ABSTRACT

With an outreach in more than 90 countries, a market share of 2.1 billion dollars and a target audience base of at least 1.2 billion people, Bollywood, aka the Mumbai film industry, is a formidable entertainment force. While the number of lives Bollywood can potentially touch is massive, no comprehensive NLP study on the evolution of social and gender biases in Bollywood dialogues exists. Via a substantial corpus of movie dialogues spanning a time horizon of 70 years, we seek to understand the portrayal of women, in a broader context studying subtle social signals, and analyze the evolving trends in geographic and religious representation in India. Our argument is simple – popular movie content reflects social norms and beliefs in some form or shape. In this project, we propose to analyze such trends over 70 years of Bollywood movies contrasting them with their Hollywood counterpart and critically acclaimed world movies.

Keywords Gender Bias · Social Bias · Bollywood · Hollywood

1 Introduction

What types of social biases can we analyze and detect through the lens of a diachronic corpus of popular entertainment? In this paper, we focus on Bollywood, aka the Mumbai film industry, and analyze a curated corpus of film subtitles for the last 70 years. While Bollywood is an entertainment industry worth billions and has a target audience of 1.2 billion people, little or no work exists that analyzed a wide range of social biases and signals that can be uncovered from this rich corpus. In this work, we contrast our findings with an analogous corpus of Hollywood and for a specific subset of research questions, we dig deeper and look into world movies.

Our primary focus is gender bias. As shown in Table 1, several Bollywood movies are riddled with sexist and misogynist dialogues. It is thus not surprising that cutting edge NLP methods would reveal some of these existing biases. We are, however, interested in a broader research question: *In a developing nation, what kind of social insights can be gleaned from popular entertainment?* Is it possible to understand subtle gender biases such as son’s preference? Can we track the evolving nature of retrograde social practises like dowry?

Our second focus in this work is broader representation questions such as geographic representation, religious representation and caste representation. In our mixed method analyses, we identify that (1) some of gender biases observed in Bollywood is very much present in it’s Western counterpart; (2) a positive trend is witnessed in observing reduced biases with progress of time and; and (3) a similar trend is observed in religious and geographic representation, with a considerable scope for improved diversity and inclusion.

*Kunal Khadilkar and Ashiqur R. KhudaBukhsh are equal contribution first authors.

Akeli ladki khuli tijori ki tarah hoti hai (Jab We Met)	A girl who is alone is like an open treasure. (Jab We Met)
Generated Movie Revenue: ≈\$14,899,137	
Marriage se pehle ladkiya jn sex object hoti hain, our marriage ke baad they object to sex! (Kambakkht Ishq)	Before marriage, girls are sex objects, and after marriage, girls object to sex. (Kambakkht Ishq)

Table 1: Illustrative examples of misogynistic dialogues present in blockbuster Bollywood movies (movie names are presented in parentheses). The dialogues (in blue) are in Romanized Hindi, and their approximate English translations are highlighted in red.

2 Research questions

We aim to answer the following research questions -

RQ 1: How is gender bias reflected through movie dialogues in the Bollywood and Hollywood movie industries?

RQ 2: How do award winning foreign feature films compare with Bollywood and Hollywood in addressing gender equality? Does genre make any difference?

RQ 3: Is beauty associated with fair skin in the movie dialogues describing women?

RQ 4: Does Bollywood reflect the well-documented son’s preference in medical and social science research? How has the sentiment around retrograde social practices such as dowry evolved?

RQ 5: Which geographical areas have been consistently underrepresented in the Indian film industry?

RQ 6: Can we gain an insight into the religious representation of a country, through a film corpus spanning 70 years?

RQ 7: Can we extract economic signals through popular film dialogues?

RQ 8: How are religions perceived in movies? Can we track evolving national priorities from popular entertainment?

3 Related Work

Studies analyzing gender stereotypes across different languages [1] and detecting bias in word embeddings [2] use books and news data sources for their analyses. Existing lines of work in uncovering entertainment industry bias focus on a single Bollywood movie [3] or a small subset of movies [4]. [5] focused on plot points and film information taken from Wikipedia. We consider a different and potentially richer data set of film subtitles spanning 70 years. We contrast our work with Hollywood and award winning world movies, and our analyses cover a broader set of aspects such as retrograde social practices, uncovering subtler biases and highlighting geographical and religious underrepresentation. Unlike previous work on movie subtitles [1], our focus is on Bollywood content largely ignored by the information science research community so far.

In terms of our dataset, our work is most similar to [6] that looked at a smaller corpus of Bollywood subtitles. Our work contrasts with [6] in the following key ways. First, our treatment to the analyses of gender bias (1) includes diachronic-word embedding analysis and word embedding association tests (WEAT); (2) is grounded on well-established lexicons; (3) looks into subtler signals such as son’s preference; (4) tracks retrograde social practices such as dowry and (5) considers additional data sources (e.g., world movies). Second, our work tackles important questions on geographic and religious representation unaddressed by [6]. Finally, we look into questions related to economic signals and show promising computational creativity results.

In this paper, we explore a wide array of NLP techniques to analyze our research questions through the lens of popular movies. We use

1. Simple *count-based statistics* relying on highly popular lexicons [7] and gender representation studies [8, 9];
2. *Cloze test*, an analysis technique that have a solid grounding in psycholinguistics literature [10, 11]. To the best of our knowledge, for the first time, we explore a recent technique [12] previously used to mine political insights [13] in the context of uncovering social biases. Through a series of cloze tests on a language model [14] fine-tuned on our data sets, we present our findings.
3. *Analysis of aligned diachronic word embedding spaces* using recently proposed techniques [15].

4. Free form text completion using GPT-2 [16], for a novel task of tracking economic signals.

We employ this broad suite of NLP techniques on a novel domain of popular entertainment.

Geographical and community representation in India has been studied by various political and social scientists. [17] showcase the population misrepresentation in political settings, while [18] focuses on underrepresentation of north-east India in mainstream newspapers. Our work complements this research [18] and presents corroborating evidence from a very different data source.

4 Data Set

We construct the following two data sets of movie subtitles.

1. Bollywood movies, $\mathcal{D}_{bollywood}$: We consider movies spanning seven decades (1950–2020). For each decade, we retrieved subtitles [19] of 100 movies (700 total films).

2. Hollywood movies, $\mathcal{D}_{hollywood}$: Similar to Bollywood movies, we considered 100 top-grossing movies from each of the seven decades (700 total films). Overall, $\mathcal{D}_{bollywood}$ and $\mathcal{D}_{hollywood}$ consist of 1.1M dialogues (6.2M Tokens) and 1M dialogues (5.4M Tokens), respectively.

For a subset of our analyses, we divide our corpus into three buckets presented in Table 2.

Corpus	Industry	Time Period	Corpus	Industry	Time Period
$\mathcal{D}_{bollywood}^{old}$	Bollywood	1950 - 1969	$\mathcal{D}_{hollywood}^{old}$	Hollywood	1950 - 1969
$\mathcal{D}_{bollywood}^{mid}$	Bollywood	1970 - 1999	$\mathcal{D}_{hollywood}^{mid}$	Hollywood	1970 - 1999
$\mathcal{D}_{bollywood}^{new}$	Bollywood	2000 - 2020	$\mathcal{D}_{hollywood}^{new}$	Hollywood	2000 - 2020

Table 2: Dataset split for Bollywood and Hollywood

We further collect 150 movies which have been nominated for the *Best International Feature Film* award 1970 onwards, at the Oscars (<https://www.oscars.org>) for a subset of our analyses.

5 Gender Bias in Movie Dialogues

RQ 1: How is gender bias reflected through movie dialogues in the Bollywood and Hollywood movie industries?

5.1 Gendered pronouns

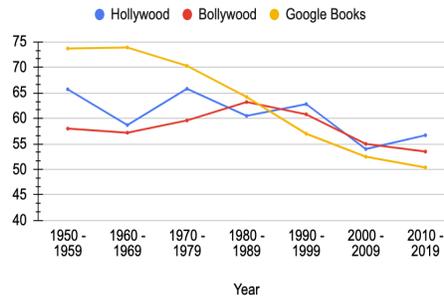

Figure 1: MPR in $\mathcal{D}_{bollywood}$ and $\mathcal{D}_{hollywood}$

Following extensive literature on gendered pronouns’ relative distributions and their implications [8, 9], we consider a simple measure of gender representation: relative occurrence of pronouns of each gender (Men: he, him. Women: she, her). Let \mathcal{N}_w denote the number of times a token w appears in a corpus. We define *Male Pronoun Ratio (MPR)* as follows: $MPR = \frac{\mathcal{N}_{he} + \mathcal{N}_{him}}{\mathcal{N}_{he} + \mathcal{N}_{him} + \mathcal{N}_{she} + \mathcal{N}_{her}} * 100$. Figure 1 plots MPR of our decade-wise movie data sets and contrasts with MPR computed using google n-grams. Our results indicate that even now, both Bollywood and Hollywood exhibit comparable skew in gendered pronoun usage.

5.2 Cloze tests

When presented with a sentence (or a sentence stem) with a missing word, a cloze task [10] is essentially a fill-in-the-blank task. For instance, in the following cloze task: *In the [MASK], it is very sunny, summer* is a likely completion for the missing word. Given a cloze test, BERT, a well-known language model [14], outputs a series of token ranked by probability. In fact, in the above cloze test, the top three tokens (ranked by probability) predicted by BERT_{base} are: summer, winter and spring. Recent lines of research has explored BERT’s masked query prediction for (1) knowledge base extraction [12] and (2) mining political insights [13].

Probe	BERT _{base}	BERT _{D^{old}_{bolly}}	BERT _{D^{new}_{bolly}}	BERT _{D^{old}_{holly}}	BERT _{D^{new}_{holly}}
<i>cloze₁</i>	man, widow, woman, doctor, slave , soldier, bachelor, merchant , farmer, lawyer, servant [4.8]	prostitute , servant , woman, slave , bachelor, doctor , lawyer, man, widow, maid , worker [4.64]	doctor, woman, servant , lawyer, maid , hindu, nurse, teacher, gardener, lady, man [5.7]	woman, slave , servant , nurse, lady, man, teacher, lawyer, peasant, maid , wife [5.3]	woman, lawyer, doctor, nurse, teacher, man, writer, secretary, prostitute , professional, carpenter [5.7]
<i>cloze₂</i>	man, soldier, gentleman, farmer, merchant , woman, slave , bachelor, doctor, carpenter, servant [5.48]	man, gentleman, lawyer, lawyer, servant , doctor, farmer, worker, craftsman, slave , criminal [5.0]	doctor, lawyer, policeman, man, farmer, bachelor, gardener, servant , soldier, mechanic, builder [5.3]	carpenter, policeman, lawyer, soldier, farmer, gentleman, servant , man, peasant, slave , doctor [5.0]	man, lawyer, soldier, doctor, carpenter, gentleman, clergyman, farmer, writer, craftsman, minister [5.78]

Table 3: Cloze test results. Predicted tokens are ranked by decreasing probability. Positive and negative words are color coded with blue and red, respectively. The number in the bracket represents the average valence score (obtained from [7]) calculated for the answers to the cloze test.

Our cloze test results are summarized in Table 3. We observe that completion results for both genders across both movie industries improve over time. In order to quantify the completion results, we consider a well-known lexicon of emotional valence ratings [7] of nearly 14,000 English words to quantify the change of cloze test completions over time. The valence score of these words are presented in a scale of 1 to 10 with 10 indicating highly positive and 1 indicating highly negative. For example, the emotional valence score of happy and sad are 8.47 and 2.10, respectively. For a given data set and a cloze test pair, we compute the average valence score of the completions (listed in square brackets in Table 17). We further note that comparing completion words across the two genders can be technically difficult simply because we observe that there can be potential bias in the scores. For instance, the valence scores for man and woman are 5.42 and 7.09, respectively. Hence we restrict ourselves to comparing within a specific gender for a given movie industry.

	Bollywood	Hollywood
Women	22%	7%
Men	5%	15%

Table 4: Percent increase in average valence score for cloze test completions between old movies and new movies.

Table 4 lists the percentage of increase in the valence score of the completion for a particular gender across different movie industries. We note that for both Bollywood and Hollywood, the valence scores for both genders improved over time. However, for Bollywood, we notice that rate of increase for women is substantially more pronounced than that for men. This observation aligns with the continual fight for gender equality in India [20] and major movements that have mobilised voices for women’s right to work [21], financial independence [22], and marital laws [23].

5.3 Diachronic word embeddings

The meaning of words and the context in which they are used change over time [24]. The language spoken in a community is representative of the cultural norms and customs followed in that region. Existing hypotheses [25] indicate that word frequency may play a role in changing the meaning of the words over time. The meanings of less-frequent words are more susceptible to drifts than that of highly frequent words. [15] provide a robust multilingual approach to align diachronic word embeddings using orthogonal procrustes. We follow the same method to align different sub-corpora for Bollywood and Hollywood. In addition to the four sub-corpora – D_{bolly}^{old} , D_{bolly}^{new} , D_{holly}^{old} , D_{holly}^{new} – we consider the time period of 1970-2000 and construct two additional sub-corpora D_{bolly}^{mid} and D_{holly}^{mid} . We train word2vec [26] with SGNS (Skip-gram with Negative Sampling), to create embeddings for each of the buckets mentioned above. Let $\mathcal{W}^{(t)} \in \mathbb{R}^{(d) \times \mathcal{V}}$ be the matrix of word embeddings learnt for period t for vocabulary \mathcal{V} . Following

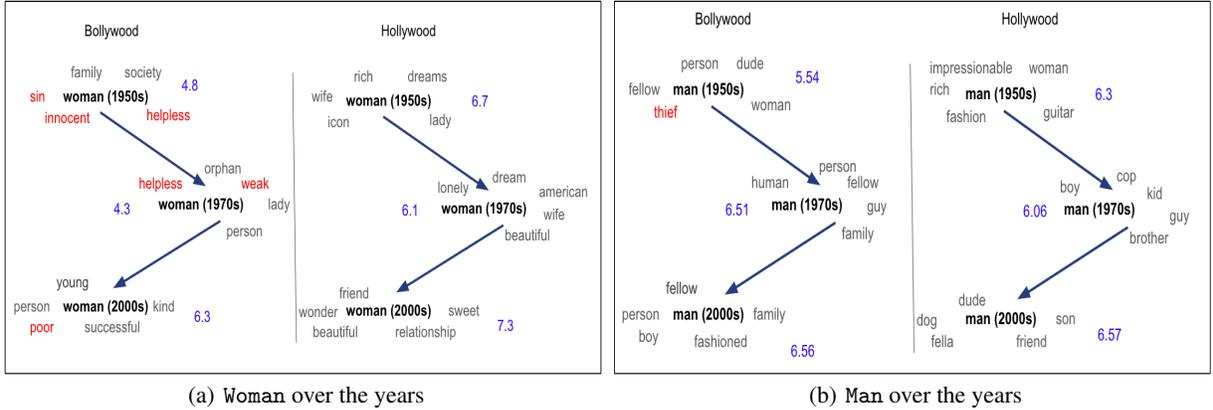

Figure 2: Nearest neighbors of man and woman over the years. The overall average valence of nearest neighbors according to the lexicon provided in [7] for a given time-period is presented in blue font.

[15], we align the word embeddings using the top 10,000 common tokens present across time periods t and $t + 1$ by optimizing:

$$R^t = \arg \min_{Q^T Q = I} \left\| QW^t - W^{(t+1)} \right\|_F \quad (1)$$

where $R^t \in \mathbb{R}^{d \times d}$.

We focus on the portrayal of women and men using these aligned embeddings. We observe that the valence scores for both genders across both movie industries show a similar pattern. The scores are the lowest during the 1970-1999 time period. The valence scores for the newer movies are better than the scores for the older movies. The dip in the valence scores during the time-period of 1970-1999 in India can be ascribed to a social and cultural crisis influenced by an unstable political climate (assassinations of two prime ministers [27, 28]), two major wars between India and Pakistan [29, 30], and a large overlap with a pre-economic liberalization period [31].

5.4 Word Embedding Association Test (WEAT) for quantifying gender bias

While valence scores give us an indication regarding the difference in valence (degree of pleasantness) scores between the two genders on Language Models cloze tests, we explore quantifying the bias in our corpus using a more popular technique of Word Embedding Association Test (WEAT) [32]. For the purpose of this analysis, We train the sub-corpora using GloVe [33] embeddings, as given in [32], to understand the evolution of gender bias through time. According to WEAT, we consider two equal sized sets of occupations, S_1 and S_2 and two sets of attribute words A_1 and A_2 .

The similarity of two words, say x and y , is given by calculating the cosine similarity of the corresponding word embeddings, $\cos(w_x, w_y)$. As given in [32], the differential association of a word c with word sets A_1 and A_2 is given by:

$$g(c, A_1, A_2, w) = \frac{\text{mean}}{a \in A_1} \cos(w_c, w_a) - \frac{\text{mean}}{b \in A_2} \cos(w_c, w_b) \quad (2)$$

Further, the WEAT is calculated as:

$$B_{\text{weat}}(w) = \frac{\frac{\text{mean}}{s \in S_1} g(s, A_1, A_2, w) - \frac{\text{mean}}{t \in S_2} g(t, A_1, A_2, w)}{\text{std-dev}} \frac{\text{mean}}{s \in S_1} g(s, A_1, A_2, w) \quad (3)$$

Here, the occupation sets taken from [34] S_1 and S_2 are:

$S_1 = [$ “maestro”, “skipper”, “protege”, “philosopher”, “captain”, “architect”, “financier”, “warrior”, “broadcaster”, “magician”, “pilot”, “boss” $]$ $S_2 = [$ “homemaker”, “nurse”, “receptionist”, “librarian”, “socialite”, “hairstylist”, “nanny”, “bookkeeper”, “stylist”, “housekeeper”, “designer”, “counselor” $]$

And the attribute word sets A_1 and A_2 are: $A_1 = [$ ‘he’, ‘man’, ‘male’ $]$ $A_2 = [$ ‘she’, ‘woman’, ‘female’ $]$

Industry	<i>Old</i>	<i>Mid</i>	<i>New</i>
Bollywood	0.601	0.559	0.543
Hollywood	0.456	0.443	0.410

Table 5: Average WEAT scores for Bollywood and Hollywood across different time periods. A larger value indicates greater gender bias.

As shown in Table 5, we find that the average WEAT scores across both industries reduced over time. As compared to Bollywood, for any given time period, Hollywood exhibits lesser gender bias.

6 Genre Specific Analysis

RQ 2: *How do award winning foreign feature films compare with Bollywood and Hollywood in addressing gender equality? Does genre make any difference?*

Along with performing a comparative study between Bollywood and Hollywood, we are further interested in comparing the WEAT scores of Bollywood and Hollywood with that of a set of critically acclaimed world movies. To this end, we construct a corpus of 150 movies nominated at the foreign film category at the Academy awards.

Industry	WEAT score
Bollywood	0.523
Hollywood	0.504
World movies	0.285

Table 6: WEAT scores for Bollywood, Hollywood and world movies.

Our results indicate that the average WEAT score obtained for nominated foreign feature films is the lowest as compared to the average WEAT score for Bollywood and Hollywood.

Adventure/Action and Romance are the two most popular genres across different industries, with hundreds of films released every year. Action films generally tend to be male dominated, compared to Romantic films. We explore this hypothesis using WEAT, for the given genres. For this analysis, we consider four token-balanced sub corpora, $G_{bollywood}^{action}$, $G_{bollywood}^{romance}$, $G_{hollywood}^{action}$, $G_{hollywood}^{romance}$, each containing 150 films. All the films were post 1990, and were chosen based on the genre lists/tags given by imdb and Google.

	<i>Romance</i>	<i>Action</i>
Hollywood	0.079	0.591
Bollywood	0.343	0.512

Table 7: WEAT scores for Romance and Action films.

Table 7 shows that the gender bias for action movies is a lot more pronounced than that in Romance movies. Across both industries and movie genres, Hollywood action films exhibit most bias.

7 Associating Beauty with Fair Skin

RQ 3: *Is beauty associated with fair skin in the movie dialogues describing women?*

We first present our cloze test results with the probe "A beautiful woman should have [MASK] skin." in Table 8. We note that while BERT_{base} model predicts *soft* in place of [MASK], all fine-tuned BERT models on the film corpora predict *fair* as the top choice. Figure 3 visualizes the nearest neighbors of beautiful in our aligned embedding spaces of Hollywood and Bollywood sub-corpora.

Let \mathcal{N}_w denote the number of times a dialogue talking about the baby’s gender w appears in a corpus. We define *Male Birth Ratio (MBR)* as follows:

$MBR = \frac{\mathcal{N}_{boy}}{\mathcal{N}_{boy} + \mathcal{N}_{girl}} * 100$. Table 9 suggests that the family dynamics portrayed in Bollywood movies have shown considerable shift, with the *MBR* being 73.9 in old movies, to almost achieving parity (54.5) in newer movies.

	<i>Old</i>	<i>Mid</i>	<i>New</i>
<i>MBR</i>	73.9	76.4	54.5

Table 9: The Male Birth Ratio (MBR) calculated based on Bollywood movie dialogues

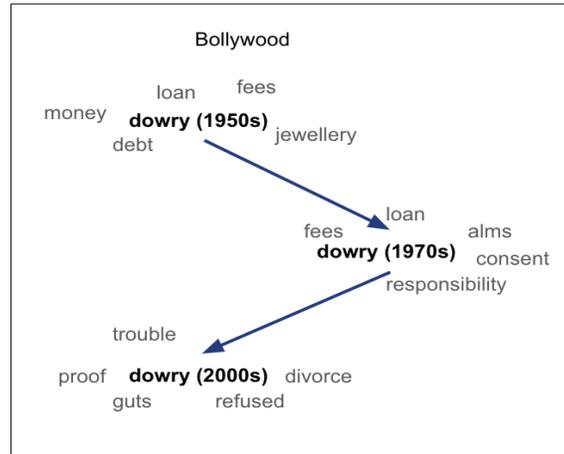

Figure 4: Nearest neighbors of dowry over the years.

8.2 Dowry

As shown in Figure 4, we observe that while nouns such as money, debt, jewellery, fees, and loan are the nearest neighbors in older films indicating compliance to this practice, modern films exhibit non-compliance (e.g., guts and refused) and indicate some of the consequences of such non-compliance (e.g., divorce and trouble) in the form of nearest neighbors. We find that indeed, films provide a snapshot of cultural values of a particular country thus allowing us to gauge the progress of a nation over time.

9 Broader Representation Questions

9.1 Geographic representation

RQ 5: Which geographical areas have been consistently underrepresented in the Indian film industry?

We now shift our focus to two broader representational aspects: geographical and religious representations. Of the 28 states in India, we next present an analysis of the relative representation of each of these states and major Indian cities.

From the beginning, Bollywood has its roots in Mumbai, and Delhi is India’s capital. Hence, it is not surprising that the cities are mentioned heavily across all time periods (see Table 10). Figure 5(a) and 5(b) compare the geographic representations in the most recent 20 years with the rest of our corpus spanning 1950–2000. We observe that initially based out of major hotspots of Delhi, Goa and cities like Mumbai, recent Bollywood content is geographically more inclusive. However, A key point we highlight in Figure 5(c) is that, in line with prior research on underrepresentation of North Eastern states in news content [18], there is severe underrepresentation of Bollywood content surrounding these North Eastern states. There have been zero mentions of the states of Manipur, Arunachal Pradesh, Meghalaya, Tripura, Mizoram in over 500 movies across 70 years.

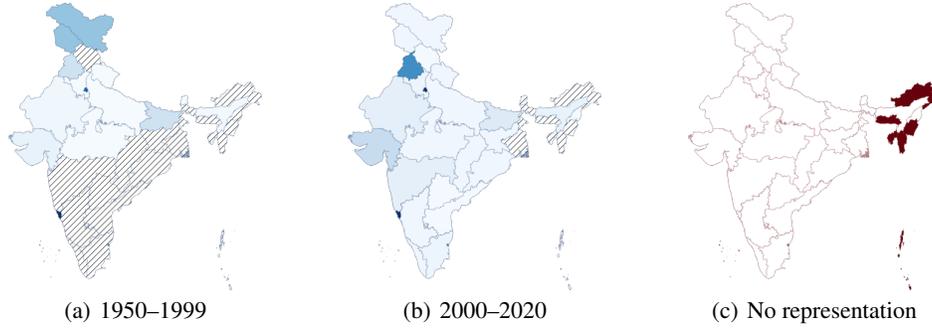

Figure 5: (a) Geographical Representation in films from 1950s to 2000s (b) Geographical Representation in films post 2000 (c) States never mentioned in our corpus in the last 70 years. The base maps used for this plot are sourced from the Government of India. The authors are aware that these maps include disputed territories. These maps do not constitute judgments on existing disputes.

<i>Old</i>	<i>Mid</i>	<i>New</i>
Bombay/Mumbai (55)	Bombay/Mumbai (73)	Bombay/Mumbai (91)
Agra (50)	Delhi (46)	Delhi (63)
Delhi (30)	Agra (46)	Agra (42)
Daman (22)	Daman (14)	Bangalore/Bengaluru (11)
Lucknow (14)	Rampur (13)	Pune (10)
Mathura (6)	Lucknow (12)	Hyderabad (9)
Srinagar (6)	Pune (9)	Amritsar (9)
Jalgaon (4)	Bangalore (8)	Lucknow (8)
Allahabad (4)	Nagpur (7)	Chandigarh (6)

Table 10: City mentions in movies

9.2 Religious representation

RQ 6: Can we gain an insight into the religious representation of a country, through a film corpus spanning 70 years?

Most-frequent surnames
Singh, Krishna, Khan, Rai, Ali, Kapoor, Sharma, Mohan, Prasad, Khanna, Shah, Lal, Thakur, Dev, Shekhar, Chaudhary, Gandhi, Verma, Gupta, Prakash, Rana, Nath, Patel, Pandey, Roy, Pandit, Saxena, Mathur, Roshan, Bachchan, Pal, Mehta, Narayan, Das, Rode, Dayal, Mehra, Bhagat, Shastri, Chandra, Patil, Banerjee, Tilak, Rao, Tripathi, Yadav, Kumari, Suman, Mukherjee, Bhatia, Acharya, Chatterjee, Rehman, Iyer

Table 11: The top surnames occurring in Bollywood movies (in decreasing order of frequency)

India is a diverse country with 6 main religions, 22 major languages and more than 700 dialects. According to the 2011 census [50], the religious distribution among the Indian population is 79.8% follow Hinduism, 14.2% adheres to Islam, 1.72% adheres to Sikhism, 2.3% adheres to Christianity, 0.7% adheres to Buddhism and 0.37% adheres to Jainism. There has been discussion in the past, regarding the religious stereotypes portrayed in Bollywood [51], and we build upon this by understanding the religious representation present in the large corpus of Bollywood subtitles. The surnames appearing in the movies (e.g., Mrs. Kapoor, Mr. Khan etc.) are annotated manually by two annotators, with each surname given one label from the list of labels: Hindu; Muslim; Sikh; Christian; Parsi; and Multiple. The annotators achieved a Cohen κ score of 0.8879 indicating high inter-rater agreement. The discrepancies were resolved by the annotators through a follow-up adjudication process and by consulting relevant literature. Figures 6, 7, 8 provide the religion distribution obtained in movies. We note that: (1) the distribution is more or less consistent with the census

Surnames of doctors
Kapoor, Chopra, Khurana, Tripathi, Kapoor, Ansari, Awasthi, Kothari, Mathur, Puri, Nayak, Bhalerao, Sawant, Tandon, Swamy, Banerjee, Verma, Rana, Ruby, Singh, Shrivastav, Khanna, Bhandari, Tiwari, Saxena, Shinde, Mehta, Goenka, Kumar, Goswami

Table 12: Surnames of doctors in Bollywood movies

numbers; (2) representation for other religions has increased in recent years; and (3) the representation of Muslims is slightly less than the community's population share.

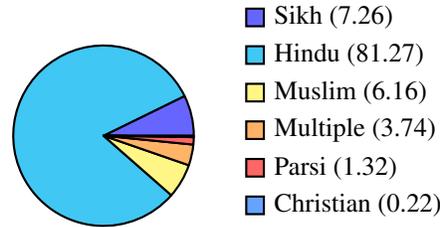

Figure 6: Religious Representation in Old movies

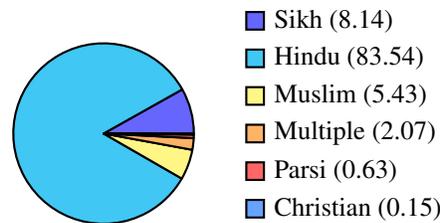

Figure 7: Religious Representation in Mid movies

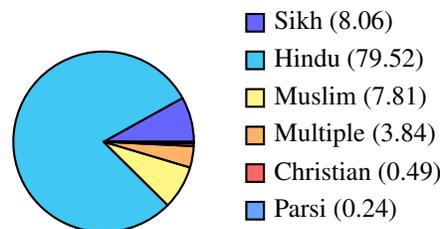

Figure 8: Religious Representation in New movies

Table 12 indicates the surnames of the doctors occurring in Bollywood movies. To retrieve these surnames from the subtitles, we employ a template based approach, searching for keywords like 'Dr.', 'doctor' from our corpus. While a broader religious representation is observed in our overall results, the observed representation for the medical profession is quite skewed, with large number of surnames being Brahmins (the uppermost caste in the Hindu caste-system in India).

10 Economic Signals

RQ 7: *Can we extract economic signals through popular film dialogues?*

By looking at a popular entertainment corpus of a developing nation, we are able to showcase the evolution of gender bias, evolving attitude towards social evils, geographic and religious representations. Can we detect economic signals

	<i>Old</i>	<i>Mid</i>	<i>New</i>
Predicted Average Ransom Amount	594,805	10,959,940	29,688,280
Inflation adjusted	-	2,194,830	21,000,280

Table 13: Average amount for text completion results on the input sentence *The ransom amount is* using fine-tuned GPT-2 models. The inflation-adjusted values for 594,805 INR in 1960 is presented in bottom row.

as well, from the Bollywood dialogues? 100 rupees in 1958 are equivalent to 8,117.22 rupees in 2020 [52]. We seek to understand whether language models can capture these noisy signals. GPT-2 [16], a popular language model with more than 100 million parameters, has achieved state of the art results for text completion, zero shot transfer learning etc. GPT-2 has been widely used for generating free form text, to create artificial newsletters, poems [53] etc. We noticed that the most common dialogues expressing monetary figures or large amounts of money were generally associated with ransom. For example, a sample dialogue is “We have kidnapped your kid, the ransom amount is 2 million Rupees.”

To understand this change at a large scale, we fine-tune GPT-2 on three Bollywood sub-corpora, each belonging to films from different time periods, for the end goal of text/dialogue generation. On these finetuned models, we input the sentence “*The ransom amount is*” and analyze the generated text by the model. Table 13 showcases the average amount across 100 generated samples from the finetuned models. We note that while our predicted values overestimate the inflation rate, the ransom amounts capture the general increasing pattern and have increased significantly over time.

11 Evolving National Priorities as Reflected in Movies and Responsible Censorship

RQ 8: *How are religions perceived in movies? Can we track evolving national priorities from popular entertainment?*

11.1 Responsible censorship

India has faced two major partitions over the last 70 years, which have resulted in considerable religious turmoil and riots [54]. The Censor Board is a governing body which along with giving each movie a certification, has the ability to remove offensive or controversial content or in some extreme cases, completely ban films from being screened in theatres. With religion being a contentious topic in India, offensive terms surrounding it are also discouraged, and this has been constant throughout the years. To validate this hypothesis, we look at the word ‘religion’ and how it has evolved over the years. Figure 10 indicates that ‘religion’ is always accompanied with neutral/mild terms, and movie dialogues have stayed away from using extreme or hateful terms surrounding religion.

Along with understanding the nearest neighbors of ‘religion’, we wanted to understand the discussion surrounding the two biggest religions in India, ‘Hindu’ and ‘Muslim’ (Figures 9(a), 9(b)). We contrast our findings on the movie corpus with prior research involving raw social media data [13]. While negative words like *ruthless*, *shameless*, and *traitor* creeping up in newer movies might indicate religious polarization, we notice that words like *terrorists* found in social media data [13], do not surface among the nearest neighbors. Along with word embedding analysis, we analyze the BERT cloze tests for the probes (1) *Hindus are* [MASK] and (2) *Muslims are* [MASK]. For both probes, we do not notice completions such as *terrorists* or *fools* previously reported in [13]. This indicates that while recent social media analyses might indicate religious polarization, film certification board largely ensured movie content do not reflect such divide.

BERT _{base}	BERT _{$\mathcal{D}_{bollywood}^{old}$}	BERT _{$\mathcal{D}_{bollywood}^{new}$}
corruption, poverty, malaria, pollution, hunger, terrorism, unemployment, drought, famine, war, tourism	poverty, love, war, hunger, unemployment, india, famine, money, marriage, education, kashmir	poverty, pakistan , kashmir , terrorism, corruption, india, drugs, dowry, unemployment, hunger, rape

Table 14: Cloze test results for *The biggest problem in India is* [MASK].

11.2 Evolving National Priorities as Reflected in Movies

Similar to BERT’s cloze test applications to uncover gender and racial bias showcased in earlier sections, we employ BERT to analyze evolving national priorities using the following two cloze tests.

1. For Bollywood: *The biggest problem in India is* [MASK].

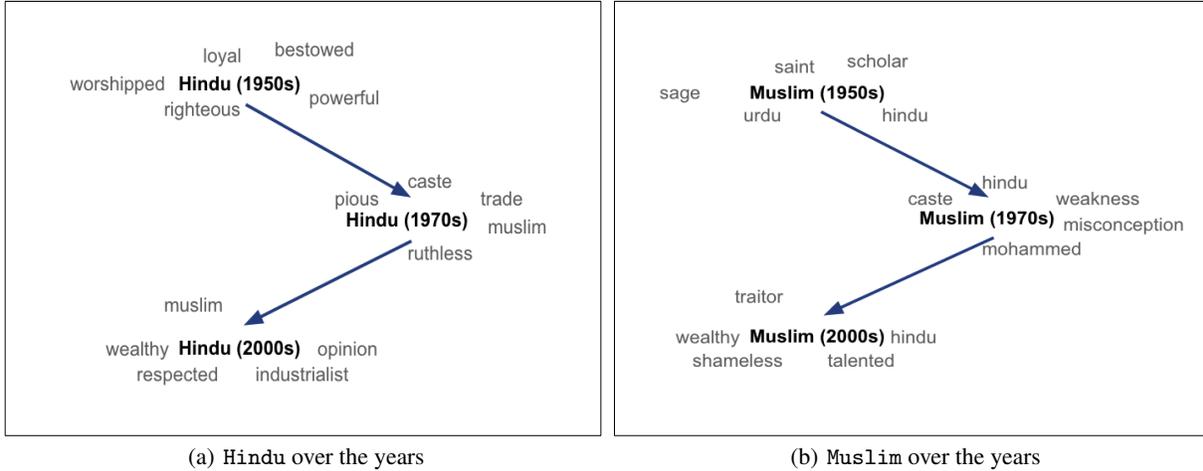

Figure 9: Nearest neighbors of Hindu and Muslim over the years.

BERT _{base}	BERT _{D^{old}_{holly}}	BERT _{D^{new}_{holly}}
poverty, corruption, unemployment, crime, terrorism, racism, pollution, hunger, war, cancer, inequality	war, poverty, money, unemployment, slavery, immigration, alcoholism, education, imperialism, russia , hunger	poverty, slavery, immigration, unemployment, money, war, racism , hunger, communism, america, education

Table 15: Cloze test results for *The biggest problem in America is* [MASK].

2. For Hollywood: *The biggest problem in America is* [MASK].

We observe that the dynamic political conditions are reflected in the completion results in Tables 14 and 15 (e.g., Kashmir, Pakistan and Russia) [29, 30, 55]. We also note that the list of ongoing problems in the U.S. contains the major issue on which the 2020 election was fought over: racism.

12 Future Directions and Conclusion

12.1 Future directions

While our current work focused on answering research questions related to inclusion and bias, our corpus may find use in several other interesting applications. Here, we outline an exploratory analysis on computational creativity.

In recent years, the emergence of neural architectures and language models like GPT-2 [16] with millions of parameters have resulted in rapid advancements for various NLP tasks. These models has proved efficient in generating artificial poems [56, 57], stories, news articles with just a few epochs of fine-tuning. We employ a similar strategy to generate

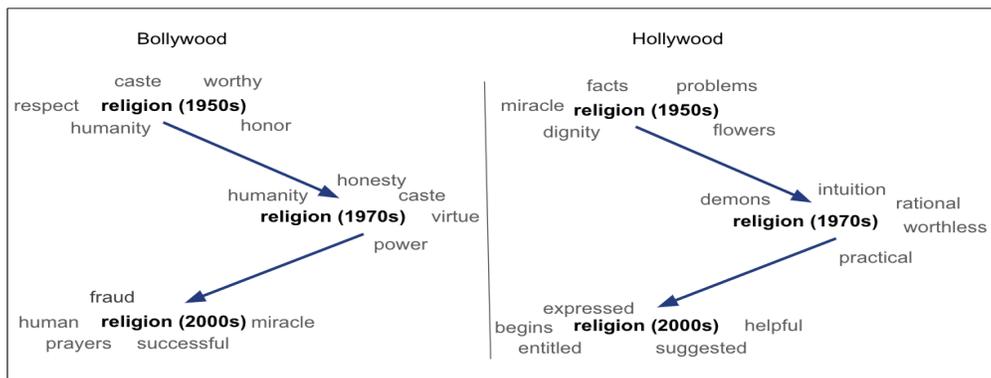

Figure 10: religion over the years

dialogues based on the subtitles collected from more than 2000 films, using GPT-2 [16]. To the best of our knowledge, ours is the first ever attempt to automatically generate artificial Bollywood dialogues with human evaluations conducted by annotators with professional experience with the Bollywood industry.

Input Probe	Artificially Generated Subtitles
The ransom for kidnapping	The ransom for kidnapping hasn't been paid yet. We'll ask for the ransom at the next hearing. Then call up Mr. Trivedi and ask him for the ransom at the next hearing. Fine. Then we'll ask for the next hearing at our doorstep. And he'll refuse. Yes, tell me. Come. Sir, please listen to me.
Your eyes are so	Your eyes are so beautiful. They don't let me sleep." They are just dreams." My heart is singing." Don't let it go, beloved." Don't let it go, beloved."
What does the police have to say about this incident?	What does the police have to say about this incident? What do you mean? They don't have a witness, madam. No case can be filed under section 302. They only record the statement of the complainants. The police is much more capable than this. Their power and reach is much more impressive.

Table 16: Machine generated subtitles using the GPT2 model. We provide the input probe to the model and output the free form text completion generated by the finetuned LM on our corpus.

Human Evaluation of the generated dialogues: We employed two annotators either working professionally or closely associated with the Bollywood film industry, to guess the dialogues into one of the two labels, Real or Generated. We provided a list of 5 real dialogue snippets taken from movies, along with 6 artificially generated subtitles. *annotator*₁ labelled 4 out of 6 artificial dialogues as being real, while *annotator*₂ labelled 3 out of 6 artificial dialogues as being real, thus showcasing the efficacy of recent advancement in language models in generating human-like movie dialogues.

12.2 Conclusions

In this paper, we analyzed how social biases and subtle gender biases get reflected on diachronic corpora of popular entertainment. Our research indicates that our NLP methods are capable of uncovering important social signals. Our results demonstrate that indeed, societal changes do get reflected in popular content. But does popular entertainment also influence the society in turn? A recent movie on acid attack, Chhapak, was inspired from a true story of an acid attack survivor who set up an NGO and was a recipient of the *International Women of Courage* [58] award. Her biopic and her initiative of *Stop Acid Sale* when released, triggered regulatory legislation that made it difficult to buy certain types of acids without legal authorization. Devising NLP methods to identify how popular entertainment influences society will be a worthy future research challenge.

A APPENDIX

A.1 Implementation Details

Experiments are conducted on a Google Colab Pro instance, using the Tesla V100 and P100 GPUs provided by Google in the Colab notebook.

We follow the standard preprocessing steps recommended to fine-tune BERT language model. For our task, we use the bert-base-uncased pretrained English model, with the following parameter details: 12 transformer layers, hidden state length of 768, 12 attention heads, 110M overall parameters. The pre-trained model is fine tuned on the target corpus using the training parameters showcased below.

- Batch size: 16
- Maximum sequence length: 128
- Maximum predictions per sequence: 20
- Fine-tuning steps: 10,000
- Warmup steps: 10
- Learning rate: 2e-5

For fine-tuning the language model for free form text completion tasks, we use the smallest GPT2 model with 124M parameters, trained for 10,000 steps. The results showcased in Table 16 are obtained from the fine-tuned model by setting length=250 and temperature=0.9.

A.2 BERT Fine Tuning Results

Probe	BERT _{base}	BERT _{$\mathcal{D}_{bollywood}^{old}$}	BERT _{$\mathcal{D}_{bollywood}^{new}$}	BERT _{$\mathcal{D}_{holly}^{old}$}	BERT _{$\mathcal{D}_{holly}^{new}$}
<i>cloze</i> ₁	man, widow, woman, doctor, slave, soldier, bachelor, merchant, farmer, lawyer, servant [4.8]	prostitute, servant, woman, slave, bachelor, doctor, lawyer, man, widow, maid, worker [4.64]	doctor, woman, servant, lawyer, maid, hindu, nurse, teacher, gardener, lady, man [5.7]	woman, slave, servant, nurse, lady, man, teacher, lawyer, peasant, maid, wife [5.3]	woman, lawyer, doctor, nurse, teacher, man, writer, secretary, prostitute, professional, carpenter [5.7]
<i>cloze</i> ₂	man, soldier, gentleman, farmer, merchant, woman, slave, bachelor, doctor, carpenter, servant [5.48]	man, gentleman, lawyer, lawyer, servant, doctor, farmer, worker, craftsman, slave, criminal [5.0]	doctor, lawyer, policeman, man, farmer, bachelor, gardener, servant, soldier, mechanic, builder [5.3]	carpenter, policeman, lawyer, soldier, farmer, gentleman, servant, man, peasant, slave, doctor [5.0]	man, lawyer, soldier, doctor, carpenter, gentleman, clergyman, farmer, writer, craftsman, minister [5.78]
<i>cloze</i> ₃	soft, beautiful, pale, tanned, smooth	fair, no, pale, tanned, tan	fair, tanned, golden, smooth, pale	fair, pale, blue, golden, gold	fair, pale, tanned, golden, dark

Table 17: Cloze test results. Predicted tokens are ranked by decreasing probability. Positive and negative words are color coded with blue and red, respectively. The number in the bracket represents the average valence score (obtained from [7]) calculated for the answers to the cloze test.
