The quantum to classical transition (QCT) is one of the central mysteries in quantum physics. This process is generally interpreted as state collapse from measurement or decoherence from interacting with the environment. Here we define the quantumness of a Hamiltonian by the free energy difference between its quantum and classical descriptions, which vanishes during QCT. We apply this criterion to the many-body Rabi model and study its scaling law across the phase transition, finding that not only the temperature and Planck constant, but also all the model parameters are important for this transition. We show that the Jaynes-Cummings and anti Jaynes-Cummings models exhibit greater quantumness than the Rabi model. Moreover, we show that the rotating wave and anti-rotating wave terms in this model have opposite quantumness in QCT. We demonstrate that the quantumness may be enhanced or suppressed at the critical point. Finally, we estimate the quantumness of the Rabi model in current trapped ion experiments. The quantumness provides an important tool to characterize the QCT in a vast number of many-body models.

Quantum and classical physics differ fundamentally. In quantum mechanics, particles are described as waves, exhibiting phenomena such as entanglement and superposition. In contrast, classical physics precludes these characteristics, with well-defined mass points satisfying the Newton's laws. The quantum to classical transition (QCT) is explained through the orthodox Copenhagen interpretation of wave function collapse from measurement $[1-4]$ $[1-4]$, which is then understood by the quantum decoherence theory $[5-14]$ $[5-14]$. The QCT is a rather subtle issue. While in principle no such boundary exists, because the bulk metals and superconductors in solids and the neutron star in astrophysics should be described by quantum mechanics; however, there are also abundant evidences that when the system temperature is high enough, or the Planck constant becomes negligible, the quantum nature may disappear. Furthermore, the importance of system size can be evidenced from macroscopic Schrödinger cat $[6, 15-18]$ $[6, 15-18]$ $[6, 15-18]$ $[6, 15-18]$. Therefore, these factors should be among the most crucial factors for this QCT. Unfortunately, a quantitative characterization of this transition is still lacking.

Definition of quantumness: Imagine a Hamiltonian $\mathcal{H}(x, p)$, where x and p are coordinate and momentum operators, respectively. In classical physics, $xp = px$ are the same; yet in quantum physics, they are different, with $[x, p] = i\hbar$, where \hbar is the Planck constant divided by 2π . Obviously, in quantum mechanics, x^2 and $p^{-1}xp^2xp^{-1}$ are different. Thus, when we say that a system exhibits quantum behaviors, we mean that it possesses some fea-

tures quantitatively different from the classical counterpart. Since in thermodynamics all observations can be determined by the partition function, we expect their difference can be reflected from their free energies. When these two descriptions yield the same free energy, they can not be distinguished from measurements. Based on this intuitive picture, we define the quantumness as

$$
\Delta_{\rm QC} = F_{\rm Q} - F_{\rm C},\tag{1}
$$

where $F_{\rm Q}$ and $F_{\rm C}$ are the free energies using quantum and classical mechanics. The QCT is exact when $\Delta_{\text{QC}} = 0$, and the nature of quantum vanishes. This work examines this quality in the many-body Rabi model, which hosts quantum phase transition. Strikingly, we show that the critical point with significant quantum (or classical) fluctuation is not necessarily associated with maximal quantumness. Finally, we will estimate the role of quantumness in the current trapped ion experiments.

We can gain some insight into this problem by investigating some simple models. (A) A free particle model with $\mathcal{H} = p^2/2m$, where m is the particle mass. The partition functions are $Z_{\rm Q} = Z_{\rm C} = \int dx dp/(2\pi\hbar)e^{-\beta\mathcal{H}} =$ $V\sqrt{2m\pi/\beta}$, where V is the real-space volume, and $\beta =$ $1/k_BT$, with k_B is the Boltzmann constant and T is the temperature. Hence $\Delta_{\text{OC}} = 0$. (B) A quantum oscillator model with $\mathcal{H} = p^2/2m + m\omega^2 x^2/2$, with eigenvalues $E_n = \hbar \omega (n + 1/2)$. We have $Z_Q = \sum_{n=0}^{\infty} e^{-\beta \hbar \omega (n + 1/2)}$, and $Z_{\rm C} = \int dx dp/(2\pi\hbar)e^{-\beta\mathcal{H}},$ yielding

$$
\Delta_{\rm QC} = \frac{1}{24} (\hbar \omega)^2 \beta - \frac{1}{2880} (\hbar \omega)^4 \beta^3 + \cdots, \qquad (2)
$$

⁵ Beijing Computational Science Research Center, Beijing 100084, China

FIG. 1. (a) Energy levels of the generalized Rabi model, in which the solid and dashed lines correspond to coupling induced by rotating wave term (g_1) and anti-rotating wave term (g_2) , respectively. When $g_2 = 0$ (JC model) or $g_1 = 0$ (aJC model), this model can be solved exactly; see discussions in (I) and (II). (b) Phase transition in this model characterized by energy gaps $\delta E_n = E_n - E_0$ by tuning of g_i . (c) Dispersion of energy levels in the normal phase $(g < g_c)$, critical point (at g_c) and superradiant phase $(g > g_c)$ when $\omega/\Omega \to 0$.

when $\beta \hbar \omega \ll 1$, which is always a positive value. When $\omega = 0$, it reduces to model (A). Thus when $k_B T \gg \hbar \omega$, the quantization effect is not important, and QCT happens. In the presence of many-body interaction, the level spacing is increased and the quantumness Δ_{QC} will also be increased in accordingly. (C) QCT from their statistics. One can find that the crossover between Bose-Einstein and Fermi-Dirac distributions and the Boltzmann-Maxwell distribution can be reached when $\beta \mu \ll -1$ (μ is the chemical potential). The last two models show that the system parameters are also important for QCT.

Quantumness in the generalized Rabi model: With these results in mind, we examine the physics in the generalized Rabi model [\[19–](#page-4-10)[27\]](#page-4-11)

$$
\mathcal{H} = \hbar\omega a^{\dagger}a + \frac{\hbar\Omega}{2}\sigma^{z} + \hbar g_{1}a\sigma^{\dagger} + \hbar g_{2}a\sigma^{-} + \text{h.c.}, \quad (3)
$$

where ω is the harmonic oscillator frequency, Ω is the spin level spacing, and q_1 , q_2 are the couplings of rotating and anti-rotating wave terms, respectively. This model has been intensively studied using trapped ions [\[28–](#page-4-12)[35\]](#page-4-13), superconducting qubits [\[36–](#page-5-0)[39\]](#page-5-1), quantum dots [\[40–](#page-5-2)[42\]](#page-5-3), and ultracold atoms [\[43](#page-5-4)[–52\]](#page-5-5), *etc.* When $g_2 = 0$ and $g_1 = 0$, it reduces to the Jaynes-Cummings (JC) model and anti-Jaynes-Cummings (aJC) model, respec-

FIG. 2. Verification of quantumness in Eq. [4.](#page-2-0) (a) JC model with $g_2 = 0$, $g_1 = 0.3$, 0.7, 1.5, with $\beta = 2$; (b) aJC model with $g_1 = 0$, $g_2 = 0.3$, 0.7, 1.5, with $\beta = 2$; (c) Rabi model with $g = 0.6$ (normal phase) and (d) $g = 1.2$ (superradiant phase), with $\beta = 5$ and $\eta = g_1/g_2$. In the Rabi model, $A = 0$, hence $x\Delta_{\mathrm{QC}}$ is independent of x. In all figures, we set $g_c = 1$.

tively. Recent investigations show that when $\omega/\Omega \to 0$, this model exhibits a second-order phase transition from a normal phase to a superradiant phase [\[29,](#page-4-14) [38,](#page-5-6) [45,](#page-5-7) [53–](#page-5-8) [55\]](#page-5-9). In contrast to the models (A - C), Eq. [3](#page-1-0) enables us to study the quantumness across the critical point. Since the rotating and anti-rotating wave terms are ubiquitous, this model enables us to explore their individual role on quantumness.

(I). JC model with $g_1 \neq 0$ and $g_2 = 0$. Let $q = g_1/g_c$, $\omega = g_c/\sqrt{x}$, and $\Omega = g_c\sqrt{x}$, where $x = \Omega/\omega$, such that $\omega \Omega = g_c^2$ is fixed during the variation of the parameters. This model can be solved analytically because the whole Hilbert space can be decoupled into small subspaces (Fig. [1](#page-1-1) (a)), with eigenvalues E_n^{\pm} = $\hbar (n + 1)\omega \pm \hbar \sqrt{g_1^2(n+1) + \frac{(\omega - \Omega)^2}{4}}$ for $n \geq 0$. The configuration in Fig. [1](#page-1-1) (a) is of particular importance in the limit $\Omega \ll k_B T$, where only the lower branch E_n^- is significant. The phase transition of this model can be manifested from the vanished energy gap, as shown in Fig. 1 (b); and the corresponding spectra are shown in Fig. 1 (c). In the normal phase, we expect $E_n^- \propto n$; and in the superradiant phase, we expect $E_n^- \sim (n - n_c)^2$. In the phase boundary, we have $n_c = 0$ and $E_n^- \propto n^2$. With this feature, the summation of n can be generalized from zero to infinity (see the filled regime in Fig. [1](#page-1-1) (c)). Using the Euler-Maclaurin formula, we can obtain the free energy in these two phases. Meanwhile, the classical free energy is obtained by defining

TABLE I. Summarized free energies in the normal phase (n) and superradiant (sr) phases. In the first column, JC, aJC refer to Jaynes-Cummings model and anti-Jaynes-Cummings model, respectively. The free energies are obtained from the partition functions $Z_{\rm C} = e^{-\beta F_{\rm C}}$ and $Z_{\rm Q} = e^{-\beta F_{\rm Q}}$ using classical and quantum treatments, and in the classical model, JC and aJC have the same free energy, because in the classical level these models are the same (upon a transformation $a \to a^*$).

$\text{Model} \left(\frac{n}{sr} \right)$	Quantum free energy F_Q	Classical free energy $F_{\rm C}$
JC(n)	$\hbar^2 \beta^2 g_c^2 (q^2-1)^3 + 24q^2$ $-\frac{\hbar g_c\sqrt{x}}{2}$ $+\frac{\hbar g_{\rm c}q^2}{2\sqrt{x}}$ $\frac{1}{\beta} \ln \left(\frac{1}{2} \right)$ $\overline{h g_c \beta (1-q^2)}$ $24\beta(q^2-1)x$	$-\frac{\hbar g_{\rm c}\sqrt{x}}{2}-\frac{1}{\beta}\ln\left(\frac{\sqrt{x}}{\hbar g_{\rm c}\beta(1-q^2)}\right)$
aJC(n)	$-\hbar^2 \beta^2 g_c^2 (q^2-1)^3 + 24q^2 \overline{(2q^2+1)}$ $\hbar g_c \sqrt{x}$ $rac{\hbar g_c q}{2\sqrt{x}}$ $rac{1}{\beta}$ ln $\overline{\hbar\beta g_c(1-q^2)}$ $24x\beta(1-q^2)$	
JC (sr)	$-\frac{\hbar g_{\rm c}(x(q^4x+x-2)+1)}{4q^2x^{3/2}}$ $\sqrt{\frac{\pi}{\hbar\beta g_c}}x^{3/4}$ $-\frac{1}{\beta}\ln(q_{\sqrt{2}})$	$-\frac{(1+q^4)\hbar g_{\rm c}}{4q^2}\sqrt{x}-\frac{1}{\beta}\ln\left(q\sqrt{\frac{\pi}{\beta\hbar g_{\rm c}}}x^{3/4}\right)$
$ aJC $ (sr)	$\hbar g_c(x(q^4x+x+2)+1)$ $-\frac{1}{\beta}\ln\left(q\sqrt{\frac{\pi}{\hbar\beta g_{\rm c}}}x^{3/4}\right)$ $4q^2x^{3/2}$	

FIG. 3. Coefficients of A and B in these three models. The red lines in (a) - (d) are calcualted by numerial fitting of Δ_{OC} at $\beta = 20$, 80 for various g_1 and g_2 , and the dashed lines are these by the analytical expressions in Eq. [5](#page-2-1) and Eq. [6.](#page-2-2) The other parameters are: $(a - b)$ $g_2 = 0$ for JC model; $(c - d)$ $g_1 = 0$ for the aJC model; and (e-f) for the generalized Rabi model for $g < g_c$ and $g > g_c$. $\eta = 0$ and $\eta = 1$ correspond to the analytic results of JC and aJC model. In (e) the two curves are identical to the empirical formula of Eq. [7.](#page-3-0)

 $a = \sqrt{\omega/2\hbar}(\hat{x} + i\hat{p}/\omega)$ and $a^{\dagger} = a^*$, which is commonly used to analyze its phase transition in the limit $\omega/\Omega \to 0$ (see Eq. [2\)](#page-0-0) $[55-57]$ $[55-57]$. Then the classical partition function is given by $Z_{\text{C}} = \sum_{s=\pm} \int dx dp/(2\pi\hbar) e^{-\beta E_s(a,a^*)}$, in which $E_{\pm} = \hbar \omega |a|^2 \pm \hbar \sqrt{(a^* g_1 + a g_2)(a g_1 + a^* g_2) + \Omega^2}$. We can solve this model using the saddle point method, which is almost exact in the low temperature regime. The

FIG. 4. Quantumness $\Delta_{\rm QC}$ near the critical point in the generalized Rabi model. (a) $\eta = 0$ (for the JC model); (b) $\eta = 0.5$ (for the ideal Rabi model); (c) $\eta = 0.75$ (for the generalized Rabi model); (d) $\eta = 1$ (for the aJC model). In all figures, we have used $g_c = 1$ and $\beta = 5$.

results of $F_{\rm Q}$ and $F_{\rm C}$ for these phases are summarized in Table [I,](#page-2-3) yielding

$$
\Delta_{\rm QC} = \frac{A}{\sqrt{x}} + \frac{B}{x} + \cdots, \quad x = \frac{\Omega}{\omega}.
$$
 (4)

If we write $\Delta_{\rm QC}(\omega) = \Delta'_{\rm QC}(0)\omega + \Delta''_{\rm QC}(0)\omega^2/2$, then $A \propto$ $\Delta'_{\rm QC}(0)$ and $B \propto \Delta''_{\rm QC}(0)$. Thus QCT happens when $x \to \infty$. We find analytically that

$$
A = \begin{cases} \frac{\hbar g_c q^2}{2} & , B = \begin{cases} \frac{\hbar^2 \beta^2 g_c^2 (q^2 - 1)^3 + 24q^2}{24\beta (q^2 - 1)} & , q < 1 \\ 0 & q > 1 \end{cases} . \end{cases} (5)
$$

(II). aJC model with $g_2 \neq 0$ and $g_1 = 0$. We define $q = g_2/g_c$, while the other parameters are the same as (I). This model can also be calculated exactly using E_n^{\pm} = $(n+\frac{1}{2})\hbar\omega \pm \frac{1}{2}(\hbar\omega - \sqrt{4\hbar^2 g^2(n+1) + \hbar^2(\omega+\Omega)^2})$ for $n \ge$ −1, which is slightly different from that in the JC model. The results are summarized in Table [I,](#page-2-3) with quantumness the same as Eq. [4.](#page-2-0) We have

$$
A = \begin{cases} -\frac{\hbar g_c q^2}{2} & , B = \begin{cases} \frac{\hbar^2 \beta^2 g_c^2 (q^2 - 1)^3 - 24(2q^2 + q^4)}{24\beta(q^2 - 1)} & , q < 1 \\ 0 & , q > 1 \end{cases} \\ 0 & , \end{cases}
$$

The classical energies are the same (see Table [I\)](#page-2-3). Physically, quantumness is fully determined the discrete nature of quantum mechanics. For example, when $\omega \ll \Omega$, we have $E_n^-(\omega) = E_n^-(0) + \kappa \omega$, where $\kappa = (dE_n^-(\omega)/d\omega)$. When $\kappa \neq 0$, we naturally have the A term. Therefore, when all these terms disappear, quantumness naturally is vanishes, indicating QCT.

The results in Eqs. [5](#page-2-1) - [6](#page-2-2) already reveal some important and sutble difference between the JC and aJC models. The scaling law of Eq. [4](#page-2-0) for these two cases are shown in Fig. [2](#page-1-2) (a) and (b); and the corresponding coefficients of A and B are shown in Fig. 3 (a) to (d). In both models, the term A is always important in the whole phase regime. Especially, A will takes on a maximal value at the phase boundary. We find that A in the JC and aJC models take opposite values, showing that the signs of the quantumness in these two models are different. The negative quantumness is in stark contrast to that in the harmonic oscillator (Eq. [2\)](#page-0-0). Besides, we find that the coefficient B is only important in the normal phase, while in the supperradiant phase, it becomes vanished.

(III). Generalized Rabi model with $g_1g_2 \neq 0$. Let $\eta =$ $g_1/(g_1+g_2)$, the phase transition happens at $(g_1+g_2)^2$ = $ωΩ$. We only need to consider the regime with $g_i ≥ 0$ [\[58\]](#page-5-11). When $\eta = 1/2$, it yields the Rabi model. This model can not be solved analytically, and we solve this model using numerical method. We find that the quantumness can still be written in the general form as Eq. [4.](#page-2-0) Our numerical results of quantumness are presented in Fig. $2(c)$ $2(c)$ - (d) and the extracted coefficients A and B are shown in Fig. [3](#page-2-4) (e) and (f). Strikingly, we find that when $\eta = 1/2$, the quantumness is only given by the B term, with $A = 0$. Thus due to the counteract effect of the JC and aJC interactions, the Rabi model has the smallest quantumness. From Fig. [3](#page-2-4) (e) we have

$$
A(\eta) = A(0)(1 - \eta) + A(1)\eta,
$$
\n(7)

where $A(0) = -A(1)$ are the coefficients in the aJC and JC models, respectively. This relation naturally explains the vanished A in the Rabi model.

(IV). Quantumness and phase transition: It is natural to explore the quantumness across the critical point, which has the strongest fluctuations in both classical and quantum mechanics. However, their difference is not necessary to be increased. From the sign of A, we see that the contribution of JC and aJC are opposite, which can yield totally different behaviors. The numerical results for these models are presented in Fig. [4.](#page-2-5) We find that with the increase of q , the quantumness is enhanced in the JC and aJC models; however, in the Rabi model, it is suppressed near the critical point. These results suggest that the quantumness is an intrinsic property of the Hamiltonian, which can be increased or decreased by the critical fluctuations. As a result, it is only in this limit $\Delta_{\text{OC}} = 0$ that the classical phase transition can happen in the general Rabi model [\[55\]](#page-5-9).

FIG. 5. QCT in experimental Rabi model with trapped ions [\[59\]](#page-5-12). Here we have used $\omega = 2\pi \times 4.0$ kHz, $\Omega = 2\pi \times 100.0$ kHz, which corresponds to a ratio $x = 25$, and the critical point is at $g_c = 2\pi \times 20.0$ kHz, showing that $\Delta_{\rm QC}/F_{\rm C} \sim 1\%$.

Quantumness in experiment with trapped ions: Finally, we discuss the relevance of our results in the current experiments with trapped ions implemented in the experiments in Duan group [\[59\]](#page-5-12). In this experiment with Rabi model, $\omega = 2\pi \times 4.0$ kHz, $\Omega = 2\pi \times 100.0$ kHz, $x = 25$, and the critical point is at $g_c = 2\pi \times 20.0$ kHz (at $T = 0$). By varying of the coupling g from 0 to 14 kHz $(1.4g_c)$, we estimate F_Q, F_C and $\Delta_{\rm QC}$ in these experiments in Fig. [5](#page-3-1) , showing that in the current setup, the quantumness is about 1% of the total classical energy. This value is small, yet nonzero, thus in experiment only a smooth crossover between the two phases can be demonstrated. We find that to observe a relative sharp transition, x must be increased to 100, yielding $\Delta_{\rm QC}/F_{\rm C}$ to be further reduced by one order of magnitude since $\Delta_{\rm QC}/F_{\rm C} \sim x^{-3/2}$, for $A = 0$ and $F_{\rm C} \propto \sqrt{x}$; see Table [I.](#page-2-3)

To conclude, we define the quantumness Δ_{QC} to quantitatively characterize the QCT, and examine this quality in the generalized Rabi model. This interpretation does not rely on the state collapse, thus is not a feature of some particular states as discussed in quantum information science $[9, 14, 60]$ $[9, 14, 60]$ $[9, 14, 60]$ $[9, 14, 60]$ $[9, 14, 60]$, instead, it is a feature of the Hamiltonian in thermal equilibrium. We show explicitly that not only the temperature and Planck constant, but also the system parameters are important for the QCT. This quantity can be applied to study the QCT in a broad range of many-body physical models, and clarify the roles of quantumness on observations and phase transitions, which could help to resolve the long-sought mysterious boundary between quantum and classical worlds. From this perspective, we expect this quantity to be important for these models which can not be described approximately by classical mechanics. It also has potential to be unified with the decoherence theory for QCT [\[5–](#page-4-5)[14\]](#page-4-6).

- [58] We focus on $g_1 > 0$ and $g_2 > 0$. When these two coefficients have opposite sign, we can make a transformation $a \rightarrow ia$, and $\sigma^- \rightarrow i\sigma^-$ to change them to have the same sign. When $g_1 < 0$ and $g_2 < 0$, we can change $a \to -a$ to change them to be positive valued.
