## Abstract

We provide a generic algorithm for constructing formulae that distinguish behaviourally inequivalent states in systems of various transition types such as nondeterministic, probabilistic or weighted; genericity over the transition type is achieved by working with coalgebras for a set functor in the paradigm of universal coalgebra. For every behavioural equivalence class in a given system, we construct a formula which holds precisely at the states in that class. The algorithm instantiates to deterministic finite automata, transition systems, labelled Markov chains, and systems of many other types. The ambient logic is a modal logic featuring modalities that are generically extracted from the functor; these modalities can be systematically translated into custom sets of modalities in a postprocessing step. The new algorithm builds on an existing coalgebraic partition refinement algorithm. It runs in time  $\mathcal{O}((m+n)\log n)$  on systems with  $n$  states and  $m$  transitions, and the same asymptotic bound applies to the dag size of the formulae it constructs. This improves the bounds on run time and formula size compared to previous algorithms even for previously known specific instances, viz. transition systems and Markov chains; in particular, the best previous bound for transition systems was  $\mathcal{O}(mn)$ .

## 1 Introduction

For finite transition systems, the Hennessy-Milner theorem guarantees that two states are bisimilar if and only if they satisfy the same modal formulae. This implies that whenever two states are not bisimilar, then one can find a modal formula that holds at one of the states but not at the other. Such a formula explains the difference of the two states' behaviour and is thus usually called a *distinguishing formula* [13]. For example, in the transition system in Figure 1, the formula  $\Box\Diamond\top$  distinguishes the states  $x$  and  $y$  because  $x$  satisfies  $\Box\Diamond\top$  whereas  $y$  does not. Given two states in a finite transition system with  $n$  states and  $m$  transitions, the algorithm by Cleaveland [13] computes a distinguishing formula in time  $\mathcal{O}(mn)$ . The algorithm builds on the Kanellakis-Smolka partition refinement algorithm [28, 29], which

## 32:2 Explaining Behavioural Inequivalence Generically in Quasilinear Time

■ **Figure 1** Example of a transition system

■ **Figure 2** Example of a Markov chain

computes the bisimilarity relation on a transition system within the same time bound.

Similar logical characterizations of bisimulation exist for other system types. For instance, Desharnais et al. [16, 17] characterize probabilistic bisimulation on (labelled) Markov chains, in the sense of Larsen and Skou [33] (for each label, every state has either no successors or a probability distribution on successors). In their logic, a formula  $\diamond_{\geq p}\phi$  holds at states that have a transition probability of at least  $p$  to states satisfying  $\phi$ . For example, the state  $x$  in Figure 2 satisfies  $\diamond_{\geq 0.5}\diamond_{\geq 1}\top$  but  $y$  does not. Desharnais et al. provide an algorithm that computes distinguishing formulae for labelled Markov chains in run time (roughly)  $\mathcal{O}(n^4)$ .

In the present work, we construct such counterexamples generically for a variety of system types. We achieve genericity over the system type by modelling state-based systems as coalgebras for a set functor in the framework of universal coalgebra [40]. Examples of coalgebras for a set functor include transition systems, deterministic automata, or weighted systems (e.g. Markov chains). Universal coalgebra provides a generic notion of behavioural equivalence that instantiates to standard notions for concrete system types, e.g. bisimilarity (transition systems), language equivalence (deterministic automata), or probabilistic bisimilarity (Markov chains). Moreover, coalgebras come equipped with a generic notion of modal logic that is parametric in a choice of modalities whose semantics is constructed so as to guarantee invariance w.r.t. behavioural equivalence; under easily checked conditions, such a *coalgebraic modal logic* in fact characterizes behavioural equivalence in the same sense as Hennessy-Milner logic characterizes bisimilarity [39, 42]. Hence, as soon as suitable modal operators are found, coalgebraic modal formulae serve as distinguishing formulae.

In a nutshell, the contribution of the present paper is an algorithm that computes distinguishing formulae for behaviourally inequivalent states in *quasilinear time*, and in fact *certificates* that uniquely describe behavioural equivalence classes in a system, in coalgebraic generality. We build on an existing efficient coalgebraic partition refinement algorithm [46], thus achieving run time  $\mathcal{O}(m \log n)$  on coalgebras with  $n$  states and  $m$  transitions (in a suitable encoding). The dag size of formulae is also  $\mathcal{O}(m \log n)$  (for tree size, exponential lower bounds are known [22]); even for labelled transition systems, we thus improve the previous best bound  $\mathcal{O}(mn)$  [13] for both run time and formula size. We systematically extract the requisite modalities from the functor at hand, requiring binary and nullary modalities in the general case, and then give a systematic method to translate these generic modal operators into more customary ones (such as the standard operators of Hennessy-Milner logic).

We subsequently identify a notion of *cancellative* functor that allows for additional optimization. E.g. functors modelling weighted systems are cancellative if and only if the weights come from a cancellative monoid, such as  $(\mathbb{Z}, +)$ , or  $(\mathbb{R}, +)$  as used in probabilistic systems. For cancellative functors, much simpler distinguishing formulae can be constructed: the binary modalities can be replaced by unary ones, and only conjunction is needed in the propositional base. On labelled Markov chains, this complements the result that a logic with only conjunction and different unary modalities (mentioned above) suffices for the construction of distinguishing formulae (but not certificates) [17] (see also [19]).

**Related Work** Cleaveland’s algorithm [13] for labelled transition systems is based on Kanellakis and Smolka’s partition refinement algorithm [29]. The coalgebraic partition refinement algorithm we employ [46] is instead related to the more efficient Paige-Tarjan algorithm [36]. König et al. [32] extract formulae from winning strategies in a bisimulation

game in coalgebraic generality; their algorithm runs in  $\mathcal{O}(n^4)$  and does not support negative transition weights. Characteristic formulae for behavioural equivalence classes taken across *all* models require the use of fixpoint logics [21]. The mentioned algorithm by Desharnais et al. for distinguishing formulae on labelled Markov processes [17, Fig. 4] is based on Cleaveland's. No complexity analysis is made but the algorithm has four nested loops, so its run time is roughly  $\mathcal{O}(n^4)$ . Bernardo and Miculan [10] provide a similar algorithm for a logic with only disjunction. There are further generalizations along other axes, e.g. to behavioural preorders [12]. The TwoTowers tool set for the analysis of stochastic process algebras [8, 9] computes distinguishing formulae for inequivalent processes, using variants of Cleaveland's algorithm. Some approaches construct alternative forms of certificates for inequivalence, such as Cranen et al.'s notion of evidence [14] or methods employed on business process models, based on model differences and event structures [5, 6, 18].

## 2 Preliminaries

We first recall some basic notation. We denote by  $0 = \emptyset$ ,  $1 = \{0\}$ ,  $2 = \{0, 1\}$  and  $3 = \{0, 1, 2\}$  the sets representing the natural numbers 0, 1, 2 and 3. For every set  $X$ , there is a unique map  $! : X \rightarrow 1$ . We write  $Y^X$  for the set of functions  $X \rightarrow Y$ , so e.g.  $X^2 \cong X \times X$ . In particular,  $2^X$  is the set of 2-valued *predicates* on  $X$ , which is in bijection with the *powerset*  $\mathcal{P}X$  of  $X$ , i.e. the set of all subsets of  $X$ ; in this bijection, a subset  $A \in \mathcal{P}X$  corresponds to its *characteristic function*  $\chi_A \in 2^X$ , given by  $\chi_A(x) = 1$  if  $x \in A$ , and  $\chi(x) = 0$  otherwise. We generally indicate injective maps by  $\mapsto$ . Given maps  $f : Z \rightarrow X$ ,  $g : Z \rightarrow Y$ , we write  $\langle f, g \rangle$  for the map  $Z \rightarrow X \times Y$  given by  $\langle f, g \rangle(z) = (f(z), g(z))$ . We denote the disjoint union of sets  $X, Y$  by  $X + Y$ , with canonical inclusion maps  $\text{in}_1 : X \mapsto X + Y$  and  $\text{in}_2 : Y \mapsto X + Y$ . More generally, we write  $\coprod_{i \in I} X_i$  for the disjoint union of an  $I$ -indexed family of sets  $(X_i)_{i \in I}$ , and  $\text{in}_i : X_i \mapsto \coprod_{i \in I} X_i$  for the  $i$ -th inclusion map. For a map  $f : X \rightarrow Y$  (not necessarily surjective), we denote by  $\ker(f) \subseteq X \times X$  the *kernel* of  $f$ , i.e. the equivalence relation

$$\ker(f) := \{(x, x') \in X \times X \mid f(x) = f(x')\}. \quad (1)$$

► **Notation 2.1** (Partitions). Given an equivalence relation  $R$  on  $X$ , we write  $[x]_R$  for the equivalence class  $\{x' \in X \mid (x, x') \in R\}$  of  $x \in X$ . If  $R$  is the kernel of a map  $f$ , we simply write  $[x]_f$  in lieu of  $[x]_{\ker(f)}$ . The intersection  $R \cap S$  of equivalence relations is again an equivalence relation. The partition corresponding to  $R$  is denoted by  $X/R = \{[x]_R \mid x \in X\}$ . Note that  $[-]_R : X \rightarrow X/R$  is a surjective map and that  $R = \ker([-]_R)$ .

A *signature* is a set  $\Sigma$ , whose elements are called *operation symbols*, equipped with a function  $a : \Sigma \rightarrow \mathbb{N}$  assigning to each operation symbol its *arity*. We write  $\sigma/n \in \Sigma$  for  $\sigma \in \Sigma$  with  $a(\sigma) = n$ . We will apply the same terminology and notation to collections of modal operators.

### 2.1 Coalgebra

*Universal coalgebra* [40] provides a generic framework for the modelling and analysis of state-based systems. Its key abstraction is to parametrize notions and results over the transition type of systems, encapsulated as an endofunctor on a given base category. Instances cover, for example, deterministic automata, labelled (weighted) transition systems, and Markov chains.

► **Definition 2.2.** A *set functor*  $F : \text{Set} \rightarrow \text{Set}$  assigns to every set  $X$  a set  $FX$  and to every map  $f : X \rightarrow Y$  a map  $Ff : FX \rightarrow FY$  such that identity maps and composition are

preserved:  $F\text{id}_X = \text{id}_{FX}$  and  $F(g \cdot f) = Fg \cdot Ff$ . An  $F$ -coalgebra is a pair  $(C, c)$  consisting of a set  $C$  (the *carrier*) and a map  $c: C \rightarrow FC$  (the *structure*). When  $F$  is clear from the context, we simply speak of a *coalgebra*.

In a coalgebra  $c: C \rightarrow FC$ , we understand the carrier set  $C$  as consisting of *states*, and the structure  $c$  as assigning to each state  $x \in C$  a structured collection of successor states, with the structure of collections determined by  $F$ . In this way, the notion of coalgebra subsumes numerous types of state-based systems, as illustrated next.

- **Example 2.3.** 1. The *powerset functor*  $\mathcal{P}$  sends a set  $X$  to its powerset  $\mathcal{P}X$  and a map  $f: X \rightarrow Y$  to the map  $\mathcal{P}f = f[-]: \mathcal{P}X \rightarrow \mathcal{P}Y$  taking direct images. A  $\mathcal{P}$ -coalgebra  $c: C \rightarrow \mathcal{P}C$  is precisely a transition system: It assigns to every state  $x \in C$  a set  $c(x) \in \mathcal{P}C$  of *successor* states, inducing a transition relation  $\rightarrow$  given by  $x \rightarrow y$  iff  $y \in c(x)$ . Similarly, coalgebras for the finite powerset functor  $\mathcal{P}_f$  (with  $\mathcal{P}_f X$  being the set of finite subsets of  $X$ ) are finitely branching transition systems.
2. Coalgebras for the functor  $FX = 2 \times X^A$ , where  $A$  is a fixed input alphabet, are deterministic automata (without an explicit initial state). Indeed, a coalgebra structure  $c = \langle f, t \rangle: C \rightarrow 2 \times C^A$  consists of a finality predicate  $f: C \rightarrow 2$  and a transition map  $C \times A \rightarrow C$  in curried form  $t: C \rightarrow C^A$ .
3. Every signature  $\Sigma$  defines a *signature functor* that maps a set  $X$  to the set

$$T_\Sigma X = \coprod_{\sigma/n \in \Sigma} X^n,$$

whose elements we may understand as flat  $\Sigma$ -terms  $\sigma(x_1, \dots, x_n)$  with variables from  $X$ . The action of  $T_\Sigma$  on maps  $f: X \rightarrow Y$  is then given by  $(T_\Sigma f)(\sigma(x_1, \dots, x_n)) = \sigma(f(x_1), \dots, f(x_n))$ . For simplicity, we write  $\sigma$  (instead of  $\text{in}_\sigma$ ) for the coproduct injections, and  $\Sigma$  in lieu of  $T_\Sigma$  for the signature functor. States in  $\Sigma$ -coalgebras describe possibly infinite  $\Sigma$ -trees.

4. For a commutative monoid  $(M, +, 0)$ , the *monoid-valued functor*  $M^{(-)}$  [25] is given by

$$M^{(X)} := \{\mu: X \rightarrow M \mid \mu(x) = 0 \text{ for all but finitely many } x \in X\} \quad (2)$$

on sets  $X$ ; for a map  $f: X \rightarrow Y$ , the map  $M^{(f)}: M^{(X)} \rightarrow M^{(Y)}$  is defined by

$$(M^{(f)})(\mu)(y) = \sum_{x \in X, f(x)=y} \mu(x).$$

A coalgebra  $c: C \rightarrow M^{(C)}$  is a finitely branching weighted transition system, where  $c(x)(x') \in M$  is the transition weight from  $x$  to  $x'$ . For the Boolean monoid  $\mathbb{B} = (2, \vee, 0)$ , we recover  $\mathcal{P}_f = \mathbb{B}^{(-)}$ . Coalgebras for  $\mathbb{R}^{(-)}$ , with  $\mathbb{R}$  understood as the additive monoid of the reals, are  $\mathbb{R}$ -weighted transition systems. The functor

$$\mathcal{D}X = \{\mu \in \mathbb{R}_{\geq 0}^{(X)} \mid \sum_{x \in X} \mu(x) = 1\},$$

which assigns to a set  $X$  the set of all finite probability distributions on  $X$  (represented as finitely supported probability mass functions), is a subfunctor of  $\mathbb{R}^{(-)}$ .

5. Functors can be composed; for instance, given a set  $A$  of labels, the composite of  $\mathcal{P}$  and the functor  $A \times (-)$  (whose action on sets maps a set  $X$  to the set  $A \times X$ ) is the functor  $FX = \mathcal{P}(A \times X)$ , whose coalgebras are  $A$ -labelled transition systems. Coalgebras for  $(\mathcal{D}(-) + 1)^A$  have been termed *probabilistic transition systems* [33] or *labelled Markov chains* [17], and coalgebras for  $(\mathcal{D}((-) + 1) + 1)^A$  are *partial labelled Markov chains* [17]. Coalgebras for  $SX = \mathcal{P}_f(A \times \mathcal{D}X)$  are variously known as *simple Segala systems* or *Markov decision processes*.

We have a canonical notion of *behaviour* on  $F$ -coalgebras:

► **Definition 2.4.** An  $F$ -coalgebra *morphism*  $h: (C, c) \rightarrow (D, d)$  is a map  $h: C \rightarrow D$  such that  $d \cdot h = Fh \cdot c$ . States  $x, y$  in an  $F$ -coalgebra  $(C, c)$  are *behaviourally equivalent* ( $x \sim y$ ) if there exists a coalgebra morphism  $h$  such that  $h(x) = h(y)$ .

$$\begin{array}{ccc} C & \xrightarrow{c} & FC \\ h \downarrow & & \downarrow Fh \\ D & \xrightarrow{d} & FD \end{array}$$

Thus, we effectively define the behaviour of a state as those of its properties that are preserved by coalgebra morphisms. The notion of behavioural equivalence subsumes standard branching-time equivalences:

- **Example 2.5.**
1. For  $F \in \{\mathcal{P}, \mathcal{P}_f\}$ , behavioural equivalence on  $F$ -coalgebras, i.e. on transition systems, is *bisimilarity* in the usual sense.
  2. For deterministic automata as coalgebras for  $FX = 2 \times X^A$ , two states are behaviourally equivalent iff they accept the same formal language.
  3. For a signature functor  $\Sigma$ , two states of a  $\Sigma$ -coalgebra are behaviourally equivalent iff they describe the same  $\Sigma$ -tree.
  4. For labelled transition systems as coalgebras for  $FX = \mathcal{P}(A \times X)$ , coalgebraic behavioural equivalence precisely captures Milner's strong bisimilarity [1].
  5. For weighted and probabilistic systems, coalgebraic behavioural equivalence instantiates to weighted and probabilistic bisimilarity, respectively [41, Cor. 4.7], [7, Thm. 4.2].
- **Remark 2.6.**
1. The notion of behavioural equivalence extends straightforwardly to states in different coalgebras, as one can canonically define the disjoint union of coalgebras.
  2. We may assume without loss of generality that a set functor  $F$  preserves injective maps [43] (see also [2, 8.1.12–17]), that is,  $Ff$  is injective whenever  $f$  is.

## 2.2 Coalgebraic Logics

We briefly review basic concepts of coalgebraic modal logic [38, 42]. Coalgebraic modal logics are parametric in a functor  $F$  determining the type of systems underlying the semantics, and additionally in a choice of modalities interpreted in terms of *predicate liftings*. For now, we use  $F = \mathcal{P}$  as a basic example, deferring further examples to Section 5.

**Syntax** The syntax of coalgebraic modal logic is parametrized over the choice of signature  $\Lambda$  of *modal operators* (with assigned arities). Then, *formulae*  $\phi$  are generated by the grammar

$$\phi_1, \dots, \phi_n ::= \top \mid \neg\phi_1 \mid \phi_1 \wedge \phi_2 \mid \heartsuit(\phi_1, \dots, \phi_n) \quad (\heartsuit/n \in \Lambda).$$

► **Example 2.7.** For  $F = \mathcal{P}$ , one often takes  $\Lambda = \{\diamond/1\}$ ; the induced syntax is that of (single-action) Hennessy-Milner logic. As usual, we write  $\Box\phi := \neg\diamond\neg\phi$ .

**Semantics** We interpret formulae as sets of states in  $F$ -coalgebras. This interpretation arises by assigning to each modal operator  $\heartsuit/n \in \Lambda$  an  $n$ -ary *predicate lifting*  $\llbracket \heartsuit \rrbracket$  [38, 42], i.e. a family of maps  $\llbracket \heartsuit \rrbracket_X: (2^X)^n \rightarrow 2^{FX}$ , one for every set  $X$ , such that the *naturality* condition

$$Ff^{-1}[\llbracket \heartsuit \rrbracket_Y(P_1, \dots, P_n)] = \llbracket \heartsuit \rrbracket_X(f^{-1}[P_1], \dots, f^{-1}[P_n]) \quad (3)$$

for all  $f: X \rightarrow Y$  and all  $P_1, \dots, P_n \in 2^X$  (for categorically-minded readers,  $\llbracket \heartsuit \rrbracket$  is a natural transformation  $(2^{(-)})^n \rightarrow 2^{F^{op}}$ ); the idea being to lift given predicates on states to predicates

## 32:6 Explaining Behavioural Inequivalence Generically in Quasilinear Time

on structured collections of states. Given these data, the *extension* of a formula  $\phi$  in an  $F$ -coalgebra  $(C, c)$  is a predicate  $\llbracket \phi \rrbracket_{(C,c)}$ , or just  $\llbracket \phi \rrbracket$ , on  $C$ , recursively defined by

$$\begin{aligned} \llbracket \top \rrbracket_{(C,c)} &= C & \llbracket \phi \wedge \psi \rrbracket_{(C,c)} &= \llbracket \phi \rrbracket_{(C,c)} \cap \llbracket \psi \rrbracket_{(C,c)} & \llbracket \neg \phi \rrbracket_{(C,c)} &= C \setminus \llbracket \phi \rrbracket_{(C,c)} \\ \llbracket \heartsuit(\phi_1, \dots, \phi_n) \rrbracket_{(C,c)} &= c^{-1}[\llbracket \heartsuit \rrbracket_C(\llbracket \phi_1 \rrbracket_{(C,c)}, \dots, \llbracket \phi_n \rrbracket_{(C,c)})] & (\heartsuit/n \in \Lambda) \end{aligned}$$

(where we apply set operations to predicates with the evident meaning). We say that a state  $x \in C$  *satisfies*  $\phi$  if  $\llbracket \phi \rrbracket(x) = 1$ . Notice how the clause for modalities says that  $x$  satisfies  $\heartsuit(\phi_1, \dots, \phi_n)$  iff  $c(x)$  satisfies the predicate obtained by lifting the predicates  $\llbracket \phi_1 \rrbracket, \dots, \llbracket \phi_n \rrbracket$  on  $C$  to a predicate on  $FC$  according to  $\llbracket \heartsuit \rrbracket$ .

► **Example 2.8.** Over  $F = \mathcal{P}$ , we interpret  $\diamond$  by the predicate lifting

$$\llbracket \diamond \rrbracket_X: 2^X \rightarrow 2^{\mathcal{P}X}, \quad P \mapsto \{K \subseteq X \mid \exists x \in K: x \in P\} = \{K \subseteq X \mid K \cap P \neq \emptyset\},$$

The arising notion of satisfaction over  $\mathcal{P}$ -coalgebras  $(C, c)$  is precisely the standard one:  $x \in \llbracket \diamond \phi \rrbracket_{(C,c)}$  iff  $y \in \llbracket \phi \rrbracket_{(C,c)}$  for some transition  $x \rightarrow y$ .

The naturality condition (3) of predicate liftings guarantees invariance of the logic under coalgebra morphisms, and hence under behavioural equivalence:

► **Proposition 2.9** (Adequacy [38, 42]). *Behaviourally equivalent states satisfy the same formulae:  $x \sim y$  implies that for all formulae  $\phi$ , we have  $x \in \llbracket \phi \rrbracket$  iff  $y \in \llbracket \phi \rrbracket$ .*

In our running example  $F = \mathcal{P}$ , this instantiates to the well-known fact that modal formulae are bisimulation-invariant, that is, bisimilar states in transition systems satisfy the same formulae of Hennessy-Milner logic.

### 3 Constructing Distinguishing Formulae

A proof method certifying behavioural equivalence of states  $x, y$  in a coalgebra is immediate by definition: One simply needs to exhibit a coalgebra morphism  $h$  such that  $h(x) = h(y)$ . In fact, for many system types, it suffices to relate  $x$  and  $y$  by a coalgebraic *bisimulation* in a suitable sense (e.g. [1, 24, 34, 40]), generalizing the Park-Milner bisimulation principle [35, 37]. It is less obvious how to certify behavioural *inequivalence*  $x \not\sim y$ , showing that such a morphism  $h$  does *not* exist. By Proposition 2.9, one option is to exhibit a (coalgebraic) modal formula  $\phi$  that is satisfied by  $x$  but not by  $y$ . In the case of (image-finite) transition systems, such a formula is guaranteed to exist by the Hennessy-Milner theorem, which moreover is known to generalize to coalgebras [39, 42]. More generally, we consider separation of *sets* of states by formulae, following Cleaveland [13, Def. 2.4]:

► **Definition 3.1.** Let  $(C, c)$  be an  $F$ -coalgebra. A formula  $\phi$  *distinguishes* a set  $X \subseteq C$  from a set  $Y \subseteq C$  if  $X \subseteq \llbracket \phi \rrbracket$  and  $Y \cap \llbracket \phi \rrbracket = \emptyset$ . In case  $X = \{x\}$  and  $Y = \{y\}$ , we just say that  $\phi$  *distinguishes  $x$  from  $y$* . We say that  $\phi$  is a *certificate* of  $X$  if  $\phi$  distinguishes  $X$  from  $C \setminus X$ , that is if  $\llbracket \phi \rrbracket = X$ .

Note that  $\phi$  distinguishes  $X$  from  $Y$  iff  $\neg\phi$  distinguishes  $Y$  from  $X$ . Certificates have also been referred to as *descriptions* [22]. If  $\phi$  is a certificate of a behavioural equivalence class  $[x]_{\sim}$ , then by definition  $\phi$  distinguishes  $x$  from  $y$  whenever  $x \not\sim y$ . To obtain distinguishing formulae for behaviourally inequivalent states in a coalgebra, it thus suffices to construct certificates for all behavioural equivalence classes, and our algorithm does just that. Of course, every certificate must be at least as large as a smallest distinguishing formula. However, already

on transition systems, distinguishing formulae and certificates have the same asymptotic worst-case size (cf. Section 6).

A natural approach to computing certificates for behavioural equivalence classes is to extend algorithms that compute these equivalence classes. In particular, *partition refinement* algorithms compute a sequence  $C/R_0, C/R_1, \dots$  of consecutively finer partitions (i.e.  $R_{i+1} \subseteq R_i$ ) on the state space, where every *block*  $B \in C/R_i$  is a union of behavioural equivalence classes, and the final partition is precisely  $C/\sim$ . Indeed, Cleaveland’s algorithm for computing certificates on labelled transition systems [13] correspondingly extends Kanelakis and Smolka’s partition refinement algorithm [28, 29], which runs in  $\mathcal{O}(mn)$  on systems with  $n = |C|$  states and  $m$  transitions. Our generic algorithm will be based on a more efficient partition refinement algorithm.

### 3.1 Paige-Tarjan with Certificates

Before we turn to constructing certificates in coalgebraic generality, we informally recall and extend the Paige-Tarjan algorithm [36], which computes the partition modulo bisimilarity of a given transition system with  $n$  states and  $m$  transitions in time  $\mathcal{O}((m+n)\log n)$ . We fix a given finite transition system, viewed as a  $\mathcal{P}$ -coalgebra  $c: C \rightarrow \mathcal{P}C$ .

The algorithm computes two sequences  $(C/P_i)_{i \in \mathbb{N}}$  and  $(C/Q_i)_{i \in \mathbb{N}}$  of partitions of  $C$  (with  $Q_i, P_i$  equivalence relations), where only the most recent partition is held in memory and  $i$  indexes the iterations of the main loop. Throughout the execution,  $C/P_i$  is finer than  $C/Q_i$  (that is,  $P_i \subseteq Q_i$  for all  $i$ ), and the algorithm terminates when  $P_i = Q_i$ . Intuitively,  $P_i$  is ‘one transition ahead’ of  $Q_i$ : if  $Q_i$  distinguishes states  $x$  and  $y$ , then  $P_i$  is based on distinguishing transitions to  $x$  from transitions to  $y$ .

Initially,  $C/Q_0 := \{C\}$  consists of only one block and  $C/P_0$  of two blocks: the live states and the deadlocks (i.e. states with no outgoing transitions). If  $P_i \subsetneq Q_i$ , then there is a block  $B \in C/Q_i$  that is the union of at least two blocks in  $C/P_i$ . In such a situation, the algorithm chooses  $S \subseteq B$  in  $C/P_i$  to have at most half the size of  $B$  and then splits the block  $B$  into  $S$  and  $B \setminus S$  in the partition  $C/Q_i$ :

$$C/Q_{i+1} = (C/Q_i \setminus \{B\}) \cup \{S, B \setminus S\}.$$

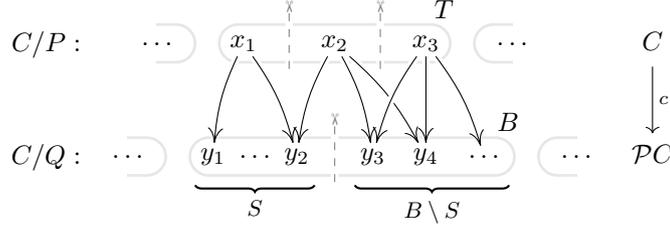

This is correct because every state in  $S$  is already known to be behaviourally inequivalent to every state in  $B \setminus S$ . By the definition of bisimilarity, this implies that every block  $T \in C/P_i$  with some transition to  $B$  may contain behaviourally inequivalent states as illustrated in Figure 3; that is,  $T$  may need to be split into smaller blocks, as follows:

- (C1) states in  $T$  with successors in  $S$  but not in  $B \setminus S$  (e.g.  $x_1$  in Figure 3),
- (C2) states in  $T$  with successors in  $S$  and  $B \setminus S$  (e.g.  $x_2$ ), and
- (C3) states in  $T$  with successors  $B \setminus S$  but not in  $S$  (e.g.  $x_3$ ).

The partition  $C/P_{i+1}$  arises from  $C/P_i$  by splitting all such predecessor blocks  $T$  of  $B$  accordingly. If no such  $T$  is properly split, then  $P_{i+1} = Q_{i+1}$ , and the algorithm terminates. It is straightforward to construct certificates for the blocks arising during the execution:

- The certificate for the only block  $C \in C/Q_0$  is  $\top$ , and the blocks for live states and deadlocks in  $C/P_0$  have certificates  $\diamond\top$  and  $\neg\diamond\top$ , respectively.
- In the refinement step, suppose that  $\delta, \beta$  are certificates of  $S \in C/P_i$  and  $B \in C/Q_i$ , respectively, where  $S \subsetneq B$ . For every predecessor block  $T$  of  $B$ , the three blocks obtained by splitting  $T$  are distinguished (see Definition 3.1) as follows:

$$(C1) \quad \neg\diamond(\beta \wedge \neg\delta), \quad (C2) \quad \diamond(\delta) \wedge \diamond(\beta \wedge \neg\delta), \quad (C3) \quad \neg\diamond\delta. \quad (4)$$

■ **Figure 3** The refinement step as illustrated in [46, Figure 6].

Of course these formulae only distinguish the states in  $T$  from each other (e.g. there may be states in other blocks with transitions to both  $S$  and  $B$ ). Hence, given a certificate  $\phi$  of  $T$ , one obtains certificates of the three resulting blocks in  $C/P_{i+1}$  via conjunction:  $\phi \wedge \neg\Diamond(\beta \wedge \neg\delta)$ , etc.

Upon termination, every bisimilarity class  $[x]_{\sim}$  in the transition system is annotated with a certificate. A key step in the generic development will be to come up with a coalgebraic generalization of the formulae for (C1)–(C3).

### 3.2 Generic Partition Refinement

The Paige-Tarjan algorithm has been adapted to other system types, e.g. weighted systems [44], and it has recently been generalized to coalgebras [20,46]. A crucial step in this generalization is to rephrase the case distinction (C1)–(C3) in terms of the functor  $\mathcal{P}$ : Given a predecessor block  $T$  in  $C/P_i$  for  $S \subsetneq B \in C/Q_i$ , the three cases distinguish between the equivalence classes  $[x]_{\mathcal{P}\chi_S^B \cdot c}$  for  $x \in T$ , where the map  $\chi_S^B: C \rightarrow \mathbb{3}$  in the composite  $\mathcal{P}\chi_S^B \cdot c: C \rightarrow \mathcal{P}\mathbb{3}$  is defined by

$$\chi_S^B: C \rightarrow \mathbb{3} \quad \chi_S^B(x) = \begin{cases} 2 & \text{if } x \in S, \\ 1 & \text{if } x \in B \setminus S, \\ 0 & \text{if } x \in C \setminus B, \end{cases} \quad \text{for sets } S \subseteq B \subseteq C. \quad (5)$$

Every case is a possible value of  $t := \mathcal{P}\chi_S^B(c(x)) \in \mathcal{P}\mathbb{3}$ : (C1)  $2 \in t \not\equiv 1$ , (C2)  $2 \in t \ni 1$ , and (C3)  $2 \notin t \ni 1$ . Since  $T$  is a predecessor block of  $B$ , the ‘fourth case’  $2 \notin t \not\equiv 1$  is not possible. There is a transition from  $x$  to some state outside of  $B$  iff  $0 \in t$ . However, because of the previous refinement steps performed by the algorithm, either all or no states of  $T$  have an edge to  $C \setminus B$  (a property called *stability* [36]), hence no distinction on  $0 \in t$  is necessary.

It is now easy to generalize from transition systems to coalgebras by simply replacing the functor  $\mathcal{P}$  with  $F$  in the refinement step. We recall the algorithm:

► **Algorithm 3.2** [46, Alg. 4.9, (5.1)]. Given a coalgebra  $c: C \rightarrow FC$ , put

$$C/Q_0 := \{C\} \quad \text{and} \quad P_0 := \ker(C \xrightarrow{c} FC \xrightarrow{F1} F1).$$

Starting at iteration  $i = 0$ , repeat the following while  $P_i \neq Q_i$ :

(A1) Pick  $S \in C/P_i$  and  $B \in C/Q_i$  such that  $S \subsetneq B$  and  $2 \cdot |S| \leq |B|$

(A2)  $C/Q_{i+1} := (C/Q_i \setminus \{B\}) \cup \{S, B \setminus S\}$

(A3)  $P_{i+1} := P_i \cap \ker( C \xrightarrow{c} FC \xrightarrow{F\chi_S^B} F\mathbb{3} )$

This algorithm formalizes the intuitive steps from Section 3.1. Again, two sequences of partitions  $P_1, Q_i$  are constructed, and  $P_i = Q_i$  upon termination. Initially,  $Q_0$  identifies all

states and  $P_0$  distinguishes states by only their output behaviour; e.g. for  $F = \mathcal{P}$  and  $x \in C$ , the value  $\mathcal{P}!(c(x)) \in \mathcal{P}1$  is  $\emptyset$  if  $x$  is a deadlock, and  $\{1\}$  if  $x$  is a live state, and for  $FX = 2 \times X^A$ , the value  $F1(c(x)) \in F1 = 2 \times 1^A \cong 2$  indicates whether  $x$  is a final or non-final state.

In the main loop, blocks  $S \in C/P_i$  and  $B \in C/Q_i$  witnessing  $P_i \subsetneq Q_i$  are picked, and  $B$  is split into  $S$  and  $B \setminus S$ , like in the Paige-Tarjan algorithm. Note that step (A2) is equivalent to directly defining the equivalence relation  $Q_{i+1}$  as

$$Q_{i+1} := Q_i \cap \ker \chi_S^B.$$

A similar intersection of equivalence relations is performed in step (A3). The intersection splits every block  $T \in C/P_i$  into smaller blocks such that  $x, x' \in T$  end up in the same block iff  $F\chi_S^B(c(x)) = F\chi_S^B(c(x'))$ , i.e.  $T$  is replaced by  $\{[x]_{F\chi_S^B(c(x))} \mid x \in T\}$ . Again, this corresponds to the distinction of the three cases (C1)–(C3). For example, for  $FX = 2 \times X^A$ , there are  $|F3| = 2 \cdot 3^{|A|}$  cases to be distinguished, and so every  $T \in C/P_i$  is split into at most that many blocks.

The following property of  $F$  is needed for correctness [46, Ex. 5.11].

► **Definition 3.3** [46]. A functor  $F$  is *zippable* if map

$$\langle F(A+!), F(1+B) \rangle: F(A+B) \longrightarrow F(A+1) \times F(1+B)$$

is injective for all sets  $A, B$ .

Intuitively,  $t \in F(A+B)$  is a term in variables from  $A$  and  $B$ . If  $F$  is zippable, then  $t$  is uniquely determined by the two elements in  $F(A+1)$  and  $F(1+B)$  obtained by identifying all  $B$ - and all  $A$ -variables with  $0 \in 1$ , respectively. E.g.  $FX = X^2$  is zippable:  $t = (\text{in}_1(a), \text{in}_2(b)) \in (A+B)^2$  is uniquely determined by  $(\text{in}_1(a), \text{in}_2(0)) \in (A+1)^2$  and  $(\text{in}_1(0), \text{in}_2(b)) \in (1+B)^2$ , and similarly for the three other cases of  $t$ . In fact, all signature functors as well as  $\mathcal{P}$  and all monoid-valued functors are zippable. Moreover, the class of zippable functors is closed under products, coproducts, and subfunctors but not under composition, e.g.  $\mathcal{P}\mathcal{P}$  is not zippable [46].

► **Remark 3.4.** To apply the algorithm to coalgebras for composites  $FG$  of zippable functors, e.g.  $\mathcal{P}(A \times (-))$ , there is a reduction [46, Section 8] that embeds every  $FG$ -coalgebra into a coalgebra for the zippable functor  $(F+G)(X) := FX + GX$ . This reduction preserves and reflects behavioural equivalence, but introduces an intermediate state for every transition.

► **Theorem 3.5** [46, Thm 4.20, 5.20]. *On a finite coalgebra  $(C, c)$  for a zippable functor, Algorithm 3.2 terminates after  $i \leq |C|$  loop iterations, and the resulting partition identifies precisely the behaviourally equivalent states ( $P_i = \sim$ ).*

### 3.3 Generic Modal Operators

The extended Paige-Tarjan algorithm (Section 3.1) constructs a distinguishing formula according to the three cases (C1)–(C3). In the coalgebraic Algorithm 3.2, these cases correspond to elements of  $F3$ , which determine in which block an element of a predecessor block  $T$  ends up. Indeed, the elements of  $F3$  will also serve as generic modalities in characteristic formulae for blocks of states, essentially by the known equivalence between  $n$ -ary predicate liftings and (in this case, singleton) subsets of  $F(2^n)$  [42] (termed *tests* by Klin [30]):

► **Definition 3.6.** The signature of  $F3$ -modalities for a functor  $F$  is

$$\Lambda = \{\ulcorner t \urcorner / 2 \mid t \in F3\};$$

that is, we write  $\ulcorner t \urcorner$  for the syntactic representation of a binary modality for every  $t \in F3$ . The interpretation of  $\ulcorner t \urcorner$  for  $F3$  is given by the predicate lifting

$$\llbracket \ulcorner t \urcorner \rrbracket : (2^X)^2 \rightarrow 2^{FX}, \quad \llbracket \ulcorner t \urcorner \rrbracket (S, B) = \{t' \in FX \mid F\chi_{S \cap B}^B(t') = t\}.$$

The intended use of  $\ulcorner t \urcorner$  is as follows: Suppose a block  $B$  is split into subblocks  $S \subseteq B$  and  $B \setminus S$  with certificates  $\delta$  and  $\beta$ , respectively:  $\llbracket \delta \rrbracket = S$  and  $\llbracket \beta \rrbracket = B$ . As in Figure 3, we then split every predecessor block  $T$  of  $B$  into smaller parts, each of which is uniquely characterized by the formula  $\ulcorner t \urcorner(\delta, \beta)$  for some  $t \in F3$ .

► **Example 3.7.** For  $F = \mathcal{P}$ ,  $\ulcorner \{0, 2\} \urcorner(\delta, \beta)$  is equivalent to  $\overbrace{\diamond \neg \beta}^{0'} \wedge \overbrace{\neg \diamond (\beta \wedge \neg \delta)}^{1'} \wedge \overbrace{\diamond (\delta \wedge \beta)}^{2'}$ .

► **Lemma 3.8.** Given an  $F$ -coalgebra  $(C, c)$ ,  $x \in C$ , and formulae  $\delta$  and  $\beta$  such that  $\llbracket \delta \rrbracket \subseteq \llbracket \beta \rrbracket \subseteq C$ , we have  $x \in \llbracket \ulcorner t \urcorner(\delta, \beta) \rrbracket$  if and only if  $F\chi_{\llbracket \delta \rrbracket}^{\llbracket \beta \rrbracket}(c(x)) = t$ .

In the initial partition  $C/P_0$  on a transition system  $(C, c)$ , we used the formulae  $\diamond \top$  and  $\neg \diamond \top$  to distinguish live states and deadlocks. In general, we can similarly describe the initial partition using modalities induced by elements of  $F1$ :

► **Notation 3.9.** Define the injective map  $j_1: 1 \rightarrow 3$  by  $j_1(0) = 2$ . Then the injection  $Fj_1: F1 \rightarrow F3$  provides a way to interpret elements  $t \in F1$  as nullary modalities  $\ulcorner t \urcorner$ :

$$\ulcorner t \urcorner := \ulcorner Fj_1(t) \urcorner(\top, \top) \quad \text{for } t \in F1.$$

(Alternatively, we could introduce  $\ulcorner t \urcorner$  directly as a nullary modality.)

► **Lemma 3.10.** For  $x \in C$ ,  $c: C \rightarrow FC$ , and  $t \in F1$ , we have  $x \in \llbracket \ulcorner t \urcorner \rrbracket$  if and only if  $F!(c(x)) = t$ .

### 3.4 Algorithmic Construction of Certificates

The  $F3$ -modalities introduced above (Definition 3.6) induce an instance of coalgebraic modal logic (Section 2.2). We refer to coalgebraic modal formulae employing the  $F3$ -modalities as  $F3$ -modal formulae, and write  $\mathcal{M}$  for the set of  $F3$ -modal formulae. As in the extended Paige-Tarjan algorithm (Section 3.1), we annotate every block arising during the execution of Algorithm 3.2 with a certificate in the shape of an  $F3$ -modal formula. Annotating blocks with formulae means that we construct maps

$$\beta_i: C/Q_i \rightarrow \mathcal{M} \quad \text{and} \quad \delta_i: C/P_i \rightarrow \mathcal{M} \quad \text{for } i \in \mathbb{N}.$$

As in Algorithm 3.2,  $i$  indexes the loop iterations. For blocks  $B, S$  in the respective partition,  $\beta_i(B)$ ,  $\delta_i(S)$  denote corresponding certificates: we will have

$$\forall B \in X/Q_i: \llbracket \beta_i(B) \rrbracket = B \quad \text{and} \quad \forall S \in X/P_i: \llbracket \delta_i(S) \rrbracket = S. \quad (6)$$

We construct  $\beta_i(B)$  and  $\delta_i(S)$  iteratively, using certificates for the blocks  $S \subsetneq B$  at every iteration:

► **Algorithm 3.11.** We extend Algorithm 3.2 by the following. Initially, put

$$\beta_0(\{C\}) := \top \quad \text{and} \quad \delta_0([x]_{P_0}) := \ulcorner F!(c(x)) \urcorner \quad \text{for every } x \in C.$$

In the  $i$ -th iteration, extend steps (A2) and (A3) by the following assignments:

$$\begin{aligned}
(\mathbf{A}2) \quad \beta_{i+1}(D) &= \begin{cases} \delta_i(S) & \text{if } D = S \\ \beta_i(B) \wedge \neg\delta_i(S) & \text{if } D = B \setminus S \\ \beta_i(D) & \text{if } D \in C/Q_i \end{cases} \\
(\mathbf{A}3) \quad \delta_{i+1}([x]_{P_{i+1}}) &= \begin{cases} \delta_i([x]_{P_i}) & \text{if } [x]_{P_{i+1}} = [x]_{P_i} \\ \delta_i([x]_{P_i}) \wedge \lceil F\chi_S^B(c(x)) \rceil (\delta_i(S), \beta_i(B)) & \text{otherwise.} \end{cases}
\end{aligned}$$

Upon termination, return  $\delta_i$ .

Like in Section 3.1, the only block of  $C/Q_0$  has  $\beta_0(\{C\}) = \top$  as a certificate. Since the partition  $C/P_0$  distinguishes by the ‘output’ (e.g. final vs. non-final states), the certificate of  $[x]_{P_0}$  specifies what  $F!(c(x)) \in F1$  is (Lemma 3.10).

In the  $i$ -th iteration of the main loop, we have certificates  $\delta_i(S)$  and  $\beta_i(B)$  for  $S \subsetneq B$  in step (A1) satisfying (6) available from the previous iterations. In (A2), the Boolean connectives describe how  $B$  is split into  $S$  and  $B \setminus S$ . In (A3), new certificates are constructed for every predecessor block  $T \in C/P_i$  that is refined. If  $T$  does not change, then neither does its certificate. Otherwise, the block  $T = [x]_{P_i}$  is split into the blocks  $[x]_{F\chi_S^B(c(x))}$  for  $x \in T$  in step (A3), which is reflected by the  $F3$  modality  $\lceil F\chi_S^B(c(x)) \rceil$  as per Lemma 3.8.

► **Remark 3.12.** In step (A2),  $\beta_{i+1}(D)$  can be simplified to be no larger than  $\delta_i(S)$ . To see this, note that for  $S \subseteq B \subseteq C$ ,  $S \in X/P_i$ , and  $B \in X/Q_i$ , every conjunct of  $\beta_i(B)$  is also a conjunct of  $\delta_i(S)$ . In  $\beta_i(B) \wedge \neg\delta_i(S)$ , one can hence remove all conjuncts of  $\beta_i(B)$  from  $\delta_i(S)$ , obtaining a formula  $\delta'$ , and then equivalently use  $\beta_i(B) \wedge \neg\delta'$  in the definition of  $\beta_{i+1}(D)$ .

► **Theorem 3.13.** *For zippable  $F$ , Algorithm 3.11 is correct, i.e. (6) holds for all  $i$ . Thus, upon termination  $\delta_i$  assigns certificates to each block of  $C/\sim = C/P_i$ .*

► **Corollary 3.14** (Hennessy-Milner). *For zippable  $F$ , states  $x, y$  in a finite  $F$ -coalgebra are behaviourally equivalent iff they agree on all  $F3$ -modal formulae.*

► **Remark 3.15.** A smaller formula distinguishing a state  $x$  from a state  $y$  can be extracted from the certificates in time  $\mathcal{O}(|C|)$ . It is the leftmost conjunct that is different in the respective certificates of  $x$  and  $y$ . This is the subformula starting at the modal operator introduced in  $\delta_i$  for the least  $i$  with  $(x, y) \notin P_i$ ; hence,  $x$  satisfies  $\lceil t \rceil (\delta, \beta)$  but  $y$  satisfies  $\lceil t' \rceil (\delta, \beta)$  for some  $t' \neq t$  in  $F3$ .

### 3.5 Complexity Analysis

The operations introduced by Algorithm 3.11 can be implemented with only constant run time overhead. To this end, one implements  $\beta$  and  $\delta$  as arrays of formulae of length  $|C|$  (note that at any point, there are at most  $|C|$ -many blocks). In the refinable-partition data structure [45], every block has an index (a natural number) and there is an array of length  $|C|$  mapping every state  $x \in C$  to the block it is contained in. Hence, for both partitions  $C/P$  and  $C/Q$ , one can look up a state’s block and a block’s certificate in constant time.

It is very likely that the certificates contain a particular subformula multiple times and that certificates of different blocks share common subformulae. For example, every certificate of a block refined in the  $i$ -th iteration using  $S \subsetneq B$  contains the subformulas  $\delta_i(S)$  and  $\beta_i(B)$ . Therefore, it is advantageous to represent all certificates constructed as one directed acyclic graph (dag) with nodes labelled by modal operators and conjunction and having precisely two outgoing edges. Moreover, edges have a binary flag indicating whether they represent negation  $\neg$ . Initially, there is only one node representing  $\top$ , and the

operations of Algorithm 3.11 allocate new nodes and update the arrays for  $\beta$  and  $\delta$  to point to the right nodes. For example, if the predecessor block  $T \in C/P_i$  is refined in step (A3), yielding a new block  $[x]_{P_{i+1}}$ , then a new node labelled  $\wedge$  is allocated with edges to the nodes  $\delta_i(T)$  and to another new node labelled  $F\chi_S^B(c(x))$  with edges to the nodes  $\delta_i(S)$  and  $\delta_i(B)$ .

For purposes of estimating the size of formulae generated by the algorithm, we use a notion of *transition* in coalgebras, inspired by the notion of canonical graph [26].

► **Definition 3.16.** *For states  $x, y$  in an  $F$ -coalgebra  $(C, c)$ , we say that there is a transition  $x \rightarrow y$  if  $c(x) \in FC$  is not in the image  $Fi[F(C \setminus \{y\})]$  ( $\subseteq FC$ ), where  $i: C \setminus \{y\} \rightarrow C$  is the inclusion map.*

► **Theorem 3.17.** *For a coalgebra with  $n$  states and  $m$  transitions, the formula dag constructed by Algorithm 3.11 has size  $\mathcal{O}(m \cdot \log n + n)$  and height at most  $n + 1$ .*

► **Theorem 3.18.** *Algorithm 3.11 adds only constant run time overhead, thus it has the same run time as Algorithm 3.2 (regardless of the optimization from Remark 3.12).*

For a tighter run time analysis of the underlying partition refinement algorithm, one additionally requires that  $F$  is equipped with a *refinement interface* [46, Def. 6.4], which is based on a given encoding of  $F$ -coalgebras in terms of *edges* between states (encodings serve only as data structures and have no direct semantic meaning, in particular do not entail a semantic reduction to relational structures). This notion of edge yields the same numbers (in  $\mathcal{O}$ -notation) as Definition 3.16 for all functors considered. All zippable functors we consider here have refinement interfaces [15, 46]. In presence of a refinement interface, step (A3) can be implemented efficiently, with resulting overall run time  $\mathcal{O}((m + n) \cdot \log n \cdot p(c))$  where  $n = |C|$ ,  $m$  is the number of edges in the encoding of the input coalgebra  $(C, c)$ , and the *run-time factor*  $p(c)$  is associated with the refinement interface. In most instances, e.g. for  $\mathcal{P}$ ,  $\mathbb{R}^{(-)}$ , one has  $p(c) = 1$ ; in particular, the generic algorithm recovers the run time of the Paige-Tarjan algorithm.

► **Remark 3.19.** The claimed run time relies on close attention to a number of implementation details. This includes use of an efficient data structure for the partition  $C/P_i$  [31, 45]; the other partition  $C/Q_i$  is only represented implicitly in terms of a queue of blocks  $S \subsetneq B$  witnessing  $P_i \subsetneq Q_i$ , requiring additional care when splitting blocks in the queue [44, Fig. 3]. Moreover, grouping the elements of a block by  $F3$  involves the consideration of a *possible majority candidate* [44].

► **Theorem 3.20.** *On a coalgebra with  $n$  states and  $m$  transitions for a zippable set functor with a refinement interface with factor  $p(c)$ , Algorithm 3.11 runs in time  $\mathcal{O}((m+n) \cdot \log n \cdot p(c))$ .*

## 4 Cancellative Functors

Our use of binary modalities relates to the fact that, as observed already by Paige and Tarjan, when splitting a block according to an existing partition of a block  $B$  into  $S \subseteq B$  and  $B \setminus S$ , it is not in general sufficient to look only at the successors in  $S$ . However, this does suffice for some transition types; e.g. Hopcroft's algorithm for deterministic automata [27] and Valmari and Franceschinis' algorithm for weighted systems (e.g. Markov chains) [44] both split only with respect to  $S$ . In the following, we exhibit a criterion on the level of functors that captures that splitting w.r.t. only  $S$  is sufficient:

► **Definition 4.1.** A functor  $F$  is *cancellative* if the map

$$\langle F\chi_{\{1,2\}}, F\chi_{\{2\}} \rangle: F3 \rightarrow F2 \times F2$$

is injective.

To understand the role of the above map, recall the function  $\chi_S^B: C \rightarrow 3$  from (5) and note that  $\chi_{\{1,2\}} \cdot \chi_S^B = \chi_B$  and  $\chi_{\{2\}} \cdot \chi_S^B = \chi_S$ , so the composite  $\langle F\chi_{\{1,2\}}, F\chi_{\{2\}} \rangle \cdot F\chi_S^B$  yields information about the accumulated transition weights into  $B$  and  $S$  but not about the one into  $B \setminus S$ ; the injectivity condition means that for cancellative functors, this information suffices in the splitting step for  $S \subseteq B \subseteq C$ . The term *cancellative* stems from the respective property on monoids; recall that a monoid  $M$  is *cancellative* if  $s + b_1 = s + b_2$  implies  $b_1 = b_2$  for all  $s, b_1, b_2 \in M$ .

► **Proposition 4.2.** *The monoid-valued functor  $M^{(-)}$  for a commutative monoid  $M$  is cancellative if and only if  $M$  is a cancellative monoid.*

Hence,  $\mathbb{R}^{(-)}$  is cancellative, but  $\mathcal{P}_f$  is not. Moreover, all signature functors are cancellative:

► **Proposition 4.3.** *The class of cancellative functors contains the all constant functors as well as the identity functor, and it is closed under subfunctors, products, and coproducts.*

For example,  $\mathcal{D}$  is cancellative, but  $\mathcal{P}$  is not because of its subfunctor  $\mathcal{P}_f$ .

► **Remark 4.4.** Cancellative functors are neither closed under quotients nor under composition. Zippability and cancellativity are independent properties. Zippability in conjunction with cancellativity implies  $m$ -zippability for all  $m \in \mathbb{N}$ , the  $m$ -ary variant [32] of zippability.

► **Theorem 4.5.** *If  $F$  is a cancellative functor,  $\ulcorner F\chi_S^B(c(x)) \urcorner (\delta_i(S), \beta_i(B))$  in Algorithm 3.11 can be replaced with  $\ulcorner F\chi_S^C(c(x)) \urcorner (\delta_i(S), \top)$ . Then, the algorithm still correctly computes certificates in the given  $F$ -coalgebra  $(C, c)$ .*

Note that in this optimized algorithm, the computation of  $\beta$  can be omitted because it is not used anymore. Hence, the resulting formulae only involve  $\wedge$ ,  $\top$ , and modalities from the set  $F3$  (with the second parameter fixed to  $\top$ ). These modalities are equivalently unary modalities induced by elements of  $F2$ , which we term *F2-modalities*; hence, the corresponding Hennessy-Milner Theorem (Corollary 3.14) adapts to  $F2$  for cancellative functors, as follows:

► **Corollary 4.6.** *For zippable and cancellative  $F$ , states in an  $F$ -coalgebra are behaviourally equivalent iff they agree on modal formulae built using  $\top$ ,  $\wedge$ , and unary  $F2$ -modalities.*

## 5 Domain-Specific Certificates

On a given specific system type, one is typically interested in certificates and distinguishing formulae expressed via modalities whose use is established in the respective domain, e.g.  $\square$  and  $\diamond$  for transition systems. We next describe how the generic  $F3$  modalities can be rewritten to domain-specific ones in a postprocessing step. The domain-specific modalities will not in general be equivalent to  $F3$ -modalities, but still yield certificates.

► **Definition 5.1.** The *Boolean closure*  $\bar{\Lambda}$  of a modal signature  $\Lambda$  has as  $n$ -ary modalities propositional combinations of atoms of the form  $\heartsuit(i_1, \dots, i_k)$ , for  $\heartsuit/k \in \Lambda$ , where  $i_1, \dots, i_k$  are propositional combinations of elements of  $\{1, \dots, n\}$ . Such a modality  $\lambda/n$  is interpreted by predicate liftings  $\llbracket \lambda \rrbracket_X: (2^X)^n \rightarrow FX$  defined inductively in the obvious way.

## 32:14 Explaining Behavioural Inequivalence Generically in Quasilinear Time

For example, the boolean closure of  $\Lambda = \{\diamond/1\}$  contains the unary modality  $\Box = \neg\diamond\neg$ .

► **Definition 5.2.** Given a modal signature  $\Lambda$  for a functor  $F$ , a *domain-specific interpretation* consists of functions  $\tau: F1 \rightarrow \bar{\Lambda}$  and  $\lambda: F3 \rightarrow \bar{\Lambda}$  assigning to each  $o \in F1$  a nullary modality  $\tau_o$  and to each  $t \in F3$  a binary modality  $\lambda_t$  such that the predicate liftings  $\llbracket \tau_o \rrbracket_X \in 2^{F^X}$  and  $\llbracket \lambda_t \rrbracket_X: (2^X)^2 \rightarrow 2^{F^X}$  satisfy

$$\llbracket \tau_o \rrbracket_1 = \{o\} \quad (\text{in } 2^{F^1}) \quad \text{and} \quad [t]_{F\chi_{\{1,2\}}} \cap \llbracket \lambda_t \rrbracket_3(\{2\}, \{1\}) = \{t\} \quad (\text{in } 2^{F^3}).$$

(Recall that  $\chi_{\{1,2\}}: 3 \rightarrow 2$  is the characteristic function of  $\{1,2\} \subseteq 3$ , and  $[t]_{F\chi_{\{1,2\}}} \subseteq F3$  denotes the equivalence class of  $t$  w.r.t.  $F\chi_{\{1,2\}}: F3 \rightarrow F2$ .)

Thus,  $\tau_o$  holds precisely at states with output behaviour  $o \in F1$ . Intuitively,  $\lambda_t(\delta, \rho)$  describes the refinement step of a predecessor block  $T$  when splitting  $B := \llbracket \delta \rrbracket \cup \llbracket \rho \rrbracket$  into  $S := \llbracket \delta \rrbracket$  and  $B \setminus S := \llbracket \rho \rrbracket$  (Figure 3), which translates into the arguments  $\{2\}$  and  $\{1\}$  of  $\llbracket \lambda_t \rrbracket_3$ . In the refinement step, we know from previous iterations that all elements have the same behaviour w.r.t.  $B$ . This is reflected in the intersection with  $[t]_{F\chi_{\{1,2\}}}$ . The axiom guarantees that  $\lambda_t$  characterizes  $t \in F3$  uniquely, but only within the equivalence class representing a predecessor block. Thus,  $\lambda_t$  can be much smaller than equivalents of  $\ulcorner t \urcorner$  (cf. Example 3.7):

► **Example 5.3.** 1. For  $F = \mathcal{P}$ , we have a domain-specific interpretation over the modal signature  $\Lambda = \{\diamond/1\}$ . For  $\emptyset, \{0\} \in \mathcal{P}1$ , take  $\tau_{\{0\}} = \diamond\top$  and  $\tau_{\emptyset} = \neg\diamond\top$ . For  $t \in \mathcal{P}3$ , we put

$$\begin{array}{ll} \lambda_t(\delta, \rho) = \neg\diamond\rho & \text{if } 2 \in t \not\equiv 1 \\ \lambda_t(\delta, \rho) = \neg\diamond\delta & \text{if } 2 \notin t \equiv 1 \end{array} \quad \begin{array}{ll} \lambda_t(\delta, \rho) = \diamond\delta \wedge \diamond\rho & \text{if } 2 \in t \equiv 1 \\ \lambda_t(\delta, \rho) = \top & \text{if } 2 \notin t \not\equiv 1 \end{array}$$

The certificates obtained via this translation are precisely the ones generated in the example using the Paige-Tarjan algorithm, cf. (4), with  $\rho$  in lieu of  $\beta \wedge \neg\delta$ .

2. For a signature (functor)  $\Sigma$ , take  $\Lambda = \{\sigma/0 \mid \sigma/n \in \Sigma\} \cup \{\langle =I \rangle/1 \mid I \in \mathcal{P}_f(\mathbb{N})\}$ . We interpret  $\Lambda$  by the predicate liftings

$$\begin{aligned} \llbracket \sigma \rrbracket_X &= \{\sigma(x_1, \dots, x_n) \mid x_1, \dots, x_n \in X\} \subseteq \Sigma X, \\ \llbracket \langle =I \rangle \rrbracket(S) &= \{\sigma(x_1, \dots, x_n) \in \Sigma X \mid \forall i \in \mathbb{N}: i \in I \leftrightarrow (1 \leq i \leq n \wedge x_i \in S)\}. \end{aligned}$$

Intuitively,  $\langle =I \rangle \phi$  states that the  $i$ th successor satisfies  $\phi$  iff  $i \in I$ . We then have a domain-specific interpretation  $(\tau, \lambda)$  given by  $\tau_o := \sigma$  for  $o = \sigma(0, \dots, 0) \in \Sigma 1$  and  $\lambda_t(\delta, \rho) := \langle =I \rangle \delta$  for  $t = \sigma(x_1, \dots, x_n) \in \Sigma 3$  and  $I = \{i \in \{1, \dots, n\} \mid x_i = 2\}$ .

3. For a monoid-valued functor  $M^{(-)}$ , take  $\Lambda = \{\langle =m \rangle/1 \mid m \in M\}$ , interpreted by the predicate liftings  $\llbracket \langle =m \rangle \rrbracket_X: 2^X \rightarrow 2^{M^{(X)}}$  given by

$$\llbracket \langle =m \rangle \rrbracket_X(S) = \{\mu \in M^{(X)} \mid m = \sum_{x \in S} \mu(x)\}.$$

A formula  $\langle =m \rangle \delta$  thus states that the accumulated weight of the successors satisfying  $\delta$  is exactly  $m$ . A domain-specific interpretation  $(\tau, \lambda)$  is then given by  $\tau_o = \langle =o(0) \rangle \top$  for  $o \in M^{(1)}$  and  $\lambda_t(\delta, \rho) = \langle =t(2) \rangle \delta \wedge \langle =t(1) \rangle \rho$  for  $t \in M^{(3)}$ . In case  $M$  is cancellative, we can also simply put  $\lambda_t(\delta, \rho) = \langle =t(2) \rangle \delta$ .

4. For labelled Markov chains, i.e.  $FX = (\mathcal{D}X + 1)^A$ , let  $\Lambda = \{\langle a \rangle_p/1 \mid a \in A, p \in [0, 1]\}$ , where  $\langle a \rangle_p \phi$  denotes that on input  $a$ , the next state will satisfy  $\phi$  with probability at least  $p$ , as in cited work by Desharnais et al. [17]. This gives rise to the interpretation:

$$\tau_o = \bigwedge_{\substack{a \in A \\ o(a) \in \mathcal{D}1}} \langle a \rangle_1 \top \wedge \bigwedge_{\substack{a \in A \\ o(a) \in 1}} \neg \langle a \rangle_1 \top \quad \lambda_t(\delta, \rho) = \bigwedge_{\substack{a \in A \\ t(a) \in \mathcal{D}3}} (\langle a \rangle_{t(a)(2)} \delta \wedge \langle a \rangle_{t(a)(1)} \rho)$$

Given a domain-specific interpretation  $(\tau, \lambda)$  for a modal signature  $\Lambda$  for the functor  $F$ , we can postprocess certificates  $\phi$  produced by Algorithm 3.11 by replacing the modalities  $\ulcorner t \urcorner$  for  $t \in F3$  according to the translation  $T$  recursively defined by the following clauses for modalities and by commutation with propositional operators:

$$T(\ulcorner t \urcorner(\top, \top)) = \tau_{F!(t)} \quad T(\ulcorner t \urcorner(\delta, \beta)) = \lambda_t(T(\delta), T(\beta) \wedge \neg T(\delta)).$$

Note that one can replace  $T(\beta) \wedge \neg T(\delta)$  with  $T(\beta) \wedge \neg T(\delta')$  for the optimized  $\delta'$  from Remark 3.12; the latter conjunction has essentially the same size as  $T(\delta)$ .

► **Proposition 5.4.** *For every certificate  $\phi$  of a behavioural equivalence class of a given coalgebra produced by either Algorithm 3.11 or its optimization (Theorem 4.5),  $T(\phi)$  is also a certificate for that class.*

Thus, the domain-specific modal signatures also inherit a Hennessy-Milner Theorem.

► **Example 5.5.** For labelled Markov chains  $(FX = (DX + 1)^A)$  and the interpretation via the modalities  $\langle a \rangle_p$  (Example 5.3.4), this yields certificates (thus in particular distinguishing formulae) in run time  $\mathcal{O}(|A| \cdot m \cdot \log n)$ , with the same bound on formula size. Desharnais et al. describe an algorithm [17, Fig. 4] that computes distinguishing formulae in the negation-free fragment of the same logic (they note also that this fragment does not suffice for certificates). They do not provide a run-time analysis, but the nested loop structure indicates that the asymptotic complexity is roughly  $|A| \cdot n^4$ .

## 6 Worst Case Tree Size of Certificates

In the complexity analysis (Section 3.5), we have seen that certificates – and thus also distinguishing formulae – have dag size  $\mathcal{O}(m \cdot \log n + n)$  on input coalgebras with  $n$  states and  $m$  transitions. However, when formulae are written in the usual linear way, multiple occurrences of the same subformula lead to an exponential blow up of the formula size in this sense, which for emphasis we refer to as the *tree size*.

Figueira and Gorín [22] show that exponential tree size is inevitable even for distinguishing formulae. The proof is based on winning strategies in bisimulation games, a technique that is also applied in other results on lower bounds on formula size [3, 4, 23].

► **Open Problem 6.1.** *Do states in  $\mathbb{R}^{(-)}$ -coalgebras generally have certificates of subexponential tree size in the number of states? If yes, can small certificates be computed efficiently?*

We note that for another cancellative functor, the answer is well-known: On deterministic automata, i.e. coalgebras for  $FX = 2 \times X^A$ , the standard minimization algorithm constructs distinguishing words of linear length.

► **Remark 6.2.** Cleaveland [13, p. 368] also mentions that minimal distinguishing formulae may be exponential in size, however for a slightly different notion of minimality: a formula  $\phi$  distinguishing  $x$  from  $y$  is *minimal* if no  $\phi$  obtained by replacing a non-trivial subformula of  $\phi$  with the formula  $\top$  distinguishes  $x$  from  $y$ . This is weaker than demanding that the formula size of  $\phi$  is as small as possible. For example, in the transition system

the formula  $\phi = \diamond^{n+2}\top$  distinguishes  $x$  from  $y$  and is minimal in the above sense. However,  $x$  can in fact be distinguished from  $y$  in size  $\mathcal{O}(1)$ , by the formula  $\diamond \neg \diamond \top$ .

## 7 Conclusions and Further Work

We have presented a generic algorithm that computes distinguishing formulae for behaviourally inequivalent states in state-based systems of various types, cast as coalgebras for a functor capturing the system type. Our algorithm is based on coalgebraic partition refinement [46], and like that algorithm runs in time  $\mathcal{O}((m+n) \cdot \log n \cdot p(c))$ , with a functor-specific factor  $p(c)$  that is 1 in many cases of interest. Independently of this factor, the distinguishing formulae constructed by the algorithm have dag size  $\mathcal{O}(m \cdot \log n + n)$ ; they live in a dedicated instance of coalgebraic modal logic [39, 42], with binary modalities extracted from the type functor in a systematic way. We have shown that for *cancellative* functors, the construction of formulae and, more importantly, the logic can be simplified, requiring only unary modalities and conjunction. We have also discussed how distinguishing formulae can be translated into a more familiar domain-specific syntax (e.g. Hennessy-Milner logic for transition systems).

There is an open source implementation of the underlying partition refinement algorithm [15], which may serve as a basis for a future implementation.

In partition refinement, blocks are successively refined in a top-down manner, and this is reflected by the use of conjunction in distinguishing formulae. Alternatively, bisimilarity may be computed bottom-up, as in a recent partition *aggregation* algorithm [11]. It is an interesting point for future investigation whether this algorithm can be extended to compute distinguishing formulae, which would likely be of a rather different shape than those computed via partition refinement.

## A Appendix: Omitted Proofs

### Details for Section 2 (Preliminaries)

#### Details for Remark 2.6.

Given a pair of  $F$ -coalgebra  $(C, c)$  and  $(D, d)$ , we have a canonical  $F$ -coalgebra structure on the the disjoint union  $C + D$  of their carriers:

$$C + D \xrightarrow{c+d} FC + FD \xrightarrow{[Fin_1, Fin_2]} F(C + D).$$

The canonical inclusion maps  $in_1: C \rightarrow C + D$  and  $in_2: D \rightarrow C + D$  are  $F$ -coalgebra morphisms. We say that states  $x \in C$  and  $y \in D$  are *behavioural equivalent* if  $in_1(x) \sim in_2(y)$ .

Note that this definition extends the original definition of  $\sim$ , in the sense that  $x, y$  in the same coalgebra  $(C, c)$  are behaviourally equivalent ( $x \sim y$ ) iff  $in_1(x) \sim in_2(y)$  in the canonical coalgebra on  $C + C$ .

#### Details on Predicate Liftings in Section 2.2.

The naturality of  $[[\heartsuit]]_X: (2^X)^n \rightarrow 2^{FX}$  in  $X$  for  $\heartsuit/n$  means that for every map  $f: X \rightarrow Y$ , the diagram

$$\begin{array}{ccc} (2^Y)^n & \xrightarrow{[[\heartsuit]]_Y} & 2^{FY} \\ (2^f)^n \downarrow & & \downarrow 2^{Ff} \\ (2^X)^n & \xrightarrow{[[\heartsuit]]_X} & 2^{FX} \end{array}$$

commutes. Since  $2^{(-)}$  is *contravariant*, the map  $f: X \rightarrow Y$  is sent to  $2^f: 2^Y \rightarrow 2^X$  which takes inverse images; writing down the commutativity element-wise yields (3). By the Yoneda lemma, one can define predicate liftings

► **Lemma A.1.** *A predicate lifting  $[[\heartsuit]]_X: (2^X)^n \rightarrow 2^{FX}$  for  $\heartsuit/n$  is uniquely defined by a map  $f: F(2^n) \rightarrow 2$ . Then  $[[\heartsuit]]_X$  is given by*

$$[[\heartsuit]]_X(P_1, \dots, P_n) \left( \underbrace{t}_{\in FX} \right) = f \left( F \left( x \mapsto \underbrace{(P_1(x), \dots, P_n(x))}_{X \rightarrow 2^n} \right) (t) \right)$$

or written as sets (considering  $f \subseteq F(2^n), P_i \subseteq X$ ):

$$[[\heartsuit]]_X(P_1, \dots, P_n) = \{t \in FX \mid F\langle \chi_{P_1}, \dots, \chi_{P_n} \rangle(t) \in f\}$$

**Proof.** The following mathematical objects are in one-to-one correspondence

$$\frac{F(2^n) \rightarrow 2}{\frac{(2^n)^X \rightarrow 2^{FX} \text{ natural in } X}{(2^X)^n \rightarrow 2^{FX} \text{ natural in } X}} \qquad \frac{f}{\frac{p \mapsto t \mapsto f(Fp(t))}{(P_1, \dots, P_n) \mapsto t \mapsto f(F\langle P_1, \dots, P_n \rangle(t))}}$$

The first correspondence is the Yoneda lemma and the second correspondence is a power law. On the right, the inhabitants of the sets are listed when starting with  $f: F(2^n) \rightarrow 2$ . By the definition of  $\langle -, - \rangle$  we have:

$$\langle P_1, \dots, P_n \rangle: X \rightarrow 2^n \qquad x \mapsto (P_1(x), \dots, P_n(x)) \quad \blacktriangleleft$$

### Details for Section 3 (Constructing Distinguishing Formulae)

#### Verification of Definition 3.6.

We verify that for every  $t \in F3$

$$\llbracket \ulcorner t \urcorner \rrbracket_X : (2^X)^2 \rightarrow 2^{FX}, \quad \llbracket \ulcorner t \urcorner \rrbracket_X(S, B) = \{t' \in FX \mid F\chi_{S \cap B}^B(t') = t\}$$

defines a predicate lifting (3). For  $f: X \rightarrow Y$  and  $S, B \in 2^X$ , note that we have

$$\chi_{S \cap B}^B \cdot f = \chi_{f^{-1}[S \cap B]}^{f^{-1}[B]} \quad (*)$$

because  $f(x) \in X'$  iff  $x \in f^{-1}[X']$  for all  $x \in X$  and  $X' \subseteq X$ . We verify:

$$\begin{aligned} Ff^{-1}[\llbracket \ulcorner t \urcorner \rrbracket_Y(S, B)] &= Ff^{-1}[\{t' \in FY \mid F\chi_{S \cap B}^B(t') = t\}] && \text{(Definition 3.6)} \\ &= \{t'' \in FX \mid F\chi_{S \cap B}^B(Ff(t'')) = t\} && \text{(def. inv. Image)} \\ &= \{t'' \in FX \mid F(\chi_{S \cap B}^B \cdot f)(t'') = t\} && \text{(Functoriality)} \\ &= \{t'' \in FX \mid F\chi_{f^{-1}[S \cap B]}^{f^{-1}[B]}(t'') = t\} && (*) \\ &= \{t'' \in FX \mid F\chi_{f^{-1}[S] \cap f^{-1}[B]}^{f^{-1}[B]}(t'') = t\} \\ &= \llbracket \ulcorner t \urcorner \rrbracket_X(f^{-1}[S], f^{-1}[B]) && \text{(Definition 3.6)} \end{aligned}$$

Hence,  $\llbracket \ulcorner t \urcorner \rrbracket$  is a predicate lifting.

#### Proof of Lemma 3.8.

This follows directly from Definition 3.6 for  $S := \llbracket \phi_S \rrbracket$  and  $B := \llbracket \phi_B \rrbracket$ , using that  $S \cap B = S$ :

$$\begin{aligned} \llbracket \ulcorner t \urcorner \rrbracket(\phi_S, \phi_B) &= c^{-1}[\llbracket \ulcorner t \urcorner \rrbracket_C(\llbracket \phi_S \rrbracket, \llbracket \phi_B \rrbracket)] \\ &= c^{-1}[\llbracket \ulcorner t \urcorner \rrbracket_C(S, B)] \\ &= c^{-1}[\{t' \in FC \mid F\chi_{S \cap B}^B(t') = t\}] \\ &= \{x \in C \mid F\chi_S^B(c(x)) = t\}. \end{aligned}$$

#### Proof of Lemma 3.10.

Note that for  $\chi_C^C: C \rightarrow 3$ , we have  $\chi_C^C = (C \xrightarrow{!} 1 \xrightarrow{j_1} 3)$  where  $j_1(0) = 2$ .

$$\begin{aligned} \llbracket \ulcorner t \urcorner \rrbracket &= \llbracket \ulcorner Fj_1(t) \urcorner \rrbracket(\top, \top) && \text{(Notation 3.9)} \\ &= \{x \in C \mid F\chi_C^C(c(x)) = Fj_1(t)\} && \text{(Lemma 3.8, } \llbracket \top \rrbracket = C) \\ &= \{x \in C \mid Fj_1(F!(c(x))) = Fj_1(t)\} && (\chi_C^C = j_1 \cdot !) \\ &= \{x \in C \mid F!(c(x)) = t\} && (Fj_1 \text{ injective}) \end{aligned}$$

In the last step use that, w.l.o.g.,  $F$  preserves injective maps (Remark 2.6).  $\blacktriangleleft$

#### Proof of Theorem 3.13.

1. We first observe that given  $x \in C$ ,  $S \subseteq B \subseteq C$ , and formulae  $\phi_S$  and  $\phi_B$  which characterize  $S$  and  $B$ , respectively, we have:

$$\llbracket F\chi_S^B(c(x)) \urcorner(\phi_S, \phi_B) = \{x' \in C \mid F\chi_{\llbracket \phi_S \rrbracket}^{\llbracket \phi_B \rrbracket}}(c(x')) = F\chi_S^B(c(x))\} \quad (7)$$

$$= [x]_{F\chi_S^B(c(x))}, \quad (8)$$

where (7) uses Lemma 3.8 and (8), holds since  $\llbracket \phi_B \rrbracket = B$  and  $\llbracket \phi_S \rrbracket = S$ .

2. We proceed to the verification of (6) by induction on  $i$ .

- In the base case  $i = 0$ , we have  $\llbracket \beta_0(\{C\}) \rrbracket = \llbracket \top \rrbracket = \{C\}$  for the only block in  $X/Q_0$ . Since  $P_0 = \ker(F! \cdot c)$ ,  $\delta_0$  is well-defined, and by Lemma 3.10 we have

$$\llbracket \delta_0([x]_{P_0}) \rrbracket = \llbracket \ulcorner F!(c(x)) \urcorner \rrbracket = \{y \in C \mid F!(c(x)) = F!(c(y))\} = [x]_{P_0}.$$

- The inductive hypothesis states that

$$\llbracket \delta_i(S) \rrbracket = S \quad \text{and} \quad \llbracket \beta_i(B) \rrbracket = B. \quad (\text{IH})$$

We prove that  $\beta_{i+1}$  is correct:

$$\begin{aligned} & \llbracket \beta_{i+1}([x]_{Q_{i+1}}) \rrbracket \\ &= \begin{cases} \llbracket \delta_i(S) \rrbracket & \text{if } [x]_{Q_{i+1}} = S, \text{ hence } S = [x]_{P_i} \\ \llbracket \beta_i(B) \rrbracket \cap C \setminus \llbracket \delta_i(S) \rrbracket & \text{if } [x]_{Q_{i+1}} = B \setminus S, \text{ hence } B = [x]_{Q_i} \\ \llbracket \beta_i([x]_{Q_i}) \rrbracket & \text{if } [x]_{Q_{i+1}} \in C/Q_i \end{cases} \\ &\stackrel{(\text{IH})}{=} \begin{cases} S & \text{if } [x]_{Q_{i+1}} = S \\ B \cap C \setminus S & \text{if } [x]_{Q_{i+1}} = B \setminus S \\ [x]_{Q_i} & \text{if } [x]_{Q_{i+1}} \in C/Q_i \end{cases} \\ &= \begin{cases} [x]_{Q_{i+1}} & \text{if } [x]_{Q_{i+1}} = S = [x]_{P_i} \\ [x]_{Q_{i+1}} & \text{if } [x]_{Q_{i+1}} = B \setminus S \quad (\text{since } B \cap C \setminus S = B \setminus S) \\ [x]_{Q_{i+1}} & \text{if } [x]_{Q_{i+1}} \in C/Q_i \quad (\text{since } [x]_{Q_i} \text{ is not split}) \end{cases} \\ &= [x]_{Q_{i+1}}. \end{aligned}$$

For  $\delta_{i+1}$ , we compute as follows:

$$\begin{aligned} & \llbracket \delta_{i+1}([x]_{P_{i+1}}) \rrbracket \\ &= \begin{cases} \llbracket \delta_i([x]_{P_i}) \rrbracket & \text{if } [x]_{P_{i+1}} = [x]_{P_i} \\ \llbracket \delta_i([x]_{P_i}) \rrbracket \cap \llbracket \ulcorner F\chi_S^B(c(x)) \urcorner \rrbracket (\delta_i(S), \beta_i(B)) & \text{otherwise} \end{cases} \\ &\stackrel{(\text{IH}) \ \& \ (8)}{=} \begin{cases} [x]_{P_i} & \text{if } [x]_{P_{i+1}} = [x]_{P_i} \\ [x]_{P_i} \cap [x]_{F\chi_S^B(c(x))} & \text{otherwise} \end{cases} \\ &\stackrel{\text{def. } P_{i+1}}{=} \begin{cases} [x]_{P_{i+1}} & \text{if } [x]_{P_{i+1}} = [x]_{P_i} \\ [x]_{P_{i+1}} & \text{otherwise} \end{cases} \\ &= [x]_{P_{i+1}} \end{aligned}$$

### Details for Remark 3.15.

In order to verify that the first differing conjunct is a distinguishing formula, we perform a case distinction on the least  $i$  with  $(x, y) \notin P_i$ :

If  $x$  and  $y$  are already split by  $P_0$ , then the conjunct at index 0 in the respective certificates of  $[x]_{\sim}$  and  $[y]_{\sim}$  differs, and we have  $t = F!(c(x))$  and  $t' = F!(c(y))$ . By Lemma 3.10,  $\ulcorner t \urcorner$  distinguishes  $x$  from  $y$  (and  $\ulcorner t' \urcorner$  distinguishes  $y$  from  $x$ ).

## 32:22 Explaining Behavioural Inequivalence Generically in Quasilinear Time

If  $x$  and  $y$  are split by  $P_{i+1}$  (but  $(x, y) \in P_i$ ) in the  $i$ th iteration, then

$$\underbrace{F\chi_S^B(c(x))}_{t :=} \neq \underbrace{F\chi_S^B(c(y))}_{t' :=}.$$

Thus, the conjuncts that differs in the respective certificates for  $[x]_{\sim}$  and  $[y]_{\sim}$  are the following conjuncts at index  $i + 1$ :

$$\lceil t^\neg(\delta_i(S), \beta_i(B)) \quad \text{and} \quad \lceil t'^\neg(\delta_i(S), \beta_i(B)).$$

By Lemma 3.8,  $\lceil t^\neg(\delta_i(S), \beta_i(B))$  distinguishes  $x$  from  $y$  (and  $\lceil t'^\neg(\delta_i(S), \beta_i(B))$  distinguishes  $y$  from  $x$ ).

### Proof of Theorem 3.17.

Before proving Theorem 3.17, we need to establish a sequence of lemmas on the underlying partition refinement algorithm. We assume wlog that  $F$  preserves finite intersections; that is pullbacks of pairs of injective maps. In fact, the functor  $G$  mentioned in Remark 2.6, which coincides with  $F$  on all nonempty sets and map and therefore has the same coalgebras, preserves finite intersections..

Let  $(C, c)$  be a coalgebra for  $F$ . As additional notation, we define for all sets  $T \subseteq C$  and  $S \subseteq C$ :

$$T \rightarrow S \quad :\iff \quad \exists x \in T, y \in S: x \rightarrow y.$$

In other words, we write  $T \rightarrow S$  if there is a transition from (some state of)  $T$  to (some state of)  $S$ . Also we define the set of predecessor states of a set as:

$$\text{pred}(S) = \{x \in C \mid \{x\} \rightarrow S\} \quad \text{for } S \subseteq C.$$

► **Lemma A.2.** *For every  $F$ -coalgebra  $(C, c)$ ,  $x \in C$ , and  $S \subseteq B \subseteq C$  with  $S$  finite, we have*

$$\{x\} \not\rightarrow S \quad \implies \quad F\chi_S^B(c(x)) = F\chi_\emptyset^B(c(x)).$$

**Proof.** For every  $y \in S$ , we have that  $x \not\rightarrow y$ . Hence, for every  $y \in S$ , there exists  $t_y \in F(C \setminus \{y\})$  such that

$$c(x) = Fi(t_y) \quad \text{for } i: C \setminus \{y\} \rightarrow C.$$

The set  $C \setminus S$  is the intersection of all sets  $C \setminus \{y\}$  with  $y \in S$ :

$$C \setminus S = \bigcap_{y \in S} (C \setminus \{y\}).$$

Since  $F$  preserves finite intersections and  $S$  is finite, we have that

$$F(C \setminus S) = \bigcap_{y \in S} F(C \setminus \{y\}).$$

Since  $c(x) \in FC$  is contained in every  $F(C \setminus \{y\})$  (as witnessed by  $t_y$ ) it is also contained in their intersection. That is, for  $m: C \setminus S \rightarrow C$  being the inclusion map, there is  $t' \in F(C \setminus S)$  with  $Fm(t') = c(x)$ . Now consider the following diagrams:

$$\begin{array}{ccc} c(x) \in FC & \xrightarrow{F\chi_S^B} & F3 \\ \uparrow Fm & \nearrow F\chi_\emptyset^B & \\ t' \in F(C \setminus S) & & \end{array} \quad \text{and} \quad \begin{array}{ccc} FC & \xrightarrow{F\chi_\emptyset^B} & F3 \\ Fm \uparrow & \nearrow F\chi_\emptyset^B & \\ F(C \setminus S) & & \end{array}$$

Both triangles commute because  $\chi_\emptyset^B = \chi_S^B \cdot m$  and  $\chi_\emptyset^B = \chi_\emptyset^B \cdot m$ . Thus, we conclude

$$F\chi_S^B(c(x)) = F\chi_S^B(Fm(t')) = F\chi_\emptyset^B(t') = F\chi_\emptyset^B(Fm(t')) = F\chi_\emptyset^B(c(x)). \quad \blacktriangleleft$$

► **Lemma A.3.** For all  $(x, x') \in P_i$  and  $B \in C/Q_i$  in Algorithm 3.2, we have

$$F\chi_\emptyset^B(c(x)) = F\chi_\emptyset^B(c(x')).$$

**Proof.** One can show[46, Prop. 4.12] that in every iteration there is a map  $c_i: C/P_i \rightarrow F(C/Q_i)$  that satisfies  $F[-]_{Q_i} \cdot c = c_i \cdot [-]_{P_i}$ :

$$\begin{array}{ccc} C & \xrightarrow{c} & FC \\ [-]_{P_i} \downarrow & & \downarrow F[-]_{Q_i} \\ C/P_i & \xrightarrow{c_i} & F(C/Q_i) \end{array}$$

where the maps  $[-]_{P_i}, [-]_{Q_i}$  send elements of  $C$  to their equivalence class (Notation 2.1). The map  $\chi_\emptyset^B: C \rightarrow 3$  for  $B \in C/Q_i$  can be decomposes as:

$$\begin{array}{ccc} C & \xrightarrow{\chi_\emptyset^B} & 3 \\ [-]_{Q_i} \downarrow & \nearrow \chi_\emptyset^{\{B\}} & \\ C/Q_i & & \end{array}$$

Combining these two diagrams, we obtain:

$$F\chi_\emptyset^B \cdot c = F\chi_\emptyset^{\{B\}} \cdot F[-]_{Q_i} \cdot c = F\chi_\emptyset^{\{B\}} \cdot c_i \cdot [-]_{P_i}. \quad (9)$$

For all  $(x, x') \in P_i$ , we have  $[x]_{P_i} = [x']_{P_i}$ , and thus we have

$$F\chi_\emptyset^B(c(x)) \stackrel{(9)}{=} F\chi_\emptyset^{\{B\}}(c_i([x]_{P_i})) = F\chi_\emptyset^{\{B\}}(c_i([x']_{P_i})) \stackrel{(9)}{=} F\chi_\emptyset^B(c(x')). \quad \blacktriangleleft$$

► **Lemma A.4.** For  $S \subsetneq B \in C/Q_i$  in the  $i$ th iteration of Algorithm 3.2, any block  $T \in C/P_i$  with no edge to  $S$  is not modified; in symbols:

$$T \not\rightarrow S \implies T \in C/P_{i+1} \quad \text{for all } T \in C/P_i.$$

**Proof.** Since  $T \not\rightarrow S$ , we have  $\{x\} \not\rightarrow S$  and  $\{x'\} \not\rightarrow S$  for all  $x, x' \in T$ . Thus,

$$\begin{aligned} F\chi_S^B(c(x)) &= F\chi_\emptyset^B(c(x)) && \text{(Lemma A.2, } \{x\} \not\rightarrow S) \\ &= F\chi_\emptyset^B(c(x')) && \text{(Lemma A.3, } (x, x') \in P_i) \\ &= F\chi_S^B(c(x')) && \text{(Lemma A.2, } \{x'\} \not\rightarrow S) \end{aligned}$$

as desired. ◀

► **Lemma A.5.** For  $S \subseteq C$  and finite  $C$  in the  $i$ th iteration of Algorithm 3.2,

$$|\{T' \in C/P_{i+1} \mid T' \notin C/P_i\}| \leq 2 \cdot |\text{pred}(S)|.$$

**Proof.** Let  $S \subsetneq B \in C/Q_i$  be used for splitting in iteration  $i$ . By contraposition, Lemma A.4 implies that if  $T' \in C/P_{i+1}$  and  $T' \notin C/P_i$ , then (the unique)  $T \in C/P_i$  with  $T' \subseteq T$  satisfies  $T \not\rightarrow C/P_{i+1}$  and therefore has a transition to  $S$ . By the finiteness of  $C$ , the block  $T \in C/P_i$

## 32:24 Explaining Behavioural Inequivalence Generically in Quasilinear Time

is split into finitely many blocks  $T_1, \dots, T_k \in C/P_{i+1}$ , representing the equivalence classes for  $F\chi_S^B \cdot c: C \rightarrow F3$ . By Lemma A.2 we know that if  $x \in T$  has no transition to  $S$ , then  $F\chi_S^B(c(x)) = F\chi_\emptyset^B(c(x))$ . Moreover, all elements of  $T \in C/P_i$  are sent to the same value by  $F\chi_\emptyset^B \cdot c$  (Lemma A.3). Hence, there is at most one block  $T_j$  with no transition to  $S$ , and all other blocks  $T_{j'}, j' \neq j$ , have a transition to  $S$ . Therefore the number blocks  $T_j$  is bounded above as follows:  $k \leq |T \cap \text{pred}(S)| + 1$ . Summing over all predecessor blocks  $T$  we obtain:

$$\begin{aligned}
& |\{T' \in C/P_{i+1} \mid T' \not\subseteq C/P_i\}| \\
& \leq |\{T' \in C/P_{i+1} \mid T' \subseteq T \in C/P_i \text{ and } T \rightarrow S\}| && \text{(Lemma A.4)} \\
& = \sum_{\substack{T \in C/P_i \\ T \rightarrow S}} |\{T' \in C/P_{i+1} \mid T' \subseteq T\}| \\
& \leq \sum_{\substack{T \in C/P_i \\ T \rightarrow S}} (|T \cap \text{pred}(S)| + 1) && \text{(bound on } k \text{ above)} \\
& \leq 2 \cdot \sum_{\substack{T \in C/P_i \\ T \rightarrow S}} |T \cap \text{pred}(S)| && |T \cap \text{pred}(S)| \geq 1 \\
& \leq 2 \cdot |\text{pred}(S)| && (T \in C/P_i \text{ are disjoint})
\end{aligned}$$

This completes the proof ◀

► **Lemma A.6.** *Throughout the execution of Algorithm 3.2 for an input coalgebra  $(C, c)$  with  $n = |C|$  states and  $m$  transitions, we have*

$$|\{T \subseteq C \mid T \in C/P_i \text{ for some } i\}| \leq 2 \cdot m \cdot \log_2 n + 2 \cdot m + n.$$

► **Remark.** Note that the proof is similar to arguments given in the complexity analysis of the Paige-Tarjan algorithm; for instance, compare to [36, p. 980] (or [46, Lem. 7.15]).

**Proof.** Because  $|S| \leq \frac{1}{2} \cdot |B|$  holds in step (A1) of Algorithm 3.2, one can show that every state  $x \in C$  is contained in the set  $S$  in at most  $(\log_2(n) + 1)$  iterations [46, Lem. 7.15]. More formally, let  $S_i \subsetneq B_i \in C/Q_i$  be the blocks picked in the  $i$ th iteration of Algorithm 3.2. Then we have

$$|\{S_i \mid x \in S_i\}| \leq \log_2 n + 1 \quad \text{for all } x \in C. \tag{10}$$

Let the algorithm terminate after  $\ell$  iterations returning  $C/P_\ell$ . Then, the number of new blocks introduced by step (A3) is bounded as follows (note that after the third step,  $x \in S_i$  is a side condition enforcing that we have a summand  $|\text{pred}(\{x\})|$  provided that  $x$  lies in  $S_i$ , whereas before we sum over all  $x \in S_i$ ):

$$\begin{aligned}
& \sum_{0 \leq i < \ell} |\{T' \in C/P_{i+1} \mid T' \not\subseteq C/P_i\}| \\
& \leq \sum_{0 \leq i < \ell} 2 \cdot |\text{pred}(S_i)| && \text{(Lemma A.5)} \\
& \leq 2 \cdot \sum_{0 \leq i < \ell} \sum_{x \in S_i} |\text{pred}(\{x\})| \\
& = 2 \cdot \sum_{\substack{x \in C \\ x \in S_i}} \sum_{\substack{0 \leq i < \ell \\ x \in S_i}} |\text{pred}(\{x\})|
\end{aligned}$$

$$\begin{aligned}
&= 2 \cdot \sum_{x \in C} |\text{pred}(\{x\})| \cdot \sum_{\substack{0 \leq i < \ell \\ x \in S_i}} 1 \\
&= 2 \cdot \sum_{x \in C} |\text{pred}(\{x\})| \cdot (\log_2 n + 1) && \text{by (10)} \\
&= 2 \cdot m \cdot (\log_2 n + 1) = 2 \cdot m \cdot \log_2 n + 2 \cdot m
\end{aligned}$$

The only blocks we have not counted so far are the blocks of  $C/P_0$ , since  $|C/P_0| \leq n$ , we have at most  $2 \cdot m \cdot \log_2 n + 2 \cdot m + n$  different blocks in  $(C/P_i)_{0 \leq i < \ell}$ . ◀

We are now ready to prove the main theorem on the dag size of formulae created by Algorithm 3.11.

**Proof of Theorem 3.17.** Regarding the height of the dag, it is immediate that  $\delta_i$  and  $\beta_i$  have a height of at most  $i + 1$ . Since  $|C/Q_i| < |C/Q_{i+1}| \leq |C| = n$  for all  $i$ , there are at most  $n$  iterations, with the final partition being  $C/P_{n+1} = C/Q_{n+1}$ .

In Algorithm 3.11 we create a new modal operator formula whenever Algorithm 3.2 creates a new block in  $C/P_i$ . By Lemma A.6, the number of modalities in the dag is thus bounded by

$$2 \cdot m \cdot \log_2 n + 2 \cdot m + n$$

In every iteration of the main loop,  $\beta$  is extended by two new formulae, one for  $S$  and one for  $B \setminus S$ . The formula  $\beta_{i+1}(S)$  does not increase the size of the dag, because no new node needs to be allocated. For  $\beta_{i+1}(B \setminus S)$ , we need to allocate one new node for the conjunction, so there are at most  $n$  new such nodes allocated throughout the execution of the whole algorithm. Even if the optimization in Remark 3.12 is applied, the additional run time can be neglected under the  $\mathcal{O}$ -notation. ◀

### Proof of Theorem 3.18.

We implement every operation of Algorithm 3.11 in constant time. The arrays for  $\beta$  and  $\delta$  are re-used in every iteration. Hence the index  $i$  is entirely neglected and only serves as an indicator for whether we refer to a value before or after the loop iteration. We proceed by case distinction as follows:

1. Initialization step:

- The only block  $\{C\}$  in  $C/Q_0$  has index 0, and so we make  $\beta(0)$  point to the node  $\top$ .
- For every block  $T$  in  $C/P_0$ , Algorithm 3.2 has computed  $F!(c(x)) \in F1$  for some (in fact every)  $x \in T$ . Since  $F1$  canonically embeds into  $F3$  (Notation 3.9), we create a new node labelled  $\lceil Fj_1(F!(c(x))) \rceil$  with two edges to  $\top$ .

For every  $T \in C/P_0$ , this runs in constant time and can be performed whenever the original Algorithm 3.2 creates a new such block  $T$ .

2. In the refinement step, we can look up the certificates  $\delta_i(S)$  resp.  $\beta_i(B)$  for  $S$  resp.  $B$  in constant time using the indices of the blocks  $S$  and  $B$ . Whenever the original algorithm creates a new block, we also immediately construct the certificate of this new block by creating at most two new nodes in the dag (with at most four outgoing edges). However, if a block does not change (that is,  $[x]_{Q_i} = [x]_{Q_{i+1}}$  or  $[x]_{P_i} = [x]_{P_{i+1}}$ , resp.), then the corresponding certificate is not changed either in steps item (A2) resp. item (A3).

In the loop body we update the certificates as follows:

(A'2) The new block  $S \in C/Q_{i+1}$  just points to the certificate  $\delta_i(S)$  constructed earlier. For the new block  $(B \setminus S) \in C/Q_{i+1}$ , we allocate a new node  $\wedge$ , with one edge to  $\beta_i(B)$  and one negated edge to  $\delta_i(S)$ . (See also details for Remark 3.12 on the run time for computing the optimized negation.)

(A'3) Not all resulting blocks have a transition to  $S$ . There may be (at most) one new block  $T' \in C/P_{i+1}$ ,  $T' \subseteq T$  with no transition to  $S$  (see the proof of Lemma A.5). In the refinable partition structure, such a block will inherit the index from  $T$  (i.e. the index of  $T$  in  $C/P_i$  equals the index of  $T'$  in  $C/P_{i+1}$ ). Moreover, every  $x \in T'$  fulfils  $F\chi_S^B(c(x)) = F\chi_\emptyset^B(c(x))$  (by Lemma A.2), and  $F\chi_\emptyset^B(c(x)) = F\chi_\emptyset^B(c(y))$  for every  $y \in T$  (by Lemma A.3).

Now, one first saves the node of the certificate  $\delta_i(T)$  in some variable  $\delta'$ , say. Then the array  $\delta$  is updated at index  $T$  by the formula

$$\lceil F\chi_\emptyset^B(c(y)) \rceil (\delta_i(S), \beta_i(B)) \quad \text{for an arbitrary } y \in T.$$

Consequently, any block  $T'$  inheriting the index of  $T$  automatically has the correct certificate.

The allocation of nodes for this formula is completely analogous to the one for an ordinary block  $[x]_{P_{i+1}} \subsetneq T$  having edges to  $S$ : One allocates a new node labelled  $\wedge$  with edges to the saved node  $\delta'$  (the original value of  $\delta_i(T)$ ) and to another newly allocated node labelled  $\lceil F\chi_S^B(c(x)) \rceil$  with edges to the nodes  $\delta_i(S)$  and  $\delta_i(B)$ . ◀

### Details for Remark 3.12.

In order to keep the formula size smaller, one can implement the optimization of Remark 3.12, but one has to take care not to increase the run time. To this end, mark every modal operator node  $\lceil t \rceil (\delta, \beta)$  in the formula dag with a boolean flag expressing whether:

$$\lceil t \rceil (\delta, \beta) \text{ is a conjunct of some } \beta_i\text{-formula.}$$

Thus, every new modal operator in (A'3) is flagged ‘false’ initially. When splitting the block  $B$  in  $C/Q_i$  into  $S$  and  $B \setminus S$  in step (A'2), the formula for block  $B \setminus S$  is a conjunction of  $\beta_i(B)$  and the negation of all ‘false’-marked conjuncts of  $\delta_i(S)$ . Afterwards these conjuncts are all marked ‘true’, because they are inherited by  $\beta_i(S)$ . The ‘false’-marked conjuncts always form a prefix of all conjuncts of a formula in  $\delta_i$ . It therefore suffices to greedily take conjuncts from the root of a formula graph while they are marked ‘false’.

As a consequence, step (A'3) does not run in constant time but instead takes as many steps as there are ‘false’-marked conjuncts in  $\delta_i(S)$ . However, over the whole execution of the algorithm this eventually amortizes because every newly allocated modal operator allocated is initially marked ‘false’ and later marked ‘true’ precisely once.

### Proof of Theorem 3.20.

The overall run time is immediate, because the underlying Algorithm 3.2 has run time  $\mathcal{O}((m+n) \cdot \log n \cdot p(c))$  and Algorithm 3.11 preserves this run time by Theorem 3.18.

## Details for Section 4 (Cancellative Functors)

### Proof of Proposition 4.2.

First note that for  $FX = M^{(X)}$  the maps in Definition 4.1 are defined by:

$$\begin{aligned} M^{(\chi_{\{1,2\}})}: M^{(3)} &\rightarrow M^{(2)}, & t &\mapsto (t(0), t(1) + t(2)), \\ M^{(\chi_{\{2\}})}: M^{(3)} &\rightarrow M^{(2)}, & t &\mapsto (t(0) + t(1), t(2)), \end{aligned}$$

where we write  $s \in M^{(2)}$  as the pair  $(s(0), s(1))$ .

For  $(\Leftarrow)$ , let  $s, t \in M^{(3)}$  with

$$\langle M^{(\chi_{\{1,2\}})}, M^{(\chi_{\{2\}})} \rangle(s) = \langle M^{(\chi_{\{1,2\}})}, M^{(\chi_{\{2\}})} \rangle(t),$$

which is written point-wise as follows:

$$\begin{aligned} (s(0), s(1) + s(2)) &= (t(0), t(1) + t(2)) \\ (s(0) + s(1), s(2)) &= (t(0) + t(1), t(2)). \end{aligned}$$

Hence,  $s(0) = t(0)$ ,  $s(2) = t(2)$  and moreover

$$s(1) + s(2) = t(1) + t(2) = t(1) + s(2).$$

Since  $M$  is cancellative, we have  $s(1) = t(1)$ , which proves that  $s = t$ . Thus, the map  $\langle M^{(\chi_{\{1,2\}})}, M^{(\chi_{\{2\}})} \rangle$  is injective.

For  $(\Rightarrow)$ , let  $a, b, c \in M$  with  $c + a = c + b$ . Define  $s, t \in M^{(3)}$  by

$$s(0) = s(2) = c, \quad s(1) = a \quad \text{and} \quad t(0) = t(2) = c, \quad t(1) = b.$$

Thus,

$$\begin{aligned} M^{(\chi_{\{1,2\}})}(s) &= (s(0), s(1) + s(2)) & M^{(\chi_{\{2\}})}(s) &= (s(0) + s(1), s(2)) \\ &= (c, a + c) & &= (c + a, c) \\ &= (c, b + c) & &= (c + b, c) \\ &= (t(0), t(1) + t(2)) & &= (t(0) + t(1), t(2)) \\ &= M^{(\chi_{\{1,2\}})}(t), & &= M^{(\chi_{\{2\}})}(t). \end{aligned}$$

Since  $\langle M^{(\chi_{\{1,2\}})}, M^{(\chi_{\{2\}})} \rangle$  is injective, we see that  $s = t$  holds. Thus, we have  $a = s(1) = t(1) = b$ , which proves that  $M$  is cancellative.  $\blacktriangleleft$

### Proof of Proposition 4.3.

1. For the constant functor  $C_X$  with value  $X$ ,  $C_X \chi_S$  is the identity map on  $X$  for every set  $S$ . Therefore  $C_X$  is cancellative.
2. The identity functor is cancellative because the map  $\langle \chi_{\{1,2\}}, \chi_{\{2\}} \rangle$  is clearly injective.
3. Let  $\alpha: F \rightarrow G$  a natural transformation with injective components and let  $G$  be cancellative. Combining the naturality squares of  $\alpha$  for  $\chi_{\{1,2\}}$  and  $\chi_{\{2\}}$ , we obtain the commutative square:

$$\begin{array}{ccc} F3 & \xrightarrow{\langle F\chi_{\{1,2\}}, F\chi_{\{2\}} \rangle} & F2 \times F2 \\ \alpha_3 \downarrow & & \downarrow \alpha_2 \times \alpha_2 \\ G3 & \xrightarrow{\langle G\chi_{\{1,2\}}, G\chi_{\{2\}} \rangle} & G2 \times G2 \end{array}$$

Every composition of injective maps is injective, and so by standard cancellation laws for injective maps,  $\langle F\chi_{\{1,2\}}, F\chi_{\{2\}} \rangle$  is injective as well, showing that the subfunctor  $F$  is cancellative.

4. Let  $(F_i)_{i \in I}$  be a family of cancellative functors, and suppose that we have elements  $s, t \in (\prod_{i \in I} F_i)(\mathfrak{3}) = \prod_{i \in I} F_i \mathfrak{3}$  with

$$\left( \prod_{i \in I} F_i \chi_{\{1,2\}} \right)(s) = \left( \prod_{i \in I} F_i \chi_{\{1,2\}} \right)(t) \quad \text{and} \quad \left( \prod_{i \in I} F_i \chi_{\{2\}} \right)(s) = \left( \prod_{i \in I} F_i \chi_{\{2\}} \right)(t).$$

Write  $\text{pr}_i$  for the  $i$ th projection function from the product. For every  $i \in I$  we have:

$$F_i \chi_{\{1,2\}}(\text{pr}_i(s)) = F_i \chi_{\{1,2\}}(\text{pr}_i(t)) \quad \text{and} \quad F_i \chi_{\{2\}}(\text{pr}_i(s)) = F_i \chi_{\{2\}}(\text{pr}_i(t)).$$

Since every  $F_i$  is cancellative, we have  $\text{pr}_i(s) = \text{pr}_i(t)$  for every  $i \in I$ . This implies  $s = t$  since the product projections  $(\text{pr}_i)_{i \in I}$  are jointly injective.

5. Again, let  $(F_i)_{i \in I}$  be a family of cancellative functors. Suppose that we have elements  $s, t \in (\prod_{i \in I} F_i)(\mathfrak{3}) = \prod_{i \in I} F_i \mathfrak{3}$  satisfying

$$\left( \prod_{i \in I} F_i \chi_{\{1,2\}} \right)(s) = \left( \prod_{i \in I} F_i \chi_{\{1,2\}} \right)(t) \quad \text{and} \quad \left( \prod_{i \in I} F_i \chi_{\{2\}} \right)(s) = \left( \prod_{i \in I} F_i \chi_{\{2\}} \right)(t).$$

This implies that there exists an  $i \in I$  and  $t', s' \in F_i$  with  $s = \text{in}_i(s')$ ,  $t = \text{in}_i(t')$ , and

$$F_i \chi_{\{1,2\}}(s) = F_i \chi_{\{1,2\}}(t) \quad \text{and} \quad F_i \chi_{\{2\}}(s) = F_i \chi_{\{2\}}(t).$$

Since  $F_i$  is cancellative, we have  $s = t$  as desired.  $\blacktriangleleft$

#### Details for Remark 4.4.

Operation	cancellative	non-cancellative		cancellative	non-cancellative
Quotient	$X \mapsto \prod_{n \in \mathbb{N}} X^n$	$\mathcal{P}_f$	zippable	$X \mapsto X$	$\mathcal{P}_f$
Composition	$\mathcal{B} = \mathbb{N}^{(-)}$	$\mathcal{B}\mathcal{B}$	non-zippable	see (11)	$\mathcal{P}_f \mathcal{P}_f$

1. Cancellative functors are not closed under quotients: e.g. the non-cancellative functor  $\mathcal{P}_f$  is a quotient of the signature functor  $X \mapsto \prod_{n \in \mathbb{N}} X^n$  (which is cancellative by Proposition 4.3).
2. Cancellative functors are not closed under composition. For the additive monoid  $(\mathbb{N}, +, 0)$  of natural numbers, the monoid-valued functor  $\mathcal{B} = \mathbb{N}^{(-)}$  sends  $X$  to the set of finite multisets on  $X$  ('bags'). Since  $\mathbb{N}$  is cancellative,  $\mathcal{B}$  is a cancellative functor. However,  $\mathcal{B}\mathcal{B}$  is not:

$$\begin{aligned} & \langle \mathcal{B}\mathcal{B}\chi_{\{1,2\}}, \mathcal{B}\mathcal{B}\chi_{\{2\}} \rangle (\{\{0, 1\}, \{1, 2\}\}) \\ &= (\{\{0, 1\}, \{1, 1\}\}, \{\{0, 0\}, \{0, 1\}\}) \\ &= (\{\{0, 1\}, \{1, 1\}\}, \{\{0, 1\}, \{0, 0\}\}) \\ &= \langle \mathcal{B}\mathcal{B}\chi_{\{1,2\}}, \mathcal{B}\mathcal{B}\chi_{\{2\}} \rangle (\{\{0, 2\}, \{1, 1\}\}) \end{aligned}$$

Here, we use  $\{\{\cdot\}\}$  to denote multisets, so  $\{0, 1\} = \{1, 0\}$  but  $\{1\} \neq \{1, 1\}$ .

3. The identity functor  $X \mapsto X$  is both zippable [46] and cancellative (Proposition 4.3).
4. The monoid-valued functor  $\mathcal{P}_f = \mathbb{B}^{(-)}$  is zippable [46], but not cancellative (Proposition 4.2), because  $\mathbb{B}$  is a non-cancellative monoid.

5. The functor  $\mathcal{P}\mathcal{P}$  is neither zippable [46, Ex. 5.10] nor cancellative because

$$\begin{aligned} \langle \mathcal{P}\mathcal{P}\chi_{\{1,2\}}, \mathcal{P}\mathcal{P}\chi_{\{2\}} \rangle (\{\{0\}, \{2\}\}) &= (\{\{0\}, \{1\}\}, \{\{0\}, \{1\}\}) \\ &= \langle \mathcal{P}\mathcal{P}\chi_{\{1,2\}}, \mathcal{P}\mathcal{P}\chi_{\{2\}} \rangle (\{\{0\}, \{1\}, \{2\}\}). \end{aligned}$$

6. Every functor  $F$  satisfying  $|F(2+2)| > 1$  and  $|F3| = 1$  is cancellative but not zippable:

- Indeed, every map with domain 1 is injective, in particular the map

$$\langle F\chi_{\{1,2\}}, F\chi_{\{2\}} \rangle : 1 \cong F3 \longrightarrow F2 \times F2,$$

whence  $F$  is cancellative.

- If  $|F(2+2)| > 1$  and  $|F3| = 1$  we have that the map

$$\langle 2+!, !+2 \rangle : \underbrace{F(2+2)}_{|-|>1} \rightarrow \underbrace{F(2+1)}_{\cong F3 \cong 1} \times \underbrace{F(1+2)}_{\cong F3 \cong 1} \cong 1$$

is not injective, whence  $F$  is not zippable.

An example for such a functor is given by

$$FX = \{S \subseteq X : |S| = 0 \text{ or } |S| = 4\} \tag{11}$$

which sends a map  $f: X \rightarrow Y$  to the map  $Ff: FX \rightarrow FY$  defined by

$$Ff(S) = \begin{cases} f[S] & \text{if } |f[S]| = 4 \\ \emptyset & \text{otherwise.} \end{cases}$$

7. For the proof of

$$F \text{ zippable \& } F \text{ cancellative} \implies F \text{ } m\text{-zippable} \quad \text{for all } m \in \mathbb{N}$$

recall from König et al. [32] that a functor  $F$  is  $m$ -zippable if the canonical map

$$\text{unzip}_m : F(A_1 + A_2 + \dots + A_m) \longrightarrow F(A_1 + 1) \times F(A_2 + 1) \times \dots \times F(A_m + 1)$$

is injective. Formally,  $\text{unzip}_m$  is given by

$$\langle F[\Delta_{i,j}]_{j \in \bar{m}} \rangle_{i \in \bar{m}} : F \prod_{j=1}^m A_j \longrightarrow \prod_{i=1}^m F(A_i + 1)$$

where  $\bar{m}$  is the set  $\bar{m} = \{1, \dots, m\}$  and the map  $\Delta_{i,j}$  is defined by

$$\Delta_{i,j} : A_j \rightarrow A_i + 1 \quad \Delta_{i,j} := \begin{cases} A_j \xrightarrow{\text{in}_1} A_i + 1 & \text{if } i = j \\ A_j \xrightarrow{!} 1 \xrightarrow{\text{in}_2} A_i + 1 & \text{if } i \neq j. \end{cases}$$

First, we show that for a zippable and cancellative functor  $F$ , the map

$$g_{A,B} := F(A+1+B) \xrightarrow{\langle F(A+!), F(!+B) \rangle} F(A+1) \times F(1+B)$$

is injective for all sets  $A, B$ . Indeed, we have the following chain of injective maps, where the index at the 1 is only notation to distinguish coproduct components more easily:

$$\begin{aligned} &F(A + (1_M + B)) \\ &\quad \downarrow \langle F(A+!), F(! + (1_M + B)) \rangle \end{aligned} \quad (F \text{ is zippable})$$

## 32:30 Explaining Behavioural Inequivalence Generically in Quasilinear Time

$$\begin{aligned}
& F(A+1) \times F(1_A + 1_M + B) \\
& \quad \Downarrow \text{id} \times \langle F(!+B), F(1_A + 1_M + !) \rangle \quad (F \text{ is zippable}) \\
& F(A+1) \times F(1+B) \times F(1_A + 1_M + 1_B) \\
& \quad \Downarrow \text{id} \times \text{id} \times \langle F\chi_{1_M+1_B}, F\chi_{1_B} \rangle \quad (F \text{ is cancellative, } 1_A + 1_M + 1_B \cong \{0, 1, 2\}) \\
& F(A+1) \times F(1+B) \times F2 \times F2
\end{aligned}$$

Call this composition  $f$ . The injective map  $f$  factors through  $g_{A,B}$ , because it matches with  $g_{A,B}$  on the components  $F(A+1)$  and  $F(1+B)$ , and for the other components, one has the map

$$h := F(A+1) \times F(1+B) \xrightarrow{F\chi_1 \times F\chi_B} F2 \times F2$$

with  $f = \langle \text{id}_{F(A+1) \times F(1+B)}, h \rangle \cdot g_{A,B}$ . Since  $f$  is injective,  $g_{A,B}$  must be injective, too. Also note that a function  $F$  is cancellative iff equivalently the map

$$\langle F(1+!), F(!+1) \rangle: F(1+1+1) \longrightarrow F(1+1) \times F(1+1)$$

is injective, for  $!: 1+1 \rightarrow 1$  and  $1+1+1 \cong 3$  and  $1+1 \cong 2$ .

We now proceed with the proof of the desired implication by induction on  $m$ . In the base cases  $m = 0$  and  $m = 1$  there is nothing to show because every functor is 0- and 1-zippable, and for  $m = 2$ , the implication is trivial (zippability and 2-zippability are identical properties). In the inductive step, given that  $F$  is 2-zippable,  $m$ -zippable ( $m \geq 2$ ), and cancellative, we show that  $F$  is  $(m+1)$ -zippable.

We have the following chain of injective maps, where we again annotate some of the singleton sets 1 with indices to indicate from which coproduct components they come:

$$\begin{aligned}
& F(A_1 + \dots + A_{m-1} + (A_m + A_{m+1})) \\
& \quad \Downarrow \text{unzip}_m \quad (F \text{ is } m\text{-zippable}) \\
& \quad \prod_{i=1}^{m-1} F(A_i + 1) \times F(A_m + A_{m+1} + 1_{1..(m-1)}) \\
& \cong \prod_{i=1}^{m-1} F(A_i + 1) \times F(A_m + 1_{1..(m-1)} + A_{m+1}) \\
& \quad \Downarrow \text{id} \times g_{A_m, A_{m+1}} \quad (\text{the above injective helper map } g) \\
& \quad \prod_{i=1}^{m-1} F(A_i + 1) \times F(A_m + 1) \times F(1 + A_{m+1}) \\
& \cong \prod_{i=1}^{m-1} F(A_i + 1) \times F(A_m + 1) \times F(A_{m+1} + 1)
\end{aligned}$$

This composition thus is injective as well, and in fact the composition is precisely  $\text{unzip}_{m+1}$ , showing that  $F$  is  $(m+1)$ -zippable.  $\blacktriangleleft$

The optimization present in the algorithms for Markov chains [44] and automata [27] can now be adapted to coalgebras for cancellative functors, where it suffices to split only according to transitions into  $S$ , neglecting transitions into  $B \setminus S$ . More formally, this means that we replace the three-valued  $\chi_S^B: C \rightarrow 3$  with  $\chi_S: C \rightarrow 2$  in the refinement step (A3):

► **Proposition A.7.** *Let  $F$  be a cancellative set functor. For  $S \in C/P_i$  in the  $i$ -th iteration of Algorithm 3.2, we have  $P_{i+1} = P_i \cap \ker(C \xrightarrow{c} FC \xrightarrow{F\chi_S} F2)$ .*

### Proof of Proposition A.7.

From the definition (1) of the kernel, we immediately obtain the following properties for all maps  $f, g: Y \rightarrow Z$ ,  $h: X \rightarrow Y$ :

$$f \text{ injective} \implies \ker(f \cdot h) = \ker(h) \quad (12)$$

$$\ker(f) = \ker(g) \implies \ker(f \cdot h) = \ker(g \cdot h) \quad (13)$$

$$\ker(\langle f, g \rangle) = \ker(f) \cap \ker(g). \quad (14)$$

For every coalgebra  $c: C \rightarrow FC$  and  $S \subseteq B \subseteq C$  we have

$$\langle F\chi_B, F\chi_S \rangle = \langle F\chi_{\{1,2\}}, F\chi_{\{2\}} \rangle \cdot F\chi_S^B.$$

Since  $F$  is cancellative,  $\langle F\chi_{\{1,2\}}, F\chi_{\{2\}} \rangle$  is injective, and we thus obtain

$$\ker(\langle F\chi_B, F\chi_S \rangle) = \ker(\langle F\chi_{\{1,2\}}, F\chi_{\{2\}} \rangle \cdot F\chi_S^B) \stackrel{(12)}{=} \ker(F\chi_S^B). \quad (15)$$

By (13), this implies that

$$\ker(\langle F\chi_B, F\chi_S \rangle \cdot c) = \ker(F\chi_S^B \cdot c). \quad (16)$$

Let  $B \in C/Q_i$  be the block that is split into  $S$  and  $B \setminus S$  in iteration  $i$ . Since  $P_i$  is finer than  $Q_i$  and  $B \in C/Q_i$ , we have  $P_i \subseteq Q_i \subseteq \ker(F\chi_B \cdot c)$ ; thus:

$$P_i = P_i \cap \ker(C \xrightarrow{c} FC \xrightarrow{F\chi_B} F2). \quad (17)$$

Now we verify the desired property:

$$\begin{aligned} P_{i+1} &= P_i \cap \ker(C \xrightarrow{c} FC \xrightarrow{F\chi_S^B} F2) && \text{(by (A3))} \\ &= P_i \cap \ker(\langle F\chi_B, F\chi_S \rangle \cdot c) && \text{(by (16))} \\ &= P_i \cap \ker(\langle F\chi_B \cdot c, F\chi_S \cdot c \rangle) && \text{(def. } \langle -, - \rangle \text{)} \\ &= P_i \cap \ker(F\chi_B \cdot c) \cap \ker(F\chi_S \cdot c) && \text{(by (14))} \\ &= P_i \cap \ker(F\chi_S \cdot c) && \text{(by (17))} \end{aligned}$$

This completes the proof.  $\blacktriangleleft$

► **Example A.8.** For coalgebras for a signature functor  $\Sigma$  or a monoid-valued functor  $M^{(-)}$  for cancellative  $M$ , the refinement step (A3) of Algorithm 3.2 can be optimized to compute  $P_{i+1}$  according to Proposition A.7.

Observe that, in the optimized step (A3),  $B$  is no longer mentioned. It is therefore unsurprising that we do not need a certificate for it when constructing certificates for the blocks of  $P_{i+1}$ . Instead, we can reflect the map  $F\chi_S \cdot c: C \rightarrow F2$  in the coalgebraic modal formula and take  $F2$  as the (unary) modal operators. Just like  $F1$  in Notation 3.9, the set  $F2$  canonically embeds into  $F3$ :

### Proof of Theorem 4.5.

Before proving Theorem 4.5, we define a new set of (unary) modalities (Notation A.9), establish a lemma about its semantics (Lemma A.10), fully phrase the entire optimized algorithm (Algorithm A.11), and then show its correctness (Theorem A.13).

► **Notation A.9.** Define the injective map  $j_2: 2 \rightarrow 3$  by  $j_2(0) = 1$  and  $j_2(1) = 2$ . Then the injection  $Fj_2: F2 \rightarrow F3$  provides a way to interpret elements  $t \in F2$  as unary modalities  $\ulcorner t \urcorner$ :

$$\ulcorner t \urcorner(\delta) := \ulcorner Fj_2(t) \urcorner(\delta, \top).$$

**Remark to Notation A.9.**

There are several different ways to define  $\ulcorner t^\top(\delta)$  for  $t \in F2$ , depending on the definition of the inclusion  $j_2$ .

$j_2: 2 \mapsto 3$	$j_2 \cdot \chi_S$ for $S \subseteq C$	Definition for $t \in F2$
$0 \mapsto 0, 1 \mapsto 1$	$j_2 \cdot \chi_S = \chi_0^S$	$\ulcorner t^\top(\delta) := \ulcorner Fj_2(t)^\top(\perp, \delta)$
$0 \mapsto 0, 1 \mapsto 2$	$j_2 \cdot \chi_S = \chi_S^S$	$\ulcorner t^\top(\delta) := \ulcorner Fj_2(t)^\top(\delta, \delta)$
$0 \mapsto 1, 1 \mapsto 2$	$j_2 \cdot \chi_S = \chi_S^C$	$\ulcorner t^\top(\delta) := \ulcorner Fj_2(t)^\top(\delta, \top)$

All these variants make the following Lemma A.10 true because in any case:

$$\ulcorner t^\top(\delta) = \ulcorner Fj_2(t)^\top(\phi, \psi) \quad \text{implies} \quad j_2 \cdot \chi_{\llbracket \delta \rrbracket} = \chi_{\llbracket \phi \rrbracket}^{\llbracket \psi \rrbracket}. \quad (18)$$

Analogously to Lemma 3.8 we can show:

► **Lemma A.10.** *Given a cancellative functor  $F$ , an  $F$ -coalgebra  $(C, c)$ ,  $t \in F2$ , a formula  $\delta$ , and  $x \in C$ , we have  $x \in \llbracket \ulcorner t^\top(\delta) \rrbracket$  if and only if  $F\chi_{\llbracket \delta \rrbracket}(c(x)) = t$ .*

In Algorithm 3.11, the family  $\beta$  is only used in the definition of  $\delta_{i+1}$  to characterize the larger block  $B$  that has been split into the smaller blocks  $S \subseteq B$  and  $B \setminus S$ . For a cancellative functor, we can replace

$$\ulcorner F\chi_S^B(c(x))^\top(\delta_i(S), \beta_i(B)) \quad \text{with} \quad \ulcorner F\chi_S(c(x))^\top(\delta_i(S))$$

in the definition of  $\delta_{i+1}$ . Hence, we can omit  $\beta_i$  from Algorithm 3.11 altogether, obtaining the following algorithm, which is again based on coalgebraic partition refinement (Algorithm 3.2).

**Proof of Lemma A.10.** Since we put  $j_2: 2 \mapsto 3$  with  $j_2(0) = 1$  and  $j_2(1) = 2$ , we have  $j_2 \cdot \chi_S = \chi_S^C$  for all  $S \subseteq C$ .

$$\begin{aligned} \llbracket \ulcorner t^\top(\delta) \rrbracket &= \llbracket \ulcorner Fj_2(t)^\top(\delta, \top) \rrbracket && \text{(Notation A.9)} \\ &= \{x \in C \mid F\chi_{\llbracket \delta \rrbracket}^C(c(x)) = Fj_2(t)\} && \text{(Lemma 3.8, } \llbracket \top \rrbracket = C) \\ &= \{x \in C \mid Fj_2(F\chi_{\llbracket \delta \rrbracket}(c(x))) = Fj_2(t)\} && (\chi_{\llbracket \delta \rrbracket}^C = j_2 \cdot \chi_{\llbracket \delta \rrbracket}) \\ &= \{x \in C \mid F\chi_{\llbracket \delta \rrbracket}(c(x)) = t\} && (Fj_2 \text{ injective}) \end{aligned}$$

In the last step, we use that  $F$  preserves injective maps (Remark 2.6) ◀

► **Algorithm A.11.** We extend Algorithm 3.2 as follows. Initially, define

$$\delta_0([x]_{P_0}) = \ulcorner F!(c(x))^\top.$$

In the  $i$ -th iteration, extend step (A3) by the additional assignment

$$(A3) \quad \delta_{i+1}([x]_{P_{i+1}}) = \begin{cases} \delta_i([x]_{P_i}) & \text{if } [x]_{P_{i+1}} = [x]_{P_i} \\ \delta_i([x]_{P_i}) \wedge \ulcorner F\chi_S(c(x))^\top(\delta_i(S)) & \text{otherwise.} \end{cases}$$

The certificates thus computed are reduced to roughly half the size compared to Algorithm 3.11; the asymptotic run time and formula size (Section 3.5) remain unchanged. More importantly:

► **Remark A.12.** The certificates constructed by Algorithm A.11 do not contain negation (or disjunction); they are built from  $\top$ , conjunction  $\wedge$ , and unary modal operators  $\ulcorner t^\top$  for  $t \in F2$  (the nullary operators  $\ulcorner t^\top$  for  $t \in F1$  embed into  $F2$ ).

**Details on Remark A.12.** Define the injective map  $j_{12}: 1 \mapsto 2$  by  $j_{12}(0) = 1$ . Hence, we can also embed the nullary  $t \in F1$  into  $F2$ :

$$\lceil t \rceil = \lceil Fj_{12}(t) \rceil(\top) \quad (\text{cf. Notation A.9}).$$

This is compatible with the notations established so far because we have  $j_2 \cdot j_{12} = j_1: 1 \mapsto 3$  for the inclusions defined in Notation 3.9 and Notation A.9. Thus, we obtain the same modal operator regardless of whether we embed  $t \in F1$  first into  $F2$  and from there into  $F3$  ( $j_2$ , Notation A.9) or directly into  $F3$  ( $j_1$ , Notation 3.9):  $\lceil t \rceil = \lceil Fj_{12}(t) \rceil(\top) = \lceil Fj_2(Fj_{12}(t)) \rceil(\top, \top) = \lceil Fj_1(t) \rceil(\top, \top)$ . ◀

► **Theorem A.13.** *For cancellative functors, Algorithm A.11 is correct; that is, for all  $i \in \mathbb{N}$  we have:*

$$\forall S \in X/P_i: \llbracket \delta_i(S) \rrbracket = S.$$

Note that the optimized Algorithm A.11 can also be implemented by directly constructing certificates for the unary modal operators  $F2$ . That is, one can treat the modal operators  $F2$  as first class citizens, in lieu of embedding them into the set  $F3$  as we did in Notation A.9. The only difference between the two implementation approaches w.r.t. the size of the formula dag is one edge per modality, namely the edge to the node  $\top$  from the node  $\lceil Fj_2(F\chi_S(c(x))) \rceil(\delta_i(\delta_i), \top)$ , which arises when step 3 is expanded according to Notation A.9.

**Proof of Theorem A.13.** We prove the desired correctness by induction over  $i$ , the index of loop iterations.

The definition of  $\delta_0$  is identical to the definition in Algorithm 3.11 whence

$$\llbracket \delta_0(S) \rrbracket = S \quad \text{for all } S \in C/P_0,$$

proved completely analogously as in the proof of Theorem 3.13.

In the  $i$ -th iteration with chosen block  $S \in C/P_i$ , we distinguish two cases, whether a block  $[x]_{P_{i+1}} \in C/P_{i+1}$  remains the same or is split into other blocks:

■ If  $[x]_{P_{i+1}} = [x]_{P_i}$ , then we have

$$\llbracket \delta_{i+1}([x]_{P_i}) \rrbracket \stackrel{3}{=} \llbracket \delta_i([x]_{P_i}) \rrbracket \stackrel{\text{I.H.}}{=} [x]_{P_i} = [x]_{P_{i+1}}.$$

■ If  $[x]_{P_{i+1}} \neq [x]_{P_i}$ , we compute as follows:

$$\begin{aligned} & \llbracket \delta_{i+1}([x]_{P_{i+1}}) \rrbracket \\ &= \llbracket \delta_i([x]_{P_i}) \wedge \lceil F\chi_S(c(x)) \rceil(\delta_i(S)) \rrbracket && 3 \\ &= \llbracket \delta_i([x]_{P_i}) \rrbracket \cap \llbracket \lceil F\chi_S(c(x)) \rceil(\delta_i(S)) \rrbracket \\ &= [x]_{P_i} \cap \llbracket \lceil F\chi_S(c(x)) \rceil(\delta_i(S)) \rrbracket && \text{(I.H.)} \\ &= [x]_{P_i} \cap \{x' \in C \mid F\chi_{\llbracket \delta_i(S) \rrbracket}(c(x')) = F\chi_S(c(x))\} && \text{(Lemma A.10)} \\ &= [x]_{P_i} \cap \{x' \in C \mid F\chi_S(c(x')) = F\chi_S(c(x))\} && \text{(I.H.)} \\ &= [x]_{P_i} \cap \{x' \in C \mid (x, x') \in \ker(F\chi_S \cdot c)\} && \text{(def. ker)} \\ &= [x]_{P_i} \cap [x]_{F\chi_S \cdot c} && \text{(def. } [x]_R) \\ &= [x]_{P_{i+1}} \end{aligned}$$

The last step is the block-wise definition of  $P_{i+1} = P_i \cap \ker(F\chi_S \cdot c)$  (see Proposition A.7). ◀

## Details for Section 5 (Domain-Specific Certificates)

### Details for Definition 5.1.

For every set  $X$ , define the set  $\mathcal{B}\ell(X)$  as terms  $K$  over the grammar

$$K ::= X \mid \neg K \mid K \wedge K. \quad (19)$$

There is an obvious way to evaluate boolean combinations of predicates using the maps

$$e_X: \mathcal{B}\ell(2^X) \rightarrow 2^X$$

defined inductively as follows:

$$e_X(S \subseteq X) = X, \quad e_X(\neg K) = X \setminus K, \quad e_X(K_1 \wedge K_2) = K_1 \cap K_2.$$

Given a signature  $\Lambda$  of modal operators  $\lambda$  and corresponding predicate liftings  $\llbracket \lambda \rrbracket$ , we can combine all of them. To this end, write  $\Lambda$  for the corresponding signature functor (cf. Example 2.3.3); we define a family of maps  $\llbracket \Lambda \rrbracket_X$  as follows:

$$\llbracket \Lambda \rrbracket_X: \Lambda(2^X) = \coprod_{\lambda/n \in \Lambda} (2^X)^n \xrightarrow{\llbracket \llbracket \lambda \rrbracket \rrbracket_{\lambda \in \Lambda}} 2^{FX}.$$

Since every  $\llbracket \lambda \rrbracket_X: (2^X)^n \rightarrow 2^{FX}$  is natural in  $X$ , so is  $\llbracket \Lambda \rrbracket_X$ . We can replace  $\Lambda$  with the signature

$$\Lambda' := \coprod_{n \in \mathbb{N}} \mathcal{B}\ell(\Lambda(\mathcal{B}\ell(n))),$$

where  $\text{in}_n(K) \in \Lambda'$ ,  $K \in \mathcal{B}\ell(\Lambda(\mathcal{B}\ell(n)))$  has the arity  $n$ . Observe that  $\mathcal{B}\ell$  is functorial; in fact, it is the (free or term) monad for the signature functor  $\Sigma X = X + X \times X$  associated to the grammar in (19). Thus  $\mathcal{B}\ell \cdot \Lambda \cdot \mathcal{B}\ell$  is a functor, too. Applying the Yoneda-Lemma to this functor, we have for every  $t/n \in \Lambda'$  the (natural) family of maps  $\alpha^t$ :

$$\alpha_X^t: X^n \rightarrow \mathcal{B}\ell(\Lambda(\mathcal{B}\ell(X))) \quad \text{for every set } X.$$

Hence, we obtain a predicate lifting for  $t$  by defining:

$$\llbracket t \rrbracket_X: ((2^X)^n \xrightarrow{\alpha_X^t} \mathcal{B}\ell(\Lambda(\mathcal{B}\ell(2^X))) \xrightarrow{\mathcal{B}\ell(\Lambda(e_X))} \mathcal{B}\ell(\Lambda(2^X)) \xrightarrow{\mathcal{B}\ell(\llbracket \Lambda \rrbracket_X)} \mathcal{B}\ell(2^{FX}) \xrightarrow{\mathcal{B}\ell(e_{FX})} 2^{FX}).$$

It is a composition of natural transformations and so is itself natural in  $X$ .

► **Definition A.14.** Given a modal signature  $\Lambda$  for a functor  $F$ , a *simple domain-specific interpretation* consists of functions  $\tau: F1 \rightarrow \bar{\Lambda}$  and  $\kappa: F2 \rightarrow \bar{\Lambda}$  assigning a nullary modality  $\tau_o$  to each  $o \in F1$  and a unary modality  $\kappa_s$  to each  $s \in F2$  such that the predicate liftings  $\llbracket \tau_o \rrbracket_X \in 2^{FX}$  and  $\llbracket \kappa_s \rrbracket: 2^X \rightarrow 2^{FX}$  satisfy

$$\llbracket \tau_o \rrbracket_1 = \{f\} \quad (\text{in } 2^{F1}) \quad \text{and} \quad [s]_{F1} \cap \llbracket \kappa_s \rrbracket_2(\{1\}) = \{s\} \quad (\text{in } 2^{F2}).$$

► **Proposition A.15.** Let  $\Lambda$  be a modal signature for a cancellative functor  $F$ , and  $(\tau, \kappa)$  a simple domain-specific interpretation. Define  $\lambda: F3 \rightarrow \bar{\Lambda}$  by  $\lambda_t(\delta, \rho) = \kappa_{F\chi_{\{2\}}(t)}(\delta)$ . Then  $(\tau, \lambda)$  is a domain-specific interpretation.

**Proof.** We verify that  $(\tau, \lambda)$  is a domain-specific interpretation (Definition 5.2) by verifying that for every  $t \in F3$ , defining

$$\tau_t(\delta, \rho) = \kappa_{F\chi_{\{2\}}(t)}(\delta)$$

satisfies

$$[t]_{F\chi_{\{1,2\}}} \cap \llbracket \tau_t \rrbracket_3(\{2\}, \{1\}) = \{t\} \quad \text{in } 2^{F3}.$$

In the following, we put  $s := F\chi_{\{2\}}(t) \in F2$ . By the naturality of the predicate lifting of  $\kappa_s$ , the following square commutes (recall that  $2^{(-)}$  is contravariant):

$$\begin{array}{ccc} 2^2 & \xrightarrow{\llbracket \kappa_s \rrbracket_2} & 2^{F2} \\ 2^{X_{\{2\}}} \downarrow & & \downarrow 2^{F\chi_{\{2\}}} \\ 2^3 & \xrightarrow{\llbracket \kappa_s \rrbracket_3} & 2^{F3} \end{array} \quad (20)$$

We thus have:

$$\begin{aligned} \llbracket \tau_t \rrbracket_3(\{2\}, \{1\}) &= \llbracket \kappa_s \rrbracket_3(\{2\}) && \text{(def. } \tau_t) \\ &= \llbracket \kappa_s \rrbracket_3(\chi_{\{2\}}^{-1}[\{1\}]) && \text{(def. } \chi_{\{2\}}) \\ &= \llbracket \kappa_s \rrbracket_3(2^{X_{\{2\}}}(\{1\})) && \text{(def. } 2^{(-)}) \\ &= 2^{F\chi_{\{2\}}}(\llbracket \kappa_s \rrbracket_2(\{1\})) && \text{(by (20))} \\ &= \{t' \in F3 \mid F\chi_{\{2\}}(t') \in \llbracket \kappa_s \rrbracket_2(\{1\})\} \end{aligned}$$

For every  $t' \in F3$ , we have

$$\begin{aligned} &t' \in [t]_{F\chi_{\{1,2\}}} \cap \llbracket \tau_t \rrbracket_3(\{2\}, \{1\}) \\ \Leftrightarrow &t' \in [t]_{F\chi_{\{1,2\}}} \text{ and } t' \in \llbracket \tau_t \rrbracket_3(\{2\}, \{1\}) \\ \Leftrightarrow &t' \in [t]_{F\chi_{\{1,2\}}} \text{ and } F\chi_{\{2\}}(t') \in \llbracket \kappa_s \rrbracket_2(\{1\}) && \text{(by the above calculation)} \\ \Leftrightarrow &t' \in [t]_{F\chi_{\{1,2\}}} \text{ and } F\chi_{\{2\}}(t') \in [F\chi_{\{2\}}(t')]_{F!} \cap \llbracket \kappa_s \rrbracket_2(\{1\}) && \text{(ker reflexive)} \\ \Leftrightarrow &t' \in [t]_{F\chi_{\{1,2\}}} \text{ and } F\chi_{\{2\}}(t') \in [F\chi_{\{2\}}(t)]_{F!} \cap \llbracket \kappa_s \rrbracket_2(\{1\}) && (t' \in [t]_{F\chi_{\{1,2\}}}) \\ \Leftrightarrow &t' \in [t]_{F\chi_{\{1,2\}}} \text{ and } F\chi_{\{2\}}(t') \in [s]_{F!} \cap \llbracket \kappa_s \rrbracket_2(\{1\}) && \text{(def. } s) \\ \Leftrightarrow &t' \in [t]_{F\chi_{\{1,2\}}} \text{ and } F\chi_{\{2\}}(t') \in \{s\} && \text{(assumption on } \kappa_s) \\ \Leftrightarrow &t' \in [t]_{F\chi_{\{1,2\}}} \text{ and } F\chi_{\{2\}}(t') \in \{F\chi_{\{2\}}(t)\} && \text{(def. } s) \\ \Leftrightarrow &F\chi_{\{1,2\}}(t') = F\chi_{\{1,2\}}(t) \text{ and } F\chi_{\{2\}}(t') = F\chi_{\{2\}}(t) \\ \Leftrightarrow &\langle F\chi_{\{1,2\}}, F\chi_{\{2\}} \rangle(t') = \langle F\chi_{\{1,2\}}, F\chi_{\{2\}} \rangle(t) && \text{(def. } \langle -, - \rangle) \\ \Leftrightarrow &t' = t && (F \text{ cancellative}) \end{aligned}$$

Note that  $\langle F\chi_{\{1,2\}}, F\chi_{\{2\}} \rangle$  is injective because  $F$  is cancellative.  $\blacktriangleleft$

### Details for Example 5.3.

1. We verify that Example 5.3.1 indeed provides domain-specific certificate (Definition 5.2).

For  $t \in \mathcal{P}3$ , we have

$$\lambda_t(\delta, \rho) = \begin{cases} \neg \diamond \rho & \text{if } 2 \in t \not\equiv 1 \\ \diamond \delta \wedge \diamond \rho & \text{if } 2 \in t \equiv 1 \\ \neg \diamond \delta & \text{if } 2 \notin t \equiv 1 \\ \top & \text{if } 2 \notin t \not\equiv 1 \end{cases}$$

## 32:36 Explaining Behavioural Inequivalence Generically in Quasilinear Time

We proceed by the following case distinction:

- If  $1 \notin \mathcal{P}_{\chi_{\{1,2\}}}(t)$ , then  $t = \emptyset$  or  $t = \{0\}$ . In both cases we have  $[t]_{\mathcal{P}_{\chi_{1,2}}} = \{t\}$ . Since  $\lambda_t(\delta, \rho) = \top$ ,

$$[t]_{\mathcal{P}_{\chi_{1,2}}} \cap \llbracket \lambda_t \rrbracket_3(\{2\}, \{1\}) = \{t\}$$

as desired.

- If  $1 \in \mathcal{P}_{\chi_{\{1,2\}}}(t)$ , then  $2 \in t$  or  $1 \in t$ . This yields

$$\begin{aligned} 2 \in t \not\equiv 1 &\implies \llbracket \overbrace{(\delta, \rho) \mapsto \neg \diamond \rho}^{\lambda_t} \rrbracket_3(\{2\}, \{1\}) = \{t' \in F3 \mid 1 \notin t'\} \\ 2 \in t \ni 1 &\implies \llbracket (\delta, \rho) \mapsto \diamond \delta \wedge \diamond \rho \rrbracket_3(\{2\}, \{1\}) = \{t' \in F3 \mid 2 \in t' \text{ and } 1 \in t'\} \\ 2 \notin t \ni 1 &\implies \llbracket (\delta, \rho) \mapsto \neg \diamond \delta \rrbracket_3(\{2\}, \{1\}) = \{t' \in F3 \mid 2 \notin t'\} \end{aligned}$$

Consequently, we have for every  $t' \in \llbracket \lambda_t \rrbracket_3(\{2\}, \{1\})$  that

$$1 \in t \text{ iff } 1 \in t' \quad \text{and} \quad 2 \in t \text{ iff } 2 \in t'.$$

To conclude, note that if  $t' \in [t]_{\mathcal{P}_{\chi_{\{1,2\}}}}$  then  $0 \in t'$  iff  $0 \in t$ . Thus

$$[t]_{\mathcal{P}_{\chi_{\{1,2\}}}} \cap \llbracket \lambda_t \rrbracket_3(\{2\}, \{1\}) = \{t\}. \quad \blacktriangleleft$$

- 2. Example 5.3.2:** For the verification for signature functors, define a helper map  $v: \Sigma 2 \rightarrow \mathcal{P}_f \mathbb{N}$  by  $v(\sigma(x_1, \dots, x_n)) = \{i \in \mathbb{N} \mid x_i = 1\}$ . The predicate lifting for the (unary) modal operator  $\langle =I \rangle$ , for  $I \subseteq \mathbb{N}$ , is obtained from Lemma A.1 by the predicate  $f_I: \Sigma 2 \rightarrow 2$  corresponding to the set

$$f_I = \{t \in \Sigma 2 \mid v(t) = I\}.$$

This gives rise to the predicate lifting

$$\begin{aligned} \llbracket \langle =I \rangle \rrbracket_X(P) &= \{t \in \Sigma X \mid F\chi_P(t) \in f_I\} && \text{(Lemma A.1)} \\ &= \{t \in \Sigma X \mid v(F\chi_P(t)) = I\}. && \text{(def. } f_I) \end{aligned}$$

Similarly, for the nullary modal operator  $\sigma$  (for the  $n$ -ary operation symbol  $\sigma/n \in \Sigma$ ), take  $\Sigma 1 \rightarrow 2$  given by the set

$$g_\sigma = \{\sigma(0, \dots, 0)\}$$

(noting that  $2^0 = 1$ ). This gives rise to the predicate lifting

$$\begin{aligned} \llbracket \sigma \rrbracket_X &= \{t \in \Sigma X \mid F!(t) \in g_\sigma\} && \text{(Lemma A.1)} \\ &= \{t \in \Sigma X \mid F\chi_P(t) \in \{\sigma(0, \dots, 0)\}\} && \text{(def. } g_\sigma) \\ &= \{\sigma(x_1, \dots, x_n) \mid x_1, \dots, x_n \in X\}. \end{aligned}$$

For the verification of the (simple) domain-specific interpretation (Definition A.14), we put

$$\kappa_s(\delta) := \langle =v(s) \rangle \delta \quad \text{for } s \in \Sigma 2$$

with then induces the claimed  $\lambda_t$  via Proposition A.15:

$$\lambda_{\sigma(x_1, \dots, x_n)}(\delta, \rho) = \langle =\{i \in \mathbb{N} \mid x_i = 2\} \rangle \delta \quad \text{for } \sigma(x_1, \dots, x_n) \in \Sigma 3$$

There is nothing to show for  $\tau_o := \sigma$  since it has the correct semantics by the definition of  $\llbracket \sigma \rrbracket_1$ . Note that  $\langle F!, v \rangle: \Sigma 2 \rightarrow \Sigma 1 \times \mathcal{P}_1 \mathbb{N}$  is injective because for every  $s \in \Sigma 2$  the operation symbol and all its parameters (from 2) are uniquely determined by  $F!(s)$  and  $v(s)$ . For  $\kappa_s := \langle =v(s) \rangle$ ,  $s \in F2$ , we have

$$[s]_{F!} = \{s' \in F2 \mid F!(s) = F!(s')\}.$$

Thus, we compute

$$\begin{aligned} & [s]_{F!} \cap \llbracket \kappa_s \rrbracket_2(\{1\}) \\ &= \{s' \in \Sigma 2 \mid s' \in [s]_{F!} \text{ and } s' \in \llbracket \kappa_s \rrbracket_2(\{1\})\} \\ &= \{s' \in \Sigma 2 \mid F!(s) = F!(s') \text{ and } s' \in \llbracket \langle =v(s) \rangle \rrbracket_2(\{1\})\} \\ &= \{s' \in \Sigma 2 \mid F!(s) = F!(s') \text{ and } v(F\chi_{\{1\}}(s')) = v(s)\} && \text{(def. } \llbracket \langle =v(s) \rangle \rrbracket_2) \\ &= \{s' \in \Sigma 2 \mid F!(s) = F!(s') \text{ and } v(s') = v(s)\} && (\text{id}_2 = \chi_{\{1\}}: 2 \rightarrow 2) \\ &= \{s' \in \Sigma 2 \mid \langle F!, v \rangle(s) = \langle F!, v \rangle(s')\} && \text{(def. } \langle -, - \rangle) \\ &= \{s\} && (\langle F!, v \rangle \text{ injective}) \end{aligned}$$

**3. Example 5.3.3:** For every  $m \in M$ , define the map

$$f_m: M^{(2)} \rightarrow 2 \quad \text{with} \quad \{\mu \in M^{(2)} \mid \mu(1) = m\}.$$

which gives rise to the predicate lifting of the unary modal operator  $\langle =m \rangle$ :

$$\begin{aligned} \llbracket \langle =m \rangle \rrbracket_X(P) &= \{\mu \in M^{(X)} \mid M^{(P)}(\mu) \in f_m\} && \text{(Lemma A.1)} \\ &= \{\mu \in M^{(X)} \mid M^{(P)}(\mu)(1) = m\} && \text{(def. } f_m) \end{aligned}$$

For the verification of the axioms of the domain-specific interpretation (Definition 5.2), we have that  $\tau$  satisfies the axiom:

$$\begin{aligned} \llbracket \tau_o \rrbracket_1 &= \llbracket \langle =o(0) \rangle \top \rrbracket_1 = \{\mu \in M^{(1)} \mid \sum_{x \in \llbracket \top \rrbracket_1} \mu(x) = o(0)\} \\ &= \{\mu \in M^{(1)} \mid \mu(0) = o(0)\} = \{o\} && (\llbracket \top \rrbracket_1 = 1 = \{0\}) \end{aligned}$$

For the other component of the domain-specific interpretation, we proceed by case distinction:

- If  $M$  is non-cancellative, we have  $\lambda_t(\delta, \rho) = \langle =t(2) \rangle \delta \wedge \langle =t(1) \rangle \rho$  for  $t \in M^{(3)}$  and thus we have for every  $t' \in M^{(3)}$ :

$$\begin{aligned} & t' \in ([t]_{F\chi_{\{1,2\}}} \cap \llbracket \lambda_t \rrbracket_3(\{2\}, \{1\})) \\ & \Leftrightarrow t' \in [t]_{F\chi_{\{1,2\}}} \text{ and } t' \in \llbracket \lambda_t \rrbracket_3(\{2\}, \{1\}) \\ & \Leftrightarrow t' \in [t]_{F\chi_{\{1,2\}}} \text{ and } t' \in \llbracket \langle =t(2) \rangle \delta \wedge \langle =t(1) \rangle \rho \rrbracket_3(\{2\}, \{1\}) && \text{(def. } \lambda_t) \\ & \Leftrightarrow t' \in [t]_{F\chi_{\{1,2\}}} \text{ and } t' \in \llbracket \langle =t(2) \rangle \rrbracket_3(\{2\}) \cap \llbracket \langle =t(1) \rangle \rrbracket_3(\{1\}) \\ & \Leftrightarrow t' \in [t]_{F\chi_{\{1,2\}}} \text{ and } t' \in \llbracket \langle =t(2) \rangle \rrbracket_3(\{2\}) \text{ and } t' \in \llbracket \langle =t(1) \rangle \rrbracket_3(\{1\}) \\ & \Leftrightarrow t' \in [t]_{F\chi_{\{1,2\}}} \text{ and } t'(2) = t(2) \text{ and } t'(1) = t(1) && \text{(def. } \llbracket \langle =m \rangle \rrbracket) \\ & \Leftrightarrow t'(0) = t(0) \text{ and } t'(1) + t'(2) = t(1) + t(2) \\ & \quad \text{and } t'(2) = t(2) \text{ and } t'(1) = t(1) \\ & \Leftrightarrow t'(0) = t(0) \text{ and } t'(2) = t(2) \text{ and } t'(1) = t(1) \\ & \Leftrightarrow t' = t \\ & \Leftrightarrow t' \in \{t\} \end{aligned}$$

## 32:38 Explaining Behavioural Inequivalence Generically in Quasilinear Time

- If  $M$  is cancellative, we put  $\kappa_s(\delta) = \langle =s(1) \rangle \delta$  for  $s \in M^{(2)}$ , which then induces  $\lambda_t(\delta, \rho) = \langle =s(2) \rangle \delta$  via Proposition A.15. We verify Definition A.14 for all  $s' \in M^{(2)}$ :

$$\begin{aligned}
& s' \in ([s]_{F!} \cap \llbracket \kappa_s \rrbracket_2(\{1\})) \\
& \Leftrightarrow s' \in [s]_{F!} \text{ and } s' \in \llbracket \kappa_s \rrbracket_2(\{1\}) \\
& \Leftrightarrow F!(s') = F!(s) \text{ and } s' \in \llbracket \langle =s(1) \rangle \rrbracket_2(\{1\}) \quad (\text{def. } \kappa_s) \\
& \Leftrightarrow F!(s') = F!(s) \text{ and } \sum_{x \in \{1\}} s'(x) = s(1) \quad (\text{def. } \langle =s(1) \rangle) \\
& \Leftrightarrow F!(s') = F!(s) \text{ and } s'(1) = s(1) \\
& \Leftrightarrow s'(0) + s'(1) = s(0) + s(1) \text{ and } s'(1) = s(1) \\
& \Leftrightarrow s'(0) = s(0) \text{ and } s'(1) = s(1) \quad (M \text{ cancellative}) \\
& \Leftrightarrow s' = s \\
& \Leftrightarrow s' \in \{s\}
\end{aligned}$$

4. **Example 5.3.4:** For  $FX = (\mathcal{D}X + 1)^A$ , the predicate lifting of  $\langle a \rangle_p$ ,  $a \in A$ ,  $p \in [0, 1]$  is:

$$\llbracket \langle a \rangle_p \rrbracket_X(S) := \{t \in FX \mid p > 0 \text{ then } t(a) \in \mathcal{D}X \text{ and } \sum_{x \in S} t(a)(x) \geq p\}$$

first note that

$$\llbracket \langle a \rangle_1 \top \rrbracket_1 = \{o \in F1 \mid o(a) \in \mathcal{D}1\} \quad \text{and} \quad \llbracket \neg \langle a \rangle_1 \top \rrbracket_1 = \{o \in F1 \mid o(a) \in 1\}.$$

Thus, we have:

$$\begin{aligned}
\llbracket \tau_o \rrbracket_1 &= \llbracket \bigwedge_{\substack{a \in A \\ o(a) \in \mathcal{D}1}} \langle a \rangle_1 \top \wedge \bigwedge_{\substack{a \in A \\ o(a) \in 1}} \neg \langle a \rangle_1 \top \rrbracket_1 \\
&= \bigcap_{\substack{a \in A \\ o(a) \in \mathcal{D}1}} \{o' \in F1 \mid o'(a) \in \mathcal{D}1\} \cap \bigcap_{\substack{a \in A \\ o(a) \in 1}} \{o' \in F1 \mid o'(a) \in 1\} = \{o\}
\end{aligned}$$

For the axiom of  $\lambda_t$ ,  $t \in F3 = (\mathcal{D}3 + 1)^A$ , we verify for all  $t' \in F3$ , where the crucial step is the arithmetic argument for replacing the inequalities by equalities:

$$\begin{aligned}
& t' \in ([t]_{F\chi_{\{1,2\}}} \cap \llbracket \lambda_t \rrbracket_3(\{2\}, \{1\})) \\
& \Leftrightarrow t' \in [t]_{F\chi_{\{1,2\}}} \text{ and } t' \llbracket \lambda_t \rrbracket_3(\{2\}, \{1\}) \\
& \Leftrightarrow t' \in [t]_{F\chi_{\{1,2\}}} \text{ and } t' \in \llbracket (\delta, \rho) \mapsto \bigwedge_{\substack{a \in A \\ t(a) \in \mathcal{D}3}} (\langle a \rangle_{t(a)(2)} \delta \wedge \langle a \rangle_{t(a)(1)} \rho) \rrbracket_3(\{2\}, \{1\}) \\
& \Leftrightarrow t' \in [t]_{F\chi_{\{1,2\}}} \text{ and } t' \in \bigcap_{\substack{a \in A \\ t(a) \in \mathcal{D}3}} \llbracket (\delta, \rho) \mapsto \langle a \rangle_{t(a)(2)} \delta \wedge \langle a \rangle_{t(a)(1)} \rho \rrbracket_3(\{2\}, \{1\}) \\
& \Leftrightarrow t' \in [t]_{F\chi_{\{1,2\}}} \text{ and } t' \in \bigcap_{\substack{a \in A \\ t(a) \in \mathcal{D}3}} \llbracket \langle a \rangle_{t(a)(2)} \rrbracket_3(\{2\}) \cap \llbracket \langle a \rangle_{t(a)(1)} \rrbracket_3(\{1\}) \\
& \Leftrightarrow t' \in [t]_{F\chi_{\{1,2\}}} \text{ and } \forall a \in A, t(a) \in \mathcal{D}3 : t' \in \llbracket \langle a \rangle_{t(a)(2)} \rrbracket_3(\{2\}) \cap \llbracket \langle a \rangle_{t(a)(1)} \rrbracket_3(\{1\}) \\
& \Leftrightarrow t' \in [t]_{F\chi_{\{1,2\}}} \text{ and } \forall a \in A, t(a) \in \mathcal{D}3 : t'(a)(2) \geq t(a)(2) \wedge t'(a)(1) \geq t(a)(1) \\
& \hspace{15em} (\text{Def. } \llbracket \langle a \rangle_p \rrbracket) \\
& \Leftrightarrow \forall a \in A : (t'(a) \in 1 \leftrightarrow t(a) \in 1) \text{ and if } a \in \mathcal{D}3 \text{ then:}
\end{aligned}$$

$$\begin{aligned}
& t'(a)(0) = t(a)(0), \quad t'(a)(1) + t'(a)(2) = t(a)(1) + t(a)(2), \\
& t'(a)(2) \geq t(a)(2), \quad t'(a)(1) \geq t(a)(1) \\
& \Leftrightarrow \forall a \in A: (t'(a) \in 1 \leftrightarrow t(a) \in 1) \text{ and if } a \in \mathcal{D}3 \text{ then:} \\
& \quad t'(a)(0) = t(a)(0), \quad t'(a)(1) = t(a)(2), \quad t'(a)(2) = t(a)(2) \quad (\text{arithmetic}) \\
& \Leftrightarrow \forall a \in A: (t'(a) \in 1 \leftrightarrow t(a) \in 1) \text{ and if } a \in \mathcal{D}3 \text{ then } t'(a) = t(a) \\
& \Leftrightarrow t' \in \{t\}
\end{aligned}$$

### Proof of Proposition 5.4.

► **Lemma A.16.** *Let  $(\tau, \lambda)$  be a domain-specific interpretation for  $F$ . For all  $t \in FC$  and  $S \subseteq B \subseteq C$  we have:*

$$([t]_{F\chi_B} \cap [\lambda_{F\chi_S^B(t)}]_C(S, B \setminus S)) = [t]_{F\chi_S^B} \quad \text{in } 2^{FC}.$$

**Proof.** Put  $d := F\chi_S^B(t)$ ; the naturality square of  $[\lambda_d]$  for  $\chi_S^B: C \rightarrow 3$  is

$$\begin{array}{ccc}
2^3 \times 2^3 & \xrightarrow{[\lambda_d]_3} & 2^{F3} \\
2^{\chi_S^B} \times 2^{\chi_S^B} \downarrow & & \downarrow 2^{F\chi_S^B} \\
2^C \times 2^C & \xrightarrow{[\lambda_d]_C} & 2^{FC}
\end{array}$$

Hence:

$$\begin{aligned}
(F\chi_S^B)^{-1} [[\lambda_d]_3(\{2\}, \{1\})] &= [\lambda_d]_C((\chi_S^B)^{-1}\{2\}, (\chi_S^B)^{-1}\{1\}) \\
&= [\lambda_d]_C(B, B \setminus S). \quad (*)
\end{aligned}$$

Now we verify for every  $t' \in FC$  that

$$\begin{aligned}
& t' \in ([t]_{F\chi_B} \cap [\lambda_{F\chi_S^B(t)}]_C(S, B \setminus S)) \\

& \Leftrightarrow t' \in [t]_{F\chi_S^B}. \quad \blacktriangleleft
\end{aligned}$$

**Proof of Proposition 5.4.** We prove by induction over the index  $i$  of main loop iterations that  $T(\delta_i([x]_{P_i}))$  and  $T(\beta_i([x]_{Q_i}))$  are a certificates for  $[x]_{P_i}$  and  $[x]_{Q_i}$ , respectively. (In the cancellative case,  $Q_i$  and  $\beta_i$  are not defined; so just put  $C/Q_i = \{C\}$ ,  $\beta_i(C) = \top$  for convenience.)

1. For  $i = 0$ , we trivially have

$$[T(\beta_0([x]_{P_0}))] = [T(\top)] = [\top] = C.$$

Furthermore, unravelling Notation 3.9,

$$\delta_0([x]_{P_0}) = \ulcorner F!(c(x)) \urcorner = \ulcorner Fj_1(F!(c(x))) \urcorner(\top, \top).$$

Consequently,

$$T(\delta_0([x]_{P_0})) = \tau_{F!(Fj_1(F!(c(x))))} = \tau_{F!(c(x))}$$

using  $! \cdot j_1 \cdot ! = ! : C \rightarrow 1$ . The naturality of  $\llbracket \tau_o \rrbracket$ ,  $o \in F1$ , implies that  $\llbracket \tau_o \rrbracket_X = \{t \in FX \mid F!(t) = o\}$ . Hence,

$$\llbracket T(\delta_0([x]_{P_0})) \rrbracket = c^{-1}[\llbracket \tau_{F!(c(x))} \rrbracket_C] = \{x' \in C \mid F!(c(x')) = F!(c(x))\} = [x]_{P_0}.$$

2. In the inductive step, there is nothing to show for  $\beta_{i+1}$  because it is only a boolean combination of  $\beta_i$  and  $\delta_i$ . For  $\delta_{i+1}$ , we distinguish two cases: whether the class  $[x]_{P_i}$  is refined or not. If  $[x]_{P_{i+1}} = [x]_{P_i}$ , then

$$\llbracket T(\delta_{i+1}([x]_{P_{i+1}})) \rrbracket = \llbracket T(\delta_i([x]_{P_i})) \rrbracket = [x]_{P_i},$$

and we are done. Now suppose that  $[x]_{P_{i+1}} \neq [x]_{P_i}$  in the  $i$ -th iteration with chosen  $S \subsetneq B \subseteq C$ . By (A'3) resp. 3 we have:

$$\delta_{i+1}([x]_{P_{i+1}}) = \delta_i([x]_{P_i}) \wedge {}^\top t^\top(\delta_i(S), \beta')$$

where  $\beta'$  is  $\beta_i(B)$  or  $\top$ ; in any case  $\llbracket \delta_i(S) \rrbracket = S \subseteq \llbracket \beta' \rrbracket$ . Note that  $t$  here is either  $F\chi_S^B(c(x))$  (Algorithm 3.11) or  $Fj_2(F\chi_S(c(x)))$  (Algorithm A.11). Put  $B' = B$  in the first case and  $B' = C$  else. Using  $\chi_S^C = j_2 \cdot \chi_S$ , we see that

$$t = F\chi_S^{B'}(c(x)) \quad \llbracket \beta' \rrbracket = B', \quad \text{and} \quad \llbracket T(\beta') \rrbracket = B',$$

where the last equation follows from the inductive hypothesis. Thus, we have

$$\delta_{i+1}([x]_{P_{i+1}}) = \delta_i([x]_{P_i}) \wedge {}^\top F\chi_S^{B'}(c(x))^\top(\delta_i(S), \beta'),$$

and therefore

$$T(\delta_{i+1}([x]_{P_{i+1}})) = T(\delta_i([x]_{P_i})) \wedge \lambda_{F\chi_S^{B'}(c(x))}(T(\delta_i(S)), T(\beta') \wedge \neg T(\delta_i(S))).$$

Moreover, we have

$$P_{i+1} = P_i \cap \ker(F\chi_S^{B'} \cdot c),$$

in the first case by item (A3), in the second case by Proposition A.7, recalling that  $\chi_S = \chi_S^C$ .

We are now prepared for our final computation:

$$\begin{aligned} & \llbracket T(\delta_{i+1}([x]_{P_{i+1}})) \rrbracket \\ &= \llbracket T(\delta_i([x]_{P_i})) \wedge \lambda_{F\chi_S^{B'}(c(x))}(T(\delta_i(S)), T(\beta') \wedge \neg T(\delta_i(S))) \rrbracket \\ &= \llbracket T(\delta_i([x]_{P_i})) \rrbracket \cap \llbracket \lambda_{F\chi_S^{B'}(c(x))}(T(\delta_i(S)), T(\beta') \wedge \neg T(\delta_i(S))) \rrbracket \\ &= \llbracket T(\delta_i([x]_{P_i})) \rrbracket \cap c^{-1}[\llbracket \lambda_{F\chi_S^{B'}(c(x))} \rrbracket_C(\llbracket T(\delta_i(S)) \rrbracket, \llbracket T(\beta') \rrbracket \cap C \setminus \llbracket T(\delta_i(S)) \rrbracket)] \\ & \hspace{15em} \text{(Semantics of } \heartsuit) \\ &= [x]_{P_i} \cap c^{-1}[\llbracket \lambda_{F\chi_S^{B'}(c(x))} \rrbracket_C(S, B' \cap C \setminus S)] \hspace{10em} \text{(I.H.)} \\ &= [x]_{P_i} \cap c^{-1}[\llbracket \lambda_{F\chi_S^{B'}(c(x))} \rrbracket_C(S, B' \setminus S)] \hspace{10em} (B' \cap C \setminus S = B' \setminus S) \\ &= [x]_{P_i} \cap [x]_{F\chi_{B'} \cdot c} \cap c^{-1}[\llbracket \lambda_{F\chi_S^{B'}(c(x))} \rrbracket_C(S, B' \setminus S)] \hspace{10em} (P_i \subseteq \ker F\chi_{B'} \cdot c) \end{aligned}$$

$$\begin{aligned}
&= [x]_{P_i} \cap c^{-1}[[c(x)]_{F\chi_{B'}}] \cap c^{-1}[[\lambda_{F\chi_S^{B'}(c(x))}]_C(S, B' \setminus S)] \\
&= [x]_{P_i} \cap c^{-1}[[c(x)]_{F\chi_{B'}} \cap [\lambda_{F\chi_S^{B'}(c(x))}]_C(S, B' \setminus S)] \\
&= [x]_{P_i} \cap c^{-1}[[c(x)]_{F\chi_S^{B'}}] \quad (\text{domain-specific interpret. (Lemma A.16)}) \\
&= [x]_{P_i} \cap [x]_{F\chi_S^{B'} \cdot c} \\
&= [x]_{P_{i+1}} \quad (P_{i+1} = P_i \cap \ker(F\chi_S^{B'} \cdot c))
\end{aligned}$$

This completes the proof.  $\blacktriangleleft$

### Details for Example 5.5.

The Algorithm 3.11 runs in  $\mathcal{O}(m \cdot \log n)$  producing certificates of a total size of  $\mathcal{O}(m \cdot \log n)$ . When translating these certificates for the modalities  $\langle a \rangle_p$  by the translation  $T$ , we obtain certificates for the input coalgebra (Proposition 5.4). However, the formula size has a blow up by the additional factor  $|A|$  because of the big conjunctions in the domain-specific interpretation (Example 5.3.4).

This represents is a better run time than that of the algorithm by Desharnais et al. [17, Fig. 4], which nests multiple loops: four loops over blocks all blocks seen so far and one loop over  $A$ , roughly leading to a total run time in  $\mathcal{O}(|A| \cdot n^4)$ .

### Details for Section 6 (Worst Case Tree Size of Certificates)

#### Details for Remark 6.2.

To verify the minimality of  $\varphi = \diamond^{n+2}\top$ , one considers all possible replacements of subformulae of  $\varphi$  by  $\top$ :

$$\diamond\top \quad \diamond\diamond\top \quad \dots \quad \diamond^n\top \quad \diamond^{n+1}\top$$

All of these hold at both  $x$  and  $y$ , because  $x$  can perform arbitrarily many transitions and  $y$  can perform  $n + 1$  transitions.

We note additionally that even the optimized algorithm for cancellative functors (cf. Algorithm A.11) constructs certificates of exponential worst-case tree size:

► **Example A.17.** Define the  $\mathbb{R}^{(-)}$ -coalgebra  $c$  on  $C = \bigcup_{k \in \mathbb{N}} \{w_k, x_k, y_k, z_k\}$  by

$$\begin{aligned}
c(w_{k+1}) &= \{w_k \mapsto 1, x_k \mapsto 2, y_k \mapsto 1, z_k \mapsto 2\} & c(w_0) &= \{w_0 \mapsto 1\} \\
c(x_{k+1}) &= \{w_k \mapsto 1, x_k \mapsto 2, y_k \mapsto 2, z_k \mapsto 1\} & c(x_0) &= \{x_0 \mapsto 2\} \\
c(y_{k+1}) &= \{w_k \mapsto 2, x_k \mapsto 1, y_k \mapsto 1, z_k \mapsto 2\} & c(y_0) &= \{y_0 \mapsto 3\} \\
c(z_{k+1}) &= \{w_k \mapsto 2, x_k \mapsto 1, y_k \mapsto 2, z_k \mapsto 1\} & c(z_0) &= \{z_0 \mapsto 4\}
\end{aligned}$$

The optimized Algorithm A.11 constructs a certificate of size  $2^k$  in the  $k$ -th layer. In this example, however, linear-sized certificates do exist for all states, e.g.

$$\llbracket \langle =2 \rangle \langle =3 \rangle^k (\langle =1 \rangle \top \vee \langle =4 \rangle \top) \rrbracket = \{x_{k+1}\}.$$

#### Details for Example A.17.

Define the  $\mathbb{R}^{(-)}$ -coalgebra  $c: C \rightarrow \mathbb{R}^{(C)}$  on the carrier

$$C := 4 \times \mathbb{N} \cong \bigcup \{L_k \mid k \in \mathbb{N}\} \quad \text{for } L_k = \{w_k, x_k, y_k, z_k\}.$$

We put

$$\begin{aligned}
 c(w_{k+1}) &= \{w_k \mapsto 1, x_k \mapsto 2, y_k \mapsto 1, z_k \mapsto 2\} & c(w_0) &= \{w_0 \mapsto 1\} \\
 c(x_{k+1}) &= \{w_k \mapsto 1, x_k \mapsto 2, y_k \mapsto 2, z_k \mapsto 1\} & c(x_0) &= \{x_0 \mapsto 2\} \\
 c(y_{k+1}) &= \{w_k \mapsto 2, x_k \mapsto 1, y_k \mapsto 1, z_k \mapsto 2\} & c(y_0) &= \{y_0 \mapsto 3\} \\
 c(z_{k+1}) &= \{w_k \mapsto 2, x_k \mapsto 1, y_k \mapsto 2, z_k \mapsto 1\} & c(z_0) &= \{z_0 \mapsto 4\}
 \end{aligned}$$

For the complexity class of the formulae generated, consider the subcoalgebra on  $L_0 \cup \dots \cup L_n$ .

The initial partition  $P_0 = \{\{w_0\}, \{x_0\}, \{y_0\}, \{z_0\}, L_1 \cup \dots \cup L_n\}$  distinguishes on the total out-degree (being 1, 2, 3, 4, or 6). Consider that after  $i \in \mathbb{N}$  iterations of the main loop of the algorithm, the states  $w_k, x_k, y_k, z_k$  have just been found to be behaviourally different and all states of  $L_{k+1} \cup \dots \cup L_n$  are still identified. Then the algorithm has to use some of the blocks  $\{w_k\}, \{x_k\}, \{y_k\}, \{z_k\}$  as the splitter  $S$  for further refinement. Assume wlog that  $S := \{w_k\}$  is used as the splitter, first. This will have the effect that  $L_{k+1} \cup \dots \cup L_n$  will be refined into the blocks

$$\{w_{k+1}, x_{k+1}\}, \quad \{y_{k+1}, z_{k+1}\}, \quad L_{k+2} \cup \dots \cup L_n.$$

Assume, that the formula for  $w_k$  is  $\delta(\{w_k\})$  at this point (we omit the index, since the singleton block  $\{w_k\}$  can not be refined further). The definition of  $\delta$  in the algorithm annotates the block  $\{w_{k+1}, x_{k+1}\}$  with  $\langle =1 \rangle \delta(\{w_k\})$  and the block  $\{y_{k+1}, z_{k+1}\}$  with  $\langle =2 \rangle \delta(\{w_k\})$ .

Splitting by  $\{x_k\}$  does not lead to further refinement. However, when splitting by  $S := \{y_k\}$  (or equivalently  $\{z_k\}$ ),  $\{w_{k+1}, x_{k+1}\}$  is split into  $\{w_{k+1}\}$  and  $\{x_{k+1}\}$  and likewise  $\{y_{k+1}, z_{k+1}\}$  into  $\{y_{k+1}\}$  and  $\{z_{k+1}\}$ . Let  $\delta(\{y_k\})$  be the certificate constructed for  $\{y_k\}$ . This implies that the formulas for  $\{w_{k+1}\}$  and  $\{y_{k+1}\}$  are respectively extended by the conjunct  $\langle =1 \rangle \delta(\{y_k\})$ ; likewise, the formulas for  $\{x_{k+1}\}$  and  $\{z_{k+1}\}$  obtain a new conjunct  $\langle =2 \rangle \delta(\{y_k\})$ . Hence, for every  $s \in L_{k+1}$  the tree-size of the formula constructed is at least:

$$|\delta(\{s\})| \geq |\delta(\{w_k\})| + |\delta(\{y_k\})|.$$

Thus the tree-size of the certificate constructed for cancellative functors may grow exponentially with the state count.

Despite the exponential tree-size of the formulas constructed, there exist linearly sized certificates for all states in the above coalgebra  $(C, c)$ . First, we have

$$\phi_k := \langle =3 \rangle^k (\langle =1 \rangle \top \vee \langle =4 \rangle \top) \text{ with } \llbracket \phi_k \rrbracket = \{w_k, z_k\}$$

This lets us define certificates for  $x_{k+1}$  and  $y_{k+1}$ :

$$\llbracket \langle =2 \rangle \phi_k \rrbracket = \{x_{k+1}\} \quad \text{and} \quad \llbracket \langle =4 \rangle \phi_k \rrbracket = \{y_{k+1}\}$$

For the remaining two state sequences  $w$  and  $z$  we first note

$$\llbracket \langle =1 \rangle \langle =4 \rangle \phi_k \rrbracket = \{w_{k+2}, y_{k+2}\}$$

and thus have certificates

$$\llbracket \phi_{k+2} \wedge \langle =1 \rangle \langle =4 \rangle \phi_k \rrbracket = \{w_{k+2}\} \quad \text{and} \quad \llbracket \phi_{k+2} \wedge \neg \langle =1 \rangle \langle =4 \rangle \phi_k \rrbracket = \{z_{k+2}\}.$$

Since  $\phi_k$  involves  $k + 2$  modal operators, every state in  $L_k$  has a certificate with at most  $2 \cdot k + 8$  modal operators.
