ABSTRACT:

Glioblastoma, a highly aggressive primary brain tumor, is associated with poor patient outcomes. Although magnetic resonance imaging (MRI) plays a critical role in diagnosing, characterizing, and forecasting glioblastoma progression, public MRI repositories present significant drawbacks, including insufficient postoperative and follow-up studies as well as expert tumor segmentations. To address these issues, we present the "Río Hortega University Hospital Glioblastoma Dataset (RHUH-GBM)," a collection of multiparametric MRI images, volumetric assessments, molecular data, and survival details for glioblastoma patients who underwent total or near-total enhancing tumor resection. The dataset features expert-corrected segmentations of tumor subregions, offering valuable ground truth data for developing algorithms for postoperative and follow-up MRI scans.

The public release of the RHUH-GBM dataset significantly contributes to glioblastoma research, enabling the scientific community to study recurrence patterns and develop new diagnostic and prognostic models. This may result in more personalized, effective treatments and ultimately improved patient outcomes.

KEYWORDS: Glioblastoma; MRI; public dataset; glioma.

INTRODUCTION

Glioblastoma, the most prevalent primary brain tumor, carries a dismal prognosis despite the extensive efforts of clinical trials and research investigations. In recent years, the integration of advanced medical image processing techniques with artificial intelligence-based algorithms has catalyzed the quest to optimize diagnostic accuracy and prognostic models. A key data source leveraged in this domain is magnetic resonance imaging (MRI). Public MRI repositories, such as The Cancer Imaging Archive (TCIA) ¹ and the Multimodal Brain Tumor Segmentation (BraTS) challenge dataset ²⁻⁴, have supplied a wealth of data for research in this field.

Nonetheless, these public resources have predominantly focused on preoperative studies, encompassing patients with diverse tumor extent of resection (EOR) categories and limited expert annotations, while primarily featuring structural sequences of MRI modalities. To address these constraints, we introduce the "Río Hortega University Hospital Glioblastoma Dataset (RHUH-GBM)", comprising multiparametric structural and diffusion MRI images captured at three critical junctures: preoperative, early postoperative (within 72 hours), and follow-up examinations upon recurrence diagnosis. Furthermore, the dataset exclusively contains patients who have undergone total or near-total resection of the enhancing tumor, along with tumor subregion segmentations for each time point. Complementing this data are clinical information, volumetric assessments of resection extents, molecular data, and survival details.

By publicly disseminating this dataset, we aim to enable the scientific community to scrutinize recurrence patterns in patients who have experienced gross total or near-total resection, and facilitate the development of novel registration and segmentation algorithms tailored for postoperative and follow-up MRI scans.

METHODS

Patient population

The dataset comprises consecutive patients who underwent surgery between January 2018 and December 2022, with a confirmed histopathological diagnosis of WHO grade 4 astrocytoma. Forty patients were selected based on the following inclusion criteria: 1) Gross total resections (GTR) or Near Total Resection (NTR), defined as having no residual tumor enhancement and an extent of resection exceeding 95% of the initial enhancing volume, respectively ^{5,6}. 2) Availability of MRI studies at three time points: preoperative, early postoperative (within 72 hours), and follow-up studies during which recurrence was diagnosed. 3) Availability of structural T1-weighted (T1w), T2-weighted (T2w), T1 contrast-enhanced (T1ce), Fluid-attenuated inversion recovery (FLAIR), and diffusion-weighted imaging-derived apparent diffusion coefficient (ADC) maps for each study. 4) Receipt of adjuvant treatment with chemotherapy and radiotherapy following the Stupp protocol ⁷.

Patients with severe image acquisition artifacts or missing MRI series were excluded. The modified Response Assessment in Neuro-Oncology (RANO) criteria were utilized to determine tumor progression ⁸. This study received approval from the Institutional Review Board of the Río Hortega University Hospital and the Ethics Committee for Drug Research (CEIm) of the West Valladolid Health Area (Ref. 22PI-208)

Clinical, Pathological, and Imaging Data

Clinical and pathological information was obtained from electronic medical records, including age, sex, histopathological diagnosis, pre- and postoperative Karnofsky Performance Score (KPS), isocitrate dehydrogenase (IDH) status, use of operative adjuncts, volumetric assessment of the extent of resection of the contrast-enhancing and non-enhancing tumor, presence of postoperative neurological deficits, details of chemotherapy and radiotherapy received, and overall survival and progression-free survival times. In this collection, all postoperative MRI scans were conducted at Río Hortega University Hospital. Out of the total sample, a subset of 11 patients had initially undergone preoperative and subsequent follow-up MRI scans at a secondary healthcare facility before being referred to the primary center. Details of the MR imaging acquisition parameters are described in Supplementary Table 1.

Image Preprocessing

Images were retrieved from the Picture Archiving Communication System (PACS) in Digital Imaging and Communications in Medicine (DICOM) format for subsequent processing. The first step involved converting the images to Neuroimaging Informatics Technology Initiative (NIfTI) format using the `dicom2niix` tool version v1.0.20220720 ⁹, available at <https://github.com/rordenlab/dcm2niix/releases/tag/v1.0.20220720>. Subsequently, the T1ce scans for each subject were registered to the SRI24 anatomical atlas space ¹⁰ using the FLIRT (FMRIB's Linear Image Registration Tool) ^{11,12} available at <https://fsl.fmrib.ox.ac.uk/fsl/fslwiki/FSL>. The T1w, T2w, FLAIR scans, and ADC maps were then registered to the transformed T1ce scan, resulting in co-registered resampled volumes of $1 \times 1 \times 1$ mm isotropic voxels. The brain was extracted from all co-registered scans using a deep learning tool called Synthstrip ¹³, included in FreeSurfer v7.3.0, available at https://github.com/freesurfer/freesurfer/tree/dev/mri_synthstrip.

Finally, intensity Z-scoring normalization was performed using the normalization tools included in Cancer Imaging Phenomics Toolkit (CaPTk) v1.9.0 ¹⁴ available at <https://www.nitrc.org/projects/captk/>

Tumor Subregions Segmentations

The preprocessed images from each time point were used as input for generating computer-aided segmentations using Deep-Medic ¹⁵. Three labels were subsequently obtained, corresponding to 1 - necrosis, 2 - peritumoral signal alteration, including edema and non-enhancing tumor, and 3 - enhancing tumor. All segmentations were carefully reviewed and manually corrected by two expert neurosurgeons specializing in neuroimaging (S.C. and S.G.), who have a solid background in such tasks.

RESULTS

A summary of the demographic data is presented in Table 1. The patients had an average age of 63 ± 9 years, consisting of 28 men (70%) and 12 women (30%). The median preoperative Karnofsky Performance Scale (KPS) score was 80. Out of the 40 patients, 38 (95%) were diagnosed with de novo glioblastomas, while two patients (5%) had recurrent

glioblastomas previously treated with standard chemoradiotherapy. Four cases (10%) were IDH-mutated, and 36 cases (90%) were IDH wild-type.

The mean preoperative contrast-enhancing tumor volume was 34.99 ± 26.59 , and the mean postoperative contrast-enhancing residual tumor volume was 0.23 ± 0.47 . The mean preoperative T2/FLAIR abnormality was 73.14 ± 43.63 , while the mean postoperative T2/FLAIR abnormality was 35.00 ± 26.74 . Among the patients, 27 (67.5%) underwent gross total resection, and 13 (32.5%) underwent near-total resection. The mean extent of resection (EOR) was $99.31 \pm 1.36\%$. The median overall survival was 364 days, and the median progression-free survival was 198 days.

Table 1. Study population demographics of the Río Hortega University Hospital Glioblastoma dataset (RHUH-GBM)

Sex	Male	28 (70%)
	Female	12 (30%)
Age (years)	63 ± 9	
Extent of resection	GTR	27 (67.5%)
	NTR	13 (32.5%)
Number of time-point MRI studies	120	
Number of MRI series	600	
IDH status	Mutant	4 (10%)
	Wild type	36 (90%)
Preoperative KPS	80 (10)	
Operative adjuncts	5'ALA	40 (100%)
	Sodium Fluorescein	7 (17.5%)
	Neuronavigation	40 (100%)
	IoUS	40 (100%)
	IONM	4 (10%)
	DES	3 (7.5%)
Preoperative contrast enhancing tumor volume	34.99 ± 26.59	
Preoperative T2/FLAIR peritumoral signal alteration volume	35.00 ± 26.74	
Postoperative contrast enhancing tumor volume	0.23 ± 0.47	
Postoperative T2/FLAIR peritumoral signal alteration volume	35.00 ± 26.74	
Radiotherapy treatment details	VMAT-IMRT-IGRT/60 Gy /30 fx	29 (72.5%)
	VMAT-IMRT-IGRT/50 Gy /20 fx	6 (15%)
	VMAT-IMRT-IGRT/40.5 Gy /15 fx	5 (12.5%)
Postoperative neurological deficit	No	26 (65%)
	Transient	6 (15%)
	Minor persistent	6 (15%)
	Major persistent	2 (5%)
Posotperative KPS	80 (20)	

Numerical values are expressed in mean and standard deviation or median and interquartile range accordingly. GTR = gross total resection, NTR = near total resection, IDH = isocitrate dehydrogenase, VMAT = Volumetric Modulated Arc Therapy, IMRT = Intensity Modulated Radiation Therapy, IGRT = Image-Guided Radiation Therapy. Radiotherapy treatments are expressed in dose (Gy) and number of fractions (fx)

DATA AVAILABILITY

The RHUH-GBM dataset will be publicly available via The Cancer Imaging Archive web site <https://www.cancerimagingarchive.net/>. The code applied for image preprocessing is available to the public through a GitHub repository <https://github.com/smcch/RHUH-GBM-dataset-MRI-preprocessing>

DISCUSSION

Numerous public MRI collections, comprising glioblastoma patients, are available for researchers investigating this aggressive form of brain cancer. These collections have significantly contributed to advancements in the field. Notable datasets include The Cancer Genome Atlas Glioblastoma Multiforme (TCGA-GBM) ¹⁶, Clinical Proteomic Tumor Analysis Consortium Glioblastoma (CPTAC-GBM) ¹⁷, Quantitative Imaging Network Glioblastoma (QIN GBM) ¹⁸, American College of Radiology Imaging Network Fluoromisonidazole-Brain (ACRIN-FMISO-Brain) ^{19,20}, and Brain Tumor Segmentation (BraTS) Challenge 2021 ²⁻⁴. While these collections are invaluable, they primarily focus on preoperative studies and often lack information on the extent of tumor resection performed. Furthermore, only the BraTS dataset includes tumor segmentations.

The Ivy Glioblastoma Atlas Project (Ivy GAP) ²¹ collection offers longitudinal studies for 39 patients, but not all include early postoperative assessments. Additionally, this collection features patients with subtotal resections and does not provide segmentations.

The recent Multi-parametric magnetic resonance imaging (mpMRI) scans for de novo Glioblastoma (GBM) patients from the University of Pennsylvania Health System (UPENN-GBM) ²² and The University of California San Francisco Preoperative Diffuse Glioma MRI (UCSF-PDGM) ²³ collections contain 611 and 501 cases, respectively. These datasets include expert-refined segmentations and additional perfusion and diffusion modalities. However, the UPENN-GBM dataset has a limited 8.9% of patients with follow-up studies and lacks early postoperative MRI scans. Meanwhile, the UCSF-PDGM dataset provides only preoperative studies for the 402 grade 4 astrocytoma cases.

The HURH-GBM collection enhances the available resources by incorporating early postoperative studies and recurrence scans. The dataset's expert-corrected segmentations are especially advantageous for postoperative scans, given the labor-intensive and time-consuming nature of differentiating peritumoral T2-FLAIR alterations from postoperative changes such as edema, hemorrhage, and ischemia. The inclusion of patients with gross total resection in this collection may potentially facilitate investigations into tumor recurrence patterns. Additionally, the provided labels could act as ground truths for the development of segmentation and coregistration algorithms targeting postoperative and follow-up studies.

ACKNOWLEDGEMENTS

This work was partially funded by a grant awarded by the "Instituto Carlos III, Proyectos I-D-i, Acción Estratégica en Salud 2022", under the project titled "Prediction of tumor recurrence in glioblastomas using magnetic resonance imaging, machine learning, and transcriptomic analysis: A supratotal resection guided by artificial intelligence," reference PI22/01680.
