

The H/Q-correspondence and a generalization of the supergravity c-map

Vicente Cortés and Kazuyuki Hasegawa

July 21, 2022

Abstract

Given a hypercomplex manifold with a rotating vector field (and additional data), we construct a conical hypercomplex manifold. As a consequence, we associate a quaternionic manifold to a hypercomplex manifold of the same dimension with a rotating vector field. This is a generalization of the HK/QK-correspondence. As an application, we show that a quaternionic manifold can be associated to a conical special complex manifold of half its dimension. Furthermore, a projective special complex manifold (with a canonical c-projective structure) associates with a quaternionic manifold. The latter is a generalization of the supergravity c-map. We do also show that the tangent bundle of any special complex manifold carries a canonical Ricci-flat hypercomplex structure, thereby generalizing the rigid c-map.

1 Introduction

The HK/QK-correspondence is a construction of a (pseudo-)quaternionic Kähler manifold from a (pseudo-)hyper-Kähler manifold of the same dimension with a rotating vector field (see Definition 3.1 and [15, 2, 16, 4]). This correspondence gives also the supergravity c-map, which associates a quaternionic Kähler manifold with a projective special Kähler manifold. The supergravity c-map was introduced in theoretical physics [13].

The inverse construction of the HK/QK-correspondence is called the QK/HK-correspondence. It has been generalized to a Q/H-correspondence, a construction of hypercomplex manifolds from quaternionic manifolds [10]. The purpose of this paper is to construct a quaternionic manifold from a hypercomplex manifold endowed with a rotating vector field and some extra data. We shall call this construction the hypercomplex/quaternionic-correspondence (H/Q-correspondence for short). We briefly explain how we obtain this correspondence. First we define the notion of a conical hypercomplex manifold (Definition 2.1). Next we construct a conical hypercomplex manifold \hat{M} for every hypercomplex manifold M with a rotating vector field Z (Theorem 3.9) and additional data: a two-form Θ on M , a $U(1)$ -bundle over M whose curvature satisfies (3.1) and a function f on M such that $df = -\iota_Z\Theta$. The manifold \hat{M} is endowed with a free action of the Lie algebra $\text{Lie}\mathbb{H}^* \cong \mathbb{R} \oplus \mathfrak{su}(2)$ and its quotient space \bar{M} carries a quaternionic structure, provided that the quotient map $\hat{M} \rightarrow \bar{M}$ is a submersion. The H/Q-correspondence is then defined as $M \mapsto \bar{M}$ (Theorems 4.1 and 4.8). In addition, we show that \bar{M} carries not only a quaternionic connection but also an (induced) affine quaternionic vector field (Proposition 4.7). Note that we give an example of our H/Q-correspondence from a hypercomplex Hopf manifold, which does not admit any hyper-Kähler structure (Example 5.3). Therefore the H/Q-correspondence is a proper generalization of the HK/QK-correspondence. Examples like hypercomplex or quaternionic Hopf manifolds show that hypercomplex and quaternionic manifolds arise naturally beyond the context of hyper-Kähler and quaternionic Kähler geometry. We refer to [25, 18, 19] for the theory of quaternionic manifolds and constructions of such manifolds.

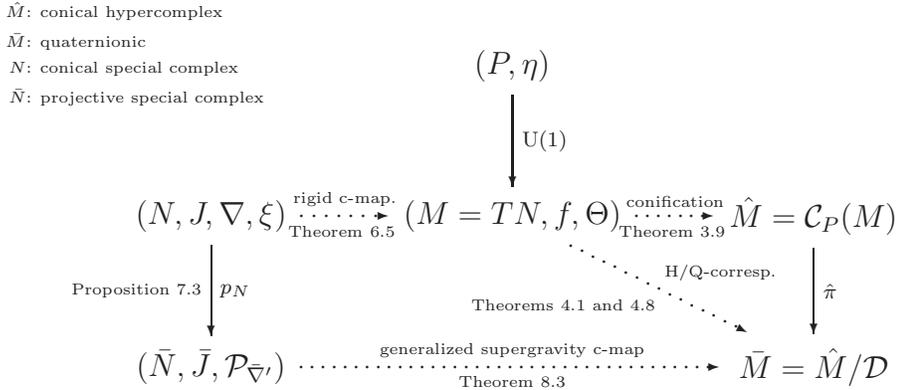

The rigid c-map [9] allows to associate with a conical special Kähler manifold its cotangent bundle endowed with a hyper-Kähler structure with a rotating vector field [2]. In the absence of a metric, we show that the tangent bundle of a special complex manifold carries a canonical hypercomplex structure and that its Obata connection is Ricci flat (Theorem 6.5). In this way we establish a generalization of the rigid c-map which assigns a Ricci flat hypercomplex manifold to each special complex manifold. When the special complex manifold is conical, the resulting hypercomplex manifold is shown to admit a canonical rotating vector field (Lemma 8.1). The notion of a (conical) special complex manifold was introduced in [3]. It is a generalization of a (conical)

special Kähler manifold. We give a local example which does not arise as a special Kähler manifold (Example 8.9). In addition, we find many (different) quaternionic structures on the tangent bundle of a conical special complex manifold in this example (Example 8.9), using a generalization of the supergravity c-map.

As an application of our H/Q-correspondence, we indeed generalize the supergravity c-map by associating a quaternionic manifold with every conical special complex manifold and therefore with every projective special complex manifold (using the extra data involved in the H/Q-correspondence), see Theorem 8.3. It is shown in Proposition 7.3 that any projective special complex manifold possesses a canonical c-projective structure and in Theorem 7.10 that its c-projective Weyl curvature is of type (1, 1). So our generalized supergravity c-map can be formulated as associating a quaternionic manifold to a projective special complex manifold endowed with its canonical c-projective structure with c-projective Weyl curvature of type (1, 1). This addresses one of the questions raised in [6], where a different construction of quaternionic manifolds from c-projective structures was obtained, compare Remark 8.5.

In the special case of the HK/QK-correspondence, the two-form Θ , which is part of the data entering the H/Q-correspondence, is the Z -invariant Kähler form ω_1 in the hyper-Kähler-triple $(\omega_1, \omega_2, \omega_3)$. However, in general, we have a freedom in the choice of Θ in the H/Q-correspondence (see Section 5). In particular we find two choices of Θ in Example 5.4 which yield different quaternionic structures on the resulting space. This shows that our H/Q-correspondence is not an inverse construction of the Q/H-correspondence without a further specification of Θ . It is left for future studies to find a suitable choice of Θ which gives an inverse construction.

We summarize our constructions in this paper as the following commutative diagram.

2 Preliminaries

Throughout this paper, all manifolds are assumed to be smooth and without boundary and maps are assumed to be smooth unless otherwise mentioned. The space of sections of a vector bundle $E \rightarrow M$ is denoted by $\Gamma(E)$.

In this section we introduce hypercomplex and quaternionic structures and derive some properties of conical hypercomplex manifolds.

We say that M is a **quaternionic manifold** with the quaternionic structure Q if Q is a subbundle of $\text{End}(TM)$ of rank 3 which at every point $x \in M$ is spanned by endomorphisms $I_1, I_2, I_3 \in \text{End}(T_x M)$ satisfying

$$(2.1) \quad I_1^2 = I_2^2 = I_3^2 = -\text{id}, \quad I_1 I_2 = -I_2 I_1 = I_3,$$

and there exists a torsion-free connection ∇ on M such that ∇ preserves Q , that is, $\nabla_X \Gamma(Q) \subset \Gamma(Q)$ for all $X \in \Gamma(TM)$. Such a torsion-free connection ∇ is called a **quaternionic connection** and the triplet (I_1, I_2, I_3) is called an **admissible frame** of Q at x . Note that we use the same letter ∇ for the connection on $\text{End}(TM)$ induced by ∇ . The dimension of the quaternionic manifold M is denoted by $4n$.

An **almost hypercomplex manifold** is defined to be a manifold M endowed with 3 almost complex structures I_1, I_2, I_3 satisfying the quaternionic relations (2.1). If I_1, I_2, I_3 are integrable, then M is called a **hypercomplex manifold**. There exists a unique torsion-free connection on a hypercomplex manifold for which the hypercomplex structures are parallel. It is called the **Obata connection** [22]. Obviously, hypercomplex manifolds are quaternionic manifolds with $Q = \langle I_1, I_2, I_3 \rangle$.

Definition 2.1. *We say that a hypercomplex manifold $(M, (I_1, I_2, I_3))$ with a vector field V is conical if $\nabla^0 V = \text{id}$ holds, where ∇^0 is the Obata connection. The vector field V is called the **Euler vector field**.*

We state some lemmas for conical hypercomplex manifolds, which will be used later.

Lemma 2.2. *Let $(M, (I_1, I_2, I_3), V)$ be a conical hypercomplex manifold. Then we have $L_V I_\alpha = 0$, $L_{I_\alpha V} I_\alpha = 0$ for $\alpha \in \{1, 2, 3\}$ and $L_{I_\alpha V} I_\beta = -2I_\gamma$ for any cyclic permutation (α, β, γ) .*

Proof. The formulas follow immediately from $L_V = \nabla_V^0 - \nabla^0 V = \nabla_V^0 - \text{id}$ and $L_{I_\alpha V} = \nabla_{I_\alpha V}^0 - I_\alpha$. \square

For a connection ∇ and $X \in \Gamma(TM)$, we define

$$(2.2) \quad (L_X \nabla)_Y Z := L_X(\nabla_Y Z) - \nabla_{L_X Y} Z - \nabla_Y(L_X Z),$$

where $Y, Z \in \Gamma(TM)$. Note that $L_X \nabla$ is a tensor.

Lemma 2.3. *Let $(M, (I_1, I_2, I_3), V)$ be a conical hypercomplex manifold. Then we have $L_V \nabla^0 = 0$ and $L_{I_\alpha V} \nabla^0 = 0$.*

Proof. By Lemma 2.2, V and $I_\alpha V$ are quaternionic vector fields, namely $L_V \Gamma(Q) \subset \Gamma(Q)$ and $L_{I_\alpha V} \Gamma(Q) \subset \Gamma(Q)$, where $Q = \langle I_1, I_2, I_3 \rangle$. By [10, Proposition 4.2], it is enough to check $\text{Ric}^{\nabla^0}(V, \cdot) = 0$ and $\text{Ric}^{\nabla^0}(I_\alpha V, \cdot) = 0$. We have

$$\text{Ric}^{\nabla^0}(V, Y) = -\text{Ric}^{\nabla^0}(Y, V) = -\text{Tr } R^{\nabla^0}(\cdot, Y)V = 0.$$

Here we used the skew-symmetry of the Ricci tensor of the Obata connection. It follows that also $\text{Ric}^{\nabla^0}(I_\alpha V, \cdot) = -\text{Ric}^{\nabla^0}(V, I_\alpha \cdot) = 0$, by the hermitian property of the Ricci tensor of the Obata connection. \square

Alternatively we could have used Lemma 2.2 and the explicit form of the Obata connection to check $L_{I_\alpha V} \nabla^0 = 0$. Note that $L_V \nabla^0 = 0$ follows from the uniqueness of the Obata connection, since the vector field V preserves the hypercomplex structure.

Example 2.4 (The Swann bundle). The principal $\mathbb{R}^{>0} \times \mathrm{SO}(3)$ bundle over a quaternionic manifold, whose fibers consist of all volume elements and admissible frames at each point, possesses a hypercomplex structure (see [24, 10]). It is conical and is called the Swann bundle. The fundamental vector field generated by $c(\neq 0) \in T_1 \mathbb{R}^{>0} = \mathbb{R}$ is the Euler vector field, as can be easily checked from the explicit representation of the Obata connection (see [5] for example). In the notation of [10] with $\varepsilon = -1$ and $c = -4(n+1)$, a basis of fundamental vector fields for the principal action is given by the vector fields $V = Z_0$ and $Z_\alpha = -I_\alpha Z_0$ with non-trivial commutators $[Z_\alpha, Z_\beta] = -2Z_\gamma$ and Lie derivatives $L_{Z_\alpha} I_\beta = -2I_\gamma$ for any cyclic permutation of $\{1, 2, 3\}$, where we have denoted by (I_1, I_2, I_3) the hypercomplex structure of the Swann bundle. Specializing to the Swann bundle $\mathbb{H}^*/\{\pm 1\}$ of a point, we see that Z_0 corresponds to 1 and (Z_1, Z_2, Z_3) to (i, j, k) in $T_1(\mathbb{H}^*/\{\pm 1\}) = T_1 \mathbb{H} = \mathbb{H}$.

Lemma 2.5. *On any conical hypercomplex manifold $(M, (I_1, I_2, I_3), V)$, the distribution $\mathcal{D} := \langle V, I_1 V, I_2 V, I_3 V \rangle$ on $\{x \in M \mid V_x \neq 0\}$ is integrable.*

Proof. This follows from Lemma 2.2. □

3 Conification of hypercomplex manifolds

The main result of this section is a construction of conical hypercomplex manifolds \hat{M} of dimension $\dim \hat{M} = \dim M + 4$ from hypercomplex manifolds M with a rotating vector field.

Let M be a hypercomplex manifold of dimension $4n$ with a hypercomplex structure $H = (I_1, I_2, I_3)$.

Definition 3.1. *A vector field Z on a hypercomplex manifold $(M, (I_1, I_2, I_3))$ is called rotating if $L_Z I_1 = 0$ and $L_Z I_2 = -2I_3$.*

Note that if Z is rotating, then $L_Z I_3 = 2I_2$. In this section we will essentially show that by choosing a (local) primitive of the one-form $\iota_Z \Theta$ we can construct a conical hypercomplex manifold (\hat{M}, \hat{H}, V) for a hypercomplex manifold (M, H) with a rotating vector field Z and a closed two-form Θ such that $L_Z \Theta = 0$.

Let f be a smooth function on M such that $df = -\iota_Z \Theta$ and $f_1 := f - (1/2)\Theta(Z, I_1 Z)$ is nowhere vanishing. Consider a principal $U(1)$ -bundle $\pi : P \rightarrow M$ with a connection form η whose curvature form is

$$(3.1) \quad d\eta = \pi^* \left(\Theta - \frac{1}{2} d((\iota_Z \Theta) \circ I_1) \right).$$

Since the curvature $d\eta$ is a basic form, we will usually identify it with its projection $\Theta - \frac{1}{2} d((\iota_Z \Theta) \circ I_1)$ on M . With this understood we have the following lemma, which follows immediately from the definition of f_1 .

Lemma 3.2. $df_1 = -\iota_Z d\eta$.

Define a vector field Z_1 on P by $Z_1 = Z^{h\eta} + (\pi^* f_1)X_P$, where $Z^{h\eta}$ is the η -horizontal lift and X_P is the fundamental vector field such that $\eta(X_P) = 1$. We will write f_1 for $\pi^* f_1$.

Remark 3.3. Note that $[X_P, Z_1] = 0$. Therefore if Z_1 generates a $U(1)$ -action on P , then its action commutes with the principal action of $\pi : P \rightarrow M$.

Set $\tilde{M} = \mathbb{H}^* \times P$. Let $(e_0^R, e_1^R, e_2^R, e_3^R)$ (resp. $(e_0^L, e_1^L, e_2^L, e_3^L)$) be the right-invariant (resp. the left-invariant) frame of \mathbb{H}^* which coincides with $(1, i, j, k)$ at $1 \in \mathbb{H}^*$. Note that $[e_1^R, e_2^R] = -2e_3^R$. We will use the same letter for vectors or vector fields canonically lifted to the product $\tilde{M} = \mathbb{H}^* \times P$ as for those on the factors \mathbb{H}^* and P . Set

$$V_1 := e_1^L - Z_1.$$

We denote the space of integral curves of V_1 by \hat{M} . We assume that the quotient map $\tilde{\pi} : \tilde{M} \rightarrow \hat{M}$ is a submersion. Note that ‘‘submersion’’ requires that the quotient space \hat{M} is smooth.

Lemma 3.4. We assume that the equation (3.1) holds. If $L_Z I_1 = 0$ and $L_Z \Theta = 0$, we have

$$L_{V_1} Y^{h\eta} = -[Z, Y]^{h\eta}$$

for all $Y \in \Gamma(TM)$.

Proof.

$$\begin{aligned} -L_{V_1} Y^{h\eta} &= -[e_1^L - Z_1, Y^{h\eta}] = [Z_1, Y^{h\eta}] \\ &= [Z^{h\eta}, Y^{h\eta}] + [f_1 X_P, Y^{h\eta}] = [Z^{h\eta}, Y^{h\eta}] - (Y^{h\eta} f_1) X_P \\ &= [Z, Y]^{h\eta} + \eta([Z^{h\eta}, Y^{h\eta}]) X_P - (Y^{h\eta} f_1) X_P \\ &= [Z, Y]^{h\eta} - d\eta(Z, Y) X_P - (Y f_1) X_P \\ &= [Z, Y]^{h\eta}, \end{aligned}$$

where we have used Lemma 3.2. □

Note that

$$\begin{aligned} T_{(z,p)} \tilde{M} &\cong T_z \mathbb{H}^* \oplus T_p P = \langle e_0^R, e_1^R, e_2^R, e_3^R \rangle_z \oplus \langle X_P \rangle_p \oplus \text{Ker } \eta_p \\ &= \langle V_1 \rangle_{(z,p)} \oplus \langle e_0^R, e_1^R, e_2^R, e_3^R \rangle_z \oplus \text{Ker } \eta_p \end{aligned}$$

for $(z, p) \in \mathbb{H}^* \times P$. We define three endomorphisms fields $\tilde{I}_1, \tilde{I}_2, \tilde{I}_3$ on \tilde{M} of rank $\tilde{I}_\alpha = 4n + 4$ ($\alpha = 1, 2, 3$) as follows:

$$\begin{aligned} \tilde{I}_\alpha V_1 &= 0, \quad \tilde{I}_\alpha e_0^R = e_\alpha^R, \quad \tilde{I}_\alpha e_\alpha^R = -e_0^R, \quad \tilde{I}_\alpha e_\beta^R = e_\gamma^R, \quad \tilde{I}_\alpha e_\gamma^R = -e_\beta^R, \\ (\tilde{I}_\alpha)_{(z,p)}((Y^{h\eta})_{(z,p)}) &= ((I'_\alpha)_{\pi(p)}(\pi_* Y))^{h\eta}_{(z,p)} \end{aligned}$$

for $Y \in T_p M$. Here I'_α is defined by

$$(3.2) \quad I'_\alpha = \sum_{\beta=1}^3 A_{\alpha\beta} I_\beta,$$

where $A = (A_{\alpha\beta}) \in \text{SO}(3)$ is the representation matrix of $\text{Ad}_z|_{\text{Im}\mathbb{H}}$ with respect to the basis (i, j, k) . Note that $\text{Ker } \tilde{I}_\alpha = \langle V_1 \rangle$, $\text{Im } \tilde{I}_\alpha = T\mathbb{H}^* \oplus \text{Ker } \eta$ ($\alpha = 1, 2, 3$) and that $\tilde{I}_1, \tilde{I}_2, \tilde{I}_3$ satisfy the quaternionic relations on $T\mathbb{H}^* \oplus \text{Ker } \eta$.

Lemma 3.5. $L_{e_0^R} \tilde{I}_\alpha = 0$.

Proof. The flow $\varphi_t : (z, p) \mapsto (e^t z, p)$ of e_0^R preserves the decomposition $\tilde{M} = \mathbb{H}^* \times P$ and acts trivially on the second factor. In particular, it preserves the distribution $\text{Ker } \eta$. The action on the first factor is tri-holomorphic with respect to the (standard) hypercomplex structure induced by (\tilde{I}_α) on \mathbb{H}^* . Since $\text{Ad}_z = \text{Ad}_{rz}$ for all $r > 0$, we also see that φ_t preserves the tensors $\tilde{I}_\alpha|_{\text{Ker } \eta}$. \square

Lemma 3.6. *If Z is rotating and $L_Z \Theta = 0$, then we have $L_{V_1} \tilde{I}_\alpha = 0$.*

Proof. By the definition of \tilde{I}_α , it is easy to obtain $(L_{V_1} \tilde{I}_\alpha) V_1 = 0$ and $(L_{V_1} \tilde{I}_\alpha) e_\delta^R = 0$ ($\delta = 0, \dots, 3$). Moreover, by Lemma 3.4, we have

$$\begin{aligned} & (L_{V_1} \tilde{I}_\alpha)_{(z,p)}(Y^{h_\eta}) \\ &= [V_1, \tilde{I}_\alpha Y^{h_\eta}]_{(z,p)} - \tilde{I}_\alpha [V_1, Y^{h_\eta}]_{(z,p)} \\ &= [e_1^L, \tilde{I}_\alpha Y^{h_\eta}]_{(z,p)} - [Z_1, \tilde{I}_\alpha Y^{h_\eta}]_{(z,p)} + \tilde{I}_\alpha [Z, Y]^{h_\eta}_{(z,p)} \\ &= [e_1^L, \tilde{I}_\alpha Y^{h_\eta}]_{(z,p)} - [Z^h, \tilde{I}_\alpha Y^{h_\eta}]_{(z,p)} - [f_1 X_P, \tilde{I}_\alpha Y^{h_\eta}]_{(z,p)} + (I'_\alpha [Z, Y])^{h_\eta}_{(z,p)} \\ &= [e_1^L, \tilde{I}_\alpha Y^{h_\eta}]_{(z,p)} - ((L_Z I'_\alpha) Y)^{h_\eta}_{(z,p)}, \end{aligned}$$

where we have used that $[Z^h, \tilde{I}_\alpha Y^{h_\eta}] + [f_1 X_P, \tilde{I}_\alpha Y^{h_\eta}] = [Z, I'_\alpha Y]^{h_\eta} + \eta([Z, I'_\alpha Y]) X_P - (I'_\alpha Y)(f_1) X_P = [Z, I'_\alpha Y]^{h_\eta}$ at the point (z, p) , by Lemma 3.2. Taking the flow φ_t generated by e_1^L , we have

$$[e_1^L, \tilde{I}_\alpha Y^{h_\eta}]_{(z,p)} = \sum_{\beta=1}^3 \left(\frac{d}{dt} \Big|_{t=0} A_{\alpha\beta}(t) \right) (I_\beta Y)^{h_\eta}_{(z,p)},$$

where

$$A(t) = (A_{\alpha\beta}(t)) = \begin{pmatrix} 1 & 0 & 0 \\ 0 & \cos 2t & \sin 2t \\ 0 & -\sin 2t & \cos 2t \end{pmatrix} \in \text{SO}(3),$$

is the matrix associated with $\varphi_t(z)$. On the other hand, we see that

$$\begin{aligned} L_Z I'_1 &= -2A_{12} I_3 + 2A_{13} I_2, \\ L_Z I'_2 &= -2A_{22} I_3 + 2A_{23} I_2, \\ L_Z I'_3 &= -2A_{32} I_3 + 2A_{33} I_2 \end{aligned}$$

and hence

$$L_Z(I'_1, I'_2, I'_3) = (L_Z I'_1, L_Z I'_2, L_Z I'_3) = (I_1, I_2, I_3) \left(\frac{d}{dt} A(t) \right).$$

Therefore we have $(L_{V_1} \tilde{I}_\alpha)_{(z,p)}(Y^{h_\eta}) = 0$. \square

By Lemma 3.6, we can define an almost hypercomplex structure $(\hat{I}_1, \hat{I}_2, \hat{I}_3)$ on \hat{M} satisfying $\tilde{\pi}_* \circ \tilde{I}_\alpha = \hat{I}_\alpha \circ \tilde{\pi}_*$.

Lemma 3.7. *The almost hypercomplex structure $\hat{H} = (\hat{I}_1, \hat{I}_2, \hat{I}_3)$ is integrable, that is, (\hat{M}, \hat{H}) is a hypercomplex manifold.*

Proof. Let \tilde{X} and \tilde{Y} be projectable vector fields on the total space of the submersion $\tilde{\pi} : \tilde{M} \rightarrow \hat{M}$ and denote by $X = \tilde{\pi}_* \tilde{X}$, $Y = \tilde{\pi}_* \tilde{Y}$ their projections. Then we have $\tilde{\pi}_*(N^{\tilde{I}_\alpha}(\tilde{X}, \tilde{Y})) = N^{\hat{I}_\alpha}(X, Y)$, where $N^{\tilde{I}_\alpha}$ and $N^{\hat{I}_\alpha}$ are the Nijenhuis tensors of \tilde{I}_α and \hat{I}_α , respectively. Using that $\tilde{I}_\alpha V_1 = 0$ and $L_{V_1} \tilde{I}_\alpha = 0$ (Lemma 3.6) we see that $N^{\tilde{I}_\alpha}(V_1, \cdot) = 0$. Since $N^{\tilde{I}_\alpha}$ and $N^{\hat{I}_\alpha}$ are tensors, it is sufficient to show that the horizontal component of $N^{\tilde{I}_\alpha}(A, B)$ vanishes for sections A and B of $\langle e_0^R, e_1^R, e_2^R, e_3^R \rangle \oplus \text{Ker } \eta$. It is easy to see that $N^{\tilde{I}_\alpha}(e_a^R, e_b^R) = 0$ and $N^{\tilde{I}_\alpha}(e_a^R, X^{h_\eta}) = 0$, for all $a, b \in \{0, \dots, 3\}$. So we only need to show that the horizontal component of $N^{\tilde{I}_\alpha}(X^{h_\eta}, Y^{h_\eta})$ vanishes, i.e. the component in $\langle e_0^R, e_1^R, e_2^R, e_3^R \rangle \oplus \text{Ker } \eta$. It is given by

$$([X, Y] + I'_\alpha[X, I'_\alpha Y] + I'_\alpha[I'_\alpha X, Y] - [I'_\alpha X, I'_\alpha Y])^{h_\eta} = 0,$$

since (I'_1, I'_2, I'_3) is a hypercomplex structure on M , for every $z \in \mathbb{H}^*$. \square

Since $L_{V_1} e_0^R = 0$, we can define a vector field $V = \tilde{\pi}_* e_0^R$ on \hat{M} . Let $\hat{\nabla}^0$ be the Obata connection with respect to \hat{H} .

Lemma 3.8. *We have $\hat{\nabla}^0 V = \text{id}$.*

Proof. Using the explicit representation of the Obata connection (see [5] for example) and Lemma 3.5, we have

$$12(\hat{\nabla}_{\tilde{\pi}_* Y}^0 \tilde{\pi}_* e_0^R) = \tilde{\pi}_* \left(\sum_{(\alpha, \beta, \gamma)} (\tilde{I}_\alpha[\tilde{I}_\beta Y, e_\gamma^R] + \tilde{I}_\alpha[e_\beta^R, \tilde{I}_\gamma Y]) + 2 \sum_{\alpha=1}^3 \tilde{I}_\alpha[e_\alpha^R, Y] \right),$$

where (α, β, γ) indicates sum over cyclic permutations of $(1, 2, 3)$ and Y is a projectable vector field on \tilde{M} commuting with e_0^R . Evaluating the expression on $Y = e_a^R$ and $Y = U^{h_\eta}$, we obtain $12\tilde{\pi}_* Y$. \square

As a consequence, by Lemmas 3.7 and 3.8, we can conclude

Theorem 3.9 (Conification). *Let M be a hypercomplex manifold with a hypercomplex structure $H = (I_1, I_2, I_3)$, a closed two-form Θ and a rotating vector field Z such that $L_Z\Theta = 0$. Let f be a smooth function on M such that $df = -\iota_Z\Theta$ and assume $f_1 := f - (1/2)\Theta(Z, I_1Z)$ does nowhere vanish. Consider a principal $U(1)$ -bundle $\pi : P \rightarrow M$ with a connection form η whose curvature form is*

$$d\eta = \pi^* \left(\Theta - \frac{1}{2}d((\iota_Z\Theta) \circ I_1) \right).$$

*If the quotient map $\tilde{\pi} : \tilde{M} \rightarrow \hat{M}$ is a submersion, then (\hat{M}, \hat{H}) is a conical hypercomplex manifold with the Euler vector field $V = \tilde{\pi}_*e_0^R$.*

Remark 3.10. The assumption that $\tilde{\pi}$ is a submersion is always satisfied locally by considering local 1-parameter subgroup generated by V_1 , since the vector field V_1 has no zeros. Note that “submersion” requires that the quotient space is a smooth manifold.

We say that (\hat{M}, \hat{H}, V) is the **conification** of (M, H, Z, f, Θ) associated with (P, η) and denote it by $(\hat{M}, \hat{H}, V) = \mathcal{C}_{(P, \eta)}(M, H, Z, f, \Theta)$ (or simply $\hat{M} = \mathcal{C}_P(M)$ if there is no confusion).

4 The hypercomplex/quaternionic-correspondence

Building on the conification construction of the last section we will now construct a quaternionic manifold \bar{M} of dimension $\dim \bar{M} = \dim M$ from a hypercomplex manifold M with rotating vector field. The resulting quaternionic manifold is endowed with a torsion-free quaternionic connection and an affine quaternionic vector field X .

The space of leaves of the integrable distribution $\mathcal{D} := \langle V, \hat{I}_1V, \hat{I}_2V, \hat{I}_3V \rangle$ on \hat{M} is denoted by \bar{M} . We shall show that $\bar{M} = \mathcal{C}_P(M)/\mathcal{D}$ is a quaternionic manifold, which is the main theorem of this paper. In addition, we show that \bar{M} has a natural quaternionic connection $\bar{\nabla}$ and an affine quaternionic vector field X induced from the fundamental vector field X_P of $P \rightarrow M$.

Using Theorem 3.9 and a similar argument as in [24, Theorem 2.1], we prove Theorem 4.1.

Theorem 4.1 (H/Q-correspondence). *Let M be a hypercomplex manifold with a hypercomplex structure $H = (I_1, I_2, I_3)$, a closed two-form Θ and a rotating vector field Z such that $L_Z\Theta = 0$. Let f be a smooth function on M such that $df = -\iota_Z\Theta$ and assume that $f_1 := f - (1/2)\Theta(Z, I_1Z)$ does nowhere vanish. Consider a principal $U(1)$ -bundle $\pi : P \rightarrow M$ with a connection form η whose curvature form is*

$$d\eta = \pi^* \left(\Theta - \frac{1}{2}d((\iota_Z\Theta) \circ I_1) \right).$$

If both quotient maps $\tilde{\pi} : \tilde{M} \rightarrow \hat{M}$ and $\hat{\pi} : \hat{M} \rightarrow \bar{M}$ defined above are submersions, then there exists an induced quaternionic structure \bar{Q} on \bar{M} .

Proof. As we proved in Theorem 3.9, $\hat{M} = \mathcal{C}_P(M)$ is a conical hypercomplex manifold with the hypercomplex structure $\hat{H} = (\hat{I}_1, \hat{I}_2, \hat{I}_3)$. Let $\varphi = \sum_{a=0}^3 \varphi_a i_a$ ($(i_0, i_1, i_2, i_3) = (1, i, j, k)$) be the right-invariant Maurer-Cartan form on \mathbb{H}^* and extend it with the same letter to \hat{M} as $\varphi|_{TP} = 0$. Set $\tilde{\theta}_0 = \varphi_0$. Since $L_{V_1} \tilde{\theta}_0 = 0$, we can define the one-form $\hat{\theta}_0$ on \hat{M} such that $\tilde{\theta}_0 = \tilde{\pi}^* \hat{\theta}_0$. We define $\hat{\theta}' = \hat{\theta}_0 + \sum_{\alpha=1}^3 (\hat{\theta}_0 \circ \hat{I}_\alpha) i_\alpha$ and take the Euler vector field V on \hat{M} as in Theorem 3.9. Here define an \hat{I}_α -invariant distribution

$$\hat{\mathcal{H}} := \text{Ker } \hat{\theta}'.$$

It holds that $T\hat{M} = \mathcal{D} \oplus \hat{\mathcal{H}}$. Since $L_V \hat{\theta}' = 0$ and $L_{\hat{I}_\alpha V} \hat{\theta}' = 2(\hat{\theta}_0 \circ \hat{I}_\beta) i_\gamma - 2(\hat{\theta}_0 \circ \hat{I}_\gamma) i_\beta$ for any cyclic permutation (α, β, γ) (these are checked by straightforward calculations), the distribution $\hat{\mathcal{H}}$ is invariant along leaves of \mathcal{D} . Since $\hat{\pi}$ is a submersion, there exist a neighborhood $\mathcal{U} \subset \bar{M}$ of $x \in \bar{M}$ and a section $s : \mathcal{U} \rightarrow \hat{M}$. Then we can define

$$\bar{I}_\alpha(Y) := \hat{\pi}_*(\hat{I}_\alpha(Y_s^{h_{\hat{\theta}'}}))$$

for $y \in \mathcal{U}$, where $Y \in T_y \bar{M}$ and $Y^{h_{\hat{\theta}'}}$ is the $\hat{\theta}'$ -horizontal lift of Y with respect to $\hat{\mathcal{H}}$. Although each \bar{I}_α depends on the sections, the subbundle $\bar{Q} = \langle \bar{I}_1, \bar{I}_2, \bar{I}_3 \rangle \subset \text{End}(T\bar{M})$ is independent of the section by Lemma 2.2. This means that (\bar{M}, \bar{Q}) is an almost quaternionic manifold.

Next we show that there exists a torsion-free connection which preserves \bar{Q} . We define a connection $\bar{\nabla}$ on \bar{M} by

$$(4.1) \quad \bar{\nabla}_Y W = \hat{\pi}_*(\hat{\nabla}_{Y^{h_{\hat{\theta}'}}}^0 W^{h_{\hat{\theta}'}}), \quad Y, W \in \Gamma(T\bar{M}),$$

where $\hat{\nabla}^0$ is the Obata connection of \hat{M} . Note that $\bar{\nabla}$ is well-defined by Lemma 2.3. Since the Obata connection is torsion-free, then so is $\bar{\nabla}$. To show that $\bar{\nabla}$ preserves \bar{Q} , we consider $I \in \Gamma(\bar{Q})$. Then $(IW)^{h_{\hat{\theta}'}} = \sum_{\alpha=1}^3 a_\alpha \hat{I}_\alpha W^{h_{\hat{\theta}'}}$ for some functions a_α with $\sum_{\alpha=1}^3 a_\alpha^2 = 1$, which implies

$$(\bar{\nabla}_Y I)W = \hat{\pi}_*\left(\sum_{\alpha=1}^3 (Y^{h_{\hat{\theta}'}} a_\alpha) \hat{I}_\alpha W^{h_{\hat{\theta}'}}\right),$$

showing that $\bar{\nabla}$ preserves \bar{Q} . Therefore (\bar{M}, \bar{Q}) is a quaternionic manifold. \square

Remark 4.2. The assumption that $\hat{\pi}$ is a submersion is always satisfied locally.

Next we shall show that our construction induces a vector field X which is an affine quaternionic vector field of $(\bar{M}, \bar{Q}, \bar{\nabla})$, where $\bar{\nabla}$ is given by (4.1).

Lemma 4.3. *We have $L_{V_1} X_P = 0$ and $L_{X_P} \tilde{I}_\alpha = 0$.*

Proof. The first equation can be checked by a straightforward calculation. The second follows from $[X_P, \tilde{I}_\alpha Y^{h_\eta}] = [X_P, (I'_\alpha Y)^{h_\eta}] = 0$. \square

By Lemma 4.3, we can define a vector field $\widehat{X}_P := \tilde{\pi}_* X_P$ on \hat{M} . Moreover \widehat{X}_P satisfies the following.

Lemma 4.4. *We have $L_{\widehat{X}_P} \widehat{I}_\alpha = 0$, in addition, $L_{\widehat{X}_P} \widehat{\nabla}^0 = 0$.*

Proof. The first claim follows from Lemma 4.3, as $(L_{\widehat{X}_P} \widehat{I}_\alpha) \circ \tilde{\pi}_* = \tilde{\pi}_* \circ (L_{X_P} \tilde{I}_\alpha)$. Since the Obata connection is uniquely determined by the hypercomplex structure, we have $L_{\widehat{X}_P} \widehat{\nabla}^0 = 0$ by the invariance of the hypercomplex structure $(\widehat{I}_1, \widehat{I}_2, \widehat{I}_3)$ under \widehat{X}_P . \square

The next two lemmas follow respectively from $[e_a^R, X_P] = 0$ and $L_{X_P} \tilde{\theta}_0 = 0$ by projection.

Lemma 4.5. *We have $L_V \widehat{X}_P = 0$ and $L_{\widehat{I}_\alpha V} \widehat{X}_P = 0$.*

Lemma 4.6. *We have $L_{\widehat{X}_P} \widehat{\theta}_0 = 0$ on \widehat{M} .*

Lemma 4.5 allows us to define a vector field $X := \hat{\pi}_* \widehat{X}_P$ on \bar{M} .

Proposition 4.7. *Let (\bar{M}, \bar{Q}) be a quaternionic manifold obtained from a hypercomplex manifold M satisfying the assumptions in Theorem 4.1 and $\bar{\nabla}$ the quaternionic connection defined by (4.1). The vector field X is an affine quaternionic vector field of $(\bar{M}, \bar{Q}, \bar{\nabla})$, that is, satisfies $L_X \Gamma(\bar{Q}) \subset \Gamma(\bar{Q})$ and $L_X \bar{\nabla} = 0$.*

Proof. It follows easily from Lemma 4.4 that X preserves the quaternionic structure \bar{Q} . From Lemma 4.4, Lemma 4.6 and the closure of $\widehat{\theta}_0$ we do also obtain that $p_v[\widehat{X}_P, Y^{h_{\hat{\theta}'}}] = 0$, where p_h and p_v denote the projections from $T\widehat{M}$ onto the horizontal and vertical subbundles, respectively. Using this, for any vector fields Y and W on \bar{M} , we compute

$$\begin{aligned} (L_X \bar{\nabla})_Y W &= \hat{\pi}_* \left([\widehat{X}_P, \widehat{\nabla}_{Y^{h_{\hat{\theta}'}}}^0 W^{\mathcal{H}}] - \widehat{\nabla}_{p_h[\widehat{X}_P, Y^{h_{\hat{\theta}'}}]}^0 W^{h_{\hat{\theta}'}} - \widehat{\nabla}_{Y^{h_{\hat{\theta}'}}}^0 p_h[\widehat{X}_P, W^{h_{\hat{\theta}'}}] \right) \\ &= \hat{\pi}_* \left((L_{\widehat{X}_P} \widehat{\nabla}^0)_{Y^{h_{\hat{\theta}'}}} W^{h_{\hat{\theta}'}} + \widehat{\nabla}_{p_v[\widehat{X}_P, Y^{h_{\hat{\theta}'}}]}^0 W^{h_{\hat{\theta}'}} + \widehat{\nabla}_{Y^{h_{\hat{\theta}'}}}^0 p_v[\widehat{X}_P, W^{h_{\hat{\theta}'}}] \right) = 0. \quad \square \end{aligned}$$

We call the correspondence from a hypercomplex manifold (M, H, Z, f, Θ) to a quaternionic manifold $(\bar{M}, \bar{Q}, \bar{\nabla}, X)$ described in Theorem 4.1 (and Proposition 4.7 for the additional structure X) the **hypercomplex/quaternionic-correspondence** (H/Q-correspondence for short). As we mentioned in Remarks 3.10 and 4.2, the global assumption in Theorem 4.1 (H/Q-correspondence) that $\tilde{\pi}$ and $\hat{\pi}$ are submersions is always satisfied locally. Under stronger assumptions and by considering Swann's twist [27], we have the following global result. We use the notation ζ_A for the action induced from the group $\langle A \rangle$ generated by a vector field A to distinguish U(1)-actions.

Theorem 4.8 (H/Q-correspondence, second version). *Let M be a hypercomplex manifold with a hypercomplex structure $H = (I_1, I_2, I_3)$, a closed two-form Θ and a rotating vector field Z such that $L_Z \Theta = 0$. Let f be a smooth function on M such that $df = -\iota_Z \Theta$ and assume that $f_1 := f - (1/2)\Theta(Z, I_1 Z)$ does nowhere vanish. Consider a principal U(1)-bundle $\pi : P \rightarrow M$ with a connection form η whose curvature form is*

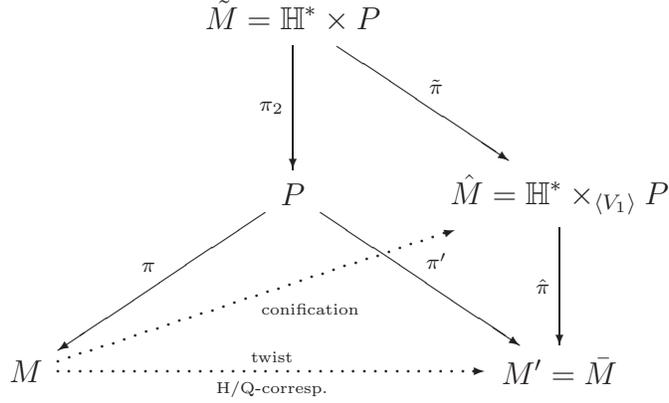

$$d\eta = \pi^* \left(\Theta - \frac{1}{2} d((\iota_Z \Theta) \circ I_1) \right).$$

If $Z_1 = Z^{h_\eta} + f_1 X_P$ generates a free U(1)-action on P , then the conification \widehat{M} of M is $\mathbb{H}^ \times_{\langle V_1 \rangle} P$ and the quaternionic manifold \bar{M} coincides with the twist of M given by the twist data $(\Theta - \frac{1}{2} d((\iota_Z \Theta) \circ I_1), Z, f_1)$ as manifolds.*

Proof. By Lemma 3.2, we see $\iota_Z d\eta = -df_1$. It follows that $L_Z d\eta = 0$ from the assumptions $L_Z \Theta = 0$ and $L_Z I_1 = 0$. Therefore we obtain a twist $M' := P/\langle Z_1 \rangle$ of M with the twist data $(\Theta - \frac{1}{2}d((\iota_Z \Theta) \circ I_1), Z, f_1)$ since $Z_1 = Z^{h_\eta} + f_1 X_P$ generates a free $U(1)$ -action. Let $\pi' : P \rightarrow M'$ be the quotient map by the action of $\langle Z_1 \rangle$. We define an action of $\langle V_1 \rangle (\cong U(1)) \subset \langle e_1^L \rangle \times \langle Z_1 \rangle$ on $\mathbb{H}^* \times P$ by

$$\zeta_{V_1}(u)(z, p) = (\zeta_{e_1^L}(u)z, \zeta_{Z_1}(u^{-1})p)$$

for $(z, p) \in \mathbb{H}^* \times P$. We see that the conification \hat{M} of M is a fiber bundle $(\mathbb{H}^* \times P)/\langle V_1 \rangle$ over M' , which is associated with $\pi' : P \rightarrow M'$ and usually denoted by $\mathbb{H}^* \times_{\langle V_1 \rangle} P$. Moreover the quotient of \hat{M} by \mathbb{H}^* is M' , that is, $\bar{M} = M'$.

In the above diagram, π_2 is the projection onto the second factor P . \square

Remark 4.9. Note that the bundle $\hat{\pi} : \hat{M} \rightarrow \bar{M}$ is associated to the principal $U(1)$ -bundle $P \rightarrow \bar{M} = M' = P/\langle Z_1 \rangle$. Therefore sections of $\hat{\pi}$ are in one-to-one correspondence with equivariant maps $P \rightarrow \mathbb{H}^*$. Let $\lambda : P \rightarrow \mathbb{H}^*$ be such that $\lambda(\zeta_{Z_1}(u)p) = \zeta_{e_1^L}(u^{-1})\lambda(p)$ for all $u \in U(1)$ and $p \in P$ and set $F_\lambda := [\lambda, \text{id}]_{\langle V_1 \rangle} : P \rightarrow \hat{M}$. If we consider a local section $s : U(\subset \bar{M} = M') \rightarrow P$, then $s' := F_\lambda \circ s : U \rightarrow \hat{M}$ is a local section of $\hat{\pi} : \hat{M} \rightarrow \bar{M}$ and the equivariance of λ implies that s' is independent of s . As we observed in the proof of Theorem 4.1, the quaternionic structure $\bar{Q} = \langle \bar{I}_1, \bar{I}_2, \bar{I}_3 \rangle$ on \bar{M} is induced from the hypercomplex structure on \hat{M} and a local section s' . For $Y \in T_x \bar{M}$, we have

$$\bar{I}_\alpha(Y) = \hat{\pi}_*(\hat{I}_\alpha Y_{s'(x)}^{h_{\hat{\theta}'}}) = \hat{\pi}_*(\hat{I}_\alpha s'_* Y),$$

since the decomposition $T\hat{M} = \mathcal{D} \oplus \hat{\mathcal{H}}$ is \hat{I}_α -invariant. From $s' = F_\lambda \circ s = [\lambda \circ s, s]_{\langle V_1 \rangle} = \hat{\pi} \circ (\lambda \circ s, s)$, it holds that

$$\begin{aligned} (4.2) \quad \bar{I}_\alpha(Y) &= \hat{\pi}_*(\hat{I}_\alpha s'_* Y) \\ &= \hat{\pi}_*(\hat{I}_\alpha(\hat{\pi}_*((\lambda \circ s)_*(Y) + s_* Y))) \\ &= \hat{\pi}_*(\tilde{\pi}_*(\tilde{I}_\alpha((\lambda \circ s)_*(Y) + s_* Y))) \\ &= \pi'_*(\pi_{2*}(\tilde{I}_\alpha((\lambda \circ s)_*(Y) + s_* Y))) \\ &= \pi'_*(\pi_{2*}(\tilde{I}_\alpha s_* Y)). \end{aligned}$$

Note that $(\lambda \circ s)_*(Y) + s_*Y \in T_{(\lambda(s(x)), s(x))} \hat{M}$.

Next we consider the decomposition $TP|_{s(U)} = \langle Z_1 \rangle \oplus s_*(TU)$. Let p^\vee be the projection from $TP|_{s(U)}$ onto $s_*(TU)$. Note that $s_*(T_xU)$ is generated by the tangent vectors of the form $p^\vee(W_{s(x)}^{h_\eta}) =: W^\vee$ at each point $s(x)$, where W is a tangent vector of M at $\pi(s(x))$ and η is the connection form on P . We define (an almost hypercomplex structure) I_α^\vee on $s(U)$ by $I_\alpha^\vee(W^\vee) = (I'_\alpha W)^\vee$ for each $W^\vee \in s_*(T_xU)$, where I'_α is given by (3.2) for $z = \lambda(s(x))$. Since $\tilde{I}_\alpha(Z_1) = \tilde{I}_\alpha(e_1^L) \in T\mathbb{H}^*$ (by $\tilde{I}_\alpha V_1 = 0$), we have

$$(4.3) \quad \begin{aligned} p^\vee(\pi_{2*}(\tilde{I}_\alpha(W^\vee))) &= p^\vee(\pi_{2*}(\tilde{I}_\alpha(W^{h_\eta} + aZ_1))) = p^\vee(\tilde{I}_\alpha W^{h_\eta}) = p^\vee((I'_\alpha W)^{h_\eta}) \\ &= (I'_\alpha W)^\vee = I_\alpha^\vee(W^\vee), \end{aligned}$$

where $a \in \mathbb{R}$. Then it holds that

$$\bar{I}_\alpha(Y) = \pi'_*(\pi_{2*}(\tilde{I}_\alpha s_*Y)) = \pi'_*(p^\vee(\pi_{2*}(\tilde{I}_\alpha(s_*Y)))) = \pi'_*(I_\alpha^\vee(s_*Y))$$

from (4.2) and (4.3). Therefore \bar{Q} can be identified with $\langle I_1^\vee, I_2^\vee, I_3^\vee \rangle$ on $s(U)$. Note that $\langle I_1^\vee, I_2^\vee, I_3^\vee \rangle$ is independent of the choice of λ , and hence it is shown again that \bar{Q} is independent of the choice of λ , which is identified with a section of \hat{M} .

Note that a quaternionic Kähler metric obtained by the HK/QK-correspondence is described directly in terms of the objects on P (instead of \hat{M}) in [4, 21].

Remark 4.10. The conification \hat{M} of M is locally isomorphic to the Swann bundle of \bar{M} , which is conical as discussed in Example 2.4. Note that the Swann bundle is an $\mathbb{H}^*/\{\pm 1\}$ -bundle over a quaternionic manifold whereas \bar{M} is the quotient of \hat{M} by \mathbb{H}^* as above. Indeed, take an open set U of \bar{M} and local sections $s : U \rightarrow \hat{M}$, $s' : U \rightarrow \mathcal{U}(\bar{M})$, where $\pi^{Sw} : \mathcal{U}(\bar{M}) \rightarrow \bar{M}$ is the Swann bundle of \bar{M} . For a local trivialization $\Phi : \hat{\pi}^{-1}(U) \rightarrow U \times \mathbb{H}^*$ associated to s and given by $\Phi(x) = (\hat{\pi}(x), \phi(x))$, we can define a double covering $F : \hat{\pi}^{-1}(U) \rightarrow (\pi^{Sw})^{-1}(U)$ by

$$F(x) = \Phi'^{-1}(s'(\hat{\pi}(x)), p(\phi(x))).$$

Here $\Phi' : (\pi^{Sw})^{-1}(U) \rightarrow U \times \mathbb{H}^*/\{\pm 1\}$ is a local trivialization associated to s' and $p : \mathbb{H}^* \rightarrow \mathbb{H}^*/\{\pm 1\}$ is the projection. See [24, 6] for the (twisted) Swann bundle.

5 Examples of the H/Q-correspondence

In this section, we give examples of the H/Q-correspondence.

Example 5.1 (HK/QK-correspondence). Let $(M, g, H = (I_1, I_2, I_3))$ be a (possibly indefinite) hyper-Kähler manifold with a rotating Killing vector field Z and f a nowhere vanishing smooth function such that $df = -\iota_Z \Theta$, where Θ is the Kähler form with respect to g and I_1 . Set $f_1 = f - (1/2)g(Z, Z)$ and assume that the functions $g(Z, Z)$ and f_1 are nowhere zero. From these data, we can obtain a (possibly indefinite) quaternionic Kähler manifold (\bar{M}, \bar{g}) [15, 2, 4]. The metric \bar{g} is positive definite under the assumptions specified in [2, Corollary 2] for the signs of the functions f, f_1 and for the signature of g . Also the sign of the scalar curvature of \bar{M} is determined by these choices.

In the HK/QK-correspondence, the initial data Θ is a non-degenerate 2-form. In our more general setting, we may also choose $\Theta = 0$, like in the following example.

Example 5.2 (Conical hypercomplex manifold). Let $(M, (I_1, I_2, I_3), V)$ be a conical hypercomplex manifold with the Euler vector field V . Choose $f_1 = f = 1$, $\Theta = 0$, and consider the trivial principal bundle $P = M \times \mathrm{U}(1)$ with the connection $\eta = dt$, where t is the angular coordinate of $\mathrm{U}(1)$ such that $dt(X_P) = 1$ on the fundamental vector field X_P . We assume that $Z := I_1 V$ generates a free $\mathrm{U}(1)$ -action on M and that the periods of Z , X_P and e_1^L are the same. It holds that Z is rotating from Lemma 2.2. Then V_1 generates a free $\mathrm{U}(1)$ -action on $\tilde{M} = \mathbb{H}^* \times P = \mathbb{H}^* \times M \times \mathrm{U}(1)$ of the same period. Therefore

$$\hat{M} (= (\mathbb{H}^* \times M \times \mathrm{U}(1)) / \langle V_1 \rangle) \ni [z, p, q] = [zq, \zeta_Z(q^{-1})p, 1] \mapsto (zq, \zeta_Z(q^{-1})p) \in \mathbb{H}^* \times M$$

gives a diffeomorphism $\hat{M} \cong \mathbb{H}^* \times M$, and hence $\bar{M} \cong M$ as smooth manifolds. In fact, we can define a diffeomorphism $\varphi' : M \rightarrow M' (= \bar{M})$ by $\varphi'(x) = \pi'(x, 1)$. A global section $\bar{M} \rightarrow \hat{M}$ gives rise to a hypercomplex structure $(\bar{I}_1, \bar{I}_2, \bar{I}_3)$ on \bar{M} but the latter does not coincide with (I_1, I_2, I_3) in general (under the diffeomorphism φ'). The quaternionic structure \bar{Q} on \bar{M} , however, coincides with $\langle I_1, I_2, I_3 \rangle$. Note that \bar{Q} is independent of the section, as shown in the proof of Theorem 4.1 and Remark 4.9. More explicitly, considering $\lambda_z : M \times \mathrm{U}(1) \rightarrow \mathbb{H}^*$ defined by $\lambda_z(x, u) = z \cdot u^{-1}$ ($z \in \mathbb{H}^*$) and the section $s : \bar{M} \rightarrow P$ defined by $s(x) = ((\varphi')^{-1}(x), 1)$, we see that the section $F_{\lambda_1} \circ s$ gives the hypercomplex structure (I_1, I_2, I_3) and, hence, the quaternionic structure $\langle I_1, I_2, I_3 \rangle$ on $\bar{M} \cong M$.

The next example shows that our H/Q-correspondence is a proper generalization of the HK/QK-correspondence.

Example 5.3 (Hypercomplex Hopf manifold). Consider $\mathbb{H}^n \cong \mathbb{R}^{4n}$ as a right-vector space over the quaternions with the standard hypercomplex structure

$$\tilde{H} = (\tilde{I}_1 = R_i, \tilde{I}_2 = R_j, \tilde{I}_3 = \tilde{I}_1 \tilde{I}_2 = -R_k)$$

and the standard flat hyper-Kähler metric \tilde{g} and set $\tilde{M} = \mathbb{H}^n \setminus \{0\}$. Take $A \in \mathrm{Sp}(n)\mathrm{Sp}(1)$ and $\lambda > 1$. Then $\langle \lambda A \rangle$ is a group of homotheties which acts freely and properly discontinuously on the simply connected manifold \tilde{M} . The quotient space $\tilde{M} / \langle \lambda A \rangle$ inherits a quaternionic structure Q and a quaternionic connection ∇ which are invariant under the centralizer G^Q of λA in $\mathrm{GL}(n, \mathbb{H})\mathrm{Sp}(1)$. In fact, the quaternionic structure \tilde{Q} on \tilde{M} is $\mathrm{GL}(n, \mathbb{H})\mathrm{Sp}(1)$ -invariant and induces therefore an almost quaternionic structure Q on $\tilde{M} / \langle \lambda A \rangle$, since $\langle \lambda A \rangle \subset \mathrm{GL}(n, \mathbb{H})\mathrm{Sp}(1)$. Moreover, the Levi-Civita connection $\tilde{\nabla}$ on (\tilde{M}, \tilde{g}) , which coincides with the Obata connection with respect to \tilde{H} , is invariant under all homotheties of \tilde{M} . Since $\langle \lambda A \rangle$ acts by homotheties, we see that $\tilde{\nabla}$ induces a torsion-free connection ∇ on $\tilde{M} / \langle \lambda A \rangle$, which preserves Q . This means that Q is a quaternionic structure on $\tilde{M} / \langle \lambda A \rangle$. In particular, if $A \in \mathrm{Sp}(n)$, then the quotient $\tilde{M} / \langle \lambda A \rangle$ inherits an induced hypercomplex structure $H = (I_1, I_2, I_3)$ from \tilde{H} , which is invariant under the centralizer G^H of λA in $\mathrm{GL}(n, \mathbb{H})$, since $\langle \lambda A \rangle$ preserves \tilde{H} . We say

that $(\tilde{M}/\langle\lambda A\rangle, Q)$ (resp. $(\tilde{M}/\langle\lambda A\rangle, H)$) is a quaternionic (resp. hypercomplex) Hopf manifold. See [23, 10].

We start with a hypercomplex Hopf manifold $M := \tilde{M}/\langle\lambda A\rangle$, where $A \in \mathrm{Sp}(n)$. Take $q \in \mathrm{Sp}(1)$ such that $q \neq \pm 1$. The centralizer of q in $\mathrm{Sp}(1)$ is isomorphic to $U(1)$, which is denoted by $U_q(1)$. We consider a $U(1)$ -action : $z \mapsto ze^{-it}$ on \tilde{M} defined by the right multiplication of $U(1) \cong U_q(1) \subset \mathrm{Sp}(n)U_q(1) \subset \mathrm{Sp}(n)\mathrm{Sp}(1)$. This action induces one on M and the corresponding vector field Z is rotating. Therefore we can apply the same procedure as in Example 5.2 under the setting $P = M \times U_q(1)$ (resp. $\tilde{P} = \tilde{M} \times U_q(1)$) and $\Theta = 0$, and we have the quaternionic manifold $\bar{M}(= M')$ (resp. $\tilde{\bar{M}}(= \tilde{M}')$) by the H/Q-correspondence. In the following, the quotient map of an action by a group G is denoted by π_G and the objects associated with \tilde{M} are denoted by the corresponding letters for M with $\tilde{}$, for example, the projection of the twist from $\tilde{M} \times U_q(1)$ is denoted as $\tilde{\pi}'$, where we use the notation of Theorem 4.8. Let R_q be the right multiplication by q .

$$\begin{array}{ccc}
\tilde{M}' = \tilde{\bar{M}} = \tilde{M} & \xrightarrow{/\langle\lambda AR_q\rangle} & M' = \bar{M} \\
\tilde{\pi}' \uparrow & & \uparrow \pi' \\
\tilde{P} = \tilde{M} \times U_q(1) & \xrightarrow{/\langle\lambda A\rangle} & P = M \times U_q(1) \\
\tilde{\pi} \downarrow & & \downarrow \pi \\
\tilde{M} & \xrightarrow{/\langle\lambda A\rangle} & M
\end{array}$$

Since $\pi' \circ \pi_{\langle\lambda A\rangle} = \pi_{\langle\lambda AR_q\rangle} \circ \tilde{\pi}'$ and $\tilde{M}' = \tilde{M}$ is a manifold with an invariant quaternionic structure under the action of $\langle\lambda AR_q\rangle$ (Example 5.2 and Proposition 4.7), we have

$$\bar{M} = M' = \tilde{M}/\langle\lambda AR_q\rangle.$$

Therefore it holds that

$$M = \tilde{M}/\langle\lambda A\rangle \xrightarrow{\mathrm{H}/\mathrm{Q}} \bar{M} = \tilde{M}/\langle\lambda AR_q\rangle.$$

In particular, we can choose $A = E_n \in \mathrm{Sp}(n)$. Then the centralizer G^H of $\lambda = \lambda E_n$ is $\mathbb{R}^{>0} \times \mathrm{SL}(n, \mathbb{H})$. We take the subgroup $\mathbb{R}^{>0} \times \mathrm{Sp}(n)$ of G^H , which acts transitively on M . Then

$$M = (\mathbb{R}^{>0}/\langle\lambda\rangle) \times \frac{\mathrm{Sp}(n)}{\mathrm{Sp}(n-1)}.$$

On the other hand, considering the subgroup $\mathbb{R}^{>0} \times \mathrm{Sp}(n)U_q(1)$ of the centralizer G^Q of λR_q , we see that

$$(\mathbb{R}^{>0}/\langle\lambda\rangle) \times \frac{\mathrm{Sp}(n)}{\mathrm{Sp}(n-1)} \xrightarrow{\mathrm{H}/\mathrm{Q}} (\mathbb{R}^{>0}/\langle\lambda\rangle) \times \frac{\mathrm{Sp}(n)U(1)}{\mathrm{Sp}(n-1)\Delta_{U(1)}},$$

where $\Delta_{U(1)}$ is a diagonally embedded subgroup of $\mathrm{Sp}(n)U(1) \subset \mathrm{Sp}(n)\mathrm{Sp}(1)$ which is isomorphic to $U(1)$. Considering the case of $n = 2$, we have an invariant quaternionic structure on the homogeneous space

$$\bar{M} = \mathbb{R}^{>0}/\langle\lambda\rangle \times \frac{\mathrm{Sp}(2)U(1)}{\mathrm{Sp}(1)\Delta_{U(1)}} = \frac{T^2 \cdot \mathrm{Sp}(2)}{U(2)}$$

by the H/Q-correspondence. Note that $T^2 \times \mathrm{Sp}(2)$ carries a hypercomplex structure and $(T^2 \times \mathrm{Sp}(2))/U(2)$ is a homogeneous quaternionic manifold considered in [19].

Since M is diffeomorphic to $S^1 \times S^{4n-1}$, M can not admit any hyper-Kähler structure. Therefore the HK/QK-correspondence can not be applied to the hypercomplex Hopf manifold M . The H/Q-correspondence is thus a proper generalization of the HK/QK one.

In the following example, the closed form Θ is non-zero and degenerate.

Example 5.4 (Lie group with left-invariant hypercomplex structure). Consider $G = \mathrm{SU}(3)$. The Lie algebra \mathfrak{g} of G is decomposed as $\mathfrak{g} = \mathfrak{g}_0 + \mathfrak{g}_1$, where $\mathfrak{g}_0 = \mathfrak{s}(\mathfrak{u}(1) \oplus \mathfrak{u}(2)) \cong \mathfrak{u}(1) \oplus \mathfrak{su}(2) \cong \mathbb{H}$ and \mathfrak{g}_1 is the unique complementary \mathfrak{g}_0 -module with the action of \mathbb{H} obtained from the adjoint action of \mathfrak{g}_0 [19]. Denote by $V \in \mathfrak{g}_0$ the vector which corresponds to $1 \in \mathbb{H}$. We use the same letters for left-invariant vector fields and corresponding elements of \mathfrak{g} in this example. Three complex structures I_1, I_2, I_3 on \mathfrak{g} can be defined as follows. They preserve the decomposition $\mathfrak{g} = \mathfrak{g}_0 + \mathfrak{g}_1$ and act on $\mathfrak{g}_0 = \mathbb{H}$ by the standard hypercomplex structure $(R_i, R_j, R_i R_j = -R_k)$. On \mathfrak{g}_1 they are defined by

$$(5.1) \quad I_\alpha|_{\mathfrak{g}_1} = -\mathrm{ad}_{I_\alpha V}|_{\mathfrak{g}_1}, \quad \alpha = 1, 2, 3.$$

These structures extend to a left-invariant hypercomplex structure on G [19], which we denote again by (I_1, I_2, I_3) .

Let $G_0 \cong (U(1) \times \mathrm{SU}(2))/\{\pm 1\} \cong U(2)$ be the subgroup of G corresponding to \mathfrak{g}_0 . Note that $G_0 \subset G$ is a hypercomplex submanifold and therefore totally geodesic with respect to the Obata connection ∇^G of G [24]. The Obata connection ∇^{G_0} of G_0 is given by $\nabla_X^{G_0} Y = XY$ for $X, Y \in \mathfrak{g}_0 = \mathbb{H}$, where XY denotes the product of the quaternions X and Y . Indeed, ∇^{G_0} is torsion-free and I_1, I_2, I_3 are parallel with respect to ∇^{G_0} . Then it holds $\nabla_X^G V = \nabla_X^{G_0} V = X$ for $X \in \mathfrak{g}_0$. For $X \in \mathfrak{g}_1$, by (5.1) and the explicit expression of the Obata connection (see [5]), we also find that $\nabla_X^G V = X$. Hence the hypercomplex manifold $(G, (I_1, I_2, I_3))$ is conical with the Euler vector field V (see also [26]).

Consider the right-action of $U(2)$ on $\mathrm{SU}(3)$ given by

$$AB := A \begin{pmatrix} B & 0 \\ 0 & \det(B)^{-1} \end{pmatrix}$$

for $A \in \mathrm{SU}(3)$ and $B \in U(2)$. Let $l : \mathrm{SU}(3) \rightarrow \mathrm{SU}(3)/U(2) \cong \mathbb{C}P^2$ be the projection and $k : S^5 \rightarrow \mathbb{C}P^2$ the Hopf fibration. The pullback bundle $P := l^\# S^5$ of $k : S^5 \rightarrow \mathbb{C}P^2$

by l is a $U(1)$ -bundle over $SU(3)$. The usual identification between the Stiefel manifold $V_2(\mathbb{C}^3)$ and $SU(3)$ is given by

$$V_2(\mathbb{C}^3) \ni (a_1, a_2) \leftrightarrow A = (a_1, a_2, \bar{a}_1 \times \bar{a}_2) \in SU(3).$$

We can write

$$\begin{aligned} P &= \{(A, u) \in SU(3) \times S^5 \mid l(A) = k(u)\} \\ &= \{(A, u) \in SU(3) \times S^5 \mid \langle c_3(A) \rangle = \langle u \rangle \in \mathbb{C}P^2\} \\ &= \{(A, \alpha c_3(A)) \in SU(3) \times S^5 \mid \alpha \in U(1)\} \\ &\cong SU(3) \times U(1), \end{aligned}$$

where $c_3(A)$ denotes the third column of A . This shows that P is a trivial bundle. Let $l_{\#} : P \rightarrow S^5$ be the bundle map given by $l_{\#}(A, \alpha) = \alpha(\bar{a}_1 \times \bar{a}_2) = \alpha c_3(A)$. Consider the pullback connection $l_{\#}^* \eta$ on P from the standard one η of k and take $\Theta = l^* \omega$, where ω is the Kähler form on $\mathbb{C}P^2$. Set $Z := I_1 V$. We see that Z generates a $U(1)$ -action on $SU(3)$ and is rotating by Lemma 2.2. Since

$$\langle Z \rangle \subset SU(2) \subset U(2),$$

Z is tangent to the fiber of l . Hence, we have $\iota_Z \Theta = 0$, $L_Z \Theta = 0$, and also have $d\Theta = 0$ by $d\omega = 0$. So we can choose $f = f_1 = 1$ (see Section 3 for the notation) and then see that Z_1 generates a free $U(1)$ -action on P given by

$$\zeta_{Z_1}(u)(A, \alpha) = (\zeta_Z(u)(A), u\alpha), \quad u \in U(1).$$

To see this, it is sufficient to check that Z is horizontal with respect to the pull back connection. The vector field Z is lifted to $SU(3) \times U(1)$ as $Z_{(A, \alpha)} = (Z_A, 0) \in TSU(3) \times TU(1)$ for $A \in SU(3)$ and $\alpha \in U(1)$ with the same letter Z . From $Z \in \mathfrak{su}(2)$, it holds that

$$\begin{aligned} l_{\#*} Z_{(A, \alpha)} &= \left. \frac{d}{dt} l_{\#} (\zeta_Z(e^{it})(A, \alpha)) \right|_{t=0} \\ &= \left. \frac{d}{dt} l_{\#} ((\zeta_Z(e^{it})(A), \alpha)) \right|_{t=0} \\ &= \left. \frac{d}{dt} \alpha c_3(\zeta_Z(e^{it})(A)) \right|_{t=0} \\ &= \left. \frac{d}{dt} \alpha c_3(A) \right|_{t=0} = 0. \end{aligned}$$

In particular, $(l_{\#}^* \eta)(Z) = 0$, that is, Z is horizontal with respect to the pullback connection. So we see that $Z_1 = Z + X_P$. Therefore, by applying the H/Q-correspondence to $G = SU(3)$, we have a quaternionic manifold

$$\bar{G} = P / \langle Z_1 \rangle = (SU(3) \times U(1)) / U(1) \cong SU(3).$$

The identification is given by

$$(\mathrm{SU}(3) \times \mathrm{U}(1)) / \mathrm{U}(1) \ni [(A, \alpha)]_{\langle Z_1 \rangle} = [(\zeta_Z(\alpha^{-1})A, 1)]_{\langle Z_1 \rangle} \cong \zeta_Z(\alpha^{-1})A \in \mathrm{SU}(3).$$

Note that there exists no Riemannian metric g on G such that g is hyper-Kählerian with respect to (I_1, I_2, I_3) since G is compact. The situation is summarized in the following diagram.

$$\begin{array}{ccc}
 & P = l^\# S^5 \cong \mathrm{SU}(3) \times \mathrm{U}(1) & \\
 & \swarrow & \searrow \\
 \mathrm{SU}(3) = G & \cdots \cdots \cdots & \bar{G} \\
 \downarrow l & & \downarrow l_\# \\
 \mathrm{SU}(3)/\mathrm{U}(2) \cong \mathbb{C}P^2 & \xleftarrow{k} & S^5
 \end{array}$$

H/Q-corresp.

Note also that $\mathrm{SU}(3) \times \mathrm{U}(1)$ is a three-fold covering of $\mathrm{U}(3) : (A, \alpha) \mapsto \alpha A$. The kernel is the cyclic group $\{(\zeta, 1, \zeta^{-1}) \mid \zeta^3 = 1\}$. The principal bundle $P \rightarrow \mathrm{SU}(3)$ induces a principal bundle $\mathrm{U}(3) = P/\mathbb{Z}_3 \rightarrow \mathrm{PSU}(3) = \mathrm{SU}(3)/\mathbb{Z}_3$. The actions generated by Z_1 and Z commutes with that of \mathbb{Z}_3 . The vector field Z (resp. Z_1) on $\mathrm{SU}(3)$ (resp. $\mathrm{SU}(3) \times \mathrm{U}(1)$) induces one on $\mathrm{PSU}(3)$ (resp. $\mathrm{U}(3)$), which is denoted by the same letter Z (resp. Z_1). We obtain the following diagram.

$$\begin{array}{ccc}
 P/\langle Z_1 \rangle = \bar{G} \cong \mathrm{SU}(3) & \xrightarrow{/\mathbb{Z}_3} & \mathrm{U}(3)/\langle Z_1 \rangle = \bar{G}_1 \cong \mathrm{SU}(3)/\mathbb{Z}^3 \\
 \uparrow / \langle Z_1 \rangle & & \uparrow / \langle Z_1 \rangle \\
 P = \mathrm{SU}(3) \times \mathrm{U}(1) & \xrightarrow{/\mathbb{Z}_3} & P/\mathbb{Z}_3 = \mathrm{U}(3) \\
 \downarrow / \mathrm{U}(1) & & \downarrow / \mathrm{U}(1) \\
 G = \mathrm{SU}(3) & \xrightarrow{/\mathbb{Z}_3} & G_1 = \mathrm{PSU}(3)
 \end{array}$$

We can apply the H/Q-correspondence to the Lie group $G_1 = \mathrm{PSU}(3)$ with the induced left-invariant hypercomplex structure and see that its resulting space is $\mathrm{SU}(3)/\mathbb{Z}^3$. In fact, since the action of $\langle Z_1 \rangle$ on $\mathrm{U}(3)$ is given by $\zeta_{Z_1}(u)(\alpha A) = (u\alpha)(\zeta_Z(u)(A))$ and its orbit $\{(u\alpha)(\zeta_Z(u)(A)) \mid u \in \langle Z_1 \rangle\}$ of $\alpha A \in \mathrm{U}(3)$ intersects $\mathrm{SU}(3)$ at exactly three

points, then the resulting space $U(3)/\langle Z_1 \rangle$ is $SU(3)/\mathbb{Z}^3$. Consequently, we have $\bar{G}_1 \cong G_1$ again.

Next we compare the quaternionic structures on the resulting space(s) derived from the pullback connection η_1 , which is not flat, and the trivial connection η_0 as in Example 5.2. Recall the notation in Remark 4.9. We claim that the two quaternionic structures are different. We label the objects obtained from η_i by the symbol η_i or just by the letter i ($i = 0, 1$), when no confusion is possible. Since $Z^{h_{\eta_0}} = Z^{h_{\eta_1}}$, $\iota_Z \Theta_0 = \iota_Z 0 = 0$ and $\iota_Z \Theta_1 = 0$, the vector field Z_1 on P is $Z_1 = Z + X_P$ for both connections η_0 and η_1 . Then the resulting spaces \bar{G}^0 and \bar{G}^1 coincide and we simply write \bar{G} for both. Let a be the 1-form on \bar{G} such that $\eta_1 - \eta_0 = \pi^* a$. Consider a local section $s : \bar{G} \rightarrow P$. Since $W^{h_{\eta_1}} - W^{h_{\eta_0}} = -a(W)X_P$ for a tangent vector W at $\pi(s(x)) \in \bar{G}$ (we omit the reference points of tangent vectors), we have

$$W^{\vee 1} - W^{\vee 0} = -a(W)\mathfrak{X}$$

where $\mathfrak{X} = p^\vee(X_P)$ and we recall that $W^{\vee i} = p^\vee(W^{h_{\eta_i}})$. Therefore we see that

$$\begin{aligned} I_\alpha^{\vee 1}(W^{\vee 1}) &= (I'_\alpha W)^{\vee 1} \\ &= (I'_\alpha W)^{\vee 0} - a(I'_\alpha W)\mathfrak{X} \\ &= I_\alpha^{\vee 0}(W^{\vee 0}) - a(I'_\alpha W)\mathfrak{X} \\ &= I_\alpha^{\vee 0}(W^{\vee 1}) + a(W)I_\alpha^{\vee 0}\mathfrak{X} - a(I'_\alpha W)\mathfrak{X}. \end{aligned}$$

On the other hand, since $W^{\vee 1} = W^{h_{\eta_1}} + cZ_1 = W^{h_{\eta_1}} + c(Z^{h_{\eta_1}} + X_P)$, we have $\eta_1(W^{\vee 1}) = c$ and $\pi_*(W^{\vee 1}) = W + cZ$. It holds that

$$(\pi^* a)(W^{\vee 1}) = a(W) + ca(Z) = a(W) + a(Z)\eta_1(W^{\vee 1}).$$

Hence we have

$$I_\alpha^{\vee 1} = I_\alpha^{\vee 0} + (\pi^* a - a(Z)\eta_1) \otimes (I_\alpha^{\vee 0}\mathfrak{X}) - ((\pi^* a - a(Z)\eta_1) \circ I_\alpha^{\vee 1}) \otimes \mathfrak{X}.$$

Set $\rho := \pi^* a - a(Z)\eta_1$ and $A := \rho \otimes (I_\alpha^{\vee 0}\mathfrak{X}) - (\rho \circ I_\alpha^{\vee 1}) \otimes \mathfrak{X}$. If $Q^{\vee 0} := \langle I_1^{\vee 0}, I_2^{\vee 0}, I_3^{\vee 0} \rangle = Q^{\vee 1} := \langle I_1^{\vee 1}, I_2^{\vee 1}, I_3^{\vee 1} \rangle$, then $A^2 = -|A|^2 \text{id}$, where $|\cdot|$ is the norm induced from the metric on $Q^{\vee 0}$ such that $I_1^{\vee 0}, I_2^{\vee 0}, I_3^{\vee 0}$ are orthonormal. As the rank of A is at most 2, this is only possible if $A = 0$. This implies $\rho = \pi^* a - a(Z)\eta_1 = 0$, which is equivalent to $a = 0$. By Remark 4.9, the quaternionic structure \bar{Q}^i can be identified with $Q^{\vee i}$ ($i = 0, 1$). Then we see that $\bar{Q}^0 \neq \bar{Q}^1$ since $\eta_0 \neq \eta_1$. This proves the claim.

6 The tangent bundle of a special complex manifold and a generalization of the rigid c-map

In this section, we consider a generalization of the rigid c-map [9, 14, 3]. The generalization associates a hypercomplex manifold M , the Obata connection of which is Ricci-flat, with a special complex manifold. In the case of a *conical* special complex manifold, we

shall show that the hypercomplex manifold carries a canonical rotating vector field Z^M (Lemma 8.1), such that we can apply our H/Q correspondence. Consequently, we shall construct a quaternionic manifold from a conical special complex manifold as the generalized supergravity c-map (Theorem 8.3). We start with defining a class of manifolds generalizing conical special Kähler manifolds [3, 21].

Definition 6.1. *A special complex manifold (N, J, ∇) is a complex manifold (N, J) endowed with a torsion-free flat connection ∇ such that the $(1, 1)$ -tensor field ∇J is symmetric. A conical special complex manifold (N, J, ∇, ξ) is a special complex manifold (N, J, ∇) endowed with a vector field ξ such that*

- $\nabla \xi = \text{id}$ and
- $L_\xi J = 0$ or, equivalently, $\nabla_\xi J = 0$.

The connection ∇ is called the **special connection**. To see that $L_\xi J = 0$ is equivalent to $\nabla_\xi J = 0$ it suffices to write $L_\xi = \nabla_\xi - \nabla \xi = \nabla_\xi - \text{id}$, using that ∇ is torsion-free and $\nabla \xi = \text{id}$. We also note that the integrability of J follows from the symmetry of ∇J since ∇ is torsion-free. We set $A := \nabla J$.

Lemma 6.2. *For every conical special complex manifold, we have $L_{J\xi} J = A_{J\xi} = 0$.*

Proof. Based on the symmetry of ∇J , we compute

$$A_{J\xi} = A(J\xi) = -J(A\xi) = -JA\xi = 0.$$

Using this and the properties listed in Definition 6.1, we then obtain

$$(L_{J\xi} J)X = -A_{JX}\xi + JA_X\xi = 0$$

for all $X \in \Gamma(TN)$. Note that in the last step we have used the symmetry of $A = \nabla J$. \square

Next we consider the tangent bundle $TN =: M$ of a special complex manifold (N, J, ∇) . We can define the ∇ -horizontal lift $X^{h\nabla}$ and the vertical lift X^v of $X \in \Gamma(TN)$. See [7] for example. The $C^\infty(M)$ -module $\Gamma(TM)$ is generated by vector fields of the form $X^{h\nabla} + Y^v$, where $X, Y \in \Gamma(TN)$. On M , we define a triple of $(1, 1)$ -tensors (I_1, I_2, I_3) by

$$(6.1) \quad I_1(X^{h\nabla} + Y^v) = (JX)^{h\nabla} - (JY)^v,$$

$$(6.2) \quad I_2(X^{h\nabla} + Y^v) = Y^{h\nabla} - X^v,$$

$$(6.3) \quad I_3(X^{h\nabla} + Y^v) = (JY)^{h\nabla} + (JX)^v$$

for $X^{h\nabla} + Y^v \in TM$. Note that (I_1, I_2, I_3) is an almost hypercomplex structure. In fact, it is easy to see $I_\alpha^2 = -\text{id}$ and

$$(I_1 \circ I_2)(X^{h\nabla} + Y^v) = I_1(Y^{h\nabla} - X^v) = (JY)^{h\nabla} + (JX)^v = I_3(X^{h\nabla} + Y^v),$$

$$(I_2 \circ I_1)(X^{h\nabla} + Y^v) = I_2((JX)^{h\nabla} - (JY)^v) = -(JY)^{h\nabla} - (JX)^v = -I_3(X^{h\nabla} + Y^v)$$

for $X^{h\nabla} + Y^v \in TM$. Note that it holds

$$(6.4) \quad [X^{h\nabla}, Y^{h\nabla}] = [X, Y]^{h\nabla}, [X^{h\nabla}, Y^v] = (\nabla_X Y)^v, [X^v, Y^v] = 0$$

for $X, Y \in \Gamma(TN)$.

Lemma 6.3. *For every special complex manifold (N, J, ∇) , the canonical almost hypercomplex structure (I_1, I_2, I_3) on $M = TN$ is integrable, that is, $(M, (I_1, I_2, I_3))$ is a hypercomplex manifold.*

Proof. Thanks to (6.4), the Nijenhuis tensors of I_1 and I_2 can be easily calculated and we find the following. Using that J is integrable, ∇ is flat and ∇J is symmetric, we see that I_1 is integrable. Because ∇ is flat and torsion-free, I_2 is integrable. The integrability of I_3 follows from that of I_1 and I_2 [5, Theorem 3.2]. \square

We define a connection ∇' by

$$\nabla' := \nabla - \frac{1}{2}J(\nabla J) = \nabla - \frac{1}{2}JA.$$

Then we see that $\nabla'J = 0$ and ∇' is torsion-free for every special complex manifold. Moreover, when the special complex manifold is conical, it holds that $\nabla'\xi = \nabla\xi = \text{id}$.

Lemma 6.4. *For every special complex manifold (N, J, ∇) , we have*

$$R_{X,Y}^{\nabla'} = -\frac{1}{4}[A_X, A_Y]$$

for $X, Y \in TN$.

Proof. Set $S = -(1/2)J(\nabla J)$. Since ∇ is flat, we see that the curvature $R^{\nabla'}$ of ∇' is given by

$$R_{X,Y}^{\nabla'} = (\nabla_X S)_Y - (\nabla_Y S)_X + [S_X, S_Y]$$

for $X, Y \in TN$. By

$$\begin{aligned} (\nabla_X S)_Y - (\nabla_Y S)_X &= -\frac{1}{2}[A_X, A_Y] - \frac{1}{2}J(R_{X,Y}^{\nabla}J), \\ [S_X, S_Y] &= \frac{1}{4}[A_X, A_Y], \end{aligned}$$

we have the conclusion. \square

Hence a special complex manifold admits the complex connection ∇' such that $R^{\nabla'}$ is of type $(1, 1)$. In fact, it follows from $A_{JX} = -JA_X$ for all $X \in TN$. The following theorem is a generalization of the rigid c-map in the absence of a metric.

Theorem 6.5 (Generalized rigid c-map). *The tangent bundle of any special complex manifold (N, J, ∇) carries a canonical hypercomplex structure, defined by (6.1)-(6.3), and the Obata connection of the hypercomplex manifold $(M = TN, (I_1, I_2, I_3))$ is Ricci flat.*

Proof. The integrability of the canonical almost hypercomplex structure defined by (6.1)-(6.3) was proven in Lemma 6.3. Let $\tilde{\nabla}^0$ be its Obata connection. Using the explicit expression of the Obata connection, we have

$$\begin{aligned} \tilde{\nabla}_{X^{h\nabla}}^0 Y^{h\nabla} &= (\nabla'_X Y)^{h\nabla}, \quad \tilde{\nabla}_{U^v}^0 X^{h\nabla} = -\frac{1}{2}(JA_X U)^v = -\frac{1}{2}(JA_U X)^v \\ \tilde{\nabla}_{X^{h\nabla}}^0 U^v &= (\nabla'_X U)^v, \quad \tilde{\nabla}_{U^v}^0 V^v = \frac{1}{2}(JA_V U)^{h\nabla} = \frac{1}{2}(JA_U V)^{h\nabla} \end{aligned}$$

for $X, Y, U, V \in \Gamma(TN)$. It can be also checked directly, using by (6.1)-(6.4), that the above formulas for $\tilde{\nabla}^0$ on horizontal and vertical lifts extend uniquely to a torsion-free connection $\tilde{\nabla}^0$ for which I_1, I_2, I_3 are parallel. We see that the bundle projection from $(TN, \tilde{\nabla}^0)$ onto (N, ∇') is an affine submersion [1]. Again, a straightforward calculation (or the fundamental equations of an affine submersion) gives

$$\begin{aligned} R_{U^v, V^v}^{\tilde{\nabla}^0} W^v &= -\frac{1}{4}(A_U A_V W)^v + \frac{1}{4}(A_V A_U W)^v = (R_{U, V}^{\nabla'} W)^v, \\ R_{U^v, V^v}^{\tilde{\nabla}^0} X^{h\nabla} &= -\frac{1}{4}(A_U A_V X)^{h\nabla} + \frac{1}{4}(A_V A_U X)^{h\nabla} = (R_{U, V}^{\nabla'} X)^{h\nabla}, \\ R_{U^v, X^{h\nabla}}^{\tilde{\nabla}^0} V^v &= -\frac{1}{2}(J(H_{U, V}^{\nabla} J)X)^{h\nabla} - \frac{1}{4}(A_X A_U V)^{h\nabla} - \frac{1}{4}(A_U A_X V)^{h\nabla}, \\ R_{U^v, X^{h\nabla}}^{\tilde{\nabla}^0} Y^{h\nabla} &= \frac{1}{2}(J(H_{X, Y}^{\nabla} J)U)^v + \frac{1}{4}(A_X A_Y U)^v + \frac{1}{4}(A_U A_X Y)^v, \\ R_{X^{h\nabla}, Y^{h\nabla}}^{\tilde{\nabla}^0} U^v &= (R_{X, Y}^{\nabla'} U)^v, \\ R_{X^{h\nabla}, Y^{h\nabla}}^{\tilde{\nabla}^0} Z^{h\nabla} &= (R_{X, Y}^{\nabla'} Z)^{h\nabla} \end{aligned}$$

for $X, Y, Z, U, V, W \in TN$, where H^∇ is the Hessian (the second covariant derivative) with respect to ∇ and we have used Lemma 6.4. Note that $(H_{X, Y}^{\nabla} J)(Z) = (H_{X, Z}^{\nabla} J)(Y)$ for all $X, Y, Z \in TN$, since ∇J is symmetric. Hence the flatness of ∇ means that the Hessian of J with respect to ∇ is totally symmetric. By these equations, the Ricci tensor of $\tilde{\nabla}^0$ satisfies

$$\begin{aligned} Ric^{\tilde{\nabla}^0}(X^{h\nabla}, Y^{h\nabla}) &= \frac{1}{2}\text{Tr}J(H_{X, Y}^{\nabla} J) + \frac{1}{2}\text{Tr}A_X A_Y, \\ Ric^{\tilde{\nabla}^0}(X^{h\nabla}, U^v) &= Ric^{\tilde{\nabla}^0}(U^v, X^{h\nabla}) = 0, \\ Ric^{\tilde{\nabla}^0}(U^v, V^v) &= \frac{1}{2}\text{Tr}J(H_{U, V}^{\nabla} J) + \frac{1}{2}\text{Tr}A_U A_V \end{aligned}$$

for $X, Y, U, V \in TN$. From $(\nabla J)J = -J(\nabla J)$, it holds that

$$\text{Tr}J(H_{X, Y}^{\nabla} J) + \text{Tr}A_X A_Y = 0$$

for all $X, Y \in TN$. Therefore the Obata connection of the manifolds obtained from our hypercomplex version of the c-map is Ricci flat. \square

Remark 6.6. The horizontal distribution on M is integrable by (6.4) and each leaf is totally geodesic with respect to the Obata connection $\tilde{\nabla}^0$, since $\tilde{\nabla}_{X^{h\nabla}}^0 Y^{h\nabla} = (\nabla'_X Y)^{h\nabla}$ for $X, Y \in \Gamma(TN)$.

Remark 6.7. In [12, Theorem A], a hypercomplex structure was obtained on a neighborhood of the zero section of the tangent bundle of a complex manifold with a complex connection whose curvature is of type $(1, 1)$. By contrast, our generalized rigid c-map gives a hypercomplex structure on the whole tangent bundle when the manifold is special complex.

7 The c-projective structure on a projective special complex manifold

In this section, we discuss projective special complex manifolds and obtain the c-projective Weyl curvature of a canonically induced c-projective structure. Let (N, J, ∇, ξ) be a conical special complex manifold. Since $L_\xi J = 0$ and $L_{J\xi} J = 0$, we obtain a complex structure \bar{J} on the quotient $\bar{N} := N/\langle \xi, J\xi \rangle$ if \bar{N} is a smooth manifold.

Lemma 7.1. *We have $L_\xi \nabla' = 0$ and $L_{J\xi} \nabla' = 0$.*

Proof. By Lemmas 6.4 and 6.2, we have

$$\begin{aligned} (L_\xi \nabla')_X Y &= [\xi, \nabla'_X Y] - \nabla'_{[\xi, X]} Y - \nabla'_X [\xi, Y] \\ &= \nabla'_\xi \nabla'_X Y - \nabla'_{\nabla'_X \xi} Y - \nabla'_{[\xi, X]} Y - \nabla'_X \nabla'_\xi Y + \nabla'_X \nabla'_Y \xi \\ &= R_{\xi, X}^{\nabla'} Y = 0 \end{aligned}$$

and

$$\begin{aligned} (L_{J\xi} \nabla')_X Y &= [J\xi, \nabla'_X Y] - \nabla'_{[J\xi, X]} Y - \nabla'_X [J\xi, Y] \\ &= \nabla'_{J\xi} \nabla'_X Y - \nabla'_{\nabla'_X J\xi} Y - \nabla'_{[J\xi, X]} Y - \nabla'_X \nabla'_{J\xi} Y + \nabla'_X \nabla'_Y J\xi \\ &= R_{J\xi, X}^{\nabla'} Y = 0 \end{aligned}$$

for all $X, Y \in \Gamma(TN)$. □

Recall [17] that a smooth curve $t \mapsto c(t)$ on a complex manifold (M, J) is called *J-planar* with respect to a connection ∇ if $\nabla_{c'} c' \in \text{span}\{c', Jc'\}$. We say that torsion-free complex connections ∇^1 and ∇^2 on a complex manifold (M, J) are **c-projectively related** [8] if they have the same *J-planar* curves. It is known that ∇^1 and ∇^2 are c-projectively related if and only if there exists a one-form θ on M such that

$$\nabla_X^1 Y = \nabla_X^2 Y + \theta(X)Y + \theta(Y)X - \theta(JX)JY - \theta(JY)JX$$

for $X, Y \in \Gamma(TM)$. See [17] for example. This defines an equivalence relation on the space of torsion-free complex connections on M . The equivalence classes are called **c-projective structures**.

Definition 7.2. *We call the complex manifold (\bar{N}, \bar{J}) a **projective special complex manifold** if $p_N : (N, J, \nabla, \xi) \rightarrow (\bar{N}, \bar{J})$ is a principal \mathbb{C}^* -bundle, where the principal \mathbb{C}^* -action is generated by the holomorphic vector field $\xi - \sqrt{-1}J\xi$.*

Note that a projective special Kähler manifold is a Kähler quotient of a conical special Kähler manifold. Similarly, a projective special complex manifold carries an induced c-projective structure as follows.

Proposition 7.3. *Any projective special complex manifold (\bar{N}, \bar{J}) carries a canonical c-projective structure.*

Proof. Consider a connection form $\hat{\alpha} = \alpha - \sqrt{-1}(\alpha \circ J)$ of type $(1, 0)$ on the principal \mathbb{C}^* -bundle $p_N : N \rightarrow \bar{N}$. (Note that any \mathbb{C}^* -invariant real one-form α such that $\alpha(\xi) = 1$ is the real part of such a connection.) We have $TN = \text{Ker } \hat{\alpha} \oplus \langle \xi, J\xi \rangle$, where $\text{Ker } \hat{\alpha}$ is J -invariant. We denote the $\hat{\alpha}$ -horizontal lift of $X \in \Gamma(T\bar{N})$ by $X^{h\alpha}$. By Lemma 7.1, we can define $\bar{\nabla}'^\alpha$ by

$$(7.1) \quad \bar{\nabla}'^\alpha X Y = p_{N*}(\nabla'_{X^{h\alpha}} Y^{h\alpha})$$

for $X, Y \in \Gamma(T\bar{N})$. We claim that $\bar{\nabla}'^\alpha \bar{J} = 0$. In fact, using that $JY^{h\alpha} = (\bar{J}Y)^{h\alpha}$ for $Y \in T\bar{N}$ we have

$$\bar{\nabla}'^\alpha(\bar{J}Y) = p_{N*}(\nabla'_{X^{h\alpha}} JY^{h\alpha}) = p_{N*}J(\nabla'_{X^{h\alpha}} Y^{h\alpha}) = \bar{J}p_{N*}(\nabla'_{X^{h\alpha}} Y^{h\alpha}).$$

To show that the c-projective structure $[\bar{\nabla}'^\alpha]$ does not depend on α , we consider another connection form $\hat{\beta} = \beta - \sqrt{-1}(\beta \circ J)$ of type $(1, 0)$. Then there exist one-forms θ_0 and θ_1 on \bar{N} such that

$$\hat{\beta} - \hat{\alpha} = (p_N^* \theta_0) + (p_N^* \theta_1) \sqrt{-1}.$$

On the other hand, we can write $X^{h\alpha} - X^{h\beta} = a\xi + bJ\xi$ for some functions a, b on N . It is easy to see that

$$a = \theta_0(X) \circ p_N, \quad b = -\theta_0(\bar{J}X) \circ p_N, \quad \theta_1 = -\theta_0 \circ \bar{J}$$

for $X \in T\bar{N}$. By the definition (7.1) of the induced connection on \bar{N} , we have

$$\begin{aligned} \bar{\nabla}'^\alpha X Y &= p_{N*}(\nabla'_{X^{h\alpha}} Y^{h\alpha}) \\ &= p_{N*}(\nabla'_{X^{h\beta} + \theta_0(X)\xi - \theta_0(\bar{J}X)J\xi} (Y^{h\beta} + \theta_0(Y)\xi - \theta_0(\bar{J}Y)J\xi)) \\ &= p_{N*}(\nabla'_{X^{h\beta}} Y^{h\beta} + \nabla'_{X^{h\beta}} \theta_0(Y)\xi - \nabla'_{X^{h\beta}} \theta_0(\bar{J}Y)J\xi \\ &\quad + \theta_0(X)(\nabla'_\xi Y^{h\beta} + \nabla'_\xi \theta_0(Y)\xi - \nabla'_\xi \theta_0(\bar{J}Y)J\xi) \\ &\quad - \theta_0(\bar{J}X)(\nabla'_{J\xi} Y^{h\beta} + \nabla'_{J\xi} \theta_0(Y)\xi - \nabla'_{J\xi} \theta_0(\bar{J}Y)J\xi) \\ &= \bar{\nabla}'^\beta X Y + \theta_0(Y)X + \theta_0(X)Y - \theta_0(\bar{J}Y)\bar{J}X - \theta_0(\bar{J}X)\bar{J}Y \end{aligned}$$

for $X, Y \in \Gamma(T\bar{N})$, which means that $\bar{\nabla}'^\alpha$ and $\bar{\nabla}'^\beta$ are c-projectively related. Here we write $\theta_0(X)$ for $\theta_0(X) \circ p_N$ etc. \square

We denote the induced c-projective structure given in Proposition 7.3 by $\mathcal{P}_{\bar{\nabla}'}$ (without a label α). Next we prove that the c-projective Weyl curvature of $\mathcal{P}_{\bar{\nabla}'}$ is of type $(1, 1)$ (see Theorem 7.10).

Note that $\xi, J\xi$ are the fundamental vector fields generated by $1, \sqrt{-1} \in \mathbb{C} = \text{Lie } \mathbb{C}^*$, respectively. Recall that $A = \nabla J$ and $A_\xi = A_{J\xi} = 0$. We also have that $L_\xi A = 0$, since $L_\xi \nabla = 0$ and $L_\xi J = 0$.

Lemma 7.4. $L_{J\xi} \nabla = A$, $L_{J\xi} A = -2JA$ and $L_{J\xi}(JA) = 2A$.

Let η be a connection form on the principal bundle $p_N : N \rightarrow \bar{N}$. As before, we assume that $\text{Ker } \eta$ is J -invariant or, equivalently, that η is of type $(1, 0)$ (but not necessarily holomorphic). Using η we can project the connection ∇' on N to a connection $\bar{\nabla}'^\eta$ on \bar{N} , which is complex with respect to \bar{J} , as shown in the proof of Proposition 7.3. Note that the quotient $p_N : (N, \nabla') \rightarrow (\bar{N}, \bar{\nabla}'^\eta)$ is an affine submersion with the horizontal distribution $\mathcal{H} := \text{Ker } \eta$ (in the sense defined in [1]). From now on the η -horizontal lift of $X \in T\bar{N}$ is denoted by \tilde{X} . Note that our sign convention for the curvature tensor is different from the one in [1]. Let $h : TN \rightarrow \mathcal{H}$ and $v : TN \rightarrow \mathcal{V}$ be the projections with respect to the decomposition $TN = \mathcal{H} \oplus \mathcal{V}$, where $\mathcal{V} = \text{Ker } p_{N*}$. We define the fundamental tensors $\mathcal{A}^{\nabla'}$ and $\mathcal{T}^{\nabla'}$ by

$$\mathcal{A}_E^{\nabla'} F = v(\nabla'_{hE} hF) + h(\nabla'_{vE} vF)$$

and

$$\mathcal{T}_E^{\nabla'} F = h(\nabla'_{vE} vF) + v(\nabla'_{hE} hF)$$

for $E, F \in \Gamma(TN)$.

Lemma 7.5. *We have $\mathcal{T}^{\nabla'} = 0$, $\mathcal{A}_X^{\nabla'} \xi = X$ and $\mathcal{A}_X^{\nabla'} J\xi = JX$ for any horizontal vector X .*

Let a and b be $(0, 2)$ -tensors defined by

$$\mathcal{A}_X^{\nabla'} Y = a(X, Y)\xi + b(X, Y)J\xi$$

for horizontal vectors X and Y . Since ∇' and the projections v, h are \mathbb{C}^* -invariant, $\mathcal{A}^{\nabla'}$ is \mathbb{C}^* -invariant, and hence, $a = p_N^* \bar{a}$ and $b = p_N^* \bar{b}$ for some tensors \bar{a} and \bar{b} on \bar{N} . For any $(0, 2)$ -tensor k on a complex manifold with a complex structure J , define the $(0, 2)$ -tensor k_J by $k_J(X, Y) := k(X, JY)$.

Lemma 7.6. *We have*

$$v((\nabla'_{\tilde{X}} J)\tilde{Y}) = (\bar{a}(X, \bar{J}Y) + \bar{b}(X, Y))\xi + (\bar{b}(X, \bar{J}Y) - \bar{a}(X, Y))J\xi$$

for $X, Y \in T\bar{N}$.

Lemma 7.7. *We have $\bar{b}(X, Y) = -\bar{a}(X, \bar{J}Y) = -\bar{a}_{\bar{J}}(X, Y)$ for tangent vectors X and Y on \bar{N} . Consequently, the fundamental tensor $\mathcal{A}^{\nabla'}$ satisfies*

$$(7.2) \quad \mathcal{A}_{\tilde{X}}^{\nabla'} \tilde{Y} = \bar{a}(X, Y)\xi - \bar{a}_{\bar{J}}(X, Y)J\xi$$

for tangent vectors X, Y on \bar{N} .

Proof. By $\nabla' J = 0$ and Lemma 7.6, we have the conclusion. \square

Let (r, θ) be the polar coordinates with respect to a (smooth) local trivialization $p_N^{-1}(\bar{U}) \cong \bar{U} \times \mathbb{C}^*$ of the principal \mathbb{C}^* -bundle $p_N : N \rightarrow \bar{N}$ such that $\xi = r\partial/\partial r$ and $J\xi = \partial/\partial\theta$. A principal connection η is locally given by

$$\eta := \eta_1 \otimes 1 + \eta_2 \otimes \sqrt{-1} = p_N^*(\gamma_1 \otimes 1 + \gamma_2 \otimes \sqrt{-1}) + \left(\frac{dr}{r} \otimes 1 + d\theta \otimes \sqrt{-1} \right)$$

for a \mathbb{C} -valued one-form $\gamma_1 \otimes 1 + \gamma_2 \otimes \sqrt{-1}$ on $\bar{U} \subset \bar{N}$. For each local trivialization $p_N^{-1}(\bar{U}) \cong \bar{U} \times \mathbb{C}^*$, we set

$$B := e^{2\theta J} A \quad (e^{2\theta J} = (\cos 2\theta)\text{id} + (\sin 2\theta)J).$$

The symmetric $(1, 2)$ -tensor field B is defined *locally* and B is projectable by Lemma 7.4, i.e. horizontal (i.e. $B_\xi = B_{J\xi} = 0$) and \mathbb{C}^* -invariant. Therefore we obtain an induced *locally* defined symmetric tensor field \bar{B} on \bar{N} .

Lemma 7.8. *The tensor $B^2 : (X, Y) \mapsto B_X \circ B_Y$ is a globally defined tensor field on N , in particular, $[B, B]$ is so. As a consequence, we have the globally defined tensor fields \bar{B}^2 and $[\bar{B}, \bar{B}]$ on \bar{N} .*

Proof. It follows from $B^2 = A^2$. □

For a $(0, 2)$ -tensor a and a $(1, 1)$ -tensor K , we define an $\text{End}(TN)$ -valued 2-form $a \wedge K$ by

$$(a \wedge K)_{X,Y}Z = a(X, Z)KY - a(Y, Z)KX$$

for tangent vectors X, Y and Z .

Proposition 7.9. *The curvature $R^{\bar{\nabla}'\eta}$ of $\bar{\nabla}'\eta$ is of the form*

$$R^{\bar{\nabla}'\eta} = -\frac{1}{4}[\bar{B}, \bar{B}] + 2\bar{a}^a \otimes \text{Id} - 2(\bar{a}_{\bar{J}})^a \otimes \bar{J} + \bar{a} \wedge \text{Id} - \bar{a}_{\bar{J}} \wedge \bar{J},$$

where $(\cdot)^a$ denotes anti-symmetrization. Moreover we have $d\gamma_1 = -2\bar{a}^a$ and $d\gamma_2 = 2(\bar{a}_{\bar{J}})^a$.

Proof. By the fundamental equation for an affine submersion [1], we have

$$(R_{X,Y}^{\bar{\nabla}'\eta}Z)^\sim = h(R_{\tilde{X},\tilde{Y}}^{\nabla'}\tilde{Z}) + h(\nabla'_{v[\tilde{X},\tilde{Y}]} \tilde{Z}) + \mathcal{A}_{\tilde{Y}}^{\nabla'} \mathcal{A}_{\tilde{X}}^{\nabla'} \tilde{Z} - \mathcal{A}_{\tilde{X}}^{\nabla'} \mathcal{A}_{\tilde{Y}}^{\nabla'} \tilde{Z}$$

for $X, Y, Z \in \Gamma(T\bar{N})$. Since

$$\begin{aligned} v[\tilde{X}, \tilde{Y}] &= \eta_1([\tilde{X}, \tilde{Y}])\xi + \eta_2([\tilde{X}, \tilde{Y}])J\xi \\ &= -(d\eta_1)(\tilde{X}, \tilde{Y})\xi - (d\eta_2)(\tilde{X}, \tilde{Y})J\xi \\ &= -(d\gamma_1)(X, Y)\xi - (d\gamma_2)(X, Y)J\xi, \end{aligned}$$

we have

$$\begin{aligned} h(\nabla'_{v[\tilde{X},\tilde{Y}]} \tilde{Z}) &= h(\nabla'_{\tilde{Z}} v[\tilde{X}, \tilde{Y}]) \\ &= h(\nabla'_{\tilde{Z}} (-(d\gamma_1)(X, Y)\xi - (d\gamma_2)(X, Y)J\xi)) \\ &= -(d\gamma_1)(X, Y)\tilde{Z} - (d\gamma_2)(X, Y)(\bar{J}Z)^\sim. \end{aligned}$$

Moreover, by

$$\mathcal{A}_{\tilde{X}}^{\nabla'} \tilde{Y} - \mathcal{A}_{\tilde{Y}}^{\nabla'} \tilde{X} = v[\tilde{X}, \tilde{Y}] = -d\gamma_1(X, Y)\xi - d\gamma_2(X, Y)J\xi,$$

we have $d\gamma_1 = -2\bar{a}^a$ and $d\gamma_2 = 2(\bar{a}_{\bar{J}})^a$. □

Now we set $\dim N = 2(n + 1)$. By Proposition 7.9 and $\text{Tr}\bar{B}_X = 0$ for all $X \in T\bar{N}$, we obtain

$$(7.3) \quad \begin{aligned} Ric^{\bar{\nabla}'\eta}(Y, Z) &= \frac{1}{4}\text{Tr}\bar{B}_Y\bar{B}_Z + (\bar{a}(Z, Y) - \bar{a}(Y, Z)) \\ &\quad - (\bar{a}(\bar{J}Y, \bar{J}Z) + \bar{a}(Y, Z)) - 2n\bar{a}(Y, Z) + \bar{a}(Y, Z) - \bar{a}(\bar{J}Y, \bar{J}Z) \\ &= \frac{1}{4}\text{Tr}\bar{B}_Y\bar{B}_Z - (2n + 1)\bar{a}(Y, Z) + \bar{a}(Z, Y) \\ &\quad - \bar{a}(\bar{J}Y, \bar{J}Z) - \bar{a}(\bar{J}Z, \bar{J}Y). \end{aligned}$$

We define a $(0, 2)$ -tensor P^D on a complex manifold (M, J) , which is called the Rho tensor of a connection D , by

$$P^D(X, Y) = \frac{1}{m+1} \left(Ric^D(X, Y) + \frac{1}{m-1} ((Ric^D)^s(X, Y) - (Ric^D)^s(JX, JY)) \right),$$

for $X, Y \in TM$, where $2m = \dim M \geq 4$, Ric^D is the Ricci tensor of D and $(\cdot)^s$ is the symmetrization of a $(0, 2)$ -tensor. The c-projective Weyl curvature $W^{c, [\bar{D}]}$ of a c-projective structure $[\bar{D}]$ is given by

$$(7.4) \quad W^{c, [\bar{D}]} = R^{\bar{D}} + (P^{\bar{D}})^a \otimes Id - (P_{\bar{J}}^{\bar{D}})^a \otimes \bar{J} + \frac{1}{2}P^{\bar{D}} \wedge Id - \frac{1}{2}P_{\bar{J}}^{\bar{D}} \wedge \bar{J}.$$

See [8]. We shall compute the c-projective Weyl curvature of $[\bar{\nabla}'\eta]$. From (7.3) it holds

$$\begin{aligned} (Ric^{\bar{\nabla}'\eta})^s(Y, Z) &= \frac{1}{4}\text{Tr}\bar{B}_Y\bar{B}_Z - 2n\bar{a}^s(Y, Z) - 2\bar{a}^s(\bar{J}Y, \bar{J}Z), \\ (Ric^{\bar{\nabla}'\eta})^s(\bar{J}Y, \bar{J}Z) &= \frac{1}{4}\text{Tr}\bar{B}_Y\bar{B}_Z - 2n\bar{a}^s(\bar{J}Y, \bar{J}Z) - 2\bar{a}^s(Y, Z) \end{aligned}$$

and hence

$$(Ric^{\bar{\nabla}'\eta})^s(Y, Z) - (Ric^{\bar{\nabla}'\eta})^s(\bar{J}Y, \bar{J}Z) = -2(n-1)(\bar{a}^s(Y, Z) - \bar{a}^s(\bar{J}Y, \bar{J}Z)).$$

From these equations, it follows that

$$\begin{aligned} (n+1)P^{\bar{\nabla}'\eta}(Y, Z) &= \frac{1}{4}\text{Tr}\bar{B}_Y\bar{B}_Z - (2n+1)\bar{a}(Y, Z) + \bar{a}(Z, Y) - \bar{a}(\bar{J}Y, \bar{J}Z) - \bar{a}(\bar{J}Z, \bar{J}Y) \\ &\quad - 2(\bar{a}^s(Y, Z) - \bar{a}^s(\bar{J}Y, \bar{J}Z)) \\ &= \frac{1}{4}\text{Tr}\bar{B}_Y\bar{B}_Z - (2n+1)\bar{a}(Y, Z) + \bar{a}(Z, Y) - (\bar{a}(Y, Z) + \bar{a}(Z, Y)) \\ &= \frac{1}{4}\text{Tr}\bar{B}_Y\bar{B}_Z - 2(n+1)\bar{a}(Y, Z). \end{aligned}$$

Setting $\bar{\mathcal{B}}(Y, Z) = \text{Tr}\bar{B}_Y\bar{B}_Z$, which is a symmetric, \bar{J} -hermitian globally defined $(0, 2)$ -tensor on \bar{N} , we have

$$(7.5) \quad \bar{a} = \frac{1}{8(n+1)}\bar{\mathcal{B}} - \frac{1}{2}P^{\bar{\nabla}'\eta}.$$

Therefore the coefficients of the curvature form $d\eta = d\gamma_1 + \sqrt{-1}d\gamma_2 = -2\bar{a}^a + 2\sqrt{-1}(\bar{a}_{\bar{j}})^a$ are determined by

$$(7.6) \quad \bar{a}^a = -\frac{1}{2}(P^{\bar{\nabla}'\eta})^a \left(= -\frac{1}{2(n+1)}(\text{Ric}^{\bar{\nabla}'\eta})^a \right),$$

$$(7.7) \quad (\bar{a}_{\bar{j}})^a = \frac{1}{8(n+1)}\bar{\mathcal{B}}_{\bar{j}} - \frac{1}{2}(P_{\bar{j}}^{\bar{\nabla}'\eta})^a \left(= \frac{1}{8(n+1)}\bar{\mathcal{B}}_{\bar{j}} - \frac{1}{2(n+1)}(\text{Ric}_{\bar{j}}^{\bar{\nabla}'\eta})^a \right).$$

By the above calculations we arrive at the following theorem.

Theorem 7.10. *Let (N, J, ∇, ξ) be a conical special complex manifold which is the total space of a (holomorphic) principal \mathbb{C}^* -bundle $p_N : N \rightarrow \bar{N}$, the base of which is a projective special complex manifold \bar{N} with $\dim \bar{N} = 2n \geq 4$. The c-projective Weyl curvature $W^{c, \mathcal{P}_{\bar{\nabla}'}}$ of the canonically induced c-projective structure $\mathcal{P}_{\bar{\nabla}'}$ is given by*

$$W^{c, \mathcal{P}_{\bar{\nabla}'}} = -\frac{1}{4}[\bar{B}, \bar{B}] - \frac{1}{4(n+1)}\bar{\mathcal{B}}_{\bar{j}} \otimes \bar{J} + \frac{1}{8(n+1)}\bar{\mathcal{B}} \wedge \text{Id} - \frac{1}{8(n+1)}\bar{\mathcal{B}}_{\bar{j}} \wedge \bar{J}.$$

In particular, $W_{\bar{J}(\cdot), \bar{J}(\cdot)}^{c, \mathcal{P}_{\bar{\nabla}'}} = W^{c, \mathcal{P}_{\bar{\nabla}'}}$, that is, $W^{c, \mathcal{P}_{\bar{\nabla}'}}$ is of type $(1, 1)$ as an $\text{End}(T\bar{N})$ -valued two-form.

Proof. Take a principal connection η of type $(1, 0)$. By Proposition 7.3, the canonically induced c-projective structure is $[\bar{\nabla}'\eta]$. From Proposition 7.9, equation (7.4) and the symmetry of $\bar{\mathcal{B}}$, it holds that

$$W^{c, [\bar{\nabla}'\eta]} = -\frac{1}{4}[\bar{B}, \bar{B}] - \frac{1}{4(n+1)}\bar{\mathcal{B}}_{\bar{j}} \otimes \bar{J} + \frac{1}{8(n+1)}\bar{\mathcal{B}} \wedge \text{Id} - \frac{1}{8(n+1)}\bar{\mathcal{B}}_{\bar{j}} \wedge \bar{J}.$$

Since $\bar{\mathcal{B}}_{\bar{j}}$, $[\bar{B}, \bar{B}]$ and $\bar{\mathcal{B}} \wedge \text{Id} - \bar{\mathcal{B}}_{\bar{j}} \wedge \bar{J}$ are of type $(1, 1)$, $W^{c, \mathcal{P}_{\bar{\nabla}'}}$ is of type $(1, 1)$. \square

The following corollary is a direct consequence of Theorem 7.10.

Corollary 7.11. *Any complex manifold (\bar{N}, \bar{J}) with a c-projective structure \mathcal{P} such that $W^{c, \mathcal{P}}$ is not of type $(1, 1)$ can not be realized as a projective special complex manifold whose canonical c-projective structure is \mathcal{P} .*

8 A generalization of the supergravity c-map

The supergravity c-map associates a (pseudo-)quaternionic Kähler manifold with any projective special Kähler manifold. In this section, we give a generalization of the supergravity c-map by using the results in previous sections. Let (N, J, ∇, ξ) be a conical special complex manifold and set $Z := J\xi$.

Lemma 8.1. *$2Z^{h\nabla}$ is a rotating vector field on TN .*

Proof. Since $L_Z J = 0$ and $\nabla_Z J = 0$ (cf. Lemma 6.2), we have $L_{Z^{h\nabla}} I_1 = 0$. Moreover we have

$$\begin{aligned} (L_{Z^{h\nabla}} I_2)(X^{h\nabla} + Y^v) &= [Z, Y]^{h\nabla} - (\nabla_Z X)^v - (\nabla_Z Y)^{h\nabla} + [Z, X]^v \\ &= -(\nabla_Y Z)^{h\nabla} - (\nabla_X Z)^v \\ &= -(JY)^{h\nabla} - (JX)^v \\ &= -I_3(X^{h\nabla} + Y^v) \end{aligned}$$

for all $X, Y \in \Gamma(TN)$. □

Remark 8.2. By the equations for $\tilde{\nabla}^0$ in the proof of Theorem 6.5, we have

$$\begin{aligned} \tilde{\nabla}_{X^{h\nabla}}^0 \xi^{h\nabla} &= (\nabla'_X \xi)^{h\nabla} = \left(\nabla_X \xi - \frac{1}{2} J A_X \xi \right)^{h\nabla} = X^{h\nabla}, \\ \tilde{\nabla}_{X^v}^0 \xi^{h\nabla} &= -\frac{1}{2} (J A_\xi X)^v = 0 \end{aligned}$$

for $X \in TN$, when (N, J, ∇, ξ) is a conical special complex manifold.

We have the following theorem.

Theorem 8.3 (Generalized supergravity c-map). *Let (N, J, ∇, ξ) be a $2(n+1)$ -dimensional conical special complex manifold. Let Θ be a closed two-form on $M = TN$ such that $L_{Z^M} \Theta = 0$, where $Z^M = 2Z^{h\nabla}$. Consider a $U(1)$ -bundle $\pi : P \rightarrow M$ over M and η a connection form whose curvature form is*

$$d\eta = \pi^* \left(\Theta - \frac{1}{2} d((\iota_{Z^M} \Theta) \circ I_1) \right).$$

Let f be a smooth function on M such that $df = -\iota_{Z^M} \Theta$ and $f_1 := f - (1/2)\Theta(Z^M, I_1 Z^M)$ does nowhere vanish. If $\tilde{\pi} : \tilde{M} \rightarrow \hat{M}$ and $\hat{\pi} : \hat{M} \rightarrow \bar{M}$ are submersions, we have an assignment from a $2n$ -dimensional projective special complex manifold $(\bar{N}, \bar{J}, \mathcal{P}_{\bar{\nabla}'})$ whose c-projective Weyl curvature is of type $(1, 1)$ to a $4(n+1)$ -dimensional quaternionic manifold

$$\bar{M}(= \overline{TN}) = \mathcal{C}_{(P, \eta)}(M, \langle I_1, I_2, I_3 \rangle, Z^M, f, \Theta) / \mathcal{D}$$

foliated by $(2n+4)$ -dimensional leaves such that \bar{N} coincides with the space of its leaves.

Proof. By Theorem 4.1, Lemma 8.1 and Proposition 7.3, we have an assignment from a $2n$ -dimensional projective special complex manifold $(\bar{N}, \bar{J}, \mathcal{P}_{\bar{\nabla}'})$ to a $4(n+1)$ -dimensional quaternionic manifold \overline{TN} . By virtue of Theorem 7.10, the c-projective Weyl curvature of $\mathcal{P}_{\bar{\nabla}'}$ is of type $(1, 1)$. Next we give a foliation on \overline{TN} whose leaves space is \bar{N} . Set $\mathcal{L} := \mathcal{V} \oplus \langle \xi^{h\nabla}, Z^{h\nabla} \rangle$, where \mathcal{V} is the vertical distribution of $T(TN) \rightarrow TN$. The distribution \mathcal{L} is $Z^M = 2Z^{h\nabla}$ -invariant and integrable by (6.4). Therefore each leaf L of \mathcal{L} is a $Z^M = 2Z^{h\nabla}$ -invariant submanifold of TN . Consider the pull-back $\iota^\# P$ of P by the inclusion $\iota : L \rightarrow TN$ with the bundle map $\iota_\# : \iota^\# P \rightarrow P$ and $\tilde{L} := \mathbb{H}^* \times \iota^\# P$. Since V_1 is tangent to \tilde{L} , then $\hat{L} := \tilde{L} / \langle V_1 \rangle$ is a submanifold \hat{M} . Moreover $V, \hat{I}_1(V), \hat{I}_2(V),$

$\hat{I}_3(V)$ are tangent to \hat{L} because V is induced by e_0^R . Taking the quotient again, we obtain a submanifold $\bar{L} := \hat{L}/\langle V, \hat{I}_1(V), \hat{I}_2(V), \hat{I}_3(V) \rangle$ on a quaternionic manifold \overline{TN} . Therefore the quaternionic manifold \overline{TN} is foliated by $(2n+4)$ -dimensional leaves such that the space of its leaves \bar{L} is the projective special complex manifold \bar{N} . \square

Remark 8.4. If we assume that $Z_1 = (Z^M)^{h_\eta} + f_1 X_P$ generates a free $U(1)$ -action on P instead of assuming that $\tilde{\pi} : \tilde{M} \rightarrow \hat{M}$ and $\hat{\pi} : \hat{M} \rightarrow \bar{M}$ are submersions, we obtain the same result as in Theorem 8.3 (see Theorem 4.8).

Remark 8.5. Borówka and Calderbank have given a construction of a quaternionic manifold from a complex manifold of half the dimension with a c-projective structure, known as the quaternionic Feix-Kaledin construction [6]. Their construction generalizes the original construction [11, 20], which yields a hyper-Kähler structure on a neighborhood of the zero set of any Kähler manifold. They also point out that this construction is a generalization of [12, Theorem A] (see [6, Proposition 5.4]). More precisely, the initial data of the quaternionic Feix-Kaledin construction are a complex manifold with a c-projective structure of type $(1, 1)$ and a complex line bundle with a connection of type $(1, 1)$. Note that this construction is different from our generalization of the supergravity c-map, in which the real dimension of the quaternionic manifold \overline{TN} is related to the real dimension of the projective special complex manifold \bar{N} by $\dim(\overline{TN}) = 2 \dim(\bar{N}) + 4$.

We consider a conical special complex manifold (N, J, ∇, ξ) , which we endow now with an additional structure. Let ψ be a J -hermitian, ∇ -parallel two-form on (N, J, ∇, ξ) . We consider a function $\mu = (1/2)\psi(\xi, J\xi)$ on N . Then we see $d\mu = -\iota_Z \psi$. Set

$$(8.1) \quad \Theta = -\pi_{TN}^* \psi,$$

$$(8.2) \quad f = -2\pi_{TN}^* \mu + c$$

for some constant c . Then it holds that

$$df = -\iota_{Z^M} \Theta, \quad f_1 = f - \frac{1}{2} \Theta(Z^M, I_1 Z^M) = 2\pi_{TN}^* \mu + c,$$

where $\pi_{TN} : TN \rightarrow N$ is the bundle projection. In fact, we have

$$df = -2d(\pi_{TN}^* \mu) = 2\pi_{TN}^*(\iota_Z \psi) = -\iota_{Z^M} \Theta$$

and

$$\begin{aligned} f_1 &= f - \frac{1}{2} \Theta(Z^M, I_1 Z^M) \\ &= -\psi(\xi, J\xi) \circ \pi_{TN} - 2\Theta(Z^{h_\nabla}, I_1 Z^{h_\nabla}) + c \\ &= \psi(J\xi, \xi) \circ \pi_{TN} + c = 2\pi_{TN}^* \mu + c. \end{aligned}$$

Corollary 8.6. *Let (N, J, ∇, ξ) be a $2n$ -dimensional conical special complex manifold and ψ a J -hermitian, ∇ -parallel two-form on N . Consider a $U(1)$ -bundle $\pi : P \rightarrow M$ over $M = TN$ and η a connection form whose curvature form is*

$$d\eta = (\pi_{TN} \circ \pi)^* \psi.$$

If $\tilde{\pi} : \tilde{M} \rightarrow \hat{M}$ and $\hat{\pi} : \hat{M} \rightarrow \bar{M}$ are submersions and $\mu^{-1}(-c/2) = \emptyset$, then the generalized supergravity c -map of Theorem 8.3 can be specialized to this setting such that the data Θ and f are related to ψ by equations (8.1) and (8.2).

Proof. By a straightforward calculation, we have $d((\iota_Z\psi) \circ J) = 2\psi$. Then it is easy to check

$$\begin{aligned} d\eta &= (\pi_{TN} \circ \pi)^*\psi \\ &= (\pi_{TN} \circ \pi)^*(-\psi + d((\iota_Z\psi) \circ J)) \\ &= (\pi_{TN} \circ \pi)^*\left(-\psi + \frac{1}{2}d((\iota_{2Z}\psi) \circ J)\right) \\ &= \pi^*\left(\Theta - \frac{1}{2}d((\iota_{Z^M}\Theta) \circ I_1)\right), \end{aligned}$$

where Θ is the two-form given by (8.1). Since $d\psi = 0$ and $\iota_Z\psi = -d\mu$, it holds $L_{Z^M}\Theta = 0$. The function $f_1 = f - (1/2)\Theta(Z^M, I_1Z^M)$ does nowhere vanish by $\mu^{-1}(-c/2) = \emptyset$. Therefore Theorem 8.3 leads to the conclusion. \square

Therefore a conical special complex manifold (N, J, ∇, ξ) with a J -hermitian, ∇ -parallel two-form ψ such that $(1/2\pi)[\psi] \in H_{DR}^2(N, \mathbb{Z})$ and $\mu = (1/2)\psi(\xi, J\xi)$ is not surjective gives rise to a quaternionic manifold of dimension $2 \dim N$ under a suitable choice of the constant c .

For $t \in \mathbb{R}/\pi\mathbb{Z}$, we define a connection ∇^t by $\nabla^t = e^{tJ} \circ \nabla \circ e^{-tJ}$, which is a special complex connection by [3, Proposition 1]. Moreover, by

$$\nabla^t = \nabla - (\sin t)e^{tJ}(\nabla J)$$

([3, Lemma 1]), we see that ∇^t satisfies $\nabla^t\xi = \text{id}$. Therefore $\{\nabla^t\}_{t \in \mathbb{R}/\pi\mathbb{Z}}$ is a family of conical special complex connections if $\nabla J \neq 0$.

Lemma 8.7. *If ψ is J -hermitian and ∇ -parallel, then ψ is ∇^t -parallel.*

Proof. Since $\nabla^t - \nabla$ is a linear combination of ∇J and $J(\nabla J) = -(\nabla J)J$, it suffices to remark that $\nabla\psi = 0$, $J \cdot \psi = 0$ and, hence, $(\nabla_X J) \cdot \psi = 0$ for all X . Here the dot stands for the action on the tensor algebra by derivations. \square

Hence, Corollary 8.6 and Lemma 8.7 imply

Corollary 8.8. *If $A(= \nabla J) \neq 0$, there exists an $(\mathbb{R}/\pi\mathbb{Z})$ -family of quaternionic manifolds obtained from a conical special complex manifold with ψ under the same assumptions of Corollary 8.6 by the H/Q -correspondence (for any chosen function f in the construction).*

Proof. By Lemma 8.7, $\nabla_X^t\psi = 0$. Since (N, J, ∇^t, ξ) are conical special complex manifolds, we have the conclusion. \square

To give an example, we recall the (local) characterization of a conical special complex manifold [3]. Let (\mathbb{C}^{n+1}, J) be the standard complex vector space and U an open subset in \mathbb{C}^{n+1} with the standard coordinate system (z_0, \dots, z_n) . We consider a holomorphic one-form $\alpha = \sum F_i dz_i$ on U , which is also viewed as a holomorphic map $\phi = \phi_\alpha$ from U to $(T^*U = U \times \mathbb{C}^{n+1} \subset \mathbb{C}^{2(n+1)})$. If $\text{Re } \phi : U \rightarrow \mathbb{R}^{2(n+1)}$ is an immersion, which is equivalent to ϕ being totally complex [3], then we can find an affine connection ∇ such that (U, J, ∇) is a special complex manifold. In fact, we can take a local coordinate system

$$(x_0 := \text{Re } z_0, \dots, x_n := \text{Re } z_n, y_0 := \text{Re } F_0, \dots, y_n := \text{Re } F_n)$$

on U induced by ϕ and a connection ∇ defined by the condition that $(x_0, \dots, x_n, y_0, \dots, y_n)$ is affine. Moreover $\sum_{i=0}^n dx_i \wedge dy_i$ is ∇ -parallel symplectic form on U . In particular, if $\alpha = -\sum_{i=0}^n \sqrt{-1} z_i dz_i$, then the induced affine coordinate system coincides with the real coordinate system underlying the holomorphic coordinate system (z_0, \dots, z_n) , hence (U, J, ∇) is trivial ($\nabla J = 0$) in that special case. In addition to being holomorphic and totally complex, we assume that ϕ is conical, which is equivalent to the condition that functions F_0, \dots, F_n are homogeneous of degree one, i.e. $F_i(\lambda z) = \lambda F_i(z)$ for all λ near $1 \in \mathbb{C}^*$ and $z \in U$. Then U is conical, that is, any conical holomorphic one-form ϕ such that $\text{Re } \phi$ is an immersion on U defines a conical special complex (and symplectic) manifold structure of complex dimension n . Conversely, any such manifold can be locally obtained in this way (see [3, Corollary 5]).

If we choose $\alpha = -\sum_{i=0}^n \sqrt{-1} z^i dz^i$ on $\mathbb{C}^{n+1} \setminus \{0\}$, then the generalized c-map associates an open submanifold of (\mathbb{H}^{n+1}, Q) with the standard quaternionic structure Q to the complex projective space $(\mathbb{C}P^n, J^{st}, [\nabla^{FS}])$, where J^{st} is the standard complex structure and ∇^{FS} is the Levi-Civita connection of the Fubini-Study metric. Here we have chosen $\Theta = 0$. We can also apply Corollary 8.6 by choosing the standard symplectic form as ψ . More generally, we have the following example.

Example 8.9. For a holomorphic function g of homogeneous degree one, we consider the holomorphic 1-form

$$\alpha = g dz_0 - \sqrt{-1} \sum_{i=1}^n z_i dz_i$$

on $U := \{(z_0, z_1, \dots, z_n) \in \mathbb{C}^{n+1} \mid \text{Im } g_0 \neq 0\}$, where $g_i = \frac{\partial g}{\partial z_i}$ ($i = 0, 1, \dots, n$). [Comment Vicente: we should perhaps use a different symbol for F to avoid Note that $d\alpha \neq 0$ if there exists i such that $g_i \neq 0$ ($i \geq 1$). Setting $z_i = u_i + \sqrt{-1}v_i$ ($i = 0, 1, \dots, n$), we have

$$\begin{aligned} (x_0, \dots, x_n, y_0, y_1, \dots, y_n) &= \text{Re } \phi(u_0, \dots, u_n, v_0, \dots, v_n) \\ &= (\text{Re } z_0, \dots, \text{Re } z_1, \text{Re } g, \text{Re } (-\sqrt{-1}z_1), \dots, \text{Re } (-\sqrt{-1}z_n)) \\ &= (u_0, \dots, u_n, \text{Re } g, v_1, \dots, v_n). \end{aligned}$$

Since its Jacobian matrix is given by

$$\frac{\partial(x_0, \dots, y_n)}{\partial(u_0, \dots, v_n)} = \begin{pmatrix} 1 & & & 0 & 0 & \dots & \dots & 0 \\ & \ddots & & \vdots & \vdots & & & \vdots \\ & & 1 & 0 & 0 & \dots & \dots & 0 \\ \text{Re } g_0 & \dots & \text{Re } g_n & -\text{Im } g_0 & -\text{Im } g_1 & \dots & \dots & -\text{Im } g_n \\ 0 & \dots & 0 & 0 & 1 & 0 & \dots & 0 \\ \vdots & & \vdots & \vdots & 0 & 1 & & 0 \\ \vdots & & \vdots & \vdots & \vdots & & \ddots & \\ 0 & \dots & 0 & 0 & 0 & & & 1 \end{pmatrix},$$

we see that $\text{Re } \phi$ is an immersion and we obtain a conical special complex structure on U . The coordinate vector fields of (x_0, \dots, y_n) are given by

$$\begin{aligned} \frac{\partial}{\partial x_i} &= \frac{\partial}{\partial u_i} + \frac{\text{Re } g_i}{\text{Im } g_0} \frac{\partial}{\partial v_0} \quad (i \geq 0), \\ \frac{\partial}{\partial y_0} &= -\frac{1}{\text{Im } g_0} \frac{\partial}{\partial v_0}, \quad \frac{\partial}{\partial y_j} = -\frac{\text{Im } g_j}{\text{Im } g_0} \frac{\partial}{\partial v_0} + \frac{\partial}{\partial v_j} \quad (j \geq 1) \end{aligned}$$

on U . Let ∇ (resp. ∇^{st}) be the flat affine connection on U such that (x_0, \dots, y_n) (resp. (u_0, \dots, v_n)) is a ∇ (resp. ∇^{st})-affine coordinate system. We define S by $\nabla = \nabla^{\text{st}} + S$. Then we calculate

$$\begin{aligned} 0 &= \nabla_X \frac{\partial}{\partial x_i} = (\nabla_X^{\text{st}} + S_X) \left(\frac{\partial}{\partial u_i} + \frac{\text{Re } g_i}{\text{Im } g_0} \frac{\partial}{\partial v_0} \right) \\ &= X \left(\frac{\text{Re } g_i}{\text{Im } g_0} \right) \frac{\partial}{\partial v_0} + S_X \frac{\partial}{\partial u_i} + \frac{\text{Re } g_i}{\text{Im } g_0} S_X \frac{\partial}{\partial v_0} \quad (i \geq 0) \end{aligned}$$

and similarly we have

$$\begin{aligned} -X \left(\frac{1}{\text{Im } g_0} \right) \frac{\partial}{\partial v_0} - \frac{1}{\text{Im } g_0} S_X \frac{\partial}{\partial v_0} &= 0, \\ -X \left(\frac{\text{Im } g_j}{\text{Im } g_0} \right) \frac{\partial}{\partial v_0} - \frac{\text{Im } g_j}{\text{Im } g_0} S_X \frac{\partial}{\partial v_0} + S_X \frac{\partial}{\partial v_j} &= 0 \quad (j > 0). \end{aligned}$$

From these equations, it holds that

$$(8.3) \quad S_X \frac{\partial}{\partial u_i} = -\frac{X \text{Re } g_i}{\text{Im } g_0} \frac{\partial}{\partial v_0}, \quad S_X \frac{\partial}{\partial v_i} = \frac{X \text{Im } g_i}{\text{Im } g_0} \frac{\partial}{\partial v_0} \quad (i \geq 0).$$

Using $A_X Y = (\nabla_X J)(Y) = S_X JY - JS_X Y$ and (8.3), we have the matrix representation

$$(8.4) \quad A = \nabla J = \frac{1}{\text{Im } g_0} \begin{pmatrix} A_0 & \dots & A_n \\ 0_2 & \dots & 0_2 \\ \vdots & \ddots & \vdots \\ 0_2 & \dots & 0_2 \end{pmatrix}$$

of A with respect to the frame

$$\left(\frac{\partial}{\partial u_0}, \frac{\partial}{\partial v_0}, \dots, \frac{\partial}{\partial u_n}, \frac{\partial}{\partial v_n} \right),$$

where

$$A_i = \begin{pmatrix} -d\operatorname{Re} g_i & d\operatorname{Im} g_i \\ d\operatorname{Im} g_i & d\operatorname{Re} g_i \end{pmatrix} \quad \text{and} \quad 0_2 = \begin{pmatrix} 0 & 0 \\ 0 & 0 \end{pmatrix}.$$

Note that we change the order of the frame for simplicity. This means that $A \neq 0$ if there exists i such that $g_i \neq \text{constant}$. By Lemma 7.8 and (8.4), $A^2 = (\nabla J)^2$ induces a globally defined tensor on \bar{U} , in particular

$$\operatorname{Tr} A^2 = \operatorname{Tr} A_0^2 = \frac{2}{(\operatorname{Im} g_0)^2} (d\operatorname{Re} g_0 \otimes d\operatorname{Re} g_0 + d\operatorname{Im} g_0 \otimes d\operatorname{Im} g_0)$$

also induces the symmetric tensor $\bar{\mathcal{B}}$ on \bar{U} . By Lemma 6.4 and (8.4), we see that

$$R^{\nabla'} = -\frac{1}{4} A \wedge A = -\frac{1}{4(\operatorname{Im} g_0)^2} \begin{pmatrix} A_0 \wedge A_0 & A_0 \wedge A_1 & \dots & A_0 \wedge A_n \\ 0_2 & 0_2 & \dots & 0_2 \\ \vdots & \vdots & \ddots & \vdots \\ 0_2 & 0_2 & \dots & 0_2 \end{pmatrix}$$

as the matrix representation.

Since

$$\begin{aligned} dx_i &= du_i \quad (i \geq 0), \quad dy_0 = \sum_{i=0}^n \operatorname{Re} g_i du_i - \operatorname{Im} g_i dv_i, \\ dy_j &= dv_j \quad (j > 0), \end{aligned}$$

a 2-form $\psi = \sum_{i=1}^n dx_i \wedge dy_i (= \sum_{i=1}^n du_i \wedge dv_i)$ is J -hermitian and ∇ -parallel. Note that $\sum_{i=0}^n dx_i \wedge dy_i = dx_0 \wedge dy_0 + \psi$ is not J -hermitian, that is, $(U, J, \nabla, dx_0 \wedge dy_0 + \psi)$ is not special Kählerian if there exists $i > 0$ such that $\operatorname{Re} g_i \neq 0$. However it is a special symplectic manifold. In fact, it holds

$$(dx_0 \wedge dy_0) \left(\frac{\partial}{\partial u_0}, \frac{\partial}{\partial u_i} \right) = \operatorname{Re} g_i \quad \text{and} \quad (dx_0 \wedge dy_0) \left(J \frac{\partial}{\partial u_0}, J \frac{\partial}{\partial u_i} \right) = 0.$$

Moreover since

$$\begin{aligned} \xi &= \sum_{i=0}^n x_i \frac{\partial}{\partial x_i} + y_i \frac{\partial}{\partial y_i} = \dots + \sum_{i=1}^n u_i \frac{\partial}{\partial u_i} + v_i \frac{\partial}{\partial v_i}, \\ J\xi &= \dots + \sum_{i=1}^n u_i \frac{\partial}{\partial v_i} - v_i \frac{\partial}{\partial u_i}, \end{aligned}$$

we have $\mu = \psi(\xi, J\xi) = (1/2) \sum_{i=1}^n (u_i^2 + v_i^2)$. Take a $U(1)$ -bundle $\pi : TU \times U(1) \rightarrow TU$ with a connection form

$$\eta = (\pi_{TU} \circ \pi)^* \left(\sum_{i=1}^n u_i dv_i \right) + d\theta,$$

where θ is the angular coordinate of $U(1)$. The special case Corollary 8.6 of Theorem 8.3 can be applied and then we obtain a quaternionic manifold.

We consider the horizontal subbundle of $p_U : U \rightarrow \bar{U}$ given by the kernel of $\kappa = -(1/2s)d\mu \circ J$ on each level set $\mu^{-1}(s) \subset U$ ($s \neq 0$). We retake U as an open set in $\cup_{s>0}\mu^{-1}(s)$. For horizontal vector fields X and Y tangent to each level set $\mu^{-1}(s)$, $XY\mu = 0$ means that

$$(p_U^*\bar{a})(X, Y) = \frac{1}{2s}\psi(JX, Y),$$

where \bar{a} is the ξ -component of the fundamental tensor of $\mathcal{A}^{\nabla'}$ as in Section 7. Here we used $d\kappa = \psi/s$. This means that \bar{a} is symmetric and \bar{J} -hermitian, and hence the Ricci tensor of the connection $\bar{\nabla}'^{\kappa}$ on \bar{U} induced from κ is symmetric and \bar{J} -hermitian. Therefore it holds

$$p_U^*\bar{a} = -\frac{1}{\sum_{i=1}^n(u_i^2 + v_i^2)} \sum_{i=1}^n du_i \otimes du_i + dv_i \otimes dv_i.$$

Hence the Ricci tensor $Ric^{\bar{\nabla}'^{\kappa}}$ of $\bar{\nabla}'^{\kappa}$ satisfies

$$\begin{aligned} & -\frac{1}{\sum_{i=1}^n(u_i^2 + v_i^2)} \sum_{i=1}^n du_i \otimes du_i + dv_i \otimes dv_i \\ &= \frac{1}{4(n+1)(\text{Im } g_0)^2} (d\text{Re } g_0 \otimes d\text{Re } g_0 + d\text{Im } g_0 \otimes d\text{Im } g_0) - \frac{1}{2(n+1)} p_U^*(Ric^{\bar{\nabla}'^{\kappa}}) \end{aligned}$$

by (7.5). In particular, we see that $Ric^{\bar{\nabla}'^{\kappa}} \geq 0$. For example, when we choose $g = -\sqrt{-1}z_1^l/z_0^{l-1}$ for $l(\neq 1) \in \mathbb{Z}$, we obtain

$$\begin{aligned} d\text{Re } g_0 &= \frac{\sqrt{-1}}{2}(-l+1)l(-w^{l-1}dw + \bar{w}^{l-1}d\bar{w}), \\ d\text{Im } g_0 &= -\frac{1}{2}(-l+1)l(w^{l-1}dw + \bar{w}^{l-1}d\bar{w}), \\ d\text{Re } g_1 &= \frac{\sqrt{-1}}{2}(-l+1)l(w^{l-2}dw - \bar{w}^{l-1}d\bar{w}), \\ d\text{Im } g_1 &= \frac{1}{2}(-l+1)l(w^{l-2}dw + \bar{w}^{l-2}d\bar{w}), \\ d\text{Re } g_j &= d\text{Im } g_j = 0 \quad (j > 1), \end{aligned}$$

where $w = z_1/z_0$. We denote the corresponding objects with subscript l for ones given by $g = -\sqrt{-1}z_1^l/z_0^{l-1}$. It holds that

$$(8.5) \quad R^{\nabla^{l'}} = -\frac{\sqrt{-1}l^2|w|^{2(l-2)}}{(w^l + \bar{w}^l)^2} \begin{pmatrix} 0 & -|w|^2 & -\text{Im } w & \text{Re } w & 0 & \dots & 0 \\ |w|^2 & 0 & -\text{Re } w & -\text{Im } w & 0 & \dots & 0 \\ 0 & 0 & 0 & 0 & 0 & \dots & 0 \\ \vdots & \vdots & \vdots & \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & 0 & 0 & 0 & \dots & 0 \end{pmatrix} dw \wedge d\bar{w}$$

and

$$(8.6) \quad \text{Tr}(A^l)^2 = \text{Tr}(\nabla^l J)^2 = \frac{4l^2 |w|^{2(l-1)}}{(w^l + \bar{w}^l)^2} (dw \otimes d\bar{w} + d\bar{w} \otimes dw).$$

Finally we consider the quaternionic Weyl curvature of TU . Let W^q be the quaternionic Weyl curvature of the quaternionic structure $Q = \langle I_1, I_2, I_3 \rangle$. In [5], the explicit expression of W^q is given and it is shown that W^q is independent of the choice of the quaternionic connection. Since the Obata connection of the c-map is Ricci flat by Theorem 6.5, we have $W^{q,l} = R^{\tilde{\nabla}^{0,l}}$ for $g = -\sqrt{-1}z_1^l/z_0^{l-1}$. If $l \neq 1$, then we see that

$$W_{X^v, Y^v}^{q,l} Z^v = R_{X^v, Y^v}^{\tilde{\nabla}^{0,l}} Z^v = \left(R_{X, Y}^{\nabla^{l'}} Z \right)^v.$$

Because the vertical lift is determined by a differential manifold structure (not by a connection), we see that $W^{q,l} \neq W^{q,k}$ on $T(U_k \cap U_l)$ if $l \neq k$, where $U_j = \{(z_0, z_1, \dots, z_n) \in \mathbb{C}^{n+1} \mid \text{Im } g_0 \neq 0\} = \{(z_0, z_1, \dots, z_n) \in \mathbb{C}^{n+1} \mid \text{Re}(z_1/z_0)^j \neq 0\}$ for $g = -\sqrt{-1}z_1^j/z_0^{j-1}$. Here we used (8.5). So we can find different quaternionic structures $Q^{\alpha_1}, \dots, Q^{\alpha_t}$ on $T(\bigcap_{i=1}^t U_{\alpha_i})$, where $1 \neq \alpha_i \in \mathbb{Z}$. Note that Q^0 is the flat quaternionic structure.

Remark 8.10. Since $d\alpha \neq 0$ except the trivial case $g = -\sqrt{-1}z_0$, Example 8.9 with $g = -\sqrt{-1}z_1^l/z_0^{l-1}$ ($l \neq 0$), which is local one, is not given by a local special Kählerian one.

Remark 8.11. For a conical special Kähler manifold N , the particular twist data which yields the quaternionic Kähler structure of the supergravity c-map on $T^*N \cong TN$ is given in [21, Lemma 5.1] in consistency with [4]. As we noted in the introduction, we also have a freedom in the choice of the data Θ etc. for our generalized supergravity c-map. For instance, the two form Θ can be chosen as trivial ($\Theta = 0$) or as in equation (8.1). For illustration, we can give yet another possible choice of Θ . Assume that $\dim N \geq 6$. Let $\{\bar{U}_\alpha\}_{\alpha \in \Lambda}$ be an open covering of \bar{N} with local trivializations $U_\alpha := p_N^{-1}(\bar{U}_\alpha) \cong \bar{U}_\alpha \times \mathbb{C}^*$ and $g_{\alpha\beta} : \bar{U}_\alpha \cap \bar{U}_\beta \rightarrow \mathbb{C}^*$ be the corresponding transition functions. Let $(r_\alpha, \theta_\alpha)$ be the polar coordinates with respect to a (smooth) local trivialization $p_N^{-1}(\bar{U}_\alpha) \cong \bar{U}_\alpha \times \mathbb{C}^*$ for each $\alpha \in \Lambda$. A principal connection η is locally given by

$$\eta = p_N^*(\gamma_1^\alpha \otimes 1 + \gamma_2^\alpha \otimes \sqrt{-1}) + \left(\frac{dr_\alpha}{r_\alpha} \otimes 1 + d\theta_\alpha \otimes \sqrt{-1} \right)$$

for a \mathbb{C} -valued one-form $\gamma_1^\alpha \otimes 1 + \gamma_2^\alpha \otimes \sqrt{-1}$ on $\bar{U}_\alpha \subset \bar{N}$ for each $\alpha \in \Lambda$. If we write $g_{\alpha\beta} = e^{f_{\alpha\beta}^1 + f_{\alpha\beta}^2 \sqrt{-1}}$, then

$$\begin{aligned} f_{\alpha\beta}^1 + f_{\beta\gamma}^1 - f_{\alpha\gamma}^1 &= 0, \\ f_{\alpha\beta}^2 + f_{\beta\gamma}^2 - f_{\alpha\gamma}^2 &\in 2\pi\mathbb{Z}, \\ \gamma_\beta^1 - \gamma_\alpha^1 &= df_{\alpha\beta}^1, \\ \gamma_\beta^2 - \gamma_\alpha^2 &= df_{\alpha\beta}^2. \end{aligned}$$

Therefore we obtain a principal $U(1)$ -bundle $p_S : S \rightarrow \bar{N}$ with transition functions $e^{f_{\alpha\beta}^2 \sqrt{-1}} : \bar{U}_\alpha \cap \bar{U}_\beta \rightarrow U(1)$ and connection η_S locally given by

$$p_S^*(\gamma_2^\alpha \otimes \sqrt{-1}) + d\theta_\alpha \otimes \sqrt{-1}.$$

In fact, the collection $\{e^{f_{\alpha\beta}^2 \sqrt{-1}}\}$ of local $U(1)$ -valued functions satisfies the cocycle condition and the collection $\{\gamma_\alpha\}$ of local $\sqrt{-1}\mathbb{R}$ -valued one-forms satisfying $\gamma_\beta^2 - \gamma_\alpha^2 = df_{\alpha\beta}^2$ defines a connection form η_S . By Proposition 7.9 and (7.7), its curvature $d\eta_S (= p_S^*(d\gamma_2^\alpha))$ is $2(\bar{a}_{\bar{J}})^a$, where $(\bar{a}_{\bar{J}})^a$ is given by

$$(\bar{a}_{\bar{J}})^a = \frac{1}{8(n+1)} \bar{B}_{\bar{J}} - \frac{1}{2} (P_{\bar{J}}^{\bar{Y}'})^a.$$

On TN , we choose the two-form $\Theta = 2(p_N \circ \pi_{TN})^*((\bar{a}_{\bar{J}})^a)$ and consider the pull-back connection $(p_{N\#} \circ \pi_{TN\#})^*\eta_S$ on the pull-back bundle $P = \pi_{TN\#} p_{N\#} S$. Since $\iota_{Z^M} \Theta = 0$, we can see that the assumptions in Theorem 8.3 hold. It is left for future studies to find a canonical choice of Θ for the generalized supergravity c-map, which allows to invert the H/Q -correspondence of [10].

As an application of Theorem 8.3, we have the following corollary by patching quaternionic manifolds locally constructed by the generalized supergravity c-maps.

Corollary 8.12. *Let $(M, J, [\nabla])$ be a complex manifold with a c -projective structure $[\nabla]$ and $\dim M = 2n$. If $2n = \dim M \geq 4$ and the harmonic curvature of its normal Cartan connection vanishes, then there exists a $4(n+1)$ -dimensional quaternionic manifold (\check{M}, Q) with the vanishing quaternionic Weyl curvature foliated by $(n+2)$ -dimensional complex manifolds whose leaves space is M .*

Proof. Since $\dim M \geq 4$ and the harmonic curvature of its normal Cartan connection vanishes, $(M, J, [\nabla])$ is locally isomorphic to $(\mathbb{C}P^n, J^{st}, [\nabla^{FS}])$ (see [8] for example). So we may assume that $M = \bigcup_\alpha U_\alpha$, where U_α is an open subset $\mathbb{C}P^n$. Set $V_\alpha := p^{-1}(U_\alpha)$, where $p : \mathbb{C}^{n+1} \setminus \{0\} \rightarrow \mathbb{C}P^n$ is the projection. We consider the standard complex structure and the standard flat connection induced from \mathbb{C}^{n+1} on each V_α . By Theorem 8.3, we have a quaternionic manifold $W_\alpha := \varphi'(TV_\alpha) \subset \mathbb{H}^{n+1}$, where φ' is the diffeomorphism given in Example 5.2. Here we have chosen the two-form $\Theta = 0$ and $f = f_1 = 1$ on TV_α for each α . We set $\check{M} := \bigcup_\alpha W_\alpha$. The induced quaternionic structure on each W_α coincides with the standard one from \mathbb{H}^{n+1} . Hence an almost quaternion structure Q on \check{M} can be obtained. Since there exists a quaternionic connection on each W_α , one can obtain a quaternionic connection on \check{M} by the partition of unity, that is, Q is a quaternionic structure with vanishing quaternionic Weyl curvature. For each $p \in TV_\alpha \cap TV_\beta$, the leaf of \mathcal{L} through p in TV_α is denoted by L^α and corresponding leaf in W_α is denoted by \hat{L}^α , that is $\hat{L}^\alpha = \varphi'(L^\alpha)$. Since $\hat{L}^\alpha = \hat{L}^\beta$ in \check{M} , we obtain leaves in \check{M} and see that its leaves space is M . Since the subbundle \mathcal{L} is an I_1 -invariant in $T(TV_\alpha)$, each leaf L is a complex manifold with $I := I_1|_L$. Each leaf \hat{L} on \check{M} is obtained by the Swann's twist with an almost complex structure \hat{I} . By [27, Proposition 3.8] and $\Theta = 0$, \hat{I} is integrable. \square
