Abstract—Recently, an opinion dynamics model has been proposed to describe a network of individuals discussing a set of logically interdependent topics. For each individual, the set of topics and the logical interdependencies between the topics (captured by a logic matrix) form a belief system. We investigate the role the logic matrix and its structure plays in determining the final opinions, including existence of the limiting opinions, of a strongly connected network of individuals. We provide a set of results that, given a set of individuals’ belief systems, allow a systematic determination of which topics will reach a consensus, and which topics will disagreement in arise. For irreducible logic matrices, each topic reaches a consensus. For reducible logic matrices, which indicates a cascade interdependence relationship, conditions are given on whether a topic will reach a consensus or not. It turns out that heterogeneity among the individuals’ logic matrices, including especially differences in the signs of the off-diagonal entries, can be a key determining factor. This paper thus attributes, for the first time, a strong diversity of limiting opinions to heterogeneity of belief systems in influence networks, in addition to the more typical explanation that strong diversity arises from individual stubbornness.

Index Terms—opinion dynamics, social networks, multi-agent systems, influence networks, agent-based models, networked systems

I. INTRODUCTION

THERE has been great interest over the past few years in agent-based network models of *opinion dynamics* that describe how individuals’ opinions on a topic evolve over time as they interact [1], [2]. The seminal discrete-time French–Harary–DeGroot model [3]–[5] (or DeGroot model for short) assumes that each individual’s opinion at the next time step is a convex combination of his/her current opinion and the current opinions of his/her neighbours. This weighted averaging aims to capture *social influence*, where individuals exert a conforming influence on each other so that over time, opinions become more similar (and thus giving rise to

the term “influence network”). For networks satisfying mild connectivity conditions, the opinions reach a consensus, i.e. the opinion values are equal for all individuals.

Since then, and to reflect real-world networks, much focus has been placed on developing models of increasing sophistication to capture different socio-psychological features that may be involved when individuals interact. The Hegselmann–Krause model [6]–[9] introduced the concept of bounded confidence, which is used to capture homophily, i.e. the phenomenon whereby individuals only interact with those other individuals whose opinion values are similar to their own. The Altafini model [10]–[13] introduced negative edge weights to model antagonistic or competitive interactions between individuals (perhaps arising from mistrust). An individual’s propensity to assimilate information in a biased manner, by more heavily weighting opinions close to his or her own, is studied in [14]. The Friedkin–Johnsen model generalised the DeGroot model by introducing the idea of “stubbornness”, where an individual remains (at least partially) attached to his or her initial opinion [15], [16]. Of particular note is that the DeGroot and Friedkin–Johnsen models have been empirically examined [16]–[18]. For more detailed discussions on opinion dynamics modelling, we refer the reader to [1], [2], [19].

Recently in [20], a multi-dimensional extension to the Friedkin–Johnsen was proposed to describe a network of individuals who simultaneously discuss a set of *logically interdependent* topics. That is, an individual’s position on Topic *A* may influence his/her position on Topic *B* due to his/her view of constraints or relations between the two topics. Such interdependencies are captured in the model by a “logic matrix”. This interdependence can greatly shift the final opinion values on the set of topics since now the interdependencies and the social influence from other individuals both affect opinion values. The model is used in [21] to explain that the shift in the US public’s opinions on the topic of whether the 2003 Invasion of Iraq was justified was due to shifting opinions on the logically interdependent topic of whether Iraq had weapons of mass destruction. The set of topics, the interdependent functionalities between the topics, and the mechanism by which an individual processes such interdependencies forms a “belief system” as termed by Converse in his now classical paper [22]. For networks where all individuals have the same logic matrix, a complete stability result is given using algebraic conditions in [20] and using graph-theoretic conditions in [23]. Of course, the assumption that all individuals have the same logic matrix is restrictive. Heterogeneous logic matrices were considered in [21], but at least one individual is required to

exhibit stubbornness in order to obtain a stability result.

This paper will also consider a generalisation of the multi-dimensional model proposed in [20] for the evolution of opinions in belief systems, going beyond [20], [21] by analysing the effects of the logic matrix, *including especially heterogeneity of the logic matrices among the individuals, on the limiting opinion distribution*. We first establish a general convergence result for the model with heterogeneous logic matrices on strongly connected networks. Then, we provide a set of results which enables the systematic determination of whether for a given topic, the opinions of the individuals will reach a consensus, or will reach a state of persistent disagreement.

We find that the nature of the heterogeneity of the logic structure among the individuals, viz. the logical interdependencies between topics, and the structure itself, plays a major role in determining whether opinions on a given topic reach a consensus or fail to do so. If the logical interdependencies do not have a cascade structure, then consensus is always secured. When the logical interdependencies have a cascade structure, and by considering topics at the top of a cascade structure to be axiom(s) that an individual's belief system is built upon, we establish that discussion of the axiomatic topics will lead to a consensus. In contrast, we discover that persistent disagreement can arise in the topics at the bottom of the cascade when certain types of heterogeneity exist in the logic matrices. A preliminary work [24] considers the special case of lower triangular logic matrices, but we go well beyond that in this paper by considering general logic matrix structures and providing a comprehensive account of the results.

We discover that if there is a failure to reach a consensus, then it is typically not minor; in general a *strong diversity* of opinions will eventually emerge. In more detail, a network is said to exhibit *weak diversity* [25] if opinions eventually converge into clusters where there is no difference between opinions in the same cluster (consensus is the special case of one single cluster). Strong diversity occurs when the opinions converge to a configuration of persistent disagreement, with a diverse range of values (there may be clusters of opinions with similar, but *not equal*, values within a cluster). Weak diversity is a common outcome in the Hegselmann–Krause model, with the network becoming disconnected into subgroups associated with the clusters. In strongly connected networks, weak diversity also emerges in the Altafini model (specifically polarisation of two opinion clusters) when the network is “structurally balanced”. However, sign reversal of some selected edges may destroy the structural balance of the network, causing the opinions to converge to a consensus at an opinion value of zero, indicating that the polarisation phenomenon is not robust to changes in the network structure.

There has been a growing interest to study models which are able to capture the more realistic outcome of *strong diversity* in networks which remain connected [25], [26]. The DeGroot model shows that social influence in a connected network acts to bring opinions closer together until a consensus is achieved, meaning some other socio-psychological process must be at work to generate strong diversity. The Friedkin–Johnsen model attributes strong diversity to an individual's stubborn attachment to his/her initial opinion [15]. In contrast,

[27] considers a model where an individual's susceptibility to interpersonal influence is dependent on the individual's current opinion; strong diversity is verified as a special case. The papers [25], [26] consider two features that might give rise to strong diversity, the first being “social distancing”, and the second being an individual's “desire to be unique”. Experimental studies are inconclusive with regards to the existence of ubiquitous and persistent antagonistic interpersonal interactions (there might be limited occurrences in the network over short time spans) [20], while it is unlikely that an individual has the same level of stubborn attachment to his or her initial opinion value for months or years.

In contrast to these works, we identify for the first time in the literature that strong diversity can arise because of the structure of individuals' belief systems, and show that heterogeneity among belief systems plays a crucial role. In the model, each individual is concurrently undergoing two driver processes; individual-level belief system dynamics to secure logical consistency of opinions across a set of topics, and interpersonal influence to reach a consensus. Our findings explain that when the two drivers do not interfere with each other, a consensus is reached, whereas conflict between the two drivers leads to persistent disagreement even though all individuals are trying to reach a consensus. This gives a new and illuminating perspective as to why strong diversity can *last for extended periods of time* in connected networks.

The rest of the paper is structured as follows. In Section II, we provide notations, an introduction to graph theory and the opinion dynamics model. At the same time, a formal problem statement is given. The main results are presented in Section III, with simulations given in Section IV for illustration, and conclusions in Section V.

II. BACKGROUND AND FORMAL PROBLEM STATEMENT

We begin by introducing some mathematical notations used in the paper. The $(i, j)^{th}$ entry of a matrix \mathbf{M} is denoted m_{ij} . A matrix \mathbf{A} is said to be nonnegative (respectively positive) if all a_{ij} are nonnegative (respectively positive). We denote \mathbf{A} as being nonnegative and positive by $\mathbf{A} \geq 0$ and $\mathbf{A} > 0$, respectively. A matrix $\mathbf{A} \geq 0$ is said to be row-stochastic (respectively, row-substochastic) if there holds $\sum_{j=1}^n a_{ij} = 1, \forall i$ (respectively, if there holds $\sum_{j=1}^n a_{ij} \leq 1, \forall i$ and $\exists k : \sum_{j=1}^n a_{kj} < 1$). The transpose of a matrix \mathbf{M} is denoted by \mathbf{M}^T . Let $\mathbf{1}_n$ and $\mathbf{0}_n$ denote, respectively, the $n \times 1$ column vectors of all ones and all zeros. The $n \times n$ identity matrix is given by \mathbf{I}_n . Two matrices $\mathbf{A} \in \mathbb{R}^{n \times m}$ and $\mathbf{B} \in \mathbb{R}^{n \times m}$ are said to be of the same type, denoted by $\mathbf{A} \sim \mathbf{B}$, if and only if $a_{ij} \neq 0 \Leftrightarrow b_{ij} \neq 0$. The Kronecker product is denoted by \otimes . The infinity norm and spectral radius of a square matrix \mathbf{A} is $\|\mathbf{A}\|_\infty$ and $\rho(\mathbf{A})$, respectively. A square matrix $\mathbf{A} \geq 0$ is *primitive* if $\exists k \in \mathbb{N} : \mathbf{A}^k > 0$ [28, Definition 1.12].

A. Graph Theory

The interaction between n individuals in a social network, and the logical interdependence between topics can be modelled using a weighted directed graph. To that end, we introduce some notations and concepts for graphs. A directed graph

$\mathcal{G}[\mathbf{A}] = (\mathcal{V}, \mathcal{E}, \mathbf{A})$ is a triple where node v_i is in the finite, nonempty set of nodes $\mathcal{V} = \{v_1, \dots, v_n\}$. The set of ordered edges is $\mathcal{E} \subseteq \mathcal{V} \times \mathcal{V}$. We denote an ordered edge as $e_{ij} = (v_i, v_j) \in \mathcal{E}$, and because the graph is directed, in general the existence of e_{ij} does not imply existence of e_{ji} . An edge e_{ij} is said to be outgoing with respect to v_i and incoming with respect to v_j . Self-loops are allowed, i.e. e_{ii} may be in \mathcal{E} . The matrix $\mathbf{A} \in \mathbb{R}^{n \times n}$ associated with $\mathcal{G}[\mathbf{A}]$ captures the edge weights. More specifically, $a_{ij} \neq 0$ if and only if $e_{ij} \in \mathcal{E}$. If \mathbf{A} is nonnegative, then all edges e_{ij} have positive weights, while a generic \mathbf{A} may be associated with a signed graph $\mathcal{G}[\mathbf{A}]$, having signed edge weights.

A directed path is a sequence of edges of the form $(v_{p_1}, v_{p_2}), (v_{p_2}, v_{p_3}), \dots$ where $v_{p_i} \in \mathcal{V}$ are unique, and $e_{p_i p_{i+1}} \in \mathcal{E}$. Node i is reachable from node j if there exists a directed path from v_j to v_i . A graph is said to be strongly connected if every node is reachable from every other node. A square matrix \mathbf{A} is irreducible if and only if the associated graph $\mathcal{G}[\mathbf{A}]$ is strongly connected. A directed cycle is a directed path that starts and ends at the same vertex, and contains no repeated vertex except the initial (which is also the final) vertex. The length of a directed cycle is the number of edges in the directed cyclic path. A directed graph is *aperiodic* if there exists no integer $k > 1$ that divides the length of every directed cycle of the graph [28]. Note that any graph with a self-loop is aperiodic.

A signed graph \mathcal{G} is said to be *structurally balanced* (respectively *structurally unbalanced*) if the nodes $\mathcal{V} = \{v_1, \dots, v_n\}$ can be partitioned (respectively cannot be partitioned) into two disjoint sets such that each edge between two nodes in the same set has a positive weight, and each edge between nodes in different sets has a negative weight [29].

The following is a useful result employed in the paper.

Lemma 1 ([28, Proposition 1.35]). *The graph $\mathcal{G}[\mathbf{A}]$, with $\mathbf{A} \geq 0$, is strongly connected and aperiodic if and only if \mathbf{A} is primitive.*

Note that the irreducibility of \mathbf{A} (implied by the strong connectivity property of $\mathcal{G}[\mathbf{A}]$) implies that if a k exists such that $\mathbf{A}^k > 0$, then $\mathbf{A}^j > 0$ for all $j > k$.

B. The Multi-Dimensional DeGroot Model

In this paper, we investigate a recently proposed multi-dimensional extension to the DeGroot and Friedkin-Johnsen models [20], [21], which considers the *simultaneous discussion of logically interdependent topics*.

Formally, consider a population of n individuals discussing simultaneously their opinions on m topics, with individual and topic index set $\mathcal{I} = \{1, \dots, n\}$ and $\mathcal{J} = \{1, \dots, m\}$, respectively. Individual i 's opinions on the m topics at time $t = 0, 1, \dots$, are denoted by $\mathbf{x}_i(t) = [x_i^1(t), \dots, x_i^m(t)]^\top \in \mathbb{R}^m$. In this paper, we adopt a standard definition of an opinion [21]. In particular, $x_i^p(t) \in [-1, 1]$ is individual i 's attitude towards topic p , which takes the form of a statement, with $x_i^p > 0$ representing i 's support for statement p , $x_i^p < 0$ representing rejection of statement p , and $x_i^p = 0$ representing a neutral stance. The magnitude of x_i^p denotes the strength

of conviction, with $|x_i^p| = 1$ being maximal support/rejection. Mild assumptions are placed on the network and individual parameters in the sequel to ensure that $x_i^p(t) \in [-1, 1]$ for all $t \geq 0$, and thus the opinion values are always well defined.

In the multi-dimensional DeGroot model, $\mathbf{x}_i(t)$ evolves according to

$$\mathbf{x}_i(t+1) = \sum_{j=1}^n w_{ij} \mathbf{C}_i \mathbf{x}_j(t), \quad (1)$$

where the nonnegative scalar w_{ij} represents the influence weight individual i accords to the vector of opinions of individual j . Thus, the influence matrix \mathbf{W} , with $(i, j)^{th}$ entry w_{ij} , can be used to define the graph $\mathcal{G}[\mathbf{W}]$ that describes the interpersonal influences of the n individuals. We assume that $w_{ii} > 0$ for all $i \in \mathcal{I}$ and $\sum_{j=1}^n w_{ij} = 1$ for all $i \in \mathcal{I}$, which implies that \mathbf{W} is row-stochastic. The matrix \mathbf{C}_i , with $(p, q)^{th}$ entry $c_{pq,i}$, is termed the *logic matrix*. In [20], [21], the authors elucidate that \mathbf{C}_i represents the logical interdependence between the m topics as seen by individual i . We note that the \mathbf{C}_i are assumed to be heterogeneous (i.e. $\exists i, j : \mathbf{C}_i \neq \mathbf{C}_j$). Indeed, a critical aspect of this paper is to study how the structure of the \mathbf{C}_i s, especially heterogeneity, can determine whether certain topics have opinions that reach a consensus or a persistent disagreement.

We now illustrate with a simple example how \mathbf{C}_i is used by individual i to obtain a set of opinions consistent with any logical interdependencies between each topic, and in doing so, motivate that certain constraints must be imposed on \mathbf{C}_i due to the problem context (these constraints are implicitly imposed in [20], [21], but without motivation).

Suppose that there are two topics. Topic 1: The exploration of Space is important to mankind's future. Topic 2: The exploration of Space should be privatised. Using Topic 1 as an example, and according to the definition of an opinion given above Eq. (1), $x_i^1 = 1$ represents individual i 's maximal *support* of the importance of Space exploration, while $x_i^1 = -1$ represents maximal *rejection* that Space exploration is important. Now, suppose that individual i has $\mathbf{x}_i(0) = [1, -0.2]^\top$, i.e. individual i initially believes with maximal conviction that Space exploration is important and initially believes with some (but not absolute) conviction that Space exploration should not be privatised¹. Let

$$\mathbf{C}_i = \begin{bmatrix} 1 & 0 \\ 0.5 & 0.5 \end{bmatrix}. \quad (2)$$

This tells us that individual i 's opinion on the importance of Space exploration is unaffected by his or her own opinion on whether Space exploration should be privatised. On the other hand, individual i 's opinion on Topic 2 depends positively on his or her own opinion on Topic 1, perhaps because individual i believes privatised companies are more effective. In the absence of opinions from other individuals, individual i 's opinions evolves as

$$\mathbf{x}_i(t+1) = \mathbf{C}_i \mathbf{x}_i(t), \quad (3)$$

¹Note that we do not require \mathbf{C}_i to be row-stochastic and nonnegative, though the \mathbf{C}_i of this example is.

which yields $\lim_{t \rightarrow \infty} \mathbf{x}_i(t) = [1, 1]^\top$, i.e. individual i eventually believes that Space exploration should be privatised. Thus, $\mathbf{x}_i(t)$ moves from $\mathbf{x}_i(0) = [1, -0.2]^\top$, where individual i 's opinions are inconsistent with the logical interdependence as captured by \mathbf{C}_i , to the final state $\mathbf{x}_i(\infty) = [1, 1]^\top$, which is consistent with the logical interdependence. Eq. (3), with opinion vector $\mathbf{x}_i(t)$ and the logical interdependencies captured by \mathbf{C}_i , models individual i 's belief system. (We explained qualitatively what a belief system was in the Introduction, and have now given the mathematical formulation.)

In general, one might expect, as do we in this paper, that an individual's belief system without interpersonal influence from neighbours will eventually become consistent. For a topic p which is independent of all other topics, one also expects that $x_i^p(t+1) = x_i^p(t)$ for all t . To ensure the belief system is consistent, we impose the following assumption.

Assumption 1. *The matrix \mathbf{C}_i , for all $i \in \mathcal{I}$, is such that each eigenvalue of \mathbf{C}_i is either 1 or has modulus less than 1. If an eigenvalue of \mathbf{C}_i is 1, then it is semi-simple². For all $i \in \mathcal{I}$ and $p \in \mathcal{J}$, there holds $\sum_{q=1}^m |c_{pq,i}| = 1$, and the diagonal entries satisfy $c_{pp,i} > 0$.*

The assumptions on the eigenvalues of \mathbf{C}_i ensure that Eq. (3) converges to a limit, and are *necessary and sufficient* for individual i 's belief system to eventually become consistent. The other assumptions lead to desirable properties for the system Eq. (1). Specifically, the reasonable assumption that $c_{pp,i} > 0$ means topic p is positively correlated with itself. The constraint $\sum_{q=1}^m |c_{pq,i}| = 1$ for all $i \in \mathcal{I}$ and $p \in \mathcal{J}$ ensures that $x_i^p(0) \in [-1, 1]$ implies $x_i^p(t) \in [-1, 1]$ for all $t \geq 0$ (see [20]), and also implies that if topic p is independent of all other topics, i.e. $c_{pq,i} = 0$ for all $q \neq p$, then $c_{pp,i} = 1$. The well-studied special case where topics are totally independent is $\mathbf{C}_i = \mathbf{I}_m$. We are now in a position to formally define this paper's objective.

C. Objective Statement

This paper is focused on establishing the effects of the set of logic matrices $\mathbf{C}_i, i \in \mathcal{I}$ on the evolution of opinions, and in particular the limiting opinion configuration. First, we record two assumptions on the logic matrix and the network topology, which will hold throughout this paper.

Assumption 2. *For every $i, j \in \mathcal{I}$, there holds $\mathbf{C}_i \sim \mathbf{C}_j$.*

Assumption 3. *The influence network $\mathcal{G}[\mathbf{W}]$ is strongly connected, \mathbf{W} is row-stochastic, and $w_{ii} > 0, \forall i \in \mathcal{I}$.*

Assumption 2 implies that, for every $i, j \in \mathcal{I}$, the graphs $\mathcal{G}[\mathbf{C}_i]$ and $\mathcal{G}[\mathbf{C}_j]$ have the same structure (but possible with different edge weights, including weights of opposing signs). This means that all individuals have the same view on which topics have dependent relationships with which other topics, but the assigned weights c_{ij} (and signs) may be different. This assumption ensures that the scope of this paper is reasonable, because otherwise the assumption that $\mathbf{C}_i \sim \mathbf{C}_j$ does not hold would introduce too many different scenarios to analyse.

²By semi-simple, we mean that the geometric and algebraic multiplicities are the same. Equivalently, all Jordan blocks of the eigenvalue 1 are 1 by 1.

Objective 1. *Let a set of logic matrices $\mathbf{C}_i, i \in \mathcal{I}$ and an influence network $\mathcal{G}[\mathbf{W}]$ be given, satisfying Assumptions 1, 2 and 3. Suppose that each individual i 's opinion vector $\mathbf{x}_i(t) \in [-1, 1]^m$ evolves according to Eq. (1). Then, for each $k \in \mathcal{J}$ and generic initial conditions $\mathbf{x}(0) \in [-1, 1]^{nm}$, this paper will investigate a method to systematically determine when there exists, and when there does not exist, an $\alpha_k \in [-1, 1]$ such that*

$$\lim_{t \rightarrow \infty} x_i^k(t) = \alpha_k, \forall i \in \mathcal{I}. \quad (4)$$

We will show that \mathbf{C}_i of a certain structure always guarantees consensus, and conversely, that \mathbf{C}_i of a certain other structure will lead to disagreement in certain identifiable topics.

Next, we provide further discussion to motivate Objective 1, including our interest in heterogeneous \mathbf{C}_i . The dynamics of the form Eq. (1) is a variation on the model studied in [20], [21], and we explain our interest in this particular variation by explaining in detail the differences between Eq. (1) and work in [20], [21].

For convenience, denote the vector of opinions for the entire influence network as $\mathbf{x} = [\mathbf{x}_1(t)^\top, \dots, \mathbf{x}_n(t)^\top]^\top \in \mathbb{R}^{nm}$. Supposing that the logic matrices were indeed homogeneous, i.e. $\mathbf{C}_i = \mathbf{C}_j = \mathbf{C}$ for all $i, j \in \mathcal{I}$, we can verify that much of the analysis becomes rather easy. For then one could write the influence network dynamics as

$$\mathbf{x}(t+1) = (\mathbf{W} \otimes \mathbf{C})\mathbf{x}(t), \quad (5)$$

and limiting behaviour is characterised by the following result.

Theorem 1 ([20, Theorem 3]). *The system Eq. (5) converges if and only if $\lim_{k \rightarrow \infty} \mathbf{C}^k \triangleq \mathbf{C}^\infty$ exist, and either $\mathbf{C}^\infty = \mathbf{0}_{m \times m}$ or $\lim_{k \rightarrow \infty} \mathbf{W}^k = \mathbf{W}^\infty$ exists³. Moreover, the system converges to $\lim_{t \rightarrow \infty} \mathbf{x}(t) = (\mathbf{W}^\infty \otimes \mathbf{C}^\infty)\mathbf{x}(0)$ if $\lim_{k \rightarrow \infty} \mathbf{W}^k = \mathbf{W}^\infty$ exists, otherwise $\lim_{t \rightarrow \infty} \mathbf{x}(t) = \mathbf{0}_{mn}$.*

For completeness and to aid discussion, we also record the Friedkin–Johnsen variant to Eq. (1), which is given as

$$\mathbf{x}_i(t+1) = \lambda_i \sum_{j=1}^n w_{ij} \mathbf{C}_i \mathbf{x}_j(t) + (1 - \lambda_i) \mathbf{x}_i(0). \quad (6)$$

Here, the parameter $\lambda_i \in [0, 1]$ represents individual i 's susceptibility to interpersonal influence, while $1 - \lambda_i$ represents the level of stubborn attachment by individual i to his/her initial opinion $\mathbf{x}_i(0)$. This paper studies the special case where there are no stubborn individuals, i.e. $\lambda_i = 1$ for all $i \in \mathcal{I}$, and thus Eq. (6) is equivalent to Eq. (1). The paper [20] mainly focuses on the considerable challenge of obtaining complete convergence results for the model in Eq. (6) *but with a homogeneous \mathbf{C}* , and aside from some short remarks, does not investigate the effect of \mathbf{C} on the final opinion distribution (assuming the opinions do in fact converge to a steady state). The paper [21] secures a convergence result for heterogeneous \mathbf{C}_i but makes an assumption that there is at least one somewhat stubborn individual. Unlike [20] and [21], the key focus of this paper is to investigate *the effect of the*

³It is clear that if we have homogeneous \mathbf{C} , then Assumption 1 is consistent with the requirement on \mathbf{C} in Theorem 1.

structure of C_i , including heterogeneity, on the final opinion distribution.

We explain this further. If $\lambda_i < 1$ and $C_i = I_m$ for all $i \in \mathcal{I}$, then existing results establish that under Assumption 3, a strong diversity of opinions emerges [20], with obviously no effects arising from the C_i matrix. On the other hand, consider the case of homogeneous logic matrices and no stubbornness. For any W satisfying Assumption 3, it is known that $\lim_{k \rightarrow \infty} W^k = \mathbf{1}_n \gamma^\top$ where γ^\top is a left eigenvector of W associated with the simple eigenvalue at 1, having entries $\gamma_j > 0$, and normalised to satisfy $\gamma^\top \mathbf{1}_n = 1$ [28]. Combining with Theorem 1, we can conclude that under Assumption 3 and if $C_i = C_j = C$ and $\lambda_i = 1$ for all $i, j \in \mathcal{I}$, the opinions of all individuals on any given topic reach a consensus. That is, for all $i \in \mathcal{I}$, there holds $\lim_{t \rightarrow \infty} \mathbf{x}_i(t) = \sum_{j=1}^n \gamma_j C^t \mathbf{x}_j(0)$.

In contrast, this paper assumes heterogeneous C_i and no stubbornness among individuals. If we can show that opinions on a given topic fail to reach a consensus in the general case of $C_i \neq I_m$, and instead strong diversity emerges, then this failure *must be attributed* to the structure, and the heterogeneity, of the C_i among individuals. This would constitute a novel insight into the emergence of strong diversity in strongly connected networks, linking it for the first time to differences in individuals' belief systems as opposed to stubbornness [15], a desire to be unique [25], [26], or social distancing [25].

To conclude this subsection, we now provide the definition of "competing logical interdependencies" which will be important in some scenarios for characterising the final opinions.

Definition 1 (Competing Logical Interdependence). *An influence network is said to contain individuals with competing logical interdependencies on topic $p \in \mathcal{J}$ if there exist individuals i, j such that for some $q \in \mathcal{J} \setminus \{p\}$, C_i and C_j have nonzero entries $c_{pq,i}$ and $c_{pq,j}$ that are of opposite signs.*

In other words, individuals with competing logical interdependencies are those who, *when having the same opinion on topic q* , move in opposite directions on the opinion spectrum for topic p . Such occurrences can be prevalent in society. Using the example in Section II-B, one might have an individual j with

$$C_j = \begin{bmatrix} 1 & 0 \\ -0.5 & 0.5 \end{bmatrix}. \quad (7)$$

because j considers that private companies are profit-driven, and therefore cannot be ethically trusted with the exploration of Space. Then, from Eq. (3), one has that $\mathbf{x}_j(\infty) = [1, -1]^\top$, i.e. individual j eventually firmly believes Space exploration should not be privatised. In particular, $x_j^1(\infty) = -x_j^2(\infty)$.

In light of Assumption 2, if two individuals have competing interdependencies on topic p , then *for every individual $i \in \mathcal{I}$* , there is necessarily some individual $k \in \mathcal{I} \setminus \{i\}$ with whom individual i has competing logical interdependence on topic p : the nonzero entries $c_{pq,i}$ and $c_{pq,k}$ are of opposite signs for some $q \in \mathcal{J}$.

Remark 1. *Recall that C_i is individual i 's set of constraints/functional dependencies between topics in i 's belief system. Thus, heterogeneity of C_i may arise for many different reasons, such as education, background, or expertise in the*

topic. For example, if the set of topics is related to sports, a professional athlete may have very different weights in C_i compared to someone that does not pursue an active lifestyle. Competing interdependencies may also arise for contentious issues, such as gun control discussions in the USA. Interestingly, [30] showed that when presented with the same published statement on an issue, different people could take opposite positions on the issue.

In the next section, we provide the set of main theoretical results of this paper to address Objective 1.

III. MAIN RESULTS

The main results are presented in two parts. First, we establish a general convergence result for the networked system. Then, we analyse the limiting opinion distribution and the role of the set of logic matrices in determining whether opinions for a given topic reach consensus or fail to do so. In order to place the focus on the theoretical results and interpretations as social phenomena, all proofs are presented to the Appendix.

A. Convergence

The network dynamics of Eq. (1) are given by

$$\mathbf{x}(t+1) = \begin{bmatrix} w_{11}C_1 & \cdots & w_{1n}C_1 \\ \vdots & \ddots & \vdots \\ w_{n1}C_n & \cdots & w_{nn}C_n \end{bmatrix} \mathbf{x}(t), \quad (8)$$

and we define the system matrix above as B . To begin, we rewrite the network dynamics Eq. (8) into a different form to aid analysis by introducing a coordinate transform (actually a reordering). In particular, define $\mathbf{y}_k(t) = [y_k^1(t), \dots, y_k^n(t)]^\top = [x_1^k(t), \dots, x_n^k(t)]^\top$, for $k \in \mathcal{J}$ as the vector of all n individuals' opinions on the k^{th} topic. Then, $\mathbf{y}(t) = [\mathbf{y}_1(t)^\top, \dots, \mathbf{y}_m(t)^\top]^\top$ captures all of the n individuals' opinions on the m topics. One obtains that

$$\mathbf{y}_k(t+1) = \sum_{j=1}^m \text{diag}(c_{kj}) W \mathbf{y}_j(t), \quad (9)$$

where $\text{diag}(c_{kj}) \in \mathbb{R}^n$ is a diagonal matrix with the i^{th} diagonal element of $\text{diag}(c_{kj})$ being $c_{kj,i}$, the $(k, j)^{\text{th}}$ entry of C_i . It follows that

$$\mathbf{y}(t+1) = \begin{bmatrix} \text{diag}(c_{11})W & \cdots & \text{diag}(c_{1m})W \\ \vdots & \ddots & \vdots \\ \text{diag}(c_{m1})W & \cdots & \text{diag}(c_{mm})W \end{bmatrix} \mathbf{y}(t). \quad (10)$$

We denote the matrix in Eq. (10) as A , with block matrix elements $A_{pq} = \text{diag}(c_{pq})W$. We now show how the system Eq. (10) can be considered as a consensus process on a multiplex (or multi-layered) signed graph.

Consider the matrix A in Eq. (10), with the associated graph $\mathcal{G}[A]$, and the matrix B in Eq. (8), with associated graph $\mathcal{G}[B]$. Clearly, the two graphs are the same up to a reordering of the nodes. In $\mathcal{G}[A]$, with node set $\mathcal{V}[A] = \{v_1, \dots, v_{nm}\}$, one can consider the node subset $\mathcal{V}_p = \{v_{(p-1)n+1}, \dots, v_{pn}\}$, $p \in \mathcal{J}$ as a layer of the multi-layer graph $\mathcal{G}[A]$ with vertices associated with the opinions of individuals $1, \dots, n$ on topic

Figure 1. An illustrative network with 2 individuals discussing 3 topics, with only selected edges drawn for clarity. Each node represents the opinion of an individual for a topic, with red and blue nodes associated with individuals 1 and 2, respectively. The black edges represent interpersonal influence via the weight w_{ij} , while the coloured edges represent logical interdependencies between topics. In $\mathcal{G}[\mathbf{B}]$, nodes are grouped and ordered by individual in node subset $\tilde{\mathcal{V}}_q$ (as illustrated by the dotted green ellipse groupings) leading to Eq. (8). In $\mathcal{G}[\mathbf{A}]$, the nodes are grouped and ordered by topic in node subset \mathcal{V}_p (as illustrated by the dotted green ellipses) leading to Eq. (10).

p . In $\mathcal{G}[\mathbf{B}]$, with node set $\mathcal{V}[\mathbf{B}] = \{v_1, \dots, v_{nm}\}$, one can consider the node subset $\tilde{\mathcal{V}}_q = \{v_{(q-1)m+1}, \dots, v_{qm}\}$, $q \in \mathcal{I}$ as a layer of a multi-layer graph with vertices associated with the opinions of individual q on topics $1, \dots, m$. This is illustrated in Fig. 1, where each layer is identified by a dotted green ellipse border. A key motivation to study $\mathcal{G}[\mathbf{A}]$ and the dynamical system Eq. (10) is that all the block diagonal entries \mathbf{A}_{ii} of \mathbf{A} are nonnegative and irreducible because Assumption 1 indicates that $\text{diag}(c_{pp})$ has positive diagonal entries. This means that the edges between nodes in the subset $\mathcal{V}_p = \{v_{(p-1)n+1}, \dots, v_{pn}\}$, $p \in \mathcal{J}$ have positive weights, and this property greatly aids in the checking of the structural balance or unbalance of the network $\mathcal{G}[\mathbf{A}]$ given $\mathcal{G}[\mathbf{W}]$ and $\mathbf{C}_i, \forall i \in \mathcal{I}$.

Verify from the row-stochastic property of \mathbf{W} and the row-sum property of \mathbf{C}_i in Assumption 1 that the entries of \mathbf{A} satisfy $\sum_{q=1}^{nm} |a_{pq}| = 1$ for all $p = 1, \dots, nm$. We therefore conclude that Eq. (10) has the same dynamics as the discrete-time Altafini model (see e.g. [10], [11]).

Remark 2. Although Eq. (10) has the same dynamics as the discrete-time Altafini model, a number of important differences exist. First, the context of negative edge weights is entirely different: in the Altafini model, $w_{ij} < 0$ implies individual i mistrusts individual j [10]. In contrast, Eq. (10) assumes nonnegative influence $w_{ij} \geq 0$, and the negative edge weights arise from negative logical interdependencies in \mathbf{C}_i . Moreover the network structure of $\mathcal{G}[\mathbf{A}]$ is affected by both the influence network $\mathcal{G}[\mathbf{W}]$ and the logic matrix graphs $\mathcal{G}[\mathbf{C}_i]$.

The main convergence result is given as follows.

Theorem 2. Suppose that for a population of n individuals, the vector of the n individuals' opinions $\mathbf{y}(t)$ evolves according to Eq. (10), with interpersonal influences captured by $\mathcal{G}[\mathbf{W}]$. Suppose further that Assumptions 1, 2, and 3 hold. Then, for any initial condition $\mathbf{y}(0) \in \mathbb{R}^{nm}$, there exists some $\mathbf{y}^* \in \mathbb{R}^{nm}$ such that there holds $\lim_{t \rightarrow \infty} \mathbf{y}(t) = \mathbf{y}^*$ exponentially fast. If $y_k^i(0) \in [-1, 1]$ for all $i \in \mathcal{I}$ and $k \in \mathcal{J}$, then $y_k^i(t) \in [-1, 1]$ for all $t \geq 0$ and $i \in \mathcal{I}$ and $k \in \mathcal{J}$.

Having established that the opinion dynamical system always converges, we now address Objective 1 by studying the influence of \mathbf{C}_i in determining the limiting opinion vector \mathbf{y}^* .

B. Consensus and Disagreement of Each Topic

We now explain how to use the logic matrices \mathbf{C}_i to systematically determine whether opinions on a given topic $p \in \mathcal{J}$ will reach a consensus or not. We defer discussion of the social interpretation of the theoretical results until Section III-C, and illustrate some of the conclusions drawn in this section with selected simulations in Section IV.

Consider the graph $\mathcal{G}[\mathbf{C}_i]$ associated with \mathbf{C}_i for some $i \in \mathcal{I}$, which is a signed graph if there are negative off-diagonal entries in \mathbf{C}_i . It turns out (see Theorem 3 immediately below) that if \mathbf{C}_i for all $i \in \mathcal{I}$ are irreducible, then all topics will reach a consensus (although the consensus value for two different topics p and q may be different). We remark that irreducible logic matrices correspond to $\mathcal{G}[\mathbf{C}_i]$ which are strongly connected, and thus for any two topics $p, q \in \mathcal{J}$, there is a (possibly signed) directed path from p to q . In other words, all topics are directly or indirectly dependent on all other topics.

Theorem 3. Let the hypotheses in Theorem 2 hold. Suppose that (i) $y_k^i(0) \in [-1, 1]$ for all $i \in \mathcal{I}$ and $k \in \mathcal{J}$, and (ii) that Assumptions 1, 2, and 3 hold. Suppose further that $\mathbf{C}_i, \forall i \in \mathcal{I}$ are irreducible⁴. Then, for all $k \in \mathcal{J}$, $\lim_{t \rightarrow \infty} \mathbf{y}_k(t) = \alpha_k \mathbf{1}_n$ exponentially fast, where $\alpha_k \in [-1, 1]$. Moreover,

- 1) If there are no competing logical interdependencies, as given in Definition 1, and $\mathcal{G}[\mathbf{C}_i], \forall i \in \mathcal{I}$ are structurally balanced⁵, then for almost all initial conditions, $|\alpha_p| = |\alpha_q| \neq 0, \forall p, q \in \mathcal{J}$.
- 2) If there are no competing logical interdependencies, and $\mathcal{G}[\mathbf{C}_i], \forall i \in \mathcal{I}$ are structurally unbalanced, then $\alpha_k = 0, \forall k \in \mathcal{J}$.
- 3) If there are competing logical interdependencies, then $\alpha_k = 0, \forall k \in \mathcal{J}$.

Further to the conclusions of Theorem 3, one can obtain the following result for the case where consensus to a nonzero opinion value is achieved.

Corollary 1. Let the hypotheses in Theorem 3 hold. Suppose that there are no competing logical interdependencies, and $\mathcal{G}[\mathbf{C}_i], \forall i \in \mathcal{I}$ are structurally balanced. For $\mathcal{G}[\mathbf{C}_i]$ with node set $\mathcal{V} = \{v_1, \dots, v_m\}$, define two disjoint subsets of nodes $\mathcal{V}[\mathbf{C}_i]^+$ and $\mathcal{V}[\mathbf{C}_i]^-$ so that each edge between two nodes in $\mathcal{V}[\mathbf{C}_i]^+$ or two nodes in $\mathcal{V}[\mathbf{C}_i]^-$ has a positive weight, and each edge between two nodes in $\mathcal{V}[\mathbf{C}_i]^+$ and $\mathcal{V}[\mathbf{C}_i]^-$ has a negative weight. Then, for any $p, q \in \mathcal{J}$, there holds

- 1) $\alpha_p = \alpha_q$ if $v_q, v_p \in \mathcal{V}[\mathbf{C}_i]^+$ or $v_q, v_p \in \mathcal{V}[\mathbf{C}_i]^-$.
- 2) $\alpha_p = -\alpha_q$ if $v_q \in \mathcal{V}[\mathbf{C}_i]^+$ and $v_p \in \mathcal{V}[\mathbf{C}_i]^-$.

Consider now the more general case where \mathbf{C}_i for all $i \in \mathcal{I}$ are reducible. Thus, $\mathcal{G}[\mathbf{C}_i]$ is no longer strongly connected.

⁴Under Assumption 2, irreducibility of one \mathbf{C}_i implies the same for all.

⁵Under Assumption 2 and in the absence of competing logical interdependencies, the presence or absence of structural balance for one \mathbf{C}_i implies the same for all.

The logic matrices of all individuals can be expressed in a lower block triangular form through an inessential reordering of the topic set. From Assumption 2, we further conclude that there exists a common permutation matrix \mathbf{P} such that, for all $i \in \mathcal{I}$, $\mathbf{P}^T \mathbf{C}_i \mathbf{P}$ is lower block triangular. Without loss of generality, we therefore assume that the topics $p \in \mathcal{J}$ are ordered such that, for each $i \in \mathcal{I}$,

$$\mathbf{C}_i = \begin{bmatrix} \mathbf{C}_{11,i} & \mathbf{0} & \cdots & \mathbf{0} \\ \mathbf{C}_{21,i} & \mathbf{C}_{22,i} & \cdots & \mathbf{0} \\ \vdots & \vdots & \ddots & \vdots \\ \mathbf{C}_{s1,i} & \mathbf{C}_{s2,i} & \cdots & \mathbf{C}_{ss,i} \end{bmatrix}, \quad (11)$$

where $\mathbf{C}_{jj,i} \in \mathbb{R}^{s_j \times s_j}$ is irreducible for any $j \in \mathcal{S} \triangleq \{1, 2, \dots, s\}$ and s_j are positive integers such that $\sum_{j=1}^s s_j = m$. Decompose the opinion set \mathcal{J} into s disjoint subsets \mathcal{J}_j for $j \in \mathcal{S}$ where

$$\mathcal{J}_j \triangleq \left\{ \sum_{i=1}^j s_{i-1} + 1, \sum_{i=1}^j s_{i-1} + 2, \dots, \sum_{i=1}^j s_{i-1} + s_j \right\}, \quad (12)$$

with $s_0 = 0$. Though reducible \mathbf{C}_i may seem to be restrictive, they are in fact common given the problem context since they imply a cascade logical interdependence structure among the topics. This may be representative of an individual i who obtains \mathbf{C}_i by sequentially building upon an axiom or axioms (the first $\mathbf{C}_{jj,i}$ block matrices). The two topics of the Space exploration example given in Eq. (2) constitute one such example of a belief system driven by an axiom (Topic 1).

From the perspective of the graph $\mathcal{G}[\mathbf{C}_i]$, the expression in Eq. (11) enables $\mathcal{G}[\mathbf{C}_i]$ to be divided into strongly connected components which are ‘‘closed’’ or ‘‘open’’. (This is related to a concept called the condensation of a graph, see [28]). Formally, we say that a subgraph $\hat{\mathcal{G}}$ is a strongly connected component of \mathcal{G} if $\hat{\mathcal{G}}$ is strongly connected and any other subgraph of \mathcal{G} strictly containing $\hat{\mathcal{G}}$ is *not* strongly connected. A strongly connected component $\hat{\mathcal{G}}$ of a graph \mathcal{G} is said to be closed if there are no incoming edges to $\hat{\mathcal{G}}$ from a node outside of $\hat{\mathcal{G}}$, and is said to be open otherwise. The simplest possible strongly connected component is a single node, and it would be closed if there were no incoming edges to it. Figure 2 shows an example of a graph $\mathcal{G}[\mathbf{C}_i]$ divided into strongly connected components (identified by the dotted line encircling a set of nodes), with the blue and purple components being closed, and the green and orange components being open. Following the notation in Eq. (11) and Eq. (12), we have for the example in Fig. 2, $s = 4$, $s_1 = 3$, $s_2 = 1$, $s_3 = 2$, $s_4 = 1$, and $\mathcal{J}_1 = \{1, 2, 3\}$, $\mathcal{J}_2 = \{4\}$, $\mathcal{J}_3 = \{5, 6\}$, $\mathcal{J}_4 = \{7\}$.

If the topic set \mathcal{J}_j corresponds to a *closed* strongly connected component of $\mathcal{G}[\mathbf{C}_i]$, then clearly in Eq. (11), $\mathbf{C}_{pj,i} = \mathbf{0}$ for all $p \neq j$. One can then use Theorem 3 and Corollary 1 to establish that for every $k \in \mathcal{J}_j$, there holds $\lim_{t \rightarrow \infty} \mathbf{y}_k(t) = \alpha_k \mathbf{1}_n$ exponentially fast, with $\alpha_k \in [-1, 1]$. That is, all opinions in topic $k \in \mathcal{J}_j$ reach a consensus. If, on the other hand, the topic set \mathcal{J}_j corresponds to an *open* strongly connected component of $\mathcal{G}[\mathbf{C}_i]$, then the results presented below can be employed sequentially in order to establish whether opinions on a given topic have reached a consensus. By ‘‘sequentially’’, we mean that we analyse

Figure 2. An illustrative example of $\mathcal{G}[\mathbf{C}_i]$, with each node representing a topic, and edges representing logical interdependencies between topics (self-loops are hidden for clarity). One can divide the nodes into strongly connected components (each dotted coloured circle denotes a strongly connected component). The results of this paper allow one to progressively analyse each component to establish which topics will have opinions reaching a consensus and which topics will have opinions reaching a persistent disagreement.

the topic sets \mathcal{J}_j with j in the order $1, 2, \dots, s$. Under Assumption 2, define for each topic $p \in \mathcal{J}$, the set

$$\hat{\mathcal{J}}_p \triangleq \{q \in \mathcal{J} : c_{pq,i} \neq 0, q \neq p\} \quad (13)$$

where $c_{pq,i}$ is the pq^{th} entry of \mathbf{C}_i . In other words, $\hat{\mathcal{J}}_p$ identifies all topics $q \in \mathcal{J}$ that topic p is logically dependent upon. Because of Assumption 2, the set $\hat{\mathcal{J}}_p$ is the same for all individuals $i \in \mathcal{I}$. In Fig. 2, $\hat{\mathcal{J}}_6$ for example is $\{4, 5\}$.

We present necessary and sufficient conditions that ensure every topic in the subset \mathcal{J}_j reaches a consensus of opinions in two theorems, the first for the case when the subset \mathcal{J}_j is a singleton (e.g. $\mathcal{J}_4 = \{7\}$ in Fig. 2), and the second for when \mathcal{J}_j has at least two elements (e.g. $\mathcal{J}_3 = \{5, 6\}$ in Fig. 2).

Theorem 4. *Let the hypotheses in Theorem 2 hold. Assume that (i) $y_k^i(0) \in [-1, 1]$ for all $i \in \mathcal{I}$ and $k \in \mathcal{J}$, and (ii) that $\mathbf{C}_i, \forall i \in \mathcal{I}$ is decomposed as in Eq. (11). Suppose that $\mathcal{J}_j = \{p\}$, as defined in Eq. (12), is a singleton, and let $\hat{\mathcal{J}}_p$ as defined in Eq. (13) be nonempty. Suppose further that all topics $q \in \hat{\mathcal{J}}_p$ satisfy $\lim_{t \rightarrow \infty} \mathbf{y}_q = \alpha_q \mathbf{1}_n$, $\alpha_q \in [-1, 1]$. Then, $\lim_{t \rightarrow \infty} \mathbf{y}_p(t) = \alpha_p \mathbf{1}_n$ for some $\alpha_p \in \mathbb{R}$ if and only if there exists a $\kappa \in [-1, 1]$ such that*

$$\kappa = \frac{\sum_{q \in \hat{\mathcal{J}}_p} \alpha_q c_{pq,i}}{\sum_{q \in \hat{\mathcal{J}}_p} |c_{pq,i}|}, \quad \forall i \in \mathcal{I}. \quad (14)$$

If such a κ exists, then $\alpha_p = \kappa$.

The key necessary and sufficient condition involves Eq. (14), which is somewhat complex and nonintuitive. We now provide a corollary which studies the condition in Eq. (14) for some situations which are important or of interest in the social context. Discussion and interpretation of these formal results are provided in the following Section III-C.

Corollary 2. *Adopting the hypotheses in Theorem 4, the following hold:*

- 1) *Suppose that $\hat{\mathcal{J}}_p = \{q\}$ is a singleton. Then, there exists a $\kappa \in [-1, 1]$ satisfying Eq. (14) if and only if there*

do not exist individuals $i, j \in \mathcal{I}$ with competing logical interdependencies on topic p (as defined in Definition 1).

- 2) If $\alpha_q = 0$ for all $q \in \hat{\mathcal{J}}_p$, then $\kappa = 0$ satisfies Eq. (14).
- 3) Suppose that $\hat{\mathcal{J}}_p = \{q_1, \dots, q_r\}$, $r \geq 2$. If $c_{pq_k, i} = c_{pq_k, j} = c_{pq_k}$ for all $k \in \{1, \dots, r\}$ and $i, j \in \mathcal{I}$, then there exists a $\kappa \in [-1, 1]$ satisfying Eq. (14).
- 4) Suppose that $\hat{\mathcal{J}}_p = \{q_1, \dots, q_r\}$, $r \geq 2$. Suppose further that $|\alpha_{q_u}| = |\alpha_{q_v}|$ for all $u, v \in \{1, \dots, r\}$. Then, there exists a $\kappa \in [-1, 1]$ satisfying Eq. (14) if either (i) the sign of $c_{pq_k, i}$ and α_{q_k} are equal for all $i \in \mathcal{I}$ and $k \in \{1, \dots, r\}$ or (ii) the sign of $c_{pq_k, i}$ and α_{q_k} are opposite for all $i \in \mathcal{I}$ and $k \in \{1, \dots, r\}$. In the case of (i), $\kappa = |\alpha_{q_k}|$, and in the case of (ii), $\kappa = -|\alpha_{q_k}|$.

When \mathcal{J}_j is not a singleton, the analysis becomes significantly more involved. To that end, we first introduce some additional notation. Define

$$\tilde{\mathcal{J}}_j \triangleq \cup_{k \in \mathcal{J}_j} \hat{\mathcal{J}}_k \setminus \mathcal{J}_j \quad (15)$$

as the set of topics not in \mathcal{J}_j that the topics in \mathcal{J}_j depend upon. For example, in Fig. 2, $\mathcal{J}_3 = \{5, 6\}$, $\hat{\mathcal{J}}_5 = \{3, 6\}$, $\hat{\mathcal{J}}_6 = \{4, 5\}$, and $\tilde{\mathcal{J}}_3 = \{3, 4\}$. Note that if $\mathcal{J}_j = \{p\}$ is a singleton, we have $\tilde{\mathcal{J}}_j = \hat{\mathcal{J}}_p$. Perhaps unsurprisingly, Theorem 4 requires that consensus must first occur for topics in $\tilde{\mathcal{J}}_j = \hat{\mathcal{J}}_p$, on which the topics in \mathcal{J}_j depend. The following theorem also has the requirement that consensus occur for all topics in $\tilde{\mathcal{J}}_j$.

Theorem 5. *Let the hypotheses in Theorem 2 hold. Assume that (i) $y_k^i(0) \in [-1, 1]$ for all $i \in \mathcal{I}$ and $k \in \mathcal{J}$, and that (ii) $\mathcal{C}_i, \forall i \in \mathcal{I}$ is decomposed as in Eq. (11). Suppose that \mathcal{J}_j , as defined in Eq. (12), has at least two elements. Let $\tilde{\mathcal{J}}_j$, as defined in Eq. (15), be nonempty and suppose further that all topics $q \in \tilde{\mathcal{J}}_j$ satisfy $\mathbf{y}_q^* = \alpha_q \mathbf{1}_n$, $\alpha_q \in [-1, 1]$. Then, $\lim_{t \rightarrow \infty} \mathbf{y}_k = \alpha_k \mathbf{1}_n$ for all $k \in \mathcal{J}_j$ if and only if, for every $k \in \mathcal{J}_j$, there exists a $\phi_k \in [-1, 1]$ such that*

$$\begin{aligned} \phi_k & \left[\sum_{r \in \mathcal{J}_j \setminus \{k\}} |c_{kr, i}| + \sum_{q \in \tilde{\mathcal{J}}_j} |c_{kq, i}| \right] \\ & = \sum_{r \in \mathcal{J}_j \setminus \{k\}} \phi_r c_{kr, i} + \sum_{q \in \tilde{\mathcal{J}}_j} \alpha_q c_{kq, i}, \quad \forall i \in \mathcal{I} \end{aligned} \quad (16)$$

If such a set of ϕ_k exist, then $\alpha_k = \phi_k$ for all $k \in \mathcal{J}_j$.

Similar to above, we now present a corollary which gives sufficient conditions for Eq. (16) in two scenarios.

Corollary 3. *Adopting the hypotheses in Theorem 5, the following hold:*

- 1) If $\alpha_q = 0$ for all $q \in \tilde{\mathcal{J}}_j$, then $\phi_k = 0 \forall k \in \mathcal{J}_j$ satisfies Eq. (16).
- 2) If $c_{kp, i} = c_{kp, h}$ for all $k \in \mathcal{J}_j$, $p \in \mathcal{J}$ and $i, h \in \mathcal{I}$, then there exist $\phi_k \in [-1, 1]$ satisfying Eq. (16) $\forall k \in \mathcal{J}_j$.

For the illustrative example in Fig. 2, one would first analyse the blue and purple components using Theorem 3. Then, one would analyse the green component using Theorem 5, and last the orange component using Theorem 4.

C. Discussion and Social Interpretations

We conclude this section by providing some discussion and comments on the main results, focusing in particular on the theorems and corollaries in Section III-B. Overall, the outcomes we have established depend on the graphical structures $\mathcal{G}[\mathcal{C}_i]$ on the one hand, and on the numerical values (including their signs) of the \mathcal{C}_i entries on the other. This dependence sometimes flows simply from the signs (the presence or absence of competing logical interdependencies), and sometimes from the precise values of the \mathcal{C}_i . Further, when consensus on a topic occurs, it is evident that sometimes a value 0 is always the outcome, and sometimes a nonzero value dependent on the initial opinions of those topics in the closed and strongly connected components of $\mathcal{G}[\mathcal{C}_i]$.

It is clear from Theorem 3 that for any topic set \mathcal{J}_j corresponding to a closed and strongly connected component of $\mathcal{G}[\mathcal{C}_i]$, every topic $k \in \mathcal{J}_j$ will reach a consensus. One interpretation is that a closed and strongly connected component corresponds to \mathcal{J}_j having a topic(s) that is an axiom (or axioms) upon which an individual builds his or her belief system (see below Eq. (12)). Our results show that discussion of axiomatic topics will always lead a consensus under the model Eq. (1) (a consensus might not be reached if, as in Eq. (6), there is stubbornness present).

Theorem 3 and Corollaries 2 and 3 also illustrate that competing logical interdependencies, if present, can play a major role in determining the final opinion values. For instance, see Theorem 3 Part 3, where given a topic set \mathcal{J}_j corresponding to a closed and strongly connected component of $\mathcal{G}[\mathcal{C}_i]$, all opinion values for all topics in \mathcal{J}_j converge to the neutral value at 0 whenever competing interdependencies are present in the topics in \mathcal{J}_j . Also, the presence of any competing logical interdependencies in topic $p \in \mathcal{J}_j$ is enough to prevent the sufficient conditions detailed in Corollary 2 Item 1), 3), and 4) and Corollary 3 Item 2) from being satisfied. Of particular note is Corollary 2 Item 1). When $\hat{\mathcal{J}}_p = \{q\}$ is a singleton, heterogeneity in the entries of $c_{pq, i}$ is not enough to prevent a consensus of opinions on topic p ; competing logical interdependencies are required. This last finding is a surprising, and non-intuitive result.

The sufficient condition in Corollary 2 Item 2) requires $\alpha_q = 0$ for all $q \in \hat{\mathcal{J}}_p$. This is not as restrictive as it first seems: one possible scenario is that all elements of $\hat{\mathcal{J}}_p$ belong to topics from the same closed and strongly connected component in $\mathcal{G}[\mathcal{C}_i]$, with the component being structurally unbalanced, or having competing logical interdependencies. The same can be said for Corollary 3 Item 1). Part of the sufficient condition for Corollary 2 Item 4) is that $|\alpha_{q_u}| = |\alpha_{q_v}|$ for all $q_u, q_v \in \hat{\mathcal{J}}_p = \{q_1, \dots, q_r\}$, $r \geq 2$. This will always hold if q_1, \dots, q_r are topics that are part of the same closed and strongly connected component in $\mathcal{G}[\mathcal{C}_i]$.

From numerous simulations, we frequently observed that minor heterogeneities in the entries of $c_{pq, i}, p \in \mathcal{J}_j$ among the individuals (e.g. if the $c_{pq, i}$ were all selected from a uniform distribution) were often sufficient to create disagreement among the opinions on topic $p \in \mathcal{J}_j$. We observed this in many different examples, except in the case of Corollary 2 Item 1),

where $\mathcal{J}_j = \{p\}$ and $\hat{\mathcal{J}}_p = \{q\}$ are both singletons, since existence of competing logical interdependencies was proven to be a necessary and sufficient condition for disagreement.

It is also clear from Theorems 3, 4 and 5 that disagreement is possible only in topic sets \mathcal{J}_j associated with an open strongly connected component of $\mathcal{G}[C_i]$. Put another way, belief systems with a cascade logical structure, viz. reducible C_i in the form of Eq. (11), including heterogeneity among individuals' belief systems, play a significant role in generating disagreement when social networks discuss multiple logically interdependent topics. Looking at Eq. (1), one can see two separate processes occurring: the DeGroot component describes interpersonal influence between individuals in an effort to reach a consensus, while the logic matrix by itself (as in Eq. (3)) captures an intrapersonal effort to secure logical consistency of opinions across several topics. These two drivers may or may not end up in conflict, and the presence of conflict or lack thereof determines whether opinions of a certain topic reach a consensus or fail to do so. Our results in Theorems 4 and 5 identify when such conflict can occur.

Remark 3. *Theorems 4 and 5 establish necessary and sufficient conditions for topic $p_k \in \mathcal{J}_j = \{p_1, \dots, p_{s_j}\}$ to reach a consensus under a particular hypothesis. Specifically, it is assumed that for the set \mathcal{J}_j under consideration, there holds*

$$\mathbf{y}_q^* = \alpha_q \mathbf{1}_n, \quad \forall q \in \hat{\mathcal{J}}_j. \quad (17)$$

*That is, all other topics that one or more topics $p_k \in \mathcal{J}_j$ depend upon are assumed to have reached a consensus. Based on numerous simulations, we believe the requirement that Eq. (17) holds is **also a necessary condition** for $\mathbf{y}_{p_k}, p_k \in \mathcal{J}_j$ to reach a consensus. In other words, if any topic $q \in \hat{\mathcal{J}}_j$ fails to reach a consensus, we conjecture that all $\mathbf{y}_{p_k}, k = 1, \dots, s_j$ will also fail to reach a consensus. Confirming this would provide yet another indication that networks with belief systems having a cascade logic structure more readily result in disagreement. We leave this to future investigations.*

IV. SIMULATIONS

We now provide simulations to illustrate some of the results in Section III using a network $\mathcal{G}[\mathbf{W}]$ of $n = 6$ individuals, with

$$\mathbf{W} = \begin{bmatrix} 0.2 & 0 & 0 & 0 & 0.8 & 0 \\ 0.5 & 0.3 & 0 & 0 & 0 & 0.2 \\ 0 & 0.3 & 0.1 & 0 & 0 & 0.6 \\ 0 & 0 & 0.85 & 0.15 & 0 & 0 \\ 0 & 0 & 0 & 0.2 & 0.8 & 0 \\ 0 & 0 & 0 & 0 & 0.5 & 0.5 \end{bmatrix}. \quad (18)$$

Note that \mathbf{W} satisfies Assumption 3. Initial conditions are generated by selecting each $x_i^p(0)$ from a uniform distribution in $[-1, 1]$, and the same initial condition vector $\mathbf{x}(0)$ is used for all simulations. We consider 5 topics, i.e. $\mathcal{J} = \{1, \dots, 5\}$.

In the first simulation, we use two logic matrices:

$$\hat{C} = \begin{bmatrix} 1 & 0 & 0 & 0 & 0 \\ -0.5 & 0.5 & 0 & 0 & 0 \\ -0.3 & -0.6 & 0.1 & 0 & 0 \\ 0 & -0.3 & 0 & 0.2 & -0.5 \\ 0 & -0.5 & 0 & -0.2 & 0.3 \end{bmatrix} \quad (19a)$$

$$\bar{C} = \begin{bmatrix} 1 & 0 & 0 & 0 & 0 \\ -0.8 & 0.2 & 0 & 0 & 0 \\ -0.3 & -0.1 & 0.6 & 0 & 0 \\ 0 & -0.3 & 0 & 0.2 & -0.5 \\ 0 & -0.5 & 0 & -0.2 & 0.3 \end{bmatrix}. \quad (19b)$$

The individuals have logic matrix $C_i = \hat{C}$ for $i = 1, 2, 3$ and $C_i = \bar{C}$ for $i = 4, 5, 6$. Notice that there are no competing logical interdependencies associated with the set of C_i . Moreover, according to Eq. (12), we have $\mathcal{J}_1 = \{1\}, \mathcal{J}_2 = \{2\}, \mathcal{J}_3 = \{3\}, \mathcal{J}_4 = \{4, 5\}$. The temporal evolution of $\mathbf{x}(t)$ is given in Fig. 3, where solid or dotted lines correspond to an individual with $C_i = \hat{C}$ or $C_i = \bar{C}$, respectively. We see that Topic 1 (Theorem 3) and Topic 2 (Corollary 2, Statement 1)) reach a consensus. In particular, notice that the entries of \hat{C} and \bar{C} are such that $\hat{c}_{21} \neq \bar{c}_{21}$ but Topic 2 still reaches a consensus because there are no competing logical interdependencies in Topic 2. In contrast, Topic 3 fails to reach a consensus (Theorem 4) despite both Topics 1 and 2 reaching a consensus. Strong diversity emerges because the heterogeneities in the third row of \bar{C} and \hat{C} are such that there does not exist a $\kappa \in [-1, 1]$ that satisfies Eq. (14), even though the sign patterns in the third row are the same between \hat{C} and \bar{C} . Topics 4 and 5, forming \mathcal{J}_4 , both reach a consensus because the fourth and fifth rows of \hat{C} and \bar{C} are the same (Corollary 3, Statement 2)).

Replacing \hat{C} with

$$\tilde{C} = \begin{bmatrix} 1 & 0 & 0 & 0 & 0 \\ 0.5 & 0.5 & 0 & 0 & 0 \\ -0.3 & -0.1 & 0.6 & 0 & 0 \\ 0 & -0.3 & 0 & 0.2 & -0.5 \\ 0 & -0.5 & 0 & -0.2 & 0.3 \end{bmatrix} \quad (20)$$

for individuals 1, 2, 3, we run the same simulation (i.e. with the same $\mathcal{G}[\mathbf{W}]$ and initial conditions $\mathbf{x}(0)$). The results are displayed in Fig. 4. Notice that the only difference between \hat{C} and \tilde{C} is a sign reversal in the c_{21} entry. Now, there are competing logical interdependencies in Topic 2, which results in a failure to reach consensus on this topic (Corollary 2, Statement 1)). Because of the cascade logic structure, Topics 3, 4 and 5 also fail to reach a consensus (illustrating our conjecture in Remark 3). This is despite no other differences when comparing \hat{C} and \tilde{C} , and Topics 4 and 5 reaching a consensus in the previous simulation when individuals 1, 2, 3 used \hat{C} . Moreover, a strong diversity of opinions emerge for Topics 2, 3, 4 and 5.

V. CONCLUSION

We have studied influence networks in which individuals discuss a set of logically interdependent topics, assuming that the network has no stubborn individuals in order to

APPENDIX

Figure 3. Temporal evolution of opinions for 5 topics coupled with C_i given in Eq. (19). The solid and dotted lines correspond to individuals with $C_i = \tilde{C}$ and $C_i = \bar{C}$, respectively.

Figure 4. Temporal evolution of opinions for 5 topics coupled with \tilde{C} replaced by \bar{C} given in Eq. (20). The solid and dotted lines correspond to individuals with $C_i = \tilde{C}$ and $C_i = \bar{C}$, respectively.

focus on the effects of the logical interdependence structure. We established that for strongly connected networks, and reasonable assumptions on the logic matrix, the opinions converge exponentially fast to some steady-state value. We then provided a systematic way to help determine whether a given topic will reach a consensus or fail to do so. It was discovered that heterogeneity of reducible logic matrices among individuals, including differences in signs of the off-diagonal entries, played a primary role in producing disagreement in the final opinion values. In the problem context, we have established that a cascade logic structure and heterogeneity of individuals' belief systems, including existence of competing logical interdependencies, generates the phenomenon of strong diversity of final opinions. We believe this to be a key new insight and explanation of strong diversity, since most existing works attribute strong diversity in connected networks to factors such as individual stubbornness. Future work will focus on proving the conjecture in Remark 3, relaxing Assumption 2, and the effect of the logic matrix on the convergence rate.

To begin, we detail a result to be used in the sequel.

Lemma 2. *Let $A \in \mathbb{R}^{n \times n}$ be a given irreducible row-substochastic matrix. Then, $\rho(A) < 1$.*

Proof. This lemma is an immediate consequence of [31, Lemma 2.8]. \square

In order to prove Theorem 2, we first establish the following lemma.

Lemma 3. *Suppose that Assumption 2 holds. Then, $\mathcal{G}[A]$, where A is the matrix in Eq. (10), is strongly connected and aperiodic if and only if, separately, $\mathcal{G}[W]$ and $\mathcal{G}[C_i], \forall i$ are strongly connected and aperiodic.*

Proof. Let \bar{C} be a nonnegative row-stochastic matrix with the same zero and non-zero pattern of entries as $C_i, \forall i \in \mathcal{I}$, i.e. $\bar{C} \sim C_i, \forall i \in \mathcal{I}$. Then, by the lemma hypothesis on Assumption 2, the graph $\mathcal{G}[\bar{C} \otimes W]$ has the same vertex and edge set as $\mathcal{G}[A]$, but with different edge weights (including the fact that all edge weights of $\mathcal{G}[\bar{C} \otimes W]$ are positive, whereas negative edge weights may exist in $\mathcal{G}[A]$). Thus, if we can prove that $\mathcal{G}[\bar{C} \otimes W]$ is strongly connected and aperiodic (as we shall do now) it will follow that $\mathcal{G}[A]$ is also strongly connected and aperiodic.

Suppose that $W \geq 0$ and \bar{C} are primitive, and specifically that $W^{k_1} > 0$ and $\bar{C}^{k_2} > 0$ for some $k_1, k_2 \in \mathbb{N}$. Then, for all $\max\{k_1, k_2\} < j \in \mathbb{N}$, there holds $W^j > 0$ and $\bar{C}^j > 0$ (see below Lemma 1). Next, observe from Lemma 1 that $\mathcal{G}[\bar{C} \otimes W]$ is strongly connected and aperiodic if and only if $\bar{C} \otimes W$ is primitive, i.e. $\exists k \in \mathbb{N} : (\bar{C} \otimes W)^k > 0$. It is straightforward to conclude that $\bar{C}^k \otimes W^k > 0$ if and only if $W^k > 0$ and $\bar{C}^k > 0$, since otherwise there is a zero element in $\bar{C}^k \otimes W^k$. By choosing $k > \max\{k_1, k_2\}$, it is straightforward to conclude that one requires $\mathcal{G}[W]$ and $\mathcal{G}[\bar{C}]$, separately, to be strongly connected and aperiodic in order for $\mathcal{G}[A]$ to be strongly connected and aperiodic. \square

A. Theorem 2

The proof is has two parts: in Part 1 and Part 2, we prove convergence for irreducible and reducible C_i , respectively.

Part 1: Consider the case where all the C_i are irreducible (i.e. $\mathcal{G}[C_i]$ is strongly connected). We have that $\mathcal{G}[W]$ and $\mathcal{G}[C_i], \forall i \in \mathcal{I}$ are separately strongly connected and aperiodic from Assumptions 1, 2, and 3 (the aperiodicity is a consequence of the assumption that $w_{ii} > 0$ and $c_{pp,i} > 0$ for all $i \in \mathcal{I}$ and $p \in \mathcal{J}$). From Lemma 1, we then conclude that $\mathcal{G}[A]$ is strongly connected and aperiodic. Moreover, every diagonal entry of A is strictly positive. Using existing results on the Altafini model for strongly connected networks [11, Theorem 1 and 2], we conclude that $\lim_{t \rightarrow \infty} \mathbf{y}(t) = \mathbf{y}^*$ exponentially fast, where $\mathbf{y}^* \in \mathbb{R}^{nm}$ is the steady-state opinion distribution.

Part 2: Consider now the case where all C_i are reducible, with C_i having the form in Eq. (11), $\mathcal{S} \triangleq \{1, 2, \dots, s\}$, and

s_j being integers satisfying $\sum_{j=1}^s s_j = m$. The matrix \mathbf{A} in Eq. (10) has the following form

$$\mathbf{A} = \begin{bmatrix} \bar{\mathbf{A}}_{11} & \mathbf{0} & \cdots & \mathbf{0} \\ \bar{\mathbf{A}}_{21} & \bar{\mathbf{A}}_{22} & \cdots & \mathbf{0} \\ \vdots & \vdots & \ddots & \vdots \\ \bar{\mathbf{A}}_{s1} & \bar{\mathbf{A}}_{s2} & \cdots & \bar{\mathbf{A}}_{ss} \end{bmatrix} \quad (21)$$

with block matrix elements $\bar{\mathbf{A}}_{pq}, p, q \in \mathcal{S}$ given

$$\bar{\mathbf{A}}_{pq} = \begin{bmatrix} \mathbf{A}_{gh} & \mathbf{A}_{g,h+1} & \cdots & \mathbf{A}_{g,h+s_q-1} \\ \mathbf{A}_{g+1,h} & \mathbf{A}_{g+1,h+1} & \cdots & \mathbf{A}_{g+1,h+s_q-1} \\ \vdots & \vdots & \ddots & \vdots \\ \mathbf{A}_{g+s_p-1,h} & \mathbf{A}_{g+s_p-1,h+1} & \cdots & \mathbf{A}_{g+s_p-1,h+s_q-1} \end{bmatrix} \quad (22)$$

Here, $g = \sum_{i=1}^p s_{i-1} + 1$ and $h = \sum_{i=1}^q s_{i-1} + 1$ for $p, q \in \mathcal{S}$ with $s_0 = 0$. From the decomposition in Eq. (11), we know that $\mathbf{C}_{pp,i}$ is irreducible for any $p \in \mathcal{S}$ and $i \in \mathcal{I}$, which implies that $\mathcal{G}[\mathbf{C}_{pp,i}]$ is strongly connected. Moreover, $\mathcal{G}[\mathbf{C}_{pp,i}]$ is aperiodic since all the diagonals are positive (see Assumption 1).

We prove the exponential convergence property by induction. First, for the base case consider the topics in \mathcal{J}_1 , which are $\{1, 2, \dots, s_1\}$. Since $\mathbf{C}_{11,i}$ is irreducible for all $i \in \mathcal{I}$, we obtain from Part 1 that for all topics $k \in \mathcal{J}_1$, there holds $\lim_{t \rightarrow \infty} \mathbf{y}_k(t) = \mathbf{y}_k^*$ exponentially fast, for some $\mathbf{y}_k^* \in \mathbb{R}^n$.

We now prove the induction step for topic k in the topic subset \mathcal{J}_p , with $p \in \mathcal{S}$ and $p \geq 2$. Suppose that for all topics $l \in \cup_{j=1}^{p-1} \mathcal{J}_j$, $\lim_{t \rightarrow \infty} \mathbf{y}_l(t) = \mathbf{y}_l^*$ exponentially fast, where \mathbf{y}_l^* is the vector of final opinions. We need to show that for all topics k in \mathcal{J}_p , there exists a vector $\mathbf{y}_k^* \in \mathbb{R}^n$ such that there holds $\lim_{t \rightarrow \infty} \mathbf{y}_k(t) = \mathbf{y}_k^*$ exponentially fast. Look at the p -th block row of matrix \mathbf{A} . Suppose first that $\bar{\mathbf{A}}_{pq} = \mathbf{0}$ for $q < p$. Since $\mathbf{C}_{pp,i}$ is irreducible for any $i \in \mathcal{I}$, then by the analysis in Part 1 of this proof, we conclude that for every $k \in \mathcal{J}_p$, there exists a $\mathbf{y}_k^* \in \mathbb{R}^n$ such that $\lim_{t \rightarrow \infty} \mathbf{y}_k(t) = \mathbf{y}_k^*$ exponentially fast. Next, suppose to the contrary, that there exists a $q < p$ such that $\bar{\mathbf{A}}_{pq} \neq \mathbf{0}$. Because $\mathcal{G}[\mathbf{C}_{pp,i}], \forall i \in \mathcal{I}$ are strongly connected and aperiodic, one can apply Lemma 3 to obtain that $\mathcal{G}[\bar{\mathbf{A}}_{pp}]$ is strongly connected and aperiodic, i.e. $\bar{\mathbf{A}}_{pp}$ is irreducible. Let $|\bar{\mathbf{A}}_{pp}|$ be the matrix whose ij^{th} entry is the absolute value of the ij^{th} entry of $\bar{\mathbf{A}}_{pp}$. Since $\bar{\mathbf{A}}_{pp}$ is irreducible, then $|\bar{\mathbf{A}}_{pp}|$ is also irreducible. Because there exists $q < p$ such that $\bar{\mathbf{A}}_{pq} \neq \mathbf{0}$, we conclude that $|\bar{\mathbf{A}}_{pp}|$ is row-substochastic. It follows from Lemma 2 that $\rho(|\bar{\mathbf{A}}_{pp}|) < 1$. Using the triangle inequality, verify that the ij^{th} entry of $|\bar{\mathbf{A}}_{pp}^k|$ is less than or equal to the ij^{th} entry of $|\bar{\mathbf{A}}_{pp}|^k$. Thus

$$\|\bar{\mathbf{A}}_{pp}^k\|_\infty = \| |\bar{\mathbf{A}}_{pp}^k| \|_\infty \leq \| |\bar{\mathbf{A}}_{pp}|^k \|_\infty.$$

It follows that

$$\lim_{k \rightarrow \infty} \|\bar{\mathbf{A}}_{pp}^k\|_\infty^{1/k} \leq \lim_{k \rightarrow \infty} \| |\bar{\mathbf{A}}_{pp}|^k \|_\infty^{1/k},$$

which in turn implies that $\rho(\bar{\mathbf{A}}_{pp}) \leq \rho(|\bar{\mathbf{A}}_{pp}|) < 1$. Recall that at the start of the induction step, we assumed that for all $l \in \cup_{j=1}^{p-1} \mathcal{J}_j$ (with $p \in \mathcal{S}$ and $p \geq 2$), there exists $\mathbf{y}_l^* \in \mathbb{R}^n$ such that $\lim_{t \rightarrow \infty} \mathbf{y}_l(t) = \mathbf{y}_l^*$ exponentially fast. Combining this assumption with the fact that $\rho(\bar{\mathbf{A}}_{pp}) < 1$, we conclude

that for every $k \in \mathcal{J}_p$, there exists a $\mathbf{y}_k^* \in \mathbb{R}^n$ such that $\lim_{t \rightarrow \infty} \mathbf{y}_k(t) = \mathbf{y}_k^*$ exponentially fast.

The invariance property in which $y_i^p(0) \in [-1, 1]$ for all $i \in \mathcal{I}$ and $p \in \mathcal{J}$ implies $y_i^p(t) \in [-1, 1]$ for all $t \geq 0$ and $i \in \mathcal{I}$ and $p \in \mathcal{J}$ was proved in [20], using the fact that $\sum_{q=1}^n |c_{pq,i}| = 1$ as detailed in Assumption 1. \square

B. Analysis for Subsection III-B

Here, we present a supporting result that links the structural balance of the graph $\mathcal{G}[\mathbf{A}]$ to the structural balance of $\mathcal{G}[\mathbf{C}_i], i \in \mathcal{I}$, which will be used to help prove the main result on consensus for irreducible \mathbf{C}_i .

First, we introduce additional graph-theoretic concepts. For a given (possibly signed) graph \mathcal{G} , an undirected cycle is a cycle of \mathcal{G} that ignores the direction of the edges, and an undirected cycle is negative if it contains an odd number of edges with negative edge weight. A signed graph \mathcal{G} is structurally unbalanced if and only if it has at least one negative undirected cycle [29].

We now establish several additional properties of how the entries $c_{ij,k}$ of \mathbf{C}_k relate to edges in $\mathcal{G}[\mathbf{A}]$.

Lemma 4. For the graph $\mathcal{G}[\mathbf{A}]$ with node set $\mathcal{V}[\mathbf{A}] = \{v_1, \dots, v_{nm}\}$, let $\mathcal{V}_p = \{v_{(p-1)n+1}, \dots, v_{pn}\}$, $p \in \mathcal{J}$ be defined as the set of nodes of the subgraph $\mathcal{G}[\mathbf{A}_{pp}]$. Suppose that Assumptions 1, 2 and 3 hold. Then,

- 1) For every $p \in \mathcal{J}$, $\mathcal{G}[\mathbf{A}_{pp}]$ is strongly connected and aperiodic with positive edge weights.
- 2) There is an edge from node $v_{(q-1)n+j}$ to $v_{(p-1)n+i}$ if and only if $w_{ij} > 0$ and $c_{pq,i} \neq 0$. Moreover, the weight of the edge the same sign as the sign of $c_{pq,i}$.
- 3) If $c_{pq,k} \neq 0 \forall k \in \mathcal{I}$, then with $p \neq q$, every node in \mathcal{V}_p has an incoming edge from a node \mathcal{V}_q , and every node in \mathcal{V}_q has an outgoing edge to a node in \mathcal{V}_p .

Proof. First, recall that $\mathbf{A}_{pq} \triangleq \text{diag}(c_{pq})\mathbf{W}$ as below Eq. (9).

Item 1): From Assumption 1, we know that $c_{pp,i} > 0 \forall i \in \mathcal{I}$ and $p \in \mathcal{J}$. This implies that $\mathbf{A}_{pp} \sim \mathbf{W}$ and $\mathbf{A}_{pp} \geq 0$ with all positive diagonals, which implies that $\mathcal{G}[\mathbf{A}_{pp}]$ is strongly connected and aperiodic.

Item 2): Notice that \mathbf{A}_{pq} is nonzero if and only if $c_{pq,i} \neq 0, i \in \mathcal{I}$. Moreover, the ij^{th} entry of a nonzero \mathbf{A}_{pq} is nonzero if and only if $w_{ij} > 0$, and has the same sign as $c_{pq,i}$. Recall that we defined node subsets $\mathcal{V}_p = \{v_{(p-1)n+1}, \dots, v_{pn}\}$, $p \in \mathcal{J}$ for the graph $\mathcal{G}[\mathbf{A}]$. It follows that an edge from node $v_{(q-1)n+j} \in \mathcal{V}_q$ to $v_{(p-1)n+i} \in \mathcal{V}_p$ exists if and only if $w_{ij} > 0$ and $c_{pq,i} \neq 0$, and has the same sign as $c_{pq,i}$.

Item 3): This statement is obtained by (i) recalling the definition of the node set $\mathcal{V}_p = \{v_{(p-1)n+1}, \dots, v_{pn}\}$, $p \in \mathcal{J}$, (ii) observing that an irreducible \mathbf{W} implies that for any $i \in \mathcal{I}$, there exists a $j \in \mathcal{I}, i \neq j$ such that $w_{ij} > 0$, and (iii) by applying Item 2). \square

We now turn to study of the structural balance of $\mathcal{G}[\mathbf{A}]$ and its relation to the structural balance of the $\mathcal{G}[\mathbf{C}_i]$ s.

Lemma 5. Suppose that Assumptions 1, 2, and 3 hold. Suppose further that \mathbf{C}_i for all $i \in \mathcal{I}$ are irreducible. The following hold:

- 1) If there are no individuals with competing logical interdependencies, as given in Definition 1, then $\mathcal{G}[\mathbf{A}]$ is structurally balanced if and only if $\mathcal{G}[\mathbf{C}_i], \forall i \in \mathcal{I}$ are structurally balanced.
- 2) If there are individuals with competing logical interdependencies, then $\mathcal{G}[\mathbf{A}]$ is structurally unbalanced.

Proof. We prove each statement separately.

Part 1: Consider the case where there are no individuals with competing logical interdependencies. Since, for any $p, q \in \mathcal{J}$, $c_{pq,i}$ for all $i \in \mathcal{I}$ are of the same sign, it follows that all graphs $\mathcal{G}[\mathbf{C}_i]$ have the same structural balance or unbalance property. Moreover, because the structural balance or unbalance property of any graph depends on the sign, and not the magnitude, of its edge weights, let us consider $\mathcal{G}[\mathbf{C}_1]$ for convenience. For brevity, we also drop the subscript 1 and simply write $\mathcal{G}[\mathbf{C}]$ for *Part 1* of this proof, with node set $\mathcal{V}_{\mathbf{C}} = \{v_{c,1}, \dots, v_{c,m}\}$. To establish the result, we will exploit Lemma 4. For each $p \in \mathcal{J}$, consider the subgraph $\mathcal{G}[\mathbf{A}_{pp}]$ of $\mathcal{G}[\mathbf{A}]$. Item 1) of Lemma 4 tells us that every edge in $\mathcal{G}[\mathbf{A}_{pp}]$ has a positive weight, while Item 2) and Item 3) of Lemma 4 establish that the edge weights for all edges from $\mathcal{G}[\mathbf{A}_{qq}]$ to $\mathcal{G}[\mathbf{A}_{pp}]$ have the same sign as the sign of the weight for the edge $(v_{c,q}, v_{c,p})$ in $\mathcal{G}[\mathbf{C}]$.

With these properties in mind, consider a structurally unbalanced $\mathcal{G}[\mathbf{C}]$; since $\mathcal{G}[\mathbf{C}]$ is strongly connected, the unbalance property implies there is at least one negative directed cycle. Without loss of generality, consider the negative cycle

$$(v_{c,p}, v_{c,z_1}), (v_{c,z_1}, v_{c,z_2}), \dots, (v_{c,z_r}, v_{c,p}) \quad (23)$$

with $z_1, \dots, z_r \in \mathcal{J}$ and $r \geq 1$. Let $u \in \mathbb{N}$ be the odd number of negative edges in the undirected cycle. From Item 2) and 3) of Lemma 4, and using the fact that $w_{ii} > 0 \forall i \in \mathcal{I}$, we find that there is an undirected cycle in $\mathcal{G}[\mathbf{A}]$ given as

$$\pi = (v_{(p-1)n+i}, v_{(z_1-1)n+i}), (v_{(z_1-1)n+i}, v_{(z_2-1)n+i}), \dots, \\ (v_{(z_r)n+i}, v_{(p-1)n+i}).$$

The undirected cycle π contains precisely u edges with negative weight, which implies that π is a negative cycle. It follows that $\mathcal{G}[\mathbf{A}]$ is structurally unbalanced.

Next, consider a structurally balanced $\mathcal{G}[\mathbf{C}]$, and assume without loss of generality that the nodes are ordered such that they can be partitioned into disjoint sets $\mathcal{V}^+ = \{v_{c,1}, \dots, v_{c,s}\}$ and $\mathcal{V}^- = \{v_{c,s+1}, \dots, v_{c,m}\}$, with $1 \leq s < m$. The two sets have the property that each edge between two nodes in \mathcal{V}^+ or \mathcal{V}^- has positive weight, while each edge between a node in \mathcal{V}^+ and a node in \mathcal{V}^- has negative weight. Without loss of generality, consider an undirected cycle, π , in $\mathcal{G}[\mathbf{A}]$ starting and ending at a node \bar{v} in the subgraph $\mathcal{G}[\mathbf{A}_{11}]$. We are going to show that any such π is not a negative undirected cycle. If π traverses only nodes in $\mathcal{G}[\mathbf{A}_{11}]$, then clearly all edges on the path have positive weight. Suppose instead that π is such that it traverses at least one node in each of the subgraphs $\mathcal{G}[\mathbf{A}_{11}], \mathcal{G}[\mathbf{A}_{z_1 z_1}], \dots, \mathcal{G}[\mathbf{A}_{z_r z_r}]$, with $z_1, \dots, z_r \in \mathcal{J}$ and $r \geq 1$ (by the definition of an undirected cycle, each node in the cycle apart from \bar{v} is distinct). If $v_{c,z_1}, \dots, v_{c,z_r} \in \mathcal{V}^+$, then we conclude from Item 2) and 3) of Lemma 4 that all edges in π have positive weight. In both cases, π is not a negative undirected

cycle. Now suppose that z_1, \dots, z_k , with $k < r$, are such that $v_{c,z_1}, \dots, v_{c,z_k} \in \mathcal{V}^-$. Notice that for any two nodes \tilde{v} and \hat{v} in the subgraphs $\mathcal{G}[\mathbf{A}_{pp}], p \in \{1, \dots, s\}$, a path from \tilde{v} to \hat{v} which traverses nodes in the subgraphs $\mathcal{G}[\mathbf{A}_{qq}], q \in \{s+1, \dots, m\}$ has an even number of edges with negative weight. This is because $v_{c,p} \in \mathcal{V}^+, p \in \{1, \dots, s\}$ and $v_{c,q} \in \mathcal{V}^-, q \in \{s+1, \dots, m\}$. From the fact that $\bar{v} \in \mathcal{G}[\mathbf{A}_{11}]$, one can use this previous property to show that there exist nonnegative integers u_1, \dots, u_k such that the number of edges in π with negative weight is precisely $\sum_{v=1}^k 2u_v + 2$. It follows that there are an even number of edges with negative weight in π , meaning π is not a negative undirected cycle. This analysis holds for every undirected cycle in $\mathcal{G}[\mathbf{A}]$. We conclude that there does not exist a negative undirected cycle in $\mathcal{G}[\mathbf{A}]$, which implies that $\mathcal{G}[\mathbf{A}]$ is structurally balanced.

We have thus proved that there exists an undirected negative cycle in $\mathcal{G}[\mathbf{A}]$ if and only if there exists an undirected negative cycle in $\mathcal{G}[\mathbf{C}]$, which implies the structural balance or unbalance of $\mathcal{G}[\mathbf{A}]$ is the same as that of $\mathcal{G}[\mathbf{C}_i], \forall i \in \mathcal{I}$.

Part 2: Consider now the case when there are individuals with competing logical interdependencies. Suppose that there exist individuals j, k such that $c_{pq,j} > 0$ and $c_{pq,k} < 0$ has negative sign (i.e. there are competing logical interdependencies in topic p). From Item 1) of Lemma 4, we know that the subgraph $\mathcal{G}[\mathbf{A}_{pp}]$ is strongly connected and all edges between nodes within $\mathcal{G}[\mathbf{A}_{pp}]$ have positive weight. From Item 2) and Item 3) of Lemma 4, and because $w_{ii} > 0$ for all i , we observe that $\mathcal{G}[\mathbf{A}]$ has an undirected cycle

$$(v_{(q-1)n+j}, v_{(p-1)n+j}), (v_{(p-1)n+j}, v_{(p-1)n+z_1}), \dots, \\ (v_{(p-1)n+z_r}, v_{(p-1)n+k}), (v_{(p-1)n+k}, v_{(q-1)n+k}), \\ (v_{(q-1)n+k}, v_{(q-1)n+z_r}), \dots, (v_{(q-1)n+z_1}, v_{(q-1)n+j})$$

with $z_1, \dots, z_r \in \mathcal{I}$ and $r \geq 1$. The single negative edge in this undirected cycle is $(v_{(p-1)n+k}, v_{(q-1)n+k})$, which means the undirected cycle is negative. It follows that $\mathcal{G}[\mathbf{A}]$ is structurally unbalanced. \square

C. Proof of Theorem 3

We first prove Statement 1). If there are no competing logical interdependencies and $\mathcal{G}[\mathbf{C}_i], \forall i \in \mathcal{I}$ are structurally balanced, then $\mathcal{G}[\mathbf{A}]$ is structurally balanced according to Lemma 5. According to [11, Theorem 1], for almost all initial conditions the system Eq. (10) converges to a nonzero modulus consensus, i.e. $\lim_{t \rightarrow \infty} |y_p^i(t)| = |y_q^j(t)| \neq 0$ for all $i, j \in \mathcal{I}$ and $p, q \in \mathcal{J}$. It remains to prove that $\lim_{t \rightarrow \infty} \mathbf{y}_k(t) = \alpha_k \mathbf{1}_n, \forall k \in \mathcal{J}$.

For a structurally balanced $\mathcal{G}[\mathbf{A}]$, the nodes $v_i \in \mathcal{V}$ can be partitioned into two disjoint sets \mathcal{V}^+ and \mathcal{V}^- , where every edge between nodes in the same set has positive weight, and every edge between nodes of \mathcal{V}^+ and \mathcal{V}^- has negative weight. Item 1) of Lemma 4 implies that for any $k \in \mathcal{J}$, the nodes $v_{(k-1)n+1}, \dots, v_{kn}$ all belong in either \mathcal{V}^+ or \mathcal{V}^- . Recalling that the node $v_{(k-1)n+i}$ corresponds to the variable y_k^i , and from [11, Theorem 1], it follows that $\lim_{t \rightarrow \infty} y_k^i(t) = y_k^j(t)$ for all $i, j \in \mathcal{I}$, and thus $\lim_{t \rightarrow \infty} \mathbf{y}_k = \alpha_k \mathbf{1}_n$ for every $k \in \mathcal{J}$.

Statements 2) and 3) can be proved simultaneously. If there are no competing logical interdependencies, and $\mathcal{G}[\mathbf{C}_i], \forall i \in$

\mathcal{I} are structurally unbalanced then according to Lemma 5, $\mathcal{G}[\mathbf{A}]$ is structurally unbalanced. Similarly, if there are competing logical interdependencies, then according to Lemma 5, $\mathcal{G}[\mathbf{A}]$ is also structurally unbalanced. From [11, Theorem 2], there holds $\lim_{t \rightarrow \infty} \mathbf{y}(t) = \mathbf{0}_{nm}$ exponentially fast. This completes the proof of the theorem. \square

D. Proof of Corollary 1

Recall from Appendix B that the structural balance or unbalance property of any graph depends on the sign, and not the magnitude, of its edge weights. Since $\mathcal{G}[\mathbf{C}_i], \forall i \in \mathcal{I}$ are structurally balanced, we can consider $\mathcal{G}[\mathbf{C}_1]$ for convenience. For brevity, we also drop the subscript 1 and simply write $\mathcal{G}[\mathbf{C}]$. Partition the nodes v_1, \dots, v_m of $\mathcal{G}[\mathbf{C}]$ into two disjoint sets $\mathcal{V}[\mathbf{C}]^+$ and $\mathcal{V}[\mathbf{C}]^-$ such that every edge between nodes in the same set has positive weight, and every edge between nodes of different sets has negative weight.

Since $\mathcal{G}[\mathbf{A}]$ is structurally balanced, let us also partition the nodes \tilde{v}_k of $\mathcal{G}[\mathbf{A}]$ into two disjoint sets \mathcal{V}^+ and \mathcal{V}^- such that every edge between nodes in the same set has positive weight, and every edge between nodes of different sets has negative weight. We know from Lemma 4 Item 1) and Lemma 5 that the nodes $\tilde{v}_{(p-1)n+1}, \dots, \tilde{v}_{pn}$ of $\mathcal{G}[\mathbf{A}]$ all belong in either \mathcal{V}^+ or \mathcal{V}^- . Recall from Item 2) and 3) of Lemma 4 that the weights of the edges from subgraph $\mathcal{G}[\mathbf{A}_{qq}]$ to subgraph $\mathcal{G}[\mathbf{A}_{pp}]$, with $p \neq q$ and $p, q \in \mathcal{J}$, have the same sign as the edges in $\mathcal{G}[\mathbf{C}]$ from v_q to v_p . One can then use the analysis in [11] and Theorem 3, Statement 1), to verify that $\alpha_p = \alpha_q$ if v_p and v_q are either both in $\mathcal{V}[\mathbf{C}]^+$ or both in $\mathcal{V}[\mathbf{C}]^-$. If, on the other hand, $v_q \in \mathcal{V}[\mathbf{C}]^+$ and $v_p \in \mathcal{V}[\mathbf{C}]^-$, then $\alpha_p = -\alpha_q$. \square

E. Proof of Theorem 4

First, observe that if $\mathcal{J}_j = \{p\}$ is a singleton, then the block diagonal matrix $\bar{\mathbf{A}}_{pp}$ in Eq. (21) is in fact $\bar{\mathbf{A}}_{pp} = \mathbf{A}_{pp} = \text{diag}(c_{pp})\mathbf{W}$, where $\text{diag}(c_{pq}), p, q \in \mathcal{J}$ is defined below Eq. (9). Since $0 < c_{pp,i} < 1$ for all $i \in \mathcal{I}$, and \mathbf{W} is row-stochastic, we have that $\|\mathbf{A}_{pp}\|_\infty < 1 \Rightarrow \rho(\mathbf{A}_{pp}) < 1$. This implies that $(\mathbf{I}_n - \mathbf{A}_{pp})^{-1}$ exists. Letting $\hat{\mathcal{J}}_p$ be the set of topics that topic p logically depends upon, as defined in Eq. (13), the vector $\mathbf{y}_p(t)$ converges exponentially fast to

$$\lim_{t \rightarrow \infty} \mathbf{y}_p(t) \triangleq \mathbf{y}_p^* = (\mathbf{I}_n - \mathbf{A}_{pp})^{-1} \left(\sum_{j \in \hat{\mathcal{J}}_p} \mathbf{A}_{pj} \mathbf{y}_j^* \right). \quad (24)$$

We now focus on proving that \mathbf{y}_p^* reaches a consensus state if and only if Eq. (14) holds for some $\alpha_p \in [-1, 1]$. Let $\mathbf{R}_{pp} = \mathbf{I}_n - \mathbf{A}_{pp}$, and because \mathbf{W} is row-stochastic, one obtains that $\mathbf{A}_{pq} \mathbf{1}_n = \text{diag}(c_{pq}) \mathbf{1}_n$ for any $q, p \in \mathcal{J}$ and $\mathbf{R}_{pp} \mathbf{1}_n = (\mathbf{I}_n - \text{diag}(c_{pp})) \mathbf{1}_n$. We use this observation several times below.

Sufficiency: Because $\mathcal{J}_j = \{p\}$, we can obtain from Eq. (11) that $c_{pq,i} = 0$ for every $q > p$. Combining this with Assumption 1 yields $1 - c_{pp,i} = \sum_{q \in \hat{\mathcal{J}}_p} |c_{pq,i}|$. This implies that if there exists a $\kappa \in [-1, 1]$ satisfying Eq. (14) for all $i \in \mathcal{I}$, then $\sum_{q \in \hat{\mathcal{J}}_p} \alpha_q \text{diag}(c_{pq}) = \kappa (\mathbf{I}_n - \text{diag}(c_{pp}))$. Recalling that by the theorem hypothesis $\mathbf{y}_q^* = \alpha_q \mathbf{1}_n$ for every $q \in \hat{\mathcal{J}}_p$, Eq. (24) then yields

$$\mathbf{y}_p^* = \mathbf{R}_{pp}^{-1} \left(\sum_{q \in \hat{\mathcal{J}}_p} \alpha_q \text{diag}(c_{pq}) \right) \mathbf{1}_n = \kappa \mathbf{1}_n.$$

This also shows that $\alpha_p = \kappa$.

Necessity: Suppose in order to obtain a contradiction, that $\mathbf{y}_p^* = \alpha_p \mathbf{1}_n$ for some α_p and there does not exist a $\kappa \in [-1, 1]$ satisfying Eq. (14) for all $i \in \mathcal{I}$. Substituting $\mathbf{y}_p^* = \alpha_p \mathbf{1}_n$ into the left hand side of Eq. (24), we obtain

$$\alpha_p \mathbf{1}_n = \mathbf{R}_{pp}^{-1} \left(\sum_{q \in \hat{\mathcal{J}}_p} \alpha_q \text{diag}(c_{pq}) \right) \mathbf{1}_n$$

Multiplying both sides by \mathbf{R}_{pp} yields

$$\alpha_p (\mathbf{I}_n - \text{diag}(c_{pp})) \mathbf{1}_n = \left(\sum_{q \in \hat{\mathcal{J}}_p} \alpha_q \text{diag}(c_{pq}) \right) \mathbf{1}_n. \quad (25)$$

However, Eq. (25) implies that for all $i \in \mathcal{I}$, there holds

$$\alpha_p \sum_{q \in \hat{\mathcal{J}}_p} |c_{pq,i}| = \sum_{q \in \hat{\mathcal{J}}_p} \alpha_q c_{pq,i}. \quad (26)$$

Clearly, this contradicts the assumption made at the start of the proof of necessity: there does not exist a $\kappa \in [-1, 1]$ satisfying Eq. (14) for all $i \in \mathcal{I}$. This completes the proof. \square

F. Proof of Corollary 2

We prove each statement of Corollary 2 separately. First, note that $|\alpha_q| \leq 1$, which implies that the quantity on the right hand side of Eq. (14) is in $[-1, 1]$ for every $i \in \mathcal{I}$.

Statement 1): For the proof of sufficiency, suppose that there are no competing logical interdependencies in topic p . Then, $\alpha_q c_{pq,i}$ has the same sign for every $i \in \mathcal{I}$ and since $\hat{\mathcal{J}}_p = \{q\}$, $\kappa = \alpha_q \text{sgn}(c_{pq,i}) \in [-1, 1]$ satisfies Eq. (14), where the signum function $\text{sgn} : \mathbb{R} \rightarrow \{-1, 0, 1\}$ satisfies $\text{sgn}(x) = 1$ if $x > 0$, $\text{sgn}(x) = 0$ if $x = 0$, and $\text{sgn}(x) = -1$ if $x < 0$.

For the proof of necessity, suppose that there are competing logical interdependencies in topic p , and suppose $c_{pq,1} > 0$ and $c_{pq,2} < 0$ (see below Eq. (7) on why we can make this assumption without loss of generality). Then, $\text{sgn}(\alpha_q c_{pq,1}) = -\text{sgn}(\alpha_q c_{pq,2})$, which implies that there does not exist a κ such that Eq. (14) simultaneously holds for $i = 1$ and $i = 2$.

Statement 2): The proof is trivial, since the right hand side of Eq. (14) is zero for all $i \in \mathcal{I}$.

Statement 3): The condition $c_{pqk,i} = c_{pqk,j} = c_{pqk}$ for all $k \in \{1, \dots, r\}$ and $i, j \in \mathcal{I}$ implies that

$$\frac{\sum_{q \in \hat{\mathcal{J}}_p} \alpha_q c_{pq,i}}{\sum_{q \in \hat{\mathcal{J}}_p} |c_{pq,i}|} = \frac{\sum_{q \in \hat{\mathcal{J}}_p} \alpha_q c_{pq,j}}{\sum_{q \in \hat{\mathcal{J}}_p} |c_{pq,j}|} \quad (27)$$

for any $i, j \in \mathcal{I}$, which means that a $\kappa \in [-1, 1]$ exists satisfying Eq. (14) for all $i \in \mathcal{I}$.

Statement 4): Observe that proving the existence of a $\kappa \in [-1, 1]$ satisfying Eq. (14) is equivalent to finding a $\kappa \in [-1, 1]$ such that

$$\sum_{k=1}^r \alpha_{q_k} \mathbf{z}_k = \kappa \sum_{k=1}^r \Xi_k \mathbf{z}_k \quad (28)$$

where $\mathbf{z}_k = [c_{pqk,1}, \dots, c_{pqk,n}]^\top$, and Ξ_k is a diagonal matrix with i^{th} diagonal entry being $\text{sgn}(c_{pqk,i})$. Because we assumed that $|\alpha_{q_u}| = |\alpha_{q_v}|$ for all $u, v \in \{1, \dots, r\}$, let $\bar{\alpha} \triangleq |\alpha_{q_k}|$.

In the case of (i), where $\text{sgn}(c_{pqk,i}) = \text{sgn}(\alpha_{qk})$ for every $k \in \{1, \dots, r\}$, it follows that $\alpha_{qk} \mathbf{z}_k = \bar{\alpha} \Xi_k \mathbf{z}_k$. Rearranging Eq. (28) yields

$$\mathbf{0}_n = \sum_{k=1}^r (\kappa - \bar{\alpha}) \Xi_k \mathbf{z}_k. \quad (29)$$

Since $\bar{\alpha} \in [-1, 1]$, choosing $\kappa = \bar{\alpha}$ ensures that Eq. (28) holds. The proof for case (ii) is the same, except that $\alpha_{qk} \mathbf{z}_k = -\bar{\alpha} \Xi_k \mathbf{z}_k$ and one selects $\kappa = -\bar{\alpha}$ to satisfy Eq. (28). \square

G. Proof of Theorem 5

First, note that for any $p, q \in \mathcal{J}$, $\mathbf{A}_{pq} \mathbf{1}_n = \text{diag}(c_{pq}) \mathbf{1}_n$, where $\text{diag}(c_{pq})$ has been defined below Eq. (9). For notational convenience, let $\mathcal{J}_j = \{k_1, \dots, k_{s_j}\}$ with $s_j \geq 2$. In other words, we replace for brevity $\sum_{i=1}^j s_{i-1} + p$ in Eq. (12) with k_p , for $p = 1, \dots, s_j$. We proved in Theorem 2 that $\rho(\bar{\mathbf{A}}_{jj}) < 1$ for every $j \in \mathcal{S}$ which, combined with the assumption that $\mathbf{y}_q^* = \alpha_q \mathbf{1}_n$, $\alpha_q \in [-1, 1]$ for all $q \in \tilde{\mathcal{J}}_j$, yields

$$\begin{bmatrix} \mathbf{y}_{k_1}^* \\ \vdots \\ \mathbf{y}_{k_{s_j}}^* \end{bmatrix} = (\mathbf{I}_{ns_j} - \bar{\mathbf{A}}_{jj})^{-1} \begin{bmatrix} \sum_{q \in \tilde{\mathcal{J}}_j} \alpha_q \text{diag}(c_{k_1 q}) \mathbf{1}_n \\ \vdots \\ \sum_{q \in \tilde{\mathcal{J}}_j} \alpha_q \text{diag}(c_{k_{s_j} q}) \mathbf{1}_n \end{bmatrix} \quad (30)$$

where $\mathbf{y}_k^* = \lim_{t \rightarrow \infty} \mathbf{y}_k(t)$ for $k \in \mathcal{J}_j$.

Sufficiency: Observe that, for any $k \in \mathcal{J}_j$, there holds

$$\sum_{r \in \mathcal{J}_j \setminus \{k\}} |c_{kr,i}| + \sum_{q \in \tilde{\mathcal{J}}_j} |c_{kq,i}| = 1 - c_{kk,i}. \quad (31)$$

This implies that if there exist $\phi_k \in [-1, 1]$ such that Eq. (16) holds for every $k \in \mathcal{J}_j$ and $i \in \mathcal{I}$, then

$$\phi_k (1 - c_{kk,i}) - \sum_{r \in \mathcal{J}_j \setminus \{k\}} \phi_r c_{kr,i} = \sum_{q \in \tilde{\mathcal{J}}_j} \alpha_q c_{kq,i}. \quad (32)$$

One can verify that Eq. (32) holding for every $k \in \mathcal{J}_j$ and $i \in \mathcal{I}$ is equivalent to the following equality:

$$(\mathbf{I}_{ns_j} - \bar{\mathbf{C}})(\Phi \otimes \mathbf{I}_n) \mathbf{1}_{ns_j} = \begin{bmatrix} \sum_{q \in \tilde{\mathcal{J}}_j} \alpha_q \text{diag}(c_{k_1 q}) \mathbf{1}_n \\ \vdots \\ \sum_{q \in \tilde{\mathcal{J}}_j} \alpha_q \text{diag}(c_{k_{s_j} q}) \mathbf{1}_n \end{bmatrix} \quad (33)$$

where $\Phi \in \mathbb{R}^{s_j}$ is a diagonal matrix with i^{th} diagonal entry ϕ_{k_i} and

$$\bar{\mathbf{C}} = \begin{bmatrix} \text{diag}(c_{k_1 k_1}) & \dots & \text{diag}(c_{k_1 k_{s_j}}) \\ \vdots & \ddots & \vdots \\ \text{diag}(c_{k_{s_j} k_1}) & \dots & \text{diag}(c_{k_{s_j} k_{s_j}}) \end{bmatrix}. \quad (34)$$

Next, observe that

$$\begin{aligned} \bar{\mathbf{C}}(\Phi \otimes \mathbf{I}_n)(\mathbf{1}_{s_j} \otimes \mathbf{1}_n) &= \bar{\mathbf{C}}(\Phi \otimes \mathbf{W})(\mathbf{1}_{s_j} \otimes \mathbf{1}_n) \\ &= \bar{\mathbf{C}}(\mathbf{I}_{s_j} \otimes \mathbf{W})(\Phi \otimes \mathbf{I}_n)(\mathbf{1}_{s_j} \otimes \mathbf{1}_n) \\ &= \bar{\mathbf{A}}_{jj}(\Phi \otimes \mathbf{I}_n)(\mathbf{1}_{s_j} \otimes \mathbf{1}_n) \end{aligned} \quad (35)$$

with the first equality obtained by recalling that $\mathbf{W} \mathbf{1}_n = \mathbf{1}_n$, and the last equality obtained by verifying from Eq. (22) that $\bar{\mathbf{A}}_{jj} \triangleq \bar{\mathbf{C}}(\mathbf{I}_{s_j} \otimes \mathbf{W})$. Returning to Eq. (30), it follows that

$$\begin{aligned} \begin{bmatrix} \mathbf{y}_{k_1}^* \\ \vdots \\ \mathbf{y}_{k_{s_j}}^* \end{bmatrix} &= (\mathbf{I}_{ns_j} - \bar{\mathbf{A}}_{jj})^{-1} (\mathbf{I}_{ns_j} - \bar{\mathbf{C}})(\Phi \otimes \mathbf{I}_n) \mathbf{1}_{ns_j} \\ &= (\Phi \otimes \mathbf{I}_n) \mathbf{1}_{ns_j}, \end{aligned} \quad (36)$$

with the first equality obtained by substituting in the left hand side of Eq. (33), and the last equality obtained from Eq. (35). It follows that $\mathbf{y}_k^* = \phi_k \mathbf{1}_n$ for every $k \in \mathcal{J}_j$.

Necessity: To obtain a contradiction, suppose that for every $p \in \{1, \dots, s_j\}$, (i) there do not exist $\phi_{k_1}, \dots, \phi_{k_{s_j}} \in [-1, 1]$ such that Eq. (16) holds for all $i \in \mathcal{I}$, and (ii) there holds $\mathbf{y}_{k_p}^* = \alpha_{k_p} \mathbf{1}_n$ for some $\alpha_{k_p} \in [-1, 1]$. Note that $\alpha_{k_p} \in [-1, 1]$ is a consequence of the invariance property of Eq. (10) (see Theorem 2). Eq. (30) yields

$$\begin{bmatrix} \alpha_{k_1} \mathbf{1}_n \\ \vdots \\ \alpha_{k_{s_j}} \mathbf{1}_n \end{bmatrix} = (\mathbf{I}_{ns_j} - \bar{\mathbf{A}}_{jj})^{-1} \begin{bmatrix} \sum_{q \in \tilde{\mathcal{J}}_j} \alpha_q \text{diag}(c_{k_1 q}) \mathbf{1}_n \\ \vdots \\ \sum_{q \in \tilde{\mathcal{J}}_j} \alpha_q \text{diag}(c_{k_{s_j} q}) \mathbf{1}_n \end{bmatrix} \quad (37)$$

Let $\bar{\alpha}$ be a diagonal matrix with i^{th} diagonal entry α_{k_i} . Recalling that $\bar{\mathbf{A}}_{jj} \triangleq \bar{\mathbf{C}}(\mathbf{I}_{s_j} \otimes \mathbf{W})$, we multiply both sides of Eq. (37) by $\mathbf{I}_{ns_j} - \bar{\mathbf{A}}_{jj}$. Simplifying using calculations similar to those appearing in Eq. (35) but with $\bar{\alpha}$ replacing Φ , we obtain

$$(\mathbf{I}_{ns_j} - \bar{\mathbf{C}})(\bar{\alpha} \otimes \mathbf{I}_n) \mathbf{1}_{ns_j} = \begin{bmatrix} \sum_{q \in \tilde{\mathcal{J}}_j} \alpha_q \text{diag}(c_{k_1 q}) \mathbf{1}_n \\ \vdots \\ \sum_{q \in \tilde{\mathcal{J}}_j} \alpha_q \text{diag}(c_{k_{s_j} q}) \mathbf{1}_n \end{bmatrix} \quad (38)$$

Notice that Eq. (38) is equivalent to

$$\alpha_k (1 - c_{kk,i}) - \sum_{r \in \mathcal{J}_j \setminus \{k\}} \alpha_r c_{kr,i} = \sum_{q \in \tilde{\mathcal{J}}_j} \alpha_q c_{kq,i} \quad (39)$$

holding for all $k \in \mathcal{J}_j$ and $i \in \mathcal{I}$. Using the equality in Eq. (31), observe that Eq. (39) is in turn equal to

$$\begin{aligned} \alpha_k \left(\sum_{r \in \mathcal{J}_j \setminus \{k\}} |c_{kr,i}| + \sum_{q \in \tilde{\mathcal{J}}_j} |c_{kq,i}| \right) \\ = \sum_{r \in \mathcal{J}_j \setminus \{k\}} \alpha_r c_{kr,i} + \sum_{q \in \tilde{\mathcal{J}}_j} \alpha_q c_{kq,i}. \end{aligned} \quad (40)$$

However, Eq. (40) contradicts the assumption made at the start of this (necessity) part of the proof: there do not exist $\phi_{k_1}, \dots, \phi_{k_{s_j}} \in [-1, 1]$ such that Eq. (16) holds for every $k_p \in \mathcal{J}_j$ and $i \in \mathcal{I}$. This completes the proof. \square

H. Proof of Corollary 3

We prove each item separately.

Item 1: This result can be immediately obtained by checking Eq. (16) with $\alpha_q = 0$ for all $q \in \tilde{\mathcal{J}}_j$.

Item 2: First, note that C_i is of the form in Eq. (11), which implies that $c_{ka,i} = 0$ for all $k \in \mathcal{J}_j$, $a > \max \mathcal{J}_j$, and $i \in \mathcal{I}$. Let \bar{A}_{jj} be defined as in Eq. (22). Similar to the proof of Theorem 5, let $\mathcal{J}_j = \{k_1, \dots, k_{s_j}\}$ with $s_j \geq 2$. Supposing that there holds $c_{kp,g} = c_{kp,h} = c_{kp}$ for $k \in \mathcal{J}_j$ and $p \in \mathcal{J}$, define

$$\bar{C} = \begin{bmatrix} c_{k_1 k_1} & \cdots & c_{k_1 k_{s_j}} \\ \vdots & \ddots & \vdots \\ c_{k_{s_j} k_1} & \cdots & c_{k_{s_j} k_{s_j}} \end{bmatrix}. \quad (41)$$

Then, $I - \bar{A}_{jj} = I_{n_{s_j}} - \bar{C} \otimes W$. Since $\rho(\bar{A}_{jj}) < 1$, we obtain from the Neumann series that $(I - \bar{A}_{jj})^{-1} = \sum_{t=0}^{\infty} \bar{A}_{jj}^t = \sum_{t=0}^{\infty} \bar{C}^t \otimes W^t$. Let $|\bar{C}|$ be the matrix whose ij^{th} entry is the absolute value of the ij^{th} entry of \bar{C} . Assumption 1 and the fact that $\mathcal{J}_j \neq \emptyset$ implies that $|\bar{C}|$ is row-substochastic. Using calculations similar to those at the end of Appendix A, one can show that $\rho(\bar{C}) < 1$, which establishes the existence of $\sum_{t=0}^{\infty} \bar{C}^t$.

Define for $p \in \{1, \dots, s_j\}$, $\tilde{\alpha}_{k_p} = \sum_{q \in \mathcal{J}_j} \alpha_q c_{k_p q}$, and observe that

$$\begin{bmatrix} \sum_{q \in \mathcal{J}_j} \alpha_q \text{diag}(c_{k_1 q}) \mathbf{1}_n \\ \vdots \\ \sum_{q \in \mathcal{J}_j} \alpha_q \text{diag}(c_{k_{s_j} q}) \mathbf{1}_n \end{bmatrix} = \tilde{\alpha} \otimes \mathbf{1}_n, \quad (42)$$

where $\tilde{\alpha} = [\tilde{\alpha}_{k_1}, \dots, \tilde{\alpha}_{k_{s_j}}]^\top$. We obtain from Eq. (30) that

$$\begin{bmatrix} \mathbf{y}_{k_1}^* \\ \vdots \\ \mathbf{y}_{k_{s_j}}^* \end{bmatrix} = \left(\sum_{t=0}^{\infty} \bar{C}^t \otimes W^t \right) \tilde{\alpha} \otimes \mathbf{1}_n = \left(\sum_{t=0}^{\infty} \bar{C}^t \tilde{\alpha} \right) \otimes \mathbf{1}_n \quad (43)$$

since W^t is a row-stochastic matrix for any $t \in \mathbb{N}$. We have thus concluded that the right hand side of Eq. (43) is equal to $\mathbf{u} \otimes \mathbf{1}_n$ for $\mathbf{u} = \sum_{t=0}^{\infty} \bar{C}^t \tilde{\alpha} \in \mathbb{R}^{s_j}$. This implies that for every $k \in \mathcal{J}_j$, we have $\mathbf{y}_k^* = \alpha_k \mathbf{1}_n$ for some $\alpha_k \in [-1, 1]$. \square

Mengbin Ye (S'13-M'18) was born in Guangzhou, China. He received the B.E. degree (with First Class Honours) in mechanical engineering from the University of Auckland, Auckland, New Zealand in 2013, and the Ph.D. degree in engineering at the Australian National University, Canberra, Australia in 2018. He is currently a postdoctoral fellow with the Faculty of Science and Engineering, University of Groningen, Netherlands.

He has been awarded the Springer PhD Thesis Prize, and was Highly Commended in the Best Student Paper Award at the 2016 Australian Control Conference. His current research interests include opinion dynamics and social networks, consensus and synchronisation of Euler-Lagrange systems, and localisation using bearing measurements.

Ming Cao is currently Professor of systems and control with the Engineering and Technology Institute (ENTEG) at the University of Groningen, the Netherlands, where he started as a tenure-track Assistant Professor in 2008. He received the Bachelor degree in 1999 and the Master degree in 2002 from Tsinghua University, Beijing, China, and the Ph.D. degree in 2007 from Yale University, New Haven, CT, USA, all in Electrical Engineering. From September 2007 to August 2008, he was a Postdoctoral Research Associate with the Department of

Mechanical and Aerospace Engineering at Princeton University, Princeton, NJ, USA. He worked as a research intern during the summer of 2006 with the Mathematical Sciences Department at the IBM T. J. Watson Research Center, NY, USA.

He is the 2017 and inaugural recipient of the Manfred Thoma medal from the International Federation of Automatic Control (IFAC) and the 2016 recipient of the European Control Award sponsored by the European Control Association (EUCA). He is an Associate Editor for IEEE Transactions on Automatic Control, IEEE Transactions on Circuits and Systems and Systems and Control Letters, and for the Conference Editorial Board of the IEEE Control Systems Society. He is also a member of the IFAC Technical Committee on Networked Systems. His research interests include autonomous agents and multi-agent systems, mobile sensor networks and complex networks.

Ji Liu (S'09-M'13) received the B.S. degree in information engineering from Shanghai Jiao Tong University, Shanghai, China, in 2006, and the Ph.D. degree in electrical engineering from Yale University, New Haven, CT, USA, in 2013. He is currently an Assistant Professor in the Department of Electrical and Computer Engineering at Stony Brook University, Stony Brook, NY, USA. Prior to joining Stony Brook University, he was a Postdoctoral Research Associate at the Coordinated Science Laboratory, University of Illinois at Urbana-Champaign, Urbana,

IL, USA, and the School of Electrical, Computer and Energy Engineering, Arizona State University, Tempe, AZ, USA. His current research interests include distributed control and computation, distributed optimization and learning, multi-agent systems, social networks, epidemic networks, and cyber-physical systems.

Lili Wang received the B.E. and M.S. degrees from Zhejiang University, Zhejiang, China, in 2011 and 2014, respectively. She is currently a Ph.D. student majored in electrical engineering in the School of Engineering & Applied Science, Yale University, USA. Her research is on the topic of cooperative multi-agent systems and distributed observer.

Brian D.O. Anderson (M'66-SM'74-F'75-LF'07) was born in Sydney, Australia. He received the B.Sc. degree in pure mathematics in 1962, and B.E. in electrical engineering in 1964, from the Sydney University, Sydney, Australia, and the Ph.D. degree in electrical engineering from Stanford University, Stanford, CA, USA, in 1966.

He is an Emeritus Professor at the Australian National University, and a Distinguished Researcher in Data61-CSIRO (previously NICTA) and a Distinguished Professor at Hangzhou Dianzi University.

His awards include the IEEE Control Systems Award of 1997, the 2001 IEEE James H Mulligan, Jr Education Medal, and the Bode Prize of the IEEE Control System Society in 1992, as well as several IEEE and other best paper prizes. He is a Fellow of the Australian Academy of Science, the Australian Academy of Technological Sciences and Engineering, the Royal Society, and a foreign member of the US National Academy of Engineering. He holds honorary doctorates from a number of universities, including Université Catholique de Louvain, Belgium, and ETH, Zürich. He is a past president of the International Federation of Automatic Control and the Australian Academy of Science. His current research interests are in distributed control, sensor networks and econometric modelling.
