(Dated: Received: date / Revised version: date)

The calculation of the parity-violating polarizations in the external electric field, which are associated with the electron electric dipole moment (eEDM) and magnetic quadrupole moment (MQM) of the ¹⁷⁵Lu nucleus, as well as the determination of the rovibrational structure for the ¹⁷⁵LuOH⁺ cation, is performed. Beyond the bending of the molecule, the slight effect of the stretching of the distance between Lu and OH is taken into account. This study is required for the preparation of the experiment and for the extraction of the eEDM and MQM values of 175 Lu from future measurements.

INTRODUCTION

The pursuit of understanding the fundamental symmetries governing the laws of physics has been a central focus in the field of theoretical and experimental physics. Among these symmetries, the invariance with respect to charge conjugation (C) , spatial parity (\mathcal{P}) , and time reversion (\mathcal{T}) has long been considered crucial. However, in the latter half of the 20th century, experimental evidence emerged, confirming the violation of both P and the combined \mathcal{CP} symmetries in weak interactions. Nowadays, the violation of \mathcal{CP} symmetry holds immense interest in the fields of cosmology and astrophysics, as it is considered one of the three fundamental conditions for baryogenesis [\[1\]](#page-4-5). As a result, the exploration of novel manifestations of symmetry violation has emerged as a prominent research area in contemporary theoretical and experimental physics [\[2\]](#page-4-6).

One of the approaches used to explore these phenomena is by studying the electron electric dipole moments (eEDM) and nuclear magnetic quadrupole moments (MQM), which serve as highly sensitive probes for testing the boundaries of the Standard Model of electroweak interactions and its extensions [\[3](#page-4-7)[–8\]](#page-4-8). The search for both eEDMand MQM has been gaining momentum. Recently the JILA group has obtained a new constraint on the eEDM, $|d_e| < 4.1 \times 10^{-30}$ e·cm (90% confidence) [\[9\]](#page-4-9), using the 180 Hf¹⁹F⁺ ions trapped in a rotating electric field. It further improves the latest ACME collaboration result obtained in 2018, $|d_e| \lesssim 1.1 \cdot 10^{-29} e \cdot \text{cm}$ [\[10\]](#page-4-10), by a factor of 2.4 and the first result $|d_e| \leq 1.3 \times 10^{-28}$ on the $^{180}Hf^{19}F^+$ ions [\[11\]](#page-4-11) by a factor of about 32. Planned experiments aiming to measure MQM with the use of molecules offer a pathway to investigate P, \mathcal{T} odd nuclear forces, quark chromo-EDMs, and other CPviolating quark interactions [\[12\]](#page-4-12).

In this paper, we focus on the ¹⁷⁵Lu MQM in the $LuOH⁺$ molecular ion, specifically in the ground rota-

tional level of the first excited bending vibrational mode. The choice of $LuOH⁺$ is motivated by its electronic structure similarities to YbOH, while demonstrating even higher sensitivity to nuclear CP-violation effects due to the significant electric quadrupole moment of 175 Lu [\[13\]](#page-4-13).

In a polar molecule with a heavy element, the \mathcal{T}, \mathcal{P} violating energy shifts induced by eEDM and MQM are

$$
\Delta E_{\mathcal{P}, \mathcal{T}} = P_e E_{\text{eff}} d_e + P_M W_M M, \tag{1}
$$

where d_e is the value of the eEDM, M is the value of the MQM, factors E_{eff} and W_M are determined by the electronic structure of the molecule, P_e and P_M are the corresponding P, \mathcal{T} -odd polarization coefficients. To extract M and d_e from the measured energy shift $\Delta E_{\mathcal{P},\mathcal{T}}$, one needs to know E_{eff} , W_M , P_e and P_M values. The value of W_M was calculated in Ref. [\[13\]](#page-4-13), E_{eff} was calculated in Ref. [\[14\]](#page-4-14). An important task is to distinguish between the two sources of symmetry violation. This can be achieved by using different molecules or different electronic states of the same molecule. However, as can be seen from Eq. [\(1\)](#page-0-0), it is also possible to utilize two or more sublevels of the same electronic state with different P_e/P_M ratios. Therefore, an accurate method for estimating these ratios is necessary. In Ref. [\[14\]](#page-4-14), we calculated the value of P_e for 175LuOH^+ . In Ref. [\[15\]](#page-4-15), a method for calculating P_M was developed and applied to the ¹⁷³YbOH molecule. The main objective of this study is to apply this method to calculate P_M for ¹⁷⁵LuOH⁺. Furthermore, more precise data for P_e , hyperfine structure, and spectroscopic constants are obtained.

METHODS

Following Ref. [\[16\]](#page-4-16), we present the Hamiltonian in the molecular reference frame as follows:

$$
\hat{\mathbf{H}} = \hat{\mathbf{H}}_{\text{mol}} + \hat{\mathbf{H}}_{\text{hfs}} + \hat{\mathbf{H}}_{\text{ext}}.
$$
\n(2)

Two approaches for the molecular Hamiltonian \dot{H}_{mol} are used:

$$
\hat{H}_{\text{mol}}^{I} = \frac{(\hat{\mathbf{J}} - \hat{\mathbf{J}}^{e-v})^2}{2\mu R_e^2} + \frac{(\hat{\mathbf{J}}^v)^2}{2\mu_{OH}r^2} + V(R_e, \theta) \tag{3}
$$

and

$$
\hat{H}_{\text{mol}}^{II} = -\frac{\hbar^2}{2\mu} \frac{\partial^2}{\partial R^2} + \frac{(\hat{\mathbf{J}} - \hat{\mathbf{J}}^{e-v})^2}{2\mu R^2} + \frac{(\hat{\mathbf{J}}^v)^2}{2\mu_{OH}r^2} + V(R, \theta),\tag{4}
$$

where μ is the reduced mass of the Lu-OH system, μ_{OH} is the reduced mass of the OH, \tilde{J} is the total electronic, vibrational, and rotational angular momentum, $\hat{\mathbf{J}}^{e-v}$ = $\hat{\mathbf{J}}^e + \hat{\mathbf{J}}^v$ is the electronic-vibrational momentum, $\hat{\mathbf{J}}^e$, is the electronic momentum, $\hat{\mathbf{J}}^v$ is the vibrational momentum, R is the distance between Lu and the center mass of OH, $R_e = 1.930$ Å is the corresponding equilibrium value for R, $r = 0.954$ Å is OH bond length, θ is the angle between OH and the axis (z axis of the molecular frame) directed from Lu to the OH center of mass and $V(R,\theta)$ is the potential energy surface obtained in the electronic structure calculations. The condition $\theta = 0$ corresponds to the linear configuration where the O atom is between Lu and H ones. R, r and θ are the so called Jacobi coordinates, see Fig. [1.](#page-1-0)

FIG. 1: Jacobi coordinates for the $LuOH⁺$ cation.

Using the Hamiltonian $\hat{H}_{\text{mol}}^{\text{I}}$, we neglect the influence of the stretching ν_1 (associated with R) and OH ligand ν_3 (associated with r) vibrational modes. However, we still consider the bending modes ν_2 (associated with θ) with fixed R and r . In this approach, the spectroscopic constants and P_e coefficient in Ref. [\[14\]](#page-4-14) were calculated. Using the Hamiltonian \hat{H}_{mol}^{II} , we additionally take into account the influence of the stretching mode. In this paper, we recalculated the spectroscopic constants (and obtained a new one for the stretching mode) and the P_e value using $\hat{H}_{\text{mol}}^{\text{II}}$. We also calculated the P_M polarization in both approaches.

The Hamiltonian for the hyperfine interaction of elec-

trons with Lu and H nuclei reads

$$
\hat{\mathbf{H}}_{\text{hfs}} = -g_{\text{H}} \mathbf{I}^{\text{H}} \cdot \sum_{a} \left(\frac{\alpha_{2a} \times r_{2a}}{r_{2a}^3} \right) +
$$

$$
-g_{\text{Lu}} \mu_N \mathbf{I}^{\text{Lu}} \cdot \sum_{a} \left(\frac{\alpha_a \times r_{1a}}{r_{1a}^3} \right) \qquad (5)
$$

$$
-e^2 \sum_{q} (-1)^q \hat{Q}_q^2 (\mathbf{I}^{\text{Lu}}) \sum_{a} \sqrt{\frac{2\pi}{5}} \frac{Y_{2q}(\theta_{1a}, \phi_{1a})}{r_{1a}^3}
$$

where g_{Lu} and g_{H} are the g-factors of the lutetium and hydrogen nuclei, α_a are the Dirac matrices for the a-th electron, r_{1a} and r_{2a} are their radius-vectors in the coordinate system centered on the Lu and H nuclei, $\hat{Q}_q^2(I^{\text{Lu}})$ is the quadrupole moment operator for 175 Lu nucleus, $I^{\text{Lu}} = 7/2, I^{\text{H}} = 1/2$ are nuclear spins for ¹⁷⁵Lu and ¹H. The Stark Hamiltonian

$$
\hat{\mathbf{H}}_{ext} = -\mathbf{D} \cdot \mathbf{E} \tag{6}
$$

describes the interaction of the molecule with the external electric field, and D is the dipole moment operator.

Wavefunctions, rovibrational energies, and hyperfine structure were obtained by numerically diagonalizing the Hamiltonian [\(2\)](#page-0-1) over the basis set of electronicrotational-vibrational-nuclear spins wavefunctions.

$$
\Psi_{\Omega m\omega} P_{lm}(\theta) \Theta_{M_J,\omega}^J(\alpha,\beta) U_{M_I^{\mathrm{H}}}^{\mathrm{H}} U_{M_I^{\mathrm{L}}^{\mathrm{u}}}^{\mathrm{L}}.
$$
 (7)

or

$$
\Psi_{\Omega m\omega} \chi_{\nu_1}(R) P_{lm}(\theta) \Theta_{M_J,\omega}^J(\alpha,\beta) U_{M_I^{\mathrm{H}}}^{\mathrm{H}} U_{M_I^{\mathrm{Lu}}}^{\mathrm{Lu}} \qquad (8)
$$

for $\hat{H}_{\text{mol}}^{\text{I}}$ or $\hat{H}_{\text{mol}}^{\text{II}}$ respectively. Here $\Theta_{M_J,\omega}^J(\alpha,\beta)$ = $\sqrt{(2J+1)/4\pi}D_{M_J,\omega}^J(\alpha,\beta,\gamma=0)$ is the rotational wavefunction, $D_{M_J,\omega}^J$ is Wigner function, α, β correspond to azimuthal and polar angles of the molecular z axis (directed from Lu to the center of mass of OH group), $U_{M^\mathrm{H}_I}^\mathrm{H}$ and $U_{M_I^{\text{Lu}}}^{\text{Lu}}$ are the hydrogen and lutetium nuclear spin wavefunctions, M_J is the projection of the molecular (electronic-rotational-vibrational) angular momentum \vec{J} on the lab axis, ω is the projection of the same momentum on z axis of the molecular frame, $M_I^{\rm H}$ and $M_I^{\rm Lu}$ are the projections of the nuclear angular momenta of hydrogen and lutetium on the lab axis, $P_{lm}(\theta)$ is the associated Legendre polynomial, l is the vibration angular momentum and m is its projection on the molecular axis, Ω is the projection of the total electronic angular momentum on the molecular axis z for linear configuration. $\Psi_{\Omega m \omega}$ is the electronic wavefunction (see Ref. [\[16\]](#page-4-16) for details).

In this calculation functions with $\omega - m = \Omega = \pm 1/2$, $l = 0 - 30$ and $m = 0, \pm 1, \pm 2, J = 1/2, 3/2, 5/2$ were included in the basis sets [\(7\)](#page-1-1) and [\(8\)](#page-1-2). The ground vibrational state $\nu_2 = 0$ corresponds to $m = 0$, the first excited bending mode $\nu_2 = 1$ to $m = \pm 1$, the second excited bending mode has states with $m = 0, \pm 2$ etc. A

common designation ν_2^m for the bending vibrational levels will be used below. No momenta is associated with ν_1 quantum number.

Provided that the electronic-vibrational matrix elements are known, the matrix elements of H between states in the basis set [\(8\)](#page-1-2) can be calculated with help of the angular momentum algebra [\[16,](#page-4-16) [17\]](#page-4-17) mostly in the same way as for the diatomic molecules [\[18\]](#page-4-18). The corresponding matrix elements are taken from Ref. [\[14\]](#page-4-14). To calculate the \mathcal{T}, \mathcal{P} -odd shifts the average value of corresponding Hamiltonians [\[19\]](#page-4-19)

$$
H_{\text{MQM}} = -\frac{M}{2I^{\text{Lu}}(2I^{\text{Lu}} - 1)} T_{ik} \frac{3}{2r^5} \epsilon_{jli} \alpha_j r_l r_k, \quad (9)
$$

where ϵ_{jli} is the unit antisymmetric tensor, α is the vector of Dirac matrices,

$$
T_{ik} = I_i^{\text{Lu}} I_k^{\text{Lu}} + I_k^{\text{Lu}} I_i^{\text{Lu}} - \frac{2}{3} \delta_{i,k} I^{\text{Lu}} (I^{\text{Lu}} + 1), \qquad (10)
$$

$$
H_{\rm EDM} = 2d_e \begin{pmatrix} 0 & 0 \\ 0 & \sigma E \end{pmatrix} , \qquad (11)
$$

E is the inner molecular electric field, and σ are the Pauli matrices. [\[15,](#page-4-15) [16\]](#page-4-16) were evaluated.

For the calculation of the potential energy surface, we employed two models to account for electron correlation effects: coupled cluster with single and double excitation amplitudes (CCSD) and coupled cluster with single, double, and perturbative triple excitation amplitudes $(CCSD(T))$. These calculations were performed within the Dirac-Coulomb Hamiltonian framework. For Lu, we utilized the uncontracted Dyall's AE3Z basis set [\[20\]](#page-4-20), while for F, we employed the aug-cc-PVTZ-DK basis set [\[21,](#page-4-21) [22\]](#page-4-22). In these calculations, the correlation treatment excluded the 1s..3d electrons, and a virtual orbital energy cutoff of 70 Hartree was set.

We obtained the CCSD and CCSD(T) potential surface $V(R, \theta)$ on the grid of coordinates (R_i, θ_k) ,

$$
{R_i} = 1.771, 1.877, 1.930, 1.983, 2.089\AA
$$
\n(12)

$$
\{\theta_k\} = 0^\circ, 5^\circ, 10^\circ, 15^\circ, 20^\circ, 25^\circ, 55^\circ, 90^\circ, 122^\circ, 155^\circ, 180^\circ
$$
\n
$$
(13)
$$

The potentials were approximated by polynomial $\sum_{n=0}^{7} \sum_{m=0}^{4} C_{nm} \theta^{n} R^{m}$. Since the linear configuration has minimum energy, the coefficients $C_{nm} = 0$ for $n = 1$.

RESULTS AND DISCUSSIONS

In Fig. [2](#page-3-0) and Table [I,](#page-2-0) we present the calculated potential energy surface and spectroscopic properties. It can be see that the results for the CCSD and CCSD(T)

models are in close agreement with each other. Incorporating non-iterative triple cluster amplitudes leads to a decrease in vibrational energies by 4–8 cm−¹ . The use of Hamiltonian $\hat{H}_{\text{mol}}^{\text{II}}$ instead of $\hat{H}_{\text{mol}}^{\text{I}}$ has a slightly greater impact on the vibrational energies. The final l−doubling value for $\nu_2 = 1$ of 24.5 MHz is approximately 1 MHz higher than the value obtained with a frozen R variable.

In Fig. [3](#page-3-1) the calculated polarizations P_e , P_M for the selected levels of the lowest $N = 1$ rotational state of the first excited $\nu_2 = 1$ bending vibrational mode with frozen R approximation as a functions of the external electric field are given. The selected 14 levels, numbered 43–56 (see Tables [II](#page-5-0) and [III\)](#page-6-0), are those which were chosen in Ref. [\[14\]](#page-4-14) for the eEDM search. The corresponding energies (order of 31 850 MHz) are given in Fig. 3 panel (a) of Ref. [\[14\]](#page-4-14). Using only levels numbered 43–56 is not enough, however, if nonzero MQM of ¹⁷⁵Lu nucleus is assumed. The reason is that the ratio $P_e/P_M \sim -10.5$ is about the same for all these levels that makes it impossible to distinguish eEDM and MQM contributions. Similarly to P_e [\[14\]](#page-4-14) there are levels with close values of P_M . These states differ by only projection $M_I^{\rm H} = \pm 1/2$ which almost does not influence P_e and P_M .

The numerical data for P_e , P_M and hyperfine energies for all $N = 1$ levels for $E = 50$ and $E = 100$ V/cm are given in Tables [II](#page-5-0) and [III](#page-6-0) respectively. To assess the influence of the stretching mode calculations with Hamiltonians $\hat{H}_{\text{mol}}^{\text{I}}$ and $\hat{H}_{\text{mol}}^{\text{II}}$ were performed. One can see that accounting for stretching mode leads to a decreasing of notable P_e , P_M values up to about 5% for $E = 50$ and 4% for $E = 100$. This is explained by increasing l−doubling value describing the energy difference between levels of opposite parity at zero electric field when stretching mode is taken into account.

Since MQM induced energy shift is proportional to P_M

TABLE I: Calculated vibrational energy levels $\text{ (cm}^{-1}\text{)}$ rotational constants $B(\text{cm}^{-1})$, and l–doubling (MHz) for the excitation modes of stretching $\nu_1 = 0 - 1$ and bending $\nu_2 = 0 - 2$ quanta of ¹⁷⁵LuOH⁺. Ligand mode

 ν_3 quanta is zero in calculations.

FIG. 2: Potential surface $V(\theta, R)$ for CCSD(T) calculations with polynomial interpolation.

for the MQM searches the levels with large P_M values are preferred. Besides, to distinguish eEDM and MQM contributions, the levels with different P_e/P_M ratios have to be used. As an example of the proposed eEDM contribution exclusion scheme, let us consider the first and fifty third levels for $E = 50$ V/cm. For the first level we have $\delta E^1 = -0.3740 E_{\text{eff}} d_e + 0.0794 W_M M$; for the fifty third level $\delta E^{53} = -0.3524 E_{\text{eff}} d_e + 0.0333 W_M M$. Then the combination $\delta E^1 - 1.0613 \delta E^{53} = 0.044 W_M M$ is independent of eEDM and can be used for MQM extraction. Similarly, for the electric field $E = 100$ V/cm, for example, one can choose levels numbered 1 (with δE^1 = $-0.4715E_{\text{eff}}d_e+0.1001W_MM$ and a ratio $P_e/P_M \approx 4.71$) and 43 (with $\delta E^{43} = 0.5294 E_{\text{eff}} d_e - 0.0502 W_M M$ and the ratio equal to 10.55). Then the obtained combination is $1.1229\delta E^{1} + \delta E^{43} = 0.0622W_{M}M$. We note also that our choice of the levels is only an example. On the base of Tables [II,](#page-5-0) [III](#page-6-0) and using formula

$$
MW_M = \frac{1}{\Delta} \left(P_e^x \delta E^y - P_e^y \delta E^x \right),
$$

$$
\Delta = P_e^x P_M^y - P_e^y P_M^x
$$
 (14)

one can choose alternative appropriate levels for the MQM search. Here x and y are numbers of chosen levels. Similarly the eEDM contribution can be determined.

Electric field $E = 100$ V/cm provides almost saturated values for P_e and P_M . As it was shown in Letter [\[23\]](#page-4-23) that in the $l - doubling$ structure, the P value tends to reach half of the maximum value for molecules with Hund's case b. Calculations showed that all levels have polarizations $P_e < 0.58$ and $P_M < 0.12$.

FIG. 3: Calculated polarizations $P_e/7$ (solid) and P_M (dashed) for the selected levels (see text for details) for the different values of M_F of the lowest $N = 1$ rotational level of the first excited the $\nu_2 = 1$ bending vibrational mode of 175 LuOH + as functions of the external electric field.

To access these energy levels in order to perform the eEDM and MQM precision measurement, trapped $LuOH⁺$ ions that are initially prepared in the ground rovibrational state by either optical pumping or quantum logic spectroscopy. From this point either of the states in the pair necessary to distinguish the eEDM from MQM can be populated by driving a Raman transition using a pair far-detuned infrared lasers with a difference frequency tuned to the energy of the desired state. As the pairs states with opposite projection of $M_I^{\rm H} = \pm 1/2$ are separated by several MHz they will be straightforward to resolve experimentally.

CONCLUSION

We calculated spectroscopic constants for the lowest vibrational levels, parity-violating polarizations P_e and P_M associated with eEDM and MQM of 175 Lu energy shifts in the first excited bending mode for the ¹⁷⁵LuOH⁺ cation. The levels suitable for the MQM search are determined.

Electronic structure calculations have been carried out using computing resources of the federal collective usage center Complex for Simulation and Data Processing for Mega-science Facilities at National Research Centre "Kurchatov Institute", [http://ckp.nrcki.ru/.](http://ckp.nrcki.ru/)

Electronic correlation calculation of the poten-

tial energy surface was supported by the Russian Science Foundation (Grant No. 19-72-10019- P (https://rscf.ru/en/project/22-72-41010/). Dirac-Hartree-Fock calculations were supported by Foundation for the Advancement of Theoretical Physics and Mathematics "BASIS" grant according to the Research Project No. 21-1-2-47-1.

TABLE II: The calculated energies (in MHz), polarizations for the different projections of the total angular momentum M_F of the lowest $N = 1$ rotational level of the first excited $v = 1$ bending vibrational mode of ¹⁷⁵LuOH⁺ for the value of the external electric field $E = 50$ V/cm. Levels are numbered by the increasing energy. Zero energy level corresponds to the lowest energy of $N = 1$ states at zero electric field. Calculation with frozen R variable are marked by (f).
