Abstract

An n-vertex graph is equitably k-colorable if there is a proper coloring of its vertices such that each color is used either $\lfloor n/k \rfloor$ or $\lceil n/k \rceil$ times. While classic VERTEX COLORING is fixed parameter tractable under well established parameters such as pathwidth and feedback vertex set, equitable coloring is W[1]-hard. We present an extensive study of structural parameterizations of EQUITABLE COLORING, tackling both tractability and kernelization questions. We begin by showing that the problem is fixed parameter tractable when parameterized by distance to cluster or by distance to co-cluster — improving on the FPT algorithm of Fiala et al. [Theoretical Computer Science, 2011] parameterized by vertex cover — and also when parameterized by distance to disjoint paths of bounded length. To justify the latter result, we adapt a proof of Fellows et al. [Information and Computation, 2011] to show that EQUITABLE COLORING is W[1]-hard when simultaneously parameterized by distance to disjoint paths and number of colors. In terms of kernelization, on the positive side we present a linear kernel for the distance to clique parameter and a cubic kernel when parameterized by the maximum leaf number; on the other hand, we show that, unlike VERTEX COLORING, EQUITABLE COLORING does not admit a polynomial kernel when jointly parameterized by vertex cover and number of colors, unless NP $\subseteq$ coNP/poly. We also revisit the literature and derive other results on the parameterized complexity of the problem through minor reductions or other observations.

1 Introduction

EQUITABLE COLORING is a variant of the classical VERTEX COLORING problem: we want to partition an n vertex graph into k independent sets such that each of these sets has either $\lfloor n/k \rfloor$ or $\lceil n/k \rceil$ vertices. The smallest integer k for which G admits an equitable k-coloring is called the *equitable chromatic number* of G. EQUITABLE COLORING was first discussed in [27], with an intended application for municipal garbage collection, and later in processor task scheduling [1], communication control [21], and server load balancing [29]. Lih [26] presented an

1

extensive survey covering many of the results developed in the last 50 years. Its focus, however, is not algorithmic, and most of the presented results are bounds on the equitable chromatic number for various graph classes.

Many complexity results for EQUITABLE COLORING arise from a related problem, known as BOUNDED COLORING, as observed by Bodlaender and Fomin [2]. On BOUNDED COLORING, we ask that the size of the independent sets be bounded by an integer ℓ. Among the positive results for BOUNDED COLORING, the problem is known to be solvable in polynomial time for: split graphs [9], complements of interval graphs [4], complements of bipartite graphs [4], and forests [1]. Baker and Coffman [1] present the first algorithm for BOUNDED COLORING on trees, while Jarvis and Zhou [23] show how to compute an optimal ℓ-bounded coloring of a tree through a novel characterization. For cographs, bipartite and interval graphs, there are polynomial-time algorithms when the number of colors k is fixed. In terms of parameterized complexity, in [2] an XP algorithm is given for EQUITABLE COLORING parameterized by treewidth, while Fiala et al. [16] show that the problem is FPT parameterized by vertex cover and Enciso et al. [13] show that it is FPT parameterized by the maximum leaf number. Recently, Gomes et al. [19] proved that, when parameterized by the treewidth of the complement graph, EQUITABLE COLORING is FPT. Reddy [28] proved that the problem is tractable when the parameter is the distance to *connected* threshold graphs, even though the connected qualifier is omitted in the claim; Another claim of [28] is that EQUITABLE COLORING admits a polynomial kernel when parameterized by distance to threshold and number of colors; the proof, however, only works for distance to *connected* threshold graphs. Our result in Section 9 shows that the original claim is false, i.e. there can be no polynomial kernel when the parameter is the distance to threshold graphs unless $\mathsf{NP} \subseteq \mathsf{coNP/poly}$.

The main contributions of this work are complexity results on EQUITABLE COLORING for parameterizations that are weaker than vertex cover, in the sense that the parameters are upper bounded by the vertex cover number, and a cubic kernel for the maximum leaf number parameterization. In particular, we show that EQUITABLE COLORING is fixed parameter tractable when parameterized by distance to cluster, distance to co-cluster, or by distance to disjoint paths of bounded length. Not only are the parameters weaker, but also in the first case, the algorithm is slightly faster than the one previously known for vertex cover, as it does not rely on INTEGER LINEAR PROGRAMMING; the running time, however, is still of the order of $2^{\mathcal{O}(k \log k)}$. On the negative side, we show that the combined parameterization distance to disjoint paths and number of colors is insufficient to guarantee tractability. Along with some of the works discussed here and in Section 2, our results cover many branches of the known graph parameter hierarchy [30].

Our results. In this work, we conduct a systematic study on the complexity of structural parameterizations for EQUITABLE COLORING. We begin by revisiting the literature in Section 2 and showing how previous work can be adapted in order to results on the parameterized complexity of EQUITABLE COLORING. Afterwards, our first technical contributions prove that the problem is fixed-parameter tractable when parameterized by distance to cluster and co-cluster; these algorithms are faster than the previously known FPT algorithm of Fiala et al. [16]. Still in terms of tractability, we improve on the reduction of Fellows

et al. [15] and show that, when parameterized by the distance to disjoint paths and number of colors, Equitable Coloring remains W[1]-hard. We then turn our attention to kernelization, by first showing that the problem admits a linear kernel when parameterized by distance to clique; we point out that the best known kernel for Vertex Coloring under this parameterization is quadratic. Afterwards, we present a cubic kernel when the max leaf number is the parameter. Finally, we adapt the reduction of Section 5 to show that, unless NP ⊆ coNP/poly, Equitable Coloring does not admit a polynomial kernel when jointly parameterized by vertex cover and number of colors; it is also worthy to note that Vertex Coloring admits a polynomial kernel under vertex cover [22]. Our contributions cover a large part of the graph parameter hierarchy [30]. We list the question of whether or not the problem is tractable under feedback edge set as our main open problem.

Notation and Terminology. We use standard graph theory notation and nomenclature for our parameters, following classical textbooks in the areas [5, 11]. Define $[k] = \{1, \ldots, k\}$ and 2^S the *powerset* of S. A *k-coloring* φ of a graph G is a function $\varphi : V(G) \mapsto [k]$. Alternatively, a k-coloring is a k-partition $V(G) \sim \{\varphi_1, \ldots, \varphi_k\}$ such that $\varphi_i = \{u \in V(G) \mid \varphi(u) = i\}$. A k-coloring is said to be *equitable* if, for every $i \in [k]$, $\lfloor n/k \rfloor \leq |\varphi_i| \leq \lceil n/k \rceil$; it is *proper* if every φ_i is an independent set. Unless stated, all colorings are proper. The Equitable Coloring problem asks whether or not G can be equitably k-colored. A graph G is a *subdivision* of a graph H if a graph isomorphic to G can be obtained by replacing some edges of H with paths of arbitrary length. A graph is a *cluster graph* if each of its connected components is a clique; a *co-cluster graph* is the complement of a cluster graph. The *distance to cluster* (*co-cluster*) of a graph G, denoted by $\mathsf{dc}(G)$ ($\mathsf{d\bar{c}}(G)$), is the size of the smallest set $U \subseteq V(G)$ such that $G - U$ is a cluster (co-cluster) graph. Using the terminology of [7], a set $U \subseteq V(G)$ is an $\mathcal{F}$-*modulator* of G if the graph $G - U$ belongs to the graph class $\mathcal{F}$. When the context is clear, we omit the qualifier $\mathcal{F}$. In particular, we say that U is a P_ℓ-modulator if each connected component of $G \setminus U$ has at most ℓ vertices and is a path. For cluster and co-cluster graphs, one can decide if G admits a modulator of size k in time FPT on k [6]. The *maximum leaf number*, often called the max leaf number and denoted by $\mathsf{ml}(G)$, is the maximum number of leaves on some spanning forest of G with as many connected components as G [14].

2   Literature corollaries and minor observations

The original NP-complete results of Bodlaender and Jansen [4], despite being initially regarded as polynomial reductions for Bounded Coloring, are a nice source of parameterized hardness. To adapt their proofs to show that Equitable Coloring parameterized by the number of colors is W[1]-hard on cographs and paraNP-hard on bipartite graphs, it suffices to consider the version of Bin-Packing where each bin must be completely filled for the first case, while the latter follows immediately since they prove that Bounded 3-Coloring is NP-hard on bipartite graphs; these imply that adding the distance to theses classes in the parameterization yields no additional power whatsoever. Fellows et al. [15] show that Equitable Coloring parameterized by treewidth and number of colors is W[1]-hard, while an XP algorithm parame-

terized by treewidth is given for both EQUITABLE COLORING and BOUNDED COLORING by Bodlaender and Fomin [2]. In fact, the reduction shown in [15] prove that, even when simultaneously parameterized by feedback vertex set, treedepth, and number of colors, EQUITABLE COLORING remains W[1]-hard. Gomes et al. [19] show that the problem parameterized by number of colors, maximum degree and treewidth is W[1]-hard on interval graphs. However, their intractability statement can be strengthened to number of colors and *bandwidth*, with no changes to the reduction. In [7], Cai proves that VERTEX COLORING is W[1]-hard parameterized by distance to split.

We also reviewed results on parameters weaker than distance to clique, since both distance to cluster and co-cluster fall under this category. For minimum clique cover, we resort to the classic result of Garey and Johnson [17] that PARTITION INTO TRIANGLES is NP-hard. By definition, a graph G can be partitioned into vertex-disjoint triangles if and only if its complement graph can be equitably $(n/3)$-colored. The reduction given in [17] is from EXACT COVER BY 3-SETS, and their gadget (which we reproduce in Figure 1) has the nice property that the complement graph $\overline{G}$ has a trivial clique cover of size nine: it suffices to pick one gadget i and one clique for each a_i^j. Thus, we have that EQUITABLE COLORING is paraNP-hard parameterized by minimum clique cover. To see that when also parameterizing by the number of colors there is an FPT algorithm, we first look at the parameterization maximum independent set α and number of colors k, both of which we assume to be given on the input. First, if $k\alpha < n$, the instance is trivially negative, so we may assume $k\alpha \geq n$; but, in this case, we can spend exponential time on the number of vertices and still run in FPT time. Finally, we reduce from EQUITABLE COLORING parameterized by the number of colors k to EQUITABLE COLORING parameterized by k and minimum dominating set. If we take the source graph G and add $\frac{n}{k}$ vertices $D = v_i, \ldots, v_{\frac{n}{k}}$ with $N(v_i) = V(G)$ for all $v_i \in D$, the set $\{v_1, u\}$, with $u \in V(G)$, is a dominating set of the resulting graph G'; moreover, G has an equitable k-coloring if and only if G' is equitably $(k+1)$-colorable, thus proving that EQUITABLE COLORING parameterized by k and minimum dominating set is paraNP-hard. A summary of the results discussed in this work is displayed in Figure 2.

Figure 1: EXACT COVER BY 3-SETS to PARTITION INTO TRIANGLES gadget of [17] representing the set $C_i = \{x_i, y_i, z_i\}$.
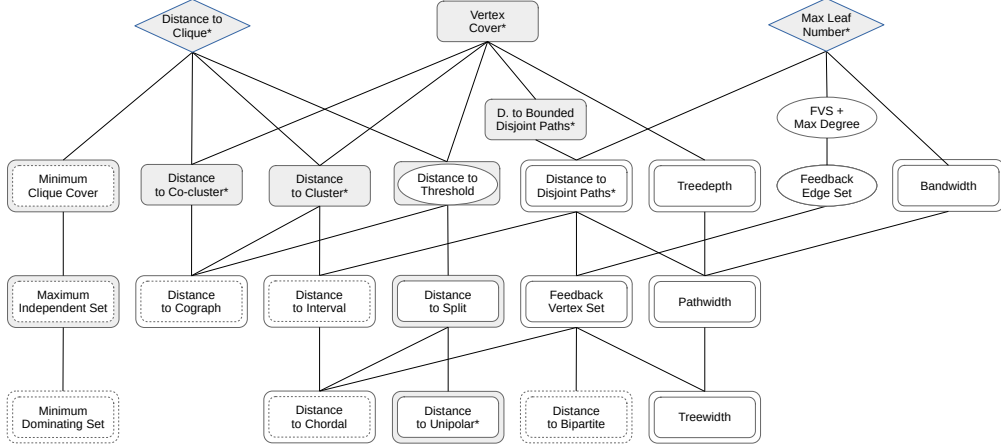

4

Figure 2: Hasse diagram of the parameterizations of EQUITABLE COLORING and their complexities. A single shaded box indicates that the problem is FPT, while a shaded rhombus highlights a case that admits a polynomial kernel; two solid boxes represent W[1]-hard even if also parameterized by the number of colors; if the inner box is dashed, the problem is paraNP-hard; if the outer box is solid and shaded, additionally using the number of colors results in an FPT algorithm; if it is not shaded, it remains W[1]-hard. Entries with a * are our main contributions. Ellipses mark open cases.

3 Equitable coloring parameterized by distance to cluster

The goal of this section is to prove that EQUITABLE COLORING can be solved in FPT time when parameterized by the distance to cluster of the input graph. As a corollary of this result, we show that unipolar graphs – the class of graphs that have a clique as a modulator – can be equitably k-colored in polynomial time. Throughout this section, we denote the modulator by U, the connected components of $G - U$ by $\mathcal{C} = \{C_1, \ldots, C_r\}$, and define $\ell = \left\lfloor \frac{n}{k} \right\rfloor$.

The central idea of our algorithm is to guess one of the possible $|U|^{|U|}$ colorings of the modulator and extend this guess to the clique vertices using max-flow. First, given U, $\mathcal{C}$, and a coloring φ' of U, we build an auxiliary graph H as follows: $V(H) = \{s, t\} \cup A \cup W \cup V(G) \setminus U$, where $A = \{a_1, \ldots, a_k\}$ represents the colors we may assign to vertices, $W = \{w_{ij} \mid i \in [k], j \in [r]\}$ whose role is to maintain the property of the coloring, s is the source of the flow, t is the sink of the flow, and $V(G) = \{v_1, \ldots, v_n\}$ are the vertices of G. For the arcs, we have $E(H) = S \cup F_0 \cup F_1 \cup R \cup T$, where $S = \{(s, a_i) \mid i \in [k]\}$, $F_0 = \{(a_i, t) \mid i \in [k]\}$, $F_1 = \{(a_i, w_{ij}) \mid i \in [k], j \in [r]\}$, $R = \{(w_{ij}, v_p) \mid v_p \in C_j, N(v_p) \cap \varphi_i' = \emptyset\}$, and $T = \{(v_i, t) \mid v_i \in V(G) \setminus U\}$. As to the capacity of the arcs, we define $c : E(H) \to \mathbb{N}$, with $c(e \in S) = \ell$, $c((a_i, t)) = |\varphi_i' \cap U|$ and $c(e \in F_1 \cup R \cup T) = 1$.

5

Semantically, the vertices of A correspond to the k colors, while each w_{ij} ensures that cluster C_j has at most one vertex of color i. Regarding the arcs, F_0 corresponds to the initial assignment of colors to the vertices of the modulator, and R encodes the adjacency between vertices of the clusters and colored vertices of the modulator. Note that the arcs in F_0 and R are the only ones affected by the pre-coloring φ'. An example of the constructed graph can be found in Figure 3.

Figure 3: (left) The input graph with $U = \{v_1, v_2\}$; (right) Auxiliary graph constructed from the precoloring of U. Solid arcs have unit capacity.

Now, let $f : E(H) \to \mathbb{N}$ be the function corresponding to the max-flow from s to t obtained using any of the algorithms available in the literature [10]. Our first observation, as given by the following lemma, is that, if no (s,t)-flow saturates the outbound arcs of s, then we cannot extend φ' to equitably k-color G.

Lemma 1. *If there is some $e \in S$ with $f(e) < \ell$, then G does not admit an equitable k-coloring that extends φ'.*

Proof. By contraposition, suppose that G admits an equitable k-coloring φ extending φ'. As such, there exists some coloring ψ satisfying $\varphi' \subset \psi \subset \varphi$ such that for all $i \in [k]$ we have $|\psi_i| = \ell$. To construct function f, begin by setting $f(e) = \ell$, for each $e \in S$. If $e = (a_i, t)$, i.e., $e \in F_0$, $f(e) = |\psi_i \cap U|$. For each $e \in T$ such that $e = (v, t)$ and v is colored by ψ, set $f(e) = 1$. For each $i \in [k], j \in [r]$, if $\psi_i \cap C_j \neq \emptyset$ then we set $f((a_i, w_{ij})) = 1$ and $f((w_{ij}, v)) = 1$, where v is the only element of $\psi_i \cap C_j$. Note that the arc (w_{ij}, v) exists since $v \in V(G) \setminus U$ belongs to clique C_j, has no neighbor with color i in U, and ψ is a coloring of G. All other arcs have $f(e) = 0$. To see that f corresponds to a feasible flow of H under c, first note that $f(e) \leq c(e)$ for every $e \in E(H)$ follows from the construction of f. To conclude the proof, it suffices to check that $\sum_{j \in [r]} f((a_i, w_{ij})) = \ell - |\psi \cap U|$, which must be the case, since $f((a_i, w_{ij})) = 1$ if and only if there is some $v \in C_j \cap \psi_i$. $\square$

We may now assume that $f(e) = c(e)$ for every $e \in S$. Let $c'(e \notin S) = c(e)$, $c'(e \in S) = c(e)+1$. We resume the search for augmenting paths on the network, replacing $c(\cdot)$ with $c'(\cdot)$, until it stops and returns the maximum (s,t)-flow g.

Lemma 2. *For every $e \in S$, $g(e) \geq f(e)$.*

Proof. Suppose that $g(e) < f(e)$ for some $e \in S$, than at some step the max-flow algorithm must have picked an augmenting path with an arc $e = (a_i, s)$, but this leads to a contradiction as the augmented path would not be simple. $\square$

6

Lemma 3. *The maximum (s,t)-flow F given by g is equal to the number of vertices of G if and only if there is an equitable k-coloring of G that extends φ'.*

Proof. Suppose that the maximum (s,t)-flow is $|V(G)|$. Reading the flow function to retrieve the coloring φ is straightforward: for each $(w_{ij}, v_p) \in R$ with $f((w_{ij}, v_p)) = 1$, color v_p with i. Since there is only one arc (v,t) with unit capacity, there is an unique i such that $v \in \varphi_i$. By Lemma 2, $\ell \leq |\varphi_i|$ and, since the capacity of each outbound arc of s is $\ell + 1$, $|\varphi_i| \leq \ell + 1$. That φ_i is a proper coloring follows from the hypothesis that φ' was a proper coloring of $G[U]$, the arcs in R encode the constraints that a vertex $v \in C_j$ cannot be colored with any of the colors $\{i \mid N(v) \cap \varphi_i \neq \emptyset\}$, and that only one vertex $v \in C_j$ satisfies $f((w_{ij}, v)) = 1$ since $c'((a_i, w_{ij})) = 1$. Finally, φ extends φ' since no vertex of U was recolored. For the converse, take an equitable k-coloring φ that extends φ' and define the flow function as in the proof of Lemma 1, but with $g((s, a_i)) = |\varphi_i|$. The same arguments hold, concluding the proof. $\square$

At this point we are essentially done. Lemmas 1 and 3 guarantee that, if the max-flow algorithm fails to yield a large enough flow, a fixed pre-coloring of U cannot be extended; moreover, the latter also implies that, if an extension is possible, max-flow correctly finds it.

Theorem 4. EQUITABLE COLORING *parameterized by distance to cluster can be solved in* FPT *time.*

Proof. Suppose we are given U. Now, for each of the $\mathcal{O}\big(B_{|U|}\big)$ possible colorings of U — where B_n is the n-th Bell number — construct H and execute the algorithm described in this section. Since max-flow can be solved in polynomial time [10] and we have an FPT number of colorings of U, we have an FPT algorithm for EQUITABLE COLORING. $\square$

It is worthy to note here that there is nothing special about the capacities of the arcs in S; they act only as upper bounds to the number of vertices a color may be assigned to. Thus, not surprisingly, the same algorithm applies to problems where the size of each color class is only upper bounded. This will be particularly useful in the next session. Looking at the proof of Theorem 4, the only non-polynomial step is guessing the coloring of the modulator. A straightforward corollary is that if there is a polynomial number of distinct colorings of U and this family can be computed in polynomial time, we can apply the same ideas and check if an equitable k-coloring of the input graph exists in polynomial time. In particular, unipolar graphs satisfy the above condition. If we parameterize by distance to unipolar the problem remains W[1]-hard due to the hardness for split graphs. On the other hand, if we parameterize by distance to unipolar d and the number of colors k we have an FPT algorithm: the central clique of $G - U$ has at most k vertices, so we can treat G as a graph with distance to cluster at most $k + d$ and apply Theorem 4.

Corollary 5. EQUITABLE COLORING *on unipolar graphs is in* P. *When parameterized by distance to unipolar, the problem remains* W[1]-hard; *if also parameterized by the number of colors, it is solvable in* FPT *time.*

We note that this corollary does not contradict the W[1]-hard proof of Gomes et al. [19] for EQUITABLE COLORING on disjoint union of split graphs when parameterized by number of colors, since the class of split graphs is not closed under disjoint union.

4 Distance to co-cluster

Before proceeding to our hardness results, we discuss an FPT algorithm when parameterized by distance to co-cluster. Interestingly, the key ingredient to our approach is the algorithm presented in Section 3, which we use to compute the transitions between states of our dynamic programming table. Much like in the previous section, we denote by U the set of vertices such that $G - U$ is a co-cluster graph, and by $\mathcal{I} = \{I_1, \ldots, I_r\}$ the independent sets of $G - U$. The following observation follows immediately from the fact that $G - U$ is a complete r-partite graph; it allows us to color the sets of $\mathcal{I}$ independently.

Observation 6. *In any k-coloring φ of G, for every color i, there is at most one $j \in [r]$ such that $\varphi_i \cap I_j \neq \emptyset$.*

Suppose we are already given U, a coloring ψ of U, and the additional restriction that colors $P \subseteq \psi(U)$ must be used on $\ell + 1$ vertices. We index our dynamic programming table by (S, p, q, j), where $S \subseteq \psi(U)$ stores which colors of the modulator still need to be extended, p is the number of colors not in $\psi(U)$ that must still be used $\ell+1$ times, q the number of colors not in $\psi(U)$ that must still be used on ℓ vertices, and $j \in [r]$ indicates which of the independent sets we are trying to color. Our goal is to show that $f_{\psi,P}(S, p, q, j) = 1$ if and only if there is a coloring of $G_j = G[U \bigcup_{i=j}^r I_i]$ respecting the constraints given by (S, p, q, j). Intuitively, guessing P allows us to index the table by the number of colors not in $\psi(U)$ according only to the capacity of each color, otherwise it would be significantly harder to know, at any time in the algorithm, how many colors should be used on $\ell + 1$ vertices. To compute $f_{\psi,P}(S, p, q, j)$, we essentially test every possibility of extension of the colors in S that respects the constraint imposed by P and allows the completion of the coloring of the j-th independent set of $G - U$. Because of Observation 6, the colors not in $\psi(U)$ are confined to a single independent set and, thus, it suffices to consider only how many colors of size $\ell + 1$ we are going to use in I_j. We implement this transitioning according to Equation 1:

$$f_{\psi,P}(S, p, q, j) = \max_{(R,x,y) \,\in\, \mathsf{ext}(S,p,q,j)} f_{\psi,P \setminus R}(S \setminus R, p - x, q - y, j + 1) \qquad (1)$$

where $\mathsf{ext}(S, p, q, j)$ is the set of all triples (R, x, y), with $R \subseteq S$, such that each color $i \in R$ can be extended to I_j, while x and y satisfy the system:

$$\begin{cases} x(\ell + 1) + y\ell = |I_j| - \alpha_j \\ 0 \leq x \leq p \\ 0 \leq y \leq q \end{cases}$$

where α_j is the number of vertices of I_j used to extend the colors of R to I_j. Note that $|\mathsf{ext}(S, p, q, j)| \leq 2^{|S|}n$, so it holds that, for each fixed ψ and P, our dynamic programming table can be computed in $\mathcal{O}^*\big(3^{|U|}\big)$ time if and only if we can compute $\mathsf{ext}(S, p, q, j)$ in $\mathcal{O}^*(|\mathsf{ext}(S, p, q, j)|)$ time.

Lemma 7. $\mathsf{ext}(S, p, q, j)$ *can be computed in* $\mathcal{O}^*(|\mathsf{ext}(S, p, q, j)|)$ *time.*

Proof. Given a triple (R, x, y), with $R \subseteq S$, satisfying the above conditions, it suffices to show that membership in $\mathsf{ext}(S, p, q, j)$ can be decided in polynomial

time. Actually, the challenge is to determine whether or not the colors in R can be extended to include I_j. In order to do so, let $U' = \{v \in U \mid \psi(v) \in R\}$, and G' be the subgraph of G induced by the vertices $I_j \cup U'$. Observe that U' is actually a vertex cover for G'; in particular, it is a modulator to cluster graph of size bounded by $\mathsf{d\bar{c}}(G)$. As such, we can interpret the task as follows: is there an induced subgraph of G' that be colored with $|R|$ colors, that extends ψ, the colors in $P \cap R$ are used exactly $\ell + 1$ times and the others $P \setminus R$ ℓ times? This can be answered with a slight modification of the algorithm given in Section 3: after the initial max-flow is executed, i.e. if the converse of Lemma 1 holds, instead of updating the capacity of every arc leaving the source to $\ell + 1$ we only update those corresponding to the colors in P, the same argumentation holds. $\qquad\square$

Lemma 8. $f_{\psi,P}(S, p, q, j) = 1$ if and only if ψ can be extended to a coloring φ of G_j using the colors of S, with each color in P used in $\ell + 1$ vertices, p extra color classes of size $\ell + 1$, and q color classes of size ℓ.

Proof. For the forward direction, we proceed by induction. The base case, where $j = r + 1$ is equal to the modulator, we can define $f_{\psi,P}(S, p, q, r+1) = 1$ if and only if $P = S = \emptyset$, and $p = q = 0$. Now, take an arbitrary entry of the table with $i < r + 1$; by Equation 1, $f_{\psi,P}(S, p, q, j) = 1$ if and only if there is some triple (R, x, y) of $\mathsf{ext}(S, p, q, j)$ with $f_{\psi,P \setminus R}(S \setminus R, p - x, q - y, j + 1) = 1$. That is, there is a coloring of G_{j+1} under the constraints imposed by $P \setminus R$ and tuple $(S \setminus R, p - x, q - y, j + 1)$. Moreover, since $V(G_j) \setminus V(G_{j+1}) = I_j$, no color of R is used in any vertex of $V(G_{j+1}) \setminus U$, and by the definition of $\mathsf{ext}(S, p, q, j)$, it is possible to extend the coloring of G_{j+1} to include the vertices of I_j while keeping it proper and respecting the constraints imposed by P.

Conversely, take a coloring φ of G_j satisfying the hypothesis, define $R = \varphi(U) \cap \varphi(I_j)$, and let φ' be the restriction of φ to G_{j+1}. By Observation 6, every color in $R \subseteq S$ is used only on vertices of $U \cup I_j$, say α_j vertices of I_j, and there must be integers $0 \leq x \leq p$, $0 \leq y \leq q$ satisfying $(\ell + 1)x + \ell y + \alpha_j = |I_j|$ - that is, there are x colors of size $\ell + 1$ and y colors of size ℓ used exclusively on the remaining vertices of I_j. By definition, the triple (R, x, y) belongs to $\mathsf{ext}(S, p, q, j)$ and if $f_{\psi,P \setminus R}(S \setminus R, p - x, q - y, j + 1) = 1$ we are done. By induction on the number of available colors, this assertion holds since $|R| + x + y \geq 1$, otherwise $I_j = \emptyset$. $\qquad\square$

Finally, all that is left is to show that the number of colorings of U and the constraint set P can both be computed in FPT time.

Theorem 9. EQUITABLE COLORING *can be solved in* FPT *time when parameterized by distance to co-cluster.*

Proof. We can guess all possible colorings ψ of $|U|$ in time $\mathcal{O}^*\big(B_{|U|}\big)$ and for each color of ψ we need to choose between adding it to P or not. So we have $\mathcal{O}^*\big(B_{|U|}2^{|U|}\big)$ cases. By Lemmas 7 and 8 each case can be solved in FPT time parameterized by $\mathsf{d\bar{c}}$, so our algorithm is FPT parameterized by $\mathsf{d\bar{c}}$. $\qquad\square$

It is important to note that the above algorithm does not contradict the NP-hardness of EQUITABLE COLORING on bipartite graphs, since solving the problem on *complete* bipartite graphs is in P. Moreover, if $U = \emptyset$, all steps of the algorithm are performed in polynomial time, yielding the following corollary.

Corollary 10. EQUITABLE COLORING *of complete multipartite graphs is in* P.

5   Distance to Disjoint Paths

We now investigate EQUITABLE COLORING parameterized by the *distance to disjoint paths*, which is upper bounded by vertex cover and lower bounded by feedback vertex set. Contrary to our expectations, we show that the problem is W[1]-hard even if we also parameterize by the number of colors. To accomplish this, we make use of two intermediate problems, namely NUMBER LIST COLORING and EQUITABLE LIST COLORING parameterized by the number of colors. The latter is very similar to EQUITABLE COLORING but to each vertex v is assigned a list $L(v) \subseteq [k]$ of admissible colors. NUMBER LIST COLORING generalizes it in the sense that now we are given a function $h : [k] \mapsto \mathbb{N}$ and color i must be used *exactly* $h(i)$ times. As a first step, we show that NUMBER LIST COLORING parameterized by the number of colors is W[1]-hard on paths. By roughly doubling the number of colors and vertices used in the construction of [15], we are able to use, essentially, the same arguments. The source problem is MULTICOLORED CLIQUE parameterized by the solution size k: given a graph H such that $V(H)$ is partitioned in k color classes $\mathcal{V} = \{V_1, \ldots, V_k\}$, we want to determine if there is a k-colored clique in H. We denote the edges between V_i and V_j by $E(V_i, V_j)$, $|V(H)|$ by n, and $|E(H)|$ by m. We may assume that $|V_i| = N$ and $|E(V_i, V_j)| = M$ for every i, j; to see why this is possible, we may take $k!$ disjoint copies of H, each corresponding to a permutation of the color classes and, for each edge $uv \in E(H)$, we connect each copy of u to each copy of v. In our reduction, we interpret a clique as a set of *oriented* edges between color classes, i.e. an edge $e \in E(V_i, V_j)$ is selected *twice*: once from V_i to V_j, and once from V_j to V_i. As such, we have *two* gadgets for each edge of H.

Construction. Due to the list nature of the problem, we assign semantic values to each set of colors. In our case, we separate them in four types:

Selection: The colors $\mathcal{S} = \{\sigma(i, j) \mid (i, j) \in [k]^2, i \neq j\}$ and $\mathcal{S}' = \{\sigma'(i, j) \mid (i, j) \in [k]^2, i \neq j\}$ are used to select which edges must belong to the clique.

Helper: $\mathcal{Y}$ and $\mathcal{X}$ satisfy $|\mathcal{Y}| = |\mathcal{X}| = |\mathcal{S}|$. These two sets of colors force the choice made at the root of the edge gadgets to be consistent across the gadget.

Symmetry: The colors $\mathcal{E} = \{\varepsilon(i, j) \mid (i, j) \in [k]^2, i < j\}$ and $\mathcal{E}' = \{\varepsilon'(i, j) \mid (i, j) \in [k]^2, i < j\}$ guarantee that, if edge $e \in E(V_i, V_j)$ is picked from V_i to V_j, it must also be picked from V_j to V_i.

Consistency: Colors $\mathcal{T} = \{\tau_i(r, s) \mid i \in [k], r, s \in [k] \setminus \{i\}, r < s\}$ and $\mathcal{T}' = \{\tau'_i(r, s) \mid i \in [k], r, s \in [k] \setminus \{i\}, r < s\}$ ensure that if the edge uv is chosen between V_i and V_j, the edge between V_i and V_r must also be incident to u.

Before detailing the gadgets themselves, we define what is, in our perception, one of the most important pieces of the proof. For each vertex $v \in V(H)$, choose an arbitrary but unique integer in the range $[n^2 + 1, n^2 + n]$ and, for each edge e, a unique integer in the range $[2n^2 + 1, 2n^2 + m]$. These are the *up-identification* numbers of vertex v and edge e, denoted by $v_\uparrow$ and $e_\uparrow$, respectively. Now, choose a suitably huge integer Z, say n^3, and define the *down-identification number* for

v as $v_\downarrow = Z - v_\uparrow$. These quantities play a key role on the numerical targets for the symmetry and consistency colors; since they are unique, these identification numbers tie together the choices between edge gadgets.

For each pair $i, j \in [k]$, with $i < j$, the input graph G of NUMBER LIST COLORING has the groups of gadgets $\mathcal{G}(i,j)$ and $\mathcal{G}(j,i)$, each containing M edge gadgets corresponding to the edges of $E(V_i, V_j)$. We say that $\mathcal{G}(i,j)$ is the *forward group* and that $\mathcal{G}(j,i)$ is the *backward group*. For the description of the gadgets, we always assume $i < j$, $e \in E(V_i, V_j)$ with $u \in V_i$ and $v \in V_j$.

Forward Edge Gadget. The gadget $G(i,j,e)$ has a root vertex $r(i,j,e)$, with list $\{\sigma(i,j), \sigma'(i,j)\}$, and two neighbors, both with the list $\{\sigma(i,j), y(i,j)\}$, which for convenience we call $a(i,j,e)$ and $b(i,j,e)$. We equate membership of edge e in the solution to MULTICOLORED CLIQUE to the coloring of $r(i,j,e)$ with $\sigma(i,j)$. When discussing the vertices of the remaining vertices of the gadget, we say that a vertex is *even* if its distance to $r(i,j,e)$ is even, otherwise it is *odd*. To $a(i,j,e)$, we append a path with $2e_\downarrow + 2(k-1)u_\downarrow$ vertices. First, we choose $e_\downarrow$ even vertices to assign the list $\{y(i,j), \varepsilon'(i,j)\}$. Next, for each r in $j < r \le k$, choose $u_\downarrow$ even vertices to assign the list $\{y(i,j), \tau'_i(j,r)\}$. Similarly, for each $s \ne i$ satisfying $s < j$, choose $u_\downarrow$ even vertices and assign the list $\{y(i,j), \tau_i(s,j)\}$. All the odd vertices - except $a(i,j,e)$ and $b(i,j,e)$ - are assigned the list $\{y(i,j), x(i,j)\}$. The path appended to $b(i,j,e)$ is similarly defined, except for two points: (i) the length and number of chosen vertices are proportional to $e_\uparrow$ and $u_\uparrow$; and (ii) when color $\varepsilon(i,j)$ (resp. $\tau_i(s,r)$) should be in the list, we add $\varepsilon'(i,j)$ (resp. $\tau'_i(s,r)$), and vice-versa. For an example of the edge gadget, please refer to Figure 4.

Figure 4: Example of a forward edge gadget $G(1,3,e)$ of group $\mathcal{G}(1,3)$, with $k = 4$, $Z = 3$, $e_\downarrow = 2$, and $u_\downarrow = 1$. Vertices with no explicit list have list equal to $\{y(1,3), x(1,3)\}$.

Backward Edge Gadget. Gadget $G(j,i,e)$ has vertices $r(j,i,e)$, $a(j,i,e)$, and $b(j,i,e)$ defined similarly as to the forward gadget, with the root vertex having the list $\{\sigma(j,i), \sigma'(j,i)\}$, while the other two have the list $\{\sigma(j,i), y(j,i)\}$. To $a(j,i,e)$, we append a path with $2e_\downarrow + 2(k-1)v_\downarrow$ vertices. First, choose $e_\downarrow$ even vertices to assign the list $\{y(j,i), \varepsilon(i,j)\}$. Now, for each r in $j < r \le k$, choose $v_\downarrow$

even vertices to assign the list $\{y(j,i), \tau_j'(i,r)\}$. Then, for each $s \neq i$ satisfying $s < j$, choose $v_\downarrow$ even vertices and assign the list $\{y(j,i), \tau_j(s,i)\}$. All the odd vertices are assigned the list $\{y(j,i), x(j,i)\}$. The path appended to $b(j,i,e)$ is similarly defined, except that: (i) the length and number of chosen vertices are proportional to $e_\uparrow$ and $v_\uparrow$; and (ii) when the color $\varepsilon(i,j)$ (resp. $\tau_j(s,r)$) is in the list, we replace it with $\varepsilon'(i,j)$ (resp. $\tau_j'(s,r)$), and vice-versa. Note that, for every edge gadget, either forward or backward, the number of vertices is equal to $3 + 2(e_\uparrow + e_\downarrow) + 2(k-1)(u_\uparrow + u_\downarrow) = 3 + 2kZ$. We say that $G(i,j,e)$ is *selected* if $r(i,j,e)$ is colored with $\sigma(i,j)$, otherwise it is *passed*.

Numerical Targets. Before defining the numerical targets, given by $h(\cdot)$, recall that $|E(V_i, V_j)| = M$ for every pair i, j and that, for every vertex u and edge e, the identification numbers satisfy the identity $v_\uparrow + v_\downarrow = Z$ and $e_\uparrow + e_\downarrow = Z$. We present the numerical targets of our instance - and some intuition - below.

Selection: $h(\sigma(i,j)) = 1 + 2(M-1)$ and $h(\sigma'(i,j)) = M - 1$. Since only one edge may be chosen from V_i to V_j, the non-selection color $\sigma'(i,j)$ must be used in $M-1$ edges of $\mathcal{G}(i,j)$. Thus, exactly one $G(i,j,e)$ is selected and, to achieve the target of $1 + 2(M-1)$, for every $f \in E(V_i, V_j) \setminus \{e\}$, both $a(i,j,f)$ and $b(i,j,f)$ must also be colored with $\sigma(i,j)$.

Helper: $h(y(i,j)) = 2 + kMZ$ and $h(x(i,j)) = kMZ - kZ$. The goal here is that, if $G(i,j,e)$ is selected, all the odd positions must be colored with $y(i,j)$, otherwise every even position must be colored with it. In the latter case, the odd positions of all but one gadget of $\mathcal{G}(i,j)$ must be colored with $x(i,j)$.

Symmetry: $h(\varepsilon(i,j)) = h(\varepsilon'(i,j)) = Z$. If the previous condition holds and $r(i,j,e)$ is colored with $\sigma(i,j)$, then $\varepsilon(i,j)$ appears in $e_\uparrow$ vertices of the gadget rooted at $r(i,j,e)$. To meet the target Z, $e_\downarrow$ vertices of another gadget must also be colored with it, as we show, the only way is if $r(j,i,e)$ is colored with $\sigma(j,i)$.

Consistency: $h(\tau_i(s,r)) = h(\tau_i'(s,r)) = Z$. Similar to symmetry colors.

Lemma 11. *If H has a k-multicolored clique, then G admits a list coloring meeting the numerical targets.*

Proof. Let Q be a clique of H of size k. Now, for each $i, j \in [k]$, with $i \neq j$, and $e \in E(V_i, V_j)$, we color G as follows: if $e \in Q$, color $r(i,j,e)$ with $\sigma(i,j)$, color every odd vertex with $y(i,j)$ and every even vertex with the unique available color to it; otherwise, color $r(i,j,e)$ with $\sigma'(i,j)$, color every even vertex with $y(i,j)$ and all odd vertices with the unique available color. This concludes the construction of the coloring φ of G.

As to the numerical targets, note that the colors of $\mathcal{S}$ and $\mathcal{S}'$ are used the appropriate number of times since only one edge of $E(V_i, V_j)$ belongs to Q. For each color $y(i,j) \in \mathcal{Y}$ and edge $e = uv$ with $u \in V_i$, gadget $G(i,j,e)$ has, at least, $e_\uparrow + e_\downarrow + (k-1)(u_\uparrow + u_\downarrow) = kZ$ vertices colored with $y(i,j)$, since either all odd vertices or even vertices are colored with it. For the remaining two uses of $y(i,j)$, note that the selected gadget $G(i,j,e)$ has $a(i,j,e)$ and $b(i,j,e)$ also colored with $y(i,j)$. As to the other helper color, $x(i,j)$, we use it only in passed gadgets and, in this case, in every odd vertex (except the a's and b's);

this sums up to $\sum_{e \in E(V_i, V_j) \setminus Q} e_\uparrow + e_\downarrow + (k-1)(u_\uparrow + u_\downarrow) = kMZ - kZ$. In terms of symmetry colors, φ only uses $\varepsilon(i,j)$ on the selected gadgets $G(i,j,e)$ and $G(j,i,e)$ ($i < j$), in particular, $\varepsilon(i,j)$ is used $e_\downarrow$ times in $G(j,i,e)$ and $e_\uparrow$ times on $G(i,j,e)$, so it holds that $|\varphi_{\varepsilon(i,j)}| = e_\uparrow + e_\downarrow = Z$. Note that the same argument applies for color $\varepsilon'(i,j)$. Finally, for consistency colors, note that $\tau_i(r,s)$ is used only in the selected gadgets $G(i,r,e)$ and $G(i,s,f)$, specifically, if $i < r < s$, $\tau_i(r,s)$ is used $u_\uparrow$ times in $G(i,r,e)$ and $u_\downarrow$ times in $G(i,s,f)$, since edges e, f must be incident to the same vertex of $Q \cap V_i$. Consequently $\tau_i(r,s)$ is used in $u_\uparrow + u_\downarrow = Z$ vertices. The reasoning for $\tau'_i(r,s)$ is similar. $\square$

We now proceed to the proof of the converse. Lemma 12 guarantees that the decision made at the root of a gadget propagates throughout the entire structure; Lemma 13 ensures that the edge selected from V_j to V_i is the same as the edge selected from V_i to V_j; finally, Lemma 14 equates the vertex of V_i incident to the edge between V_i and V_j to the vertex incident to the edge between V_i and V_s.

Lemma 12. *In every list coloring of G satisfying h, exactly one gadget of each $\mathcal{G}(i,j)$ is selected, each passed $G(i,j,e)$ has all of its kZ even vertices colored with $y(i,j)$, and the selected $G(i,j,f)$ has all of its $2 + kZ$ odd vertices colored with $y(i,j)$.*

Proof. For the first statement, if no gadget was selected, $\sigma'(i,j)$ would be used $M > M - 1$ times; if more than one is selected, $\sigma'(i,j)$ does not meet the target. If $G(i,j,f)$ is selected then $a(i,j,f)$ and $b(i,j,f)$ are colored with $y(i,j)$. After removing these vertices, we are left with two even paths of which at most half of its vertices are colored with the same color. As such there are at most $2 + f_\downarrow + (k-1)u_\downarrow + f_\uparrow + (k-1)u_\uparrow = 2 + kZ$ vertices colored with $y(i,j)$ in this gadget; moreover this bound is achieved if and only if the odd vertices are colored with $y(i,j)$. For each passed $G(i,j,e)$, $a(i,j,e)$ and $b(i,j,e)$ are colored with $\sigma(i,j)$, otherwise the numerical target of $\sigma(i,j)$ cannot be met. After the removal of $a, b, r(i,j,e)$ we are again left with two even paths. Thus, at most $e_\downarrow + (k-1)u_\downarrow + e_\uparrow + (k-1)u_\uparrow = kZ$ vertices have color $y(i,j)$ in this gadget. To see that $y(i,j)$ must be used only for even vertices of $G(i,j,e)$ to meet this bound, note that, if this is not done, then $x(i,j)$ will never meet its bound, since exactly $kMZ - kZ$ vertices remain (after the coloring of $G(i,j,f)$) that can be colored with $x(i,j)$, which is precisely its target. $\square$

Lemma 13. *In every list coloring φ of G, if $G(i,j,e)$ is selected, so is $G(j,i,e)$.*

Proof. Suppose $i < j$. By Lemma 12 we know that for a selected gadget every odd vertex is colored with $y(i,j)$, so each even vertex is colored with a non-helper color. Note that color $\varepsilon'(i,j)$ is used $e_\downarrow$ times in gadget $G(i,j,e)$. Now, we need to select one backward gadget of $\mathcal{G}(j,i)$; suppose we select gadget $G(j,i,f)$, $f \neq e$. Again by Lemma 12, the number of occurrences of $\varepsilon'(i,j)$ is $f_\uparrow$ times in $G(j,i,f)$, but we have that $e_\downarrow + f_\uparrow \neq Z$, a contradiction that φ satisfies h. $\square$

Lemma 14. *In every list coloring φ of G, if $G(i,j,e)$ is selected and $e = uv$, then, for every $s \neq i$, the edge f of H corresponding to the selected gadget $G(i,s,f)$ must be incident to u.*

13

Proof. We divide our proof in two cases. First, suppose $i < j$ and $s < j$. By Lemma 12 $\tau_i(s,j)$ is used in $u_\uparrow$ vertices of $G(i,j,e)$. Now, note that the only possible gadgets $G(i,s,f)$ that can be chosen such that the endpoint w of f in V_i satisfies $u_\uparrow + w_\downarrow = Z$ must have $w = u$, since $\tau_i(s,j)$ is used $w_\downarrow$ times in gadget $G(i,s,f)$. The case $j < s$ is similar, but we replace τ_i with τ_i'. $\qquad\square$

Theorem 15. NUMBER LIST COLORING *on paths parameterized by the number of colors that appear on the lists is* W[1]-hard.

Corollary 16. EQUITABLE LIST COLORING *on paths parameterized by the number of colors that appear on the lists is* W[1]-hard.

Corollary 17. EQUITABLE COLORING *parameterized by the number of colors and distance to disjoint paths is* W[1]-hard.

Theorem 15 and its corollaries follow from the previous lemmas. For the first corollary, we add isolated vertices with lists of size one to the input of NUMBER LIST COLORING so as to make all colors have the same numerical target. For the second, we add a clique of size r, the number of colors of the instance of EQUITABLE LIST COLORING, and label them using the integers $[r]$; afterwards, for each vertex u of the input graph that does not have color i in its list, we add an edge between the i-th vertex of the clique and u.

6 Distance to disjoint paths of bounded size

The reduction in Section 5 heavily relies on the length of the disjoint paths to show that EQUITABLE COLORING is W[1]-hard parameterized by distance to disjoint paths and number of colors. In this section, we show that, by replacing the number of colors with the length of the longest path in the parameterization, the problem becomes FPT. We divide our analysis in two cases: when the number k of colors is at most $|U| + 2$ and when it is bigger.

6.1 Bounded number of colors

We first study the case where the number of colors is bounded by $|U| + 2$. To this end, we show how to translate an instance (G, L, h) of NUMBER LIST COLORING where the input graph is a collection of disjoint paths into an instance of INTEGER LINEAR PROGRAMMING, which is fixed-parameter tractable when parameterized by the number of variables [25]. If $A = \langle a_1, \ldots, a_\ell \rangle$ is one of the disjoint paths of G, we say that the *pattern* of A, denoted by $\mathsf{pat}(A)$, is the sequence $\langle L(a_1), \ldots, L(a_\ell) \rangle$. A set of disjoint paths $\mathcal{A}$ is *compatible* if, for every two $A, B \in \mathcal{A}$, $\mathsf{pat}(A) = \mathsf{pat}(B)$, and there is no other path of G with the same pattern. In an abuse of notation, we say that $\mathsf{pat}(A) = \mathsf{pat}(\mathcal{A})$. We denote the partition of G into compatible sets by $\mathcal{P}(G)$ and say that a pattern p is in $\mathcal{P}(G)$ if there is some $\mathcal{A} \in \mathcal{P}(G)$ with $\mathsf{pat}(\mathcal{A}) = p$.

Lemma 18. *If* (G, L, h) *is an instance of* NUMBER LIST COLORING *such that each connected component of G is a path of length at most ℓ and $k = |\bigcup_{v \in V(G)} L(v)|$, then there is an algorithm that runs in $f(|\mathcal{P}(G)|, k, \ell)n^{\mathcal{O}(1)}$ time and correctly solves (G, L, h).*

Proof. Our goal is to construct an integer linear program that correctly computes a coloring of G subject to the coloring constraints imposed by L that meets the numerical targets given by h. For each $\mathcal{A}_p \in \mathcal{P}(G)$, we write $\mathsf{pat}(\mathcal{A}_p) = \{L_{p,1}, \ldots, L_{p,q_p}\}$, where $q_p = |\mathsf{pat}(\mathcal{A}_p)|$, and construct a flow network H_p as follows: $V(H_p) = \{s_p, t_p\} \bigcup_{j \in [q_p], i \in L_{p,j}} \{u_{p,j,i}, v_{p,j,i}\}$. The source s_p has an outbound arc to each $u_{p,1,i}$, every $u_{p,j,i}$ is an in-neighbor of $v_{p,j,i}$, every $v_{p,j,i}$ has an outbound arc to each $u_{p,j+1,a}$ that satisfies $i \neq a$, and each $v_{p,q_p,i}$ is an in-neighbor of the sink t_p; all arcs have capacity equal to $|\mathcal{A}_p|$. An example of H_p is shown in Figure 5.

Figure 5: Flow network H_p where $\mathsf{pat}(\mathcal{A}_p) = \{\{1,2\}, \{1,3\}, \{2,3\}\}$ and all arcs have capacity equal to $|\mathcal{A}_p|$. We omit p from the subscript.

Now, let $\Pi(H_p, \mathcal{A}_p, \eta)$ be the following set of linear constraints, where $x(e)$ is the variable storing how much flow is passing through arc $e \in E(H_p)$, $E_{p,i} = \bigcup_{j \in [q_p]} \{(u_{p,j,i}, v_{p,j,i})\}$, $E^-(v)$ is the set of inbound arcs of v, $E^+(v)$ the set of outbound arcs, and $\eta(p, i)$ is (for now) an integer limiting how many vertices of $\mathcal{A}_p$ must be colored with color i:

$$\sum_{e \in E^-(v)} x(e) - \sum_{e \in E^+(v)} x(e) = 0 \qquad \forall v \in V(H) \setminus \{s_p, t_p\} \qquad (2)$$

$$\sum_{e \in E^+(s)} x(e) = \sum_{e \in E^-(t)} x(e) = |\mathcal{A}_p| \qquad (3)$$

$$\sum_{e \in E_{p,i}} x(e) = \eta(p, i) \qquad \forall i \in \bigcup_{j \in [q_p]} L_{p,j} \qquad (4)$$

$$0 \leq x(e) \leq |\mathcal{A}_p| \qquad \forall e \in E(H_p) \qquad (5)$$

Before proving the next claim, we note that Equations 2, 3, and 5 are standard flow conservation constraints, while Equation 4 imposes the constraints on how many times the flow must pass through arcs of $E_{p,i}$. Intuitively, each flow unit corresponds to one path $A \in \mathcal{A}_p$ and the (s,t)-path taken by the unit in H_p corresponds to a coloring of A in G.

Claim 19. $\mathcal{A}_p$ *has a coloring respecting the lists given by L and the numerical targets given by $\eta(p, i)$ if and only if $\Pi(H_p, \mathcal{A}_p, \eta)$ is feasible.*

Proof of the claim. For the forward direction, let φ be a coloring of H_p that respects L and meets $\eta(p, i)$. For each $A_r \in \mathcal{A}_p$, we push one unit of flow from s_p along the path of H_p described by the coloring of $A_r = \{v_1, \ldots, v_{q_p}\}$, so that

15

$(u_{p,j,i}, v_{p,j,i})$ is in the path if $v_j \in \varphi_i$, and all other arcs are chosen appropriately; this procedure does not violate Equations 2 through 5 since this is an (s,t)-flow, each arc is picked at most once per path of $\mathcal{A}_p$ and the number of flow units coursing through the arcs of each $E_{p,i}$ is equal to $\eta(p,i)$ since $|\varphi_i| = \eta(p,i)$.

For the converse, suppose that $\mathbf{x}$ is an assignment of the variables satisfying $\Pi(H_p, \mathcal{A}_p, \eta)$. Our proof is by induction on $|\mathcal{A}_p|$. For the base case, where $A = \langle a_1, \ldots, a_{q_p} \rangle$ is the unique element of $\mathcal{A}_p$, we color a_j with i if $x((u_{p,j,i}, v_{p,j,i}))$; since $(v_{p,j,i}, u_{p,j+1,i}) \notin E(H_q)$, no two adjacent vertices of A have the same color and, since Equation 4 is satisfied and $x(e) \leq 1$ for very edge of $E(H_p)$, $|\varphi_i| = \eta(p,i)$ for every color i. For the general case, let $W = \langle s, u_1, v_1, \ldots, u_{q_p}, v_{q_p}, t \rangle$ be a path of H_p so that every arc e with both endpoints in W has $x(e) \neq 0$ and the set of all saturated arcs of H_p (possibly empty) is contained in W; there exists such a path since H_p is acyclic and $\sum_{i \in [k]} x((u_{p,j,i}, v_{p,j,i})) = |\mathcal{A}_p|$. Now, let $\mathbf{x}(W)$ be the vector where the positions corresponding to each arc in W are equal to one, $\eta' = \{\eta(p,i) - |E(W)E_{p,i}| \cap | i \in [q_p]\}$ be a new set of numerical targets, and $\mathcal{A}'_p$ be a subset of size $|\mathcal{A}_p| - 1$ of $\mathcal{A}_p$. Note that $\mathbf{x}' = \mathbf{x} - \mathbf{x}(W)$ is a solution to $\Pi(H_p, \mathcal{A}'_p, \eta')$ since $\max_e \mathbf{x}(e) \leq |\mathcal{A}_p| - 1$. By the inductive hypothesis, we can convert $\mathbf{x} - \mathbf{x}(W)$ into a coloring of $|\mathcal{A}_p| - 1$ paths with pattern $\mathsf{pat}(\mathcal{A}_p)$. For the $|\mathcal{A}_p|$-th path, we color it according to W as done in the base case; such a coloring does not violate the capacity of the arcs since $\mathbf{x}'(e) \leq |\mathcal{A}_p - 1|$ for each arc e of W. $\qquad \square$

Armed with the claim, we may now formulate and prove correctness of the complete linear program $\Lambda(G, k, L, h)$. Note that, unlike in program Π, the $\eta(p,i)$'s are variables of program Λ.

$$\Pi(H_p, \mathcal{A}_p, \eta) \qquad\qquad\qquad \forall p \in \mathcal{P}(G) \qquad (6)$$

$$\sum_{i \in [k]} \eta(p,i) = |\mathcal{A}_p| q_p \qquad\qquad \forall p \in \mathcal{P}(G) \qquad (7)$$

$$\sum_{p \in \mathcal{P}(G)} \eta(p,i) = h(i) \qquad\qquad \forall i \in [k] \qquad (8)$$

$$0 \leq \eta(p,i) \leq h(i) \qquad\qquad \forall p \in \mathcal{P}(G), i \in [k] \qquad (9)$$

To see that $\Lambda(G, k, L, h)$ is feasible if and only if (G, L, h) is a positive instance of NUMBER LIST COLORING, note that Equations 7 and 8 are satisfied if and only if we allow the algorithm to use one color for each vertex in $\mathcal{A}_p$ and each color precisely the number of times demanded by h, respectively. Moreover, by our previous Claim, if every $\Pi(H_p, \mathcal{A}_p, \eta)$ is feasible, then there is a coloring of $\bigcup_{p \in \mathcal{P}(G)} G[\mathcal{A}_p] = G$ satisfying the desired numerical targets. As to the running time of the algorithm, $\Lambda(G, k, L, h)$ has $\mathcal{O}(k\ell|\mathcal{P}(G)|)$ variables; since each connected component of G has at most ℓ vertices and to each vertex of G one of 2^k possible lists was assigned, we have that G has at most $2^{k\ell}$ compatible sets, i.e $|\mathcal{P}(G)| \leq 2^{k\ell}$. As shown in [25], LINEAR INTEGER PROGRAMMING can be solved in FPT time on the number of variables, so it follows that our algorithm runs in $f(|\mathcal{P}(G)|, k, \ell)n^{\mathcal{O}(1)}$ time. $\qquad\qquad \square$

To solve EQUITABLE COLORING itself, note that, for each of the $|U|^{|U|}$ possible colorings of the P_ℓ-modulator $U \subseteq V(G)$, we have that each vertex in $G \setminus U$

has a list of available colors of size at most $|U|+2$. Fixed this precoloring φ of U and which of the k colors will be used $\lceil \frac{n}{k} \rceil$ times, by Lemma 18, we can decide in $f(|\mathcal{P}_\varphi(G \setminus U)|, |U|+2, \ell)n^{\mathcal{O}(1)}$ time whether $G \setminus U$ can be colored respecting the lists and meeting the targets imposed by the precoloring φ

6.2 Unbounded number of colors

The second case of our analysis has some similar ideas to the previous one. This time, however, we are going to extend the precoloring of U so that every color that appears in φ is taken care of using an integer linear program, while the remaining $k - |U| \geq 3$ colors will be assigned using the Hajnal-Szemerédi theorem [20], which states that every graph can be equitably k-colored if k is at least the maximum degree plus one.

Lemma 20. *Let (G, k) be an instance of* EQUITABLE COLORING, *$U \subset V(G)$ be a P_ℓ-modulator of G, φ a precoloring of U, and $\gamma : \varphi(U) \mapsto \{\lfloor \frac{n}{k} \rfloor, \lceil \frac{n}{k} \rceil\}$ be a function dictating how many times each color in $\varphi(U)$ must be used in the entire graph. There exists an algorithm that runs in $f(|U|, \ell)n^{\mathcal{O}(1)}$ time and decides if φ can be extended to an equitable k-coloring G that respects γ.*

Proof. Throughout this proof, we use $|\varphi(U)| = \rho$. Let $(G \setminus U, L, h)$ be the instance of NUMBER LIST COLORING that, for each $v \in V(G) \setminus U$, has $L(v) = [\rho + 2] \setminus \varphi(N_G(v) \cap U)$, and h be the function $h : [\rho + 2] \mapsto [n]$ where $h(i) = \gamma(i) - |\varphi_i(U)|$ for every $i \in \varphi(U)$, $h(\rho + 1) = \left\lfloor \frac{n - \sum_{i \in \varphi(U)} \gamma(i)}{2} \right\rfloor$, and $h(\rho + 2) = \left\lceil \frac{n - \sum_{i \in \varphi(U)} \gamma(i)}{2} \right\rceil$.

We claim that $(G \setminus U, L, h)$ is a positive instance if and only if we can extend φ to an equitable k-coloring of G that respects γ. Let φ' be the desired extension and X the set of vertices not colored with a color of $\varphi(U)$. We know that $G[X]$ is a family of disjoint paths. We prove that we can greedily recolor X with two colors $\rho + 1$ and $\rho + 2$ in order to meet the targets given by h. Since we are going to color paths with only two colors, vertices on even positions are colored with one color, and in odd positions with the other. As such, paths of even length do not increase the difference between the number of vertices colored with $\rho+1$ and $\rho+2$, while paths of odd length increase it by one unit. As such, we begin by recoloring all even length paths properly but arbitrarily. Before proceeding, note that $h(\rho+1) = h(\rho+2)$ if and only if we have an even number of odd length paths. If $\{B_1, \ldots, B_r\}$ are all such paths, we color the odd-indexed paths starting with $\rho + 2$ and the even-indexed paths starting with $\rho + 1$; this guarantees that each of the was used at least $\sum_{i \in [r]} \left\lfloor \frac{|B_i|}{2} \right\rfloor = \left\lfloor \frac{n - \sum_{i \in \varphi(U)} h_i}{2} \right\rfloor$ times, with $\rho + 2$ having an additional usage if and only if $G[X]$ has an odd number of odd length paths. Since $\rho + 1$ and $\rho + 2$ are not used in any other vertex, we have obtained a proper coloring of $G \setminus U$ that respects L and satisfies the numerical targets.

For the converse, let $\mathbf{x}$ be an assignment satisfying the integer linear program $\Lambda(G \setminus U, \rho + 2, L, h)$. By Lemma 18, $\mathbf{x}$ has an associated coloring of the vertices of $G \setminus U$ meeting the targets given by h. It follows immediately that all colors $i \in \varphi(U)$ were used $h(i) + |\varphi_i(U)| = \gamma(i)$ times. Now, let $X \subseteq V(G) \setminus)$ be the set of vertices colored with $\rho + 1$ or $\rho + 2$, k_1 (resp. k_2) be the number of colors of an equitable k-coloring of G that must have size $\lceil \frac{n}{k} \rceil$ (resp. $\lfloor \frac{n}{k} \rfloor$),

$\rho_1 = |\{i \mid \gamma(i) = \lceil \frac{n}{k} \rceil\}|$, and $\rho_2 = \rho - \rho_1$. We note that $|X| = n - \rho_1 \lceil \frac{n}{k} \rceil - \rho_2 \lfloor \frac{n}{k} \rfloor = (k_1 - \rho_1) \lceil \frac{n}{k} \rceil + (k_2 - \rho_2) \lfloor \frac{n}{k} \rfloor$, i.e if we want to equitably $(k - \rho)$-color X, each color must use $\lceil \frac{n}{k} \rceil$ or $\lfloor \frac{n}{k} \rfloor$ colors. Since $G[X]$ has maximum degree two and $k - \rho \geq 3$, the Hajnal-Szemerédi theorem guarantees that there is an equitable $(k - \rho)$-coloring of $G[X]$, which can be computed in polynomial time [24]; since $G[X]$ uses no color in $\varphi(V(G) \setminus X)$, we have found an equitable k-coloring of G. The overall running time is the same as in Lemma 18, since the additional step of transforming the coloring on $\rho + 2$ colors of $G \setminus U$ can be performed in polynomial time. □

The next theorem follows directly from the previous two lemmas. The only additional steps necessary are guessing a coloring of the P_ℓ-modulator and which of these colors of the modulator will be used in $\lceil \frac{n}{k} \rceil$ vertices. Moreover, we do not need to assume that the modulator has been given to us beforehand: we may adapt the well known vertex cover branching algorithm [11] to find a P_ℓ-modulator of size t in $\ell^{\mathcal{O}(t)} n^2$ time.

Theorem 21. EQUITABLE COLORING *can be solved in* FPT *time when parameterized by distance to paths of length at most ℓ and ℓ.*

7 A linear kernel for distance to clique

Let (G, k) be the input to EQUITABLE COLORING, $U \subseteq V(G)$ be such that $G \setminus U$ is a complete graph, and define $n = |V(G)|$. Our kernel is a direct consequence of the following lemma.

Lemma 22. *If $k > |U|$, then (G, k) can be solved in polynomial time.*

Proof. Let $d = |U|$ and $Q = V(G) \setminus U$. Since $G[Q]$ is a clique, we know that $k - d > 0$ colors must necessarily be used only on Q and only once, so no color may be used more than twice to obtain an equitable k-coloring of G. As such, let $M = \{u_1 v_1, \ldots, u_m v_m\}$ be a maximum matching of $\overline{G}$, i.e. a family of pairs of vertices of maximum size where $u_i v_i \notin E(G)$ for every $i \in [m]$, which can be found in polynomial time [12]. Note that $\{u_i, v_i\} \nsubseteq Q$, since $\overline{G}[Q]$ is an independent set. Moreover, since M is of maximum size, m is the largest number of colors that may be simultaneously used in two vertices, i.e. if $n - 2m > k - m$, we answer NO — G has no equitable k-coloring — because the previous condition implies that at least one more color must be used in two vertices. For the final case, where $n \leq k + m$, let k' be such that $n = k' \lceil \frac{n}{k} \rceil + (k - k') \lfloor \frac{n}{k} \rfloor$ and note that $k' \leq m$, otherwise G would not be equitably k-colorable. As such, for each $i \in [k']$, pick the non-edge $u_i v_i \in M$ and color both u_i and v_i with i, and color the remaining $n - 2k' = k - k'$ vertices with an arbitrary but unique color of the set $[k] \setminus [k']$; since $u_i v_i \notin E(G)$, this coloring is proper. □

Theorem 23. *When parameterized by the distance to clique d,* EQUITABLE COLORING *admits a kernel with $4d$ vertices.*

Proof. Suppose we are not given U in advance. Note that there is a naive polynomial time algorithm that yields a clique modulator U of size at most $2d$: for each non-edge uv of G, remove both u and v from G. As such, we obtain

a modulator U where $|U| \leq 2d$ and $G \setminus U$ is isomorphic to a complete graph. If $k > |U|$, we use Lemma 22 and provide the answer for (G, k) in polynomial time. Otherwise, $k \leq |U| \leq 2d$, and $|V(G) \setminus U|$ must be at most k, otherwise it is clearly impossible to even k-color $G \setminus U$. Consequently, $V(G) \leq k + |U| \leq 4d$. $\square$

8 A cubic kernel for max leaf number

We now show a polynomial kernel for EQUITABLE COLORING when parameterized by the max leaf number ℓ. As before, we always assume that (G, k) is our input instance. Our result heavily relies on a previous proof of Estivill-Castro et al. [14] that G has max leaf number ℓ if and only if it is a subdivision of a graph H on 4ℓ vertices, and a recent paper of Cappelle et al. [8] that gives an upper bound of $5\ell + \lfloor \frac{\ell}{2} \rfloor$ on the number of subdivided edges of H; graph H is also called the *host graph* of G. We may assume that $k \geq 3$, otherwise the problem would be solvable in polynomial time by finding a maximum matching in the complement graph. Throughout this section, let H be the graph that G is a subdivision of, let $P(u, v)$ be the path that replaced $uv \in E(H)$ in order to obtain G — note that $u, v \notin P(u, v)$ — and let $\mathcal{P}_2(G)$ be the connected components of $G - H$.

Given a (partial) k-coloring $\varphi = \{\varphi_1, \ldots, \varphi_k\}$ of $V(G)$, we assume that $|\varphi_i| \leq |\varphi_j|$ for every $i \leq j$; we say that φ is α-*balanced* if $|\varphi_k| - |\varphi_1| = \alpha$. Our first goal is to show how we can extend a partial coloring φ' of $G \setminus P$, for some $P \in \mathcal{P}_2(G)$, in such a way that the resulting coloring φ is similarly balanced.

Lemma 24. *Let Q be an induced subgraph of G that does not contain any vertex of some path $P \in \mathcal{P}_2(G)$ and φ be an α-balanced coloring of Q. If $|P| \geq k + 2$, then it is possible to extend φ into an α^*-balanced coloring of $Q \cup P$, so that $\alpha^* \leq \alpha + 1$ and $\alpha^* = \alpha + 1$ only if $\alpha = 0$.*

Proof. The proof is by induction on $p = |P|$; also, let s be the largest integer so that $|\varphi_1| = |\varphi_s|$ and $P = \langle w_1, \ldots, w_p \rangle$. We may assume that, since each vertex of P has two neighbors in G, the neighbors of the endpoints of P are in Q; so let u be the neighbor of w_1 and w_p be the neighbor of v so that $u \in \varphi_i$, $v \in \varphi_j$, and $i \leq j$. For the base case of $p = k + 2$, we branch our analysis on s:

- If $s = 1$, we assign color 1 to w_1 and color k to w_2 if $\varphi(u) \neq 1$, otherwise we swap the colors of w_1 and w_2; we repeat this process with w_p and w_{p-1}, depending $\varphi(v)$. Now, we have $k - 2$ colors to be freely used on $k + 2 - 4 = k - 2$ vertices. Since colors 1 and k were used twice in P, the relative difference of their sizes remains the same. Since each color i different from 1 and k was used only once in P, the relative difference between $|\varphi_i|$ and the size of φ_k increased by at most one; but, since $s = 1$, we had $|\varphi_k| - |\varphi_2| \leq \alpha - 1$, which ensures that the balance α^* of the new coloring is at most α.

- If $1 < s < k$, for each color $i \in [s]$, pick one vertex of $\{w_1, \ldots, w_s\}$ and color it with i; since $s > 1$, we can do so and have $\varphi(w_1) \neq \varphi(u)$. Do the same for each color $j \in [k] \setminus [s]$ and $\{w_{s+1}, \ldots, w_k\}$. Finally, color $\{w_{k+1}, w_{k+2}\}$ with colors $1, 2$ so $\varphi(w_{k+2}) \neq \varphi(v)$. Since $s \neq k$ and each color in $[k] \setminus [2]$ was used once in P, the new coloring has the same balance as φ unless $k = 3$, in which case, $\alpha^* = \alpha - 1$.

- If $s = k$, color P so each color is used at least once, $\varphi(u) \neq \varphi(w_1)$ and $\varphi(w_{k+2}) = \varphi(v)$, which can be done since $k \geq 3$. This implies that the new coloring is $(\alpha+1)$-balanced, since $(k+2) \mod k \not\equiv 0$ whenever $k > 2$, but, since $|\varphi_1| = |\varphi_k|$, $\alpha = 0$.

Before proceeding, we first deal with a corner case when $p = k + 3$, $s = 1$, and $u, v \in \varphi_1$: color w_1 with k, w_2 with 1, w_3 with 2, and $\{w_4, \ldots, w_{k+3}\}$ so color i is assigned to w_{i+3}; since $s = 1$ this maintains the balance of the coloring intact. For the general case of $p > k + 2$, we again branch on s.

- If $s = 1$ and $u \notin \varphi_1$, color w_1 with 1 and apply the inductive hypothesis to $Q' = Q \cup \{w_1\}$, $P' = P \setminus \{w_1\}$, and the coloring φ' of Q', which is α'-balanced. Note that $\alpha' = \alpha - 1$, so after extending φ' to a coloring φ^* of $Q \cup P$, we have that the balance of the latter is at most $\alpha^* \leq \alpha' + 1 \leq \alpha$. If $s = 1$ and $u \in \varphi_1$, but $v \notin \varphi_1$, we proceed in a similar manner, but color w_p with 1.

- If $s = 1$ and $u, v \in \varphi_1$, we either have $p = k + 3$, in which case we have fallen into our corner case, or $p \geq k + 4$, in which case we color w_1 with k and w_2 with 1, and apply the inductive hypothesis on $Q' = Q \cup \{w_1, w_2\}$, $P' = P \setminus \{w_1, w_2\}$, and on the coloring φ' of Q', which is α-balanced; note, however, that $\alpha \neq 0$, so by extending φ' to a coloring φ^* of $Q \cup P$, we have that φ^* is α^*-balanced with $\alpha^* \leq \alpha$.

- If $1 < s < k$, there is at least one color $i \in [s] \setminus \{\varphi(u)\}$, so color w_1 with i and apply the inductive hypothesis to $Q' = Q \cup \{w_1\}$, $P' = P \setminus \{w_1\}$, and the coloring φ' of Q', which is still α-balanced since $s > 1$. Once again, the extension φ^* of φ' to $Q \cup P$ is α^*-balanced and, since $\alpha \neq 0$, $\alpha^* \leq \alpha$.

- If $s = k$, color w_1 with any color different from $\varphi(u)$ and again apply the inductive hypothesis to $Q' = Q \cup \{w_1\}$, $P' = P \setminus \{w_1\}$, and the coloring φ' of Q'. This time, we have that φ' is 1-balanced since $s = k$, so the extension φ^* of φ to $Q \cup P$ is either 0 or 1-balanced.

$\square$

We now show how to safely bring an α-balanced coloring closer to an equitable coloring, which is either 0 or 1-balanced. It is worthy to note that, in the next lemma, c is unbounded, i.e it could be the case that $c \geq k + 1$. This is not a problem, however, since we only want to show that, if we have x segments of length $k + 1$, we can bring the difference $|\varphi_k| - |\varphi_1|$ down by x units or make the coloring equitable.

Lemma 25. *Let Q be an induced subgraph of G that does not contain any vertex of some path $P \in \mathcal{P}_2(G)$ and φ be an α-balanced coloring of Q. If $|P| = k + 2 + x(k + 1) + c$, where $c \geq 0$ and $x \geq 1$, then it is possible to extend φ into an α^*-balanced coloring of $Q \cup P$, so that $\alpha^* \leq \max\{\alpha - x, 1\}$.*

Proof. We proceed by induction on x, and again define s to be the largest integer that has $|\varphi_1| = |\varphi_s|$, $P = \{w_1, \ldots, w_p\}$, $N_Q(w_1) = \{u\}$, and $N_Q(w_p) = \{v\}$. To prove the base case when $x = 1$, we divide our analysis based on the value of s.

- If $s = 1$, color w_1 with any color i different from 1 and $\varphi(u)$, assign color 1 to w_2, distribute colors $[k] \setminus \{1, i\}$ to $\{w_3, \ldots, w_k\}$ arbitrarily and color w_{k+1} with color 1; this way we have that this intermediate coloring φ' is $(\alpha - 1)$-balanced. Now, we apply Lemma 24 to $Q \cup \{w_1, \ldots, w_{k+1}\}$, $P \setminus \{w_1, \ldots, w_{k+1}\}$, and φ' to obtain a coloring φ^* of $Q \cup P$ that is α-balanced if $\alpha > 1$, or either 0 or 1-balanced if $\alpha = 1$.

- If $s > 1$, assign colors in $[s]$ arbitrarily to $\{w_1, \ldots, w_s\}$ while guaranteeing $\varphi(u) \neq \varphi(w_1)$, which is possible since $s \geq 2$, and apply Lemma 24 to $Q \cup \{w_1, \ldots, w_s\}$, $P \setminus \{w_1, \ldots, w_s\}$, and φ' to obtain a coloring φ^* of $Q \cup P$ that is α-balanced if $\alpha > 1$, or either 0 or 1-balanced if $\alpha \leq 1$.

When $x \geq 2$, we repeat the coloring procedures we delineated in the base case to color the vertices of the first section of size $k + 1$ of P, obtaining the partial coloring φ', which is 0-balanced if $\alpha = 0$ (implying $s = k$) or $(\alpha - 1)$-balanced otherwise. Now, we apply the inductive hypothesis on the remainder of the path to obtain an α^*-balanced coloring φ^* that extends φ' and has $\alpha^* \leq \max\{(\alpha - 1) - (x - 1), 1\} = \max\{\alpha - x, 1\}$. $\qquad\square$

Now, let $\mathcal{R}(G) = \{P(u_1, v_1), \ldots, P(u_r, v_r)\}$ be the set of paths that replaced edges of H and have at least $2k + 3$ vertices; in particular, $|P(u_i, v_i)| = k + 2 + c_i + x_i(k + 1)$, where $x_i \geq 1$ and $0 \leq c_i \leq k$, i.e x_i is maximum. Set $\mathcal{X}(G)$ is the collection of all x_i's of paths of $\mathcal{R}(G)$. Also, let Q be the induced subgraph of G obtained by removing the vertices of the paths in $\mathcal{R}(G)$, and $q = |V(Q)|$.

Lemma 26. If $\sum_{x \in \mathcal{X}(G)} x \geq q$, then G can be equitably k-colored if and only if Q can be k-colored.

Proof. If G is equitably k-colorable, then G is k-colorable and so is every induced subgraph of G, including Q. For the converse, let φ be an α-balanced k-coloring of Q. By Lemma 25, with each path $P(u_i, v_i) \in \mathcal{R}(G)$, we can extend φ while either reducing the gap between $|\varphi_k|$ and all colors used $|\varphi_1|$ times by x_i, or we can obtain a k-coloring of $Q \cup P(u_i, v_i)$ that is either 0 or 1-balanced, which is an equitable coloring. Since $\sum_{x \in \mathcal{X}(G)} x \geq q \geq \alpha$, we can extend φ to G and obtain an equitable k-coloring of G. $\qquad\square$

Corollary 27. If $\sum_{x \in \mathcal{X}(G)} x \geq q$, then G can be equitably k-colored if and only if the graph obtained by adding $q(k - 1)$ isolated vertices to Q can be equitably k-colored.

Proof. For the forward direction, note that any k-coloring of an n-vertex graph can be made equitable by adding $n(k-1)$ isolated vertices to it. For the converse, if $Q \cup I$ admits an equitable k-coloring φ', its restriction φ to Q is α-balanced for some $\alpha \leq q$; reasoning as in Lemma 26, we can $\qquad\square$

Lemma 28. Q has at most $4\ell + (k + 1)(11\ell - 2)$ vertices.

Proof. $|Q|$ is maximized when only one of the $5\ell + \frac{\ell}{2} - 1$ paths that replaced edges of H is in $\mathcal{R}(G)$, while all others have at most $2k + 2$ vertices, so $q \leq 4\ell + (5\ell + \frac{\ell}{2} - 1)(2k + 2) = 11k\ell + 15\ell - 2k - 2 = 4\ell + (k + 1)(11\ell - 2)$. $\qquad\square$

Theorem 29. *When parameterized by the max leaf number ℓ and number of colors k,* EQUITABLE COLORING *admits a kernel with* $(4\ell + (k+1)(11\ell - 2))(k +$

$2) + 11\ell(k + 1)$ *vertices. If H is given in the input, then the algorithm runs in polynomial time.*

Proof. If $|V(G)| \leq q(k + 2) + 8\ell(k + 1)$, we are done. On the other hand, if $|V(G)| > q(k+2) + 8\ell(k+1)$, we claim that $\sum_{x \in \mathcal{X}(G)} x \geq q$. To see that this is the case, recall that $G \setminus Q = \mathcal{R}(G)$ is a set of $r \leq 5\ell + \frac{\ell}{2}$ disjoint paths, each with at least $2k + 3$ vertices, and contains more than $8\ell(k + 1) + q(k + 1)$ vertices; consequently we have:

$$11\ell(k + 1) + q(k + 1) \leq \sum_{P_i \in \mathcal{R}(G)} |P_i|$$

$$11\ell(k + 1) + q(k + 1) \leq r(k + 2) + \sum_{i \in [r]} (c_i + (k + 1)x_i)$$

$$11\ell(k + 1) + q(k + 1) \leq r(k + 2) + rk + (k + 1) \sum_{i \in [r]} x_i$$

$$q \leq \sum_{i \in [r]} x_i$$

Now, by applying Corollary 27, we have that $Q \cup I$, where I is an independent set with $q(k-1)$ vertices, can be equitably k-colored if and only if G is equitably k-colorable.

As to the running time, the first step is listing $\mathcal{R}(G)$, which, since we have H in hand, can be done in time linear on $|E(H)| + |V(G)|$: for each edge uv of H, list the path $P(u, v)$ in G and check if it has at least $2k + 3$ vertices. If $|V(G)| \leq q(k + 2) + 11\ell(k + 1)$ we are done; otherwise we remove the paths of $\mathcal{R}(G)$ and add I. Since the latter steps can be done in time linear on $|V(G)|$, the kernelization algorithm runs in $\mathcal{O}(|E(H)| + |V(G)|)$ time. $\square$

Corollary 30. *When parameterized by the max leaf number ℓ, EQUITABLE COLORING admits a kernel with $4\ell(44\ell^2 - 18\ell - 1)$ vertices. If H is given in the input, then the algorithm runs in polynomial time.*

Proof. Since G is a subdivision of a graph on 4ℓ vertices, the maximum degree Δ of G is at most $4\ell - 1$; by the Hajnal-Szemerédi theorem [20], if $k \geq \Delta + 1$, then G is equitably k-colorable. The result follows immediately by substituting k with $4\ell - 1$ in the bound of Theorem 29. $\square$

9 A lower bound for vertex cover + number of colors

Our final result is a proof that EQUITABLE COLORING parameterized by vertex cover and number of colors does not admit a polynomial kernel unless $\mathsf{NP} \subseteq \mathsf{coNP/poly}$. Our proof makes heavy use of the reduction of Section 5. We are going to show: (i) an OR-cross-composition [3] from MULTICOLORED CLIQUE to NUMBER LIST COLORING parameterized by $\nu + q$, (ii) a PPT reduction from NUMBER LIST COLORING parameterized by $\nu + q$ to EQUITABLE LIST COLORING under the same parameterization, and (iii) a PPT reduction from

EQUITABLE LIST COLORING parameterized by vertex cover and number of colors to EQUITABLE COLORING parameterized by $\nu + q$. For step (i), we employ edge gadgets and list assignments based on previous work [18], although the assignments and the numerical targets suffer adjustments in order to translate the construction from a parameterized reduction to an OR-cross-composition.

Throughout this section, let $\mathcal{H} = \{(H_0, \mathcal{V}_1), \ldots, (H_t, \mathcal{V}_t)\}$ be a set of instances of MULTICOLORED CLIQUE so that: $V(H_p) = [n]$ and $|\mathcal{V}_p| = k$, for every $p \in [t]$. Moreover, we may assume that for each $V_i^p, V_j^p \in \mathcal{V}_p$, $|E(V_i^p, V_j^p)| = M$ and $|V_i| = |V_j| = N$, for every $p \in [t]$, where $E(V_i^p, V_j^p)$ denotes the set of edges between V_i^p and V_j^p. We also may safely assume that $|\mathcal{H}|$ is a power of two: if it is not, we may add at most t copies of any instance to $\mathcal{H}$ without changing the outcome of the composition. We shall denote by (G, L, h) the instance of NUMBER LIST COLORING where G is the input graph, L is a q-list-assignment, $h : [q] \mapsto \mathbb{N}$ is a function describing the numerical targets of each color, and the goal is to find an L-list-coloring of G so that $|\varphi_i| = h(i)$ for every color $i \in \bigcup_{v \in V(G)} L(v)$. For the remainder of this section, q is the number of colors. Intuitively, we are going to interpret each edge $uv \in E(H_p)$ as the pair of *oriented edges* (u, v) and (v, u) and a multicolored clique of size k as a set of $2\binom{k}{2}$ edges. Each gadget of G will correspond to one such oriented edge and the coloring of the gadget corresponding to (u, v) will tell us if: (i) the edge belongs to the instance $(H_p, \mathcal{V}_p)$ that contains the solution, and (ii) if (u, v) is part of the solution to $(H_p, \mathcal{V}_p)$.

Construction. We begin the construction of (G, L, h) by labeling the colors of the set $[q]$ according to role they are going to play in the composition. As we can see, the number of colors q is a quadratic function of k.

Selection: The colors $\mathcal{S} = \{\sigma(i, j) \mid (i, j) \in [k]^2, i \neq j\}$ and $\mathcal{S}' = \{\sigma'(i, j) \mid (i, j) \in [k]^2, i \neq j\}$ are used to select which edges must belong to the clique.

Helper: $\mathcal{Y}$ and $\mathcal{X}$ satisfy $|\mathcal{Y}| = |\mathcal{X}| = |\mathcal{S}|$. These two sets of colors force the choice made at the root of the edge gadgets to be consistent across the gadget.

Symmetry: The colors $\mathcal{E} = \{\varepsilon(i, j) \mid (i, j) \in [k]^2, i < j\}$ and $\mathcal{E}' = \{\varepsilon'(i, j) \mid (i, j) \in [k]^2, i < j\}$ guarantee that, if edge $e \in E(V_i, V_j)$ is picked from V_i to V_j, it must also be picked from V_j to V_i.

Consistency: Colors $\mathcal{T} = \{\tau_i(r, s) \mid i \in [k], r, s \in [k] \setminus \{i\}, r < s\}$ and $\mathcal{T}' = \{\tau_i'(r, s) \mid i \in [k], r, s \in [k] \setminus \{i\}, r < s\}$ ensure that if the edge uv is chosen between V_i and V_j, the edge between V_i and V_r must also be incident to u.

Suppression: We have four colors $\mathcal{U} = \{\alpha, \gamma, \rho, \lambda\}$ whose purpose is to color gadgets that correspond to edges not present in the graph H_p that contains the solution.

Shading: For each Selection, Helper, Symmetry, Consistency, and Suppression color c, we have an additional color $\bar{c}$, which is used in the instance selector gadget to remove the influence of some vertices in the coloring of the edge gadgets.

Propagation: A single color β is used to enforce that choices in a part of the instance selector gadget are propagated to the whole gadget.

As in [18, 15], let Z be a huge integer, say $Z = n^3$. The *up-identification number* for vertex $v \in [n]$, denoted by $v_\uparrow$, is a unique number in the interval $[n^2 + 1, n^2 + n]$, while the *down-identification number* $v_\downarrow$ for vertex v is given by $v_\downarrow = Z - v_\uparrow$. The up-identification number $e_\uparrow$ for edge e is defined similarly, but taken from the interval $\left[2n^2 + 1, 2n^2 + |\bigcup_{p \in [t]} E(H_p)|\right]$, while the down-identification number is defined by $e_\downarrow = Z - e_\uparrow$.

Moving on to the gadgets themselves, we say that a tuple (i, j, u, v) belongs to $(H_p, \mathcal{V}_p)$ if $i, j \in [k]$, $uv \in E(V_i^p, V_j^p)$, and $u \in V_i^p$; note that there are at most $(kn)^2$ possible tuples, regardless of how many instances we have in $\mathcal{H}$.

Forward Edge Gadget. For each $p \in [t] \cup \{0\}$ and each tuple $(i, j, u, v) \in (H_p, V_p)$ where $i < j$, we add to G a forward edge gadget, which we denote by $\overrightarrow{G}(i, j, u, v)$. This gadget has a root vertex $r(i, j, u, v)$, with list $\{\sigma(i, j), \sigma'(i, j), \alpha\}$, and two neighbors, both with the list $\{\sigma(i, j), y(i, j), \rho\}$, which for convenience we label as $a(i, j, u, v)$ and $b(i, j, u, v)$. We equate membership of edge e in the solution to one of the instances of MULTICOLORED CLIQUE to the coloring of $r(i, j, u, v)$ with $\sigma(i, j)$. When discussing the remaining vertices of the gadget, we say that a vertex is *even* if its distance to $r(i, j, u, v)$ is even, otherwise it is *odd*. To $a(i, j, u, v)$, we append a path with $2e_\downarrow + 2(k-1)u_\downarrow$ vertices. First, we choose $e_\downarrow$ even vertices to assign the list $\{y(i, j), \varepsilon'(i, j), \lambda\}$. Next, for each r in $j < r \le k$, choose $u_\downarrow$ even vertices to assign the list $\{y(i, j), \tau_i'(j, r), \lambda\}$. Similarly, for each $s \ne i$ satisfying $s < j$, choose $u_\downarrow$ even vertices and assign the list $\{y(i, j), \tau_i(s, j), \lambda\}$. All the odd vertices - except $a(i, j, u, v)$ and $b(i, j, u, v)$ - are assigned the list $\{y(i, j), x(i, j), \gamma\}$. The path appended to $b(i, j, u, v)$ is similarly defined, except for two points: (i) the length and number of chosen vertices are proportional to $e_\uparrow$ and $u_\uparrow$; and (ii) when color $\varepsilon(i, j)$ (resp. $\tau_i(s, r)$) should be in the list, we the list contains $\varepsilon'(i, j)$ (resp. $\tau_i'(s, r)$) instead, and vice-versa. For an example of the forward edge gadget, please refer to Figure 6.

Figure 6: Example of a forward edge gadget $\overrightarrow{G}(1, 3, u, v)$ with $k = 4$, $Z = 3$, $e_\downarrow = 2$, and $u_\downarrow = 1$. Vertices with no explicit list have list equal to $\{y(1, 3), x(1, 3), \gamma\}$.

24

Backward Edge Gadget. For each $p \in [t] \cup \{0\}$, once again, let $(i, j, u, v) \in (H_p, \mathcal{V}_p)$ be a tuple where $i < j$. We add to G a backward edge gadget, denoted by $\overleftarrow{G}(j, i, v, u)$. This gadget has vertices $r(j, i, v, u)$, $a(j, i, v, u)$, and $b(j, i, v, u)$ defined similarly as to the forward gadget, with the root vertex having the list $\{\sigma(j, i), \sigma'(j, i), \alpha\}$, while the other two have the list $\{\sigma(j, i), y(j, i), \rho\}$. To $a(j, i, v, u)$, we append a path with $2e_\downarrow + 2(k-1)v_\downarrow$ vertices. First, choose $e_\downarrow$ even vertices to assign the list $\{y(j, i), \varepsilon(i, j), \lambda\}$. Now, for each r in $j < r \le k$, choose $v_\downarrow$ even vertices to assign the list $\{y(j, i), \tau'_j(i, r), \lambda\}$. Then, for each $s \ne i$ satisfying $s < j$, choose $v_\downarrow$ even vertices and assign the list $\{y(j, i), \tau_j(s, i), \lambda\}$. All the odd vertices are assigned the list $\{y(j, i), x(j, i), \gamma\}$. The path appended to $b(j, i, v, u)$ is similarly defined, except that: (i) the length and number of chosen vertices are proportional to $e_\uparrow$ and $v_\uparrow$; and (ii) when the color $\varepsilon(i, j)$ (resp. $\tau_j(s, r)$) is in the list, we replace it with $\varepsilon'(i, j)$ (resp. $\tau'_j(s, r)$), and vice-versa. Note that, for every edge gadget, either forward or backward, the number of vertices is equal to $3 + 2(e_\uparrow + e_\downarrow) + 2(k-1)(u_\uparrow + u_\downarrow) = 3 + 2kZ$. We say that an edge gadget is *selected* if its root vertex is colored with $\sigma(i, j)$, we say that it is *passed* if the root is colored with $\sigma'(i, j)$, otherwise we say that it is *suppressed*.

Instance Selector Gadget. We now move on to a more delicate piece of the composition: the instance selector gadget. For each color c that is neither a Shading color nor a Propagation color, we add a choice gadget $\mathcal{C}(c)$ which contains a perfect matching $B_c = \{b(c, 1), \dots, b(c, s)\}$, where $s = \log_2 |\mathcal{H}| = \log_2(t + 1)$ and $b(c, i) = \{(c, i)_0, (c, i)_1\}$ is an edge of the matching, and an independent set $I_c = \{z_0(c), \dots, z_t(c)\}$. We say that $b(c, i)$ is the i-th bit of gadget $\mathcal{C}(c)$ and that the i-th bit is equal to $\mu \in \{0, 1\}$ if $(c, i)_\mu$ is colored with β. We connect $z_p(c)$ to B_c as follows: if the i-th least significant bit of p is 0, connect $z_p(c)$ to $(c, i)_0$, otherwise connect it to $(c, i)_1$. As to the lists, we define $L((c, j)_0) = L((c, j)_1) = \{c, \beta\}$ and $L(z_p(c)) = \{c, \bar{c}\}$. Intuitively, the vertices of the matching that are colored with β encode the binary representation of a unique $p \in [t] \cup \{0\}$, which implies that only $z_p(c)$ may be colored with c, all other vertices of I_c must be colored with $\bar{c}$. This index p will be precisely the index of the instance $(H_p, \mathcal{V}_p)$ that will be a YES instance of MULTICOLORED CLIQUE.

Naturally, our goal is to force that the same p is encoded by all choice gadgets, i.e. that the same instance $(H_p, \mathcal{V}_p)$ is picked for all colors. To do so, we pick any choice gadget $\mathcal{C}(c)$ to be a primary gadget, and, for every other choice gadget $\mathcal{C}(d)$, we add the edges $(c, i)_0(d, i)_1$ and $(c, i)_1(d, i)_0$; this way, the i-th bit of $\mathcal{C}(d)$ has $(d, i)_0$ colored with β if and only if $(c, i)_0$ is colored with β. The union of all these choice gadgets is our instance selector gadget, which we present an example of in Figure 7.

To conclude the construction of G, let c be a color that has an associated choice gadget $\mathcal{C}(c)$, $z_p(c)$ be a vertex of the independent set I_c, and $G(i, j, u, v)$ be an edge gadget (either forward or backward). If c is a Suppression color and $uv \in E(V_i^p, V_j^p)$ (suppose $u \in V_i^p$), then add an edge between $z_p(c)$ and every vertex in $G(i, j, u, v)$ that has c in its list. Otherwise, if c is **not** a Suppression color and $e \notin E(V_i^p, V_j^p)$, then add an edge between $z_i(c)$ and every vertex in $G(i, j, u, v)$.

Numerical Targets. The final ingredients are the numerical targets. Recall that q is the number of colors, that $M = |E(V_i^p, V_j^p)|$ for every triple i, j, p,
Figure 7: Instance selector gadget for $\log_2 |\mathcal{H}| = 2$. Black rectangles are vertices corresponding to bit value 1; white rectangles correspond to bit value 0.

that $k = |\mathcal{V}_p|$ for every $p \in [t] \cup \{0\}$, and that Z is the suitable huge integer of the order of n^3. For simplicity, we define $W = \log_2 |\mathcal{H}|$. The numerical targets are defined according to the following list; the term $W + 1$ in most targets comes from the fact that, for each color c that is neither a Shading color nor the Propagation color, we must use c exactly $W + 1$ times in the instance selector gadget. Intuitively, the numerical targets for these colors fulfill the exact the same roles as in Section 5, the extra $W + 1$ term is present so we can appropriately color the instance selector gadget.

Selection: $h(\sigma(i,j)) = 1 + 2(M-1) + W + 1 = 2M + W$ and $h(\sigma'(i,j)) = M - 1 + W + 1 = M + W$. Since only one edge may be chosen from V_i^p to V_j^p, the non-selection color $\sigma'(i,j)$ must be used in $M - 1$ edges of $\mathcal{G}(i,j)$. Thus, exactly one $G(i,j,u,v)$ is selected and, to achieve the target of $1 + 2(M-1)$, for every $fg \in E(V_i^p, V_j^p) \setminus \{uv\}$, both $a(i,j,f,g)$ and $b(i,j,f,g)$ must also be colored with $\sigma(i,j)$.

Helper: $h(y(i,j)) = 2 + kMZ + W + 1 = 3 + kMZ + W$ and $h(x(i,j)) = kMZ - kZ + W + 1 = (M-1)kZ + W + 1$. The goal here is that, if a forward or backward gadget $G(i,j,u,v)$ is selected, all the odd positions must be colored with $y(i,j)$, otherwise every even position must be colored with it.

Symmetry: $h(\varepsilon(i,j)) = h(\varepsilon'(i,j)) = Z + W + 1$. If the previous condition holds and $r(i,j,u,v)$ is colored with $\sigma(i,j)$, then $\varepsilon(i,j)$ appears in $e_\uparrow$ vertices of the gadget rooted at $r(i,j,u,v)$. To meet the target Z, $e_\downarrow$ vertices of another gadget must also be colored with it; as we show, the only way is if $r(j,i,v,u)$ is colored with $\sigma(j,i)$.

Consistency: Simply set $h(\tau_i(s,r)) = h(\tau_i'(s,r)) = Z + W + 1$. Similar to symmetry colors.

Suppression: Let $Q = \left| \bigcup_{p \in [t] \cup \{0\}} \{(i,j,u,v) \mid (i,j,u,v) \in (H_p, \mathcal{V}_p)\} \right|$, i.e. the number of tuples (i,j,u,v) that belong to some of the $t+1$ instances of MULTICOLORED CLIQUE, which equals the number of edge gadgets we added to G. We first set $h(\alpha) = Q - 2\binom{k}{2}M + W + 1$: we want that every

26

gadget corresponding to a tuple (i, j, u, v) not in the chosen instance be suppressed, i.e. have the root colored with α. Then, we set $h(\rho) = 2(Q - 2\binom{k}{2}M) + W + 1$: the same gadgets that have the root colored with α must have the neighbors of the root colored with ρ. Afterwards, we set $h(\lambda) = h(\gamma) = (Q - 2\binom{k}{2}M)kZ + W + 1$: each gadget whose root was colored by α will have every vertex, except for the root and its neighbors, colored with λ or γ; since the gadget is a path and has $2kZ + 3$ vertices, each suppressed gadget will contribute with kZ vertices colored with λ and kZ colored with γ.

Shading: For a Selection, Helper, Symmetry, Consistency, or Suppression color c, set $h(\bar{c}) = t - 1$: color $\bar{c}$ can only by used in the independent set I_c, and $\bar{c}$ must be used in all but one vertex of I_c, since only one $z_p(c)$ will not be adjacent to a vertex of B_c colored with c.

Propagation: Finally, we set $h(\beta) = \frac{q-1}{2}W$, since each of the $\frac{q-1}{2}$ choice gadgets has exactly W vertices that must be colored with β.

We now show that the composition is correct. We being with the auxiliary Lemma 31, as it presents many of the ideas required for the proof of Theorem 40.

Lemma 31. *Let φ be a list coloring of G that meets the numerical targets for Shading colors, c be the color corresponding to the primary choice gadget, and $z_p(c) \in I_c$ be such that $\varphi(z_p(c)) = c$. Then, the following conditions hold:*

1. *For every choice gadget $\mathcal{C}(d)$, $\varphi(z_p(d)) = d$.*

2. *The Propagation color β is used exactly $h(\beta)$ times.*

3. *If $d \neq \beta$ and d is not a Shading color, then d is used in $W + 1$ vertices of the instance selector gadget.*

4. *The Suppression colors can be used on a (forward or backward) edge gadget $G(i, j, u, v)$ if and only if $(i, j, u, v) \notin (H_p, \mathcal{V}_p)$.*

5. *Suppression colors are the only colors that can be used on a (forward or backward) edge gadget $G(i, j, u, v)$ where $(i, j, u, v) \notin (H_p, \mathcal{V}_p)$.*

6. *For every Suppression color d, $|\varphi_d| = h(d)$.*

Proof. Note that we do not assume that φ satisfies every numerical target given by h, it is simply a proper coloring of G that respects the lists given by L. We prove the conditions in the order they were given in the statement.

1. By construction, the i-th bit of $\mathcal{C}(c)$ is equal to 0 if and only if the i-th bit of the binary representation of p is equal to 0. Moreover, for every other color d with a choice gadget, the i-th bit of $\mathcal{C}(d)$ cannot be equal to 1, otherwise, $(c, i)_0(d, i)_1$ would be a monochromatic edge. Thus, $z_p(d)$ is the unique vertex of I_d that does not have a neighbor colored with d and, since, $|\varphi_{\bar{d}}| = h(\bar{d})$, $\varphi(z_p(d)) = d$.

2. This follows directly from the fact that there are $\frac{q-1}{2}$ choice gadgets and, in each $\mathcal{C}(d)$, β can only be used in the perfect matching B_d and must be used $\frac{|B_d|}{2} = \log_2 |\mathcal{H}| = W$.

3. Note that that d is used in every vertex of B_d not colored with β and there is $z_p(d)$ is the unique vertex of I_d where $\varphi(z_p(d)) = d$. Since no other choice gadget contains a vertex with d on their list, d is used $\frac{|B_d|}{2} + 1 = W + 1$ times.

4. If a Suppression color d can be used on $G(i, j, u, v)$, then $z_p(d)$ is not adjacent to any vertex of $G(i, j, u, v)$, which, by construction, implies the $(i, j, u, v) \notin (H_p, \mathcal{V}_p)$. For the converse, if $(i, j, u, v) \notin (H_p, \mathcal{V}_p)$ then $z_p(d)$ is not adjacent to the vertices of $G(i, j, u, v)$, which implies that d can be used in $G(i, j, u, v)$. By condition 1, these arguments hold for every Suppression color.

5. Let g be a vertex of $G(i, j, u, v)$, $L(g) = \{d, e, f\}$, and d be the unique suppression color in $L(v)$. By the construction of G, v is adjacent to $z_p(e)$ and $z_p(f)$ which, again by condition 1, satisfy $\varphi(z_p(e)) = e$ and $\varphi(z_p(f)) = f$. Moreover, $g z_p(d) \notin E(G)$, every neighbor of g in $\mathcal{C}(d)$ is colored with $\bar{d}$, and no neighbor of g in $G \setminus \mathcal{C}(d)$ has color d on their list, so g can only be colored with d.

6. Once again, let $Q = \left| \bigcup_{p \in [t] \cup \{0\}} \{(i, j, u, v) \mid (i, j, u, v) \in (H_p, \mathcal{V}_p)\} \right|$. By the previous conditions, Suppression color α is used $W + 1 = \log_2 |\mathcal{H}| + 1$ times in the instance selector gadget and, for every $(i, j, u, v) \notin (H_p, \mathcal{V}_p)$, α is used once; equivalently, for every element of $S = \{(i, j, u, v) \mid (i, j, u, v) \in (H_p, \mathcal{V}_p)\}$, α is not used. Thus, α is used in $Q - |S| + W + 1 = Q - 2\binom{k}{2}M + W + 1 = h(\alpha)$ vertices. For color ρ, note that ρ can must be used on $a(i, j, u, v)$ and $b(i, j, u, v)$ if $r(i, j, u, v)$ is colored with α, so ρ is used twice as many times on the edge gadgets, i.e. $|\varphi_\rho| = 2|\varphi_\alpha| - (W + 1) = 2(Q - 2\binom{k}{2}M) + W + 1 = h(\rho)$. Finally, color λ is used on half of the $2kZ$ vertices of $G(i, j, u, v) \setminus N[r(i, j, u, v)]$, and γ on the other half, whenever $r(i, j, u, v)$ is colored with α. Consequently, $|\varphi_\lambda| = |\varphi_\gamma| = |\varphi_\alpha| kZ - (kZ - 1)(W + 1) = (Q - 2\binom{k}{2}M)kZ + W + 1 = h(\lambda) = h(\gamma)$.

$\square$

Lemma 32. *If $(H_p, \mathcal{V}_p)$ admits a solution Q, then (G, L, h) admits a list coloring that satisfies by h.*

Proof. Let Q be the solution to $(H_p, \mathcal{V}_p)$ and be c the color corresponding to the primary choice gadget. We begin with the following partial coloring φ' of G:

- For every choice gadget $\mathcal{C}(d)$, set $\varphi'(z_p(d)) = d$ and, for every $z_q(d) \in I_c \setminus \{z_p(d)\}$, set $\varphi'(z_q(d)) = \bar{d}$.

- Color the i-th bit of B_d so that $\varphi'((d, i)_0) = \beta$ if and only if the i-th least significant bit of p if 0; the other vertex of $b(d, i)$ is colored with d.

- For every tuple $(i, j, u, v) \notin (H_p, \mathcal{V}_p)$ that has an associated edge gadget $G(i, j, u, v)$, color its vertices using the unique Suppression color present on their list.

Claim 33. *The partial coloring φ' is a proper partial coloring of G.*

Proof of the claim. First, no two adjacent vertices of the instance selector gadget have the same color since: (i) each bit $b(d,i) \in B_d$ has one vertex of each color, (ii) every neighbor of $z_p(d)$ is colored with β, (iii) no neighbor of $z_s(d) \in I_d \setminus \{z_s(d)\}$ has $\bar{d}$ on their list, and (iv) the vertex of $b(c,i)$ colored with β is adjacent to the vertex of $b(d,i)$ that is colored with d. As to the colored edge gadgets, each pair of adjacent vertices in such a gadget $G(i,j,u,v)$ has a different Suppression color on their list; since these were the colors currently used, no monochromatic edge may exist in $G(i,j,u,v)$. Finally, no $z_p(d)$ is adjacent to a vertex of $G(i,j,u,v)$ colored with d, since we only used Suppression colors in $G(i,j,u,v)$ and, when d is a Suppression color, $z_p(d)$ is adjacent to edge gadgets where $(i,j,u,v) \in (H_p, \mathcal{V}_p)$. $\qquad\square$

Using a similar analysis to Lemma 31, we conclude that $|\varphi'_d| = h(d)$ for every Suppression, Shading, and Propagation color d and, for all other colors f, we must use f exactly $h(f) - (W + 1)$. Moreover, the only edge gadgets $G(i,j,u,v)$ that remain uncolored are those where $(i,j,u,v) \in (H_p, \mathcal{V}_p)$, and no Suppression color d can be used in vertices of $G(i,j,u,v)$ since $z_p(d)$ is adjacent to vertices of $G(i,j,u,v)$ if and only if $(i,j,u,v) \in (H_p, \mathcal{V}_p)$. We proceed to extend φ' into a coloring φ of G as follows: for each edge $uv \in Q$, we color the root of $G(i,j,u,v)$ with $\sigma(i,j)$, each odd vertex with $y(i,j)$, and every even vertex with the only remaining color; for all other still uncolored gadgets, we color the root with $\sigma'(i,j)$, every even vertex with $y(i,j)$ and all odd vertices with the only possible color left on their lists. The following claim concludes the proof of this lemma.

Claim 34. *The coloring φ is a proper coloring of G that meets the numerical targets given by h.*

Proof of the claim. First, note that each Selection color $d \in \mathcal{S} \cup \mathcal{S}'$ is used the appropriate number of times since: (i) it is used $W + 1$ times in the instance selector gadget, (ii) no gadget $G(i,j,u,v)$ where $(i,j,u,v) \notin (H_p, \mathcal{V}_p)$ can be colored with d, and (iii) only one edge $uv \in E(V_i^p, V_j^p)$ belongs to Q. For each color $y(i,j) \in \mathcal{Y}$ and edge uv with $u \in V_i^p$, gadget $G(i,j,u,v)$ has, at least, $e_\uparrow + e_\downarrow + (k-1)(u_\uparrow + u_\downarrow) = kZ$ vertices colored with $y(i,j)$, since either all odd vertices or even vertices are colored with it. For the remaining $W + 3$ uses of $y(i,j)$, note that the selected gadget $G(i,j,u,v)$ has $a(i,j,u,v)$ and $b(i,j,u,v)$ also colored with $y(i,j)$, and $\mathcal{C}_{y(i,j)}$ has $W + 1$ vertices colored with $y(i,j)$. As to the other helper color, $x(i,j)$, we use it only on $\mathcal{C}_{x(i,j)}$ and on passed gadgets – in this case, in every odd vertex (except the a's and b's); this sums up to $W + 1 \sum_{e \in E(V_i^p, V_j^p) \setminus Q} e_\uparrow + e_\downarrow + (k-1)(u_\uparrow + u_\downarrow) = kMZ - kZ + W + 1 = h(x(i,j))$. In terms of symmetry colors, φ only uses $\varepsilon(i,j)$ on $\mathcal{C}_{\varepsilon(i,j)}$ and on the selected gadgets $G(i,j,u,v)$ and $G(j,i,v,u)$ ($i < j$); in particular, $\varepsilon(i,j)$ is used $e_\downarrow$ times in $G(j,i,v,u)$ and $e_\uparrow$ times on $G(i,j,u,v)$, so it holds that $|\varphi_{\varepsilon(i,j)}| = e_\uparrow + e_\downarrow + W + 1 = Z + W + 1$. Note that the same argument applies for color $\varepsilon'(i,j)$. Finally, for consistency colors, note that $\tau_i(r,s)$ is used only on $\mathcal{C}_{\tau_i(r,s)}$ and on the selected gadgets $G(i,r,u,v)$ and $G(i,s,u,w)$, specifically, if $i < r < s$, $\tau_i(r,s)$ is used $u_\uparrow$ times in $G(i,r,u,v)$ and $u_\downarrow$ times in $G(i,s,u,w)$, since edges uv, uw must be incident to the same vertex of $Q \cap V_i^p$. Consequently $\tau_i(r,s)$ is used in $u_\uparrow + u_\downarrow + W + 1 = Z + W + 1$ vertices. The reasoning for $\tau'_i(r,s)$ is similar. For all other colors, we had already established that their

numerical targets had already been met; since no additional vertex used any of them, it follows that φ meets all numerical targets and is a proper coloring. $\square$

$\square$

Lemma 35. *If G admits a list coloring φ that respects L and satisfies the numerical targets h, then at least one instance $(H_p, \mathcal{V}_p)$ of $\mathcal{H}$ admits a solution.*

Proof. Let $\mathcal{C}(c)$ be the primary choice gadget of G and $z_p(c)$ be the unique vertex of I_c where $\varphi(z_p(c)) = c$. We are going to show that $(H_p, \mathcal{V}_c)$ contains a multicolored clique of appropriate size. As a consequence of Lemma 31, a gadget $G(i, j, u, v)$ is not suppressed if and only if $(i, j, u, v) \in (H_p, \mathcal{V}_p)$. Moreover, these gadgets must be colored using Selection, Helper, Symmetry, and Consistency colors, and each color d of this family must still be used $h'(d) = h(d) - W - 1$ times. We break the proof in the following claims, where $\mathcal{G}_p(i, j)$ are all the gadgets where $(i, j, u, v) \in (H_p, \mathcal{V}_p)$.

Claim 36. *In every list coloring of G satisfying h, exactly one gadget of each $\mathcal{G}_p(i, j)$ is selected, each passed $G(i, j, w, z)$ has all of its kZ even vertices colored with $y(i, j)$, and the selected $G(i, j, u, v)$ has all of its $2 + kZ$ odd vertices colored with $y(i, j)$.*

Proof of the claim. For the first statement, if no gadget was selected, $\sigma'(i, j)$ would be used $M > M - 1$ times; if more than one is selected, $\sigma'(i, j)$ does not meet the target. If $G(i, j, u, v)$ is selected then $a(i, j, u, v)$ and $b(i, j, u, v)$ are colored with $y(i, j)$. After removing these vertices, we are left with two even paths of which at most half of its vertices are colored with the same color. As such there are at most $2 + f_\downarrow + (k-1)u_\downarrow + f_\uparrow + (k-1)u_\uparrow = 2 + kZ$ vertices colored with $y(i, j)$ in this gadget; moreover this bound is achieved if and only if the odd vertices are colored with $y(i, j)$. For each passed $G(i, j, w, z)$, $a(i, j, w, z)$ and $b(i, j, w, z)$ are colored with $\sigma(i, j)$, otherwise the numerical target of $\sigma(i, j)$ cannot be met. After the removal of $a, b, r(i, j, w, z)$ we are again left with two even paths. Thus, at most $e_\downarrow + (k-1)u_\downarrow + e_\uparrow + (k-1)u_\uparrow = kZ$ vertices have color $y(i, j)$ in this gadget. To see that $y(i, j)$ must be used only for even vertices of $G(i, j, w, z)$ to meet this bound, note that, if this is not done, then $x(i, j)$ will never meet its bound, since exactly $kMZ - kZ$ vertices remain (after the coloring of $G(i, j, u, v)$ and the instance selector gadget) that can be colored with $x(i, j)$, which is precisely the number of vertices that must still be colored with $x(i, j)$ to meet its target. $\square$

Claim 37. *In every list coloring φ of G, if $G(i, j, u, v)$ is selected, so is $G(j, i, v, u)$.*

Proof of the claim. Suppose $i < j$, and let $e = uv$, and $\bar{e} = vu$ By Claim 36 we know that for a selected gadget every odd vertex is colored with $y(i, j)$, so each even vertex is colored with a non-Helper color. Note that color $\varepsilon'(i, j)$ is used $e_\downarrow$ times in gadget $\overrightarrow{G}(i, j, u, v)$. Now, we need to select one backward gadget of $\mathcal{G}_p(j, i)$; suppose we select gadget $G(j, i, w, z)$, $wz = f \neq \bar{e}$. Again by Claim 36, the number of occurrences of $\varepsilon'(i, j)$ is $f_\uparrow$ times in $G(j, i, w, z)$, but we have that $e_\downarrow + f_\uparrow \neq Z$, a contradiction that φ satisfies h. $\square$

Claim 38. *In every list coloring φ of G, if $G(i, j, u, v)$ is selected and $e = uv$, then, for every $s \neq i$, the edge wz of H_p corresponding to the selected gadget $G(i, s, w, z)$ have $w = u$.*

Proof. We divide our proof in two cases. First, suppose $i < j$ and $s < j$. By Claim 36 $\tau_i(s, j)$ is used in $u_\uparrow$ vertices of $G(i, j, u, v)$. Now, note that the only possible gadget $G(i, s, w, z)$ that can be chosen such that $w \in V_i$ satisfies $u_\uparrow + w_\downarrow = Z$ must have $w = u$, since $\tau_i(s, j)$ is used $w_\downarrow$ times in gadget $G(i, s, w, z)$. The case $j < s$ is similar, but we replace τ_i with τ_i' in the analysis. $\square$

The previous claims guarantee that: two edges incident to vertices of V_i^p have the same endpoint in V_i^p for every $i \in k$ and, consequently, for every pair of edges $uv \in E(V_i^p, V_j^p)$, $uw \in E(V_i^p, V_\ell^p)$, if $G(i, j, u, v)$ and $G(i, j, u, w)$ are selected, then $(j, \ell, w, v) \in (H_p, \mathcal{V}_p)$ and $G(j, \ell, w, v)$ is also selected. $\square$

Lemma 39. *Graph G has a vertex cover of size* $\mathsf{poly}(n + \log_2 |\mathcal{H}|)$.

Proof. Note that there are at most $\binom{k}{2}\binom{n}{2}$ edge gadgets since we have at most this many tuples of the form (i, j, u, v) where $i, j \in [k]$ and $u, v \in [n]$. Moreover, for each choice gadget $\mathcal{C}(d)$, we have $|\mathcal{C}(d) \setminus I_d| = \log_2 |\mathcal{H}|$ and, between the primary choice gadget $\mathcal{C}(c)$ and any other $\mathcal{C}(d)$ the only edges are between the bits, i.e. the union of the independent sets of the choice gadgets is also an independent set $\mathcal{I}$. Finally, since we have $\frac{q-1}{2} \in \mathcal{O}(k^2)$ choice gadgets and $k \leq n$, $G \setminus \mathcal{I}$ has $\mathsf{poly}(n + \log_2 |\mathcal{H}|)$ vertices and is a vertex cover of G. $\square$

Lemmas 32, 35, and 39 directly imply Theorem 40: the first two lemmas show that the some $(H_p, \mathcal{V}_p) \in \mathcal{H}$ admits a solution if and only if (G, L, h) admit a solution, while the third shows that the parameters in (G, L, h) are bounded by a polynomial on $n + \log_2 |\mathcal{H}|$.

Theorem 40. Number List Coloring *does not admit a polynomial kernel when parameterized by vertex cover and number of colors, unless* $\mathsf{NP} \subseteq \mathsf{coNP/poly}$.

To obtain the next two corollaries, note that: (i) adding isolated vertices with singleton lists to G is a PPT reduction from Number List Coloring parameterized by vertex cover and number of colors to Equitable List Coloring under the same parameterization, and (ii) adding a clique R of same size as the number of colors and edges between R and vertices of G to simulate the lists is also a PPT reduction from Equitable List Coloring to Equitable Coloring; note that the clique may be safely added to the vertex cover, since its size is linear on the number of colors, which is a parameter.

Corollary 41. Equitable List Coloring *does not admit a polynomial kernel when parameterized by vertex cover and number of colors, unless* $\mathsf{NP} \subseteq \mathsf{coNP/poly}$.

Corollary 42. Equitable Coloring *does not admit a polynomial kernel when parameterized by vertex cover and number of colors, unless* $\mathsf{NP} \subseteq \mathsf{coNP/poly}$.

10 Final Remarks

In this work we presented an extensive study of multiple parameterizations for the Equitable Coloring problem, obtaining both tractability, intractability, and kernelization results. Specifically, we proved that it is fixed parameter tractable when parameterized by distance to cluster and by distance to

co-cluster. As corollaries, we have that there is an FPT algorithm when parameterizing the problem by distance to unipolar and number of colors. Meanwhile, EQUITABLE COLORING remains W[1]-hard when simultaneously parameterized by distance to disjoint paths and number of colors; if, on the other hand, we parameterize by distance to disjoint paths of length at most ℓ, the problem is fixed-parameter tractable. We then presented a linear kernel under distance to clique and a cubic kernel when parameterized by the maximum leaf number; along with Reddy's [28] polynomial kernel when parameterized by distance to connected threshold and number of colors, these are the only examples of positive kernelization results we know of. Our final result showed that, under a standard complexity hypothesis, EQUITABLE COLORING has no polynomial kernel when jointly parameterized by vertex cover and number of colors. We also revisited previous works in the literature and restated them in terms of parameterized complexity. This review settled the complexity for some parameterizations weaker than distance to clique and show that some of our results are, in a sense, optimal: searching for parameters weaker than distance to (co-)cluster will most likely not yield FPT algorithms. VERTEX COLORING is already notoriously hard to find polynomial kernels for, as shown by Jansen and Kratsch [22]; in fact, most of the parameterizations under which classical coloring admits a polynomial kernel do not make EQUITABLE COLORING tractable, painting a quite bleak future for kernelization algorithms for EQUITABLE COLORING. We leave three main questions about the tractability of EQUITABLE COLORING: distance to disconnected threshold, feedback edge set, and the stronger joint parameterization feedback vertex set and maximum degree, with the first two being the most interesting cases. We believe it is also possible to improve the constants on our max leaf number kernel result, but do not yet know how to obtain a subcubic kernel under the this parameterization. Another interesting direction would be to improve the running times of known tractable cases and determining lower bounds for parameters such as vertex cover and distance to clique. In particular, we would like to know if the algorithms presented in Sections 3, 4, and 6 have optimal running times or, if not, how one can obtain faster algorithms.
