Abstract.

Typically, Table-to-Text generation models directly expand tables line by line into a long string as input makes it difficult for generators (Language Models) to focus on saliency units or data units relevant to the query from the unstructured, lengthy strings. To address this issue, we propose a two-step solution called HeLM which consists of two modules: a table highlighter that identifies relevant row evidence, and a table summarizer that generates sentences based on the highlighted table. To facilitate this, we utilized the open-sourced large language model LLaMA2 as the backbone for these two modules and efficient finetuning on it. We also propose a searching algorithm along with label distillation to construct highlighting labels for obtaining the table highlighter. On both the FetaQA and QTSumm datasets, our approach achieved state-of-the-art results in ROUGE and BLEU scores. Additionally, experiment results show that highlighting the key evidence on input tables significantly enhances the model's performance and provides valuable interpretability.

1 Introduction

Tabular data represents a common form of structured information within the realm of computing, particularly within databases. Analyzing and manipulating tabular data holds significance in the domain of Natural Language Processing (NLP). A practical scenario for automated table processing involves posing a query or requirement to the table, which can take the form of questioning [28, 25] or summarization [44], among others. Subsequently, based on this demand, a response is generated, typically in the form of sentences or paragraphs. This type of task is referred to as table-to-text generation. The recent emergence of Large Language Models (LLMs) [3, 26, 38, 35, 8, 39] showcase impressive capabilities in multiple NLP tasks, unveiling vast potential in handling tabular data. Therefore, this paper delves specifically into the application of LLMs in table-to-text generation tasks, exploring the immense potential of LLMs in tabular data generation through relevant research and empirical analysis.

Recent approach [5, 41] in utilizing LLMs for table-based tasks usually relies on invoking online APIs for few-shot learning or inte-

grated techniques such as chain-of-thought [38] or in-context learning, achieving comparable performance even without fine-tuning. However, these methods necessitate frequent API calls and, in practical application, entail uploading table data, thereby posing a risk of information leakage. Therefore, a finetuned LLM system specialized in handling tabular data stands as an effective solution. With the availability of open-sourced LLMs[12, 35, 36, 29, 18] and the introduction of parameter-efficient training methods[16, 11], fine-tuning a large language model with limited computational resources is now available. Therefore, in this study, we employ QLoRA [11] to fine-tune the LLaMA2 [36] base model specifically for Table-to-Text generation.

To enable the model to adeptly handle tabular data, it requires the capability to reason intricately across textual, numerical, and logical domains. Some methods [1, 17] achieve this by synthesizing executable languages, such as SQL. Others [14, 22, 19, 13] pretrain on additional table data to acquire table reasoning capabilities. However, most LLMs often lack table reasoning capabilities due to their pretraining text containing minimal tabular data content. In this paper, we conceptualize table reasoning as the capacity to identify crucial evidence within a table according to the output requirements. In this context, we define evidence as the specific row-level data crucial for answering the final output. Considering that input tables are often extensive, essential information usually resides within a small portion. Identifying and conveying these row data effectively to the model can significantly enhance the model's output quality.

In real-world scenarios, input of table-to-text generation often consists solely of entire tables and queries, necessitating an automated process to gather evidence data. This paper introduces a two-step methodology designed to tackle these challenges. The first is an LLM-based table highlighter, aimed at identifying and Hightlighting evidence given input table. Then another Large Language Model based table summarizer model acquiring highlighted table as input and generates the final output. This methodology is termed as HeLM.

The pivotal component of HeLM lies in the table highlighter, which outputs evidence(relevant row indexes) based on the given table and query. However, most datasets lack evidence labels, making the fine-tuning of LLMs inconvenient. To address this issue, we propose two methods for obtaining evidence labels. One direct approach

^{*} Email: 20110240003@fudan.edu.cn

^{**} Corresponding Author

is to distill evidence labels from more powerful LLMs. Additionally, we also designed an algorithm that, without relying on distillation, automatically constructs evidence labels using only the original input-output data from the dataset. After that, combining evidence labels obtained from different methods can further enhance the quality of evidence. The table highlighter trained in this manner not only improves the overall performance of HeLM but also provides valuable interpretability. The contributions of this paper are as follows:

- We propose a two-step table-to-text approach named HeLM, which utilizes a table highlighter to highlight input tables, aiding downstream table summarizers in producing better text outputs.
- We introduce a search-based evidence label construction method and a workflow for training HeLM's highlighter and summarizer.
- HeLM attains state-of-the-art results in terms of BLEU and ROUGE scores on both the FetaQA and QTSumm datasets and the code¹ is released.

2 Related work

2.1 Reasoning Over Tables

Enhancing a model's table reasoning capabilities is pivotal for tablerelated tasks. A prevailing strategy is to pre-train models on reasoning data that combines tables and text. Such pre-training methods can be encoder-based, as exemplified by Tapas [14], which pre-trains on a large-scale corpus of text-table pairs. TaBERT [42], on the other hand, employs Masked Column Prediction and Cell Value Recovery as pre-training tasks to fine-tune a BERT-based table encoder. [10] introduce the Masked Entity Recovery objective for pre-training to distill the semantics and knowledge within vast amounts of unlabeled data. There are also generative pre-training models like Tapex [22], which utilize a novel SQL execution task to conduct table pretraining on a diverse, large-scale, and high-quality synthetic dataset. UnifiedSKG [40] transforms various types of structured data tasks into a unified text-to-text format for joint training, including those involving tabular data. TableGPT[43] fine-tuned on LLM while utilizing an accompanying table encoder to attain a comprehensive understanding of the input table.

The above models often gain table reasoning capabilities in an end-to-end manner, sacrificing explainability. Some studies first use explicit methods for table reasoning, before proceeding with generation. The approach, named by REFACTOR [44], suggests generating query-relevant facts from tables as intermediate results for LLM's input. Another noteworthy method[6], employs Codex [4] to synthesize SQL for executing logical forms against tables in question-answering tasks. Dater [41] takes an approach by reducing the original table into relevant sub-tables and ask LLMs to execute query-focused SQL language to get numerical context. Our approach employs a highlighter first for explicit table reasoning, followed by generation. The reasoning capability of the highlighter stems from tabular data and distillation.

2.2 Instruction Tuning

Instruction tuning [24, 9, 33] is a learning paradigm that converts conventional supervised learning datasets into an instruction-following format, By learning the corresponding outputs for instructions, thereby guiding the output of LLMs. Recent breakthroughs

[34, 7, 30] have also facilitated the development of smaller models demonstrating task-adherence capabilities, achieved through fine-tuning on instruction data generated by LLMs, such as ChatGPT or GPT4 [26].

Instruction fine-tuning is typically applied in general NLP tasks [37]. Despite some methods [41, 5] exploring instruction design for direct LLM inference, the utilization of instruction tuning in table-to-text generation remains underexplored.

3 Methodology

3.1 Task Formulation

In table-to-text generation datasets, the input consists of a structured Table T containing rows and columns of data, along with a natural language question Q. The golden output is denoted as \mathcal{Y} . A table-to-text generation system is required to generate a response $\hat{\mathcal{Y}}$ that answers the question, leveraging the information encoded within the table.

3.2 HeLM Framework

Our framework consists of two components: a table highlighter \mathcal{M}_H and a table summarizer \mathcal{M}_S . As shown in the Figure 1, the table highlighter identifies the indexes of row data relevant to the query within the table. For this component, we employ an LLM that directly generates index numbers as text. To achieve this, we design a Prompt $_H$ that concatenates rows of the table into a string along with the query and task description, forming the input for the table highlighter \mathcal{M}_H . the details of the Prompt $_H$ is in Figure 2. In training, golden evidence is incorporated into the Prompt $_H$. At inference, the *golden output* is set to empty:

$$E = \mathcal{M}_H \left(\mathsf{Prompt}_H(T, Q) \right) \tag{1}$$

The output $E = \{e_i, ...\}$ of \mathcal{M}_H is a list of indices, where e_i corresponds to the row number in the input table T.

After obtaining the evidence indexes, we become aware of which row data in the original table T is relevant to the query Q. We highlight this evidence on T to produce the modified table T^* . The highlighting operation $HL(\cdot)$ involves adorning each data cell of a key row with a distinctive '*' character, signifying its importance, an exmple is illustrated in Figure 4.

$$T^* = HL(T, E) \tag{2}$$

The table summarizer will subsequently produce the final result based on the prompt generated by highlighted table T^{*} associated with query Q and task description:

$$\hat{\mathcal{Y}} = \mathcal{M}_S \left(\text{Prompt}_S(T^*, Q) \right) \tag{3}$$

3.3 Evidence Labels

Training a good highlighter necessitates high-quality evidence labels. Prior to delving into evidence label searching and evidence label merging, we first introduce Evidence Feedback.

###Input:[table] \n ##Question:[query] \n ##Answer:[golden output]

Figure 3. Prompt of evidence labels distillation. *Evidence Feedback*

To distinguish the quality of an evidence label, we require a feedback model denoted as \mathcal{M}_F . Given an evidence E. Upon combining the evidence with the table and using it as input, the feedback model \mathcal{M}_F will produce an output $\hat{\mathcal{Y}}$:

$$\hat{\mathcal{Y}} = \mathcal{M}_F(\text{Prompt}_S(HL(T, E), Q)) \tag{4}$$

Figure 4. Case of table highlighting, $\{1\}$ corresponds to E in equation 2, and the visualized table corresponds to T. The output below is T^* .

The quality of the evidence is assessed based on the goodness of this output:

$$Reward = eval(\mathcal{Y}, \hat{\mathcal{Y}}) \tag{5}$$

Alternatively to highlighting within the table, there is a more sensitive feedback approach that directly extracts row data from the table based on the evidence, resulting in a sub-table, which we define as SubTab(T,E).

Essentially, the function of the feedbacker \mathcal{M}_F and the summarizer \mathcal{M}_S is the same; both return results based on a table that has been modified by evidence. However, the performance requirements for \mathcal{M}_F are not high; it only needs to be sensitive to the evidence, meaning that results derived from good evidence should be significantly better than those from poor evidence. Before obtaining a high-quality \mathcal{M}_S , we can utilize limited resources to first train an \mathcal{M}_F .

3.4 Evidence Labels Construction

Query-focused evidence indexes are necessary for fine-tuning a table highlighting module, and we summarize three sources for obtaining these evidence labels.

- Human annotated evidence E_{manul}: Some datasets, such as QT-Summ [44], inherently include labels for relevant evidence, and they are obtained through manual annotation.
- Distilled evidence E_{distill}: Labels can also be distilled from other LLMs such as GPTs [26]. To better capture evidence, we designed an few-shots in-context learning prompt(see Figure 3), incorporating golden labels Y to better capture evidence.

$$E_{distill} = \text{LLMs}(\text{Prompt}_{distill}(T, Q, \mathcal{Y}, \text{Examples})) \quad (6)$$

• Searched evidence E_{search} : Evidence labels can also be obtained through search algorithms, which require feedback for different E. This feedback system has two requirements: one is the golden output $\mathcal Y$ corresponding to the input table and query, and the other is a feedback table summarizer $\mathcal M_F$. For more details of this algorithm, please refer to section 3.5.

$$E_{search} = Search(T, Q, \mathcal{Y}, \mathcal{M}_F)$$
 (7)

The table evidence labels obtained through various methods showcase significant disparities. By integrating these evidence labels, higher-quality evidence can be attained. This process entails using highlighted tables associated with different evidence and getting sentences via the feedbacker \mathcal{M}_F . The evidence label for the current sample is chosen based on the sentence that receives the highest evaluated score. The formula for generating the merged label E_{merge} is outlined as follows:

$$E_{merge} = Merge(\mathbf{E}, T, Q, \mathcal{Y}, \mathcal{M}_F)$$
 (8)

Here, E represents the available evidence label set. For datasets lacking human annotated evidence, $E = \{E_{search}, E_{distill}\}$.

3.5 Evidence Labels by Searching

As mentioned earlier, the search algorithm requires a feedback system. The feedback system includes the golden output $\mathcal Y$ corresponding to the table query and a feedbacker $\mathcal M_F$, $\mathcal M_F$'s output is evaluated by computing the BLEU score against $\mathcal Y$ to derive numerical feedback value.

In label searching, the input for \mathcal{M}_F is the sub-table corresponding to the evidence. The reason for using the sub-table as input to search for evidence is that \mathcal{M}_F is more sensitive to sub-table evidence compared to the input of the complete table with evidence highlighted. Because even when relevant row data is not highlighted as evidence in the complete table input, \mathcal{M}_F might still capture it.

Assuming the table has n rows of data, and each row can be either selected or not, the search space for this algorithm is 2^n . This implies that for each training example, one would need to invoke LLMs (summarizer) 2^n times to construct the optimal evidence, which is impractical. Therefore, we propose a greedy search method to construct labels, reducing the searching complexity from $O(2^n)$ to O(n).

The core idea of this algorithm is that query-relevant evidence can enhance the summarizer feedback score, while irrelevant evidence cannot. During evidence construction, the initial evidence is an empty set. Based on feedback results, we expand this evidence by adding row index one by one, and we repeat this process until the score no longer increases or reach a certain step. We have also designed heuristic steps to efficiently select evidence rows. A more detailed procedure is shown in Algorithm 1.

Algorithm 1: Reasoning evidence labels by search

```
Input: Table T(n \text{ rows}), Query Q, Answer \mathcal{Y}, Feedback
           summarizer \mathcal{M}_F
Output: Searched evidence Label E_{search}
Generate n evidence labels E = \{E_1, E_2, ..., E_n\}, where
E_i = \{i\} for i \leftarrow 1 to n do
     \hat{\mathcal{Y}}_i = \mathcal{M}_F(\operatorname{Prompt}_S(\operatorname{SubTab}(T, E_i), Q))
     R_i = \text{eval}(\hat{\mathcal{Y}}_i, \mathcal{Y})
end
Reorder the E according to reward R.
Evidence label E_s is initialized with empty set.
Evidence label reward: R_s = 0
for i \leftarrow 1 to n do
     \mathcal{Y}_i = \mathcal{M}_F(\operatorname{Prompt}_S(\operatorname{SubTab}(T, E_i + E_s), Q))
     R_i = \text{eval}(\mathcal{Y}_i, \mathcal{Y})
     if R_i > R_s then R_s = R_i
           E_s = E_i + E_s
     end
end
```

3.6 HeLM Training

HeLM comprises two modules: Highlighter and Summarizer. The training of the Highlighter utilizes the highest-quality evidence label E_{merge} . Training a complete HeLM modules involves the following steps:

Step 1. Obtain feedback summarizer: Distilling $E_{distill}$ through LLMs, and training a rough table feedbacker/summarizer \mathcal{M}_F using $E_{distill}$.

$$\{\operatorname{HL}(E_{distill}, T), Q, \mathcal{Y}\} \to \mathcal{M}_F$$
 (9)

Step 2. Obtain merged evidence: Obtaining E_{search} using Algorithm 1, then combining the existing evidence through Equation 8 to obtain E_{merge} .

Step 3. Fine-tuning highlighter and summarizer: Train highlighter \mathcal{M}_S using E_{merge} , and train summarizer \mathcal{M}_R using \mathcal{Y} and T^* corresponding to E_{merge} .

$$\{T^*, Q, \mathcal{Y}\} \to \mathcal{M}_S$$
 (10)

$$\{T, Q, E_{merge}\} \to \mathcal{M}_H$$
 (11)

Figure 1 displays the comprehensive training and inference process of HeLM.

Facing the immense size of recent LLMs, conducting full-parameters fine-tuning is prohibitively expensive. As a practical alternative, we adopt the parameter-efficient finetuning strategy, QLoRA [11, 16], to train our highlighter and summarizer. This approach significantly reduces trainable parameters to 0.6% of the original, enabling fine-tuning of LLMs on consumer devices.

4 Experiments

4.1 Dataset and Evaluation

FeTaQA: FeTaQA is a dataset designed for free-form table question-answering, constructed using information from Wikipedia. It introduces a table question answering scenario, where questions are answered in natural language. The FeTaQA dataset comprises 7,326 question-answer pairs in the training set, 1,000 in the validation set,

and 2,006 in the test set. For the evaluation of results on the FeTaQA dataset, we employ commonly adopted metrics, including ROUGE-1, ROUGE-2, ROUGE-L [20], and the BLEU [27, 31] score.

QTSumm: QTSumm is a query-focused table summarization dataset, requiring text generation models to engage in human-like reasoning and analysis over the provided table to generate a tailored summary. The training and validation sets consist of 4,981 and 1,052 examples respectively, and the test set comprises 1,078 examples. Notably, in comparison to the FeTaQA dataset, QTSumm exhibits longer output lengths. For the evaluation of results on QTSumm, we employ not only ROUGE-L and BLEU scores but also the METEOR [2] as the evaluation metric.

4.2 Implementation Details

All models are executed on a single NVIDIA-A100 GPU with 80G of memory. We optimized our baseline LLMs through 4-bit QLoRA finetuning, utilizing an effective batch size of 8 for 2 epochs. The optimization process employed the AdamW [23] optimizer with default momentum parameters and a constant learning rate schedule set at 2e-4. For QLoRA, NormalFloat4 with double quantization was applied to the base models, and LoRA adapters were added to all linear layers with parameters r=16 and $\alpha=32$. The maximum input length was constrained to 2048. For generating outputs from the LLMs, we employed nucleus sampling [15] with parameters p=0.9 and a temperature of 0.1.

Our model, HeLM-13B, denotes that both the summarizer and highlighter utilize Llama2-13b-hf[36] as the backbone model for parameter-efficient fine-tuning.

4.3 Baselines

There are primarily two types of baselines for Table-to-Text task, that is, fine-tuning methods, and few-shot methods using LLMs. In the FeTaQA dataset, fine-tuning baselines contain the T5-based [32] models (T5-Small, T5-Base, and T5-Large), as well as TAPEX [22], OmniTab [19], and PLOG [21]. TAPEX and OmniTab are both BART-based models, with additional pre-training on custom training data.

HeLM-13B refers to a model where both the highlighter and summarizer are fine-tuned on the basis of LLaMA2-13B in a parameter-efficient manner with the parameters used for training constituting merely 0.6% of the LLaMA2. In contrast, we have also present the approach of directly parameter-efficient fine-tuning LLaMA2-13B.

In FeTaQA dataset, methods using LLMs for few-shot learning include Dater (Codex) [41] and TabCOT [5]. The few-shot LLMs baselines for the QTSumm dataset are directly adapted from [44], including methods such as LLaMA2-7B,13B,70B and GPT-3.5,4.

4.4 Main Results

HeLM-13B demonstrate superior performance on both the QTSumm and FeTaQA datasets. Specifically, on the FeTaQA dataset (see Table 1), HeLM-13B outperforms the previous leading method, Dater, with a 1.8 and 1.9 improvement in Rouge-1 and Rouge-L respectively. More notably, there is a substantial improvement in the BLEU score, with an increase of 3.26.

The results for the QTSumm dataset are presented in Table 2. HeLM-13B achieved the best results in both the BLEU and ROUGE-L metrics, with improvements of 1.7 and 2.5 respectively over the second-ranked LLaMA2-13B. In terms of the METER metric, HeLM-13B ranked second, showing an improvement of 3.3 over LLaMA2-13B, and was 1.1 behind GPT-4. This demonstrates the effectiveness of highlighting mechanism.

4.5 Human Evaluation

Relying solely on the ROUGE and BLEU scores cannot comprehensively assess the model's performance. Therefore, human evaluation is necessary. In human evaluation, we recruited and paid three well-educated graduate students. Before starting the annotation, we wrote a unified annotation manual to guide the annotators on how to perform the annotations. The three annotators were required to rank the outputs of three methods on 100 samples. For each sample, we provided the input table, query, and the golden answer for reference.

We conducted a human evaluation in three aspects: (1) **Fluency** (whether the output sentences are fluent and without grammar errors). (2) **Correctness** (the accuracy of numerical values and logical correctness of sentences). (3) **Adequacy** (whether the output results cover all aspects of the questions). Compared models included LLaMA2-13B LoRA, which is also based on efficient fine-tuning, as well as Tabcot, an LLMs-based few-shot method. Among these three metrics, correctness is the most indicative table reasoning ability. In table 3, TabCot performs lower on fluency compared to LLaMA2-13B LoRA, but its correctness is significantly better. This suggests that fine-tuning on a specific dataset is more focused on learning

surface-level features. Regarding the table reasoning ability as indicated by correctness, LLMs like GPT-3 showcase superior capabilities. HeLM performs best in correctness, indicating the positive impact of HeLM's highlighter on the overall accuracy of the results.

Models	Fluency	Correct	Adequate
TabCot (GPT3)	2.05	1.98	2.02
LLaMA2-13B QLoRA	2.00	2.11	2.06
HeLM-13B	1.96	1.92	1.91

Table 3. Human evaluation on FeTaQA. The numbers in the table indicate the average ranking.

4.6 Ablation Study

4.6.1 Impact of Model Size

As shown in Table 4, when using LLaMA2-7B as the base model for fine-tuning, HeLM-7B showed a 2.15 decrease in BLEU score and a 2.5 decrease in ROUGE-L score compared to HeLM-13B. Directly fine-tuning LLaMA2-7B using LoRA also exhibited a 1.4 decrease in ROUGE-L compared to LLaMA2-13B.

The phenomenon of model performance increasing with size is quite common. At the same time, we have also found that the performance improvement of HeLM with increased model size is significantly higher than that of LLaMA2. This underscores the importance of table highlighting in HeLM. It is also suggested that simply increasing the model size without considering the model's reasoning capabilities does not yield substantial returns.

4.6.2 Impact of Table Highlighting

HeLM's summarizer takes tables highlighted with evidence as input, and different evidence will have different effects on the output results of the summarizer. We record this experiment in Table 5. When the summarizer of HeLM-13B receives unmodified tables as input, specifically, the result of -w/o highlight showed a decrease of both BLEU and ROUGE-L. This signifies the effectiveness of highlighting crucial information in LLM's input tables. Additionally, when using the same evidence for input table, and constructing a sub-table with only key row information as input instead of retaining all table data, the approach -subTab has a 2.82 decrease in BLEU score. This suggests the benefit of retaining sufficient table information. Another observation is that when no highlighting is applied to the input table, LLaMA2 outperformed HeLM-w/o HL. This happens because HeLM's summarizer generated dependency on highlighted evidence during training. However, during testing, when the highlighting is absent, it results in poorer performance compared to LLaMA2.

Models	R-1	R-2	R-L	BLEU
LLaMA2-7B [†]	65.0	43.0	54.8	32.68
LLaMA2-13B [†]	66.5(+0.5)	44.7(+1.7)	56.2(+1.4)	33.24(+0.56)
HeLM-7B [†]	65.4	43.5	55.4	32.95
HeLM-13B [†]	67.8(+2.4)	46.4(+2.9)	57.9(+2.5)	35.10(+2.15)

Table 4. Ablation study with different model size on FeTaQA dataset.

Models	R-1	R-2	R-L	BLEU

Table 5. Ablation study on FeTaQA dataset with different evidence.

4.6.3 Impact of Evidence Labels

During evaluation, the evidence used for highlighting the input table in our base model HeLM is generated by the HeLM's highlighter. By keeping the summarizer of HeLM-13B fixed, we also examine the output derived from employing various evidence labels for table highlighting, aiming to illustrate the impact of evidence labels quality.

 $E_{distill}$ and E_{search} are reasoning evidence mentioned in section 3.4, while E_{merge} is a combination of the two evidence labels in FeTaQA dataset and is the training labels for hightlighter. It's important to note that all three labels were obtained with knowledge of the golden summary \mathcal{Y} . According to Table 5, the evaluation score corresponding to E_{merge} is the highest, indicating that the evidence quality of E_{merge} is the best. This also indicates that although the overall quality of E_{search} obtained through greedy search is lower than $E_{distill}$, the quality on some individual samples is higher than $E_{distill}$.

4.7 Cases Analysis

We showcase some instances at of accurate and inaccurate evidence generated by HeLM's table highlighter, alongside outputs from HeLM-13B, TabCot(GPT3) and LLaMA2-13B-QLoRA respectively, as shown in Figure 5. For instance, case (2) shows the results given two questions about numerical calculation. HeLM's highlighter accurately finds the player's records during their tenure at Coventry, aiding the table summarizer in precisely calculating the player's tenure and total appearances. In contrast, both LLaMA2-QLoRA and TabCot(GPT3) give wrong answers for the two questions.

Cases (3) and (4) represent instances where the highlighter made inaccurate judgments. In case (3), the highlighter highlighted two irrelevant rows, one of which appeared in the summarizer's output. In case (4), the highlighter missed highlighting one row, leading the summarizer to fabricate a ninth-ranking entry, but the table only contained data for the top eight ranks. Therefore, it's evident that the summarizer places significant emphasis on the highlighted segments of the table as identified by the highlighter.

5 Conclusion

In this paper, leveraging existing open-source LLM, we devised a lightweight two-step table-to-text solution named HeLM. HeLM comprises two modules: table highlighter and table summarizer. Both modules adopt LLaMA2 as the backbone model and conduct efficient fine-tuning using designed prompts. Additionally, we explored diverse methods for constructing reasoning evidence, encompassing distillation from ChatGPT and construction by a searching algorithm. Our experimental findings showcase that leveraging the highlighter to highlight important row data of the input table significantly elevates the quality of the output and provides valuable interpretability.

(1) Table caption: 2014 Newark by-election

party	Candidate	Votes	%	±
Conservative	Robert Jenrick	17,431	45.0	8.9
UKIP	Roger Helmer	10,028	25.9	22.1
Labour	Michael Payne	6,842	17.7	4.7
Independent	Paul Baggaley	1,891	4.9	N/A
Green	David Kirwan	1,057	2.7	N/A
Majority	Majority	7,403	19.1	12.4

Query: Who won the 2014 Newark by-election and by what margin? Golden: Conservative Robert Jenrick won with a majority of 7.403.

HeLM: The 2014 Newark by-election was won by Robert Jenrick of the Conservative Party with a majority of 7,403 votes.

LLaMA2-QLoRA: The Conservative Party's Robert Jenrick won the 2014 Newark by-election with 45.0% of the vote, a majority of 19.1%.

TabCot (GPT3): The Conservative party held the seat in the 2014 Newark by-election. The margin of victory was 19.1%.

(2) Table caption: Paul Williams (footballer, born 1971)

(2) Tubic caption: I dui Williams (Tootballer, Born 1971)						
Club	Season	League		Total	Total	
Club	Season	Division		Apps	Goals	
Dearby County	1989-90	First Division		10	1	
Dearby County	1990-91	First Division		19	4	
Coventry City	1995-96	Premier League		37	2	
Coventry City	1995-96	Premier League		38	2	
Coventry City	1995-96	Premier League		25	0	
Coventry City	2001-02	Premier League		5	0	
Coventry City	Total	Total		199	5	
Southampton	2001-02	Premier League		30	0	

Query: How many appearances did Williams make for Coventry City, and for how many seasons did he play for the club?

Golden: Williams made 199 appearances for Coventry City in 7 consecutive seasons.

 $\ensuremath{\text{\textbf{HeLM}}}\xspace$: Williams made 199 appearances for Coventry City in seven seasons.

LLaMA2-QLoRA: Williams made 58 appearances for Coventry City in two seasons.

TabCot (GPT3): Williams made 169 appearances for Coventry City over six seasons.

(3) Table caption: Cliff Gorman

Year	Title	Role	Note
1969	Justine	Toto	-
1970	The Boys in the band	Emory	
1980	Night of the Juggler	Gus Soltic	-
1981	The Bunker	Joseph Gobbels	TV movie
1984	Angel	Lt. Andrews	-
1992	Night and the City	Phil Nasseros	-
1992	Hoffa	Solly Stein	-

Query: What roles did Cliff Gorman play between 1981 to 1984?

Golden: Cliff Gorman played as Joseph Goebbels in the 1981 TV movie The Bunker and as Lt. Andrews in the film Angel (1984).

HeLM: Cliff Gorman played the role of Joseph Goebbels in the TV movie The Bunker (1981), Lieutenant Andrews in Angel (1984), and Solly Stein in Hoffa (1992)

LLaMA2-QLoRA: Cliff Gorman played the role of Joseph Goebbels in the TV movie The Bunker (1981) and the role of Lt. Andrews in Angel (1984).

TabCot (GPT3): Cliff Gorman played the roles of Lt. Andrews in Angel (1981), Joseph Goebbels in The Bunker (1981), and Solly Stein in Hoffa (1992).

(4) Table caption: Swimming at the 2012 Summer Olympics – Women's 200 metre backstroke

	•	•			
Rank	Lane	Name	Nationality	Time	Notes
-	5	Missy Franklin	United States	2:04.06	WR
-	6	Anastasia Zuyeva	Russia	2:05.92	-
-	4	Elizabeth Beisel	United States	2:06.55	-
4	1	Elizabeth Simmonds	Great Britain	2:07.26	-
5	3	Meagen Nay	Australia	2:07.43	-
6	7	Kirsty Coventry	Zimbabwe	2:08.18	-
7	2	Alexianne Castel	France	2:08.43	-
8	8	Sinead Russell	Canada	2:09.86	-

Query: Who were the last two finishers of the at the 2012 Summer Olympics for the Women's 200 metre backstroke?

Golden: France's Alexianne Castel (2:08.43) and Canada's Sinead Russell (2:09.86) closed out the championship field.

HeLM: Canada's Sinead Russell finished eighth in 2:09.86 and Australia's Belinda Hutchison rounded out the finale in ninth with a time of 2:10.00.

LLaMA2-QLoRA: The last two finishers of the Women's 200 metre backstroke were Kirsty Coventry with a time of 2:08.18 and Alexianne Castel with a time of 2:08.43.

TabCot (GPT3): The last two finishers were Sinead Russell in 8th place with a time of 2:09.86 and Kirsty Coventry in 6th place with a time of 2:08.18.

Figure 5. Cases from the FeTaQA Dataset. The highlighter of HeLM has highlighted specific parts of the table using red boxes. The rows in the table with a green background represent manually observed evidence related to the query.

Despite HeLM achieving good results on two table-to-text datasets, there are still some limitations and space for further improvement: (1) We haven't extensively investigated table highlighting formats, and there might be more effective ways. (2) Currently, HeLM is trained for specific datasets, lacking generalization; training HeLM on a mixture of table-to-text datasets could be a better solution. (3) The evidence labels generated by greedy search in table highlighter could be further improved. For instance, we can employ reinforcement learning to search for more optimal evidence labels. (4) Despite our model achieving high scores in BLEU and ROUGE metrics, its advantages in numerical and textual accuracy aren't notably pronounced compared to some powerful LLMs.
