Abstract

Three independent components of critical current density, one for the H//c axis and the other two for the H//ab plane, have been studied in CaKFe₄As₄ single crystals. When the magnetic field is applied along the *c* axis, we observed fish-tail-like peaks in the *M*-*H* hysteresis loop, and the magnetization at higher temperatures exceeds that at lower temperatures at high fields. When the field is applied parallel to the *ab* plane, a dip structure is observed in the *M*-*H* hysteresis loop near the self-field. In addition, for the H//ab plane, we succeeded in separately evaluating the large and significantly anisotropic in-plane and out-of-plane J_c . Transmission electron microscopy revealed the presence of planar defects parallel to the *ab* plane in CaKFe₄As₄, which have not been observed in any other iron-based superconductors. We discuss the possible relationship between the anomalous J_c behavior and the planar defects.

Introduction

The discovery of iron-based superconductors (IBSs) in 2008 [1] has prompted great interest not only in their unconventional superconducting mechanism with high transition temperatures, but also in their potential for applications. The most attractive material for applications among various kinds of IBSs is the 122-type (Ba,K)Fe₂As₂. It has a high transition temperature T_c of ~38 K for bulk [2], high upper critical field, H_{c2} (> 700 kOe) [3,4], and small anisotropy ($\gamma < 2$) [4]. It has also been demonstrated that the critical current density (J_c) in 122-type IBS single crystals exceeds 1 × 10⁶ A /cm² [5], and it can be enhanced further by introducing artificial defects [5–10].

Recently, a new type of IBSs, i.e., 1144-type with CaKFe₄As₄ as one of their representatives, has been found [11]. Its crystal structure is similar to 122-type compounds. CaKFe₄As₄ has a tetragonal structure (*P4/mmm*), where the Ca and K layers stack alternatively along the *c* axis [11,12]. Several properties of 1144-type compounds have been studied such as superconducting gap state [13,14], penetration depth [15,16], pressure effects on crystal structure [17,18], and so on. CaKFe₄As₄ shows similar superconducting properties to those of optimally doped (Ba,K)Fe₂As₂. *T_c* is approximately 35 K and *H_{c2}* is larger than 630 kOe [12]. However, alternate stacking of Ca and K along the *c* axis may lead to different physical properties. The characteristic properties of CaKFe₄As₄ caused by the unique crystal structure and common properties similar to that of 122-type compounds, such as large critical current density, should be evaluated.

In this study, phase-pure CaKFe₄As₄ single crystals are synthesized and detailed superconducting properties including anisotropic J_c are evaluated. We observed a non-monotonic temperature dependence of in-plane J_c . When the magnetic field is applied parallel to the *ab*-plane, a pronounced dip structure in the magnetization hysteresis loop around the self-field is also observed. Furthermore, we find a very large anisotropy between the in-plane and out-of-plane J_c when the field is applied parallel to the *ab*-plane. Transmission electron microscopy revealed the presence of planar defects along the *ab*-plane, which naturally explains the large anisotropy of J_c when the field is applied parallel to the *ab*-plane.

Experimental details

Single crystals of CaKFe₄As₄ were synthesized by the self-flux method using FeAs. We used Ca pieces (99.5%), K ingots (99.5%), and FeAs powder as starting materials. FeAs was prepared by sealing stoichiometric amounts of As grains (6N) and Fe powder (99.9%) in an evacuated quartz tube and reacting them at 900 °C for 10 h after heating at 500 °C for 10 h. A mixture with a ratio of Ca : K : FeAs = 1 : 1.2 : 10 was placed in an alumina crucible in an argon-filled glove box. The alumina crucible was sealed in a tantalum tube using the arc melting method. The tantalum tube was sealed in an evacuated quartz tube. The whole assembly was heated for 5 h at 1180 °C after a preliminary heating at 650 °C for 5 h, and cooled to 1050 °C at a rate of 26 °C/h, followed by cooling

to 930 °C at a rate of 1.5 °C/h for the crystal growth. Bulk magnetization was measured by a superconducting quantum interference device (SQUID) magnetometer (MPMS-5XL, Quantum Design). For the evaluation of two components of J_c for the H//ab plane, samples were cut into a rectangular shape using a focused ion beam. Electrical resistivity was measured with a Quantum Design physical property measurement system (PPMS) in the ac mode. For magneto-optical (MO) imaging, an iron-garnet indicator film was placed in direct contact with the sample surface and the whole assembly was attached to the cold finger of a He-flow cryostat (Microstat-HR, Oxford Instruments). MO images were acquired by using a cooled-CCD camera with 12-bit resolution (ORCA-ER, Hamamatsu). Cross-sectional observations of the single crystals were performed with a high-resolution scanning transmission electron microscopy (STEM; JEOL, JEM-2100F). The specimens to analyze using TEM were prepared by digging and milling using a focused-ion beam (FIB), which is called the microsampling technique. The final milling using FIB was conducted at an acceleration voltage of 30 kV and with a very weak ion current of approximately 10 pA without tilting the specimen. The phase identification was carried out by means of powder x-ray diffraction (XRD) with Cu-K α radiation (Smartlab, Rigaku).

Experimental Results

Figure 1(a) shows the temperature dependence of magnetization at 5 Oe for a CaKFe₄As₄ single crystal. As shown in the inset of Fig. 1(a), T_c defined by the onset of diamagnetism is 36.0 K and ΔT_c is less than 1 K. The superconducting transition is also confirmed by the temperature dependence of electrical resistivity as shown in Fig. 1(b). The residual resistivity ratio (RRR) defined by the ratio of resistivity just above T_c and that at room temperature, $\rho(300 \text{ K})/\rho(36 \text{ K})$, is 15.2. This value is consistent with the former report by Meier *et al.* with $\rho(300 \text{ K})/\rho(36 \text{ K}) \sim 15$ [12]. The residual resistivity $\rho(0 \text{ K}) = 3.8 \ \mu\Omega \text{ cm}$ is evaluated using the data between 36 and 50 K by fitting to the formula $\rho(T) = \rho(0 \text{ K}) + AT^2$. All these data indicate that our crystals are highly pure.

Figures 2(a) and 2(b) show the in-plane electrical resistivity for the H//c axis and H//ab plane measured at various magnetic fields up to 90 kOe. It is clear that the superconducting transition for the H//c axis shifts rapidly to lower temperatures compared to that for the H//ab plane. The anisotropy parameter $\gamma = H_{c2}^{ab}/H_{c2}^{c}$ is evaluated from the temperature dependence of $H_{c2}(T)$. The temperature dependences of H_{c2} are summarized in Fig. 2(c). The definitions of T_c onset and T_c end are shown in Fig. 2(a). Estimated γ at $T \sim 34$ K is 2.2. This value is consistent with the former report by Meier *et al.* [12], and similar to that of 122-type compounds of (Ba,K)Fe₂As₂ with $\gamma \sim 2-3$ near T_c [4].

Next we performed magneto-optical (MO) imaging of a CaKFe₄As₄ single crystal to evaluate its homogeneity and the value of in-plane J_c . Figure 3(c) shows an optical micrograph of the crystal, which shows a smooth surface with no visible cracks. Figures 3(a) and 3(b) display MO images of

the CaKFe₄As₄ single crystal in the remanent state at (a) 5 K and (b) 35 K, respectively, after cycling the field up to 1.6 kOe for 0.2 s. At 5 K, the magnetic field does not fully penetrate the sample because of large J_c and limitation of the value of the applied field. On the other hand, the magnetic field fully penetrates the sample at 35 K, and the MO image shows the critical state field profile expected for a uniform thin-plate superconductor with clear current discontinuity lines (*d*-lines). Local magnetic induction profiles at different temperatures taken along the dotted line in Fig. 3(a) are shown in Fig. 3(d). Magnetic induction profiles at higher temperatures of 30 and 35 K show roof-top patterns, indicating that the large and homogeneous current flows throughout the sample. At lower temperatures, however, the magnetic induction profiles are saturated around 700 G because of large J_c and the saturation of the magnetization of the indicator film. From the value of the trapped field, J_c can be roughly evaluated [19]. At 30 K, magnetic induction ΔB of 580 G is trapped. Using the approximate formula of $J_c \sim \Delta B / (t * \beta)$ with t = 0.00048 cm being the thickness of the sample (β is a parameter determined by the sample dimensions and the setting of the garnet film, and $\beta = 3.64$ in the present case) [19], J_c at 30 K under the self-field is evaluated as 0.33 MA/cm².

In-plane J_c in a CaKFe₄As₄ single crystal was also evaluated from magnetization measurements by applying the magnetic field along the c-axis using the extended Bean model [5,20,21]. The inset of Fig. 4 shows the magnetic field dependence of magnetization at various temperatures. Evaluated J_c as a function of temperature is summarized in Fig. 4. J_c at 2 K under the self-field and 40 kOe are approximately 1.6 and 0.18 MA/cm², respectively. These values of J_c are between those of Co-doped BaFe₂As₂ [7] and K-doped BaFe₂As₂ [8]. The value of J_c at 30 K under the self-field is 0.29 MA/cm². This value is consistent with that evaluated from the analysis of the MO image. Figure 4 also shows the magnetic field dependence of in-plane J_c at various temperatures. The magnetic field dependence of J_c above 20 K becomes very weak, or J_c even show a broad maximum at higher fields. Such a non-monotonic field dependence of J_c is often referred to as the fish-tail effect and has been found in cuprate superconductors [22-25] and other IBSs [26-28]. In most cases, however, the evolution of the fish-tail peak is continuous and no crossings of M-H curves at different temperatures occur. The abrupt change of field dependence of J_c around 15 K may indicate the presence of crossover in the dominant pinning mechanisms, which could be related to the specific defect structure discussed later. As a result, J_c at higher temperatures (~20-25 K) becomes larger than that at lower temperatures (~5-15 K) above 20 kOe. In most IBSs, the increase of J_c at higher temperatures at a fixed field has not been observed except for over-doped BaFe₂(As,P)₂ [26].

Next, we evaluated the critical current density for the H//ab plane. As shown in Fig. 5(a) and 5(b), there are two independent critical currents in this configuration, one flowing in the *ab* plane and another flowing along the *c* axis. We tentatively designate the former as J_{c2} and the latter as J_{c3} . It is obvious that two components of J_c cannot be evaluated from a single *M*-*H* measurement. We made two independent *M*-*H* measurements for the H//ab plane at each temperature and evaluated J_{c2} and

 J_{c3} . The detailed scheme to calculate the J_{c2} and J_{c3} is described in the Supplemental Material [29]. *M-H* loops for the two in-plane field directions are shown in Fig. 5(c) and 5(d). Both magnetic hysteresis loops show dips around zero field. These dip structures are similar to those observed in superconductors with columnar defects [7] caused by the suppression of pinning due to misalignment of vortices from the direction of columnar defects [30]. The magnetic field dependence of J_{c2} and J_{c3} at various temperatures is summarized in Fig. 5(e) and 5(f), respectively. Calculated J_{c2} and J_{c3} near zero field and higher fields corresponding to the dip and return branch of the hysteresis loop in Fig. 5(c) and 5(d) are omitted. The evaluated J_{c2} and J_{c3} are highly anisotropic and larger than J_c when the magnetic field is applied along the *c* axis, as shown in Fig. 4. For example, J_{c} , J_{c2} , and J_{c3} at 2 K and 15 kOe are 0.4, 5.1, and 1.0 MA/cm², respectively. J_{c2} is five times larger than J_{c3} . This large anisotropy of J_c cannot be explained by the small anisotropy of $\gamma \sim 2.2$ determined by the resistivity measurements shown in figure 2.

First of all, let us summarize the fundamental properties of anisotropic (quasi two-dimensional) superconductors with effective mass m_{ab} and m_c for carrier motion along the ab plane and c axis. Let us define the anisotropy ratio $\gamma = (m_c/m_{ab})^{0.5}$. The resistivity ratio, ρ_c/ρ_{ab} , should be $m_c/m_{ab} = \gamma^2$. Anisotropic H_{c2} for H//c and H//ab are given by $\Phi_0/2\pi\xi_{ab}^2$ and $\Phi_0/2\pi\xi_{ab}\xi_c$, respectively. So the ratio of H_{c2} , $H_{c2}^{ab}/H_{c2}^{c} = \gamma$. The pinning force is described as a derivatives of pinning potential U with respect to characteristic length x, dU/dx. If the dimension of defects is large enough, U is independent of the direction of the vortex motion for H//ab. In this case, the larger coherence length indicates the smaller dU/dx. So the pinning force for J_{c2} or J_{c3} is inversely proportional to the out-plane coherence length ξ_c or the in-plane coherence length ξ_{ab} , respectively. That is why, $J_{c2}/J_{c3} = \xi_{ab} / \xi_c = \gamma$. In our crystal, estimated $\gamma = H_{c2}^{ab}/H_{c2}^{c} = \xi_{ab} / \xi_c = 2.2$. This simple consideration tells us that J_{c2}/J_{c3} should be 2.2. In addition to this simple consideration, one may need to consider the path for the critical current. When the defects are extended, the superconducting current can flow only in a narrow region between defects. In the present case, the width of the planar defects is larger than the height of it, which restricts the region for J_{c3} flowing parallel to the c axis, making J_{c3} even smaller than J_{c2} . Namely, J_{c2}/J_{c3} can be larger than γ .

To reveal the presence of anisotropic defects, observations by a high-resolution scanning transmission electron microscope (STEM) were performed. Figures 6(a) and 6(b) show STEM images on the cross section parallel and perpendicular to the *c* axis in CaKFe₄As₄, respectively. As shown in Fig. 6(a) and 6(b), planar defects are present in the whole area of the *ac* plane and *bc* plane. STEM images taken from the [100] and [010] directions are almost identical, suggesting that these defects are two-dimensional planar defects nearly parallel to the *ab*-plane. Each defect is ~50 x 10 nm², and is separated by ~50 nm and ~40 nm along the *ab*-plane and *c*-axis, respectively. These planar defects are observed as faint oval objects in the STEM image from the [001] direction, as shown in Fig. 6(c). These planar defects should produce significantly anisotropic J_c for the H//ab

plane since they suppress the motion of vortices along the *c* axis effectively, and block the current flow along the *c* axis. These planar defects along the *ab* plane are not observed in any other IBSs or even in cuprate superconductors, and their origin is still unclear. It should be noted that energy-dispersive x-ray (EDX) analyses of the elemental composition show no chemical inhomogeneities around these defects. Planar defects with ~2 nm height and 20 nm width can be observed from the higher resolution STEM image taken from the [100] direction as shown in Fig. 6(d). So they are not due to simple stacking disorder of Ca and K along the *c* axis.

Another supporting evidence for the planar defects is obtained from x-ray diffraction measurements. Figure 7 shows the single-crystal x-ray diffraction pattern of CaKFe₄As₄. Only the (00*l*) peaks are detected. Peaks with odd numbers of *l* are the evidence for the formation of a 1144-type structure in CaKFe₄As₄ [11]. Peaks from possible impurities such as KFe₂As₂ and CaFe₂As₂ are not observed. Despite the high phase purity of the crystal, the observed peaks are broad. The inset of Fig. 7 shows a comparison between the (008) peaks for the CaKFe₄As₄ and (Ba,K)Fe₂As₂ single crystals [31]. (Ba,K)Fe₂As₂ shows a sharp single set of (008) peaks from Cu K_{a1} and K_{a2}, while multiple (008) peaks are observed in CaKFe₄As₄. This indicates that the lattice constant along the *c* axis is inhomogeneous. It should be caused by inhomogeneous stacking periodicity along the *c* axis in CaKFe₄As₄ and is consistent with the presence of planar defects observed by STEM shown in Fig. 6(a).

Discussion

We found anomalous features of magnetic hysteresis loops in CaKFe₄As₄ single crystals. First, when the magnetic field is applied along the c-axis, magnetization at higher temperatures exceeds that at lower temperatures at high fields as shown in Fig. 4. One of the possible origins for that is field-induced pinning centers, which are effective only at high magnetic fields and high temperatures. Such field-induced pinning centers can be created due to the local distributions of T_c in the crystal such as KFe_2As_2 and $CaFe_2As_2$, which are possibly embedded as impurity phases in $CaKFe_4As_4$ [32]. They can pin vortices only at higher temperatures than their $T_{\rm c}$. Another possible origin for the anomalous temperature dependence of J_c is the presence of large-scale local variation of superconducting properties due to chemical inhomogeneities. However, as shown in Fig. 3, MO images clearly show no local variation of J_c in our crystal. In addition, as mentioned above, secondary phases were not detected from x-ray diffraction analyses. We infer that anomalous features of magnetic hysteresis loops are analogous to the fish-tail effect observed in other superconductors, such as cuprate [22-25] and iron-based superconductors [26-28]. For example, in the magnetization loop at 30 K, a dip at 5 kOe and broad peak at ~15 kOe are found. The origin of a fish-tail-like peak in IBSs is still not clear although it is suggested that a crossover from the collective to the plastic creep in field is the possible origin of the fish-tail peak in Ba(Fe,Co)₂As₂

[33]. A similar dip and peak in the hysteresis loop in $CaKFe_4As_4$ imply the same origin, although the phenomenon that magnetization at higher temperatures exceeds that at lower temperatures is very rare. Second, we have succeeded in evaluating two components of J_c when the field is applied along the *ab* plane. In this configuration, J_{c2} with current along the *ab* plane is more than five times larger than J_{c3} with current along the c axis. Anisotropic J_c for the H//ab plane has not been studied properly in other iron-based and even cuprate superconductors. For instance, $Ba(Fe,Co)_2As_2$ and Fe(Te,Se) single crystals are reported to show isotropic J_c [7, 34]. In these reports, J_c for the H//caxis has a similar value to that for the H//ab plane in 122 and 11 systems with the assumption that two components of J_c for the H//ab plane are equal. However, in CaKFe₄As₄, anisotropic J_c for the H/ab plane has been successfully evaluated since J_{c2} is much larger than J_{c3} . In all studies to date, J_{c2} and J_{c3} are assumed to be equal and only the "average" J_c for the H//ab plane has been evaluated, i.e., $J_{c2} = J_{c3} = 20\Delta M/\alpha l(1-\alpha/3)$ (see Supplemental Material [29]). Third, when the magnetic field is applied along the *ab*-plane, a significant dip structure around zero field is observed. This dip structure observed in CaKFe₄As₄ has not been observed in any other pristine iron-based superconductors such as Ba(Fe,Co)₂As₂ and Fe(Te,Se) [7, 34]. Similar dip structures in the magnetization hysteresis loop around the self-field are observed in cuprate and iron-based superconductors with columnar defects when the magnetic field is applied parallel to the defects [35-37]. The dip structure might be produced by inhomogeneous magnetic field distribution around the self-field [7] because the planar defects can also enhance pinning forces similar to columnar defects. However, this mechanism for the dip can only be realized when the magnetic field is applied perpendicular to the surface of thin crystals (H//c axis). When the magnetic field is applied along the large plane of the crystal, the demagnetization effect can be neglected. In such a case, the curvature of vortices due to the self-field is negligible and J_c cannot be suppressed near zero field. Considering the planar defects in CaKFe₄As₄, the possibility of the matching between thee magnetic field and the defect structure can be suggested. Enhancement of J_c is reported in superconducting films with a regular array of holes when the number of vortices matches with the number of holes [38,39]. The areal density of the observed defects shown in Fig. 6 is $1/(\sim 50 \times 40) = 5 \times 10^{-4} \text{ nm}^{-2}$, leading to the matching field of 10.3 kOe. This is very similar to the magnetic field range of the dip around the self-field shown in Fig. 5. In Fig. 8, we compared the characteristic value of fields in the hysteresis loops of M_1 and M_2 from Fig. 5(c) and 5(d). The widths of the return branch and $J_{c2}t$ or $J_{c3}\alpha l$ are comparable, respectively (see Supplemental Material [29]). It indicates that our evaluations of J_{c2} and J_{c3} were performed precisely. As shown in Fig. 8, at a glance, the field range of the dips seems to be correlated to the widths of the return branch since these values are almost the same. However, the temperature dependence of the characteristics field of the dip is weaker compared with the width of the return branch. The smaller temperature dependence suggests that the origin of the dip cannot be explained by the self-field effect. The matching effect may play a key role for the emergence of the

dip structure. It is also found that both J_{c2} and J_{c3} are larger than J_c for the H//c axis since planar defects parallel to the *ab* plane do not work as vortex pinning centers for J_c for the H//c axis. Needless to say, the very large J_c of CaKFe₄As₄ due to naturally-introduced defects is advantageous for applications. J_c can be further enhanced by introducing defects by particle irradiation. Actually, it has been demonstrated that J_c in the 122 system is enhanced significantly by swift particle irradiation [6]. Similar enhancements of J_c in CaKFe₄As₄ by 3 MeV proton and 800 MeV Xe irradiation have been confirmed, and details of these effects will be published in a presented elsewhere.

Finally, we comment on a recent report by Singh *et al.* on the same material [40]. Although the qualitative behavior of J_c in their report is similar to ours, the values of J_c evaluated by them are significantly larger than ours.

Conclusion

In summary, CaKFe₄As₄ single crystals were synthesized and their critical current density was characterized including its anisotropy. The sharp onset of diamagnetism with low residual resistivity demonstrates their high phase purity, and MO images confirmed uniform flow of the shielding current. When the magnetic field is applied along the *c* axis, the temperature dependence of J_c shows non-monotonic temperature dependence. We interpret this anomalous behavior as an enhanced fish-tail effect rather than field-induced pinning centers. From the magnetization measurements and their analyses for a magnetic field parallel to the *ab* plane, we have successfully evaluated two components of J_c , i.e., one parallel to the *ab* plane (J_{c2}) and another parallel to the *c* axis (J_{c3}). J_{c2} turns out to be much larger than J_{c3} and even larger that in-plane J_c for the magnetic field parallel to the *c* axis. TEM observations clarified the presence of planar defects along the *ab* plane. We interpret the strong enhancement of J_{c2} and J_{c3} at low fields due to the geometrical matching of vortices to these planar defects.

Fig. 1. (a) Temperature dependence of magnetization (*M*) at 5 Oe for CaKFe₄As₄ single crystal. The inset shows a blow-up of *M*-*T* near T_c . Dimensions of the sample are 0.138 x 0.083 x 0.0040 cm³. (b) Temperature dependence of electrical resistivity (ρ) for CaKFe₄As₄ single crystal. The inset shows a blow-up of ρ -*T* near T_c .

Fig. 2. Temperature dependence of electrical resistivity in CaKFe₄As₄ single crystal under various magnetic fields parallel to (a) *c* axis and (b) *ab* plane. (c) Anisotropic H_{c2} evaluated from temperature-dependent resistivity presented in (a) and (b).

Fig. 3. Differential MO images of CaKFe₄As₄ single crystal in the remanent state at (a) 5 K and (b) 35 K after cycling the field up to 1.6 kOe for 0.2 s. Dimensions of the sample are 0.036 x 0.030 x 0.0005 cm³. The spatial resolution of the MO image is approximately 1 μ m. (c) Optical micrograph of CaKFe₄As₄ single crystal. (d) Local magnetic induction profiles at different temperatures taken along the dotted line in (a). The yellow bar in (a) corresponds to 200 μ m.

Fig. 4. Magnetic field dependence of magnetic J_c in CaKFe₄As₄ single crystal at various temperatures for the field parallel to the *c* axis. The same sample was used for Fig. 1(a) and this figure. The inset shows the magnetic field dependence of the magnetization in CaKFe₄As₄ single crystal at various temperatures.

Fig. 5. Two components of critical current density J_{c2} and J_{c3} for fields parallel to the *ab* plane along (a) short and (b) long edges of the crystal. Dimension of the sample are 0.046 x 0.0094 x 0.0029 cm³. (c), (d) The magnetic field dependences of in-plane magnetization for the cases of (a) M_1 and (b) M_2 , respectively. (e), (f) The magnetic field dependences of J_{c2} and J_{c3} calculated from the analyses described in the Supplemental Material [29].

Fig. 6. STEM images of CaKFe₄As₄ for an electron beam injected along the (a) a axis, (b) b axis, and (c) c axis. Insets of (a) and (b) are the higher magnification image for the a-axis and b-axis injection, respectively. (d) Higher-resolution STEM image of CaKFe₄As₄ for an electron beam injected along the a axis. The solid lines in (a)-(c), dashed line in (d), and dotted line in the inset correspond to 200, 5, and 50 nm, respectively.

Fig. 7. Single-crystal x-ray diffraction pattern of $CaKFe_4As_4$. The inset shows a comparison of the (0 0 8) peaks for the $CaKFe_4As_4$ and $(Ba,K)Fe_2As_2$ single crystals.

Fig. 8. (a), (b) Temperature dependence of the field ranges of the return branches and dips, and products of J_{c2} and t and that of J_{c3} and αl , referred from the magnetization hysteresis loops in Figs. 5(c) and 5(d), respectively. The inset shows an example of the hysteresis loop, where an arrow and dotted arrow indicate the ranges of the return branch and dip, respectively. An arrow or dotted arrow indicates the range of a return branch or a dip, respectively.

Estimation of anisotropic critical current density J_c from magnetization measurements

1 Detail of analyses

Figure S1 : Rectangular samples in applying magnetic field (a) parallel to the c-axis and (b), (c) perpendicular to c-axis. Critical currents densities of J_{c2} and J_{c3} , corresponding d-lines are also described in each lower figures.

Here, we consider a critical state in a thin platelet superconductor (thickness t) with a layered structure and tetragonal symmetry with its symmetry axis along the *c*-axis. Without loss of generality, we assume that the length (l) of the sample is larger than the width $(w = \alpha l, 0 < \alpha < 1)$. When the magnetic field is applied parallel to the *c*-axis, tetragonal symmetry imposes isotropic in-plane critical current density, J_c , resulting in the current discontinuity line as shown in figure S1(b). J_c can be evaluated from ΔM , which is the width of M - H hysteresis loop, using the extended Bean model;

$$J_c = \frac{20\Delta M}{\alpha l(1 - \frac{\alpha}{3})} \tag{1}$$

On the other hand, when the magnetic field is applied parallel to the *ab*plane, we have two independent critical current densities, one along the *ab*-pane, J_{c2} , and another along the *c*-axis, J_{c3} as shown in figures S1(c) and (d). These two J_c generate *d*-lines on the lateral surface of the sample as shown in figures S1(e) and (f). In order to evaluate these two components of J_c , we need two independent magnetization measurements for fields along the short (M_1) and long (M_2) edges of the sample.

Figure S2 : (a)-(e) Schematic drawings of d lines and corresponding critical current densities of J_{c2} and J_{c3} . In right parts, conditions of $\frac{J_{c2}}{J_{c3}}$ are shown.

Figures S2(a)-(e) show several cases of *d*-lines on two orthogonal lateral surfaces when the magnetic field is applied parallel to the *ab*-plane. Numbers and locations of *d*-lines depend both on the ratios of the lengths of edges on the lateral surface, $\alpha \frac{l}{t}$, $\frac{l}{t}$, and the ratio of J_{c2} and J_{c3} . Conditions for the all *d*-line patterns are summarized in Figures S2(a)-(e). There are three cases; $0 < \frac{J_{c2}}{J_{c3}} < \alpha \frac{l}{t}$ (case 1), $\alpha \frac{l}{t} < \frac{J_{c2}}{J_{c3}} < \frac{l}{t}$ (case 2) and $\frac{J_{c2}}{J_{c3}} > \frac{l}{t}$ (case 3). ΔM_1 and ΔM_2 for the three cases are expressed by the following equations (2) and (3).

$$\Delta M_1 = \begin{cases} \frac{tJ_{c2}}{20} \left(1 - \frac{tJ_{c2}}{3lJ_{c3}}\right) & \left(0 < \frac{J_{c2}}{J_{c3}} < \frac{l}{t}; \text{case 1 and 2}\right) \\ \frac{lJ_{c3}}{20} \left(1 - \frac{lJ_{c3}}{3tJ_{c2}}\right) & \left(\frac{J_{c2}}{J_{c3}} > \frac{l}{t}; \text{case 3}\right) \end{cases}$$
(2)

$$\Delta M_2 = \begin{cases} \frac{tJ_{c2}}{20} \left(1 - \frac{tJ_{c2}}{3\alpha l J_{c3}} \right) & \left(0 < \frac{J_{c2}}{J_{c3}} < \alpha \frac{l}{t}; \text{case } 1 \right) \\ \frac{\alpha l J_{c3}}{20} \left(1 - \frac{\alpha l J_{c3}}{3t J_{c2}} \right) & \left(\frac{J_{c2}}{J_{c3}} > \alpha \frac{l}{t}; \text{case } 2 \text{ and } 3 \right) \end{cases}$$
(3)

Using ΔM_1 and ΔM_2 described in equations (2) and (3), J_{c2} and J_{c3} can be calculated for each case. For cases 1 and 3, J_{c2} and J_{c3} can be expressed

analytically as shown in equations (4), (5), (8) and (9). For case 2, however, cubic equations shown in equations (6) and (7) should be solved to obtain J_{c2} and J_{c3} .

Case 1 :
$$\left(0 < \frac{J_{c2}}{J_{c3}} < \alpha \frac{l}{t}\right)$$

$$J_{c2} = \frac{20(\alpha \Delta M_2 - \Delta M_1)}{t(\alpha - 1)}$$
(4)

$$J_{c3} = \frac{20(\alpha \Delta M_2 - \Delta M_1)^2}{3\alpha l(\alpha - 1)(\Delta M_2 - \Delta M_1)}$$
(5)

Case 2 :
$$\left(\alpha \frac{l}{t} < \frac{J_{c2}}{J_{c3}} < \frac{l}{t}\right)$$

 $\left(\frac{\alpha t^3}{3} - \frac{\alpha^2 t^3}{27}\right) J_{c2}^3 - 20 \left(\frac{\alpha t^2}{3} \Delta M_1 + t^2 \Delta M_2\right) J_{c2}^2 + 800 t \Delta M_1 \Delta M_2 J_{c2} - 8000 (\Delta M_1)^2 \Delta M_2 = 0$ (6)

$$\left(\frac{\alpha^3 l^3}{3} - \frac{\alpha^4 l^3}{27}\right) J_{c3}^3 - 20 \left(\alpha^2 l^2 \Delta M_1 + \frac{\alpha^2 l^2}{3} \Delta M_2\right) J_{c3}^2 + 800\alpha l \Delta M_1 \Delta M_2 J_{c3} - 8000 \Delta M_1 (\Delta M_2)^2 = 0$$
(7)

Case 3 : $\left(\frac{l}{t} < \frac{J_{c2}}{J_{c3}}\right)$

$$J_{c2} = \frac{20(\Delta M_2 - \alpha^2 \Delta M_1)^2}{3\alpha t (1 - \alpha)(\Delta M_2 - \alpha \Delta M_1)}$$
(8)

$$J_{c3} = \frac{20(\Delta M_2 - \alpha^2 \Delta M_1)}{\alpha l(1 - \alpha)} \tag{9}$$

When we evaluate J_{c2} and J_{c3} , we first need to decide which case's formula should be used. This is determined from experimentally obtained ΔM_1 and ΔM_2 data. Here we define $\sigma = \frac{J_{c2}}{J_{c3}}$ and $\mu(\sigma) = \frac{\Delta M_1}{\Delta M_2}$. From equations (2) and (3), $m(\sigma)$ is calculated as shown in equation (10).

$$\mu(\sigma) = \begin{cases} \frac{1 - \frac{t}{3l}\sigma}{1 - \frac{t}{3\alpha l}\sigma} & \left(0 < \sigma < \alpha \frac{l}{t}; \operatorname{case} 1\right) \\ \frac{t}{\alpha l}\sigma \frac{1 - \frac{t}{3l}\sigma}{1 - \frac{\alpha l}{3t}\frac{1}{\sigma}} & \left(\alpha \frac{l}{t} < \sigma < \frac{l}{t}; \operatorname{case} 2\right) \\ \frac{1}{\alpha} \frac{1 - \frac{l}{3t}\frac{1}{\sigma}}{1 - \frac{\alpha l}{3t}\frac{1}{\sigma}} & \left(\sigma > \frac{l}{t}; \operatorname{case} 3\right) \end{cases}$$
(10)

The derivatives of μ , $\frac{d\mu(\sigma)}{d\sigma}$ is positive in all cases. So $\mu(\sigma)$ should monotonically increase as a function of σ . Values of $\mu(\sigma)$ for special values of σ are summarized in equation (11).

$$\mu(\sigma) = \begin{cases} 1 & (\sigma \to 0) \\ \frac{3-\alpha}{2} & \left(\sigma = \alpha \frac{l}{t}\right) \\ \frac{2}{\alpha(3-\alpha)} & \left(\sigma = \frac{l}{t}\right) \\ \frac{1}{\alpha} & (\sigma \to \infty) \end{cases}$$
(11)

From these relations, three cases are redefined using μ , as summarized in table 1.

Table S1: Three cases of *d*-line patterns described using $\sigma = \frac{J_{c2}}{J_{c3}}$ or $\mu = \frac{\Delta M_1}{\Delta M_2}$

	2	
case	range of σ	range of μ
1	$0 < \sigma < \alpha \frac{l}{t}$	$1 < \mu < \frac{3-\alpha}{2}$
2	$\alpha \frac{l}{t} < \sigma < \frac{l}{t}$	$\frac{3-\alpha}{2} < \mu < \frac{2}{\alpha(3-\alpha)}$
3	$\sigma > \frac{l}{t}$	$\frac{2}{\alpha(3-\alpha)} < \mu < \frac{1}{\alpha}$

It should be noted that sometimes the value of μ is out of the range for three cases. For example, near the self-field and return branch at high fields, μ may show anomalous values due to strong field dependence of J_c or counter-flow of critical currents. When the sample is partially cleaved it is possible that μ is out range of the conditions. Furthermore, sample dimensions affect the range of μ . If α is close to 1, ranges of μ and σ are too narrow to analyze. In addition, if μ is close to α and $\frac{1}{\alpha}$, J_{c2} and J_{c3} diverge.

In summary, anisotropic J_{c2} and J_{c3} can be calculated using ΔM_1 and ΔM_2 from equations (4)-(9), which were evaluated from two independent magnetization measurements where magnetic fields are applied parallel to the *ab*-plane. Which case of formula should be used is decided by the value of $\mu(=\frac{\Delta M_1}{\Delta M_2})$. For proper evaluations of J_{c2} and J_{c3} , the dimensions of sample size should be carefully chosen.

2 Experiments

The details how we evaluated J_{c2} and J_{c3} is explained below. The dimensions of rectangular sample were $0.0464 \times 0.0094 \times 0.0029$ cm³. So l, t, and α are 0.0464, 0.0029, and 0.203, respectively. The values of $\frac{3-\alpha}{2}$, $\frac{2}{\alpha(3-\alpha)}$, and $\frac{1}{\alpha}$, are 1.399, 3.529, and 4.936, respectively. From two kinds of magnetization measurements, ΔM_1 and ΔM_2 were evaluated as shown in figures 5 (a) and (b) in the main text. Magnetic field dependences of $\frac{\Delta M_1}{\Delta M_2}$ at different temperatures are shown in figure S3. ΔM_1 and ΔM_2 are selected with reference to figure S3. When $\frac{\Delta M_1}{\Delta M_2}$ is less than unity, those data points were ignored. Evaluated J_{c2} and J_{c3} are summarized in figures S4 (a) and (b). In figure 5 (a) in the main text, reduction of magnetization around the self-field (-15 kOe ~ 15 kOe) and return branch at high fields (above 35 kOe and below -35 kOe) are observed.

As described in the previous section, the extended Bean model with a fieldindependent J_c cannot be adopted. So the data of J_{c2} and J_{c3} around self-field and return branch at high field are omitted in figures 5 (c) and (d) in the main text.

Figure S3 : Magnetic field dependence of $\frac{\Delta M_1}{\Delta M_2}$ at various temperatures. Red, blue, and green hatched areas indicate the case 1, 2, 3 respectively.

Figure S4 : Estimated magnetic field dependence of (a) J_{c2} (b) J_{c3} in CaKFe₄As₄ a single crystal at various temperatures.
