrow}^{\dagger}H_{E}^{'}C_{k-\delta,\uparrow}|0\rangle = \left(\frac{E_{0}^{(x)}}{2} + i\frac{E_{0}^{(y)}}{2}\right)eR\cos\omega t, \tag{42g}
$$

$$
\langle 0|C_{k\uparrow}^{\dagger}H_{E}^{'}C_{k-\delta,\downarrow}|0\rangle = \left(-i\frac{E_{0}^{(x)}}{4} + \frac{E_{0}^{(y)}}{4} + \frac{E_{0}^{(z)}}{2}\right)eW\cos\omega t,\tag{42h}
$$

$$
\langle 0 | C_{k\downarrow}^{\dagger} H_{E}^{'} C_{k-\delta,\uparrow} | 0 \rangle = \left(i \frac{E_{0}^{(x)}}{4} - \frac{E_{0}^{(y)}}{4} \right) eW \cos \omega t, \tag{42i}
$$

$$
\langle 0 | C_{k\downarrow}^{\dagger} H_E C_{k-\delta,\downarrow} | 0 \rangle = \left(\frac{E_0^{(x)}}{2} + i \frac{E_0^{(y)}}{2} \right) eR \cos \omega t, \tag{42}
$$

$$
\langle 0| C_{k\downarrow}^{\dagger} H_E C_{k+2\delta,\uparrow} |0\rangle = \left(-i \frac{E_0^{(x)}}{4} - \frac{E_0^{(y)}}{4} \right) eW \cos \omega t.
$$
 (42k)

For example, because in Eq. [\(42\)](#page-9-1), the matrix element is nonzero between the states $|k, \uparrow\rangle$ and $|k, \downarrow\rangle$, and there are contributions from all three components of the electric field, the transition $|k, \uparrow\rangle \rightleftharpoons |k, \downarrow\rangle$ can be electric-dipole induced for all three polarizations of the electric field. Based on Eq. [\(42\)](#page-9-1), the selection rules for the electric-dipole induced transitions are summarized as

$$
|k,\downarrow\rangle \stackrel{x,y,z}{\rightleftharpoons} |k,\uparrow\rangle, |k,\downarrow\rangle \stackrel{x,y}{\rightleftharpoons} |k+2\delta,\uparrow\rangle, |k,\downarrow\rangle \stackrel{x,y,z}{\rightleftharpoons} |k+\delta,\uparrow\rangle, |k,\downarrow\rangle \stackrel{x,y}{\rightleftharpoons} |k-\delta,\uparrow\rangle,
$$
\n(43)

where the superscripts over the arrows indicate the polarization of the electric field.

Under the dipole approximation, the interaction Hamiltonian with the magnetic field is written as [\[3,](#page-6-20) [4\]](#page-6-21)

$$
H'_{B} = -\vec{m} \cdot \vec{B}_0 \cos \omega t. \tag{44}
$$

Straightforward calculations show the following non-vanishing matrix elements,

$$
\langle 0|C_{k\uparrow}^{\dagger}H_{B}^{'}C_{k\uparrow}|0\rangle = -\left\{2W^{2}\left(\cos(k-\delta) - \cos k\right)B_{0}^{(y)} + \left[W^{2}\left(\cos k - \cos(k-2\delta) - \cos(k-\delta) + \cos(k+\delta)\right)\right]\right. \\ \left. + 4R^{2}\left(\cos(k+\frac{\delta}{2}) - \cos(k-\frac{3}{2}\delta)\right)\right|B_{0}^{(z)}\right\}\frac{e\xi}{8\hbar}\cos\omega t,
$$
\n(45a)

$$
\langle 0| C_{k\uparrow}^{\dagger} H_B C_{k\downarrow} |0\rangle = -\left\{ \left[V + \xi \left(\cos(k-\delta) - \cos(k+\frac{\delta}{2}) \right) \right] \left(B_0^{(x)} - i B_0^{(y)} \right) \right. \\ \left. + 2i \xi \cos \frac{\delta}{4} \left(\cos(k-\frac{5\delta}{4}) - \cos(k+\frac{3}{4}\delta) \right) B_0^{(z)} \right\} \frac{e R W}{4\hbar} \cos \omega t, \tag{45b}
$$

$$
\langle 0| C_{k\downarrow}^{\dagger} H'_B C_{k\uparrow} |0 \rangle = -\left\{ \left[V + \xi \left(\cos(k - \delta) - \cos(k + \frac{\delta}{2}) \right) \right] \left(B_0^{(x)} + i B_0^{(y)} \right) + 2i \xi \cos \frac{\delta}{4} \left(\cos(k + \frac{3\delta}{4}) - \cos(k - \frac{5}{4}\delta) \right) B_0^{(z)} \right\} \frac{e R W}{4\hbar} \cos \omega t, \tag{45c}
$$

$$
\langle 0|C_{k\downarrow}^{\dagger}H'_{B}C_{k\downarrow}|0\rangle = -\left[W^{2}B_{0}^{(y)}\sin\frac{\delta}{2} - \left(2R^{2} + W^{2}\cos\frac{\delta}{2}\right)B_{0}^{(z)}\sin\delta\right]\frac{e\xi}{2\hbar}\sin k\cos\omega t,\tag{45d}
$$

$$
\langle 0|C_{k\uparrow}^{\dagger}H_B'C_{k+\delta,\uparrow}|0\rangle = (\cos(k-\delta) - \cos(k+\delta))\left(iB_0^{(x)} + B_0^{(y)} - B_0^{(z)}\right) \frac{eW^2\xi}{8\hbar}\cos\omega t, \tag{45e}
$$

$$
\langle 0|C_{k\uparrow}^{\dagger}H_B'C_{k+\delta,\downarrow}|0\rangle = -\left\{ \left[V + \xi\left(\cos k - \cos(k + \frac{\delta}{2})\right) \right] \left(B_0^{(x)} - iB_0^{(y)}\right) - 2i\xi\cos\frac{\delta}{4}\left(\cos(k - \frac{5\delta}{4}) - \cos(k + \frac{3}{4}\delta)\right)B_0^{(z)}\right\} \frac{eRW}{4\hbar}\cos\omega t,\tag{45f}
$$

$$
\langle 0| C_{k\downarrow}^{\dagger} H_B C_{k+\delta,\uparrow} |0\rangle = \left\{ \left[V + \xi \left(\cos(k+\delta) - \cos(k-\frac{\delta}{2}) \right) \right] \left(B_0^{(x)} - i B_0^{(y)} \right) \right\}
$$

$$
-i\xi \left(\cos(k-\delta) - \cos(k+\delta) - \cos(k+\frac{3\delta}{2}) + \cos(k-\frac{\delta}{2}) \right) B_0^{(z)} \right\} \frac{eRW}{4\hbar} \cos\omega t, \tag{45g}
$$

$$
\langle 0|C_{k\downarrow}^{\dagger}H_B'C_{k+\delta,\downarrow}|0\rangle = \left(\cos(k-\frac{\delta}{2})-\cos(k+\frac{3\delta}{2})\right)\left(iB_0^{(x)}+B_0^{(y)}-B_0^{(z)}\right)\frac{eW^2\xi}{8\hbar}\cos\omega t,\tag{45h}
$$

$$
\langle 0|C_{k\uparrow}^{\dagger}H_B'C_{k-\delta,\uparrow}|0\rangle = -\left(\cos(k-2\delta) - \cos k\right)\left(iB_0^{(x)} - B_0^{(y)} + B_0^{(z)}\right)\frac{eW^2\xi}{8\hbar}\cos\omega t,\tag{45i}
$$

$$
\langle 0| C_{k\uparrow}^{\dagger} H_B C_{k-\delta,\downarrow} |0\rangle = \left\{ \left[V + \xi \left(\cos k - \cos(k - \frac{3\delta}{2}) \right) \right] \left(B_0^{(x)} + i B_0^{(y)} \right) + i\xi \left(\cos(k - \frac{3\delta}{2}) + \cos(k - 2\delta) - \cos k - \cos(k + \frac{\delta}{2}) \right) B_0^{(z)} \right\} \frac{eRW}{4\hbar} \cos\omega t, \tag{45}
$$

$$
\langle 0|C_{k\downarrow}^{\dagger}H_B'C_{k-\delta,\uparrow}|0\rangle = -\left[V + \xi\left(\cos(k-\delta) - \cos(k-\frac{\delta}{2})\right)\right] \left(B_0^{(x)} + iB_0^{(y)}\right) \frac{eRW}{4\hbar} \cos\omega t,\tag{45k}
$$

$$
\langle 0|C_{k\downarrow}^{\dagger}H_B'C_{k-\delta,\downarrow}|0\rangle = \left(\cos(k-\frac{3\delta}{2}) - \cos(k+\frac{\delta}{2})\right)\left(-iB_0^{(x)} + B_0^{(y)} - B_0^{(z)}\right)\frac{eW^2\xi}{8\hbar}\cos\omega t,\tag{45}
$$

$$
\langle 0|C_{k\uparrow}^{\dagger}H_B'C_{k+2\delta,\uparrow}|0\rangle = i(\cos k - \cos(k+\delta))\left(B_0^{(x)} - iB_0^{(y)}\right)\frac{eW^2\xi}{8\hbar}\cos\omega t,\tag{45m}
$$

$$
\langle 0|C_{k\downarrow}^{\dagger}H'_{B}C_{k+2\delta,\uparrow}|0\rangle = \left[V + \xi\left(\cos(k+\delta) - \cos(k+\frac{\delta}{2})\right)\right] \left(B_{0}^{(x)} - iB_{0}^{(y)}\right) \frac{eRW}{4\hbar}\cos\omega t,\tag{45n}
$$

$$
\langle 0|C_{k\downarrow}^{\dagger}H'_{B}C_{k+2\delta,\downarrow}|0\rangle = i\left(\cos(k+\frac{\delta}{2})-\cos(k+\frac{3\delta}{2})\right)\left(B_{0}^{(x)}-iB_{0}^{(y)}\right)\frac{eW^{2}\xi}{8\hbar}\cos\omega t.
$$
\n(450)

Therefore, we have the following selection rules for the magnetic-dipole-induced transitions, i.e.,

$$
|k,\downarrow\rangle \stackrel{x,y,z}{\rightleftharpoons} |k,\uparrow\rangle, |k,\downarrow\rangle \stackrel{x,y}{\rightleftharpoons} |k+2\delta,\uparrow\rangle, |k,\downarrow\rangle \stackrel{x,y,z}{\rightleftharpoons} |k+\delta,\uparrow\rangle, |k,\downarrow\rangle \stackrel{x,y}{\rightleftharpoons} |k-\delta,\uparrow\rangle,
$$
\n(46)

which is the same as the selection rules (43) for the electric-dipole induced transitions.

Because a transition can take place when there is an electron in the highest occupied molecular orbital (HOMO),

and the lowest unoccupied molecular orbital (LUMO) is unoccupied. The transitions allowed by both electric and magnetic dipole couplings are schematically shown in Fig. 2 of the main text.

III. PERMITTIVITY

According to the selection rules of optical transitions in Möbius molecules, there are four possible transitions from a given initial state. Generally speaking, the permittivity is a second-rank tensor with nine matrix elements, i.e.,

$$
\overleftrightarrow{\varepsilon_r} = \sum_{i,j=x,y,z} \varepsilon_r^{i,j} \hat{e}_i \hat{e}_j. \tag{47}
$$

According to Eqs. [\(39,](#page-8-0)[42\)](#page-9-1), the three diagonal components can be calculated as

$$
\varepsilon_r^{xx} = 1 - \sum_k \left(\eta'_{k,k} + \eta'_{k,k+\delta} + \eta'_{k,k+2\delta} + \eta'_{k,k-\delta} \right),\tag{48a}
$$

$$
\varepsilon_r^{yy} = 1 - \sum_k \left(\eta'_{k,k} + \eta'_{k,k+\delta} + \eta'_{k,k+2\delta} + \eta'_{k,k-\delta} \right),\tag{48b}
$$

$$
\varepsilon_r^{zz} = 1 - \sum_k \left(4\eta'_{k,k} + 4\eta'_{k,k+\delta} \right),\tag{48c}
$$

where $\eta'_{k,k'}(\omega)$ is the real part of $\eta_{k,k'}(\omega) = \eta'_{k,k'}(\omega) + i\eta''_{k,k'}(\omega)$,

$$
\eta_{k,k} = \frac{1}{16\hbar\varepsilon_0 v_0} \frac{e^2 W^2}{\omega - 2V - 2\xi \left[\cos k - \cos\left(k - \frac{\delta}{2}\right)\right] + i\gamma},\tag{49a}
$$

$$
\eta_{k,k+\delta} = \frac{1}{16\hbar\varepsilon_0 v_0} \frac{e^2 W^2}{\omega - 2V - 2\xi \left[\cos k - \cos\left(k + \frac{\delta}{2}\right)\right] + i\gamma},\tag{49b}
$$

$$
\eta_{k,k+2\delta} = \frac{1}{16\hbar\varepsilon_0 v_0} \frac{e^2 W^2}{\omega - 2V - 2\xi \left[\cos k - \cos\left(k + \frac{3\delta}{2}\right)\right] + i\gamma},\tag{49c}
$$

$$
\eta_{k,k-\delta} = \frac{1}{16\hbar\varepsilon_0 v_0} \frac{e^2 W^2}{\omega - 2V - 2\xi \left[\cos k - \cos\left(k - \frac{3\delta}{2}\right)\right] + i\gamma}.
$$
\n(49d)

Notice that $\eta'_{k,k'}$ are of the same form but with a different central frequency. The six off-diagonal matrix elements of the relative permittivity read

$$
\varepsilon_r^{xy} = -\varepsilon_r^{yx} = \sum_k i \left(\eta'_{k,k} - \eta'_{k,k+\delta} - \eta'_{k,k+2\delta} + \eta'_{k,k-\delta} \right),\tag{50a}
$$

$$
\varepsilon_r^{xz} = -\varepsilon_r^{zx} = \sum_k 2i \left(\eta'_{k,k} - \eta'_{k,k+\delta} \right),\tag{50b}
$$

$$
\varepsilon_r^{yz} = \varepsilon_r^{zy} = -\sum_k 2\left(\eta'_{k,k} + \eta'_{k,k+\delta}\right). \tag{50c}
$$

In addition to the selection rules of optical transitions, the electric response can only occur at those transitions from the HOMOs to the LUMOs. The relative permittivity $\overleftrightarrow{\varepsilon_r}$ can be further simplified as

$$
\overleftrightarrow{\varepsilon_r} = 1 + \sum_{k \in \text{HOMO}} \sum_{k' \in \text{LUMO}} \overleftrightarrow{\chi}_{k,k'}^{\text{E}}, \tag{51}
$$

where the second term can be explicitly given as

$$
\sum_{k \in \text{HOMO}} \sum_{k' \in \text{LUMO}} \overleftrightarrow{\chi}_{k,k'}^E = \frac{1}{2} \left(\overleftrightarrow{\chi}_{-\frac{2\pi}{3}, -\frac{5\pi}{6}}^E + \overleftrightarrow{\chi}_{-\frac{2\pi}{3}, -\frac{2\pi}{3}}^E + \overleftrightarrow{\chi}_{-\frac{2\pi}{3}, -\frac{\pi}{2}}^E + \overleftrightarrow{\chi}_{-\frac{2\pi}{3}, -\frac{\pi}{3}}^E \right) + \overleftrightarrow{\chi}_{-\frac{\pi}{2}, -\frac{2\pi}{3}}^E + \overleftrightarrow{\chi}_{-\frac{\pi}{2}, -\frac{\pi}{2}}^E + \overleftrightarrow{\chi}_{-\frac{\pi}{2}, -\frac{\pi}{3}}^E + \overleftrightarrow{\chi}_{-\frac{\pi}{2}, \frac{\pi}{2}}^E + \overleftrightarrow{\chi}_{\frac{\pi}{2}, \frac{\pi}{2}}^E + \overleftrightarrow{\chi}_{\frac{2\pi}{3}, \frac{\pi}{2}}^E + \overleftrightarrow{\chi}_{\frac{2\pi}{3}, \frac{\pi}{2}}^E + \overleftrightarrow{\chi}_{\frac{2\pi}{3}, \frac{\pi}{2}}^E \right). \tag{52}
$$

In the first and third lines, the factors $1/2$ are due to half occupation of the levels at $|\pm \frac{2\pi}{3}, \uparrow\rangle$. The components of the tensor

$$
\overleftrightarrow{\chi}_{k,k'}^{\mathcal{E}} = \sum_{i,j=x,y,z} \chi_{k,k'}^{\mathcal{E},i,j} \hat{e}_i \hat{e}_j \tag{53}
$$

are respectively

$$
\chi_{k,k'}^{\mathcal{E},xx} = \chi_{k,k'}^{\mathcal{E},yy} = -\eta'_{k,k'},\tag{54a}
$$

$$
\chi_{k,k'}^{\mathcal{E},zz} = -4\eta'_{k,k'},\tag{54b}
$$

$$
\chi_{k,k'}^{\text{E},xy} = -\chi_{k,k'}^{\text{E},xy} = i\eta_{k,k'}'(\delta_{k',k} - \delta_{k',k+\delta} - \delta_{k',k+2\delta} + \delta_{k',k-\delta}),\tag{54c}
$$

$$
\chi_{k,k'}^{\mathcal{E},xz} = -\chi_{k,k'}^{\mathcal{E},zx} = i2\eta_{k,k'}'(\delta_{k',k} - \delta_{k',k+\delta}),\tag{54d}
$$

$$
\chi_{k,k'}^{\mathcal{E},yz} = \chi_{k,k'}^{\mathcal{E},zy} = -2\eta_{k,k'}'(\delta_{k',k+\delta} + \delta_{k',k}).\tag{54e}
$$

IV. PERMEABILITY

Following the same procedure, we can calculate the nine components of the relative permeability, i.e.,

$$
\overleftrightarrow{\mu_r} = \sum_{i,j=x,y,z} \mu_r^{i,j} \hat{e}_i \hat{e}_j. \tag{55}
$$

According to Eqs. [\(40,](#page-8-1)[45\)](#page-10-0), the three diagonal components of the relative permeability are respectively

$$
\mu_r^{xx} = 1 - \sum_k \left(\alpha_{k,k}^2 \eta_{k,k}' + \alpha_{k,k+1}^2 \eta_{k,k+1} + \alpha_{k,k+2\delta}^2 \eta_{k,k+2\delta}' + \alpha_{k,k-1}^2 \eta_{k,k-1}' \right),
$$
\n(56a)

$$
\mu_r^{yy} = 1 - \sum_k \left(\alpha_{k,k}^2 \eta'_{k,k} + \alpha_{k,k+1}^2 \eta'_{k,k+1} + \alpha_{k,k+2}^2 \eta'_{k,k+2} + \alpha_{k,k-1}^2 \eta'_{k,k-1} \right),\tag{56b}
$$

$$
\mu_r^{zz} = 1 - \sum_k \left(4\beta_{k,k}^2 \eta'_{k,k} + 4\beta_{k,k+\delta}^2 \eta'_{k,k+\delta} \right),\tag{56c}
$$

where

$$
\alpha_{k,k} = \frac{R}{\hbar c} \left\{ V + \varepsilon \left[\cos(k - \delta) - \cos \left(k + \frac{\delta}{2} \right) \right] \right\} = \frac{R}{\hbar c} \left[V + 2\varepsilon \sin \left(k - \frac{\delta}{2} \right) \sin \frac{3\delta}{4} \right],\tag{57a}
$$

$$
\alpha_{k,k+\delta} = \frac{R}{\hbar c} \left\{ V + \varepsilon \left[\cos(k+\delta) - \cos\left(k - \frac{\delta}{2}\right) \right] \right\} = \frac{R}{\hbar c} \left[V - 2\varepsilon \sin\left(k - \frac{\delta}{2}\right) \sin\frac{3\delta}{4} \right],\tag{57b}
$$

$$
\alpha_{k,k+2\delta} = \frac{R}{\hbar c} \left\{ V + \varepsilon \left[\cos(k+\delta) - \cos\left(k+\frac{\delta}{2}\right) \right] \right\} = \frac{R}{\hbar c} \left[V - 2\varepsilon \sin\left(k+\frac{3\delta}{4}\right) \sin\frac{\delta}{4} \right],\tag{57c}
$$

$$
\alpha_{k,k-\delta} = \frac{R}{\hbar c} \left\{ V + \varepsilon \left[\cos(k-\delta) - \cos\left(k - \frac{\delta}{2}\right) \right] \right\} = \frac{R}{\hbar c} \left[V + 2\varepsilon \sin\left(k - \frac{3\delta}{4}\right) \sin\frac{\delta}{4} \right],\tag{57d}
$$

$$
\beta_{k,k} = \frac{R\varepsilon}{\hbar c} \cos\frac{\delta}{4} \left[\cos\left(k + \frac{3\delta}{4}\right) - \cos\left(k - \frac{5\delta}{4}\right) \right] = -\frac{2R\varepsilon}{\hbar c} \sin\left(k - \frac{\delta}{4}\right) \sin\delta\cos\frac{\delta}{4},\tag{57e}
$$

$$
\beta_{k,k+\delta} = \frac{R\varepsilon}{2\hbar c} \left[\cos(k-\delta) - \cos(k+\delta) - \cos\left(k+\frac{3\delta}{2}\right) \right] + \cos\left(k-\frac{\delta}{2}\right) \right] = \frac{2R\varepsilon}{\hbar c} \sin\left(k+\frac{\delta}{4}\right) \sin\delta\cos\frac{\delta}{4}.\tag{57f}
$$

The six off-diagonal components are respectively

$$
\mu_r^{xy} = -\mu_r^{yx} = \sum_k i \left(\alpha_{k,k}^2 \eta'_{k,k} - \alpha_{k,k+1}^2 \eta'_{k,k+1} - \alpha_{k,k+2\delta}^2 \eta'_{k,k+2\delta} + \alpha_{k,k-\delta}^2 \eta'_{k,k-\delta} \right),\tag{58a}
$$

$$
\mu_r^{xz} = -\mu_r^{zx} = \sum_k 2i \left(\alpha_{k,k} \beta_{k,k} \eta'_{k,k} - \alpha_{k,k+1} \beta_{k,k+1} \eta'_{k,k+1} \right),\tag{58b}
$$

$$
\mu_r^{yz} = \mu_r^{zy} = -\sum_k 2 \left(\alpha_{k,k} \beta_{k,k} \eta'_{k,k} + \alpha_{k,k+1} \beta_{k,k+1} \eta'_{k,k+1} \right). \tag{58c}
$$

$$
\overleftrightarrow{\mu_r} = 1 + \sum_{k \in \text{HOMO}} \sum_{k' \in \text{LUMO}} \overleftrightarrow{\chi}_{k,k'}^{\text{B}}, \tag{59}
$$

where

$$
\sum_{k \in \text{HOMO}} \sum_{k' \in \text{LUMO}} \overleftrightarrow{\chi}_{k,k'}^{B} = \frac{1}{2} \left(\overleftrightarrow{\chi}_{-\frac{2\pi}{3},-\frac{5\pi}{6}}^{B} + \overleftrightarrow{\chi}_{-\frac{2\pi}{3},-\frac{2\pi}{3}}^{B} + \overleftrightarrow{\chi}_{-\frac{2\pi}{3},-\frac{\pi}{2}}^{B} + \overleftrightarrow{\chi}_{-\frac{2\pi}{3},-\frac{\pi}{3}}^{B} \right) + \overleftrightarrow{\chi}_{-\frac{\pi}{2},-\frac{2\pi}{3}}^{B} + \overleftrightarrow{\chi}_{-\frac{\pi}{2},-\frac{\pi}{2}}^{B} + \overleftrightarrow{\chi}_{-\frac{\pi}{2},-\frac{\pi}{3}}^{B} + \overleftrightarrow{\chi}_{-\frac{\pi}{2},-\frac{\pi}{3}}^{B} + \overleftrightarrow{\chi}_{-\frac{\pi}{2},-\frac{\pi}{3}}^{B} + \overleftrightarrow{\chi}_{-\frac{\pi}{2},-\frac{\pi}{3}}^{B} + \overleftrightarrow{\chi}_{-\frac{\pi}{2},-\frac{\pi}{2}}^{B} + \overleftrightarrow{\chi}_{\frac{\pi}{2},\frac{\pi}{2}}^{B} + \overleftrightarrow{\chi}_{\frac{2\pi}{3},\frac{\pi}{2}}^{B} + \overleftrightarrow{\chi}_{\frac{2\pi}{3},\frac{\pi}{2}}^{B} + \overleftrightarrow{\chi}_{\frac{2\pi}{3},\frac{\pi}{2}}^{B} \right).
$$
\n(60)

In the first and third lines, the factors $1/2$ are due to half occupation of the levels at $|\pm \frac{2\pi}{3}, \uparrow\rangle$. The components of the tensor

$$
\overleftrightarrow{\chi}_{k,k'}^{\text{B}} = \sum_{i,j=x,y,z} \chi_{k,k'}^{\text{B},i,j} \hat{e}_i \hat{e}_j,\tag{61}
$$

are respectively

$$
\chi_{k,k'}^{\mathbf{B},xx} = \chi_{k,k'}^{\mathbf{B},yy} = -\alpha_{k,k'}^2 \eta'_{k,k'},\tag{62a}
$$

$$
\chi_{k,k'}^{\mathcal{B},zz} = -4\beta_{k,k'}^2 \eta'_{k,k'} (\delta_{k',k+\delta} + \delta_{k',k}),\tag{62b}
$$

$$
\chi_{k,k'}^{\mathbf{B},xy} = -\chi_{k,k'}^{\mathbf{B},xy} = i\alpha_{k,k'}^2 \eta_{k,k'}' (\delta_{k',k} - \delta_{k',k+\delta} - \delta_{k',k+2\delta} + \delta_{k',k-\delta}),\tag{62c}
$$

$$
\chi_{k,k'}^{\mathbf{B},xz} = -\chi_{k,k'}^{\mathbf{B},zx} = 2i\alpha_{k,k'}\beta_{k,k'}\eta_{k,k'}'(\delta_{k',k} - \delta_{k',k+\delta}),
$$
\n(62d)\n
$$
\chi_{k,k'}^{\mathbf{B},yz} = \chi_{k,z}^{\mathbf{B},zz} - 2\alpha_{k,z}\beta_{k,z} \eta_{k,k'}'(\delta_{k,z,z} + \delta_{k,z})
$$
\n(62e)

$$
\chi_{k,k'}^{\mathbf{b},yz} = \chi_{k,k'}^{\mathbf{b},zy} = -2\alpha_{k,k'}\beta_{k,k'}\eta_{k,k'}'(\delta_{k',k+\delta} + \delta_{k',k}).\tag{62e}
$$

For the transitions $|k, \downarrow\rangle \leftrightarrows |k', \uparrow\rangle$ $(k' = k, k + \delta)$, the three eigenvalues are, respectively,

$$
\mu_r^1 = 1 - 2 \sum_{k \in \text{HOMO}} \sum_{k' \in \text{LUMO}} \alpha_{k,k'}^2 \eta'_{k,k'}, \tag{63a}
$$

$$
\mu_r^2 = 1 - 2 \sum_{k \in \text{HOMO}} \sum_{k' \in \text{LUMO}} \left(\beta_{k,k'}^2 + \beta_{k,k'} \sqrt{2\alpha_{k,k'}^2 + \beta_{k,k'}^2} \right) \eta_{k,k'}', \tag{63b}
$$

$$
\mu_r^3 = 1 - 2 \sum_{k \in \text{HOMO}} \sum_{k' \in \text{LUMO}} \left(\beta_{k,k'}^2 - \beta_{k,k'} \sqrt{2\alpha_{k,k'}^2 + \beta_{k,k'}^2} \right) \eta_{k,k'}'. \tag{63c}
$$

For the transitions $|k, \downarrow\rangle \leftrightarrows |k', \uparrow\rangle$ $(k' = k - \delta, k + 2\delta)$, the three eigenvalues are respectively

$$
\mu_r^1 = 1 - 2 \sum_{k \in \text{HOMO}} \sum_{k' \in \text{LUMO}} \alpha_{k,k'}^2 \eta_{k,k'}^2, \ \mu_r^2 = \mu_r^3 = 1. \tag{64}
$$

In both cases, the lowest eigenvalues is μ_r^1 , because $(\beta_{k,k'}/\alpha_{k,k'})^2 \sim \delta^2 \ll 1$. Therefore, the bandwidth of the negative refraction is determined by

$$
\mu_r^1 = 1 - 2 \sum_{k \in \text{HOMO}} \sum_{k' \in \text{LUMO}} \alpha_{k,k'}^2 \eta'_{k,k'} = 0.
$$
 (65)

Because the second terms of $\alpha_{k,k'}$ are proportional to δ , the maximum of $\alpha_{k,k}$ and $\alpha_{k,k+\delta}$ are generally larger than those of $\alpha_{k,k-\delta}$ and $\alpha_{k,k+2\delta}$. Assuming $\varepsilon = V$, we have

$$
\max\left(\alpha_{k,k}\right) \simeq \alpha_{\frac{\pi}{2} + \frac{\delta}{2}, \frac{\pi}{2} + \frac{\delta}{2}} = \frac{RV}{\hbar c} \left(1 + 2\sin\frac{3\delta}{4}\right) \simeq \frac{RV}{\hbar c} \left(1 + \frac{6\delta}{4}\right) \simeq \frac{7RV}{4\hbar c},\tag{66}
$$

$$
\max\left(\alpha_{k,k+\delta}\right) \simeq \alpha_{-\frac{\pi}{2}+\frac{\delta}{2}, -\frac{\pi}{2}+\frac{3\delta}{2}} = \frac{RV}{\hbar c} \left(1 + 2\sin\frac{3\delta}{4}\right) \simeq \frac{RV}{\hbar c} \left(1 + \frac{6\delta}{4}\right) \simeq \frac{7RV}{4\hbar c}.\tag{67}
$$

In Ref. $[6]$, the bandwidth of the negative refraction is determined by

$$
\alpha_{0,0} = \frac{RV}{\hbar c} \left(1 - 2 \sin \frac{\delta}{2} \sin \frac{3\delta}{4} \right) \simeq \frac{RV}{\hbar c} \left(1 - 2 \times \frac{\delta}{2} \times \frac{3\delta}{4} \right) \simeq \frac{13RV}{16\hbar c}.
$$
\n(68)

Since

$$
\left(\frac{\alpha_{\frac{\pi}{2}+\frac{\delta}{2},\frac{\pi}{2}+\frac{\delta}{2}}}{\alpha_{0,0}}\right)^2 = \left(\frac{\alpha_{-\frac{\pi}{2}+\frac{\delta}{2},-\frac{\pi}{2}+\frac{3\delta}{2}}}{\alpha_{0,0}}\right)^2 \simeq 5,\tag{69}
$$

and there are 4 simultaneous transitions with the same frequency, the bandwidth of the negative refraction is about 20 times that of Ref. [\[6\]](#page-6-1).

V. BANDWIDTHS OF NEGATIVE REFRACTION FOR DIFFERENT TRANSITIONS

As shown in Fig. 2 of the main text, there are 20 possible transitions on account of the initial condition, where there is an electron occupying the initial state, and the final condition, where there is no electron occupying the final state. By scanning over all transition frequencies, we obtain the bandwidths of the negative refraction for all transitions, as listed in Table [I.](#page-14-1) Due to simultaneous multi-electron transitions, the bandwidths of the negative refraction are generally larger than the corresponding single-electron transition and that in Ref. [\[6\]](#page-6-1). Interestingly, the bandwidths of five transitions are larger than the previous observation by one order of magnitude, as highlighted in red in Table [I.](#page-14-1)

| Δ_{if} (eV) | bandwidth $(\mu$ eV) | participating transitions | |
|--------------------|----------------------|---|--|
| 1.736503 | 9 | $\ket{\frac{2\pi}{3}, \downarrow} \rightleftharpoons \ket{\frac{\pi}{2}, \uparrow}, \ket{-\frac{2\pi}{3}, \downarrow} \rightleftharpoons \ket{-\frac{\pi}{3}, \uparrow}$ | |
| 5.336503 | 80 | $ \frac{\pi}{2},\downarrow\rangle \rightleftarrows \frac{\pi}{2},\uparrow\rangle, - \frac{\pi}{2},\downarrow\rangle \rightleftarrows - \frac{\pi}{3},\uparrow\rangle$ | |
| 5.463497 | 36 | $\ket{\frac{2\pi}{3},\downarrow}\rightleftharpoons\ket{\frac{2\pi}{3},\uparrow},\ket{-\frac{2\pi}{3},\downarrow}\rightleftharpoons\ket{-\frac{\pi}{2},\uparrow}$ | |
| 8.691169 | 15 | $\ket{\frac{2\pi}{3}, \downarrow} \rightleftharpoons \ket{\frac{5\pi}{6}, \uparrow}, \ket{-\frac{2\pi}{3}, \downarrow} \rightleftharpoons \ket{-\frac{2\pi}{3}, \uparrow}$ | |
| 8.936503 | 39 | $ \frac{\pi}{3}, \downarrow\rangle \rightleftarrows \frac{\pi}{2}, \uparrow\rangle, - \frac{\pi}{3}, \downarrow\rangle \rightleftarrows - \frac{\pi}{3}, \uparrow\rangle$ | |
| 9.063497 | 45 | $ \frac{\pi}{2}, \downarrow\rangle \rightleftarrows \frac{2\pi}{3}, \uparrow\rangle, -\frac{\pi}{2}, \downarrow\rangle \rightleftarrows -\frac{\pi}{2}, \uparrow\rangle$ | |
| 10.554666 | 3.7 | $\ket{\frac{2\pi}{3}, \downarrow} \rightleftharpoons \ket{\pi, \uparrow}, \ket{-\frac{2\pi}{3}, \downarrow} \rightleftharpoons \ket{-\frac{5\pi}{6}, \uparrow}$ | |
| 11.571886 | 7 | $ \frac{\pi}{6}, \downarrow\rangle \rightleftarrows \frac{\pi}{2}, \uparrow\rangle, -\frac{\pi}{6}, \downarrow\rangle \rightleftarrows -\frac{\pi}{3}, \uparrow\rangle$ | |
| 12.291169 | 6 | $ \frac{\pi}{2}, \downarrow\rangle \rightleftarrows \frac{5\pi}{6}, \uparrow\rangle, -\frac{\pi}{2}, \downarrow\rangle \rightleftarrows - \frac{2\pi}{3}, \uparrow\rangle$ | |
| 12.663497 | 6 | $ \frac{\pi}{3}, \downarrow\rangle \rightleftarrows \frac{2\pi}{3}, \uparrow\rangle, - \frac{\pi}{3}, \downarrow\rangle \rightleftarrows - \frac{\pi}{2}, \uparrow\rangle$ | |

Table I: The bandwidths of the negative refraction around different transition frequencies Δ_{if} . In the third column, the participating transitions are explicitly given.

The comparison of the bandwidths of the negative refraction in the literatures and present paper is explicitly given in Table [II.](#page-14-2) The bandwidth has been broadened by at least two orders of magnitude as compared to Refs. [\[7–](#page-5-19)[10\]](#page-6-4).

Table II: Comparison of the bandwidths of the negative refraction in the literatures and present paper.

| Reference | $\rm Present$ | Ref. [6] | Refs. [7, 8] | Ref. [9] | Ref. [10] |
|-------------------------------|-----------------------|-----------------------|----------------------|-------------------------|-------------------|
| \vert bandwidth $(Hz)\vert$ | 1.93×10^{10} | 0.966×10^{9} | $\sim 2 \times 10^5$ | $\sim 5.03 \times 10^4$ | 1.6×10^8 |
