Abstract

A kombucha is a tea and sugar fermented by over sixty kinds of yeasts and bacteria. This symbiotic community produces kombucha mats, which are cellulose-based hydrogels. The kombucha mats can be used as an alternative to animal leather in industry and fashion once they have been dried and cured. Prior to this study, we demonstrated that living kombucha mats display dynamic electrical activity and distinct stimulating responses. For use in organic textiles, cured mats of kombucha are inert. To make kombucha wearables functional, it is necessary to incorporate electrical circuits. We demonstrate that creating electrical conductors on kombucha mats is possible. After repeated bending and stretching, the circuits maintain their functionality. In addition, the abilities and electronic properties of the proposed kombucha, such as being lighter, less expensive, and more flexible than conventional electronic systems, pave the way for their use in a diverse range of applications.

Keywords: symbiotic culture, zooglear mats, flexible circuits, wearable electronics, bacterial cellulose

1. Introduction

Kombucha is fermented by a symbiotic community of bacteria and yeasts [1, 2, 3, 1, 4, 5]. The symbiotic culture of bacteria and yeasts produces a cellulose-based hydro-gel, also known as bacterial cellulose, biofilm, commensal biomass, tea-fungus, scoby and zooglea. A tea fermented by the symbiotic community allegedly exhibits a range of health beneficial properties [6, 7, 2], however these will not be discussed in the present work.

Kombucha mats are unique symbiotic systems where over sixty species of yeasts and bacteria cooperate [1]. A kombucha is an example of a proto-multicellularity — an organism combined of multiple species each one pursuing

a common goal of prolonging a life time of the collective organism. Electrical properties of kombucha mats can further advance ideas on electricity based integration, and possibly, protocognition of symbiotic organisms [8, 9, 10, 11]. Similar bacterial cellulose mats, for example, produced by *Acetobacter aceti* colonies, have been shown to feature interesting electrical properties and pressure sensing capabilities [12].

Kombucha mats, when properly cured, show properties similar to textiles [13, 14, 15, 16, 17, 18], and might make a competitive alternative to fungal leather and wearables [19, 20].

In a light of ongoing research on sensing and computing mechanisms embedded in living wearables [21, 22, 23, 24] we aim to evaluate kombucha zoogal mats as potentially embeddable cyber-physical wearable devices with non-linear and non-trivial electrical properties. To achieve the aim we test if basic components of the electrical circuits could be made on dry kombucha mats.

Modern electrical circuits require reliable electrical connections between electronic components (including sensors) and external signals for their construction and continued operation [25, 26, 27]. Printed circuit boards (PCBs) are typically constructed from silkscreen, solder mask, copper, and substrate [28, 29]. Material selection is crucial to the successful operation of printed circuit boards, especially thermal behaviour. The majority of PCB substrates fall into one of two categories: hard/rigid or soft/flexible. Ceramic-based materials typically provide excellent thermal conductivity, good dielectric properties, a high operating temperature, and a low expansion coefficient. The most popular rigid material is FR-4, a glass-reinforced epoxy laminate that is both inexpensive and versatile [30, 31]. Above a few GHz, the substantial dielectric loss (dissipation factor) of FR-4 renders it unsuitable for high-speed digital or high-frequency analogue circuits [32, 33].

PCBs for wearables must often be mechanically flexible, waterproof, and shockproof and by default light [34, 35, 36, 37, 38]. Traditionally they are plastic based although they typically lack sustainability and cost-effectiveness. Polymeric soft materials offer superior resistance to stretching, bending and washing cycles [39]. Moreover, wearables are intended to interact closely with their wearer, therefore bio-compatibility is advantageous, or at least resistance to the active chemical environment offered by the human skin. Therefore, the combination of bio-based PCBs and biodegradable components (including ICs) is especially advantageous for wearables.

2. Methods and materials

The kombucha zooglea was commercially sourced (Freshly Fermented Ltd, UK) to grow mats of kombucha *in situ*. The infusion was prepared as follows; 2% tea (PG Tips, UK), 5% sugar (Silver Spoon, UK), and 1 l of boiled mains water. Containers with kombucha (Fig. 1) were stored at ambient temperature (20 °C to 23 °C) in darkness. The solution was refreshed each week. Kombucha mats were removed from the cultivation container and air-dried on plastic or paper at ambient temperature (several techniques were tried).

(a)

(b)

Figure 1: (a) Container with kombucha live mat on the surface of the liquid culture. (b) Dried mat.

Four manufacturing technologies to add conductive tracks, attaching electronic components, and cut profiles of kombucha mats were explored.

Aerosol jet printing of PODO:T:PSS was implemented as follows. Organic-based electrodes and interconnecting lines were printed by Aerosol Jet Printing (AJP200, Optomec, US [40]) by using an a highly-conductive inkjet formulation of PEDOT:PSS (Clevios P JET N V2, Heraeus, US [41]). Printing parameters were optimised for achieving conductive traces over the surface of kombucha mats used as the substrate. Electrochemical measurements were performed by a potentiostat (PalmSens4, PalmSens BV, NL [42]).

To 3D print TPU with 15% carbon infill and metal-polymer composite — biodegradable polyester and copper — two compositions of filament (2.85 mm diameter) were hot extruded onto kombucha mats via 0.4 mm nozzle on 3D printer (S5, Ultimaker, UK [43]). The composition filaments were ‘Conductive Filaflex Black’ rated $3.9 \Omega \text{ cm}^{-1}$ [44] and ‘Electrifi Conductive Filament’ rated $0.006 \Omega \text{ cm}^{-1}$ [45].

Conductive pathways were drawn onto kombucha mats with two compositions of conductive ink, including ‘Bare Conductive’ rated $55 \Omega \text{ sq}^{-1}$ at $50 \mu\text{m}$ thickness [46] and ‘XD-120 conductive silver ink’ rated $0.00003 \Omega \text{ cm}^{-1}$ [47].

When shaping was involved, kombucha mats of $0.45 \pm 0.1 \text{ mm}$ thickness were cut with 75 W CNC laser cutter (Legend 36EXT, Epiloglasers, US, [48]) while parameters (speed of motion, beam power, pulses per inch) were adjusted to determine the optimal settings.

3. Results

Kombucha mats are proven to be robust to tearing, and are not destroyed even by immersion in water for several days. The mat survived oven temperature up to 200C but burn when exposed to open flame. We have demonstrated that it possible to (1) precisely cut kombucha mats with laser, (2) aerosol jet print PODO:T:PSS circuits on kombucha mats, (3) 3D printing TPU and metal-polymer composite on kombucha mats, (4) draw conductive tracks and arrange functional elements with conductive paints.

Laser cutting proved to be a problem free procedure. Exemplars of kombucha mats cut with laser cutter are shown in Fig. 2. The laser settings (e.g. speed of motion, beam power and number of laser pulses per inch) were found to be critical to accurate cutting. The optimal setting for $0.45 \pm 0.1 \text{ mm}$ thickness was found to be 80 inches per second, $\sim 18 \text{ W}$, and 500 pulses per inch, as shown in Fig. 2(c). If the beam power is raised above optimal level the cut becomes wider than desirable, as shown in Fig. 2(b). Conversely, if the beam power is lower than optimal level the mat is only partly cut through, as shown in Fig. 2(d). With optimised settings, kombucha mats were found to cut well with minimal smoke. Some cut sections needed to be agitated free for removal.

Organic electrical conductors have been printed by Aerosol Jet Printing (AJP) with the aim of creating circuits over kombucha mats, exploited as potential substrates in wearable electronics. Circuits over kombucha can act in

Figure 2: Kombucha mats cut with laser cutter (a) letters and holes of different sizes, (b) nominal 1 mm hole cut to ~ 1.1 mm diameter with ~ 25 W laser power, (c) nominal 1 mm hole cut to ~ 1.0 mm diameter with ~ 18 W laser power, (d) nominal 1 mm holes only partly cut out to ~ 1.0 mm diameter with ~ 10 W laser power.

perspective as sensors or biosensors, coupled also with printed antennas for wireless data communication and storing in clouds. Herein, we are going to explore basic properties of printed traces over the surface of kombucha.

Aerosol Jet Printing is particularly suitable for printing over irregular surfaces, flexible and/or stretchable substrates made of natural materials (biopolymers) because of it operates in non-contact mode at a fixed distance from the substrate. Basic principles and mechanisms of AJP techniques have been discussed in literature [49, 50, 51, 52]. This technology belongs to the additive manufacturing sector and offers advantages with respect to other well known technologies and broadly distributed, such as ink jet printing (normally referred to liquid inks jetted using thermal or piezoelectric nozzles [53]).

A highly conductive formulation of PEDOT:PSS was used as ink: 2mL of ink was uploaded in the ultrasonic atomiser of AJP 200, by setting the gas flows at 30 and 25 sccm for the atomiser and sheath gas, respectively. A 200 μ m size nozzle was mounted on the printed head. The printing run was operated on cool-conditions to avoid exposure of kombucha to heat treatments. Elementary circuit elements were printed firstly, 3 circular electrodes (2mm diameter) at a fixed distance, acting as the working, counter and reference electrodes, for the evaluation of impedance of the electrode-kombucha interface, by Impedance Electrochemical Spectroscopy (EIS) analysis.

Exemplars of deposition of PEDOT:PSS circuits and measurements of electrical properties are shown in Fig. 3. The figure shows the acquired data of EIS over 1) three free points over the kombucha surface; 2) three PEDOT:PSS

Figure 3: Exemplars of deposition of PEDOT:PSS circuits and measurements of electrical properties (a) PEDOT:PSS round pads at a fixed distance from each other with interconnecting tracks (b) Aerosol Jet Printing nozzle (c) defined gap between tracks (d) spring loaded electrodes on PEDOT:PSS pads (e) spring loaded electrodes on surface of kombucha (f) hydration of PEDOT:PSS

electrodes used as the working (RE), counter (CE) and reference (RE) electrodes, placed at fixed distances and the same as the free points of 1); 3) the same measurements of 2) after hydration, where hydration was performed by placing $20 \mu\text{L}$ of water drops in the surrounding area of the electrodes over the kombucha surface. Being kombucha a cellulose-based material, it is very sensitive to water absorption, and up-taking water in the kombucha backbone make the kombucha foil more conductive. Impedance measurements increase almost instantly after water dropping, and stabilise quickly; the measurements after 30 min after water dropping show a more stable signal. Electrical properties of kombucha mat with and without PEDOT:PSS circuits are shown in Fig. 4.

Exemplar of tracks of TPU (with 15% carbon infill) 3D printed on kombucha mat are shown in Fig. 5. Track resistance of TPU (with 15% carbon infill) and Electrifi (metal-polymer composite — biodegradable polyester and copper) was found to vary with width and thickness, as summarised in Tab. 1. Tracks of 100 mm length were measured with LCR meter (891, BK Precision, UK). Flexibility of the tracks was found to vary with thickness. Both TPU and Electrifi tracks remained attached to kombucha after a couple of days of immersion in water. Their attachment might be 'mechanical' rather than chemical as the liquid (melted) polymers are effectively 'injected' into/onto the surface of kombucha effectively filling any surface irregularities which then act as 'grips' holding track in position.

With regards to electrically conductive paint, experiments demonstrated that 'Bare Conductive' [54] adheres well to the kombucha mats and sustains

Figure 5: 3D printing of flexible TPU (with 15% carbon infill) tracks on kombucha mat.

Table 1: Track resistance of TPU (with 15% carbon infill) and Electrifi.

Width (mm)	Thickness (mm)	Cross-section (mm ²)	TPU with 15% carbon ($\Omega \text{ cm}^{-1}$)	Electrifi ($\Omega \text{ cm}^{-1}$)
10	5	50	650	
10	3	30	920	
10	1	10	2,450	
5	3	15	1,400	
5	2	10	2,120	0.28
5	1	5	3,440	0.43
3	1	3	4,490	0.89

(a)

some degree of flexibility. Typical electrical conductivity for tracks is shown in Fig. 6. Track resistance of the conductive paint tracks on kombucha mats varied between $20 \Omega \text{ cm}^{-1}$ to $200 \Omega \text{ cm}^{-1}$. These values roughly align with the ‘Bare Conductive’ data-sheet [54] with ‘thick’ tracks. Track resistance of XD-120 conductive silver ink on kombucha mat was also found to vary. Typical range $1.5 \Omega \text{ cm}^{-1}$ to $10 \Omega \text{ cm}^{-1}$.

4. Discussion

Four technologies for manufacturing kombucha based PCBs were explored aerosol jet printing of PODOT:PSS, 3D printing of TPU and metal-polymer composite, adding ink with conductive filler and laser cutting. Each offered advantages and disadvantages compared to other technologies.

As demonstrated in Fig. 7, it is feasible to construct electrical circuits on kombucha mats. Two track widths (~ 3 and ~ 5 mm) and two packages (3020 and 5050) of surface mount devices (SMD) are displayed. A silver-loaded, conductive, two-part epoxy (Chemtronics CW2400 [55]) was manually applied to mechanically attach and electrically connect SMDs to polymer tracks. For volume manufacture, SMDs would be automatically mounted using a pick and place machine and conductive epoxy precisely and automatically dispensed with in-line dispensers.

Figure 7: Exemplar of metal-polymer composite (Electrifi) tracks on kombucha mat (a) ~ 3 mm wide track with SMD LED (3020 package) green colour (b) ~ 5 mm wide track with SMD LED (5050 package) white colour (scale of ruler in mm).

Two potential methods of forming cross connections on kombucha mats via 3D printing of conductive material — single sided cross-over bridges and through-hole double sided via laser hole cutting — are illustrated Fig. 8.

Kombucha mats show properties that can be exploited to envision potential and future kombucha-based devices. The hydration-dependent electrical con-

Figure 8: Methods of cross connecting on kombucha mats (a) single sided cross-over bridge with insulator between (b) through-hole double sided with laser hole cutting.

duction of kombucha allows to extend the potential operational frequency range of surface-electrodes over kombucha mats, as well as to exploit the kombucha mat as a resistive switching device in a planar electro-chemical cell.

Future research will be concerned with printing advanced functional circuits, capable for detecting, and may be recognising, mechanical, optical and chemical stimuli, implementing sensorial fusion and distributed information processing.

5. Acknowledgements

We are grateful to Geoff Sims for laser cutting of kombucha mats. We thank Ultimaker/MakerBot Technical Support for guidance on optimising print settings with Ultimaker S5. We thank Dr Shengrong Ye (Multi3D) for guidance on 3D printing Electrifi filament.

6. Availability of data

The raw data-sets obtained in this study are available from the corresponding author on reasonable request.
