(Dated: October 12, 2023)

The total energy is the most fundamental quantity in *ab initio* studies. To include electronphonon interaction (EPI) contribution to the total energy, we have recast Allen's equation, for the case of semiconductors and insulators. This equivalent expression can be computed using available software, leading to more accurate total energy. We calculate the total energies and their differences for carbon-diamond and carbon-hexagonal polytypes. Contrary to the current understanding, where per-atom quantities are computed from the primitive unit cell, our results, unexpectedly, show that the per-atom total energy (EPI included) depends on the unit cell size and violates the unit cell independence. For example, it differs for carbon-diamond by 1 eV/atom between the primitive cell and supercells. This norm-violating behaviour arises from the partial Fan-Migdal (FM) self-energy term present in Allen's equation. Consequently, to determine the total energy differences between polytypes, supercells with identical number of atoms are necessary. A crucial inference of general validity is that any equation that contains a partial Fan-Midgal self-energy term violates the unit cell independence, contrary to the current understanding. Further theoretical studies are needed to establish if the total energy (EPI included) is an exception or can be reconciled with the unit cell independence.

The total energy is the most fundamental quantity in the *ab initio* studies of materials, which also lay the basis of the density functional theory (DFT) [1, 2]. In *ab initio* studies of crystalline solids, the accepted norm is to determine the total energy and other properties only for the primitive unit cell. This is because the per-atomic total energy and other properties remain invariant, whether calculated for the primitive unit cell (PC) or for any supercell (SC). This is referred to as "unit cell independence" in the present manuscript. Consequently, in *ab initio* studies, the total energy is first minimized, using variational methods, with respect to structural parameters for the PC. Only then are the other quantities, e.g. band-structure, electronic, optical properties etc. computed for the so obtained relaxed ground state structure.

The *ab initio* total energy is of prime interest in determining the stable structure and energy differences and phase boundaries of polymorphs. Thus, it is essential to determine the total energy as accurately as possible. DFT studies [1, 2] have been successful in determining the stable structure and energy differences between polymorphs for many materials. However, for some materials, the DFT and experimental results are at variance. Hence, additional contributions from van der Waals (vdW) dispersion and zero-point vibrational energy (ZPVE) are also included to obtain accurate total energy [3–8].

We have recently proposed the inclusion of electronphonon interaction (EPI) contribution to the total energy [9]. Referring to our work, Allen has formally derived the expression for including the same from second-order perturbation theory [10]. This equation cannot be computed, as such, using available software. Hence, in earlier studies, we have approximated Allen's equation [10] and computed the EPI contribution to the total energy for C, Si, SiC and BN polymorphs [9, 11]. Our results show that the EPI contribution is more important than the vdW and ZPVE contributions due to its greater sensitivity to crystal structure [9, 11].

However, for accurate total energy studies, it is necessary to compute the complete Allen's equation (Eq. 4 of Ref. [10]) for the EPI contribution. In this paper, we recast this equation, for the case of semiconductors and insulators. The recast (equivalent) expression can be computed using existing software, leading to more accurate total energy for all semiconductors and insulators.

However, our results raise serious theoretical issues. Allen's equation [10] for the EPI contribution to the total energy contains a partial Fan-Migdal (FM) self-energy term, identical to that present in the earliest EPI studies by Fröhlich [12] and Fan [13]. Our computational results on carbon polytypes show that the presence of the partial FM self-energy term makes the *ab initio* total energy violate the unit cell independence, a most surprising result. Due to this, use of supercells with identical number of atoms are necessary to determine the total energy differences between polytypes. Our results show that any equation that contains a partial Fan-Midgal self-energy term violates the unit cell independence. This is likely the first case where per-atom quantities are not uniquely obtained from the primitive unit cell. Further theoretical studies are needed to understand and resolve this issue.

In the Allen-Heine theory, EPI contribution to the eigenenergy arises from the Debye-Waller (DW) and Fan-Migdal (FM) terms and, at 0 K, is given by [14, 15]

$$\Delta \epsilon_{n\mathbf{k}}(0) = \Delta^{\mathrm{DW}} \epsilon_{n\mathbf{k}}(0) + \Delta^{\mathrm{FM}} \epsilon_{n\mathbf{k}}(0) \tag{1}$$

The FM self-energy term includes contributions from

both conduction and valence bands [14, 15]. It can also be written as a sum of their separate contributions as [16]

$$\Delta^{\mathrm{FM}} \epsilon_{n\mathbf{k}}(0) = \Delta^{\mathrm{FM}}_{\mathrm{occ}} \epsilon_{n\mathbf{k}}(0) + \Delta^{\mathrm{FM}}_{\mathrm{unocc}} \epsilon_{n\mathbf{k}}(0) \qquad (2)$$

These partial FM self-energy terms are given by [16]

$$\Delta_{\text{unocc}}^{\text{FM}} \epsilon_{n\mathbf{k}}(0) = \frac{1}{N_{\mathbf{q}}} \sum_{\mathbf{q}j}^{\text{BZ}} \sum_{n'}^{\text{unocc}} \frac{|\langle \mathbf{k}n | H_j^{(1)} | \mathbf{k} + \mathbf{q}n' \rangle|^2}{\omega - \epsilon_{\mathbf{k} + \mathbf{q}n'} - \omega_{\mathbf{q}j} + i\eta'}$$
(3)

and

$$\Delta_{\rm occ}^{\rm FM} \epsilon_{n\mathbf{k}}(0) = \frac{1}{N_{\mathbf{q}}} \sum_{\mathbf{q}j}^{\rm BZ} \sum_{n'}^{\rm occ} \frac{\left|\langle \mathbf{k}n | H_j^{(1)} | \mathbf{k} + \mathbf{q}n' \rangle\right|^2}{\omega - \epsilon_{\mathbf{k} + \mathbf{q}n'} + \omega_{\mathbf{q}j} + i\eta'} \quad (4)$$

Because EPI alters all eigenenergies, the total energy is also altered [9]. Using second-order perturbation theory, Allen has derived the expression for the EPI contribution to the total energy, $\Delta E_{\rm EP}(V, 0)$, as [10]

$$\Delta E_{\rm EP}(V,0) = \sum_{k} \left[\langle k | V^{(2)} | k \rangle + \sum_{Q} \frac{|\langle k | V^{(1)} | k + Q \rangle|^2}{\epsilon_k - \epsilon_{k+Q}} (1 - f_{k+Q}) \right] f_k$$
(5)

The terms in the square bracket in Eq. 5 differ from the terms in the original expression for $\Delta \epsilon_{n\mathbf{k}}(0)$ (Eq. 1) in the Allen-Heine theory [14, 15], only by the presence of the $(1 - f_{k+Q})$ factor in the second term. The first (DW) term is the same in both expressions. Due to the $(1 - f_{k+Q})$ factor, the existing computational packages cannot compute the quantity inside the square bracket in Eq. 5, but can compute $\Delta \epsilon_{n\mathbf{k}}(0)$.

We describe below a method to accurately compute Eq. 5 based on the EPI implementation (TDepES) in the ABINIT software package [17–19].

The ABINIT module TDepES [19] (Temperature Dependence of the Electronic Structure) calculates the EPI correction, $\Delta \epsilon_{n\mathbf{k}}(0)$, for any eigenenergy, $\epsilon_{n\mathbf{k}}$. The underlying theory has been discussed by Poncé *et al.* [20, 21]. This module has been widely used to obtain temperature dependent band-structures and band-gaps [20–27].

We note that the second term in Eq. 5 is identical to that in the earliest EPI studies of Fröhlich (Eq.2.11) [12] and Fan (Eq.4) [13]. The presence of the $(1-f_{k+Q})$ factor is to ensure that the state k+Q is an empty state to satisfy the Pauli principle [12, 13]. For semiconductors and insulators, the Fermi-Dirac distribution function, f_{k+Q} and f_k , equals one for the occupied (valence) states and equals zero for the unoccupied (conduction) states [16]. It follows that for the second term, the contributions from the occupied bands is zero due to the $(1 - f_{k+Q})$ factor. Hence, the second term only includes contributions from unoccupied bands. Alternately, by opening the $(1-f_{k+Q})$ factor, it becomes $\Delta^{\text{FM}} \epsilon_{n\mathbf{k}}(0) - \Delta^{\text{FM}}_{\text{occ}} \epsilon_{n\mathbf{k}}(0)$. Thus, Eq. 5 can be rewritten as

$$\Delta E_{\rm EP}(V,0) = \sum_{n,\mathbf{k}}^{\rm occ} \left[\Delta^{\rm DW} \epsilon_{n\mathbf{k}}(0) + \Delta^{\rm FM}_{\rm unocc} \epsilon_{n\mathbf{k}}(0) \right]$$
$$= \sum_{n,\mathbf{k}}^{\rm occ} \left[\Delta \epsilon_{n\mathbf{k}}(0) - \Delta^{\rm FM}_{\rm occ} \epsilon_{n\mathbf{k}}(0) \right]$$
$$= \Delta E_{\rm bs}^{\rm ep}(V,0) - \Delta E_{\rm occ}^{\rm FM,tot}$$
(6)

The equivalent expression, Eq. 6, shows that the EPI contribution to the total energy comes from the EPI contribution to the band-structure energy, $\Delta E_{\rm bs}^{\rm ep}(V,0)$, corrected by the total FM-occupied contribution, $\Delta E_{\rm occ}^{\rm FM,tot}$.

To compute Eq. 6, we first run the TDepES module [19] with the optimized number of bands, $M = N_{\text{tot}}$, that includes conduction and valence bands [20]. This will give the EPI correction to the eigenenergy, $\Delta \epsilon_{n\mathbf{k}}(0)$, the first term in Eq. 6. We run the TDepES module a second time with $M = N_{\text{val}}$ to obtain the FM-occupied contribution, $\Delta_{\text{occ}}^{\text{FM}} \epsilon_{n\mathbf{k}}(0)$, [16, 21] the second term in Eq. 6. The summation in Eq. 6 can be written as a weighted sum over all the k-points in the Irreducible Brillouin Zone (IBZ). Thus, the EPI contribution to the total energy, Eq. 6, is computed as

$$\Delta E_{\rm EP}(V,0) = 2\sum_{n,\mathbf{k}}^{\rm occ,IBZ} w_{\mathbf{k}} \Delta \epsilon_{n\mathbf{k}}(V,0) - 2\sum_{n,\mathbf{k}}^{\rm occ,IBZ} w_{\mathbf{k}} \Delta_{\rm occ}^{\rm FM} \epsilon_{n\mathbf{k}}(V,0) \quad (7)$$

Using Eq. 7 to include EPI contribution, a more accurate *ab initio* total energy can be computed for all semiconductors and insulators.

We report below the results for the total energy (EPI included) and their differences for C-dia and C-hex polytypes for their PCs and SCs. All computations were performed using the ABINIT software package [17–19]. The ONCV [28, 29] pseudopotential with PBE [30] exchangecorrelation functional was used. The computational details are described in Supplementary Information I.

Before beginning our studies on using the $\Delta E_{\text{occ}}^{\text{FM}}$ term, we benchmarked with the results of Nery et al. [16] for MgO using the ONCV(PBE) pseudopotential. Our (and Nery et al. [16]) values for the $E_{\text{occ}}^{\text{FM}}$ and $\Delta E_{\text{unocc}}^{\text{FM}}$ at VBM are 0.3493 (0.349) eV and -4.330 (-4.327) eV respectively. See Supplementary Information II.

For C-dia, the C-dia-2p (2 atoms (at)/u.c.) primitive unit cell and supercells of the conventional fcc C-dia-8 (8 at/u.c.), the hexagonal C-dia-6 (6 at/u.c.) [31, 32] and hexagonal C-dia-12 (12 at/u.c.) were used. For C-hex, we have used the primitive C-hex-4p (4 at/u.c.) unit cell and the hexagonal C-hex-8 (8 at/u.c.) and C-hex-12 (12 at/u.c.) supercells. (Supplementary Information I).

Our studies on SCs were motivated by the large energy difference obtained between the PCs of C-dia and C-hex.

From these studies, the main reason has been identified. A similar effect is also seen in the studies on the zeropoint renormalization (ZPR), due to EPI, of the valence band maxima (VBM). Hence, we discuss first the results for the ZPR of VBM (adiabatic approximation) and later the results for the EPI contributions to the total energies.

Table I gives the details of the ZPR of VBM for the PCs and SCs of C-dia and C-hex. The ZPR term and its components, DW and FM terms, are identical for the C-dia-2p (PC), C-dia-6 (SC) and C-dia-8 (SC). However, the $\Delta E_{\rm occ}^{\rm FM}$ term, (present in the equivalent Allen's equation, Eq. 6) differs drastically between the PC and SCs. The $\Delta E_{\rm unocc}^{\rm FM}$ term, (present in the original Allen's equation, Eq. 5) also differs drastically between the unit cells.

Similar results are obtained (Table I) among the Chex unit cells. For C-hex-4p (PC) and C-hex-8 (SC), the ZPR is identical and the DW and FM terms differ marginally. However, both $\Delta E_{\rm occ}^{\rm FM}$ and $\Delta E_{\rm unocc}^{\rm FM}$ terms vary significantly, consistent with the results for C-dia unit cells.

TABLE I. The ZPR shift $(\Delta E_{\rm ep}^{\rm tot})$ at VBM(Γ) for carbon polytypes for primitive cells and supercells. The DW $(\Delta E_{\rm ep}^{\rm DW})$ and FM $(\Delta E_{\rm ep}^{\rm FM})$ shifts along with the partial FM contributions, $\Delta E_{\rm occ}^{\rm FM}$ and $\Delta E_{\rm unocc}^{\rm FM}$, are reported. For the 12 at/u.c. studies, only the FM occupied studies were performed due to computational constraints. All energies are in meV.

Structure	$\Delta E_{\rm ep}^{\rm tot}$	$\Delta E_{\rm ep}^{\rm DW}$	$\Delta E_{\rm ep}^{\rm FM}$	$\Delta E_{\rm occ}^{\rm FM}$	$\Delta E_{\rm unocc}^{\rm FM}$
C-Diamond					
C-dia-2p (prim)	142.1	1736.8	-1594.8	373.5	-1968.3
(2 at/u.c.)					
C-dia-6	142.1	1735.5	-1593.4	-69	-1524.4
(6 at/u.c.)

(8 at/u.c.)					
C-hex-12				82.1	_
(12 at/u.c.)					

Table I shows that only the partial FM self-energy terms, $\Delta E_{\rm occ}^{\rm FM}$ and $\Delta E_{\rm unocc}^{\rm FM}$, violate the unit cell independence. To confirm the generality of this result, we have performed similar studies on the PC and conventional fcc SC of MgO using the GGA.fhi pseudopotential. The $\Delta E_{\rm occ}^{\rm FM}$ at VBM of MgO for PC (475 meV) and for the SC (100 meV) differ drastically by 375 meV, consistent with results in Table I (Supplementary Information III). Thus, $\Delta E_{\rm occ}^{\rm FM}$ violates the unit cell independence for MgO as well, suggesting that it is likely to be a universal feature in all crystalline materials.

We next discuss the EPI contribution to the total en-

ergy and its components, for the PCs and SCs of C-dia and C-hex reported in Table II. From the results for ZPR of VBM discussed above, it is likely that $\Delta E_{\rm bs}^{\rm ep}(V,0)$ is identical, while $E_{\rm occ}^{\rm FM,tot}$ is different for PC and SCs.

TABLE II. For the primitive cells and supercells of carbon polytypes, the EPI contribution to the total energy ($\Delta E_{\rm EP}(V,0)$) and its components, EPI contribution to the band-structure energy ($\Delta E_{\rm bs}^{\rm EP}(V,0)$) and the total FM-occupied contribution ($\Delta E_{\rm occ}^{\rm FM,tot}$). All energies are in meV/atom.

Structure	$\Delta E_{\rm bs}^{\rm ep}(V,0)$	$\Delta E_{\rm occ}^{\rm FM,tot}$	$\Delta E_{\rm EP}(V,0)$
C-Dia			
C-dia-2p	-46.4	138.7	-185.1
C-dia-6	-63.1	-740.3	677.2
C-dia-8	-45.04	-882.8	837.8
C-dia-12		-1158.6	
C-Hex			
C-hex-4p	-2.75	-466.68	463.93
C-hex-8	-23.34	-883.1	859.8
C-hex-12		-1117.5	

We first compare the EPI energy terms for the PCs, Cdia-2p and C-hex-4p. The $\Delta E_{\rm bs}^{\rm ep}(V,0)$ term stabilizes Cdia-2p by 44 meV/atom. The $\Delta E_{\rm occ}^{\rm FM,tot}$ values for C-dia-2p and C-hex-4p differ drastically and stabilize C-dia-2p by 605 meV/atom. This leads to a total EPI stabilization ($\Delta E_{\rm EP}(V,0)$ difference) of C-dia-2p by 649 meV/atom over C-hex-4p. The C-dia-2p and C-hex-4p structures are analogous to the zincblende and wurtzite structures respectively and vary only in the orientation of the sp^3 bonded tetrahedra [31–33]. Thus, such a large difference in $\Delta E_{\rm EP}(V,0)$ of 649 meV/atom is questionable and requires further study. This motivated the calculation of $\Delta E_{\rm EP}(V,0)$ for various SCs.

In principle, $\Delta E_{\rm bs}^{\rm ep}(V,0)$, should be identical for PCs and SCs. One possible reason for the slight variation (Table II) is that the total number of bands, $N_{\rm tot}$, was optimized for only the PCs. For the SCs, for computational reasons, following Nery *et al.* [16], we used $N_{\rm tot}$ to be the number of bands with energy below 10-12 eV above the conduction band minima (CBM).

We now compare the $\Delta E_{\rm occ}^{\rm FM,tot}$ term for the various C-dia PC and SCs. Table II shows that $\Delta E_{\rm occ}^{\rm FM,tot}$ varies with the unit cell size and has not reached convergence. In particular, $\Delta E_{\rm occ}^{\rm FM,tot}$ varies drastically by 1.02 eV/atom between C-dia-2p (PC) and C-dia-8 SC. Similar results are obtained for the C-hex PC and SCs, where $\Delta E_{\rm occ}^{\rm FM,tot}$ differs by 417 meV/atom between Chex-4p (PC) and C-hex-8 SC.

To confirm the generality of the unit cell dependence of $\Delta E_{\rm occ}^{\rm FM,tot}$, we have computed (non-adiabatic approximation) this term for the PC and SC of MgO using the GGA.fhi pseudopotential. The values for the 1 f.u./u.c. PC (1697 meV/f.u.) and the 4 f.u./u.c. conventional fcc SC (-1114 meV/f.u.) differ drastically by 2.8 eV/f.u (Supplementary Information II). Thus, the unit cell dependence of $\Delta E_{\rm occ}^{\rm FM,tot}$ is likely to be a universal feature in all crystalline materials.

We also can compare the differences in the EPI contributions for the C-hex and C-dia polytypes.

From Table II, for the C-dia-2p and C-hex-4p PCs, $\Delta E_{\rm occ}^{\rm FM,tot}$ differs by 605 meV/atom. In contrast, for the C-dia-8 and C-hex-8 SCs, the difference in $\Delta E_{\rm occ}^{\rm FM,tot}$ is ~ 0 meV/atom. Even for the C-dia-12 and C-hex-12 SCs, the difference in $\Delta E_{\rm occ}^{\rm FM,tot}$ is ~ 40 meV/atom, which is relatively small. Thus, the differences in $\Delta E_{\rm occ}^{\rm FM,tot}$ are negligible/small when SCs of the C-dia and C-hex polytypes have identical number of atoms.

FIG. 1. The electronic band-structures of carbon polytypes: (a) C-dia-2p, (b) C-hex-4p, (c) C-dia-8 and (d) C-hex-8.

Figure 1 shows the band structures of the PCs and the 8 at/u.c. SCs of the C-dia and C-hex polytypes. The C-dia-2p has 4 valence bands while C-hex-4p has 8 valence bands. In contrast, the C-dia-8 and C-hex-8 band structures have 16 valence bands.

For the SCs with identical number of atoms, e.g. C-dia-8 and C-hex-8, all important parameters are identical, and the difference in the $\Delta E_{\rm occ}^{\rm FM,tot}$ term is mainly due to structural differences. Hence, this is the most reliable method to obtain EPI energy differences between the Cdia and C-hex polytypes, especially when the $\Delta E_{\rm occ}^{\rm FM,tot}$ term has not converged and the unit cell independence is violated.

For SCs with 12 at/u.c., C-dia-12 and C-hex-12, we could not compute the $\Delta E_{\rm bs}^{\rm ep}(V,0)$ term due to computational limitations. However, it is to be noted that the $\Delta E_{\rm occ}^{\rm FM,tot}$ term has not converged and hence, in principle even larger SCs need to used.

Therefore, we report the energy differences for the SCs of C-dia-8 and and C-hex-8, for which all terms have been calculated.

The DFT energy for the PCs and SCs differ by < 1 meV/atom for each polytype. The DFT energy stabilizes C-dia over C-hex by 25 meV/atom. The EPI contribution ($\Delta E_{\text{EP}}(V,0)$) stabilizes C-dia-8 over C-hex-8 by 22 meV/atom. The final (DFT + EPI)

stability of C-dia-8 over C-hex-8, is 47 meV/atom. This clearly shows that the EPI term contributes significantly and must be included in all *ab initio* total energy studies.

Our results have serious theoretical implications as discussed below.

In earlier studies, the band-structures of zincblende (ZB) and wurtzite (WZ) structures have been compared by taking 2 primitive unit cells of ZB along the [111] direction [34–37]. This leads to hexagonal 2 f.u./u.c unit cells for ZB and WZ. Their Brillouin Zone (BZ) volumes and band-structures are similar [34–37]. Murayama and Nakayama [37] also state that another valid approach is to use 3 times the above unit cells, leading to a 6 f.u/u.c hexagonal SCs for ZB and WZ and the same BZ.

The above studies [34–37] justify our using C-dia and C-hex SCs with identical number of atoms for computing EPI energy differences. In such cases, the differences in $\Delta E_{\rm occ}^{\rm FM,tot}$ are marginal (Table II) as expected for similar crystal structures.

Figure 1 shows the PC and SC band-structures of Cdia and C-hex. The SC band-structures have more bands because of band folding [38, 39]. In our studies, the SCs are integral multiples of the PCs, so that the band unfolding would be exact [39].

The $\Delta E_{\rm bs}^{\rm ep}(V,0)$ is similar for PCs and their respective SCs. However, the $\Delta E_{\rm occ}^{\rm FM,tot}$ term is different for PCs and their respective SCs (Table II) and the foldingunfolding relations are not valid for this term.

The results from Tables I and II suggest a crucial inference of general validity, viz. any equation that contains a partial FM term i.e. FM-occ or FM-unocc, will violate the unit cell independence.

The $\Delta_{\text{occ}}^{\text{FM}} \epsilon_{n\mathbf{k}}(0)$ term involves the summation over different number of valence bands for the PC and SC. Thus, N_{val} and the $\left(\frac{1}{\epsilon_{\mathbf{k}n}-\epsilon_{\mathbf{k}+\mathbf{q}n'}}\right)$ factor are the most likely reason for the difference in $\Delta_{\text{occ}}^{\text{FM}} \epsilon_{n\mathbf{k}}(0)$ between PC and SC. For the same reasons, the $\Delta_{\text{unocc}}^{\text{FM}} \epsilon_{n\mathbf{k}}(0)$ term also varies between PC and SC. However, their sum, $\Delta^{\text{FM}} \epsilon_{n\mathbf{k}}(0)$ is identical for PC and SC. Given that the conduction and valence bands do not contribute to $\Delta_{\text{occ}}^{\text{FM}} \epsilon_{n\mathbf{k}}(0)$ and $\Delta_{\text{unocc}}^{\text{FM}} \epsilon_{n\mathbf{k}}(0)$ respectively, it suggests a hidden and nonobvious relation between $\Delta_{\text{occ}}^{\text{FM}} \epsilon_{n\mathbf{k}}(0)$ and $\Delta_{\text{unocc}}^{\text{FM}} \epsilon_{n\mathbf{k}}(0)$ such that their total is identical for PC and SC, even as the individual terms vary.

An important implication follows for the quasiparticle weights in cumulant method studies. The quasiparticle weight, Z_{kn} , is give by [16]

$$Z_{\mathbf{k}n} = \exp\left(\Re \mathfrak{e} \frac{\partial \sum^{\operatorname{Fan}}(\mathbf{k}n,\omega))}{\partial \omega}|_{\omega = \varepsilon_{\mathbf{k}n}}\right)$$
(8)

From Eq. 2 it follows that Eq. 8 can be rewritten as a product of the quasiparticle weights due to the occupied

and unoccupied bands [16]

$$\mathbf{Z}_{\mathbf{k}n}^{\mathrm{R}} = \mathbf{Z}_{\mathbf{k}n}^{\mathrm{un}} \mathbf{Z}_{\mathbf{k}n}^{\mathrm{oc}} \tag{9}$$

From our results, it follows that $Z_{\mathbf{k}n}^{\mathrm{R}}$ is independent of unit cell size. However, both $Z_{\mathbf{k}n}^{\mathrm{un}}$ and $Z_{\mathbf{k}n}^{\mathrm{oc}}$ depend on unit cell size.

Nery *et al.* [16] have reported, for VBM of MgO and LiF, the total FM and also the partial FM-occ and FMunocc contributions. In addition, they report $Z_{\mathbf{k}n}$ and also the $Z_{\mathbf{k}n}^{\mathrm{un}}$ and $Z_{\mathbf{k}n}^{\mathrm{oc}}$ values. They also cite earlier studies (Ref. 22, 102 of their paper) where the full FM self-energy term is replaced by the FM-occ or FM-unocc term. They also report earlier studies (Ref. 9, 10, 22, 102 of their paper) where only one of the quasiparticle weights, $Z_{\mathbf{k}n}^{\mathrm{un}}$ or $Z_{\mathbf{k}n}^{\mathrm{oc}}$ is used. These results in the above studies will violate the unit cell independence, and hence, need to be revisited. Thus, our results have implications beyond total energy studies.

For total energy studies, we reiterate the robustness of our results. The partial FM self-energy term is derived in independent studies separated by seven decades [10, 12, 13]. Comparing the computations to obtain the full FM and partial FM self-energy terms, the only parameter that is altered is to replace the number of bands $M = N_{\text{tot}}$ by $M = N_{\text{val}}$. The results for the former are independent of unit cell size, consistent with expectations, whereas results for the latter are strongly dependent on unit cell size, violating the unit cell independence. This clearly shows that the norm-violating behaviour is an intrinsic feature of partial FM self-energy term. Thus, further theoretical studies are necessary to fully understand and resolve this issue.

In conclusion, to include EPI contribution to the total energy, we have recast Allen's equation, for semiconductors and insulators. This equivalent expression can be computed using available software, leading to more accurate total energy for all semiconductors and insulators. We have calculated the total energy (EPI included) and their differences for the C-dia and C-hex polytypes. However, serious theoretical issues are identified from our studies. They show that the total energy is not uniquely determined by using the primitive unit cell and is dependent on the unit cell size. This most surprising result is due to the partial FM self-energy term present in Allen's equation. Due to this, to obtain reliable total energy differences between the C-dia and C-hex polytypes, instead of primitive cells, it becomes necessary to use supercells with identical number of atoms. We infer a hidden and non-obvious relation between the occupied and unoccupied Fan-Midgal terms. A crucial inference of general validity is that any equation that contains a partial Fan-Midgal term violates the unit cell independence. This is likely the first case where per-atom quantities are not uniquely obtained from the primitive unit cell. Further theoretical studies are needed to establish if the *ab initio* total energy (EPI

included) is an exception or can be reconciled with the unit cell independence and be uniquely determined from the primitive unit cell.

We thank Prof. Sumiran Pujari for helpful discussions. We thank the "Spacetime" HPC facility of IIT Bombay for computational support.
