Abstract—There has been growing interest in implementing massive MIMO systems by one-bit analog-to-digital converters (ADCs), which have the benefit of reducing the power consumption and hardware complexity. One-bit MIMO detection arises in such a scenario. It aims to detect the multiuser signals from the one-bit quantized received signals in an uplink channel. In this paper, we consider one-bit maximum-likelihood (ML) MIMO detection in massive MIMO systems, which amounts to solving a large-scale nonlinear integer programming problem. We propose an efficient global algorithm for solving the one-bit ML MIMO detection problem. We first reformulate the problem as a mixed integer linear programming (MILP) problem that has a massive number of linear constraints. The massive number of linear constraints raises computational challenges. To solve the MILP problem efficiently, we custom build a light-weight branch-andbound tree search algorithm, where the linear constraints are incrementally added during the tree search procedure and only small-size linear programming subproblems need to be solved at each iteration. We provide simulation results to demonstrate the efficiency of the proposed method.

Index Terms—One-bit MIMO detection, maximum-likelihood, mixed integer linear programming

## I. INTRODUCTION

When the massive multiple-input multiple-output (MIMO) system is realized by employing dedicated radio-frequency (RF) chains, power consumption and hardware complexity can be prohibitively high. This has become an impediment in practical implementations for 5G systems and beyond. To resolve the above issue, low-resolution, particularly, one-bit analog-to-digital converters (ADCs) and digital-to-analog converters (DACs) can be employed to cut down the power consumption and hardware complexity, because the power consumption of ADCs and DACs increases exponentially with the resolution [1]. Unfortunately, the use of one-bit ADCs/DACs leads to severe quantization distortion on the signals, and this calls for customized quantized signal processing methods.

In this paper, we study the uplink multiuser signal detection problem in a massive MIMO system with one-bit ADCs. Researchers have proposed different detection methods, including linear receivers [2]–[4], maximum-likelihood (ML) detection [5]–[7] and maximum a posteriori (MAP) detection [8]–[11]. Among the existing methods, maximum-likelihood (ML) detection is an important formulation that tries to address the quantization effect [5]–[7], [12]–[18]. However, the ML formulation involves a large-scale nonlinear integer programming problem, and solving it by brute-force exhaustive search can be computationally too demanding. Researchers have proposed a variety of approximate algorithms to strike a balance between detection performance and computational complexity, by means of relaxation and optimization [5]–[7], [12], deep learning [7], [13]–[15], statistical inference [15]– [17] and coding theory [18]. Unfortunately, there is *no* efficient global algorithm for one-bit ML MIMO detection in the literature.

In this paper, we propose an efficient global algorithm for one-bit ML MIMO detection. We first transform the one-bit ML MIMO detection problem into a mixed integer linear programming (MILP) problem. The crux lies in that the MILP problem has exponentially many inequality constraints (with respect to the number of users), which results in high computational complexity if it is directly solved by an MILP solver like CPLEX [19]. We propose an incremental optimization strategy to alleviate the high computational burden. It starts with a relaxed MILP problem with only a selected small subset of the inequality constraints. Then, we iteratively and incrementally add the inequality constraints into the relaxed MILP problem. In order to develop a light-weight global algorithm, we solve each relaxed MILP problem inexactly, which is achieved by embedding the incremental optimization strategy into one branch-and-bound procedure. In this way, the algorithm only needs to solve linear programming (LP) subproblems with significantly much smaller problem sizes (compared with the MILP reformulation of the original problem), and is computationally efficient as demonstrated by simulations. The proposed global algorithm offers an important benchmark for performance evaluation of existing approximate algorithms for solving the same ML problem, showing how well they perform compared to the global ML solutions.

### II. SIGNAL MODEL

Consider a multiuser multiple-input single-output (MISO) uplink transmission, where  $\tilde{K}$  single-antenna users concur-

This work was partly supported by a General Research Fund (GRF) of Hong Kong Research Grant Council (RGC) under Project ID CUHK 14203721.

rently send their signals to a base station (BS) having  $\tilde{N}$  antennas. At the BS, the received signal can be modeled by

$$\tilde{y} = \tilde{H}\tilde{x} + \tilde{v}, \quad \tilde{r} = \mathcal{Q}(\tilde{y}),$$
(1)

where  $\tilde{\boldsymbol{x}} \in \mathbb{C}^{\tilde{K}}$  is the multiuser transmit signal vector, drawn from the Quadrature Phase Shift Keying (QPSK) constellation  $\{\pm 1 \pm j\}$ ;  $\tilde{\boldsymbol{H}} \in \mathbb{C}^{\tilde{N} \times \tilde{K}}$  is the multiuser channel matrix;  $\tilde{\boldsymbol{v}} \in \mathbb{C}^{\tilde{N}}$  is additive complex Gaussian noise with mean **0** and covariance matrix  $\tilde{\sigma}^2 \boldsymbol{I}$ ;  $\mathcal{Q}(x) := \operatorname{sgn}(\Re(x)) + j \cdot \operatorname{sgn}(\Im(x))$  is the one-bit quantizer for both the real and imaginary parts of x, and

$$\operatorname{sgn}(x) = \begin{cases} 1, & \text{if } x \ge 0; \\ -1, & \text{otherwise,} \end{cases}$$

is the one-bit quantization function that operates on each element of its argument;  $\tilde{r} \in \mathbb{C}^{\tilde{N}}$  is the one-bit received signal. The one-bit MIMO detection problem is to detect  $\tilde{x}$  from the one-bit received signal  $\tilde{r}$ , with given  $\tilde{H}$ .

For convenience of presentation, we consider the following equivalent real-valued model. Define

$$oldsymbol{y} = egin{bmatrix} \Re( ilde{oldsymbol{y}}) \ \Im( ilde{oldsymbol{y}}) \end{bmatrix} \in \mathbb{R}^N, oldsymbol{H} = egin{bmatrix} \Re( ilde{oldsymbol{H}}) & -\Im( ilde{oldsymbol{H}}) \ \Im( ilde{oldsymbol{H}}) \end{bmatrix} \in \mathbb{R}^{N imes K}, \ oldsymbol{x} = egin{bmatrix} \Re( ilde{oldsymbol{y}}) \ \Im( ilde{oldsymbol{x}}) \end{bmatrix} \in \mathbb{R}^K, oldsymbol{r} = egin{bmatrix} \Re( ilde{oldsymbol{h}}) \ \Im( ilde{oldsymbol{H}}) \end{bmatrix} \in \mathbb{R}^N, oldsymbol{v} = egin{bmatrix} \Re( ilde{oldsymbol{x}}) \ \Im( ilde{oldsymbol{x}}) \end{bmatrix} \in \mathbb{R}^N, oldsymbol{v} = egin{bmatrix} \Re( ilde{oldsymbol{v}}) \ \Im( ilde{oldsymbol{v}}) \end{bmatrix} \in \mathbb{R}^N, \ oldsymbol{v} = egin{bmatrix} \Re( ilde{oldsymbol{v}}) \ \Im( ilde{oldsymbol{v}}) \end{bmatrix} \in \mathbb{R}^N, oldsymbol{v} = egin{bmatrix} \Re( ilde{oldsymbol{v}}) \ \Im( ilde{oldsymbol{v}}) \end{bmatrix} \in \mathbb{R}^N, \ oldsymbol{v} = egin{bmatrix} \Re( ilde{oldsymbol{v}}) \ \Im( ilde{oldsymbol{v}}) \end{bmatrix} \in \mathbb{R}^N, \ oldsymbol{v} = egin{bmatrix} \Re( ilde{oldsymbol{v}}) \ \Im( ilde{oldsymbol{v}}) \end{bmatrix} \in \mathbb{R}^N, \ oldsymbol{v} = egin{bmatrix} \Re( ilde{oldsymbol{v}}) \ \Im( ilde{oldsymbol{v}}) \end{bmatrix} \in \mathbb{R}^N, \ oldsymbol{v} = egin{bmatrix} \Re( ilde{oldsymbol{v}}) \ \Im( ilde{oldsymbol{v}}) \end{bmatrix} \in \mathbb{R}^N, \ oldsymbol{v} = egin{bmatrix} \Re( ilde{oldsymbol{v}}) \ \Im( ilde{oldsymbol{v}}) \ \Im( ilde{oldsymbol{v}}) \end{bmatrix} \in \mathbb{R}^N, \ oldsymbol{v} = egin{bmatrix} \Re( ilde{oldsymbol{v}}) \ \Im( ilde{oldsymbol{v}}) \end{bmatrix} \in \mathbb{R}^N, \ oldsymbol{v} = egin{bmatrix} \Re( ilde{oldsymbol{v}}) \ \Im( ilde{oldsymbol{v}}) \ \Im( ilde{oldsymbol{v}}) \end{bmatrix} \in \mathbb{R}^N, \ oldsymbol{v} = egin{bmatrix} \Re( ilde{oldsymbol{v}}) \ \Im( ilde{oldsymbol{v}}) \ \Im( ilde{oldsymbol{v}}) \ \Im( ilde{oldsymbol{v}}) \ \blacksquare( ilde{oldsymbol{v}}) \ \Im( ilde{oldsymbol{v}}) \ \blacksquare( ilde{oldsymbol{v}}) \ \Im( ilde{oldsymbol{v}}) \ \oiint( ilde{oldsymbol{v}}) \ \blacksquare( ilde{oldsymbol{v}}) \ \oiint( ilde{oldsymbol{v}}) \ \oiint( ilde{oldsymbol{v}}) \ \oiint( ilde{oldsymbol{v}}) \ \oiint( ilde{oldsym$$

where  $N = 2\tilde{N}$ ,  $K = 2\tilde{K}$  and v follows the standard Gaussian distribution with mean **0** and covariance  $\sigma^2 I$ . We convert (1) to a real-valued form

$$\boldsymbol{y} = \boldsymbol{H}\boldsymbol{x} + \boldsymbol{v}, \ \boldsymbol{r} = \operatorname{sgn}(\boldsymbol{y}),$$
 (2)

where  $x \in \{-1, 1\}^{K}$ .

We consider maximum-likelihood (ML) detection [6], which can be expressed as

$$\min_{\boldsymbol{x} \in \{-1,1\}^{K}} f(\boldsymbol{x}) := -\sum_{i=1}^{N} \log \Phi\left(\frac{r_{i}\boldsymbol{h}_{i}^{\top}\boldsymbol{x}}{\sigma}\right), \quad (3)$$

where f(x) is the negative log-likelihood function and  $\Phi(z) = \int_{-\infty}^{z} \frac{1}{\sqrt{2\pi}} e^{-t^2} dt$  is the cumulative distribution function of the standard Gaussian distribution. Problem (3) is a nonlinear integer programming problem. To globally solve (3), exhaustive search can be applied, which examines all feasible solutions with a complexity order of  $\mathcal{O}(2^K)$ . To the best of our knowledge, off-the-shelf efficient mixed integer programming solvers such as CPLEX cannot handle  $\Phi(\cdot)$ , which is an integral. In the literature, there are many approximate algorithms for solving problem (3) that seek to strike a balance between detection performance and computational complexity [5]–[7], [12]–[17]. In this paper, we aim to propose an efficient algorithm for globally solving problem (3), which can serve as a benchmark to evaluate the performance of the existing approximate algorithms.

# III. AN EFFICIENT GLOBAL ALGORITHM

In this section, we propose an efficient *global* algorithm for solving problem (3).

# A. An MILP Reformulation

We first equivalently reformulate problem (3) as

$$\min_{\boldsymbol{x},\boldsymbol{w}} \sum_{i=1}^{N} w_i$$
s.t.  $w_i \ge g_i(\boldsymbol{x}), \ i = 1, 2, \dots, N,$ 
 $\boldsymbol{x} \in \{-1, 1\}^K,$ 

$$(4)$$

where  $w = (w_1, w_2, ..., w_N)$  and

$$g_i(\boldsymbol{x}) := -\log \Phi\left(\frac{r_i \boldsymbol{h}_i^{\top} \boldsymbol{x}}{\sigma}\right).$$

Note that  $g_i$  is a convex function with respect to x. The following linear inequality

$$g_i(\boldsymbol{x}) \ge g_i(\hat{\boldsymbol{x}}) + \langle \nabla g_i(\hat{\boldsymbol{x}}), \boldsymbol{x} - \hat{\boldsymbol{x}} \rangle, \ \forall \hat{\boldsymbol{x}} \in \{-1, 1\}^K$$
(5)

is valid, where

$$\nabla g_i(\boldsymbol{x}) = -\frac{\phi(r_i \boldsymbol{h}_i^\top \boldsymbol{x}/\sigma)}{\Phi(r_i \boldsymbol{h}_i^\top \boldsymbol{x}/\sigma)} \frac{r_i \boldsymbol{h}_i}{\sigma}$$

is the gradient of  $g_i$  at x, and  $\phi(t) = \frac{1}{\sqrt{2\pi}}e^{-t^2}$  is the probability distribution function of the standard Gaussian distribution. Then, with (5), we reformulate problem (4) as

$$(\boldsymbol{x}^{\star}, \boldsymbol{w}^{\star}) = \arg\min_{\boldsymbol{x}, \boldsymbol{w}} \sum_{i=1}^{N} w_i$$
  
s.t.  $w_i \ge g_i(\hat{\boldsymbol{x}}) + \langle \nabla g_i(\hat{\boldsymbol{x}}), \boldsymbol{x} - \hat{\boldsymbol{x}} \rangle$ , (6a)  
 $i = 1, 2, \dots, N, \ \forall \hat{\boldsymbol{x}} \in \{-1, 1\}^K,$   
 $\boldsymbol{x} \in \{-1, 1\}^K.$  (6b)

**Fact 1** Problems (3) and (6) are equivalent, in the sense that they have the same optimal solution for x.

Fact 1 can be obtained by noting that inequality (5) is tight when  $\hat{x} = x$ , which establishes the equivalence between problems (4) and (6). This, together with the equivalence between (3) and (4), leads to the desired result.

The upshot of problem (6) is that the inequalities (6a) are *linear* in both x and w. As a result, problem (6) is an MILP problem. In principle, problem (6) can be solved by off-the-shelf MILP solvers such as CPLEX [19]. However, the number of inequality constraints in (6a) is  $N \cdot 2^K$ , where both N and K can be large in massive MIMO systems, which can lead to prohibitively high computational complexity.

# B. An Incremental Algorithmic Framework

To tackle the computational issue, we propose to solve problem (6) through an incremental optimization strategy. We define

$$C = \{(i, \hat{x}) \mid i = 1, 2, \dots, N, \ \hat{x} \in \{-1, 1\}^{K}\}$$

and select  $S \subseteq C$  as a subset of C. We consider the following relaxation of problem (6):

Algorithm 1 An Incremental Optimization Framework for Solving Problem (6)

1: **input:** Initialization  $S \subseteq C$ ; 2: repeat //one iteration Solve problem (7) to obtain its optimal solution  $(\bar{x}, \bar{w})$ ; 3: if  $\bar{w}_i < q_i(\bar{x})$  for some *i*'s then 4:  $\mathcal{S} \leftarrow \mathcal{S} \cup \{(i, \bar{\boldsymbol{x}}) \mid \bar{w}_i < g_i(\bar{\boldsymbol{x}}), i = 1, 2, \dots, N\};$ 5: else 6: 7: break: end if 8: 9: **until**  $\bar{w}_i \geq g_i(\bar{x})$  holds for all *i*; 10: **output**  $(x^{\star}, w^{\star}) = (\bar{x}, \bar{w}).$ 

$$(\bar{\boldsymbol{x}}, \bar{\boldsymbol{w}}) \in \arg\min_{\boldsymbol{x}, \boldsymbol{w}} \sum_{i=1}^{N} w_{i}$$
  
s.t.  $w_{i} \geq g_{i}(\hat{\boldsymbol{x}}) + \langle \nabla g_{i}(\hat{\boldsymbol{x}}), \boldsymbol{x} - \hat{\boldsymbol{x}} \rangle, \ (i, \hat{\boldsymbol{x}}) \in \mathcal{S},$   
 $\boldsymbol{x} \in \{-1, 1\}^{K}.$  (7)

We have the following result.

# Fact 2 Consider problems (6) and (7). The following hold.

- a)  $\sum_{i=1}^{N} \bar{w}_i \leq \sum_{i=1}^{N} w_i^{\star}$ . b) if  $\bar{w}_i \geq g_i(\bar{x})$  holds for all *i*, then  $(\bar{x}, \bar{w})$  is also optimal to problem (6).

*Proof*: Since problem (7) is a relaxed version of problem (6), it holds that  $\sum_{i=1}^{N} \bar{w}_i \leq \sum_{i=1}^{N} w_i^*$ . This proves a).

If  $\bar{w}_i \ge g_i(\bar{x})$  for all i, then  $(\bar{x}, \bar{w})$  is a feasible solution to problem (4). Thus,  $\sum_{i=1}^N \bar{w}_i \ge \sum_{i=1}^N w_i^*$ . This, together with a), implies  $\sum_{i=1}^N \bar{w}_i = \sum_{i=1}^N w_i^*$ . Thus,  $(\bar{x}, \bar{w})$  is an optimal solution to problem (4), and also problem (6).

Fact 2 offers a hint to the algorithmic design. Specifically, we start from solving problem (7) with an  $S \subseteq C$ . If  $\bar{w}_i \geq$  $g_i(\bar{x})$  holds for all *i*, then  $(\bar{x}, \bar{w})$  is already optimal to problem (6). Otherwise, if  $\bar{w}_i < q_i(\bar{x})$  for some *i*, then the constraint

$$w_i \ge g_i(\bar{\boldsymbol{x}}) + \langle \nabla g_i(\bar{\boldsymbol{x}}), \boldsymbol{x} - \bar{\boldsymbol{x}} \rangle$$
 (8)

is added into problem (7), i.e., adding  $(i, \bar{x})$  into S. Then, we solve problem (7) again with the new S. This process is repeated until  $\bar{w}_i \geq g_i(\bar{x})$  holds for all *i*. This incremental optimization framework is described in Algorithm 1.

### C. An Efficient Branch-and-Bound Algorithm

Algorithm 1 requires (possibly) solving multiple MILP problems in the form of (7) (e.g., by branch-and-bound algorithms [20]) and solving each MILP problem can be timeconsuming. Therefore, the complexity of Algorithm 1 can still be high (especially when the number of iterations is large). To further reduce the computational complexity of Algorithm 1, we propose to solve each MILP problem (7) inexactly, which is done by embedding the incremental optimization iterations (cf. lines 3-8 in Algorithm 1) into one branch-and-bound algorithm. Branch-and-bound algorithms are tree search methods that recursively partition the feasible region (i.e., a rooted tree) into small subregions (i.e., branches). In particular, our proposed branch-and-bound algorithm solves the LP relaxation in the form of (10) at each iteration and gradually tightens the relaxation by adding appropriate  $(i, \hat{x})$  in the set S and fixing more elements of x to be  $\{-1, 1\}$ . The resulting algorithm is still an global algorithm to problem (6). Note that the proposed algorithm only needs to solve an LP problem at each iteration, which is in sharp contrast to solving the MILP problem (7) in Algorithm 1. Below, we present the proposed algorithm in more details.

1) Subproblems and Their LP Relaxations: Denote  $\mathcal{F}_+$  and  $\mathcal{F}_{-}$  as some subsets of  $\{1, 2, \ldots, N\}$  such that  $x_{j} = 1$  for  $j \in \mathcal{F}_+$  and  $x_j = -1$  for  $j \in \mathcal{F}_-$ , and  $\mathcal{F}_+ \cap \mathcal{F}_- = \emptyset$ . The subproblem to explore at the branch defined by  $\mathcal{F}_+$  and  $\mathcal{F}_$ is given by

$$\min_{\boldsymbol{x},\boldsymbol{w}} \sum_{i=1}^{N} w_i$$
s.t.  $w_i \ge g_i(\hat{\boldsymbol{x}}) + \langle \nabla g_i(\hat{\boldsymbol{x}}), \boldsymbol{x} - \hat{\boldsymbol{x}} \rangle, \ (i, \hat{\boldsymbol{x}}) \in \mathcal{C},$  (9a)

$$x_j = 1, \ j \in \mathcal{F}_+, \ x_j = -1, \ j \in \mathcal{F}_-,$$
 (9b)

$$\boldsymbol{x} \in \{-1, 1\}^{\kappa} . \tag{9c}$$

Also, consider the following LP relaxation of problem (9):

N

$$\min_{\boldsymbol{x},\boldsymbol{w}} \sum_{i=1}^{N} w_i$$
s.t.  $w_i \ge g_i(\hat{\boldsymbol{x}}) + \langle \nabla g_i(\hat{\boldsymbol{x}}), \boldsymbol{x} - \hat{\boldsymbol{x}} \rangle, \ (i, \hat{\boldsymbol{x}}) \in \mathcal{S},$  (10a)

$$x_j = 1, \ j \in \mathcal{F}_+, \ x_j = -1, \ j \in \mathcal{F}_-,$$
 (10b)

$$\boldsymbol{x} \in [-1,1]^K,\tag{10c}$$

where  $S \subseteq C$ . Problem (10) is a relaxation of problem (9) by replacing C with S and by relaxing binary variables  $x_i$ 's with  $x_i \notin \mathcal{F}_+ \cup \mathcal{F}_-$  to [-1, 1]. Therefore, solving the LP problem (10) provides a lower bound for the MILP problem (9).

2) Proposed Algorithm: Now, we present the main steps of the proposed branch-and-bound algorithm based on the LP relaxation in (10). We use  $(\check{x}, \check{w})$  to denote the best known feasible solution that provides the smallest objective value at the current iteration and use U to denote its objective value (called the *upper bound* of problem (6)). In addition, we use  $(\mathcal{F}_+, \mathcal{F}_-, \mathcal{S})$  to denote subproblem (9) where  $\mathcal{S} \subseteq \mathcal{C}$  relates to its current LP relaxation (10), and  $\mathcal{P}$  to denote the problem set of the current unprocessed subproblems. At the beginning, we initialize  $\mathcal{P} \leftarrow \{(\emptyset, \emptyset, \mathcal{S})\}$  for some  $\mathcal{S} \subseteq \mathcal{C}$ . At each iteration, we pick a subproblem  $(\mathcal{F}_+, \mathcal{F}_-, \mathcal{S})$  from  $\mathcal{P}$ , and solve problem (10) to obtain its solution  $(x_{LP}, w_{LP})$  and objective value  $f_{\mathsf{LP}} = \sum_{i=1}^{N} [w_{\mathsf{LP}}]_i$ . Then, we have the following cases:

- (1) If  $f_{LP} \ge U$ , then problem (9) cannot contain a feasible solution that provides an objective value better than U(and this subproblem does not need to be explored).
- (2) If  $f_{\mathsf{LP}} < U$  and  $x_{\mathsf{LP}} \in \{-1, 1\}^K$ , there are two subcases.
- (2.1) If  $[w_{LP}]_i \geq g_i(x_{LP})$  for all i = 1, 2, ..., N, then  $(x_{\text{LP}}, w_{\text{LP}})$  must be an optimal solution to problem (9). We update  $(\check{\boldsymbol{x}}, \check{\boldsymbol{w}}) \leftarrow (\boldsymbol{x}_{\mathsf{LP}}, \boldsymbol{w}_{\mathsf{LP}})$  and  $U \leftarrow f_{\mathsf{LP}}$ .
- (2.2) Otherwise, we apply the incremental optimization strat-

Algorithm 2 A Global Algorithm for Solving Problem (6)

-	
1:	input: Initialize $\mathcal{P} = \{(\emptyset, \emptyset, \mathcal{S})\}$ for some $\mathcal{S} \subseteq \mathcal{C}$ and
	$U \leftarrow +\infty.$
2:	while $\mathcal{P} \neq arnothing$ do
3:	Choose a subproblem $(\mathcal{F}_+, \mathcal{F}, \mathcal{S}) \in \mathcal{P}$ and set $\mathcal{P} \leftarrow$
	$\mathcal{P} \setminus \{(\mathcal{F}_+, \mathcal{F}, \mathcal{S})\};$
4:	loop
5:	Solve the LP problem (10) to obtain its optimal
	solution $(\boldsymbol{x}_{LP}, \boldsymbol{w}_{LP})$ and objective value $f_{LP}$ =
	$\sum_{i=1}^{N} [oldsymbol{w}_{LP}]_i;$
6:	if $f_{\sf LP} \ge U$ then
7:	<b>break</b> ; //case (1)
8:	else if $oldsymbol{x}_{LP} \in \{-1,1\}^K$ then
9:	if $[\boldsymbol{w}_{LP}]_i \geq g_i(\boldsymbol{x}_{LP})$ for all $i = 1, 2, \dots, N$ then
10:	Update $(\check{\boldsymbol{x}},\check{\boldsymbol{w}}) \leftarrow (\boldsymbol{x}_{LP},\boldsymbol{w}_{LP})$ and $U \leftarrow f_{LP}$ ;
11:	<b>break</b> ; //case (2.1)
12:	else
13:	$\mathcal{S} \leftarrow \mathcal{S} \cup \{(i, \pmb{x}_{LP}) \mid [\pmb{w}_{LP}]_i < g_i(\pmb{x}_{LP}), i = 0$
	$1, 2, \ldots, N$ ; //case (2.2)
14:	end if
15:	else
16:	Choose an index j such that $-1 < [\mathbf{x}_{LP}]_j < 1$ ;
17:	Add two new subproblems $(\mathcal{F}_+ \cup \{j\}, \mathcal{F}, \mathcal{S})$ and
	$(\mathcal{F}_+,\mathcal{F}\cup\{j\},\mathcal{S})$ into $\mathcal{P};$ //case (3)
18:	break;
19:	end if
20:	end loop
21:	end while
22:	output $(\boldsymbol{x}^{\star}, \boldsymbol{w}^{\star}) \leftarrow (\check{\boldsymbol{x}}, \check{\boldsymbol{w}}).$

egy by adding  $(i, \boldsymbol{x}_{\mathsf{LP}})$  with all  $[\boldsymbol{w}_{\mathsf{LP}}]_i < g_i(\boldsymbol{x}_{\mathsf{LP}})$  into S to obtain a tightened problem (10).

(3) If f<sub>LP</sub> < U and x<sub>LP</sub> ∉ {-1,1}<sup>K</sup>, then we choose an index j with -1 < [x<sub>LP</sub>]<sub>j</sub> < 1 and branch on variable x<sub>j</sub> by partitioning problem (F<sub>+</sub>, F<sub>-</sub>, S) into two new subproblems (F<sub>+</sub> ∪ {j}, F<sub>-</sub>, S) and (F<sub>+</sub>, F<sub>-</sub> ∪ {j}, S). We add the two subproblems into the problem set P.

The above process is repeated until  $\mathcal{P} = \emptyset$ . The whole procedure is summarized as Algorithm 2.

In lines 3 and 16 of Algorithm 2, there exist different strategies to choose a subproblem  $(\mathcal{F}_+, \mathcal{F}_-, \mathcal{S})$  from set  $\mathcal{P}$  and to choose a branching variable index j [20]. It is worthwhile to remark that Algorithm 2 can be embedded into state-of-theart MILP solvers like CPLEX through the so-called *callback routine* [19], which uses the (default) fine-tune subproblem selection and branching strategies of MILP solvers.

### **IV. SIMULATION RESULTS**

In this section, we provide simulation results to illustrate the efficiency of the proposed global algorithm for solving the one-bit MIMO detection problem. The simulation settings are described as follows. The channel  $\tilde{H}$  is generated by elementwise i.i.d. circular Gaussian distribution with mean zero and unit variance. The symbols  $\tilde{x}$  are independently and identically

Fig. 1: BER performance under different problem sizes.

distributed drawn from the QPSK constellation  $\{\pm 1 \pm j\}$ . The signal-to-noise ratio (SNR) is defined as  $\text{SNR} = \frac{\|\tilde{H}\tilde{x}\|_2^2}{\|\tilde{v}\|_2^2}$ . In Algorithm 2, we initialize S by setting  $\hat{x}$  as a zero-forcing (ZF) solution, i.e.,  $\hat{x} = \text{sgn}(H^{\dagger}r)$  with  $^{\dagger}$  denoting the matrix pseudo-inverse. A number of 1,000 Monte-Carlo trials were run to obtain the bit-error rates of our algorithm and the benchmarked algorithms.

We first demonstrate the bit-error rate (BER) performance. We name Algorithm 2 Global One-Bit MIMO Detection (GOBMD). We also show state-of-the-art algorithms that are designed to handle problem (3), including the nML and twostage nML in [6] and HOTML in [7]. Fig. 1 shows the BER performance under different MIMO sizes. It is seen from Fig. 1(a) that GOBMD achieves the same BER performance as exhaustive search, as both of them globally solve the ML problem (3); in Fig. 1(b), exhaustive search is computationally too demanding to complete the job. GOBMD provides an ML BER benchmark for the other algorithms for solving the same problem.

Fig. 2 shows the runtime comparison between GOBMD and exhaustive search. When the problem size is small, GOBMD and exhaustive search are computationally comparable. However, the computational complexity of exhaustive search grows rapidly with the problem size, while that of GOBMD increases with a much slower rate.

Fig. 3 shows the average ratio  $|\mathcal{S}|/|\mathcal{C}|$  when Algorithm 2 converges under fixed N = 36 and SNR =10 dB. It is seen that  $|\mathcal{S}|/|\mathcal{C}|$  is lower than 1%. In other words, Algorithm 2 only needs to solve LP problems that have 99% less inequality

Fig. 2: Runtimes under different K; N = 36.

Fig. 3: The average ratio |S|/|C| under different problem sizes.

constraints than problem (6). Also, we see that the ratio |S|/|C| decreases when K increases, which indicates that GOBMD has good scalability for massive systems with many users.

Finally, as a fundamental investigation and also future work, we are interested in whether and when the ML formulation (3) can exactly recover the user transmitted signals. Intuitively, when the ratio between the numbers of antennas and users N/K is large, and when the noise power  $\sigma^2$  is small, solving the ML detection problem will recover the user transmitted symbols (with a high probability). The simulation result in Fig. 4 supports this intuition. The colorbar illustrates the BER level: the darker the color, the higher the BER. We see a clear phase transition from the left-bottom region with high BER to the right-top region with low BER. In the future, we will quantitatively analyze the conditions under which the ML solution can exactly identify the user signals. We will also extend the study to account for multi-bit quantization and higher-order modulations.
