Abstract

We consider the problem of communicating over a classical-quantum (CQ) multiple access channel with classical states non-causally available at the transmitter, henceforth referred to as a QMSTx. QMSTx is a classical-quantum multiple access analogue of the channel studied [1] by Gelfand and Pinsker in 1980. We undertake a Shannon-theoretic study and focus on the problem of characterizing inner bounds to the capacity region of a QMSTx. We propose a new coding scheme based on *union coset codes* - codes possessing algebraic closure properties and derive a new inner bound that subsumes the largest known inner bound based on IID random coding. We identify examples for which the derived inner bound is strictly larger.

I. INTRODUCTION

Consider the scenario of communicating over a classical-quantum (CQ) multiple access channel with classical states (QMSTx) depicted in Fig. 1. S_1, S_2 model a pair of channel states that are jointly distributed and whose evolution across time is IID. Transmitter (Tx) j is provided the entire realization of the state S_j non-causally and is required to communicate its message M_j to a receiver (Rx) that is uninformed of the states. If the channel is in state s_1, s_2 and Txs $1, 2$ choose input symbols x_1, x_2 respectively, then the Rx is provided the quantum state $\rho_{x_1 x_2 s_1 s_2}$. Our focus is on the problem of characterizing an inner bound to the capacity region of a general QMSTx. In the sequel, we describe our motivation and contributions.

Our motivation in addressing this problem is four fold. Firstly, QMSTx is a network for which the conventional long established technique of proving inner bounds via IID random codes, also referred to herein as unstructured codes, is sub-optimal. In this article, we design a coding scheme based on *union coset codes* (UCC) - codes possessing algebraic closure properties - that strictly outperforms the best known coding scheme based on IID codes. Specifically, we analyze performance of the designed coding scheme to derive an inner bound (Thms. 2, 3) to the capacity region of a QMSTx that, not only subsumes the largest inner bound via unstructured codes, but strictly enlarges the same for identified examples (Ex. 1, Prop. 3). These findings build on our earlier work [2], [3] and maybe viewed as another step [4], [5] in our pursuit of designing coding schemes based on coset codes for network CQ communication.

While the utility of coset codes have been established in several networks [3]–[8], their use for a QMSTx is unique and leads us to our second motivation. Coset codes have facilitated higher rates in communication scenarios wherein a compressive bivariate function of the messages or codewords have to be decoded. For instance, on both the $3-$user interference [4], [9] and broadcast channels [8], coset codes enable efficient decoding of the bivariate interference. QMSTx is a CQ MAC wherein both messages need to be decoded and decoding a compressive bivariate function of either the codewords or the messages can lead to obfuscation of the messages. Indeed, coset codes have no role in communication over a CQ-MAC without Tx states. It is therefore natural to question the utility of structured codes in communicating over a QMSTx. A second motivation of our work is to demonstrate how algebraic closure properties can be exploited to *efficiently sieve relevant information* and thereby facilitate enhanced communication over a QMSTx. We illustrate this phenomena in the context of an example (Ex. 1) and a self contained discussion (Secs. III-B, III-C). In particular, Sec. III enables us convey the main ideas of this article.

Thirdly, this study enables us enrich the family of coset codes for CQ communication beyond nested coset codes (NCC) [4], [5] and partitioned coset codes (PCC) [10] studied recently. As elaborated in [3] and recent works [11], [12], coding schemes based on NCC or PCC designed for a classical analogue of a QMSTx, i.e., a classical MAC with states, can be strictly inferior to a coding scheme based on UCC. We have taken this cue and designed UCC based coding schemes and our results in Sec. VI also prove that UCCs achieve capacity of a single sender CQ channel. Lastly, our findings maybe viewed as developing new strategies to handle various network scenarios arising in an eventual quantum communication network.

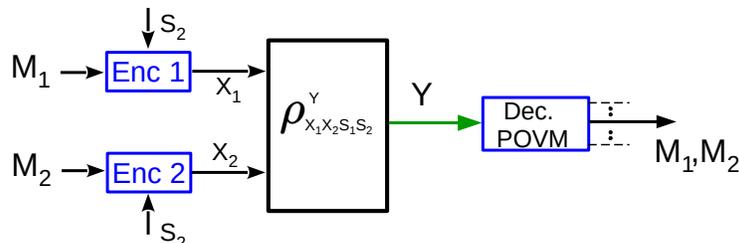

Fig. 1.

Our presentation is organized in a modular fashion. In Sec. III, we illustrate the main ideas of our work through a discussion in the context of a carefully chosen example (Ex. 1). A general coding scheme for a QMSTx consists of two layers - unstructured codes and UCC. In order to illustrate the new elements in a simplified setting, we present a simplified coding scheme involving only the UCC layer in Sec. IV, wherein we provide a detailed description and proof steps. In Sec. V, we present our inner bound that comprises of both unstructured and UCC layers. In Sec. VI, we prove that a coding scheme based on UCCs can achieve the best known single-letter inner bound to the capacity region of a single sender version of a QMSTx, i.e., single Tx, single Rx classical-quantum channel with random classical channel states available only at the Tx, referred to therein as a QSTx. In this article, we focus on conveying the ideas and techniques developed.

The study of channels with Tx state information traces its roots back to Shannon [13] and has had considerable influence on other problems. Indeed, Gelfand and Pinkser's coding scheme [1] for the classical single Tx channel with states, henceforth referred to as the Gelfand-Pinsker channel, forms the core of Marton's coding [14] for the broadcast channel. Recently, Boche, Cai and Nötzel [15] studied the CQ analogue of the Gelfand-Pinsker channel and proved achievability of a corresponding inner bound. Their work exploits the method of types and the findings by Nötzel [16] in proving achievability of the inner bound. Moreover, their work [15] highlights the difference between the causal and the non-causal availability of state information at the Tx in regards to the single-letterization of the capacity. Our focus is on designing a new coding scheme and characterizing its performance via a single-letter expression. We have not commented on optimality of the bounds derived herein.

II. PRELIMINARIES AND PROBLEM STATEMENT

For $n \in \mathbb{N}$, $[n] \triangleq \{1, \cdots, n\}$. $\mathcal{F}_q$ denotes the finite field of size q and $\oplus_q$ denotes addition within $\mathcal{F}_q$. For a Hilbert space $\mathcal{H}$, $\mathcal{L}(\mathcal{H}), \mathcal{P}(\mathcal{H})$ and $\mathcal{D}(\mathcal{H})$ denote the collection of linear, positive and density operators acting on $\mathcal{H}$ respectively. We let an underline denote an appropriate aggregation of pairs of objects. For example, $\underline{\mathcal{U}} \triangleq \mathcal{U}_1 \times \mathcal{U}_2$ denotes the Cartesian product for sets, $\underline{x} \triangleq (x_1, x_2) \in \underline{\mathcal{X}}$ and $\underline{x}^n \triangleq (x_1^n, x_2^n)$. The specific aggregation will be clear from context. We abbreviate probability mass function as PMF.

Consider a (generic) *QMSTx* specified through (i) two finite input sets $\mathcal{X}_1, \mathcal{X}_2$, (ii) two finite sets $\mathcal{S}_1, \mathcal{S}_2$ of states, (iii) a PMF $\mathsf{p}_{\underline{S}}(\cdot)$ on $\underline{\mathcal{S}}$, (iii) a collection $(\rho_{\underline{xs}} \triangleq \rho_{x_1 x_2 s_1 s_2} \in \mathcal{D}(\mathcal{H}_Y) : (\underline{x}, \underline{s}) \in \underline{\mathcal{X}} \times \underline{\mathcal{S}})$ of density operators and (iv) cost functions $\kappa_j : \mathcal{X}_j \times \mathcal{S}_j \to [0, \infty)$ for $j \in [2]$. The cost function is additive, i.e., having observed the state sequence s_j^n the cost incurred by sender j in preparing the state $\otimes_{t=1}^n \rho_{\underline{x}_t \underline{s}_t}$ is $\overline{\kappa}_j(x_j^n, s_j^n) \triangleq \frac{1}{n} \sum_{t=1}^n \kappa_j(x_{jt}, s_{jt})$. Reliable communication on a QMSTx entails identifying a code.

Defn. 1. *An $(n, \underline{\mathcal{M}}, \underline{e}, \lambda)$ QMSTx code consists of two message index sets $\mathcal{M}_j : j \in [2]$, two encoder maps $e_j : [\mathcal{M}_j] \times \mathcal{S}_j^n \to \mathcal{X}_j^n$ and a decoder POVM $\lambda \triangleq \{\lambda_{\underline{m}} = \lambda_{m_1, m_2} \in \mathcal{P}(\mathcal{H}^{\otimes n}) : \underline{m} \in \underline{\mathcal{M}}\}$. The average error probability of the code is*

$$\overline{\xi}(\underline{e}, \lambda) \triangleq 1 - \frac{1}{|\underline{\mathcal{M}}|} \sum_{\underline{m} \in \underline{\mathcal{M}}} \sum_{\underline{s}^n \in \underline{\mathcal{S}}^n} \mathsf{p}_{\underline{S}}^n(\underline{s}^n) \operatorname{tr}(\lambda_{\underline{m}} \rho_{\underline{m}, \underline{s}^n}).$$

where $\rho_{\underline{m}, \underline{s}^n} \triangleq \otimes_{t=1}^n \rho_{\underline{x}_t \underline{s}_t}$ and $(x_{j1}, \cdots, x_{jn}) = e_j(m_j, s_j^n)$. Average cost incurred by sender j in transmitting m_j is $\tau_j(e_j|m_j) \triangleq \sum_{s_j^n} \mathsf{p}_{S_j}^n(s_j^n) \kappa_j(e_j(m_j, s_j^n), s_j^n)$ and the average cost incurred by sender j is $\tau_j(e_j) \triangleq \frac{1}{|\mathcal{M}_j|} \sum_{m_j} \tau_j(e_j|m_j)$.

The object of interest is the capacity region of a QMSTx defined below. In this article, we focus on characterizing inner bounds to the capacity region of a QMSTx.

Defn. 2. *A rate-cost quadruple $(\underline{R}, \underline{\tau}) \in [0, \infty)^4$ is achievable if there exists a sequence of QMSTx codes $(n, \underline{\mathcal{M}}^{(n)}, \underline{e}^{(n)}, \lambda^{(n)})$ for which $\lim_{n \to \infty} \overline{\xi}(\underline{e}^{(n)}, \lambda^{(n)}) = 0$,*

$$\lim_{n \to \infty} n^{-1} \log \mathcal{M}_j^{(n)} = R_j, \text{ and } \lim_{n \to \infty} \tau_j(e_j^{(n)}) \leq \tau_j.$$

The capacity region $\mathscr{C}$ of the QMSTx is the set of all achievable rate-cost vectors and $\mathscr{C}(\underline{\tau}) \triangleq \{\underline{R} : (\underline{R}, \underline{\tau}) \in \mathscr{C}\}$.

III. ROLE OF ALGEBRAIC STRUCTURE/CLOSURE

In this section, we explain *how* and *why* structured codes can facilitate enhanced communication over a QMSTx. We begin by reviewing the best known unstructured coding scheme.

A. Joint Decoding of Unstructured Codes

A QMSTx is a 'MAC extension' of a single sender CQ channel with random states [15]. A coding scheme for the QMSTx can therefore be obtained by combining the Gelfand-Pinsker encoding scheme [1] with a simultaneous decoder of a MAC [17, Thm. 2]. Specifically, each sender j builds a U_j-code (Tab. II) on an auxillary set $\mathcal{U}_j$. The U_j-code comprises of $2^{n(R_j + B_j)}$ codewords partitioned into 2^{nR_j} bins. The message $m_j \in [2^{nR_j}]$ indexes a bin and the encoder looks for a codeword within this bin that is jointly typical with the state sequence s_j^n. The chosen codeword, denoted as $u_j^n(m_j, s_j^n)$, and the state sequence s_j^n are mapped to an input sequence in $\mathcal{X}_j^n$.

$$2^{R_j} \text{ bins}$$

w	t	$\gamma(w,t)$
0	0	$\lvert 0 \rangle\langle 0 \rvert$
0	1	$\lvert v_\theta^\perp \rangle\langle v_\theta^\perp \rvert$
1	0	$\lvert 1 \rangle\langle 1 \rvert$
1	1	$\lvert v_\theta \rangle\langle v_\theta \rvert$

TABLE I
$\rho_{x_1 x_2 s_1 s_2} = \gamma(x_1 \oplus x_2, s_1 \oplus s_2)$

TABLE II
ENCODING RULE FOR SENDER j.

The decoder POVM performs simultaneous decoding on the U_1, U_2-codebooks. Specifically, one can adopt the decoding POVM proposed in proof of [17, Thm. 2]. Leveraging the 'projector trick' therein and the 'overcounting trick' [18] in the context of Marton decoding, we can analyze the error probability and derive an inner bound. The latter is the largest known inner bound achievable via any unstructured coding scheme and we provide a characterization of the same below.

Theorem 1. *A rate-cost quadruple $(\underline{R}, \underline{\tau})$ is achievable if there exists finite sets $\mathcal{U}_1, \mathcal{U}_2$, conditional distributions $p_{X_j, U_j | S_j}$ on $\mathcal{X}_j \times \mathcal{U}_j$ for $j \in [2]$ such that $p_{\underline{SUX}}(\underline{s}, \underline{u}, \underline{x}) = p_{\underline{S}}(\underline{s}) \prod_{j=1}^{2} p_{X_j U_j | S_j}(x_j, u_j | s_j)$ with respect to which*

$$R_j < I(U_j; Y, U_{\bar{j}})_\sigma - I(U_j; S_j)_\sigma, \mathbb{E}\{\kappa_j(X_j, S_j)\} \leq \tau_j,$$
$$R_1 + R_2 < I(\underline{U}; Y)_\sigma + I(U_1, S_1; U_2, S_2)_\sigma,$$

for $j \in [2]$, where all informations are computed wrt the state

$$\sigma^{Y \underline{X} \underline{S} \underline{U}} \triangleq \sum_{\underline{s}, \underline{x}, \underline{u}} p_{\underline{SUX}}(\underline{s}, \underline{u}, \underline{x}) \rho_{\underline{x}\underline{s}} \otimes \lvert \underline{x}\ \underline{u}\ \underline{s} \rangle\langle \underline{x}\ \underline{u}\ \underline{s} \rvert . \tag{1}$$

B. Binary Double Dirty MAC

Our discussion for the following example portrays the deficiency of unstructured codes and the role of structure.

Ex. 1. *Let $\mathcal{X}_1 = \mathcal{X}_2 = \mathcal{S}_1 = \mathcal{S}_2 = \{0,1\}$, $p_{\underline{S}}(\underline{s}) = \frac{1}{4}$ for every $\underline{s} \in \underline{\mathcal{S}}$, $\lvert v_\theta \rangle = [\cos\theta\ \sin\theta]^T$ and $\lvert v_\theta^\perp \rangle = [\sin\theta\ -\cos\theta]^T$. For $(\underline{x}, \underline{s}) \in \{0,1\}^4$, let $\rho_{x_1 x_2 s_1 s_2} = \gamma(x_1 \oplus x_2, s_1 \oplus s_2)$, where $\gamma(\cdot, \cdot)$ is provided in Table I, $\oplus$ denotes addition in the binary field $\mathbb{F}_2$ and the cost function $\kappa_j(x_j, s_j) = \mathbb{1}_{\{x_j = 1\}}$ is the Hamming weight function. For a $\tau \in (0, \frac{1}{2})$, what is $\mathscr{C}(\tau, \tau)$?*

Our discussion below for the $\theta = 0$ case leads us pedagogically to the non-commuting case $\theta \in (0, \frac{\pi}{2})$ which follows. The classical channel corresponding to $\theta = 0$ was first studied by Philosof and Zamir [19] and the following discussion describes their findings.

Case $\theta = 0$: Since the collection $\left(\rho_{\underline{x}\underline{s}} : (\underline{x}, \underline{s}) \in \{0,1\}^4 \right)$ is commuting, we identify this as a classical MAC with distributed states whose output $Y \in \{0,1\}$, inputs $X_1, X_2 \in \{0,1\}$ and states $S_1, S_2 \in \{0,1\}$ are related as $Y = X_1 \oplus S_1 \oplus X_2 \oplus S_2$. S_1, S_2 are uniformly distributed and the average Hamming weight of the inputs is constrained to $\tau < \frac{1}{2}$. The latter constraint precludes the senders from negating the effect of the state. What rate pairs are then achievable?

We first study the best unstructured coding scheme and characterize the corresponding largest known inner bound. Towards that end, observe that the effective classical channel of Ex. 1 is a 'MAC extension' of a single sender channel with random parameters whose output $Y \in \{0,1\}$, Hamming cost-constrained input $X \in \{0,1\}$ and uniformly distributed state $S \in \{0,1\}$ are related as $Y = X \oplus S$. Philosof and Zamir [19] proved that the best unstructured coding strategy for Ex. 1 is obtained by replicating, at both the senders, the capacity achieving strategy for the single sender channel. Specifically, they prove the optimal choice of parameters in Thm. 1 for Ex. 1 to be binary auxiliary sets $\mathcal{U}_1 = \mathcal{U}_2 = \{0,1\}$, $p_{U_j | S_j}(1|0) = p_{U_j | S_j}(0|1) = \tau = 1 - p_{U_j | S_j}(0|0) = 1 - p_{U_j | S_j}(1|1)$ and $X_j = U_j \oplus S_j$ for $j \in [2]$.

We now detail the coding scheme corresponding to the above choice to shed light on its deficiency. To communicate at rate $R_j < h_b(\tau)$, sender j randomly partitions the entire set of 2^n sequences into 2^{nR_j} bins. The message m_j indexes the bin within which the sender looks for a codeword that is within an average Hamming distance of τ from the observed state sequence. Since each bin contains $2^{n(1-R_j)} > 2^{n(1-h_b(\tau))}$ sequences chosen randomly, the sender finds such a codeword whp. Let U_j^n denote the chosen codeword and S_j^n the observed state sequence. Sender j inputs $X_j^n = U_j^n \oplus S_j^n$ on the channel. The choice of the U_j-codeword guarantees that the Hamming weight constraint is met.

Observe that the channel relationship $Y = X_1 \oplus S_1 \oplus X_2 \oplus S_2$ implies that the received vector is $Y^n = U_1^n \oplus U_2^n$. Recall that each message m_j of sender j is assigned a bin of U_j-codewords. The space of received sequences occupied by a *single message pair* (m_1, m_2) is therefore got by adding all possible codeword pairs in the two bins indexed by m_1, m_2. Since the codewords in each bin is picked uniformly and independently without any joint structure, every pair yields whp a distinct sum, resulting in the range of this addition to be of size $2^{n(2-R_1-R_2)} > 2^{2n(1-h_b(\tau))}$. Since the 'fan-out' of every message pair is of size atleast $2^{2n(1-h_b(\tau))}$, we cannot hope to pack more than $\frac{2^n}{2^{2n(1-h_b(\tau))}}$ fan-outs in the binary output space resulting in the following fact.

Fact. 1. *Consider Ex. 1 with average Hamming cost constraint $\tau < \frac{1}{2}$. Any rate pair (R_1, R_2) achievable by unstructured coding schemes satisfies $R_1 + R_2 < uce\{\max\{0, 2h_b(\tau) - 1\}\}$ where $uce\{f(\tau)\}$ denotes the upper convex envelope of the function $f(\tau)$. See [19] for a proof.*

We now present a linear coding scheme that can achieve any rate pair (R_1, R_2) satisfying $R_1 + R_2 < h_b(\tau)$. For simplicity, we describe achievability of the rate pair $(h_b(\tau), 0)$. Our coding scheme is identical to the unstructured coding scheme with two key differences. The first key difference is that the bins of each sender's codebook are chosen to be *cosets of a common linear code*. Let λ_2 denote a linear code of rate $1 - h_b(\tau)$ whose cosets can quantize a uniform source to with an average Hamming distortion of τ. In other words, a uniformly and randomly chosen coset of λ_2 contains a codeword within an average Hamming distance of τ of the observed state sequence whp. See [20] or [3] for proof of existence. Since sender 2 has no message to transmit, it is provided with just λ_2 that serves as its only bin. Sender 1 is provided with all of the $2^{nh_b(\tau)}$ cosets of λ_2, each of which serves as its bins. The encoding is identical to that for unstructured coding.

The codebook of sender 2 when added to any bin of user 1's code results in a coset of λ_2, and therefore contains at most $2^{n(1-h_b(\tau))}$ codewords. Moreover, since U_2^n lies in λ_2, user 1's codeword U_1^n and the received vector $Y^n = U_1^n \oplus_2 U_2^n$ lie in the same coset. The receiver can identify the coset from which sender 1 chose his U_1-codeword and hence gather sender 1's message. Since the channel is noiseless, sender 1 may employ all cosets of λ_2 and therefore communicate at rate $h_b(\tau)$ which is larger than $2h_b(\tau) - 1$ for all $\tau \in (0, \frac{1}{2})$.

Case $\theta \in (0, \frac{\pi}{2})$: The arguments in [19] can be used to prove that the optimal choice of parameters in Thm. 1 for this case too is $\mathcal{U}_1 = \mathcal{U}_2 = \{0, 1\}$, $p_{U_j|S_j}(1|0) = p_{U_j|S_j}(0|1) = \tau = 1 - p_{U_j|S_j}(0|0) = 1 - p_{U_j|S_j}(1|1)$ and $X_j = U_j \oplus S_j$ where $\oplus$ denotes addition mod-2. This implies the quantum state corresponding to which we compute our information quantities is

$$\sigma^{YS_1S_2X_1X_2U_1U_2} = \sum_{s_1,s_2} \frac{\tau(1-\tau)}{4} \left[\mathbb{1}_{\{s_1 \oplus s_2 = 0\}} |1\rangle\langle 1| + \mathbb{1}_{\{s_1 \oplus s_2 = 1\}} |v_\theta\rangle\langle v_\theta| \right] \otimes |s_1 \ s_2\rangle\langle s_1 \ s_2| \otimes \left[\begin{array}{l} |0 \ 1 \ s_1 \ 1 \oplus s_2\rangle\langle 0 \ 1 \ s_1 \ 1 \oplus s_2| + \\ |1 \ 0 \ 1 \oplus s_1 \ s_2\rangle\langle 1 \ 0 \ 1 \oplus s_1 \ s_2| \end{array} \right]$$

$$+ \sum_{s_1,s_2} \left[\mathbb{1}_{\{s_1 \oplus s_2 = 0\}} |0\rangle\langle 0| + \mathbb{1}_{\{s_1 \oplus s_2 = 1\}} |v_\theta^\perp\rangle\langle v_\theta^\perp| \right] \otimes |s_1 \ s_2\rangle\langle s_1 \ s_2| \otimes \left[\begin{array}{l} \frac{(1-\tau)^2}{4} |0 \ 0 \ s_1 \ s_2\rangle\langle 0 \ 0 \ s_1 \ s_2| + \\ \frac{\tau^2}{4} |1 \ 1 \ 1 \oplus s_1 \ 1 \oplus s_2\rangle\langle 1 \ 1 \ 1 \oplus s_1 \ 1 \oplus s_2| \end{array} \right].$$

The bound on the sum rate achievable using IID random codes as stated in Thm. 1 is $I(U_1U_2; Y)_\sigma - I(U_1; S_1) - I(U_2; S_2)_\sigma$. In Appendix A, we have provided characterization of the component quantum states with respect to which the above information quantities have to be computed. Referring to the same, it can be verified that $I(U_1U_2; Y)_\sigma - I(U_1; S_1) - I(U_2; S_2)_\sigma = \alpha - 2 + 2h_b(\tau)$ where

$$\alpha = \tilde{h}_b((1-2\tau)^2 \sin\theta) - \tilde{h}_b(\sqrt{1 - 4\epsilon(1-\epsilon)\sin^2\theta}), \quad \tilde{h}_b(x) \triangleq h_b\left(\frac{1}{2} + \frac{x}{2}\right) \quad \text{and} \quad \epsilon = 2\tau(1-\tau). \tag{2}$$

It maybe verified that $\alpha = 1$ if $\theta = 0$ indicating the maximum sum rate achievable is a continuous function of θ as one expects. In Prop. 3, we verify that the linear coding scheme achieves any rate pair satisfying $R_1 + R_2 < uce\{\max\{0, \alpha - 1 + h_b(\tau)\}\}$ which strictly subsumes that achievable above.

Two important observations are in order. Firstly, since exponentially many pairs of codewords from λ_2 and the coset chosen by sender 1 have the same sum, the receiver cannot disambiguate the pair of codewords chosen by the two senders. It can only disambiguate the sum $U_1^n \oplus U_2^n$. The second key difference in this coding scheme is that the receiver must not attempt to decode the pair, but instead decipher the message by decoding the sum of the two codewords.

C. Sieving Relevant Information via Algebraic Closure

The key difference between the structured and unstructured coding scheme is the decoding rule. While the former pins down the pair, the latter only decodes the sum, leaving uncertainity in the pair. Note that, the codeword $u_j^n(m_j, s_j^n)$ chosen by sender j contains, in addition to the message, information about s_j^n. By requiring the receiver to pin down the pair $(u_j^n(m_j, s_j^n) : j \in [2])$ of chosen codewods, the unstructured coding scheme is forcing the receiver to gather information of the state seqeuences that is not of value to it. Is there a function of $(u_j^n(m_j, s_j^n) : j \in [2])$ that, while containing information of the pair m_1, m_2 of messages can also suppress the amount of information of the pair s_1^n, s_2^n and can the coding scheme enable the Rx decode this function efficiently? The structured coding scheme is enabling the Rx do this via the mod-2 function.

IV. INNER BOUND BASED ON UNION COSET CODES

Theorem 2. *A rate-cost quadruple $(\underline{R}, \underline{\tau})$ is achievable if there exists a finite field $\mathcal{V}_1 = \mathcal{V}_2 = \mathcal{W} = \mathcal{F}_q$ and conditional PMFs $p_{X_j V_j | S_j}$ on $\mathcal{X}_j \times \mathcal{V}_j$ for $j \in [2]$ with respect to which*

$$R_1 + R_2 < \min\{H(V_1|S_1)_\sigma : j \in [2]\} - H(V_1 \oplus_q V_2 | Y)_\sigma \tag{3}$$

where all mutual informations are computed wrt the state

$$\sigma^{Y\underline{X}V S} \triangleq \sum_{\underline{s},\underline{v},w,\underline{x}} p_{\underline{S}VW\underline{X}}(\underline{s},\underline{v},w,\underline{x})\rho_{\underline{x}\underline{s}} \otimes |\underline{x}\ \underline{v}\ w\ \underline{s}\rangle\langle\underline{x}\ \underline{v}\ w\ \underline{s}| \ with$$

$$p_{\underline{S}VW\underline{X}}(\underline{s},\underline{v},w,\underline{x}) = p_{\underline{S}}(\underline{s})\prod_{j=1}^2 p_{X_j V_j | S_j}(x_j,v_j|s_j)\mathbb{1}_{\left\{\substack{w= \\ v_1 \oplus_q v_2}\right\}}.$$

for all $(\underline{s},\underline{v},w,\underline{x}) \in \underline{\mathcal{S}} \times \underline{\mathcal{V}} \times \mathcal{W} \times \underline{\mathcal{X}}.$

Proof. We begin by outlining our techniques and identifying the new elements. The main novelty is in the code structure we design and the decoding POVM we propose. In Sec. IV-A, we characterize a UCC and describe our codes. The Gelfand-Pinsker encoding (Sec. IV-B) is employed by both senders. We decode only the sum codeword and hence employ a single user decoding POVM (Sec. IV-C). Since we decode into a UCC obtained by adding two statistically correlated UCCs, our analysis is not a standard one and detailed in Sec. IV-D.

A. Code Structure

The gain in rates for Ex. 1 crucially relied on the bins of both codes being coset shifts of a common linear code, thereby ensuring that the size of the sum of any pair of bins was contained. We observe that the shifts can be arbitrary and there are no structural requirement on the union of these cosets. We are thus led to a UCC.

Defn. 3. *A UCC built over $\mathcal{F}_q$ is specified through a generator matrix $g \in \mathcal{F}_q^{k \times n}$ and a map $\iota : \mathcal{F}_q^l \to \mathcal{F}_q^n$ of coset shifts. The collection $c(m) \triangleq \{v^n(a,m) = ag \oplus_q \iota(m)\}$ forms the bin corresponding to message $m \in \mathcal{F}_q^l$ and the union $\cup_u c(m)$ of bins forms the code. We refer to this as an (n,k,l,g,ι) UCC or an (n,k,l,g,c) UCC.*

We employ UCCs as the codebook for both senders. The symmetry in Ex. 1 permitted us to design codes of the same rate for both senders. In general, to enable codes of different rates, we propose a 'nesting' of the two UCCs. Without loss of generality, assume the size of sender 1's bins is the smaller of the two. We equip user j with UCC $(n, k_j, l_j, g_j, \iota_j)$ and enforce $g_2 = \begin{bmatrix} g_1^T & g_{2/1}^T \end{bmatrix}^T$. This ensures that the bins of user 1's code are sub-cosets of the bins of user 2's code, thus guaranteeing the desirable property mentioned prior to Defn. 3. Let $\lambda_j \triangleq (v_j^n(a_j, m_j) \triangleq a_j g_j \oplus_q \iota_j(m_j) : (a_j, m_j) \in \mathcal{V}^{k_j} \times \mathcal{V}^{l_j})$ denote the codebook of sender j

B. Encoding

Our encoding is identical to that described for unstructured codes in Sec. III-A. On observing message $m_j \in [q^{l_j}]$ and state sequence s_j^n, sender j looks for a codeword in $c_j(m_j)$ that is jointly typical with s_j^n. It it finds atleast one, one among these is chosen and denoted $v_j^n(m_j, s_j^n)$. If it finds none, $v_j^n(m_j, s_j^n)$ is set to a default codeword in $c_j(m_j)$. The pair $(s_j^n, v_j^n(m_j, s_j^n))$ is mapped to an input sequence via a 'fusion map' $f_j : \mathcal{S}_j^n \times \mathcal{V}_j^n \to \mathcal{X}_j^n$. For the sake of the ensuing analysis, we formalize this encoding with some notation.

Let $\alpha_j(m_j, s_j^n) \triangleq \sum_{a_j} \mathbb{1}_{\{(v_j^n(a_j, m_j), s_j^n) \in T_\eta(p_{S_j V_j})\}}$ be the number of available jointly typical codewords and let

$$\mathcal{L}_j(m_j, s_j^n) \triangleq \begin{cases} \{a_j : (v_j^n(a_j, m_j), s_j^n) \in T_\eta(p_{V_j S_j})\} & \text{if } \alpha_j(m_j, s_j^n) \geq 1 \\ \{0^{k_j}\} & \text{otherwise} \end{cases}$$

For every pair (m_j, s_j^n), $a_j(m_j, s_j^n)$ is an element chosen from $\mathcal{L}_j(m_j, s_j^n)$. We define $v_j^n(m_j, s_j^n) \triangleq v_j^n(a_j(m_j, s_j^n), s_j^n)$. A predefined 'fusion map' $f_j : \mathcal{S}_j^n \times \mathcal{V}_j^n \to \mathcal{X}_j^n$ is used to map the pair $s_j^n, v_j^n(m_j, s_j^n)$ to an input sequence in $\mathcal{X}_j^n$ henceforth denoted $x_j^n(m_j, s_j^n)$.

C. Decoding POVM

Consider the UCC $(n, k_2, l_1+l_2, g_2, \iota_\oplus)$ where $\iota_\oplus(\underline{m}) = \iota_1(m_1) \oplus_q \iota(m_2)$ and let $w^n(a, \underline{m}) \triangleq a g_2 \oplus_q \iota_1(m_1) \oplus_q \iota_2(m_2)$ denote its codewords. Let $\pi_{a,\underline{m}}$ be the conditional typical projector of $\otimes_{t=1}^n \rho_{w_t(a,\underline{m})}$ wrt the state $\rho_w = \sum_{\underline{x},\underline{s}} p_{XS|W}(\underline{x}, \underline{s}|w) \rho_{\underline{x}\underline{s}}$: $w \in \mathcal{W}$ where p_{SXW} is as defined in the Thm. statement. We define $\gamma_{a,\underline{m}} \triangleq \pi^Y \pi_{a,\underline{m}} \pi^Y$ where π^Y is the unconditional typical projector of the state $\sum_{\underline{x},\underline{s}} p_{\underline{XS}}(\underline{x}, \underline{s}) \rho_{\underline{xs}}$. The decoding POVM is

$$\lambda_{\underline{m}} \triangleq \left(\sum_{\hat{a}, \hat{m}_1, \hat{m}_2} \gamma_{\hat{a}, \hat{m}_1, \hat{m}_2} \right)^{-\frac{1}{2}} \sum_a \gamma_{a, \underline{m}} \left(\sum_{\hat{a}, \hat{m}_1, \hat{m}_2} \gamma_{\hat{a}, \hat{m}_1, \hat{m}_2} \right)^{-\frac{1}{2}} \tag{4}$$

and $\lambda_{-1} \triangleq I^{\otimes n} - \sum_{\underline{m}} \lambda_{\underline{m}}$.

D. Probability of Error Analysis

We begin our analysis by stating the distribution of the random code. Specifying $g_1, g_{2/1}, \iota_j(m_j), a_j(m_j, s_j^n), x_j^n(m_j, s_j^n)$: $(m_j, s_j^n) \in [q^{l_j}] \times \mathcal{S}_j^n$ completely specifies the code. A distribution for the random code is therefore specified through a distribution of these objects. We let upper case letters denote the corresponding random objects. $(G_2, G_{2/1}, \iota_j(m_j) : m_j \in [q^{l_j}] : j \in [2]$ are mutually independent and uniformly distributed on their respective range spaces. $A_j(m_j, s_j^n)$ is conditionally independent of the earlier mentioned objects given $\alpha_j(m_j, S_j^n)$ and uniformly distributed in $\mathcal{L}(m_j, s_j^n)$. Finally, given all of the earlier mentioned objects, $X_j^n(m_j, s_j^n) \sim p_{X|VS}^n(\cdot|V_j(m_j, S_j^n), S_j^n)$.

The average probability of error is

$$\xi(\underline{e}, \lambda) = \sum_{\underline{m}} \frac{\zeta(\underline{m})}{|\mathcal{M}|} \text{ where } \zeta(\underline{m}) \triangleq \sum_{\underline{s}^n} p_{\underline{S}}^n(\underline{s}^n) \zeta(\underline{m}|\underline{s}^n) \tag{5}$$

$$\zeta(\underline{m}|s^n) \triangleq \text{tr}\{(I - \lambda_{\underline{m}}) \rho_{\underline{m},s^n}\}, \rho_{\underline{m},s^n} \triangleq \bigotimes_{t=1}^n \rho_{x_1(m_1,s_1^n)_t x_2(m_2,s_2^n)_t \underline{s}_t}$$

where $I = I^{\otimes n}$, $\mathcal{M}_j = [q^{l_j}]$ and hence $|\mathcal{M}| = q^{l_1+l_2}$. Henceforth, we focus on a generic term $\zeta(\underline{m})$. Let $a_\oplus \triangleq a_1(m_1, s_1^n) \, 0^{k_2-k_1} \oplus a_2(m_2, s_2^n)$ and $\mathcal{E}_j \triangleq \{\alpha_j(m_j, s_j^n) \geq 1\}$, $\mathcal{E} \triangleq \mathcal{E}_1 \cap \mathcal{E}_2$. With these, we have,

$$\zeta(\underline{m}|\underline{s}^n) \leq \mathtt{t}_0 + \mathtt{t}_1 + \mathtt{t}_2 \text{ where } \mathtt{t}_0 \triangleq \mathbb{1}_{\mathcal{E}_1^c} + \mathbb{1}_{\mathcal{E}_2^c} \tag{6}$$

$$\mathtt{t}_1 = \text{tr}\{(I - \gamma_{a_\oplus,\underline{m}}) \rho_{\underline{m},s^n}\} \mathbb{1}_\mathcal{E}, \quad \mathtt{t}_2 \triangleq \sum_{\substack{\hat{a}_\oplus \neq a_\oplus \\ \hat{\underline{m}} \neq \underline{m}}} \text{tr}(\gamma_{\hat{a}_\oplus, \hat{\underline{m}}} \rho_{\underline{m},s^n}) \mathbb{1}_\mathcal{E}$$

where, we recall $\gamma_{a,\underline{m}} = \pi^Y \pi_{a,\underline{m}} \pi^Y$ and $\pi_{a,\underline{m}}$ is the conditional typical projector of $\otimes_{t=1}^n \rho_{w_t(a,\underline{m})}$. The rest of our proof derives upper bounds on $\mathtt{T}_i \triangleq \sum_{s^n} p_{\underline{S}}^n(\underline{s}^n) \mathbb{E}\{\mathtt{t}_i\}$ for $i \in [3]$.

Upper bound on $\mathtt{T}_0$: $\mathcal{E}_1, \mathcal{E}_2$ are events involving only classical probabilities and we refer to [2, Lemma 7 in Appendix B] for a proof of the following.

Prop. 1. *For any* $\eta > 0$, $\exists N_\eta \in \mathbb{N}$ *such that* $\forall n \geq N(\eta)$, $\mathbb{E}\{T_0\} \leq \exp\{-n\eta\}$ *if* $\frac{k_j \log q}{n} > \log q - H(V_j|S_j)$ *for* $j \in [2]$.

To comprehend the above bound, note that codewords of a random UCC are uniformly distributed. The expected number of codewords jointly typical with a typical state sequence s_j^n is $|T_\eta(V_j|s_j^n)| q^{k-n}$ whose exponent is $k \log q - n \log q + n H(V_j|S_j)$. Prop. 1 guarantees the latter exponent is positive.

Upper bound on $\mathtt{T}_1$: Since $\mathtt{t}_1$ involves the event $\mathcal{E} = \mathcal{E}_1 \cap \mathcal{E}_2$, an upper bound on $\mathtt{T}_1$ can be derived using pinching and gentle operator lemma. Since this is fairly straightforward we refer the reader to a subsequent version of this manuscript for details.

Upper bound on $\mathtt{T}_2$: In our study, we have assumed $k_2 \geq k_1$, i.e., the size of bins in sender 2's code to be larger of the two. Under this assumption, we get only one bound on $\frac{k_1+2k_2+l_1+l_2}{n} \log q$, but in general, we get two bounds that are stated below.

Prop. 2. *For any* $\eta > 0$, *there exists* $N_\eta \in \mathbb{N}$ *such that for all* $n \geq N(\eta)$, $\mathtt{T}_2 \leq \exp\{-n\eta\}$ *if*

$$\max_{j=1,2} \left\{ \frac{k_j}{n} \right\} + \sum_{i=1}^2 \frac{k_i+l_i}{n} < 3 - \frac{H(W|Y)_\sigma - \sum_{i=1}^2 H(V_i|S_i)_\sigma}{\log q}$$

Proof. Proof is provided in Appendix B. □

By eliminating $\frac{k_1 \log q}{n}, \frac{k_2 \log q}{n}$ from the bounds in Prop. 1 and 2 and equating $R_j = \frac{l_j \log q}{n}$, we obtain the condition stated in the theorem statement. □
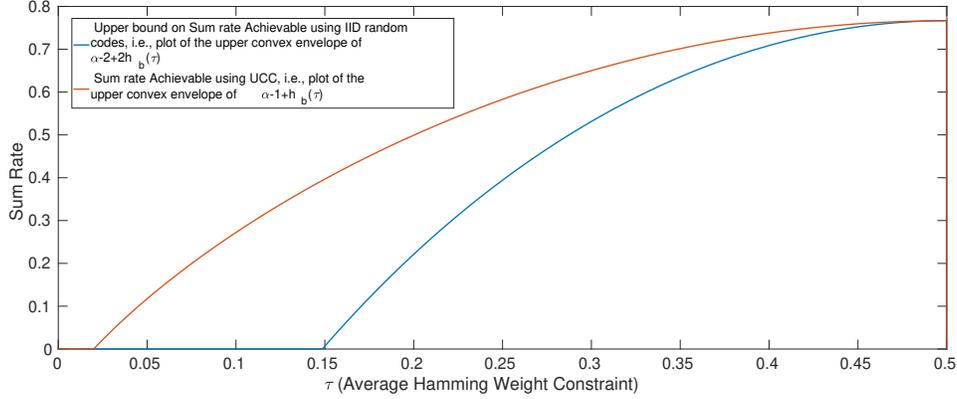

Fig. 2. Bound $uce\{\max\{0, \alpha-2+2h_b(\tau)\}\}$ on the sum rate achievable via IID random codes is plotted in blue and the sum rate $uce\{\max\{0, \alpha-1+h_b(\tau)\}\}$ achievable via UCC is plotted in red.

Prop. 3. *Consider Ex.1 for $\tau \in (0, \frac{1}{2})$ and $\theta = \frac{\pi}{8}$. The inner bound achievable via UCCs is strictly larger than that achievable via unstructured codes.*

Proof. By choosing $\mathcal{V}_1 = \mathcal{V}_2 = \mathcal{F}_2$ the binary field and $p_{X_j V_j | S_j}(1, 1 \oplus s_j | s_j) = \tau = 1 - p_{X_j V_j | S_j}(0, s_j | s_j)$ for $s_j \in \{0, 1\}$ and $j \in [2]$ and evaluating the inner bound in Thm. 2, it can be verified that any rate pair (R_1, R_2) satisfying $R_1 + R_2 < uce\{\max\{0, \alpha - 1 + h_b(\tau)\}\}$ is achievable where α is as defined in (2). See Fig. 2 for plots of the rate regions $R_1 + R_2 < uce\{\max\{0, \alpha - 2 + 2h_b(\tau)\}\}$ and $R_1 + R_2 < uce\{\max\{0, \alpha - 1 + h_b(\tau)\}\}$ achievable via IID and structured codes respectively to verify the latter is strictly larger. $\square$

V. ENHANCING IID CODING SCHEMES VIA UCCs

The UCC based coding scheme can enable efficient decoding of $V_1 \oplus V_2$. On a QMSTx wherin the latter function contains the information of the pair of messages, the UCC coding scheme can outperform the use of unstructured codes. In general, the information corresponding to the message pair can be embedded in both univariate and bivariate functions of auxillary RVs. A general coding scheme for QMSTx must therefore incorporate both unstructured codes and UCCs. We present the following inner bound that subsumes the inner bounds stated in Thms. 1, 2.

Theorem 3. *A rate-cost $(\underline{R}, \underline{\tau})$ quadruple is achievable if there exists finite sets $\mathcal{U}_1, \mathcal{U}_2$, a finite field $\mathcal{V}_1 = \mathcal{V}_2 = \mathcal{W} = \mathcal{F}_q$ of size q and conditional PMFs $p_{U_j V_j X_j | S_j} : j \in [2]$ wrt which*

$$
\begin{aligned}
R_j &\leq I(U_j; U_{\not j} Y)_\sigma - I(U_j; S_j)_\sigma - H(W | \underline{U} Y)_\sigma \\
&\quad + \min\{H(V_1 | U_1 S_1)_\sigma, H(V_2 | U_2 S_2)_\sigma\}, \text{ for } j = 1, 2, \\
R_1 + R_2 &\leq I(\underline{U}; Y)_\sigma - I(\underline{U}; \underline{S})_\sigma - H(W | \underline{U} Y)_\sigma \\
&\quad + \min\{H(V_1 | U_1 S_1)_\sigma, H(V_2 | U_2 S_2)_\sigma\},
\end{aligned}
$$

where the above entropies are evaluated wrt the state

$$
\sigma^{Y\underline{XUV}W\underline{S}} \triangleq \sum_{\underline{s}, \underline{u}, \underline{v}, w, \underline{x}} p_{\underline{SUV}W\underline{X}}(\underline{s}, \underline{u}, \underline{v}, w, \underline{x}) \rho_{\underline{x}\underline{s}} \otimes |\underline{x}\,\underline{u}\,\underline{v}\,w\,\underline{s}\rangle\langle\underline{x}\,\underline{u}\,\underline{v}\,w\,\underline{s}|,
$$

$$
p_{\underline{SUV}W\underline{X}}(\underline{s}, \underline{u}, \underline{v}, w, \underline{x}) = \mathsf{p}_{\underline{S}}(\underline{s}) \prod_{j=1}^{2} p_{X_j V_j U_j | S_j}(x_j, v_j, u_j | s_j) \mathbb{1}_{\{v_1 \oplus_q v_2 = w\}}.
$$

for all $(\underline{s}, \underline{v}, w, \underline{x}) \in \underline{\mathcal{S}} \times \underline{\mathcal{V}} \times \mathcal{W} \times \underline{\mathcal{X}}$.

By choosing $\mathcal{V}_1 = \mathcal{V}_2 = \phi$, we can recover the inner bound achievable via IID codes in 1. By choosing $\mathcal{U}_1 = \mathcal{U}_2 = \phi$, we can recover the inner bound in Thm. 2, thus proving that above inner bound subsumes all known inner bounds for a general QMSTx. We now outline the main elements of our proof and furnish details in a subsequent version of this manuscript. The code structure and the encoding is identical to the classical MAC with distributed states and is provided in [2]. Decoding is based on a combination of joint and successive decoding. A joint decoding POVM is employed to decode into U_1, U_2. Following this, decoding of $V_1 \oplus V_2$ is performed on the collapsed state. We leverage an alternate form of the 'overcounting trick' that we have used in [10] to obtain the same pre-Fourier Motzkin bounds as those in [2, Proof of Thm. 5].

VI. Communicating over Classical-Quantum Channel with Random States using UCCs

We begin with a formal description of a point-to-point classical quantum channel with classical random states available non-causally at the transmitter. We henceforth refer to this channel as a QSTx.

Consider a (generic) *QSTx* specified through (i) a finite input set $\mathcal{X}$, (ii) a finite set $\mathcal{S}$ of states, (iii) a PMF $\mathrm{p}_S(\cdot)$ on $\mathcal{S}$, (iii) a collection $(\rho_{xs} \in \mathcal{D}(\mathcal{H}_Y) : (x,s) \in \mathcal{X} \times \mathcal{S})$ of density operators and (iv) cost function $\kappa : \mathcal{X} \times \mathcal{S} \to [0, \infty)$. The cost function is additive, i.e., having observed the state sequence s^n the cost incurred by the sender in preparing the state $\otimes_{t=1}^n \rho_{x_t s_t}$ is $\overline{\kappa}(x^n, s^n) \triangleq \frac{1}{n} \sum_{t=1}^n \kappa(x_t, s_t)$. Reliable communication on a QSTx entails identifying a code.

Defn. 4. *An $(n, \mathcal{M}, e, \lambda)$ QSTx code consists of a message index set $\mathcal{M}$, an encoder map $e : \mathcal{M} \times \mathcal{S}^n \to \mathcal{X}^n$ with codewords denoted $(x^n(m, s^n) = (x^n(m, s^n)_t : 1 \le t \le n) : (m, s^n) \in \mathcal{M} \times \mathcal{S}^n)$ and a decoder POVM $\lambda \triangleq \{\lambda_m \in \mathcal{P}(\mathcal{H}_Y^{\otimes n}) : m \in \mathcal{M}\}$. The average error probability of the code is*

$$\overline{\xi}(e, \lambda) \triangleq 1 - \frac{1}{|\mathcal{M}|} \sum_{m \in \mathcal{M}} \sum_{s^n \in \mathcal{S}^n} \mathrm{p}_S^n(s^n) \mathrm{tr}\big(\lambda_m \rho_{x^n(m,s^n),s^n}\big) \text{ where } \rho_{x^n(m,s^n),s^n} = \bigotimes_{t=1}^n \rho_{x(m,s^n)_t, s_t}.$$

Average cost incurred by the sender in transmitting message m is $\tau(e|m) \triangleq \sum_{s^n} \mathrm{p}_S^n(s^n) \kappa(e(m, s^n), s^n)$ and the average cost incurred by the sender is $\tau(e) \triangleq \frac{1}{|\mathcal{M}|} \sum_m \tau(e|m)$.

The object of interest is the capacity region of a QSTx defined below. In this section, we prove achievability of the current known largest single-letter inner bounds to the capacity region of a QSTx.

Defn. 5. *A rate-cost quadruple $(R, \tau) \in [0, \infty)^2$ is achievable if there exists a sequence of QSTx codes $(n, \mathcal{M}^{(n)}, e^{(n)}, \lambda^{(n)})$ for which $\lim_{n \to \infty} \overline{\xi}(e^{(n)}, \lambda^{(n)}) = 0$,*

$$\lim_{n \to \infty} n^{-1} \log \mathcal{M}^{(n)} = R, \text{ and } \lim_{n \to \infty} \tau(e^{(n)}) \le \tau.$$

The capacity region $\mathscr{C}$ of the QSTx is the set of all achievable rate-cost vectors and $\mathscr{C}(\tau) \triangleq \{R : (R, \tau) \in \mathscr{C}\}$.

Theorem 4. *Consider a QSTx characterized through a finite set $\mathcal{S}$ of states, a PMF p_S on $\mathcal{S}$ modeling the distribution of the random state, an input set $\mathcal{X}$ and a collection of density operators $(\rho_{xs} \in \mathcal{D}(\mathcal{H}_Y) : (x,s) \in \mathcal{X} \times \mathcal{S})$. For $\tau > 0$, $R \in \mathscr{C}(\tau)$ if there exists a PMF $\mathrm{p}_S p_{VX|S}$ on $\mathcal{S} \times \mathcal{V} \times \mathcal{X}$ for which $\sum_{x,s} \mathrm{p}_S(s) p_{X|S}(x|s) \kappa(x, s) \le \tau$ and $R < I(V; Y) - I(V; S)$ where all information quantities are computed with respect to the quantum state*

$$\sigma_{YSXV} \triangleq \sum_{x,s,v} \mathrm{p}_S(s) p_{VX|S}(v, x|s) \rho_{xs} \otimes |s\ x\ v\rangle\langle s\ x\ v|. \tag{7}$$

Proof. The two new elements in our proof are the code structure (Sec. VI-A). Specifically, we build a union coset code to communicate over the QSTx. Since the codewords of a random union coset code are not mutually independent and are uniformly distributed, a standard information theoretic proof is not applicable. We therefore provide detailed steps in Sec. VI-D, Sec. VI-E.

A. Code Structure

Let $\mathcal{V} = \mathcal{F}_q$ be a finite field of size q. Consider a (n, k, l, g, ι) UCC whose codewords are $(v^n(a, m) \triangleq ag \oplus_q \iota(m) : (a, m) \in \mathcal{V}_k \times \mathcal{V}^l)$. The message index set $\mathcal{M} = [q^l]$ and the bin corresponding to message m is the collection $c(m) \triangleq (ag \oplus_q \iota(m) : a \in \mathcal{V}_k)$. As we describe in the sequel, the encoder observes the state sequence $s^n \in \mathcal{S}^n$ and chooses a codeword in $c(m)$ where $m \in \mathcal{M}$ is the message that needs to communicated to the Rx.

B. Encoding

For every possible pair (m, s^n) of message and state sequence, let

$$\alpha(m, s^n) \triangleq \sum_{a \in \mathcal{V}^k} \mathbb{1}_{\{(v^n(a,m), s^n) \in T_\eta^n(p_{VS})\}} \tag{8}$$

be the number of codewords in the bin indexed by the mesage that is jointly typical with the observed state sequence $s^n \in \mathcal{S}^n$. Let

$$\mathcal{L}(m, s^n) \triangleq \begin{cases} \{a : (v^n(a,m), s^n) \in T_\eta(p_{VS})\} & \text{if } \alpha(m, s^n) \ge 1 \\ \{0^k\} & \text{otherwise, i.e. } \alpha(m, s^n) = 0. \end{cases} \tag{9}$$

be a list of candidate code words that is available to the encoder for the message, state sequence pair (m, s^n). Let a_{m,s^n}^* be chosen from $\mathcal{L}(m, s^n)$ and $v^*(m, s^n) \triangleq v^n(a_{m,s^n}^*, m)$. A predefined 'fusion map' $f : \mathcal{S}^n \times \mathcal{V}^n \to \mathcal{X}^n$ is used to map the pair $s^n, v^*(m, s^n)$ to an input sequence in $\mathcal{X}^n$ henceforth denoted $x^n(m, s^n)$. On observing state sequence s^n and message m, the encoder chooses state sequence $x^n(m, s^n) = (x(m, s^n)_t : 1 \le t \le n)$, and we define $\rho_{m,s^n} \triangleq \bigotimes_{t=1}^n \rho_{x(m,s^n)_t s_t}$.

C. Decoding POVMs

Consider a PMF $p_{SVX} = \mathsf{p}_S p_{VX|S}$ on $\mathcal{S} \times \mathcal{V} \times \mathcal{X}$. Let

$$\rho \triangleq \sum_{x,s} p_{SX}(s,x)\rho_{xs}, \rho_v \triangleq \sum_{x,s} p_{XS|V}(x,s|v)\rho_{xs} \quad \begin{array}{c}\text{have spectral}\\ \text{decompositions}\end{array} \quad \rho = \sum_{y\in\mathcal{Y}} q(y)\,|f_y\rangle\langle f_y| \text{ and } \rho_v = \sum_{y\in\mathcal{Y}} r_{Y|V}(y|v)\,|e_{y|v}\rangle\langle e_{y|v}|$$

respectively. Let

$$\pi^Y \triangleq \sum_{y^n\in\mathcal{Y}^n} \bigotimes_{t=1}^n |f_{y_t}\rangle\langle f_{y_t}| \, \mathbb{1}_{\{y^n\in T_\eta^n(q)\}} \text{ and } \pi_{v^n} \triangleq \begin{cases} 0 & \text{if } v^n \notin T_\eta^n(p_V) \\ \sum_{y^n\in\mathcal{Y}^n} \bigotimes_{t=1}^n |e_{y_t|v_t}\rangle\langle e_{y_t|v_t}| \, \mathbb{1}_{\{(v^n,y^n)\in T_\eta^n(p_V r_{Y|V})\}} & \text{otherwise.} \end{cases} \quad (10)$$

be the unconditional and conditional typical projectors. For $(a,m) \in \mathcal{V}^k \times \mathcal{V}^l$, let

$$\gamma_{a,m} \triangleq \pi^Y \pi_{v^n(a,m)} \pi^Y \text{ and } \lambda_m \triangleq \left(\sum_{\hat{a},\hat{m}\in\mathcal{V}^k\times\mathcal{V}^l} \gamma_{\hat{a},\hat{m}}\right)^{-\frac{1}{2}} \sum_{a\in\mathcal{V}^k} \gamma_{a,m} \left(\sum_{\hat{a},\hat{m}\in\mathcal{V}^k\times\mathcal{V}^l} \gamma_{\hat{a},\hat{m}}\right)^{-\frac{1}{2}} \text{ for } m \in [q^l] \text{ and } \lambda_{-1} = I_{\mathcal{H}_Y}^{\otimes n} - \sum_{m\in\mathcal{M}} \lambda_m \quad (11)$$

and $\{\lambda_m : m \in \mathcal{M} = [q^l], \lambda_{-1}\}$ be the decoding POVM.

D. Error Probability

As is standard in information theory, we derive an upper bound on the error probability of the best code by averaging the error probability over an ensemble of codes. We begin by specifying the distribution of a random code in our ensemble. Note that a code is completely specified via (i) the generator matrix $g \in \mathcal{V}^{k\times n}$, the map $\iota : \mathcal{V}^l \to \mathcal{V}^n$ and the collection $(a_{m,s^n}^* \in \mathcal{V}^k : (m,s^n) \in \mathcal{M} \times \mathcal{S}^n)$. The generator matrix G, the map ι and the collection $(A_{m,s^n}^* \in \mathcal{V}^k : (m,s^n) \in \mathcal{M} \times \mathcal{S}^n)$ of a random code are distributed with PMF

$$P\left(\begin{array}{c} G = g, \iota(\tilde{m}) = d^n(\tilde{m}) : \tilde{m} \in \mathcal{V}^l, \\ a_{m,s^n}^* = a(m,s^n) : (m,s^n) \in \mathcal{M} \times \mathcal{S}^n \end{array}\right) = \frac{1}{q^{kn}} \left[\prod_{\tilde{m}\in\mathcal{V}^l} \frac{1}{q^n}\right] \cdot \left[\prod_{m\in\mathcal{V}^l} \prod_{s^n\in\mathcal{S}^n} \frac{1}{|\mathcal{L}(m,s^n)|} \mathbb{1}_{\{a(m,s^n)\in\mathcal{L}(m,s^n)\}}\right]. \quad (12)$$

From (12), it can be verified that the generator matrix G and the range of $(\iota(m) : m \in \mathcal{V}^l)$ are mutually independent and uniformly distributed in the respective range spaces. Moreover, for $(m,s^n) \in \mathcal{M} \times \mathcal{S}^n$ and any $a \in \mathcal{L}(m,s^n)$, we note that

$$P\left(\begin{array}{c} a_{m,s^n}^* = a(m,s^n) \text{ for} \\ (m,s^n) \in \mathcal{M} \times \mathcal{S}^n \end{array} \middle| \begin{array}{c} G = g, \iota(\tilde{m}) = d^n(\tilde{m}) \\ \text{for } \tilde{m} \in \mathcal{V}^l \end{array}\right) = \frac{1}{|\mathcal{L}(m,s^n)|} \mathbb{1}_{\{a(m,s^n)\in\mathcal{L}(m,s^n)\}}, \quad (13)$$

a relation we shall opportunity to use in our analysis. For a specific code, the average error probability of the code is

$$\bar{\xi}(e,\lambda) \triangleq \frac{1}{q^l} \sum_m \sum_{s^n} \mathsf{p}_S^n(s^n) \operatorname{tr}\{(\boldsymbol{I} - \lambda_m)\rho_{m,s^n}\} \leq \mathsf{t}_0 + \frac{1}{q^l} \sum_m \sum_{s^n} \mathsf{p}_S^n(s^n) \operatorname{tr}\{(\boldsymbol{I} - \lambda_m)\rho_{m,s^n}\} \mathbb{1}_{\mathcal{E}_{L-\eta}}, \text{ where,}$$

$$\mathsf{t}_0 \triangleq \frac{1}{q^l} \sum_{m,s^n} \mathsf{p}_S^n(s^n) \mathbb{1}_{\mathcal{E}_{L-\eta}^c}, \mathcal{E}_A \triangleq \{\alpha(m,s^n) \geq 2^{nA}\}. \text{ Suppose } S = \gamma_{a_{m,s^n}^*,m}, T = \sum_{a\neq a_{m,s^n}^*} \gamma_{a,m} + \sum_{\hat{m}\neq m} \sum_a \gamma_{a,\hat{m}}, \text{ then}$$

$\lambda_m \geq (S+T)^{-\frac{1}{2}} S (S+T)^{-\frac{1}{2}}$ and the operator inequalities $0 \leq S \leq \boldsymbol{I}$, $0 \leq T$ hold. In breaking down the error event, we have considered the event $\mathcal{E}^{L-\eta}$ and the choice of L will be specified in due course. From the Hayashi Nagaoka inequality [21] [22, Lemma 16.4.1], we have

$$I^{\otimes n} - \lambda_m \leq I^{\otimes n} - (S+T)^{-\frac{1}{2}} S (S+T)^{-\frac{1}{2}} \leq 2(I-S) + 4(I-T) \text{ and hence } \bar{\xi}(e,\lambda) \leq \mathsf{t}_0 + \mathsf{t}_1 + \mathsf{t}_2 \text{ where}$$

$$\mathsf{t}_1 \triangleq \frac{2}{q^l} \sum_m \sum_{s^n} \mathsf{p}_S^n(s^n) \operatorname{tr}\left(\left[\boldsymbol{I} - \gamma_{a_{m,s^n}^*,m}\right]\rho_{m,s^n}\right) \mathbb{1}_{\mathcal{E}_{L-\eta}}, \mathsf{t}_2 = \mathsf{t}_{21} + \mathsf{t}_{22}, \mathsf{t}_{21} \triangleq \frac{4}{q^l} \sum_m \sum_{s^n} \sum_{\hat{a}\neq a_{m,s^n}^*} \mathsf{p}_S^n(s^n) \operatorname{tr}(\gamma_{\hat{a},m}\rho_{m,s^n}) \mathbb{1}_{\mathcal{E}_{L-\eta}}$$

$$\text{and } \mathsf{t}_{22} \triangleq \frac{4}{q^l} \sum_m \sum_{s^n} \sum_{\hat{m}\neq m} \sum_{\hat{a}} \mathsf{p}_S^n(s^n) \operatorname{tr}(\gamma_{\hat{a},\hat{m}}\rho_{m,s^n}) \mathbb{1}_{\mathcal{E}_{L-\eta}}.$$

Let $\mathsf{T}_i : 0 \leq i \leq 3$ denote abov terms corresponding to a random code whose distribution is specified in (12). In the sequel, we derive upper bounds for each of the four terms $\mathsf{t}_0, \mathsf{t}_1, \mathsf{t}_{21}, \mathsf{t}_{22}$ corresponding to the best code by evaluating upper bounds on $\mathbb{E}\{\mathsf{T}_i\} : 0 \leq i \leq 3$.

Bound on $\mathbb{E}\{\mathsf{T}_0\}$: We note that t_0 concerns only the event that the encoder cannot find atleast $2^{n(L-\eta)}$ codewords in the bin indexed by the message that is jointly typical with the observed state sequence. The analysis of this event involves only classical probabilities. Using a standard second moment method similar to that in [2, Lemma 7 in Appendix B] or [8, Lemma 8 in Appendix A]. Employing these techniques, the following lemma can be proved.

Lemma 1. *For every $\eta > 0$, there exists $N_\eta \in \mathbb{N}$ such that for all $n \geq N_\eta$, we have*

$$\mathbb{E}\{\mathtt{T}_0\} \leq \exp\left\{-n\left(\frac{k\log q}{n} - [\log q - H(V|S) + L - \eta]\right)\right\}. \tag{14}$$

Bound on $\mathbb{E}\{\mathtt{T}_1\}$: For a specific code, we have $\mathtt{t}_1 = \mathtt{t}_{11} + \mathtt{t}_{12}$, where

$$\mathtt{t}_{11} \triangleq \frac{2}{q^l}\sum_m\sum_{s^n}\mathsf{p}_S^n(s^n)\,\mathrm{tr}\left(\left[\boldsymbol{I} - \gamma_{a_{m,s^n}^*,m}\right]\rho_{m,s^n}\right)\mathbb{1}\left\{\begin{array}{c}\alpha(m,s^n) \geq 2^{n(L-\eta)}, (s^n, v^*(m,s^n)) \in T_\eta^n(p_{SV})\\ x^n(m,s^n) \notin T_\eta^n(p_{X|SV}|s^n, v^*(m,s^n))\end{array}\right\}$$

$$\mathtt{t}_{12} \triangleq \frac{2}{q^l}\sum_m\sum_{s^n}\mathsf{p}_S^n(s^n)\,\mathrm{tr}\left(\left[\boldsymbol{I} - \gamma_{a_{m,s^n}^*,m}\right]\rho_{m,s^n}\right)\mathbb{1}\left\{\alpha(m,s^n) \geq 2^{n(L-\eta)}, (s^n, v^*(m,s^n), x^n(m,s^n)) \in T_\eta^n(p_{SVX})\right\}.$$

A bound on $\mathbb{E}\{\mathtt{T}_{11}\}$ can be derived using standard bounds on typical sequences. Indeed, since $X^n(m,s^n)$ is conditionally picked wrt $\prod p_{X|VS}(\cdot|v^*(m,s^n), s^n)$, the probability that it is not conditionally typically falls exponentially. In the following, we indicate how we breakup $\mathtt{t}_{12}$ and indicate how each term in corresponding breakup can be bounded.

Bound on $\mathbb{E}\{\mathtt{T}_{12}\}$: We have

$$\mathtt{t}_{12} \leq \frac{2}{q^l}\sum_{\substack{m\in\mathcal{V}^l\\a\in\mathcal{V}^k}}\sum_{\substack{(s^n,v^n,x^n)\\\in T_\eta^n(p_{SVX})}}\mathsf{p}_S^n(s^n)\,\mathrm{tr}\left(\left[\boldsymbol{I} - \pi^Y\pi_{v^n}\pi^Y\right]\rho_{x^n,s^n}\right)\mathbb{1}\left\{a_{m,s^n}^* = a, v^n(a,m) = v^n, x^n(m,s^n) = x^n\right\}$$

$$\leq \frac{2}{q^l}\sum_{\substack{m\in\mathcal{V}^l\\a\in\mathcal{V}^k}}\sum_{\substack{(s^n,v^n,x^n)\\\in T_\eta^n(p_{SVX})}}\mathsf{p}_S^n(s^n)\,\mathrm{tr}\left(\left[\boldsymbol{I} - \pi^Y\pi_{v^n}\pi^Y\right]\rho_{x^n,s^n}\right)\mathbb{1}\left\{v^n(a,m) = v^n, x^n(m,s^n) = x^n\right\} = \mathtt{t}_{121} - \mathtt{t}_{122}$$

$$\mathtt{t}_{121} \triangleq \frac{2}{q^l}\sum_{\substack{m\in\mathcal{V}^l\\a\in\mathcal{V}^k}}\sum_{\substack{(s^n,v^n,x^n)\\\in T_\eta^n(p_{SVX})}}\mathsf{p}_S^n(s^n)\mathbb{1}\left\{v^n(a,m) = v^n, x^n(m,s^n) = x^n\right\}$$

$$\mathtt{t}_{122} \triangleq \frac{2}{q^l}\sum_{\substack{m\in\mathcal{V}^l\\a\in\mathcal{V}^k}}\sum_{\substack{(s^n,v^n,x^n)\\\in T_\eta^n(p_{SVX})}}\mathsf{p}_S^n(s^n)\,\mathrm{tr}\left(\left[\pi^Y\pi_{v^n}\pi^Y\right]\rho_{x^n,s^n}\right)\mathbb{1}\left\{v^n(a,m) = v^n, x^n(m,s^n) = x^n\right\}.$$

A lower bound on $\mathbb{E}\{\mathtt{T}_{122}\}$ can be derived using gentle operator lemma and pinching. Specifically, we have

$$\mathbb{E}\{\mathtt{T}_{122}\} = \frac{2}{q^l}\sum_{\substack{m\in\mathcal{V}^l\\a\in\mathcal{V}^k}}\sum_{\substack{(s^n,v^n,x^n)\\\in T_\eta^n(p_{SVX})}}\mathsf{p}_S^n(s^n)\,\mathrm{tr}\left(\left[\pi^Y\pi_{v^n}\pi^Y\right]\rho_{x^n,s^n}\right)P\left(v^n(a,m) = v^n, x^n(m,s^n) = x^n\right)$$

$$= \frac{2}{q^{l+n}}\sum_{\substack{m\in\mathcal{V}^l\\a\in\mathcal{V}^k}}\sum_{\substack{(s^n,v^n,x^n)\\\in T_\eta^n(p_{SVX})}}\mathsf{p}_S^n(s^n)\,\mathrm{tr}\left(\pi_{v^n}\pi^Y\rho_{x^n,s^n}\pi^Y\right)p_{X|VS}(x^n|v^n,s^n)$$

$$\geq \frac{2}{q^{l+n}}\sum_{\substack{m\in\mathcal{V}^l\\a\in\mathcal{V}^k}}\sum_{\substack{(s^n,v^n,x^n)\\\in T_\eta^n(p_{SVX})}}\mathsf{p}_S^n(s^n)\left[\mathrm{tr}(\pi_{v^n}\rho_{x^n,s^n}) - \left\|\pi^Y\rho_{x^n,s^n}\pi^Y - \rho_{x^n,s^n}\right\|_1\right]p_{X|VS}(x^n|v^n,s^n). \tag{15}$$

The first term on the RHS of (15) can be lower bounded by the pinching lemma [22, Property 15.2.7] and the second term can be upper bounded via gentle operator lemma [22, Lemma 9.4.2]. We now proceed to $\mathbb{E}\{\mathtt{T}_{11}\}$

Bound on $\mathtt{t}_{11}$:

$$\mathtt{t}_{11} \leq \frac{2}{q^l}\sum_m\sum_{s^n}\mathsf{p}_S^n(s^n)\mathbb{1}\left\{(s^n, v^*(m,s^n)) \in T_\eta^n(p_{SV}), x^n(m,s^n) \notin T_\eta^n(p_{X|SV}|s^n, v^*(m,s^n))\right\} \text{ and}$$

$$\tag{16}$$

In the sequel, we compute upper bound on $\mathbb{E}\{T_{11}\}$ and lower bound on $\mathbb{E}\{\overline{T}_{12}\}$. We begin with the latter. We have

$$
\begin{aligned}
\mathbb{E}\{\overline{t}_{12}\} &= \frac{2}{q^l} \sum_m \sum_{\substack{(s^n,v^n,x^n) \\ \in T_\eta(p_{SVX})}} p_S^n(s^n)\,\mathrm{tr}\big(\pi^Y \pi_{v^n} \pi^Y \rho_{x^n,s^n}\big) P(X^n(m,s^n)=x^n, V^*(m,s^n)=v^n) \\
&= \frac{2}{q^l} \sum_m \sum_{\substack{(s^n,v^n,x^n) \\ \in T_\eta(p_{SVX})}} p_S^n(s^n)\,\mathrm{tr}\big(\pi^Y \pi_{v^n} \pi^Y \rho_{x^n,s^n}\big) p_{X|VS}(x^n|v^n,s^n) P(V^*(m,s^n)=v^n) \\
&\geq \frac{2}{q^l} \sum_m \sum_{\substack{(s^n,v^n,x^n) \\ \in T_\eta(p_{SVX})}} p_S^n(s^n)\,\mathrm{tr}\big(\pi^Y \pi_{v^n} \pi^Y \rho_{x^n,s^n}\big) p_{X|VS}(x^n|v^n,s^n) P(V^*(m,s^n)=v^n) \quad (17)
\end{aligned}
$$

Bound on $\mathbb{E}\{T_{21}\}$: Before we study $\mathbb{E}\{T_{21}\}$, we begin by noting that

$$
t_{21} = \frac{4}{q^l} \sum_m \sum_{s^n} \sum_{\hat{a} \neq a^*_{m,s^n}} p_S^n(s^n)\,\mathrm{tr}(\gamma_{\hat{a},m}\rho_{m,s^n})\mathbb{1}_{\mathcal{E}_{L-\eta}} = \frac{4}{q^l} \sum_m \sum_{s^n} \sum_{\hat{a} \neq a^*_{m,s^n}} p_S^n(s^n)\,\mathrm{tr}\big(\pi^Y \pi_{v^n(\hat{a},m)}\pi^Y \rho_{m,s^n}\big)\mathbb{1}_{\mathcal{E}_{L-\eta}} \quad (18)
$$

$$
= \frac{4}{q^l} \sum_m \sum_{s^n} \sum_{\substack{a,\hat{a}\in\mathcal{V}^k \\ a\neq\hat{a}}} \sum_{v^n,\hat{v}^n,x^n} p_S^n(s^n)\,\mathrm{tr}\big(\pi^Y \pi_{\hat{v}^n}\pi^Y \rho_{x^n,s^n}\big)\mathbb{1}\left\{\begin{array}{c} \alpha(m,s^n)\geq 2^{n(L-\eta)}, a^*_{m,s^n}=a, v^n(a,m)=v^n \\ v^n(\hat{a},m)=\hat{v}^n, x^n(m,s^n)=x^n \end{array}\right\} \quad (19)
$$

$$
= \frac{4}{q^l} \sum_m \sum_{s^n} \sum_{\substack{a,\hat{a}\in\mathcal{V}^k \\ a\neq\hat{a}}} \sum_{\hat{v}^n,x^n} p_S^n(s^n)\,\mathrm{tr}\big(\pi^Y \pi_{\hat{v}^n}\pi^Y \rho_{x^n,s^n}\big)\mathbb{1}\left\{\begin{array}{c} \alpha(m,s^n)\geq 2^{n(L-\eta)}, a^*_{m,s^n}=a, v^n(a,m)=v^n, \hat{v}^n\in T_\eta(p_V) \\ v^n(\hat{a},m)=\hat{v}^n, x^n(m,s^n)=x^n, (v^n,s^n)\in T_\eta^n(p_{VS}) \end{array}\right\} \quad (20)
$$

where (i) $\rho_{m,s^n} = \bigotimes_{t=1}^n \rho_{x(m,s^n)_t s_t}$ is as defined earlier, (ii) (19) follows by summing over all possible choices for the corresponding codewords, (iii) (20) holds for $L \geq \eta$ since the encoding rule guarantees $a^*_{m,s^n} \in \mathcal{L}(m,s^n)$ and the latter set defined in (9) contains indices corresponding to codewords that are jointly typical with the observed state sequence whenever $\alpha(m,s^n) \geq 1$ and (iv) (20) is true since, as defined in (11), $\pi_{\hat{v}^n}$ is the zero projector if $\hat{v}^n \notin T_\eta^n(p_V)$. This implies

$$
\mathbb{E}\{T_{21}\} = \frac{4}{q^l} \sum_{\substack{m,(v^n,s^n) \\ \in T_\eta^n(p_{VS})}} \sum_{\substack{a,\hat{a}\in\mathcal{V}^k \\ a\neq\hat{a}}} \sum_{\substack{\hat{v}^n\in T_\eta^n(p_V) \\ x^n\in\mathcal{X}^n}} p_S^n(s^n)\,\mathrm{tr}\big(\pi^Y \pi_{\hat{v}^n}\pi^Y \rho_{x^n,s^n}\big) P\left(\begin{array}{c} \alpha(m,s^n)\geq 2^{n(L-\eta)}, a^*_{m,s^n}=a, v^n(a,m)=v^n \\ v^n(\hat{a},m)=\hat{v}^n, x^n(m,s^n)=x^n, \end{array}\right). \quad (21)
$$

For $(v^n,s^n)\in T_\eta^n(p_{VS})$ and $\hat{a}\neq a$, we have

$$
P\left(\begin{array}{c} \alpha(m,s^n)\geq 2^{n(L-\eta)}, a^*_{m,s^n}=a, V^n(a,m)=v^n \\ V^n(\hat{a},m)=\hat{v}^n, X^n(m,s^n)=x^n, \end{array}\right) = P\left(\begin{array}{c} V^n(a,m)=v^n \\ V^n(\hat{a},m)=\hat{v}^n \end{array}\right) P\left(\begin{array}{c} \alpha(m,s^n)\geq \\ 2^{n(L-\eta)} \end{array}\Big| \begin{array}{c} V^n(a,m)=v^n \\ V^n(\hat{a},m)=\hat{v}^n \end{array}\right) \quad (22)
$$

$$
\times P\left(a^*_{m,s^n}=a \Big| \begin{array}{c} \alpha(m,s^n)\geq 2^{n(L-\eta)} \\ V^n(a,m)=v^n, V^n(\hat{a},m)=\hat{v}^n \end{array}\right) P\left(X^n(m,s^n)=x^n \Big| \begin{array}{c} a^*_{m,s^n}=a, \alpha(m,s^n)\geq 2^{n(L-\eta)} \\ V^n(a,m)=v^n, V^n(\hat{a},m)=\hat{v}^n \end{array}\right)
$$

$$
\leq \frac{1}{q^{2n}} \cdot 1 \cdot \frac{1}{\alpha(m,s^n)} p_{X|SV}(x^n|s^n,v^n)\mathbb{1}_{\{\alpha(m,s^n)\geq 2^{n(L-\eta)}\}} \leq \frac{1}{q^{2n}} \cdot \frac{p_{X|SV}(x^n|s^n,v^n)}{2^{n(L-\eta)}} \leq \frac{2^{n(H(V|S)+3\eta)}p_{XV|S}(x^n,v^n|s^n)}{q^{2n}2^{n(L-\eta)}}, \quad (23)
$$

where the first inequality in (23) follows the fact that codewords of a UCC are pairwise independent and uniformly distributed [3] and the second inequality in (23) follows from standard bounds on conditional probability of jointly typical sequences.

Substituting the bound in the RHS of (23) in (21), we have

$$
\mathbb{E}\{\mathrm{T}_{21}\} \leq \frac{4 \cdot 2^{n(H(V|S)+3\eta)}}{q^{l+2n} \cdot 2^{n(L-\eta)}} \sum_{m} \sum_{\substack{(v^n,s^n) \\ \in T_\eta^n(p_{VS})}} \sum_{\substack{a,\hat{a} \in \mathcal{V}^k \\ a \neq \hat{a}}} \sum_{\substack{\hat{v}^n \in T_\eta^n(p_V) \\ x^n \in \mathcal{X}^n}} \mathrm{tr}\big(\pi^Y \pi_{\hat{v}^n} \pi^Y p_{XVS}(x^n,v^n,s^n) \rho_{x^n,s^n}\big)
$$

$$
\leq \frac{4 \cdot 2^{n(H(V|S)+3\eta)}}{q^{l+2n} \cdot 2^{n(L-\eta)}} \sum_{m} \sum_{\substack{a,\hat{a} \in \mathcal{V}^k \\ a \neq \hat{a}}} \sum_{\substack{\hat{v}^n \in \\ T_\eta^n(p_V)}} \mathrm{tr}\big(\pi^Y \pi_{\hat{v}^n} \pi^Y \rho^{\otimes n}\big) = \frac{4 \cdot 2^{n(H(V|S)+3\eta)}}{q^{l+2n} \cdot 2^{n(L-\eta)}} \sum_{m} \sum_{\substack{a,\hat{a} \in \mathcal{V}^k \\ a \neq \hat{a}}} \sum_{\substack{\hat{v}^n \in \\ T_\eta^n(p_V)}} \mathrm{tr}\big(\pi_{\hat{v}^n} \pi^Y \rho^{\otimes n} \pi^Y\big) \quad (24)
$$

$$
\leq \frac{4 \cdot 2^{n(H(V|S)-H(Y)+6\eta)}}{q^{l+2n} \cdot 2^{n(L-\eta)}} \sum_{m} \sum_{\substack{a,\hat{a} \in \mathcal{V}^k \\ a \neq \hat{a}}} \sum_{\substack{\hat{v}^n \in \\ T_\eta^n(p_V)}} \mathrm{tr}\big(\pi_{\hat{v}^n} \pi^Y\big) \leq \frac{4 \cdot 2^{n(H(V|S)-H(Y)+6\eta)}}{q^{l+2n} \cdot 2^{n(L-\eta)}} \sum_{m} \sum_{\substack{a,\hat{a} \in \mathcal{V}^k \\ a \neq \hat{a}}} \sum_{\substack{\hat{v}^n \in \\ T_\eta^n(p_V)}} \mathrm{tr}\big(\pi_{\hat{v}^n}\big) \quad (25)
$$

$$
\leq \frac{4 \cdot 2^{n(H(V|S)-H(Y)+H(V,Y)+12\eta)}}{q^{l+2n} \cdot 2^{n(L-\eta)}} \sum_{m} \sum_{\substack{a,\hat{a} \in \mathcal{V}^k \\ a \neq \hat{a}}} 1 \leq \frac{4 \cdot 2^{n(H(V|S)-H(Y)+H(V,Y)+12\eta)}}{q^{2n-2k} \cdot 2^{n(L-\eta)}} \quad (26)
$$

$$
\leq \exp\left\{-n\left(L - \left[\frac{k \log q}{n} - \log q + H(V|S)\right] + \log q - H(V|Y) - \frac{k \log}{n}\right)\right\} \quad (27)
$$

where (24) follows from the operator inequality

$$
\sum_{\substack{(v^n,s^n) \\ \in T_\eta^n(p_{VS})}} \sum_{x^n \in \mathcal{X}^n} p_{XVS}(x^n,v^n,s^n)\rho_{x^n,s^n} \leq \sum_{\substack{x^n,s^n,v^n \\ \in \mathcal{X}^n \times \mathcal{S}^n \times \mathcal{V}^n}} p_{XVS}(x^n,v^n,s^n)\rho_{x^n,s^n} = \rho^{\otimes n}
$$

which follows from the positivity of the density operators, (25) follows from the operator inequalities $\pi^Y \rho^{\otimes n} \pi^Y \leq 2^{-n[H(Y)-3\eta]}\pi^Y$ [22, Property 15.1.3] and $\pi^Y \leq \boldsymbol{I}$, (26) follows from $\mathrm{tr}(\pi_{\hat{v}^n}) \leq 2^{n[H(Y|V)+3\eta]}$ for $\hat{v}^n \in T_\eta^n(p_V)$ [22, Property 15.1.2] and $|T_\eta^n(p_V)| \leq 2^{n[H(V)+3\eta]}$ and the last bound (27) follows by collating all exponents.

Bound on $\mathbb{E}\{\mathrm{T}_{22}\}$: Our analysis of $\mathbb{E}\{\mathrm{T}_{22}\}$ is very similar to $\mathbb{E}\{\mathrm{T}_{21}\}$. The only difference between these analyses stems from the fact that the legitimate codeword $V^n(a_{m,s^n}^*,m)$ and an incorrect codeword in the same bin $V^n(\hat{a},m)$ are not statistically independent, however the legitimate codeword $V^n(a_{m,s^n}^*,m)$ and any codeword in a different bin $V^n(\hat{a},\hat{m})$ for $\hat{m} \neq m$ are statistically independent. This suggests that we can derive the bounds without having to condition on the realization of a_{m,s^n}^* as in (22) - (23). Except for this minor difference, the rest of the analysis provided below is identical. We have

$$
\mathrm{t}_{22} = \frac{4}{q^l} \sum_{\substack{m,\hat{m} \\ m \neq \hat{m}}} \sum_{s^n} \sum_{\hat{a}} \mathrm{p}_S^n(s^n) \mathrm{tr}(\gamma_{\hat{a},\hat{m}} \rho_{m,s^n}) \mathbb{1}_{\mathcal{E}_{L-\eta}} = \frac{4}{q^l} \sum_{\substack{m,\hat{m} \\ m \neq \hat{m}}} \sum_{s^n} \sum_{\hat{a}} \mathrm{p}_S^n(s^n) \mathrm{tr}\big(\pi^Y \pi_{v^n(\hat{a},\hat{m})} \pi^Y \rho_{m,s^n}\big) \mathbb{1}_{\mathcal{E}_{L-\eta}} \quad (28)
$$

$$
= \frac{4}{q^l} \sum_{\substack{m,\hat{m} \\ m \neq \hat{m}}} \sum_{s^n} \sum_{\hat{a}} \sum_{v^n,\hat{v}^n,x^n} \mathrm{p}_S^n(s^n) \mathrm{tr}\big(\pi^Y \pi_{\hat{v}^n} \pi^Y \rho_{x^n,s^n}\big) \mathbb{1}\left\{\begin{matrix} \alpha(m,s^n) \geq 2^{n(L-\eta)}, V^*(m,s^n) = v^n \\ v^n(\hat{a},\hat{m}) = \hat{v}^n, x^n(m,s^n) = x^n \end{matrix}\right\} \quad (29)
$$

$$
= \frac{4}{q^l} \sum_{\substack{m,\hat{m} \\ m \neq \hat{m}}} \sum_{s^n} \sum_{\hat{a}} \sum_{\substack{v^n \\ \hat{v}^n,x^n}} \mathrm{p}_S^n(s^n) \mathrm{tr}\big(\pi^Y \pi_{\hat{v}^n} \pi^Y \rho_{x^n,s^n}\big) \mathbb{1}\left\{\begin{matrix} \alpha(m,s^n) \geq 2^{n(L-\eta)}, V^*(m,s^n) = v^n, \hat{v}^n \in T_\eta(p_V) \\ v^n(\hat{a},\hat{m}) = \hat{v}^n, x^n(m,s^n) = x^n, (v^n,s^n) \in T_\eta^n(p_{VS}) \end{matrix}\right\} \quad (30)
$$

where as earlier, (i) $\rho_{m,s^n} = \bigotimes_{t=1}^{n} \rho_{x(m,s^n)_t s_t}$, (ii) (29) follows by summing over all possible choices for the corresponding codewords, (iii) (30) holds for $L \geq \eta$ since the encoding rule guarantees $a_{m,s^n}^* \in \mathcal{L}(m,s^n)$ and the latter set defined in (9) contains indices corresponding to codewords that are jointly typical with the observed state sequence whenever $\alpha(m,s^n) \geq 1$ and (iv) (30) is true since, as defined in (11), $\pi_{\hat{v}^n}$ is the zero projector if $\hat{v}^n \notin T_\eta^n(p_V)$. This implies

$$
\mathbb{E}\{\mathrm{T}_{22}\} = \frac{4}{q^l} \sum_{\substack{m,\hat{m} \\ m \neq \hat{m}}} \sum_{\substack{(v^n,s^n) \\ \in T_\eta^n(p_{VS})}} \sum_{\hat{a}} \sum_{\substack{\hat{v}^n \in T_\eta^n(p_V) \\ x^n \in \mathcal{X}^n}} \mathrm{p}_S^n(s^n) \mathrm{tr}\big(\pi^Y \pi_{\hat{v}^n} \pi^Y \rho_{x^n,s^n}\big) P\left(\begin{matrix} \alpha(m,s^n) \geq 2^{n(L-\eta)}, V^*(m,s^n) = v^n \\ V^n(\hat{a},m) = \hat{v}^n, x^n(m,s^n) = x^n \end{matrix}\right). \quad (31)
$$

For $(v^n,s^n) \in T_\eta^n(p_{VS})$ and $\hat{m} \neq m$, we have

$$
P\left(\begin{matrix} \alpha(m,s^n) \geq 2^{n(L-\eta)}, V^*(m,s^n) = v^n \\ V^n(\hat{a},\hat{m}) = \hat{v}^n, X^n(m,s^n) = x^n \end{matrix}\right) = \sum_{a \in \mathcal{V}^k} P\left(\begin{matrix} \alpha(m,s^n) \geq 2^{n(L-\eta)}, a_{m,s^n}^* = a, V^n(a,m) = v^n \\ V^n(\hat{a},\hat{m}) = \hat{v}^n, X^n(m,s^n) = x^n, \end{matrix}\right)
$$

$$
\leq \frac{2^{n(H(V|S)+3\eta)} p_{XV|S}(x^n,v^n|s^n)}{q^{-k+2n} 2^{n(L-\eta)}}, \quad (32)
$$

where (32) follows from the same set of arguments that got us from (22) to (23). Substituting the above upper bound in (31), we have

$$\mathbb{E}\{T_{22}\} \leq \frac{4 \cdot 2^{n(H(V|S)+3\eta)}}{q^{-k+l+2n} \cdot 2^{n(L-\eta)}} \sum_{\substack{m,\hat{m} \\ m \neq \hat{m}}} \sum_{\substack{(v^n,s^n) \\ \in T_\eta^n(p_{VS})}} \sum_{\hat{a}} \sum_{\substack{\hat{v}^n \in T_\eta^n(p_V) \\ x^n \in \mathcal{X}^n}} \text{tr}\big(\pi^Y \pi_{\hat{v}^n} \pi^Y p_{XVS}(x^n,v^n,s^n) \rho_{x^n,s^n}\big)$$

$$\leq \frac{4 \cdot 2^{n(H(V|S)+3\eta)}}{q^{-k+l+2n} \cdot 2^{n(L-\eta)}} \sum_{\substack{m,\hat{m} \\ m \neq \hat{m}}} \sum_{\hat{a}} \sum_{\substack{\hat{v}^n \in \\ T_\eta^n(p_V)}} \text{tr}\big(\pi^Y \pi_{\hat{v}^n} \pi^Y \rho^{\otimes n}\big) = \frac{4 \cdot 2^{n(H(V|S)+3\eta)}}{q^{-k+l+2n} \cdot 2^{n(L-\eta)}} \sum_{\substack{m,\hat{m} \\ m \neq \hat{m}}} \sum_{\hat{a}} \sum_{\substack{\hat{v}^n \in \\ T_\eta^n(p_V)}} \text{tr}\big(\pi_{\hat{v}^n} \pi^Y \rho^{\otimes n} \pi^Y\big) \quad (33)$$

$$\leq \frac{4 \cdot 2^{n(H(V|S)+3\eta)}}{q^{-k+l+2n} \cdot 2^{n(L-\eta)}} \sum_{\substack{m,\hat{m} \\ m \neq \hat{m}}} \sum_{\hat{a}} \sum_{\substack{\hat{v}^n \in \\ T_\eta^n(p_V)}} \text{tr}\big(\pi_{\hat{v}^n} \pi^Y\big) \leq \frac{4 \cdot 2^{n(H(V|S)+3\eta)}}{q^{-k+l+2n} \cdot 2^{n(L-\eta)}} \sum_{\substack{m,\hat{m} \\ m \neq \hat{m}}} \sum_{\hat{a}} \sum_{\substack{\hat{v}^n \in \\ T_\eta^n(p_V)}} \text{tr}(\pi_{\hat{v}^n}) \quad (34)$$

$$\leq \frac{4 \cdot 2^{n(H(V|S)+3\eta)}}{q^{-k+l+2n} \cdot 2^{n(L-\eta)}} \sum_{\substack{m,\hat{m} \\ m \neq \hat{m}}} \sum_{\hat{a}} 1 \leq \frac{4 \cdot 2^{n(H(V|S)-H(Y)+H(V,Y)+12\eta)}}{q^{2n-2k-l} \cdot 2^{n(L-\eta)}} \quad (35)$$

$$\leq \exp\left\{-n\left(L - \left[\frac{k\log q}{n} - \log q + H(V|S)\right] + \log q - H(V|Y) - \frac{k\log}{n} - \frac{l\log}{n}\right)\right\} \quad (36)$$

where (33) follows from the operator inequality

$$\sum_{\substack{(v^n,s^n) \\ \in T_\eta^n(p_{VS})}} \sum_{x^n \in \mathcal{X}^n} p_{XVS}(x^n,v^n,s^n) \rho_{x^n,s^n} \leq \sum_{\substack{x^n,s^n,v^n \\ \in \mathcal{X}^n \times \mathcal{S}^n \times \mathcal{V}^n}} p_{XVS}(x^n,v^n,s^n) \rho_{x^n,s^n} = \rho^{\otimes n}$$

which follows from the positivity of the density operators, (34) follows from the operator inequalities $\pi^Y \rho^{\otimes n} \pi^Y \leq 2^{-n[H(Y)-3\eta]}\pi^Y$ [22, Property 15.1.3] and $\pi^Y \leq I$, (35) follows from $\text{tr}(\pi_{\hat{v}^n}) \leq 2^{n[H(Y|V)+3\eta]}$ for $\hat{v}^n \in T_\eta^n(p_V)$ [22, Property 15.1.2] and $|T_\eta^n(p_V)| \leq 2^{n[H(V)+3\eta]}$ and the last bound (36) follows by collating all exponents.

E. Collating Bounds and Characterization of a Single-letter achievable Rate Region

Through the above analysis, we have proved that for every choice of a finite field $\mathcal{V} = \mathcal{F}_q$ and a PMF p_{SVX} on $\mathcal{S} \times \mathcal{V} \times \mathcal{X}$, there exists a code of block length n specified through an encoder e, a decoding POVM λ consisting of q^l codewords with error probability

$$\begin{aligned}
\overline{\xi}(e,\lambda) \leq\ & \exp\left\{-n\left(\frac{k\log q}{n} - [\log q - H(V|S) + L - \eta]\right)\right\} \\
& + \exp\left\{-n\left(L - \left[\frac{k\log q}{n} - \log q + H(V|S)\right] + \log q - H(V|Y) - \frac{k\log}{n}\right)\right\} \\
& + \exp\left\{-n\left(L - \left[\frac{k\log q}{n} - \log q + H(V|S)\right] + \log q - H(V|Y) - \frac{k\log}{n} - \frac{l\log}{n}\right)\right\}
\end{aligned}$$

if $L \geq \eta > 0$. By choosing $L \triangleq \frac{k\log q}{n} - \log q + H(V|S) - 4\eta$ we can guarantee $\overline{\xi}(e,\lambda) \leq 3\exp\{-n\eta\}$ if

$$\frac{k\log q}{n} - \log q + H(V|S) > 5\eta > 0 \text{ and } \frac{(k+l)\log q}{n} < \log q - H(V|Y) \quad (37)$$

where are information quantities are computed with respect to the state defined in (7). We therefore choose

$$\frac{k\log q}{n} = \log q - H(V|S) + 5\eta \text{ and } \frac{l\log q}{n} > H(V|S) - H(V|Y) - 5\eta = I(V;Y) - I(V;S) - 5\eta \quad (38)$$

and guarantee $\overline{\xi}(e,\lambda) \leq 3\exp\{-n\eta\}$. This completes the proof. □

APPENDIX A
CHARACTERIZATION OF THE QUANTUM STATES IN EVALUATION OF INFORMATION QUANTITIES FOR EX. 1

Consider Ex. 1 for $\theta \in (0, \frac{\pi}{2})$. In this appendix, we provide characterization of the quantum state in (1) for the choice $\mathcal{U}_1 = \mathcal{U}_2 = \{0,1\}$, $p_{U_j|S_j}(1|0) = p_{U_j|S_j}(0|1) = \tau = 1 - p_{U_j|S_j}(0|0) = 1 - p_{U_j|S_j}(1|1)$ and $X_j = U_j \oplus S_j$ for $j \in [2]$, where $\oplus$ denotes addition mod-2. The characterizations below enable us compute the information quantities and thereby quantify

the upper bound on the sum rate achievable via IID random codes. The latter is stated in our discussion prior to Sec. III-C. For the choice of parameters stated earlier, the quantum state in (1) is

$$\sigma^{YS_1S_2X_1X_2U_1U_2} = \sum_{s_1,s_2} \frac{\tau(1-\tau)}{4} \Big[\mathbb{1}_{\{s_1 \oplus s_2 = 0\}} |1\rangle\langle 1| + \mathbb{1}_{\{s_1 \oplus s_2 = 1\}} |v_\theta\rangle\langle v_\theta| \Big] \otimes |s_1\ s_2\rangle\langle s_1\ s_2| \otimes \begin{bmatrix} |0\ 1\ s_1\ 1 \oplus s_2\rangle\langle 0\ 1\ s_1\ 1 \oplus s_2| + \\ |1\ 0\ 1 \oplus s_1\ s_2\rangle\langle 1\ 0\ 1 \oplus s_1\ s_2| \end{bmatrix}$$

$$+ \sum_{s_1,s_2} \Big[\mathbb{1}_{\{s_1 \oplus s_2 = 0\}} |0\rangle\langle 0| + \mathbb{1}_{\{s_1 \oplus s_2 = 1\}} |v_\theta^\perp\rangle\langle v_\theta^\perp| \Big] \otimes |s_1\ s_2\rangle\langle s_1\ s_2| \otimes \begin{bmatrix} \frac{(1-\tau)^2}{4} |0\ 0\ s_1\ s_2\rangle\langle 0\ 0\ s_1\ s_2| + \\ \frac{\tau^2}{4} |1\ 1\ 1 \oplus s_1\ 1 \oplus s_2\rangle\langle 1\ 1\ 1 \oplus s_1\ 1 \oplus s_2| \end{bmatrix}.$$

Partial tracing over the appropriate component systems, we have

$$\sigma^{S_1S_2U_1U_2} = \sum_{s_1,s_2} \frac{\tau(1-\tau)}{4} \left(|s_1\ s_2\ 1 \oplus s_1\ s_2\rangle\langle s_1\ s_2\ 1 \oplus s_1\ s_2| + |s_1\ s_2\ s_1\ 1 \oplus s_2\rangle\langle s_1\ s_2\ s_1\ 1 \oplus s_2| \right)$$

$$+ \sum_{s_1,s_2} \frac{\tau^2}{4} |s_1\ s_2\ 1 \otimes s_1\ 1 \oplus s_2\rangle\langle s_1\ s_2\ 1 \otimes s_1\ 1 \oplus s_2| + \sum_{s_1,s_2} \frac{(1-\tau)^2}{4} |s_1\ s_2\ s_1\ s_2\rangle\langle s_1\ s_2\ s_1\ s_2| \text{ implying}$$

$$\sigma^{S_jU_j} = \sum_{s_j} \frac{\tau(1-\tau)+\tau^2}{2} |s_j\ 1 \oplus s_j\rangle\langle s_j\ 1 \oplus s_j| + \sigma^{S_jU_j} = \sum_{s_j} \frac{\tau(1-\tau)+(1-\tau)^2}{2} |s_j\ s_j\rangle\langle s_j\ s_j|$$

$$= \frac{\tau}{2} |0\ 1\rangle\langle 0\ 1| + \frac{\tau}{2} |1\ 0\rangle\langle 1\ 0| + \frac{1-\tau}{2} |0\ 0\rangle\langle 0\ 0| + \frac{1-\tau}{2} |1\ 1\rangle\langle 1\ 1| \text{ for } j \in [2] \text{ and}$$

$$\sigma^{YU_1U_2} = \sum_{s_1,s_2} \frac{\tau(1-\tau)}{4} \Big[\mathbb{1}_{\{s_1 \oplus s_2 = 0\}} |1\rangle\langle 1| + \mathbb{1}_{\{s_1 \oplus s_2 = 1\}} |v_\theta\rangle\langle v_\theta| \Big] \otimes \Big[|s_1\ 1 \oplus s_2\rangle\langle s_1\ 1 \oplus s_2| + |1 \oplus s_1\ s_2\rangle\langle 1 \oplus s_1\ s_2| \Big]$$

$$+ \sum_{s_1,s_2} \Big[\mathbb{1}_{\{s_1 \oplus s_2 = 0\}} |0\rangle\langle 0| + \mathbb{1}_{\{s_1 \oplus s_2 = 1\}} |v_\theta^\perp\rangle\langle v_\theta^\perp| \Big] \otimes \Big[\frac{(1-\tau)^2}{4} |s_1\ s_2\rangle\langle s_1\ s_2| + \frac{\tau^2}{4} |1 \oplus s_1\ 1 \oplus s_2\rangle\langle 1 \oplus s_1\ 1 \oplus s_2| \Big]$$

$$= \frac{2\tau(1-\tau)}{4} |1\rangle\langle 1| \otimes (|0\ 1\rangle\langle 0\ 1| + |1\ 0\rangle\langle 1\ 0|) + \frac{2\tau(1-\tau)}{4} |v_\theta\rangle\langle v_\theta| \otimes (|0\ 0\rangle\langle 0\ 0| + |1\ 1\rangle\langle 1\ 1|)$$

$$+ \Big[\frac{(1-\tau)^2+\tau^2}{4} \Big] \Big[|0\rangle\langle 0| \otimes (|0\ 0\rangle\langle 0\ 0| + |1\ 1\rangle\langle 1\ 1|) + |v_\theta^\perp\rangle\langle v_\theta^\perp| \otimes (|0\ 1\rangle\langle 0\ 1| + |1\ 0\rangle\langle 1\ 0|) \Big] \text{ implying}$$

$$= \frac{(\epsilon |1\rangle\langle 1| + (1-\epsilon) |v_\theta^\perp\rangle\langle v_\theta^\perp|)}{4} \otimes (|0\ 1\rangle\langle 0\ 1| + |1\ 0\rangle\langle 1\ 0|) + \frac{(\epsilon |v_\theta\rangle\langle v_\theta| + (1-\epsilon) |0\rangle\langle 0|)}{4} \otimes (|0\ 0\rangle\langle 0\ 0| + |1\ 1\rangle\langle 1\ 1|) \text{ implying}$$

$$\sigma^Y = \frac{\epsilon}{2} |1\rangle\langle 1| + \frac{(1-\epsilon)}{2} |v_\theta^\perp\rangle\langle v_\theta^\perp| + \frac{\epsilon}{2} |v_\theta\rangle\langle v_\theta| + \frac{(1-\epsilon)}{2} |0\rangle\langle 0|, \quad \sigma^{U_1U_2} = \frac{1}{4} \sum_{u_1,u_2} |u_1\ u_2\rangle\langle u_1\ u_2|$$

where $\epsilon = 2\tau(1-\tau)$.

APPENDIX B
PROOF OF PROP. 2 : BOUND ON T_2

We begin by defining events

$$\mathcal{F}_1 \triangleq \left\{ \begin{smallmatrix} V_j^n(a_j,m_j)=v_j^n:j\in[2],\underline{S}^n=\underline{s}^n, \\ W^n(\hat{a},\hat{\underline{m}})=\hat{w}^n, W^n(a_\oplus,\underline{m})=w^n \end{smallmatrix} \right\}, \mathcal{F}_2 \triangleq \left\{ \begin{smallmatrix} A_j(m_j,s_j^n) \\ =a_j:j\in[2] \end{smallmatrix} \right\} \cap \mathcal{E}$$

$$\mathcal{F}_3 \triangleq \left\{ \begin{smallmatrix} X_j^n(m_j,s_j^n) \\ =x_j^n:j\in[2] \end{smallmatrix} \right\}, \beta \triangleq \left\{ \begin{smallmatrix} (v_j^n,s_j^n)\in T_\eta(p_{V_jS_j}), \\ w^n=v_1^n \oplus_q v_2^n, \end{smallmatrix} \right\}, \omega \triangleq \left\{ \begin{smallmatrix} w^n \in T_\eta(p_W) \\ \hat{w}^n \in T_\eta(p_W) \end{smallmatrix} \right\}.$$

From the definition of $a_\oplus$ and the distribution of the random code, we have

$$P(\mathcal{F}_1 \cap \mathcal{F}_2 \cap \mathcal{F}_3) \mathbb{1}_\beta \mathbb{1}_\omega \le P(\mathcal{F}_1) P(\mathcal{F}_3 | \mathcal{F}_1 \cap \mathcal{F}_2) \mathbb{1}_\beta \mathbb{1}_\omega \tag{39}$$

$$\le \frac{1}{q^{3n}} \mathrm{p}_{\underline{S}}(\underline{s}^n) \prod_{j=1}^2 p_{X_j|V_jS_j}^n(x_j^n|v_j^n,s_j^n) \mathbb{1}_\beta \mathbb{1}_\omega \tag{40}$$

$$\le \frac{2^{n(H(V_1|S_1)+2\eta)}}{q^{3n}2^{-n(H(V_2|S_2))}} \mathrm{p}_{\underline{S}}(\underline{s}^n) \prod_{j=1}^2 p_{X_jV_j|S_j}^n(x_j^n,v_j^n|s_j^n) \mathbb{1}_\beta \mathbb{1}_\omega \tag{41}$$

$$= \Theta p_{SVX}^n(\underline{s}^n, \underline{v}^n, \underline{x}^n) \mathbb{1}_\beta \mathbb{1}_\omega \text{ where } \Theta \triangleq \frac{2^{n(H(V_1|S_1)+2\eta)}}{q^{3n}2^{-n(H(V_2|S_2))}} \tag{42}$$

where (40) folows from the property of a uniformly distributed UCC proven in [2, Lemma 9 in Appendix E], (41) follows from the presence of $\mathbb{1}_\beta$ in the factors. The term corresponding to T_2 from (6), (5) in $\mathbb{E}\{\xi(\underline{e}, \lambda)\}$ is

$$
\sum_{\underline{s}^n} p_{\underline{S}}(\underline{s}^n) \mathbb{E}\{T_2\} = \sum_{\substack{a_1, a_2, \underline{v}^n, \underline{s}^n, \underline{x}^n, w^n \\ (\hat{a}, \hat{\underline{m}}) \neq (a_\oplus, \underline{m}), \hat{w}^n}} \operatorname{tr}\left(\pi^Y \pi_{\hat{w}^n} \pi^Y \rho_{\underline{x}^n, \underline{s}^n}\right) P\left(\bigcap_{k=1}^3 \mathcal{F}_k\right) \mathbb{1}_\beta \mathbb{1}_\omega
$$

$$
\leq \Theta \sum_{\substack{a_1, a_2, w^n, \hat{w}^n \\ (\hat{a}, \hat{\underline{m}}) \neq (a_\oplus, \underline{m})}} \mathbb{1}_\omega \operatorname{tr}\left(\pi^Y \pi_{\hat{w}^n} \pi^Y \sum_{\underline{v}^n, \underline{s}^n, \underline{x}^n} p_{\underline{SVX}}^n(\underline{s}^n, \underline{v}^n, \underline{x}^n) \rho_{\underline{x}^n, \underline{s}^n} \mathbb{1}_\beta\right) \tag{43}
$$

$$
\leq \Theta \sum_{\substack{a_1, a_2, w^n, \hat{w}^n \\ (\hat{a}, \hat{\underline{m}}) \neq (a_\oplus, \underline{m})}} \mathbb{1}_\omega \operatorname{tr}\left(\pi^Y \pi_{\hat{w}^n} \pi^Y p_W^n(w^n) \rho_{w^n}\right) \tag{44}
$$

$$
\leq \Theta \sum_{\substack{a_1, a_2, \hat{w}^n \\ (\hat{a}, \hat{\underline{m}}) \neq (a_\oplus, \underline{m})}} \mathbb{1}_\omega \operatorname{tr}\left(\pi^Y \pi_{\hat{w}^n} \pi^Y \rho^{\otimes n}\right) = \Theta \sum_{\substack{a_1, a_2, \hat{w}^n \\ (\hat{a}, \hat{\underline{m}}) \neq (a_\oplus, \underline{m})}} \mathbb{1}_\omega \operatorname{tr}\left(\pi_{\hat{w}^n} \pi^Y \rho^{\otimes n} \pi^Y\right)
$$

$$
\leq \frac{\Theta}{2^{nH(Y)_\sigma}} \sum_{\substack{a_1, a_2, \hat{w}^n \\ (\hat{a}, \hat{\underline{m}}) \neq (a_\oplus, \underline{m})}} \mathbb{1}_\omega \operatorname{tr}\left(\pi_{\hat{w}^n} \pi^Y\right) = \frac{\Theta q^{k_1 + 2k_2} 2^{n(H(Y,W)_\sigma + 6\eta)}}{2^{nH(Y)_\sigma} q^{-l_1 - l_2}} \tag{45}
$$

$$
\leq \exp\left\{-n\left(3\log q \; - \; H(W|Y)_\sigma + \sum_{i=1}^2 H(U_i|S_i)_\sigma - \frac{k_1 + 2k_2 + l_1 + l_2}{n}\log q - 8\eta\right)\right\}
$$

where (43) follows by substituting the upper bound (42), (44) follows from averaging the density operators and the fact that density operators are positive, (45) follows again by averaging and cyclicity of the trace, (45) follows from the operator inequality $\pi^Y \rho^{\otimes n} \pi^Y \leq 2^{-n(H(Y)_\sigma - 2\eta)} \pi^Y$ and the fact that for typical $\hat{w}^n$, we have $\operatorname{tr}\left(\pi_{\hat{w}^n} \pi^Y\right) \leq \operatorname{tr}(\pi_{\hat{w}^n}) \leq 2^{nH(Y|W)_\sigma + 2n\eta}$ and the last inequality follows by substituting the value of Θ from (42). We obtained the above bound on $\frac{k_1 + 2k_2 + l_1 + l_2}{n}\log q$ since we have assumed $k_2 \geq k_1$. In general, we obtain the bound

$$
\sum_{\underline{s}^n} p_{\underline{S}}(\underline{s}^n) \mathbb{E}\{T_2\} \leq \exp\left\{-n\left(3\log q \; - \; H(W|Y)_\sigma + \sum_{i=1}^2 H(U_i|S_i)_\sigma - \frac{k_1 + k_2 + \max\{k_1, k_2\} + l_1 + l_2}{n}\log q - 8\eta\right)\right\}
$$
