Abstract

In this work, we study the problem of monotone non-submodular maximization with partition matroid constraint. Although a generalization of this problem has been studied in literature, our work focuses on leveraging properties of partition matroid constraint to (1) propose algorithms with theoretical bound and efficient query complexity; and (2) provide better analysis on theoretical performance guarantee of some existing techniques. We further investigate those algorithms' performance in two applications: Boosting Influence Spread and Video Summarization. Experiments show our algorithms return comparative results to the state-of-the-art algorithms while taking much fewer queries.

1 Introduction

Maximizing classes of set functions, generalizing submodular functions, has emerged recently due to its wide range applications in real-world problems. Among those works, non-submodular maximization subject to cardinality constraint was studied the most extensively, including but not limited to [Bian *et al.*, 2017; Das and Kempe, 2011; Qian *et al.*, 2018; Kuhnle *et al.*, 2018].

However, cardinality constraint may not be sufficient to capture some natural requirements of various applications. For example, in many viral marketing campaigns, it is important to ensure the diversity and fairness among different ethnics and genders. These applications aim to distribute budget to feed information fairly among different groups of users while guaranteeing to maximize the influence spread in the network. Another example is data summarization. In many situations, a large data may be formed by elements of various classes. The problem, thus, aims to find a representative subset to cover the dataset's content as much as possible while imposing a constraint that the subset should contain a number of members of each class to guarantee diversity.

Motivated by those observation, we study the following problem: Given a ground set V , a non-negative monotone function $f : 2^V \rightarrow \mathbb{R}^{\geq}$; let V_1, \dots, V_k be a collection of disjoint subsets forming V (i.e. $V = V_1 \uplus \dots \uplus V_k$), and b_1, \dots, b_k be k integers that $1 \leq b_i \leq |V_i| \forall i \in [k]$. The

problem asks for:

$$\max_{S \subseteq V} \{f(S) : |S \cap V_i| \leq b_i \forall i \in [k]\} \quad (\text{MAXMP})$$

MAXMP is formally represented as monotone non-submodular maximization with partition matroid constraint. This constraint is a special case of matroid constraint and generalizes cardinality constraint.

Non-submodular maximization beyond cardinality constraint was only received attention recently. The most recent works are [Chen *et al.*, 2018] and [Gatmiry and Gomez-Rodriguez, 2018], in which they studied the performance guarantee of GREEDY or RESIDUAL GREEDY (RESGREEDY) [Buchbinder *et al.*, 2014] on monotone non-submodular maximization subject to matroid constraint. However, those algorithms requires $O(nK)$ queries of f (K is a rank of a matroid), which may not be desirable in practice. Researchers [Mirzasoleiman *et al.*, 2016; Badanidiyuru and Vondrák, 2014; Kuhnle *et al.*, 2018] have sought ways to speed up the GREEDY algorithm. Unfortunately, these approaches were only for cardinality constraint; or relied upon the submodularity of f .

To our knowledge, there exists no specific work dedicating for non-submodular maximization subject to partition matroid constraint. That leaves us open questions on: (1) With partition matroid, does there exist an algorithm with a better ratio or can we improve the ratio of the existing algorithms, whose performance guarantees have been proven with a matroid constraint? (As partition matroid is a special case of matroid constraint, perhaps we can get a tighter ratio if we only considered the partition matroid.) (2) Can we leverage partition matroid properties to devise approximation algorithms with more query-efficient?

Our Contribution. In this work, we focus on answering those two above questions. First, to quantify the non-submodularity of a function, we introduce Partition Matroid Curvature α and Partition Matroid Diminishing-Return ratio γ . These two quantities are derived from a same concept with the diminishing-return ratio [Lehmann *et al.*, 2006; Bogunovic *et al.*, 2017] and generalized curvature [Bian *et al.*, 2017; Conforti and Cornuéjols, 1984; Iyer *et al.*, 2013] but have more relaxed requirement.

Our main contribution is to introduce a novel approximation algorithm, named PROB, with approximation ratio of $(1/\gamma' - 1 + \alpha')(1 - 1/\Theta(\max_{i \in [k]} |V_i|)) + 1$ where γ' and α'

are non-trivial and obtainable bounds of γ and α . PROB’s novelty lies in a random process of selecting a new element, in which the algorithm introduces a new probability distribution among non-selected elements. That probability distribution is a key for PROB to obtain its ratio. Furthermore, by utilizing a sampling technique to reduce searching space, we propose FASTPROB, an algorithm improving from PROB with efficient query complexity of $O(n \ln^2 \sum_{i \in [k]} b_i)$.

Moreover, we re-investigate theoretical performance of two existing techniques, GREEDY and THRESHOLD GREEDY (THRGREEDY). We proved that: with partition matroid constraint, GREEDY can obtain a ratio of $\min(\alpha/(1 - (1 - \alpha\gamma/\sum_{i \in [k]} b_i)^{\min_{i \in [k]} b_i}), (1 + \gamma\alpha)/\gamma)$, which - in comparing with existing work of [Friedrich *et al.*, 2019] in matroid constraint - has its own advantage in some certain range of non-submodular quantification parameters.

Finally, we investigate our algorithms’ performance on two applications of MAXMP: Boosting Influence Spread and Video Summarization. We provide bounds on the objective functions’ partition matroid curvature and diminishing ratio to have a better insight on theoretical guarantees of our algorithms. Experimental results show our algorithms return comparable solutions to the state-of-the-art techniques while totally outperform them in the number of queries.

2 Related Work

Quantifying non-submodularity. To bound how close a function to submodularity, three most popular quantities in literature are: (1) weakly submodular ratio; (2) diminishing return ratio; and (3) generalized curvature. Weakly submodular ratio, denoted as γ_s , was first introduced by [Das and Kempe, 2011] and further used by [Elenberg *et al.*, 2017; Qian *et al.*, 2015; Chen *et al.*, 2018]. γ_s is defined as the maximum value in range $[0, 1]$ such that $f(S \cup T) - f(S) \leq \frac{1}{\gamma_s} \sum_{e \in T \setminus S} (f(S \cup \{e\}) - f(S))$ for all $S, T \subseteq V$. Diminishing-return (DR) ratio γ_d [Bogunovic *et al.*, 2018; Lehmann *et al.*, 2006; Qian *et al.*, 2018; Kuhnle *et al.*, 2018] is defined as the largest value in range $[0, 1]$ that guarantees $f(T \cup \{e\}) - f(T) \leq \frac{1}{\gamma_d} (f(S \cup \{e\}) - f(S))$ for all $S \subseteq T \subseteq V$ and $e \notin T$. γ_d was proven to be at most the value of γ_s [Kuhnle *et al.*, 2018]. General curvature α_c [Bian *et al.*, 2017; Conforti and Cornuéjols, 1984; Iyer *et al.*, 2013], on another hand, is the smallest number in $[0, 1]$ that $f(T \cup \{e\}) - f(T) \geq (1 - \alpha_c)(f(S \cup \{e\}) - f(S))$.

In this work, we adapt DR-ratio and curvature but with more relaxed requirements. To be specific, instead of requiring those quantities applicable for all sets, we narrow down the collection of subsets $S \subseteq T$ that need to satisfy those properties to $|(T \setminus S) \cap V_i| \leq b_i$ for all $i \in [k]$. If considering size constraint, this relaxation is corresponding to the definition of Greedy DR-ratio and Greedy Curvature [Bian *et al.*, 2017; Kuhnle *et al.*, 2018]. Not only this relaxation is sufficient to bound our approximation ratios; but also it helps us obtaining meaningful bounds of those quantities in the MAXMP’s applications of our experiments.

Beyond Cardinality Constraint. *Non-submodular* max-

imization beyond cardinality constraint has received attention recently. [Chen *et al.*, 2018] was the first one brought up the concept of non-submodular maximization subject to matroid constraint. In this work, the author proved that RESGREEDY can obtain the ratio of $(1 + \frac{1}{\gamma_s})^2$. [Gatmiry and Gomez-Rodriguez, 2018] then proved GREEDY is able to obtain a ratio of $\frac{\sqrt{\gamma_s K} + 1}{0.4\gamma_s}$ and $1 + 1/\gamma_d$.

In *submodular* maximization, the study beyond cardinality constraint is too extensive to give a comprehensive overview. Due to space limit, we only go over representative works; and refer readers to comprehensive discussion on [Calinescu *et al.*, 2011; Buchbinder *et al.*, 2019; Friedrich *et al.*, 2019].

For decades, GREEDY- with ratio of 2 [Cornnejoles *et al.*, 1977] - has been considered as the best algorithm for monotone submodular maximization subject to matroid constraint. This was up until [Calinescu *et al.*, 2011] introduced a concept of multilinear extension of submodular functions to devise a $1/(1 - 1/e)$ algorithm. However, their expensive complexity remains a significant bottleneck to make the algorithm applicable; and how to reduce or improve it is still an intriguing open question for future research. The newest breakthrough is of [Buchbinder *et al.*, 2019], who devised an algorithm, namely SPLITGROW, with a ratio of $1/0.5008$ and $\tilde{O}(nK^2 + KT)$ complexity - where T is the complexity to find a maximum weight perfect matching in a bipartite graph with $2K$ vertices.

The most recent work on partition matroid, to our knowledge, is of [Friedrich *et al.*, 2019], in which the authors proved GREEDY is able to obtain a ratio of $\alpha_c/(1 - \exp[-\alpha_c \frac{\min_{i \in [k]} b_i}{\sum_{i \in [k]} b_i}])$. We generalizes this work to non-submodular objective function by providing analysis that GREEDY can obtain a ratio of $\min(\alpha/(1 - (1 - \alpha\gamma/\sum_{i \in [k]} b_i)^{\min_{i \in [k]} b_i}), 1/\gamma + \alpha)$. If only considering submodular objective function, our ratio has an advantage that it is bounded by $1/\gamma + \alpha$. Therefore, its ratio does not degrade when the input is formed by many partitions.

We also provide approximation ratio of THRGREEDY. THRGREEDY has been studied by [Kuhnle *et al.*, 2018] in the problem of monotone non-submodular maximization with cardinality constraint. Since partition matroid generalizes cardinality constraint, our analysis techniques are totally different to [Kuhnle *et al.*, 2018]. If projecting our ratio to cardinality constraint, our ratio is better than the one of [Kuhnle *et al.*, 2018], which is $1/(1 - e^{-\gamma_d \gamma_s (1 - \epsilon)} - \epsilon)$. The keys help us obtain a better ratio are (1) γ_s is not necessary to bound inequality between obtained solutions and the optimal solution; and (2) we utilizes the general curvature to tighten the inequality equations, thus our ratio becomes better if the curvature moves away from the trivial value 1.

3 Definitions and Notations

Given a set function f , a set S and $e \notin S$, denote $\Delta_e f(S) := f(S \cup \{e\}) - f(S)$.

Given the partition matroid constraint of MAXMP, including $V = V_1 \uplus \dots \uplus V_k$ and b_1, \dots, b_k , denote $b = \sum_{i \in [k]} b_i$;

$n = |V|$; $n_i = |V_i| \forall i \in [k]$. Let $\bar{n} = \max_{i \in [k]} n_i$ and $\hat{b} = \min_{i \in [k]} b_i$. A set $S \subseteq V$ is called a *maximal* set to the constraint iff $|S \cap V_i| = b_i \forall i \in [k]$.

Definition 1. Given an instance of MAXMP, including $V = V_1 \uplus \dots \uplus V_k$; $\{b_1, \dots, b_k\}$ and f . The **Partition Matroid (PM) Diminishing Return** ratio γ of the objective function f is defined as the maximum value in $[0, 1]$ that guarantees $\Delta_e f(T) \leq \frac{1}{\gamma} \Delta_e f(S)$ for any $S \subseteq T$ that $|(T \setminus S) \cap V_i| \leq b_i \forall i \in [k]$ and $e \in V \setminus T$.

Definition 2. Given an instance of MAXMP, including $V = V_1 \uplus \dots \uplus V_k$; $\{b_1, \dots, b_k\}$ and f . The **Partition Matroid (PM) Curvature** α of the objective function f is defined as the minimum value in $[0, 1]$ that guarantees $\Delta_e f(T) \geq (1 - \alpha) \Delta_e f(S)$ for any $S \subseteq T$ that $|(T \setminus S) \cap V_i| \leq b_i \forall i \in [k]$ and $e \in V \setminus T$.

It is unknown in the literature on how hard it is to obtain exact values of quantities quantifying non-submodularity. γ and α are not exception either. Fortunately, for some applications, we can obtain non-trivial bounds of γ and α , which can help assess approximation ratios of our algorithms. We denote γ' as a lower bound of γ , e.g. $\gamma \geq \gamma' \geq 0$; and α' as an upper bound of α , e.g. $\alpha \leq \alpha' \leq 1$.

W.l.o.g, we assume the objective function f is *normalized*, i.e. $f(\emptyset) = 0$, and $b_i \leq n_i$ for all $i \in [k]$. In our algorithms' analysis, we denote S^* as an optimal solution, i.e. $f(S^*) = \max_{S: |S \cap V_i| \leq b_i} f(S)$.

4 PROB and FASTPROB Algorithms

In this section, we describe PROB, a randomized algorithm with approximation ratio of $(1/\gamma' - 1 + \alpha')(1 - 1/O(\bar{n})) + 1$. Pseudocode of PROB is presented by Alg. 1. In general, PROB works in rounds, and at each round, one member of a group V_i is added to the obtained solution S if $|S \cap V_i| < b_i$. The key for PROB to obtain efficient performance guarantee lies in a random process, which introduces a probability distribution, defined locally for each group, to select a new element of each group to add into the obtained solution (line 6 Alg. 1). This random process allows us to construct a sequence of maximal sets in order to form a recursive relationship among changes on the f 's values of the obtained solutions, which is critical to bound PROB's approximation ratio.

Theorem 1. PROB obtains a $(\frac{1}{\gamma'} + \alpha' - 1)(1 - \frac{1}{\bar{n}+2}) + 1$ -approximation solution and has query complexity of $O(\sum_{i \in [k]} n_i b_i)$.

Proof. Denote $\beta = (\frac{1}{\gamma'} + \alpha' - 1)(1 - \frac{1}{\bar{n}+2})$ and S_1, \dots, S_b as a sequence of obtained solution by PROB. We prove the approximation ratio of PROB by constructing a sequence of maximal sets S_0^*, \dots, S_b^* that satisfies the following properties: (1) $S_0^* = S^*$ and $S_b^* = S_b$; (2) $S_t \subset S_{t+1}^*$ for all $t = 0, \dots, b-1$ and $S_b = S_b^*$; (3) $f(S_t^*) - f(S_{t+1}^*) \leq \beta E[f(S_{t+1}) - f(S_t)]$

Algorithm 1 PROB

Input $V = V_1 \uplus \dots \uplus V_k$; b_1, \dots, b_k ; f ; γ' , α'

- 1: $I = [k]$; $S_0 = \emptyset$; $t = 0$
- 2: **while** $I \neq \emptyset$ **do**
- 3: **for** each $i \in I$ **do**
- 4: $a = \lceil \frac{|V_i \setminus S_t| + 1}{1 - \gamma'(1 - \alpha')} \rceil - 1$
- 5: $e_t = \text{select from } V_i \setminus S_t \text{ with probability}$
 $\frac{(\Delta_{e_t} f(S_t))^a}{\sum_{u \in V_i \setminus S_t} (\Delta_u f(S_t))^a}$
- 6: $S_{t+1} = S_t \cup \{e_t\}$; $t = t + 1$
- 7: **if** $|S_t \cap V_i| \geq b_i$ **then** $I = I \setminus \{i\}$

Return S_b

for $t = 0 \rightarrow b - 1$. Then, we have:

$$\begin{aligned} f(S^*) &= \sum_{t=0}^{b-1} \left(f(S_t^*) - f(S_{t+1}^*) \right) + f(S_b^*) \\ &\leq \beta \sum_{t=0}^{b-1} E[f(S_{t+1}) - f(S_t)] + f(S_b) \leq (\beta + 1)E[f(S_b)] \end{aligned}$$

To construct the sequence, starting with $S_0^* = S^*$, for each $t = 1, \dots, b-1$, S_{t+1}^* is formed from S_t^* , S_t and e_t as follows: Let i be the index being considered at the **for** loop (line 3 Alg. 1); and e_t will be added into S_t . Since $S_t \subset S_t^*$ and $|S_t \cap V_i| < b_i$, $(S_t^* \setminus S_t) \cap V_i \neq \emptyset$. Let e' be any arbitrary element in $(S_t^* \setminus S_t) \cap V_i$. S_{t+1}^* is set as follows:

- If $e_t \in (S_t^* \setminus S_t) \cap V_i$, $S_{t+1}^* := S_t^*$.
- Otherwise, let $S_{t+1}^* := S_t^* \setminus \{e'\} \cup \{e_t\}$.

Denote $\rho_e = \Delta_e f(S_t)$ and $\text{Pr}_e = \frac{\rho_e^a}{\sum_{v \in V_i \setminus S_t} \rho_v^a}$ (i.e. Pr_e is probability e is selected). We have:

$$E[f(S_t^*) - f(S_{t+1}^*)] \tag{1}$$

$$= \sum_{u \in V_i \setminus S_t^*} \left[f(S_t^*) - f(S_t^* \setminus \{e'\} \cup \{u\}) \right] \times \text{Pr}_u \tag{2}$$

$$= \sum_{u \in V_i \setminus S_t^*} \left[\Delta_{e'} f(S_t^* \setminus \{e'\}) - \Delta_u f(S_t^* \setminus \{e'\}) \right] \times \text{Pr}_u \tag{3}$$

$$\leq \sum_{u \in V_i \setminus S_t^*} \left[\frac{1}{\gamma} \rho_{e'} - (1 - \alpha) \rho_u \right] \times \text{Pr}_u \tag{4}$$

$$= \frac{1}{\gamma} \sum_{u \in V_i \setminus S_t^*} \frac{\rho_{e'} \rho_u^a}{\sum_{v \in V_i \setminus S_t} \rho_v^a} - (1 - \alpha) \sum_{u \in V_i \setminus S_t^*} \rho_u \text{Pr}_u \tag{5}$$

$$\leq \frac{1}{\gamma(a+1)} \sum_{u \in V_i \setminus S_t^*} \frac{\rho_{e'}^{a+1} + a \rho_u^{a+1}}{\sum_{v \in V_i \setminus S_t} \rho_v^a} \tag{6}$$

$$- (1 - \alpha) \sum_{u \in V_i \setminus S_t^*} \rho_u \text{Pr}_u \tag{7}$$

$$= \frac{|V_i \setminus S_t^*|}{\gamma(a+1)} \rho_{e'} \text{Pr}_{e'} + \left(\frac{1}{\gamma} \frac{a}{a+1} + \alpha - 1 \right) \sum_{u \in V_i \setminus S_t^*} \rho_u \text{Pr}_u \tag{8}$$

where Equ. (4) is from properties of γ and α ; while Equ. (7) is from AM-GM inequality.

Replacing $a = \lceil \frac{|V_i \setminus S_t| + 1}{1 - \gamma'(1 - \alpha')} \rceil - 1$, we have

$$\frac{|V_i \setminus S_t^*|}{\gamma(a + 1)} \leq \frac{|V_i \setminus S_t|}{\gamma(|V_i \setminus S_t| + 1)/(1 - \gamma'(1 - \alpha'))} \quad (9)$$

$$\leq \left(\frac{1}{\gamma'} + \alpha' - 1 \right) \left(1 - \frac{1}{\bar{n} + 1} \right) \quad (10)$$

$$\frac{1}{\gamma} \frac{a}{a + 1} + \alpha - 1 \leq \frac{1}{\gamma} \left(1 - \frac{1 - \gamma'(1 - \alpha')}{|V_i \setminus S_t| + 2} \right) + \alpha - 1 \quad (11)$$

$$\leq \left(\frac{1}{\gamma'} + \alpha' - 1 \right) \left(1 - \frac{1}{\bar{n} + 2} \right) \quad (12)$$

Therefore, combining Equ. (10), (12) to (8), we have:

$$(8) \leq \left(\frac{1}{\gamma'} + \alpha' - 1 \right) \left(1 - \frac{1}{\bar{n} + 2} \right) \mathbb{E} [f(S_{t+1}) - f(S_t)]$$

The query complexity of PROB can be trivially inferred from the algorithm's pseudocode. \square

How PROB's theoretical performance compares to existing algorithms?

Due to differences in definition of the quantities quantifying non-submodularity and how algorithms' ratios depend on them, it is no straight way to compare their ratios. For example, RESGREEDY obtains $(1 + \frac{1}{\gamma_s})^2$ -ratio [Chen *et al.*, 2018]. Although $\gamma_s \geq \gamma \geq \gamma'$, it is unclear how this ratio is compared with PROB's ratio. However, PROB has a better query complexity than RESGREEDY ($O(nb)$).

When f is submodular ($\gamma = 1$), PROB can obtain a ratio of $1 + \alpha'(1 - \frac{1}{\bar{n} + 2})$. Although PROB's ratio is still not comparable to the best ratio $(1 - 1/e)$ of [Calinescu *et al.*, 2011], their expensive complexity $O(n^8)$ remains a significant bottleneck to make their algorithm applicable in practice. In compare with the most recent work [Buchbinder *et al.*, 2019], PROB can reach a better ratio than SPLITGROW ($\frac{1}{0.5008}$) with appropriate values of α' and \bar{n} ; and PROB has much better query complexity than SPLITGROW ($O(nb^2)$).

Improve PROB's complexity

PROB's query complexity can be improved by observing that the proof of Theorem 2 can non-trivially go through if e_t is selected from a set that overlaps with $(S_t^* \setminus S_t) \cap V_i$ for all $t = 1, \dots, b$. This always works in Alg. 1 since e_t is selected from $V_i \setminus S_t$. Therefore, we can use sampling to reduce the space of selecting e_t as in Alg. 2.

We call Alg. 2 FASTPROB. The condition, which helps FASTPROB has the same ratio as PROB with probability at least $1 - \delta$, is guaranteed as stated in the following lemma.

Lemma 1. $(S_t^* \setminus S_t) \cap R_t \neq \emptyset$ for all $t = 0, \dots, b - 1$ with probability at least $1 - \delta$

Proof. We prove for each $t = 0, \dots, b - 1$, $\Pr \left[(S_t^* \setminus S_t) \cap R_t = \emptyset \right] \leq \frac{\delta}{b}$. Then using union bound, $(S_t^* \setminus S_t) \cap R_t \neq \emptyset$ for all

Algorithm 2 FASTPROB

Input $V = V_1 \uplus \dots \uplus V_k; f, \gamma', \alpha'; b_1, \dots, b_k; \delta \in [0, 1]$

- 1: $I = [k]; S_0 = \emptyset; t = 0$
- 2: **while** $I \neq \emptyset$ **do**
- 3: **for each** $i \in I$ **do**
- 4: $R_t = \text{pick min } \left(\frac{n_i - |S_t \cap V_i|}{b_i - |S_t \cap V_i|} \ln \frac{b}{\delta}, |V_i \setminus S_t| \right)$
 random elements from $V_i \setminus S_t$
- 5: $a = \lceil \frac{|R_t| + 1}{1 - \gamma'(1 - \alpha')} \rceil - 1$
- 6: $e_t = \text{select from } R_t \text{ with probability } \frac{(\Delta_{e_t} f(S_t))^\alpha}{\sum_{u \in R_t} (\Delta_u f(S_t))^\alpha}$
- 7: $S_{t+1} = S_t \cup \{e_t\}; t = t + 1$
- 8: **if** $|S_t \cap V_i| \geq b_i$ **then** $I = I \setminus \{i\}$

Return S_b

$t = 0, \dots, b - 1$ with probability at least $1 - \delta$. This probability is trivial if $R_t = V_i \setminus S_t$. If $|R_t| = \frac{n_i - |S_t \cap V_i|}{b_i - |S_t \cap V_i|} \ln \frac{b}{\delta}$, since $S_t \subseteq S_t^*$, $|(S_t^* \setminus S_t) \cap V_i| = b_i - |S_t \cap V_i|$. We have:

$$\begin{aligned} \Pr \left[(S_t^* \setminus S_t) \cap R_t = \emptyset \right] &\leq \left(\frac{|V_i \setminus S_t^*|}{|V_i \setminus S_t|} \right)^{|R_t|} \\ &= \left(1 - \frac{|(S_t^* \setminus S_t) \cap V_i|}{|V_i \setminus S_t|} \right)^{|R_t|} \leq e^{-|R_t| \frac{b_i - |S_t \cap V_i|}{n_i - |S_t \cap V_i|}} \leq \frac{\delta}{b} \end{aligned}$$

which completes the proof. \square

Theorem 2. FASTPROB obtains a $\left(\frac{1}{\gamma'} + \alpha' - 1 \right) \left(1 - \frac{1}{\bar{n} + 2} \right) + 1$ -approximation solution with probability at least $1 - \delta$ and has query complexity of $O(n \ln b \ln \frac{b}{\delta})$.

Proof. Majority proof of FASTPROB's approximation ratio overlaps with the proof of PROB. Due to space limit and for the sake of completeness, we provide the proof of FASTPROB's ratio in Appendix A.

In term of query complexity, it is trivial that the number of queries of FASTPROB is $\sum_{t=0}^{b-1} |R_t|$. We have:

$$\sum_{t=0}^{b-1} |R_t| \leq \sum_{i \in [k]} \sum_{j=0}^{b_i-1} \frac{n_i - j}{b_i - j} \ln \frac{b}{\delta} \quad (13)$$

$$= \ln \frac{b}{\delta} \left(\sum_{i \in [k]} b_i + (n_i - b_i) \sum_{j=0}^{b_i-1} \frac{1}{b_i - j} \right) \quad (14)$$

$$\leq b \ln \frac{b}{\delta} + \ln \frac{b}{\delta} \sum_{i \in [k]} (n_i - b_i) \ln b_i \leq O(\ln \frac{b}{\delta} \sum_{i \in [k]} n_i \ln b_i) \quad (15)$$

$$\leq O(n \ln \frac{b}{\delta} \ln \sum_{i \in [k]} \frac{n_i b_i}{n}) \leq O(n \ln b \ln \frac{b}{\delta}) \quad (16)$$

where Equ. (16) is from the fact that $\log x$ is a concave function, so $\sum_i \alpha_i \log x_i \leq \log \alpha_i x_i$ if $\sum_i \alpha_i = 1$; and $\sum_{i \in [k]} \frac{n_i b_i}{n} \leq \sum_{i \in [k]} \frac{n_i}{n} \sum_{i \in [k]} b_i = b$. \square

Algorithm 3 GREEDY

Input $V = V_1 \uplus \dots \uplus V_k; f; b_1, \dots, b_k$

- 1: $I = [k]; S_0 = \emptyset; t = 0$
- 2: **while** $I \neq \emptyset$ **do**
- 3: $e, i = \operatorname{argmax}_{e \in V_i \setminus S_t; i \in I} \Delta_e f(S_t)$
- 4: $S_{t+1} = S_t \cup \{e\}; t = t + 1$
- 5: **if** $|S_t \cap V_i| \geq b_i$ **then** $I = I \setminus \{i\}$

Return S_b

5 GREEDY-like Algorithms

We re-study the theoretical performance guarantee of two algorithms, GREEDY and THRGREEDY. Our analysis provides better ratios of GREEDY than existing works on matroid constraint [Gatmiry and Gomez-Rodriguez, 2018] or submodular objective function [Friedrich *et al.*, 2019].

In general, GREEDY works in round and at each round, an element of maximal marginal gain, whose addition does not violate partition matroid constraint, is added to the obtained solution. The algorithm terminates when the obtained solution is maximal. THRGREEDY, on the other hand, works by always keeping a threshold τ , which bounds the maximum marginal gain to the objective by any non-selected elements. The algorithm runs in rounds; at each round, any element with a marginal gain at least τ will be added to the solution if it does not violate the partition matroid constraint. After each round, τ is decreased by a factor $1 - \epsilon$ in order to guarantee new elements can be added to the solution at successive rounds. The algorithm continues until the obtained solution becoming a maximal set or the threshold is below a value defined by ϵ and b . GREEDY's pseudocode is presented by Alg. 3 and THRGREEDY's is Alg. 4.

Theorem 3. GREEDY obtains a $\min(\frac{1}{r_1^{(g)}}, \frac{1}{r_2^{(g)}})$ -approximation solution, where

$$r_1^{(g)} = \frac{\gamma}{1 + \gamma\alpha} \quad r_2^{(g)} = \frac{1}{\alpha} \left[1 - \left(1 - \frac{\alpha\gamma}{b} \right)^{\hat{b}} \right]$$

and has a query complexity of $O(nb)$.

Theorem 4. THRGREEDY obtains a $\min(\frac{1}{r_1^{(t)}}, \frac{1}{r_2^{(t)}})$ -approximation solution, where

$$r_1^{(t)} = \frac{\gamma(1 - \epsilon)^2}{1 + \gamma\alpha(1 - \epsilon)} \quad r_2^{(t)} = \frac{1}{\alpha} \left[1 - \left(1 - \frac{\alpha\gamma(1 - \epsilon)}{b} \right)^{\hat{b}} \right]$$

and has a query complexity of $O(\frac{n}{\epsilon} \ln b)$.

Due to space limit, the full proof of Theorem 3 and 4 is provided in Appendix B.

In case of submodular objective function, $r_2^{(g)}$ of GREEDY is identical to the ratio obtained by [Friedrich *et al.*, 2019]. With cardinality constraint, $r_2^{(g)}$ matches with the ratio of [Bian *et al.*, 2017], which was also proven to be tight. However, with $\hat{b}/b \rightarrow 0$ (e.g. the input is formed by many partitions), $r_2^{(g)}$ and $r_2^{(t)}$ approach 0 and become undesirable. In this case, $r_1^{(g)}$ and $r_1^{(t)}$ should be a better bound on the performance of GREEDY and THRGREEDY.

Algorithm 4 THRGREEDY

Input $V = V_1 \uplus \dots \uplus V_k; f; b_1, \dots, b_k; \epsilon \in [0, 1]$

- 1: $I = [k]; S_0 = \emptyset; t = 0$
- 2: $\tau = \tau_0 = \max_{e \in V} \Delta_e f(S_0)$
- 3: **while** $I \neq \emptyset$ and $\tau \geq \frac{\epsilon(1 - \epsilon)\tau_0}{b}$ **do**
- 4: **for each** $i \in I$ and $e \in V_i \setminus S_t$ **do**
- 5: **if** $\Delta_e f(S_t) \geq \tau$ **then**
- 6: $S_{t+1} = S_t \cup \{e\}; t = t + 1$
- 7: **if** $|S_t \cap V_i| \geq b_i$ **then** $I = I \setminus \{i\}$
- 8: $\tau = \tau(1 - \epsilon)$

6 Applications and Experimental Results

In this section, we consider two applications of MAXMP: Boosting Influence Spread and Video Summarization.

Boosting Influence Spread. In this problem, a social directed graph $G = (V, E)$ is given, where V represents a set of social network users; and E represents friendship between social users in V . An information will start spreading at a set $I \subset V$ of users. The problem asks for a set S of users to strengthen the influence spread in order to maximize the number of users the information can reach.

Boosting Influence Spread under size constraint has been studied by [Lin *et al.*, 2017]. In their model, each edge $e = (u, v) \in E$ is associated with two weight values p_e^0, p_e^1 ($p_e^0 \leq p_e^1 \leq 1$). The probability v adopts the information from u is p_e^1 if $v \in S$; p_e^0 otherwise. In this application, $f(S)$ measures expected number of users the information can reach if S is selected. The authors has proven that f is monotone non-submodular; but did not show how close f is to submodularity. We provide the bound γ', α' of γ and α of f as in Lemma 2, and full proof is provided in Appendix C.

Lemma 2. Given a Boosting Influence Spread instance, let Δ be the maximum in-degree of the input directed graph. For any $S \subseteq T$ that $|S \cap V_i| \leq b_i \forall i \in [k]$ and $u \in V \setminus T$:

$$\min_{|E'| \leq b\Delta} \prod_{e \in E'} \frac{1 - p_e^1}{1 - p_e^0} \leq \frac{\Delta_u f(S)}{\Delta_u f(T)} \leq \max_{|E'| \leq b\Delta} \prod_{e \in E'} \frac{p_e^1}{p_e^0} \quad (17)$$

Video Summarization Given a video, this application aims to pick a few representative frames from the video which can contains as much content as possible. The video contains n frames; each frame is represented by a p -dimensional vector. Let $X \in \mathbb{R}^{n \times n}$ be the Gramian matrix of the n resulting vectors and the Gaussian kernel; i.e. X_{ij} is the value of the Gaussian kernel between the i -th and j -th vectors. The objective function is defined as $f(S) = \det(I + X_S)$, where X_S is the submatrix of X indexed by S ; and I is a unit matrix.

$f(S)$ was proved to be supermodular by [Bian *et al.*, 2017], thus its curvature $\alpha = 0$. The authors also bounded the weakly submodular ratio, which is not useful in our algorithms. We bound the value of γ as in the following lemma, and full proof is provided in Appendix C.

Lemma 3. Given a Video Summarization instance, let $A = I + X$ and $\lambda_i(M)$ be the i -th eigenvalue of a positive definite

matrix M in a way that $\lambda_1(M) \geq \dots \geq \lambda_{\text{rank}(M)}(M)$. For any $S \subseteq T$ that $|(T \setminus S) \cap V_i| \leq b_i \forall i \in [k]$ and $e \in V \setminus T$:

$$\Delta_e f(S) \geq \Delta_e f(T) \times \frac{\lambda_n(A) - 1}{\lambda_1(A) - 1} \prod_i^b \frac{1}{\lambda_i(A)} \quad (18)$$

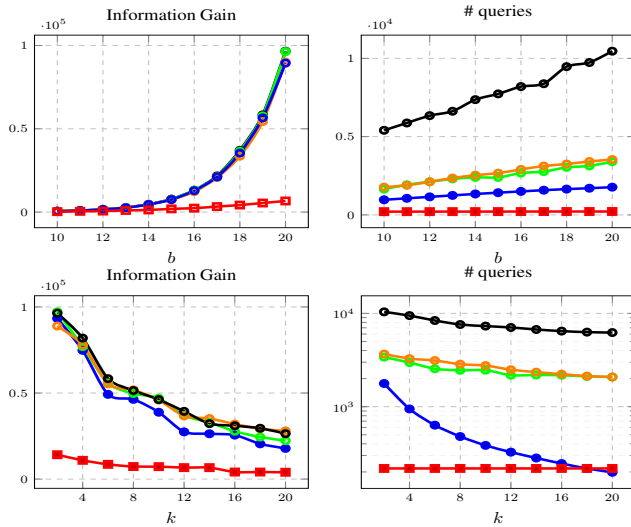

Figure 2: Performance in Video Summarization

6.1 Settings and Compared Algorithms

With Boosting Influence Spread, we use Facebook dataset from SNAP database [Leskovec and Krevl, 2014], an undirected graph with 4,039 nodes and 88,234 edges. Since it is undirected, we treat each edge as two directed edges. For each edge $e = (u, v)$, $p_e^0 = \frac{1}{d_u}$ and $p_e^1 = \frac{2}{d_v}$ where d_v is in-degree of v . Information starts spreading at a node of highest degree. Due to lack of information, a user is randomly

assigned to a group V_i . The budget is distributed equally to each group, i.e. $b_1 \approx \dots \approx b_k \approx \frac{b}{k}$. The objective is estimated over 100 pre-sampled graph realizations of G .

With Video Summarization, we chose a video of roughly 3.5 minutes. The video is segmented to k equal-length parts; and the algorithms will pick $\frac{b}{k}$ frames from each part.

With FASTPROB, we set $\delta = 0.001$, which guarantees FASTPROB to return solutions almost similar to PROB but be much better in the number of queries. With THRGREEDY, we set $\epsilon = 0.5$. Results were averaged over 10 repetitions.

We varied values of b and k ; and compare FASTPROB, GREEDY and THRGREEDY with RESGREEDY [Chen *et al.*, 2018] and SPLITGROW [Buchbinder *et al.*, 2019]. Although SPLITGROW's performance is unknown if f is submodular, we used it as a heuristic to compare. Source code is available at <https://github.com/lannn2410/maxmp>.

6.2 Numerical Results

Fig. 1 and 2 show experimental results of different algorithms on Boosting Influence Spread and Video Summarization. With experiments that we varied values of b , we fixed $k = 2$. With the one that k is varied, we fixed $b = 100$ in Boosting Influence Spread and $b = 20$ in Video Summarization.

In these experiments, FASTPROB, GREEDY and SPLITGROW performed approximately equal in term of solution quality while THRGREEDY was always the worst one. Especially, in Video Summarization, the supermodular objective function made the marginal gain of non-included elements increase with larger obtained solutions. Therefore, THRGREEDY easily reached a maximal solution just by one or two iterations of decreasing threshold. That explained why THRGREEDY took very few number of queries but has undesirable returned solution quality. In term of the number of queries, FASTPROB outperformed GREEDY, RESGREEDY and SPLITGROW.

FASTPROB closed the gap or even surpassed THRGREEDY to become the best algorithm in the number of queries in the experiments with fixed b and varied k . In these experiments, we can see that the number of queries of all algorithms, except FASTPROB, almost did not change or just slightly decreased with larger k . FASTPROB's numbers, on the other hand, decreased significantly as k increased. This phenomenon is also reflected on the theoretical bound of FASTPROB's complexity. In Equ. (15), FASTPROB's complexity is bounded by $O(\ln \frac{b}{\delta} \sum_{i \in [k]} n_i \ln b_i)$. With n_i s are roughly equal (the same with b_i s), FASTPROB's complexity becomes $O(n \ln \frac{b}{k} \ln \frac{b}{\delta})$, which decreases w.r.t k .

7 Discussion

We proposed PROB and later FASTPROB to solve monotone non-submodular maximization with partition matroid constraint. The experimental results demonstrated that FASTPROB can perform closely to the best algorithms in solution quality, and outperform other algorithms (except THRGREEDY - the worst in solution quality) in the number of queries. Although there is no superior algorithm in general,

FASTPROB should be considered as the best algorithm in scenarios that scalability issues are concerned, e.g. algorithms with fast runtime and relatively high solution quality.

There is still an open question on what is the best algorithm in approximation ratio? PROB's ratio depends on γ', α' - which can be undesirable in some settings of our experiments. However, it is unknown on how hard to obtain exact value of γ, α or other non-submodular quantities. And it is too expensive for us if computing those quantities by enumerating all possible S, T that $T \setminus S$ satisfies partition matroid. Therefore, it is still open on how different between GREEDY, THRGREEDY, RESGREEDY and PROB's ratio.

A Proof of FASTPROB's Ratio

Similar to PROB, we prove that: In FASTPROB, with high probability (i.e. $1 - \delta$) there exists a way to construct a sequence of maximal sets S_0^*, \dots, S_b^* that satisfies (1) $S_0^* = S^*$ and $S_b^* = S_b$; (2) $S_t \subseteq S_t^*$ for all $t = 0, \dots, b$; and (3) $f(S_t^*) - f(S_{t+1}^*) \leq \beta \mathbb{E}[f(S_{t+1}) - f(S_t)]$. If these three properties are guaranteed, the ratio of FASTPROB follows.

For each $t = 0, \dots, b - 1$, a set S_{t+1}^* is formed from S_t^* , S_t and e_t but with a condition that $(S_t^* \setminus S_t) \cap R_t \neq \emptyset$, which is guaranteed with high probability by Lemma 1.

Let's consider a moment when the t -th element is added into the solution. Let i be the index being considered when e_t is added into S_{t-1} . With $(S_t^* \setminus S_t) \cap R_t \neq \emptyset$, let e' be an arbitrary element in $(S_t^* \setminus S_t) \cap R_t$, then S_{t+1}^* is set as follows:

- If $e_t \in (S_t^* \setminus S_t) \cap R_t$, $S_{t+1}^* := S_t^*$
- Otherwise, $S_{t+1}^* := S_t^* \setminus \{e'\} \cup \{e_t\}$

Then we have:

$$\mathbb{E}[f(S_t^*) - f(S_{t+1}^*)] = \sum_{u \in R_t \setminus S_t^*} [f(S_t^*) - f(S_t^* \setminus \{e'\} \cup \{u\})] \times \Pr_u \quad (19)$$

$$= \sum_{u \in R_t \setminus S_t^*} [\Delta_{e'} f(S_t^* \setminus \{e'\}) - \Delta_u f(S_t^* \setminus \{e'\})] \times \Pr_u \quad (20)$$

$$\leq \sum_{u \in R_t \setminus S_t^*} \left[\frac{1}{\gamma} \rho_{e'} - (1 - \alpha) \rho_u \right] \times \Pr_u \quad (21)$$

$$= \frac{1}{\gamma} \sum_{u \in R_t \setminus S_t^*} \frac{\rho_{e'} \rho_u^a}{\sum_{v \in R} \rho_v^a} - (1 - \alpha) \sum_{u \in R_t \setminus S_t^*} \rho_u \Pr_u \quad (22)$$

$$\leq \frac{1}{\gamma(a+1)} \sum_{u \in R_t \setminus S_t^*} \frac{\rho_{e'}^{a+1} + a \times \rho_u^{a+1}}{\sum_{v \in R} \rho_v^a} - (1 - \alpha) \sum_{u \in R_t \setminus S_t^*} \rho_u \times \Pr_u \quad (23)$$

$$= \frac{|R_t \setminus S_t^*|}{\gamma(a+1)} \rho_{e'} \Pr_{e'} + \left(\frac{1}{\gamma} \frac{a}{a+1} + \alpha - 1 \right) \sum_{u \in R_t \setminus S_t^*} \rho_u \Pr_u \quad (24)$$

where Equ. (21) is from properties of γ and α ; while Equ. (23) is from AM-GM inequality.

With $a = \lceil \frac{|R_t|+1}{1-\gamma'(1-\alpha')} \rceil - 1$, we have

$$\begin{aligned} \frac{|R_t \setminus S_t^*|}{\gamma(a+1)} &\leq \frac{|R_t|}{\gamma \frac{|R_t|+1}{1-\gamma'(1-\alpha')}} \leq \left(\frac{1}{\gamma'} + \alpha' - 1 \right) \left(1 - \frac{1}{\bar{n}+1} \right) \\ \frac{1}{\gamma} \frac{a}{a+1} + \alpha - 1 &\leq \frac{1}{\gamma} \left(1 - \frac{1-\gamma'(1-\alpha')}{|R_t|+2} \right) + \alpha - 1 \leq \left(\frac{1}{\gamma'} + \alpha' - 1 \right) \left(1 - \frac{1}{\bar{n}+2} \right) \end{aligned}$$

Therefore,

$$(24) \leq \left(\frac{1}{\gamma'} + \alpha' - 1 \right) \left(1 - \frac{1}{\bar{n}+2} \right) \mathbb{E}[f(S_{t+1}) - f(S_t)]$$

which completes the proof.

B Proofs of GREEDY & THRGREEDY

We use a common framework that can be used to prove approximation ratio of both GREEDY and THRGREEDY. Denote e_0, e_1, \dots, e_{t-1} as a sequence of elements added to the obtained solution, i.e. $S_j = \{e_0, e_1, \dots, e_{j-1}\}$. In THRGREEDY, we assume $\tau_0 = \max_{e \in V} \Delta_e f(S_0) \leq \gamma f(S^*)$ since if not, the ratio can be obtained trivially by: $f(S_t) \geq \Delta_{e_0} f(S_0) \geq \gamma f(S^*)$.

The reason we use a common proof for GREEDY and THRGREEDY because both algorithms guarantee: For each $j = 0, \dots, t-1$, $\Delta_{e_j} f(S_j) \geq \gamma \sigma \Delta_u f(T)$ for any $T \supseteq S_j$ and $u \in V_i \setminus S_j$ that $|S_j \cap V_i| < b_i$, where $\sigma = 1$ in GREEDY and $1 - \epsilon$ in THRGREEDY. This guarantee is trivial with GREEDY due to PM DR-ratio γ 's property. To prove this guarantee in THRGREEDY, we observe that: since $u \notin S_j$, there should exist $j' \leq j$ that $\Delta_u f(S_{j'}) \leq \frac{\tau_j}{1-\epsilon} \leq \frac{\Delta_{e_j} f(S_j)}{1-\epsilon}$, where τ_j is the threshold τ when e_j is added. And because $S_{j'} \subseteq S_j \subseteq T$, $\Delta_u f(S_{j'}) \geq \gamma \Delta_u f(T)$.

For simplicity, in the common proof, we denote r_1 as $r_1^{(g)}$ (for GREEDY) and $r_1^{(t)}$ (for THRGREEDY). The same notation is applied for r_2 . The ratios of two algorithms means that: (1) $f(S_t) \geq r_1 f(S^*)$ and (2) $f(S_t) \geq r_2 f(S^*)$. Therefore, our proof focuses on proving these two statements.

Lemma 4. $f(S_t) \geq r_1 f(S^*)$

Proof. The lemma is proven by constructing a sequence of maximal sets S_0^*, \dots, S_t^* as follows: Starting with $S_0^* = S^*$. Assuming $i \in I$ is the index being consider when the algorithm adds e_j into the current obtained solution S_j , pick an arbitrary $u \in S_j^* \setminus S_j \cap V_i$. if $u = e_j$ then $S_{j+1}^* := S_j^*$ and we have $f(S_j^*) - f(S_{j+1}^*) = 0$. Otherwise, set $S_{j+1}^* := S_j^* \setminus \{u\} \cup \{e_j\}$, we have:

$$f(S_j^*) - f(S_{j+1}^*) = \Delta_u f(S_j^* \setminus \{u\}) - \Delta_{e_j} f(S_j^* \setminus \{u\}) \leq \left(\frac{1}{\gamma\sigma} + \alpha - 1\right) \Delta_{e_j} f(S_j)$$

Therefore, from the sequence S_0^*, \dots, S_t^* , we have:

$$f(S^*) - f(S_t^*) = \sum_{j=0}^{t-1} \left(f(S_j^*) - f(S_{j+1}^*)\right) \leq \left(\frac{1}{\gamma\sigma} + \alpha - 1\right) \sum_{j=0}^{t-1} \left[f(S_{j+1}) - f(S_j)\right] \leq \left(\frac{1}{\gamma\sigma} + \alpha - 1\right) f(S_t) \quad (25)$$

With GREEDY, the lemma follows from Equ. (25) since in GREEDY, $t = b$ and $S_b^* = S_b$. This is also applied to THRGREEDY if the returned S_t is maximal. Otherwise, denote $\{e'_1, \dots, e'_{b-t}\}$ as a sequence of elements in $S_t^* \setminus S_t$. Then for each $e'_i \in S_t^* \setminus S_t$, there exists $j \leq t$ such that $S_j \subseteq S_t \subseteq S_t \cup \{e'_1, \dots, e'_{i-1}\}$ and $\Delta_{e'_i} f(S_t \cup \{e'_1, \dots, e'_{i-1}\}) \leq \frac{1}{\gamma} \Delta_{e'_i} f(S_j) \leq \frac{\epsilon\tau_0}{\gamma b}$. Therefore,

$$f(S_t^*) - f(S_t) = \sum_{l=1}^{b-t} \Delta_{e'_l} f(S_t \cup \{e'_1, \dots, e'_{l-1}\}) \leq b \frac{\epsilon\tau_0}{\gamma b} \leq \epsilon f(S^*) \quad (26)$$

Combining Equ. (25) and (26), we complete the lemma in the THRGREEDY case. \square

Lemma 5. $f(S_t) \geq r_2 f(S^*)$

Proof. Denote $S^* = \{e_1^*, \dots, e_b^*\}$. We consider two cases that can happen when the algorithms terminates: (1) $|S_t \cap V_i| < b_i$ for all $i \in [k]$; and (2) There exists $i \in [k]$ that $|S_t \cap V_i| = b_i$.

Case (1) never happens with GREEDY. If it happens with THRGREEDY, then for each $e_i^* \in S^* \setminus S$, there should exists $j \leq t$ such that $S_j \subseteq S \subseteq S \cup \{e_1^*, \dots, e_{i-1}^*\}$ and $\Delta_{e_i^*} f(S \cup \{e_1^*, \dots, e_{i-1}^*\}) \leq \frac{1}{\gamma} \Delta_{e_i^*} f(S_j) \leq \frac{\epsilon\tau_0}{\gamma b}$. We have:

$$\begin{aligned} f(S^*) - f(S) &\leq f(S^* \cup S) - f(S) = \sum_{e_i^* \in S^*} \Delta_{e_i^*} f(S \cup \{e_1^*, \dots, e_{i-1}^*\}) \\ &= \sum_{e_i^* \in S^* \setminus S} \Delta_{e_i^*} f(S \cup \{e_1^*, \dots, e_{i-1}^*\}) \leq b \frac{\epsilon\tau_0}{\gamma b} \leq \epsilon f(S^*) \end{aligned}$$

Therefore, Lemma 5 mainly follows from case (2). **With case (2), our proof is inspired from [Bian et al., 2017] and [Friedrich et al., 2019]. We write down the detail of our proof for the sake of completeness.**

Denote q as a minimum number in $0, \dots, t$ that there exists $i \in [k]$ in which $|S_q \cap V_i| = b_i$. Denote $i \in [k]$ as the index that $|S_q \cap V_i| = b_i$. For simplicity, for each $j = 1, \dots, t$, denote $\rho_j = \Delta_{e_{j-1}} f(S_{j-1})$.

Claim 1. For each $j = 0, \dots, q - 1$:

$$f(S^*) \leq \sum_{r \leq j: e_r \in S^*} \rho_r + \alpha \sum_{r \leq j: e_r \notin S^*} \rho_r + \frac{|S^* \setminus S_j|}{\gamma\sigma} \rho_{j+1}$$

Proof. Consider for each $j = 0, \dots, q - 1$, we have:

$$f(S^*) = f(S^* \cup S_j) - \sum_{r \leq j} \Delta_{e_r} f(S^* \cup S_r) = f(S^* \cup S_j) - \sum_{r \leq j: e_r \notin S^*} \Delta_{e_r} f(S^* \cup S_r) \quad (27)$$

$$\leq f(S^* \cup S_j) - (1 - \alpha) \sum_{r \leq j: e_r \notin S^*} \rho_{r+1} \quad (28)$$

On the other hand,

$$f(S^* \cup S_j) - f(S_j) = \sum_{e_i^* \in S^*} \Delta_{e_i^*} f(S \cup \{e_1^*, \dots, e_{i-1}^*\}) \leq \frac{1}{\gamma\sigma} \sum_{e_i^* \in S^*} \Delta_{e_i^*} f(S_j) \leq \frac{|S^* \setminus S_j|}{\gamma\sigma} \rho_{j+1} \quad (29)$$

The claim follows by combining Equ. (28), (29) and the fact that $f(S_j) = \sum_{r \leq j} \rho_r$. \square

For each $j = 1, \dots, t$, denote $x_j = \frac{\rho_j}{f(S^*)}$; and $\beta_j = \alpha$ if $e_j \notin S^*$, 1 otherwise. Since $\frac{f(S)}{f(S^*)} = \sum_{j \leq t} x_j \geq \sum_{j \leq q} x_j$, by Claim 1, $\frac{f(S)}{f(S^*)}$ is at least the value of the optimal solution of the following linear programming.

$$\min \sum_{j=1}^q x_j \quad (30)$$

$$\text{s.t. } \sum_{r=1}^{j-1} \beta_r x_r + \frac{|S^* \setminus S_{j-1}|}{\gamma \sigma} x_j \geq 1 \quad \forall j = 1, \dots, q \quad (31)$$

$$x_j \geq 0 \quad \forall j = 1, \dots, q \quad (32)$$

Let's call this linear programming *GrLP*. We have the following claim.

Claim 2. *If x_1^*, \dots, x_q^* is optimal solution of GrLP, then*

$$\sum_{j=1}^q x_j^* \geq \frac{1}{\alpha} \left[1 - \left(1 - \frac{\alpha \gamma \sigma}{b} \right)^q \right]$$

Claim 2 also concludes the proof for Lemma 5. Before proving Claim 2, we have the following lemma, which is critical to obtain the optimal solution of GrLP.

Lemma 6. *For each $r = 1, \dots, q$, if $e_r \in S^*$ then $x_r^* \leq x_{r+1}^*$.*

Proof. We use contradiction: Assume $x_r^* > x_{r+1}^*$, then we can construct a feasible solution y_1, \dots, y_q to GrLP such that $\sum_{r=1, \dots, q} y_r < \sum_{r=1, \dots, q} x_r^*$, thus contradicts to the fact that x_1^*, \dots, x_q^* is the optimal one.

Denote $p_t = |S^* \setminus S_t|$ for all $t = 0, \dots, q$. It is trivial that p_0, \dots, p_q is monotone non-increasing. Since $e_r \in S^*$, $p_{r-1} = p_r + 1$.

Let $\eta = \frac{(p_{r-1} - \sigma \gamma)x_r^* - p_r x_{r+1}^*}{p_{r-1}} \geq \frac{p_r}{p_{r-1}}(x_r^* - x_{r+1}^*) \geq 0$. The construction of y_1, \dots, y_q is as follows:

- $y_{r'} = x_{r'}^*$ for all $r' < r$.
- $y_r = x_r^* - \eta$
- $y_{r'} = x_{r'}^* + \eta_{r'}$ for all $r' > r$, where
 - $\eta_{r+1} = \eta \times \frac{\gamma \sigma}{p_r}$
 - $\eta_{r+1+u} = \eta_{r+u} \times \frac{p_{r-u+1} - \gamma \sigma}{p_{r-u}}$

Claim 3. y_1, \dots, y_q satisfy the constraint (32) of GrLP.

Proof. It is trivial that $y_{r'} \geq x_{r'} \geq 0$ for all $r' \neq r$. On the other hand:

$$y_r = x_r^* - \eta = x_r^* - \frac{(p_{r-1} - \sigma \gamma)x_r^* - p_r x_{r+1}^*}{p_{r-1}} = \frac{\sigma \gamma x_r^* + p_r x_{r+1}^*}{p_{r-1}} \geq 0$$

which completes the proof. \square

Claim 4. y_1, \dots, y_q satisfy the constraint (31) of GrLP.

Proof. As $y_{r'} = x_{r'}^*$ for all $r' < r$, y_1, \dots, y_q satisfy the constraints of Equ. (31) for all $t < r$. In the following parts, we first prove the constraint (31) at $t = r$ is still satisfied by y_1, \dots, y_q .

From the constraint (31) at $t = r + 1$, we have that:

$$\sum_{a < r: e_a \in S^*} x_a^* + \alpha \sum_{a < r: e_a \notin S^*} x_a^* + x_r^* + \frac{p_r}{\gamma \sigma} x_{r+1}^* \geq 1 \quad (33)$$

Take the different between left-hand side (l.h.s) of the constraint (31) at $t = r$ with y_1, \dots, y_q and l.h.s of (33), we have

$$\begin{aligned} & \left[\sum_{a < r: e_a \in S^*} y_a + \alpha \sum_{a < r: e_a \notin S^*} y_a + \frac{p_{r-1}}{\gamma \sigma} y_r \right] - \left[\sum_{a < r: e_a \in S^*} x_a^* + \alpha \sum_{a < r: e_a \notin S^*} x_a^* + x_r^* + \frac{p_r}{\gamma \sigma} x_{r+1}^* \right] \\ &= \frac{p_{r-1}}{\gamma \sigma} \left(x_r^* - \frac{(p_{r-1} - \sigma \gamma)x_r^* - p_r x_{r+1}^*}{p_{r-1}} \right) - x_r^* - \frac{p_r}{\gamma \sigma} x_{r+1}^* = 0 \end{aligned}$$

Thus the constraint (31) at $t = r$ is still satisfied with y_1, \dots, y_q .

Next, we would need to prove that y_1, \dots, y_q satisfy the constraint (31) at $t > r$. Denote:

$$\delta_{r+u} = \left(\text{l.h.s of (31) with } y_1, \dots, y_q \text{ at } t = r + u \right) - \left(\text{l.h.s of (31) with } x_1^*, \dots, x_q^* \text{ at } t = r + u \right)$$

To prove y_1, \dots, y_q satisfy the constraint (31) at $t > r$, we show that δ_{r+u} is monotone non-decreasing for all $u \geq 1$ and $\delta_{r+1} = 0$.

Let's consider the constraint (31) at $t = r + 1$ with y_1, \dots, y_q , we have:

$$\begin{aligned} & \sum_{a < r: e_a \in S^*} y_a + \alpha \sum_{a < r: e_a \notin S^*} y_a + y_r + \frac{p_r}{\gamma\sigma} y_{r+1} \\ &= \sum_{a < r: e_a \in S^*} x_a^* + \alpha \sum_{a < r: e_a \notin S^*} x_a^* + x_r^* - \eta + \frac{p_r}{\gamma\sigma} (x_{r+1}^* + \eta \frac{\gamma\sigma}{p_r}) \\ &= \text{l.h.s of the constraint (31) at } t = r + 1 \text{ with } x_1^*, \dots, x_q^* \\ &\geq 1 \end{aligned}$$

Thus, $\delta_{r+1} = 0$ and the constraint (31) at $t = r + 1$ is still satisfied with y_1, \dots, y_q .

Next, we prove $\delta_{r+u+1} \geq \delta_{r+u}$ for all $u \geq 1$. The l.h.s of (31) with y_1, \dots, y_q at $t = r + u$ is as follows:

$$\sum_{a < r+u: e_a \in S^*} y_a + \alpha \sum_{a < r+u: e_a \notin S^*} y_a + \frac{p_{r+u-1}}{\gamma\sigma} y_{r+u}$$

In $t = r + u + 1$, there will be 2 cases: (1) $e_{r+u} \in S^*$; and (2) $e_{r+u} \notin S^*$.

With case (1), $p_{r+u} = p_{r+u-1} - 1$; the l.h.s of the constraint at $t = r + u + 1$ becomes:

$$\sum_{a < r+u+1: e_a \in S^*} y_a + \alpha \sum_{a < r+u+1: e_a \notin S^*} y_a + y_{r+u} + \frac{p_{r+u-1} - 1}{\gamma\sigma} y_{r+u+1}$$

As $p_{r+u-1} \geq p_r - u + 1$, we have:

$$\begin{aligned} \delta_{r+u+1} - \delta_{r+u} &= \frac{p_{r+u-1} - 1}{\gamma\sigma} \eta_{r+u+1} - \frac{p_{r+u-1} - \gamma\sigma}{\gamma\sigma} \eta_{r+u} \\ &= \left[(p_{r+u-1} - 1) \times \frac{p_r - u + 1 - \gamma\sigma}{p_r - u} - (p_{r+u-1} - \gamma\sigma) \right] \frac{\eta_{r+u}}{\gamma\sigma} \\ &\geq \left[(p_{r+u-1} - 1) \times \frac{p_{r+u-1} - \gamma\sigma}{p_{r+u-1} - 1} - (p_{r+u-1} - \gamma\sigma) \right] \frac{\eta_{r+u}}{\gamma\sigma} \\ &\geq 0 \end{aligned}$$

With case (2), $p_{r+u} = p_{r+u-1}$; the l.h.s of the constraint at $t = r + u + 1$ becomes:

$$\sum_{a < r+u+1: e_a \in S^*} y_a + \alpha \sum_{a < r+u+1: e_a \notin S^*} y_a + \alpha y_{r+u} + \frac{p_{r+u-1}}{\gamma\sigma} y_{r+u+1}$$

As $\eta_{r+u+1} \geq \eta_{r+u}$, we have:

$$\begin{aligned} \delta_{r+u+1} - \delta_{r+u} &= \frac{p_{r+u-1}}{\gamma\sigma} \eta_{r+u+1} - \frac{p_{r+u-1} - \alpha\gamma\sigma}{\gamma\sigma} \eta_{r+u} \\ &\geq \frac{p_{r+u-1}}{\gamma\sigma} (\eta_{r+u+1} - \eta_{r+u}) \geq 0 \end{aligned}$$

Therefore, y_1, \dots, y_q satisfy the constraint (31). □

Claim 5. $\sum_{a=1}^q y_a \leq \sum_{a=1}^q x_a^*$

Proof. We have $\sum_{a=1}^1 y_a = \sum_{a=1}^q x_a^* - \eta + \sum_{a=r+1}^q \eta_a$, where

$$-\eta + \sum_{a=r+1}^q \eta_a = \eta \left[-1 + \frac{\gamma\sigma}{p_r} + \sum_{a=r+2}^q \frac{\gamma\sigma}{p_r} \prod_{l=1}^{a-r-1} \frac{p_r - l + 1 - \gamma\sigma}{p_r - l} \right]$$

On the other hand,

$$\begin{aligned}
& -1 + \frac{\gamma\sigma}{p_r} + \sum_{a=r+2}^q \frac{\gamma\sigma}{p_r} \prod_{l=1}^{a-r-1} \frac{p_r - l + 1 - \gamma\sigma}{p_r - l} \\
& = -1 + \frac{\gamma\sigma}{p_r} + \frac{\gamma\sigma}{p_r} \frac{p_r - \gamma\sigma}{p_r - 1} + \dots + \frac{\gamma\sigma}{p_r} \frac{p_r - \gamma\sigma}{p_r - 1} \dots \frac{p_r - q + r + 1 - \gamma\sigma}{p_r - q + r} \\
& = -\frac{(p_r - \gamma\sigma)(p_r - 1 - \gamma\sigma)\dots(p_r - q + r + 1 - \gamma\sigma)}{p_r(p_r - 1)\dots(p_r - q + r)} < 0
\end{aligned}$$

□

Claim 5 means that not only y_1, \dots, y_q is feasible to GrLP but also has better objective value than x_1^*, \dots, x_q^* , which violates the assumption that x_1^*, \dots, x_q^* is the optimal solution. That completes the proof for Lemma 6. □

In the next part, we will bound the value of $\sum_{j=1}^q x_j^*$. Denote $LP(\{a_1, \dots, a_l\})$ as the optimal result of GrLP if $\{a_1, \dots, a_l\} = \{r \mid e_r \in S^*\}$. For simplicity, we also refer $LP(\{a_1, \dots, a_l\})$ as GrLP if $\{a_1, \dots, a_l\} = \{r \mid e_r \in S^*\}$.

We will prove that $LP(\{a_1, \dots, a_l\}) \geq LP(\emptyset)$ by the following lemmas.

Lemma 7. *If there exists $s \leq l$, such that $a_s + 1 \notin \{a_1, \dots, a_l\}$, then*

$$LP(\{a_1, \dots, a_{s-1}, a_s, a_{s+1}, \dots, a_l\}) \geq LP(\{a_1, \dots, a_{s-1}, a_s + 1, a_{s+1}, \dots, a_l\})$$

Proof. For simplicity, assume x_1^*, \dots, x_q^* as the optimal solution of $LP(\{a_1, \dots, a_{s-1}, a_s, a_{s+1}, \dots, a_l\})$. We gonna prove x_1^*, \dots, x_q^* is feasible to $LP(\{a_1, \dots, a_{s-1}, a_s + 1, a_{s+1}, \dots, a_l\})$.

It is trivial that x_1^*, \dots, x_q^* satisfy the constraint (31) at $t = 1, \dots, a_s$ of $LP(\{a_1, \dots, a_{s-1}, a_s + 1, a_{s+1}, \dots, a_l\})$.

From constraint (31) at $t = a_s + 1$ of $LP(\{a_1, \dots, a_{s-1}, a_s, a_{s+1}, \dots, a_l\})$ we have:

$$\sum_{r < a_s: e_r \in S^*} x_r^* + \alpha \sum_{r < a_s: e_r \notin S^*} x_r^* + x_{a_s}^* + \frac{p_{a_s}}{\gamma\sigma} x_{a_s+1}^* \geq 1 \quad (34)$$

Plugging x_1^*, \dots, x_q^* to the l.h.s of constraint (31) at $t = a_s + 1$ of $LP(\{a_1, \dots, a_{s-1}, a_s + 1, a_{s+1}, \dots, a_l\})$, we have:

$$\sum_{r < a_s: e_r \in S^*} x_r^* + \alpha \sum_{r < a_s: e_r \notin S^*} x_r^* + \alpha x_{a_s}^* + \frac{p_{a_s} + 1}{\gamma\sigma} x_{a_s+1}^* \quad (35)$$

The difference between (35) and the l.h.s of (34) is $\frac{1}{\gamma\sigma} x_{a_s+1}^* - (1 - \alpha)x_{a_s}^* \geq 0$, which means x_1^*, \dots, x_q^* satisfy constraint (31) at $t = a_s + 1$ of $LP(\{a_1, \dots, a_{s-1}, a_s + 1, a_{s+1}, \dots, a_l\})$.

At $t > a_s + 1$, x_1^*, \dots, x_q^* trivially satisfy since the difference between l.h.s of constraint (31) of $LP(\{a_1, \dots, a_{s-1}, a_s + 1, a_{s+1}, \dots, a_l\})$ and the l.h.s of the one of $LP(\{a_1, \dots, a_{s-1}, a_s, a_{s+1}, \dots, a_l\})$ is always $(1 - \alpha)(x_{a_s+1}^* - x_{a_s}^*) \geq 0$

Therefore, x_1^*, \dots, x_q^* is feasible to $LP(\{a_1, \dots, a_{s-1}, a_s + 1, a_{s+1}, \dots, a_l\})$, which also means $LP(\{a_1, \dots, a_{s-1}, a_s, a_{s+1}, \dots, a_l\}) \geq LP(\{a_1, \dots, a_{s-1}, a_s + 1, a_{s+1}, \dots, a_l\})$. □

Lemma 7 means that: as long as there exists s that $a_s + 1 < a_{s+1}$, we keep increase the index of a_s by 1 to obtain a new GrLP with lower optimal result. In the end, we have $LP(\{a_1, \dots, a_l\}) \geq LP(\{q - l + 1, \dots, q\})$.

Lemma 8. $LP(\{q - l + 1, \dots, q\}) \geq LP(\{q - l + 2, \dots, q\})$

Proof. Denote y_1^*, \dots, y_q^* as the optimal solution of $LP(\{q - l + 1, \dots, q\})$. We need to prove y_1^*, \dots, y_q^* is feasible to $LP(\{q - l + 2, \dots, q\})$.

It is trivial that y_1^*, \dots, y_q^* satisfy the constraints (31) at $t = 1, \dots, q - l + 1$ of $LP(\{q - l + 2, \dots, q\})$.

At $t = q - l + 2, \dots, q$, with $LP(\{q - l + 1, q - l + 2, \dots, q\})$ we have:

$$\alpha \sum_{r < q-l+1} y_r^* + y_{q-l+1}^* + \sum_{r=q-l+2}^t y_r^* + \frac{B - t + q - l + 1}{\gamma\sigma} y_t^* \geq 1 \quad (36)$$

Plugging y_1^*, \dots, y_q^* to the l.h.s of this constraint but with $LP(\{q - l + 2, \dots, q\})$, we have:

$$\alpha \sum_{r < q-l+1} y_r^* + \alpha y_{q-l+1}^* + \sum_{r=q-l+2}^t y_r^* + \frac{B - t + q - l + 2}{\gamma\sigma} y_t^* \quad (37)$$

The difference between (37) and the l.h.s of (36), therefore, is $\frac{1}{\gamma\sigma} y_t^* - (1 - \alpha)y_{q-l+1}^* \geq 0$ since $y_{q-l+1}^* \leq y_{q-l+2}^* \leq \dots \leq y_q^*$ (Lemma 6).

Therefore, y_1^*, \dots, y_q^* is feasible to $LP(\{q - l + 2, \dots, q\})$, which means $LP(\{q - l + 1, \dots, q\}) \geq LP(\{q - l + 2, \dots, q\})$. □

Therefore, from Lemma 8, we have

$$LP(\{q-l+1, \dots, q\}) \geq LP(\{q-l+2, \dots, q\}) \geq \dots \geq LP(\emptyset)$$

GrLP with $LP(\emptyset)$ is formulated as follows:

$$\begin{aligned} \min \quad & \sum_{r=1, \dots, q} x_r \\ \text{s.t.} \quad & \alpha \sum_{r < t} x_r + \frac{b}{\gamma\sigma} x_t \geq 1 \quad \forall t = 1, \dots, q \\ & x_r \geq 0 \quad \forall r = 1, \dots, q \end{aligned}$$

Trivially, $LP(\emptyset)$ reaches optimum at $x_r = \frac{\gamma\sigma}{b} \left(1 - \frac{\alpha\gamma\sigma}{b}\right)^{r-1}$ for $r = 1, \dots, q$, where

$$LP(\emptyset) = \sum_{r=1}^q \frac{\gamma\sigma}{b} \left(1 - \frac{\alpha\gamma\sigma}{b}\right)^{r-1} = \frac{1}{\alpha} \left[1 - \left(1 - \frac{\alpha\gamma\sigma}{b}\right)^q\right]$$

which concludes the proof for claim 2.

The query complexity of GREEDY can be trivially inferred. With THRGREEDY, the value of τ reduces by a factor of $1 - \epsilon$ after each **while** loop (line 3 Alg. 4). Therefore, THRGREEDY runs at most $O(\frac{1}{\epsilon} \ln b)$ loops, where each loop queries f at most $O(n)$ times. Therefore, THRGREEDY's query complexity is $O(\frac{n}{\epsilon} \ln b)$, which completes the proof. \square

C Omitted Proofs of Experiment Section

C.1 Proof of Lemma 2

A graph realization g of G is defined as a subgraph of G where edges' state were determined. Denote $R_g(I)$ as a number of reachable nodes from I in g . Given a boosted set H , the probability g is formed is given by

$$\rho_H(g) = \prod_{e \in g} p_H(e) \prod_{e \notin g} (1 - p_H(e))$$

where $p_H(e) = p_e^0$ if $e = (u, v)$ has $v \notin H$; otherwise $p_H(e) = p_e^1$.

Let \mathcal{G} be a collection of all graph realization of G . We have:

$$f(H) = \sum_{g \in \mathcal{G}} \rho_H(g) \times R_g(I)$$

Given sets W, H that $H \subset W$ and $|(W \setminus H) \cap V_i| \leq b_i$ for all $i \in [k]$, $u \notin W$ and a graph realization g . For each $v \in W$, any edge in form $e = (w, v)$ satisfies $p_H(e) = p_{H \cup \{u\}}(e)$ and $p_W(e) = p_{W \cup \{u\}}(e)$. On the other hand, any edge in form $e = (w, u)$ will have weights that $p_H(e) = p_W(e) = p_e^0$ and $p_{H \cup \{u\}}(e) = p_{W \cup \{u\}}(e) = p_e^1$. Therefore, we always have $\frac{p_{W \cup \{u\}}(e)}{p_{H \cup \{u\}}(e)} = \frac{p_H(e)}{p_W(e)}$ and $\frac{1 - p_{W \cup \{u\}}(e)}{1 - p_{H \cup \{u\}}(e)} = \frac{1 - p_H(e)}{1 - p_W(e)}$ for all $e \in g$, which means $\frac{\rho_W(g)}{\rho_H(g)} = \frac{\rho_{W \cup \{u\}}(g)}{\rho_{H \cup \{u\}}(g)}$.

On the other hand:

$$\frac{\rho_W(g)}{\rho_H(g)} = \prod_{e=(w,v) \in g; v \in W \setminus H} \frac{\rho_e^1}{\rho_e^0} \prod_{e=(w,v) \notin g; v \in W \setminus H} \frac{1 - \rho_e^1}{1 - \rho_e^0}$$

Since $|W \setminus H| \leq b$, we have

$$\min_{E' \subseteq E: |E'| \leq b\Delta} \prod_{e \in E'} \frac{1 - p_e^1}{1 - p_e^0} \leq \frac{\rho_W(g)}{\rho_H(g)} \leq \max_{E' \subseteq E: |E'| \leq b\Delta} \prod_{e \in E'} \frac{p_e^1}{p_e^0} \quad (38)$$

We have:

$$f(W \cup \{u\}) - f(W) = \sum_{g \in \mathcal{G}} (\rho_{W \cup \{u\}}(g) - \rho_W(g)) \times R_g(S) \quad (39)$$

$$= \sum_{g \in \mathcal{G}} \left[\frac{\rho_{W \cup \{u\}}(g)}{\rho_{H \cup \{u\}}(g)} \rho_{H \cup \{u\}}(g) - \frac{\rho_W(g)}{\rho_H(g)} \rho_H(g) \right] R_g(S) \quad (40)$$

$$= \sum_{g \in \mathcal{G}} \frac{\rho_W(g)}{\rho_H(g)} (\rho_{H \cup \{u\}}(g) - \rho_H(g)) \times R_g(S) \quad (41)$$

The lemma follows by combining Equ. (38) and (41).

C.2 Proof of Lemma 3

For any set S , denote $A_S = I + X_S$. Given a set $T, S \subset T$ and $e \notin T$, we have:

$$\begin{aligned}
 f(S \cup \{e\}) - f(S) &= \prod_{i=1}^{|\mathcal{S} \cup \{e\}|} \lambda_i(A_{\mathcal{S} \cup \{e\}}) - \prod_{i=1}^{|\mathcal{S}|} \lambda_i(A_S) \\
 &= \lambda_{|\mathcal{S} \cup \{e\}|}(A_{\mathcal{S} \cup \{e\}}) \prod_{i=1}^{|\mathcal{S}|} \lambda_i(A_{\mathcal{S} \cup \{e\}}) - \prod_{i=1}^{|\mathcal{S}|} \lambda_i(A_S) \\
 &\geq \left(\lambda_{|\mathcal{S} \cup \{e\}|}(A_{\mathcal{S} \cup \{e\}}) - 1 \right) \prod_{i=1}^{|\mathcal{S}|} \lambda_i(A_S)
 \end{aligned}$$

where the last inequality comes from Cauchy interlacing inequality. On the other hand,

$$\begin{aligned}
 f(T \cup \{e\}) - f(T) &= \prod_{i=1}^{|\mathcal{T} \cup \{e\}|} \lambda_i(A_{\mathcal{T} \cup \{e\}}) - \prod_{i=1}^{|\mathcal{T}|} \lambda_i(A_T) \\
 &= \lambda_1(A_{\mathcal{T} \cup \{e\}}) \prod_{i=2}^{|\mathcal{T} \cup \{e\}|} \lambda_i(A_{\mathcal{T} \cup \{e\}}) - \prod_{i=1}^{|\mathcal{T}|} \lambda_i(A_T) \\
 &\leq \left(\lambda_1(A_{\mathcal{T} \cup \{e\}}) - 1 \right) \prod_{i=1}^{|\mathcal{T}|} \lambda_i(A_T) \\
 &= \left(\lambda_1(A_{\mathcal{T} \cup \{e\}}) - 1 \right) \prod_{i=|\mathcal{T}|-|\mathcal{S}|+1}^{|\mathcal{T}|} \lambda_i(A_T) \prod_{i=1}^{|\mathcal{T}|-|\mathcal{S}|} \lambda_i(A_T) \\
 &\leq \left(\lambda_1(A_{\mathcal{T} \cup \{e\}}) - 1 \right) \prod_{i=1}^{|\mathcal{S}|} \lambda_i(A_S) \prod_{i=1}^{|\mathcal{T}|-|\mathcal{S}|} \lambda_i(A_T)
 \end{aligned}$$

Therefore:

$$\begin{aligned}
 \frac{f(T \cup \{e\}) - f(T)}{f(S \cup \{e\}) - f(S)} &\leq \frac{\left(\lambda_1(A_{\mathcal{T} \cup \{e\}}) - 1 \right) \prod_{i=1}^{|\mathcal{S}|} \lambda_i(A_S) \prod_{i=1}^{|\mathcal{T}|-|\mathcal{S}|} \lambda_i(A_T)}{\left(\lambda_{|\mathcal{S} \cup \{e\}|}(A_{\mathcal{S} \cup \{e\}}) - 1 \right) \prod_{i=1}^{|\mathcal{S}|} \lambda_i(A_S)} \\
 &\leq \frac{\lambda_1(A) - 1}{\lambda_n(A) - 1} \prod_{i=1}^b \lambda_i(A)
 \end{aligned}$$

which completes the proof.
