# QUASI-OPTIMAL DISCONTINUOUS GALERKIN DISCRETISATIONS OF THE *p*-DIRICHLET PROBLEM\*

JAN BLECHTA<sup>†</sup>, PABLO ALEXEI GAZCA-OROZCO<sup>‡</sup>, ALEX KALTENBACH<sup>§</sup>, AND MICHAEL RŮŽIČKA<sup>‡</sup>

Abstract. The classical arguments employed when obtaining error estimates of Finite Element (FE) discretisations of elliptic problems lead to more restrictive assumptions on the regularity of the exact solution when applied to non-conforming methods. The so-called minimal regularity estimates available in the literature relax some of these assumptions, but are not truly of minimal regularity, since a data oscillation term appears in the error estimate. Employing an approach based on a smoothing operator, we derive for the first time error estimates for Discontinuous Galerkin (DG) type discretisations of non-linear problems with  $(p, \delta)$ -structure that only assume the natural  $W^{1,p}$ -regularity of the exact solution, and which do not contain any oscillation terms.

**Key words.** *p*-Dirichlet problem, Discontinuous Galerkin, *a priori* error estimates, quasi-optimality, best-approximation

MSC codes. 35J66, 35J92, 65N12, 65N30

**1. Introduction.** In this paper, we examine Local Discontinuous Galerkin (LDG) and Incomplete Interior penalty Discontinuous Galerkin (IIDG) discretisations of non-linear problems of p-Dirichlet type, i.e.,

(1.1) 
$$-\operatorname{div} \boldsymbol{\mathcal{S}}(\nabla \boldsymbol{u}) = \boldsymbol{f} \quad \text{in } \Omega, \\ \boldsymbol{u} = \boldsymbol{0} \quad \text{on } \partial\Omega.$$

Here  $\Omega \subseteq \mathbb{R}^d$ ,  $d \geq 2$ , is a bounded polyhedral domain having a Lipschitz continuous boundary  $\partial\Omega$ ,  $\boldsymbol{f}: \Omega \to \mathbb{R}^n$  is a given vector field, and we seek a vector field  $\boldsymbol{u}: \overline{\Omega} \to \mathbb{R}^n$ solving the system (1.1). The non-linear operator  $\boldsymbol{\mathcal{S}}: \mathbb{R}^{n \times d} \to \mathbb{R}^{n \times d}$  is assumed to have  $(p, \delta)$ -structure, cf. Definition 2.1; the prototypical example falling in to this class is

$$\boldsymbol{\mathcal{S}}(
abla \boldsymbol{u}) = (\delta + |
abla \boldsymbol{u}|)^{p-2} 
abla \boldsymbol{u}$$

where  $p \in (1, \infty)$  and  $\delta \ge 0$ .

The central objective of this work is to establish a *quasi-optimal* (a priori) error estimate, i.e., a best-approximation result of the form

(1.2) 
$$\begin{aligned} \|\boldsymbol{\mathcal{F}}(\bar{\nabla}_{h}\boldsymbol{u}_{h}) - \boldsymbol{\mathcal{F}}(\nabla\boldsymbol{u})\|_{2,\Omega}^{2} + m_{\varphi_{\boldsymbol{\beta}_{h}(\boldsymbol{u}_{h}),h}}(\boldsymbol{u}_{h}) \\ \lesssim \inf_{\boldsymbol{v}_{h}\in V_{h}} \left( \|\boldsymbol{\mathcal{F}}(\tilde{\nabla}_{h}\boldsymbol{v}_{h}) - \boldsymbol{\mathcal{F}}(\nabla\boldsymbol{u})\|_{2,\Omega}^{2} + m_{\varphi_{\boldsymbol{\beta}_{h}(\boldsymbol{u}_{h}),h}}(\boldsymbol{v}_{h}) \right) \,, \end{aligned}$$

where  $\boldsymbol{u}_h \in V_h$  is the discrete solution,  $\tilde{\nabla}_h \colon W^{1,p}(\mathcal{T}_h)^n \to L^p(\Omega)^{n \times d}$  is a suitable discrete gradient, and  $\boldsymbol{\mathcal{F}}$  and  $m_{\varphi_{\boldsymbol{\mathcal{B}}_h}(\boldsymbol{u}_h),h}$  are appropriate measures of the error related

to the  $(p, \delta)$ -structure of  $\boldsymbol{\mathcal{S}}$ ; here,  $V_h$  is typically a space of broken polynomials, i.e.,  $V_h := \mathbb{P}^k(\mathcal{T}_h)^n$ , on a triangulation  $\mathcal{T}_h$  of  $\Omega$ , which is meant to approximate the full space  $W^{1,p}(\Omega)^n$ . Crucially, when deriving the estimate (1.2) we only assume the natural regularity of the continuous problem; namely,  $\boldsymbol{u} \in W_0^{1,p}(\Omega)^n$  and  $\boldsymbol{f} \in W^{-1,p'}(\Omega)^n$ . Then, as a corollary we obtain convergence rates, depending on additional regularity conditions.

The main issue with classical approaches based on Strang's Lemma (cf. [37]; see also [7, p. 106] and [17, Sec. 2.3]) or similar tools (cf. [14]) when deriving error estimates for non-conforming discretisations, is that they rely either on integratingby-parts (and, e.g., requiring that div  $\mathcal{S}(\nabla u)$  is an integrable function) or on assuming that traces of  $\mathcal{S}(\nabla u)$  are well-defined on the mesh edges to handle consistency in the jump terms. The first work that got around the assumption of additional unnatural regularity is that of Gudi (cf. [20]), where the author proved, using tools from a posteriori error analysis, the following estimate for the Dirichlet problem, assuming just  $u \in W_0^{1,2}(\Omega)^n$ :

(1.3) 
$$\|\boldsymbol{u}-\boldsymbol{u}_h\|_{1,h} \lesssim \inf_{\boldsymbol{v}_h \in V_h} \|\boldsymbol{u}-\boldsymbol{v}_h\|_{1,h} + \operatorname{osc}_h(\boldsymbol{f}),$$

where  $\|\cdot\|_{1,h}$  is a broken Sobolev norm and  $\operatorname{osc}_h(f)$  is a measure for the oscillation of  $f \in L^2(\Omega)^n$ . Such estimates are in the literature often qualified as being of *minimal regularity*, and the idea has been extended to various other contexts; see, e.g., [10, 22, 9, 21, 30, 2, 31, 3] and, in particular, [25] for systems of *p*-Dirichlet type. While this is certainly an improvement over the classical approach, it should be noted that such estimates are not quite minimal in their regularity assumptions, since an additional assumption on the data is needed, namely  $-\Delta u = f \in L^2(\Omega)^n$ . In contrast, we strive for minimal regularity estimates which entail the equivalence of the error and the distance to  $V_h$ .

A whole theory dealing with the characterisation of truly quasi-optimal discretisations of symmetric and elliptic linear problems in  $W_0^{1,2}(\Omega)^n$  was developed in [38, 40, 39] (see also [41, 29, 28] for similar results for the Stokes system). In those works, the authors established that quasi-optimality is achieved exactly when the discretisation is *fully algebraically consistent* (i.e., if the exact solution belongs to the discrete space, then it coincides with the discrete solution), and *fully stable* (i.e., the map  $(\mathbf{f} \mapsto \mathbf{u}_h) \colon W^{-1,2}(\Omega)^n \to V_h$  is well-defined and bounded). In particular, it is necessary that the scheme is *entire*, meaning that it is well-defined for general forcing terms  $\mathbf{f} \in W^{-1,2}(\Omega)^n$ . This is achieved by working with modified schemes of the form: Find  $\mathbf{u}_h \in V_h$  such that for every  $\mathbf{v}_h \in V_h$ , it holds that

(1.4) 
$$(\nabla_h \boldsymbol{u}_h, \nabla \boldsymbol{\mathcal{E}}_h \boldsymbol{v}_h)_{\Omega} = \langle \boldsymbol{f}, \boldsymbol{\mathcal{E}}_h \boldsymbol{v}_h \rangle_{W_0^{1,p}(\Omega)}$$

where  $\boldsymbol{\mathcal{E}}_h: V_h \to W_0^{1,2}(\Omega)$  is a bounded operator (a so-called *smoothing operator*) leaving  $V_h \cap W_0^{1,2}(\Omega)$  invariant; see also [18], where  $\boldsymbol{\mathcal{E}}_h: V_h \to W_0^{1,2}(\Omega)$  is applied to the unknown  $\boldsymbol{u}_h \in V_h$  as well. In order to obtain a quasi-optimal scheme, the smoothing operator is constructed in such a way that it preserves certain moments. More precisely, in the DG setting, for every  $\boldsymbol{z}_h \in V_h$ , one has that

(1.5a) 
$$(\boldsymbol{q}_F, \boldsymbol{\mathcal{E}}_h \boldsymbol{z}_h)_F = (\boldsymbol{q}_F, \{\!\!\{\boldsymbol{z}_h\}\!\!\})_F$$
 for all  $F \in \Gamma_h^i, \ \boldsymbol{q}_F \in \mathbb{P}^{k-1}(F),$ 

(1.5b) 
$$(\boldsymbol{q}_K, \boldsymbol{\mathcal{E}}_h \boldsymbol{z}_h)_K = (\boldsymbol{q}_K, \boldsymbol{z}_h)_K$$
 for all  $K \in \mathcal{T}_h$ ,  $\boldsymbol{q}_K \in \mathbb{P}^{k-2}(K)$ 

where  $\{\!\!\{\cdot\}\!\!\}$  stands for facet average,  $\Gamma_h^i$  is the set of internal facets, and we set  $\mathbb{P}^{-1}(K) \coloneqq \emptyset$ ; see section 2 for more details on the DG notation.

An important consequence of the preservation properties (1.5) (at least in the linear case) is that in practice one does not need to implement the smoothing operator on the left-hand side of (1.4). To see this, take an arbitrary element  $\mathbf{T}_h \in \Sigma_h := \mathbb{P}^{k-1}(\mathcal{T}_h)^{n \times d}$  (which will represent the flux). Then, using the preservation properties (1.5), for every  $\mathbf{z}_h \in V_h$ , integration-by-parts yields that

$$(\mathbf{T}_{h}, \nabla \boldsymbol{\mathcal{E}}_{h} \boldsymbol{z}_{h})_{\Omega} = -(\operatorname{div}_{h} \mathbf{T}_{h}, \boldsymbol{\mathcal{\mathcal{E}}}_{h} \boldsymbol{z}_{h})_{\Omega} + (\llbracket \mathbf{T}_{h} \boldsymbol{n} \rrbracket, \boldsymbol{\mathcal{\mathcal{E}}}_{h} \boldsymbol{z}_{h})_{\Gamma_{h}^{i}} + (\llbracket \mathbf{T}_{h} \rrbracket, \llbracket \boldsymbol{\mathcal{E}}_{h} \boldsymbol{z}_{h} \boldsymbol{n} \rrbracket)_{\Gamma_{h}}$$

$$(1.6) = -(\operatorname{div}_{h} \mathbf{T}_{h}, \boldsymbol{z}_{h})_{\Omega} + (\llbracket \mathbf{T}_{h} \boldsymbol{n} \rrbracket, \boldsymbol{z}_{h})_{\Gamma_{h}^{i}}$$

$$= (\mathbf{T}_{h}, \boldsymbol{\mathcal{G}}_{h} \boldsymbol{z}_{h})_{\Omega},$$

where  $\boldsymbol{\mathcal{G}}_h: W^{1,p}(\mathcal{T}_h)^n \to L^p(\Omega)^{n \times d}$  is the usual DG gradient (cf. subsection 2.2.2). In other words, if the fluxes are broken polynomials of one degree less than polynomial degree of the solution  $\boldsymbol{u}_h \in V_h$ , the smoothing operator needs to be implemented only in the right-hand side (akin to modifying only the forcing term as  $\boldsymbol{\mathcal{E}}_h^* \boldsymbol{f} \in V_h^*$ , where  $\boldsymbol{\mathcal{E}}_h^*: (W^{1,p}(\mathcal{T}_h)^n)^* \to V_h^*$  is the adjoint to  $\boldsymbol{\mathcal{E}}_h: V_h \to W^{1,p}(\mathcal{T}_h)^n$ ).

In this work, we first prove a best-approximation result of the type (1.2) for a non-linear analogue of the problem (1.4) (cf. Theorem 4.6); since we do not have a Hilbert structure at our disposal (in contrast to the works [38, 40, 39]), our approach is based on working directly with an error equation. This is to our knowledge the first best-approximation result for non-conforming discretisations of non-linear systems of *p*-Dirichlet type that is genuinely minimal in its regularity assumptions. One disadvantage of the scheme in the non-linear case is that for polynomial degree  $k \ge 2$ , the argument (1.6) cannot be employed (since non-linear functions of elementwise polynomials are in general not element-wise polynomials) and it is, therefore, necessary to implement the smoothing operator also in the left-hand side. As an alternative to this, we propose also a mixed discretisation in which the flux variable belongs, by construction, to  $\Sigma_h = \mathbb{P}^{k-1}(\mathcal{T}_h)^{n\times d}$  and, as a result, (1.6) applies. For this mixed discretisation, we prove a minimal regularity error estimate as well (cf. Theorem 5.5).

This paper is organized as follows: In section 2, we introduce the employed notation, define relevant function spaces, basic assumptions on S, and the used discrete operators. In section 3, we recall the construction of the smoothing operator and prove an interpolation error estimate in terms of N-functions. In section 4, we introduce the continuous and the discrete primal problem, establish their well-posedness and the validity of a quasi-optimal (a priori) error estimate of the form (1.2). Then, from the latter, we deduce the convergence of the discrete primal problem under minimal regularity assumptions and derive fractional error decay rates given fractional regularity assumptions expressed in Nikolskiĭ spaces. In addition, aided by the quasi-optimal error estimate, we carry out an ansatz class competition that shows that the approximation capabilities of LDG and IIDG approximations and continuous Lagrange approximations of the problem (1.1) are comparable. In section 5, we introduce the continuous and the discrete mixed problem, establish their well-posedness and the validity of a quasi-optimal (a priori) error estimate in a similar form as (1.2). In section 6, we carry out numerical experiments to complement the theoretical findings.

2. Preliminaries. We employ c, C > 0 to denote generic constants, that may change from line to line and may depend only on the polynomial degree k, the chunk-iness  $\omega_0$ , the characteristics of  $\boldsymbol{S}$ , and the dimensions n, d.

Moreover, we write  $f \leq g$  if there exist a constant c > 0 such that  $f \leq cg$ , and  $f \sim g$  if and only if there exists constants c, C > 0 such that  $cf \leq g \leq Cf$ .

Throughout the entire paper, let  $\Omega \subseteq \mathbb{R}^d$ ,  $d \in \mathbb{N}$ , is a bounded, polyhedral Lipschitz domain and  $M \subseteq \mathbb{R}^d$ ,  $d \in \mathbb{N}$ , a (Lebesgue) measurable set. Then, for every  $k \in \mathbb{N}$  and  $p \in [1, \infty]$ , we employ the customary Lebesgue spaces  $(L^p(M), \|\cdot\|_{p,M})$  and Sobolev spaces  $(W^{k,p}(M), \|\cdot\|_{k,p,M})$ . The space  $W_0^{1,p}(M)$  is defined as the closure of the vector space of smooth and compactly supported functions  $C_c^{\infty}(M)$  in  $W^{1,p}(M)$ . We equip  $W_0^{1,p}(M)$  with the norm  $\|\nabla \cdot\|_{p,M}$ .

We always denote vector-valued functions by boldface letters and tensor-valued functions by capital boldface letters. The Euclidean scalar product between two vectors  $\boldsymbol{a} = (a_1, \ldots, a_n)^{\top}, \boldsymbol{b} = (b_1, \ldots, b_n)^{\top} \in \mathbb{R}^n, n \in \mathbb{N}$ , is defined by  $\boldsymbol{a} \cdot \boldsymbol{b} \coloneqq \sum_{i=1}^n a_i b_i$ , while the Frobenius scalar product between two tensors  $\boldsymbol{A} = (A_{ij})_{1 \leq i \leq n; 1 \leq j \leq \ell}, \boldsymbol{B} = (B_{ij})_{1 \leq i \leq n; 1 \leq j \leq \ell} \in \mathbb{R}^{n \times \ell}, n, \ell \in \mathbb{N}$ , is defined by  $\boldsymbol{A} : \boldsymbol{B} \coloneqq \sum_{i=1}^n \sum_{j=1}^\ell A_{ij} B_{ij}$ . Then, the Euclidean norm of a vector  $\boldsymbol{a} \in \mathbb{R}^n, n \in \mathbb{N}$ , is defined by  $|\boldsymbol{a}| \coloneqq \sqrt{\boldsymbol{a} \cdot \boldsymbol{a}}$ , while the Frobenius norm of a tensor  $\boldsymbol{A} \in \mathbb{R}^{n \times \ell}, n, \ell \in \mathbb{N}$ , is defined by  $|\boldsymbol{A}| \coloneqq \sqrt{\boldsymbol{A} \cdot \boldsymbol{A}}$ .

The mean value of a locally integrable function f is denoted by  $\langle f \rangle_M \coloneqq \int_M f \, dx$  $\coloneqq \frac{1}{|M|} \int_M f \, dx$ . Moreover, we employ the notation  $(f,g)_M \coloneqq \int_M fg \, dx$ , whenever the right-hand side is well-defined.

Drawing from the theory of Orlicz spaces  $L^{\psi}(M)$  (cf. [33]) and generalized Orlicz spaces  $L^{\psi(\cdot)}(M)$  (cf. [24]), we employ N-functions  $\psi \colon \mathbb{R}^{\geq 0} \to \mathbb{R}^{\geq 0}$  and generalized N-functions  $\psi \colon M \times \mathbb{R}^{\geq 0} \to \mathbb{R}^{\geq 0}$ , i.e.,  $\psi$  is a Carathéodory function such that  $\psi(x, \cdot)$  is an N-function for a.e.  $x \in M$ , respectively. The modular is defined via  $\rho_{\psi,M}(f) \coloneqq \int_M \psi(|f|) \, dx$  if  $\psi$  is an N-function, and via  $\rho_{\psi,M}(f) \coloneqq \int_M \psi(x, |f(x)|) \, dx$ , if  $\psi$  is a generalized N-function. An N-function  $\psi$  satisfies the  $\Delta_2$ -condition (in short,  $\psi \in \Delta_2$ ), if there exists K > 2 such that for every  $t \geq 0$ , it holds that  $\psi(2t) \leq K \psi(t)$ . We denote the smallest such constant by  $\Delta_2(\psi) > 0$ . We define the (convex) conjugate (generalized) N-function  $\psi^* \colon M \times \mathbb{R}^{\geq 0} \to \mathbb{R}^{\geq 0}$  via  $\psi^*(x,t) \coloneqq \sup_{s \geq 0} ts - \psi(x,s)$  for all  $t \geq 0$  and a.e.  $x \in M$ . If  $\psi, \psi^* \in \Delta_2$ , then we have that

(2.1) 
$$\psi^* \circ \psi' \sim \psi \,,$$

with constants depending only on  $\Delta_2(\psi), \Delta_2(\psi^*) > 0$ . We will also need the  $\varepsilon$ -Young inequality: for every  $\varepsilon > 0$ , there exits a constant  $c_{\varepsilon} > 0$ , depending only on  $\Delta_2(\psi), \Delta_2(\psi^*) < \infty$ , such that for every  $s, t \ge 0$ , it holds that

(2.2) 
$$ts \le \varepsilon \psi(t) + c_{\varepsilon} \psi^*(s).$$

**2.1.** Basic properties of the non-linear operator. Throughout the paper, we always assume that the non-linear operator  $\boldsymbol{S}$  has  $(p, \delta)$ -structure. A detailed discussion and proofs can be found, e.g., in [12, 35].

For  $p \in (1,\infty)$  and  $\delta \ge 0$ , we define a special N-function  $\varphi = \varphi_{p,\delta} \colon \mathbb{R}^{\ge 0} \to \mathbb{R}^{\ge 0}$  via

(2.3) 
$$\varphi(t) \coloneqq \int_0^t \varphi'(s) \, \mathrm{d}s, \quad \text{where} \quad \varphi'(t) \coloneqq (\delta + t)^{p-2} t, \quad \text{for all } t \ge 0.$$

The properties of  $\varphi$  are discussed in detail in [12, 35, 27]. An important tool in our analysis play *shifted N-functions*  $\{\psi_a\}_{a\geq 0}$ , cf. [13, 35]. For a given N-function  $\psi \colon \mathbb{R}^{\geq 0} \to \mathbb{R}^{\geq 0}$  we define the family of shifted N-functions  $\psi_a \colon \mathbb{R}^{\geq 0} \to \mathbb{R}^{\geq 0}$ ,  $a \geq 0$ , via

(2.4) 
$$\psi_a(t) \coloneqq \int_0^t \psi_a'(s) \,\mathrm{d}s$$
, where  $\psi_a'(t) \coloneqq \psi'(a+t) \frac{t}{a+t}$ , for all  $t \ge 0$ .

DEFINITION 2.1 (( $p, \delta$ )-structure). Let  $\boldsymbol{\mathcal{S}} \in C^0(\mathbb{R}^{n \times d}, \mathbb{R}^{n \times d})$  satisfy  $\boldsymbol{\mathcal{S}}(\mathbf{0}) = \mathbf{0}$ . Then, we say that  $\boldsymbol{\mathcal{S}}$  has  $(p, \delta)$ -structure if for some  $p \in (1, \infty)$ ,  $\delta \in [0, \infty)$ , and the N-function  $\varphi = \varphi_{p,\delta}$  (cf. (2.3)), there exist constants  $C_0, C_1 > 0$  such that

(2.5) 
$$\begin{aligned} \left( \boldsymbol{\mathcal{S}}(\mathbf{Q}) - \boldsymbol{\mathcal{S}}(\mathbf{P}) \right) : \left( \mathbf{Q} - \mathbf{P} \right) &\geq C_0 \,\varphi_{|\mathbf{Q}|}(|\mathbf{Q} - \mathbf{P}|) \,, \\ \left| \boldsymbol{\mathcal{S}}(\mathbf{Q}) - \boldsymbol{\mathcal{S}}(\mathbf{P}) \right| &\leq C_1 \,\varphi_{|\mathbf{Q}|}'(|\mathbf{Q} - \mathbf{P}|) \end{aligned}$$

are satisfied for all  $\mathbf{Q}, \mathbf{P} \in \mathbb{R}^{n \times d}$  with  $\mathbf{Q} \neq \mathbf{0}$ . The constants  $C_0, C_1 > 0$  and  $p \in (1, \infty)$  are called the characteristics of  $\boldsymbol{S}$ .

REMARK 2.2. (i) Assume that  $\boldsymbol{S}$  has  $(p, \delta)$ -structure for some  $\delta \in [0, \delta_0]$ . Then, if not otherwise stated, the constants in the estimates depend only on the characteristics of  $\boldsymbol{S}$  and on  $\delta_0 \geq 0$ , but are independent of  $\delta \geq 0$ .

(ii) Let  $\varphi$  be defined in (2.3) and  $\{\varphi_a\}_{a\geq 0}$  be the corresponding family of the shifted N-functions. Then, the operators  $\boldsymbol{\mathcal{S}}_a : \mathbb{R}^{n\times d} \to \mathbb{R}^{n\times d}_{\text{sym}}$ ,  $a \geq 0$ , for every  $a \geq 0$  and  $\boldsymbol{\mathsf{Q}} \in \mathbb{R}^{n\times d}$ , defined via

(2.6) 
$$\boldsymbol{\mathcal{S}}_{a}(\mathbf{Q}) \coloneqq \frac{\varphi_{a}'(|\mathbf{Q}|)}{|\mathbf{Q}|} \mathbf{Q} = (\delta + a + |\mathbf{Q}|)^{p-2} \mathbf{Q},$$

have  $(p, \delta + a)$ -structure. In this case, the characteristics of  $S_a$  depend only on  $p \in (1, \infty)$  and are independent of  $\delta \ge 0$  and  $a \ge 0$ .

(iii) Note that  $\varphi_a(t) \sim (\delta + a + t)^{p-2}t^2$  and  $(\varphi_a)^*(t) \sim ((\delta + a)^{p-1} + t)^{p'-2}t^2$ uniformly with respect to  $t, a \geq 0$ . The families  $\{\varphi_a\}_{a\geq 0}$  and  $\{(\varphi_a)^*\}_{a\geq 0}$  satisfy the  $\Delta_2$ -condition uniformly with respect to  $a \geq 0$ , with  $\Delta_2(\varphi_a) \lesssim 2^{\max\{2,p\}}$  and  $\Delta_2((\varphi_a)^*) \lesssim 2^{\max\{2,p'\}}$ , respectively. Moreover, for all  $0 \leq a \leq b$ , we have that for every  $t \geq 0$ , it holds that  $(\varphi_a)^*(t) \geq (\varphi_b)^*(t), \varphi_a(t) \leq \varphi_b(t)$  if  $p \geq 2$  and  $(\varphi_a)^*(t) \leq (\varphi_b)^*(t), \varphi_a(t) \geq \varphi_b(t)$  if  $p \leq 2$ .

Closely related to the non-linear operator  $\boldsymbol{\mathcal{S}}$  with  $(p, \delta)$ -structure are the non-linear operators  $\boldsymbol{\mathcal{F}}, \boldsymbol{\mathcal{F}}^* \colon \mathbb{R}^{n \times d} \to \mathbb{R}^{n \times d}$ , for every  $\mathbf{Q} \in \mathbb{R}^{n \times d}$ , defined via

(2.7) 
$$\begin{aligned} \mathcal{F}(\mathbf{Q}) &\coloneqq (\delta + |\mathbf{Q}|)^{\frac{p}{2}} \mathbf{Q}, \\ \mathcal{F}^*(\mathbf{Q}) &\coloneqq (\delta^{p-1} + |\mathbf{Q}|)^{\frac{p'-2}{2}} \mathbf{Q} \end{aligned}$$

The connections between  $\mathcal{S}, \mathcal{F}, \mathcal{F}^* \colon \mathbb{R}^{n \times d} \to \mathbb{R}^{n \times d}$  and  $\varphi_a, (\varphi_a)^* \colon \mathbb{R}^{\geq 0} \to \mathbb{R}^{\geq 0}, a \geq 0$ , are best explained by the following result (cf. [12, 35, 14]).

PROPOSITION 2.3. Let **S** have  $(p, \delta)$ -structure, let  $\varphi$  be defined in (2.3), and let  $\mathcal{F}, \mathcal{F}^*$  be defined in (2.7). Then, uniformly with respect to  $\mathbf{Q}, \mathbf{P} \in \mathbb{R}^{n \times d}$ , we have that

(2.8)  
$$\begin{aligned} \left( \boldsymbol{\mathcal{S}}(\mathbf{Q}) - \boldsymbol{\mathcal{S}}(\mathbf{P}) \right) &: (\mathbf{Q} - \mathbf{P}) \sim \left| \boldsymbol{\mathcal{F}}(\mathbf{Q}) - \boldsymbol{\mathcal{F}}(\mathbf{P}) \right|^2 \\ &\sim \varphi_{|\mathbf{Q}|}(|\mathbf{Q} - \mathbf{P}|) \\ &\sim (\varphi_{|\mathbf{Q}|})^* (|\boldsymbol{\mathcal{S}}(\mathbf{Q}) - \boldsymbol{\mathcal{S}}(\mathbf{P})|) \\ &\sim (\varphi^*)_{|\boldsymbol{\mathcal{S}}(\mathbf{Q})|} (|\boldsymbol{\mathcal{S}}(\mathbf{Q}) - \boldsymbol{\mathcal{S}}(\mathbf{P})|) \end{aligned}$$

(2.9) 
$$|\boldsymbol{\mathcal{S}}(\mathbf{Q}) - \boldsymbol{\mathcal{S}}(\mathbf{P})| \sim \varphi'_{|\mathbf{Q}|}(|\mathbf{Q} - \mathbf{P}|),$$

(2.10) 
$$\left|\boldsymbol{\mathcal{F}}^{*}(\mathbf{Q}) - \boldsymbol{\mathcal{F}}^{*}(\mathbf{P})\right|^{2} \sim (\varphi^{*})_{|\mathbf{Q}|}(|\mathbf{Q} - \mathbf{P}|),$$

(2.11) 
$$|\boldsymbol{\mathcal{F}}^*(\boldsymbol{\mathcal{S}}(\mathbf{P})) - \boldsymbol{\mathcal{F}}^*(\boldsymbol{\mathcal{S}}(\mathbf{Q}))|^2 \sim |\boldsymbol{\mathcal{F}}(\mathbf{P}) - \boldsymbol{\mathcal{F}}(\mathbf{Q})|^2$$

The constants in (2.8)–(2.11) depend only on the characteristics of **S**.

REMARK 2.4. For the operators  $\boldsymbol{\mathcal{S}}_a : \mathbb{R}^{n \times d} \to \mathbb{R}^{n \times d}_{\text{sym}}$ ,  $a \geq 0$ , defined in (2.6), the assertions of Proposition 2.3 hold with  $\varphi : \mathbb{R}^{\geq 0} \to \mathbb{R}^{\geq 0}$  replaced by  $\varphi_a : \mathbb{R}^{\geq 0} \to \mathbb{R}^{\geq 0}$ ,  $a \geq 0$ .

The following results can be found in [13, 35].

LEMMA 2.5 (Change of shift). Let  $\varphi$  be defined in (2.3) and let  $\mathcal{F}$  be defined in (2.7). Then, for each  $\varepsilon > 0$ , there exists  $c_{\varepsilon} \ge 1$  (depending only on  $\varepsilon > 0$  and p) such that for every  $\mathbf{Q}, \mathbf{P} \in \mathbb{R}^{n \times d}$  and  $t \ge 0$ , it holds that

$$\begin{aligned} \varphi_{|\mathbf{P}|}(t) &\leq c_{\varepsilon} \,\varphi_{|\mathbf{Q}|}(t) + \varepsilon \,\left| \mathcal{F}(\mathbf{P}) - \mathcal{F}(\mathbf{Q}) \right|^{2},\\ (\varphi_{|\mathbf{P}|})^{*}(t) &\leq c_{\varepsilon} \,(\varphi_{|\mathbf{Q}|})^{*}(t) + \varepsilon \,\left| \mathcal{F}(\mathbf{P}) - \mathcal{F}(\mathbf{Q}) \right|^{2} \end{aligned}$$

**2.2.** Mesh regularity. Throughout the entire paper,  $\{\mathcal{T}_h\}_{h>0}$  always denotes a family of conforming triangulations of  $\overline{\Omega} \subseteq \mathbb{R}^d$ ,  $d \geq 2$ , cf. [11], consisting of *d*dimensional closed simplices *K*. The parameter h > 0, refers to the maximal meshsize of  $\mathcal{T}_h$ , i.e., if we define  $h_K := \operatorname{diam}(K)$  for all  $K \in \mathcal{T}_h$ , then  $h := \max_{K \in \mathcal{T}_h} h_K$ . For simplicity, we assume that  $h \leq 1$ . For a simplex  $K \in \mathcal{T}_h$ , we denote by  $\rho_K > 0$ , the supremum of diameters of inscribed balls. We assume that there exists a constant  $\omega_0 > 0$ , independent of h > 0, such that  $h_K \rho_K^{-1} \leq \omega_0$  for every  $K \in \mathcal{T}_h$ . The smallest such constant is called the chunkiness of  $\{\mathcal{T}_h\}_{h>0}$ .

We define the sets of (d-1)-dimensional faces  $\Gamma_h$ , interior faces  $\Gamma_h^i$ , and boundary faces  $\Gamma_h^\partial$  of the partition  $\mathcal{T}_h$  via

$$\begin{split} \Gamma_h^i &\coloneqq \{K \cap K' \mid K, K' \in \mathcal{T}_h, \dim_{\mathscr{H}}(K \cap K') = d - 1\}, \\ \Gamma_h^\partial &\coloneqq \{K \cap \partial\Omega \mid K \in \mathcal{T}_h, \dim_{\mathscr{H}}(K \cap \partial\Omega) = d - 1\}, \\ \Gamma_h &\coloneqq \Gamma_h^i \cup \Gamma_h^\partial, \end{split}$$

where for every subset  $S \subseteq \mathbb{R}^d$ , we denote by  $\dim_{\mathscr{H}}(S) \coloneqq \inf\{d' \ge 0 \mid \mathscr{H}^{d'}(S) = 0\}$ , the Hausdorff dimension  $(\mathscr{H}^{d'}(S)$  represents here the d'-dimensional Hausdorff measure of S). The (local) mesh-size function  $h_{\mathcal{T}} \colon \overline{\Omega} \to \mathbb{R}$  is defined via  $h_{\mathcal{T}}|_K \coloneqq h_K$  for all  $K \in \mathcal{T}_h$ . The (local) face-size function  $h_{\Gamma} \colon \Gamma_h \to \mathbb{R}$  is defined via  $h_{\Gamma}|_F \coloneqq h_F \coloneqq$  diam(F) for all  $F \in \Gamma_h$ .

**2.2.1. Broken function spaces and projectors.** For every  $k \in \mathbb{N}_0$  and  $K \in \mathcal{T}_h$ , we denote by  $\mathbb{P}^k(K)$ , the space of polynomials of degree at most k on K. Then, for given  $k \in \mathbb{N}_0$ , we define the space of broken polynomials of global degree at most k via

$$\mathbb{P}^{k}(\mathcal{T}_{h}) \coloneqq \left\{ v_{h} \in L^{\infty}(\Omega) \mid v_{h}|_{K} \in \mathbb{P}^{k}(K) \text{ for all } K \in \mathcal{T}_{h} \right\},\$$

and the space of broken polynomials via  $\mathbb{P}(\mathcal{T}_h) := \bigcup_{k \in \mathbb{N}} \mathbb{P}^k(\mathcal{T}_h)$ . In addition, we define the space of element-wise continuous functions via

$$C^{0}(\mathcal{T}_{h}) \coloneqq \left\{ w_{h} \in L^{\infty}(\Omega) \mid w_{h}|_{K} \in C^{0}(K) \text{ for all } K \in \mathcal{T}_{h} \right\},$$

and for given  $p \in (1, \infty)$ , we define the broken Sobolev space via

$$W^{1,p}(\mathcal{T}_h) \coloneqq \left\{ w_h \in L^p(\Omega) \mid w_h \mid_K \in W^{1,p}(K) \text{ for all } K \in \mathcal{T}_h \right\}.$$

For each  $\boldsymbol{w}_h \in W^{1,p}(\mathcal{T}_h)^n$ , we denote by  $\nabla_h \boldsymbol{w}_h \in L^p(\Omega)^{n \times d}$  the *local gradient*: for every  $K \in \mathcal{T}_h$  it is defined via  $(\nabla_h \boldsymbol{w}_h)|_K \coloneqq \nabla(\boldsymbol{w}_h|_K)$  for all  $K \in \mathcal{T}_h$ . For each  $K \in \mathcal{T}_h$ ,  $\boldsymbol{w}_h \in W^{1,p}(\mathcal{T}_h)^n$  admits a trace  $\operatorname{tr}^K(\boldsymbol{w}_h) \in L^p(\partial K)^n$ . For each face  $F \in \Gamma_h$  of a given element  $K \in \mathcal{T}_h$ , we define this interior trace via  $\operatorname{tr}_F^K(\boldsymbol{w}_h) \in L^p(F)^n$ . Then, given some multiplication operator  $\odot : \mathbb{R}^n \times \mathbb{R}^d \to \mathbb{R}^\ell$ ,  $\ell \in \mathbb{N}$ , for every  $\boldsymbol{w}_h \in W^{1,p}(\mathcal{T}_h)^n$ and interior faces  $F \in \Gamma_h^i$  shared by adjacent elements  $K_F^-, K_F^+ \in \mathcal{T}_h$ , we denote by

$$\{\!\!\{\boldsymbol{w}_h\}\!\!\}_F \coloneqq \frac{1}{2} \left( \operatorname{tr}_F^{K^+}(\boldsymbol{w}_h) + \operatorname{tr}_F^{K^-}(\boldsymbol{w}_h) \right) \in L^p(F)^n, \\ [\![\boldsymbol{w}_h \odot \boldsymbol{n}]\!]_F \coloneqq \operatorname{tr}_F^{K^+}(\boldsymbol{w}_h) \odot \boldsymbol{n}_F^+ + \operatorname{tr}_F^{K^-}(\boldsymbol{w}_h) \odot \boldsymbol{n}_F^- \in L^p(F)^\ell,$$

the average and jump, respectively, of  $\boldsymbol{w}_h$  on F. Moreover, for every  $\boldsymbol{w}_h \in W^{1,p}(\mathcal{T}_h)^n$ and boundary faces  $F \in \Gamma_h^\partial$ , we define boundary averages and boundary jumps, respectively, via

$$\{\!\!\{ \boldsymbol{w}_h \}\!\!\}_F \coloneqq \operatorname{tr}_F^{\Omega}(\boldsymbol{w}_h) \in L^p(F)^n , \| \!\!\{ \boldsymbol{w}_h \odot \boldsymbol{n} \|\!\!\}_F \coloneqq \operatorname{tr}_F^{\Omega}(\boldsymbol{w}_h) \odot \boldsymbol{n} \in L^p(F)^\ell .$$

If there is no danger of confusion, we will omit the index  $F \in \Gamma_h$ ; in particular, if we interpret jumps and averages as global functions defined on the whole of  $\Gamma_h$ . In addition, for every  $\boldsymbol{w}_h \in W^{1,p}(\mathcal{T}_h)^n$ , we introduce the DG norm via

$$\|oldsymbol{w}_h\|_{h,p}\coloneqq ig(\|
abla_holdsymbol{w}_h\|_{p,\Omega}^p+ig\|harphi_\Gamma^{-1/p'}[\![oldsymbol{w}_h\otimesoldsymbol{n}]]\!ig\|_{p,\Gamma_h}^pig)^{1/p}$$

which turns  $W^{1,p}(\mathcal{T}_h)^n$  into a Banach space. We denote by  $\Pi_h^k \colon L^1(\Omega) \to \mathbb{P}^k(\mathcal{T}_h)$ , the (local)  $L^2$ -projection onto  $\mathbb{P}^k(\mathcal{T}_h)$ , defined for every  $v \in L^1(\Omega)$  via  $(\Pi_h^k v, v_h)_{\Omega} = (v, v_h)_{\Omega}$  for all  $v_h \in \mathbb{P}^k(\mathcal{T}_h)$ . Analogously, we define the (local)  $L^2$ -projections into  $\mathbb{P}^k(\mathcal{T}_h)^n$ , i.e.,  $\Pi_h^k \colon L^1(\Omega)^n \to \mathbb{P}^k(\mathcal{T}_h)^n$ , and into  $\mathbb{P}^k(\mathcal{T}_h)^{n \times d}$ , i.e.,  $\Pi_h^k \colon L^1(\Omega)^{n \times d} \to \mathbb{P}^k(\mathcal{T}_h)^{n \times d}$ .

**2.2.2. DG gradient and jump operator.** For every  $k \in \mathbb{N}$ , we define the (global) jump lifting operator  $\mathcal{R}_h^k \colon W^{1,p}(\mathcal{T}_h)^n \to \mathbb{P}^{k-1}(\mathcal{T}_h)^{n \times d}$  (using Riesz representation) for every  $\boldsymbol{w}_h \in W^{1,p}(\mathcal{T}_h)^n$  via

$$(\mathcal{R}_h w_h, \mathsf{T}_h)_\Omega \coloneqq \langle \llbracket w_h \otimes \mathbf{n} \rrbracket, \llbracket \mathsf{T}_h 
brace 
angle_{\Gamma_h} \quad ext{ for all } \mathsf{T}_h \in \mathbb{P}^{k-1}(\mathcal{T}_h)^{n imes d}.$$

Then, for every  $k \in \mathbb{N}_0$ , the *DG* gradient  $\mathcal{G}_h : W^{1,p}(\mathcal{T}_h)^n \to L^p(\Omega)^{n \times d}$ , for every  $\boldsymbol{w}_h \in W^{1,p}(\mathcal{T}_h)^n$ , is defined via

$$\boldsymbol{\mathcal{G}}_h \boldsymbol{w}_h \coloneqq 
abla_h \boldsymbol{w}_h - \boldsymbol{\mathcal{R}}_h \boldsymbol{w}_h \quad ext{ in } L^p(\Omega)^{n imes d}$$

Owing to [14, (A.26)–(A.28)], there exists a constant c > 0 such that  $\boldsymbol{w}_h \in W^{1,p}(\mathcal{T}_h)^n$ , it holds that

(2.12) 
$$c^{-1} \|\boldsymbol{w}_h\|_{h,p} \leq \left( \|\boldsymbol{\mathcal{G}}_h \boldsymbol{w}_h\|_{p,\Omega}^p + \|h_{\Gamma}^{-1/p'}[\![\boldsymbol{w}_h \otimes \boldsymbol{n}]\!]\|_{p,\Gamma_h}^p \right)^{1/p} \leq c \|\boldsymbol{w}_h\|_{h,p} .$$

For a generalized N-function  $\psi \colon \Omega \times \mathbb{R}^{\geq 0} \to \mathbb{R}^{\geq 0}$ , the pseudo-modular<sup>1</sup>  $m_{\psi,h} \colon W^{1,\psi}(\mathcal{T}_h)^n \to \mathbb{R}^{\geq 0}$ , for every  $\boldsymbol{w}_h \in W^{1,\psi}(\mathcal{T}_h)^n$  is defined via

$$m_{\psi,h}(\boldsymbol{w}_h) \coloneqq \sum_{F \in \Gamma_h} h_F \int_F \psi(h_F^{-1}\llbracket \boldsymbol{w}_h \otimes \mathbf{n} \rrbracket) \,\mathrm{d}s$$

For  $\psi = \varphi_{p,0}$ , it holds that  $m_{\psi,h}(\boldsymbol{w}_h) = \|h_{\Gamma}^{-1/p'}[\boldsymbol{w}_h \otimes \mathbf{n}]\|_{p,\Gamma_h}^p$  for all  $\boldsymbol{w}_h \in W^{1,\psi}(\mathcal{T}_h)^n$ .

<sup>&</sup>lt;sup>1</sup>The definition of a pseudo-modular can be found in [32]. We extend the notion of DG Sobolev spaces to DG Sobolev–Orlicz spaces  $W^{1,\psi}(\mathcal{T}_h) := \{w_h \in L^1(\Omega) \mid w_h \in W^{1,1}(K) \text{ with } \psi(\cdot, \nabla(w_h|_K)) \in L^1(K) \text{ for all } K \in \mathcal{T}_K\}.$ 

3. Construction of moment-preserving operators. We employ here the smoothing operator  $\mathcal{E}_h \coloneqq \mathcal{E}_{h,k} \colon C^0(\mathcal{T}_h)^n \to \mathbb{P}^{k+d}(\mathcal{T}_h)^n \cap W_0^{1,1}(\Omega)^n, k \in \mathbb{N}$ , introduced in [39]. The operator, for every  $\boldsymbol{w}_h \in C^0(\mathcal{T}_h)^n$ , is constructed as:

$$\boldsymbol{\mathcal{E}}_h \boldsymbol{w}_h \coloneqq \boldsymbol{\mathcal{A}}_h \boldsymbol{w}_h + \boldsymbol{\mathcal{B}}_h (\boldsymbol{w}_h - \boldsymbol{\mathcal{A}}_h \boldsymbol{w}_h) \qquad \text{in } \mathbb{P}^{k+d}(\mathcal{T}_h) \cap W_0^{1,p}(\Omega)^n \,,$$

where

$$\boldsymbol{\mathcal{B}}_h \boldsymbol{w}_h \coloneqq \boldsymbol{\mathcal{B}}_h^{(1)} \boldsymbol{w}_h + \boldsymbol{\mathcal{B}}_h^{(2)} (\boldsymbol{w}_h - \boldsymbol{\mathcal{B}}_h^{(1)} \boldsymbol{w}_h) \qquad ext{in } \mathbb{P}^{k+d}(\mathcal{T}_h) \cap W_0^{1,p}(\Omega)^n \, ,$$

and

$$\boldsymbol{\mathcal{A}}_{h} \coloneqq \boldsymbol{\mathcal{A}}_{h,k} \colon C^{0}(\mathcal{T}_{h})^{n} \to \mathbb{P}^{k}(\mathcal{T}_{h})^{n} \cap W_{0}^{1,1}(\Omega)^{n}, 
\boldsymbol{\mathcal{B}}_{h}^{(1)} \coloneqq \boldsymbol{\mathcal{B}}_{h,k}^{(1)} \colon C^{0}(\mathcal{T}_{h})^{n} \to \mathbb{P}^{k+d-1}(\mathcal{T}_{h})^{n} \cap W_{0}^{1,1}(\Omega)^{n}, 
\boldsymbol{\mathcal{B}}_{h}^{(2)} \coloneqq \boldsymbol{\mathcal{B}}_{h,k}^{(2)} \colon C^{0}(\mathcal{T}_{h})^{n} \to \mathbb{P}^{k+d}(\mathcal{T}_{h})^{n} \cap W_{0}^{1,1}(\Omega)^{n}$$

are defined via:

•  $\mathcal{A}_h$  (simplified nodal averaging with 1 dof): Denote by  $\mathcal{L}_k^{\text{int}}(\mathcal{T}_h)$  the set of interior Lagrange node on  $\mathcal{T}_h$  of degree k and for every  $y \in \mathcal{L}_k^{\text{int}}(\mathcal{T}_h)$  by  $\varphi_y^k \in \mathbb{P}^k(\mathcal{T}_h)$ , the corresponding basis function. In addition, for every  $y \in \mathcal{L}_k^{\text{int}}(\mathcal{T}_h)$  fix an arbitrary  $K_y \in \mathcal{T}_h$  such that  $y \in K_y$ . Then, the operator  $\mathcal{A}_h: C^0(\mathcal{T}_h)^n \to \mathbb{P}^k(\mathcal{T}_h) \cap W_0^{1,1}(\Omega)^n$ , for every  $w_h \in C^0(\mathcal{T}_h)^n$ , is defined via

$$\mathcal{A}_h \boldsymbol{w}_h \coloneqq \sum_{y \in \mathcal{L}_k^{\mathrm{int}}(\mathcal{T}_h)} (\boldsymbol{w}_h|_{K_y})(y) \varphi_y^k \quad ext{ in } \mathbb{P}^k(\mathcal{T}_h)^n \cap W_0^{1,1}(\Omega)^n \, .$$

•  $\boldsymbol{\mathcal{B}}_{h}^{(1)}$  (facet bubble smoother): Denote for  $F \in \Gamma_{h}$  by  $\mathcal{L}_{k-1}(F)$  the set of Lagrange nodes on F of degree k-1 and by  $\varphi_{F} := \varphi_{y_{1}}^{1} \cdot \ldots \cdot \varphi_{y_{d}}^{1} \in \mathbb{P}^{d}(F) \cap$  $W_{0}^{1,1}(F)$ , where  $y_{1}, \ldots, y_{d} \in \mathcal{L}_{1}(F)$  are such that  $F = \operatorname{conv}\{y_{1}, \ldots, y_{d}\}$ , the corresponding facet bubble function. Then, the operator  $\boldsymbol{\mathcal{B}}_{h}^{(1)} \colon C^{0}(\mathcal{T}_{h})^{n} \to$  $\mathbb{P}^{k+d-1}(\mathcal{T}_{h})^{n} \cap W_{0}^{1,1}(\Omega)^{n}$ , for every  $\boldsymbol{w}_{h} \in C^{0}(\mathcal{T}_{h})^{n}$ , is defined via

$$\boldsymbol{\mathcal{B}}_{h}^{(1)}\boldsymbol{w}_{h} \coloneqq \sum_{F \in \Gamma_{h}^{i}} \sum_{y \in \mathcal{L}_{k-1}(F)} (\boldsymbol{\mathcal{Q}}_{F} \{\!\!\{\boldsymbol{w}_{h}\}\!\!\})(y) \varphi_{y}^{k-1} \varphi_{F} \quad \text{ in } \mathbb{P}^{k+d-1}(\mathcal{T}_{h})^{n} \cap W_{0}^{1,1}(\Omega)^{n},$$

where  $\mathbf{Q}_F: C^0(\mathcal{T}_h)^n \to \mathbb{P}^{k-1}(F)^n$  is the weighted  $L^2$ -projection, for every  $\mathbf{w}_h \in C^0(\mathcal{T}_h)^n$  and  $\mathbf{z}_h \in \mathbb{P}^{k-1}(F)^n$ , defined via

$$(arphi_F oldsymbol{Q}_F oldsymbol{w}_h, oldsymbol{z}_h)_F = (oldsymbol{v}_h, oldsymbol{z}_h)_F$$

•  $\mathcal{B}_h^{(2)}$  (interior bubble smoother): Denote for  $K \in \mathcal{T}_h$  by  $\mathcal{L}_k(K)$  the set of Lagrange nodes on K of degree k and by  $\varphi_K \coloneqq \varphi_{y_1}^1 \cdot \ldots \cdot \varphi_{y_{d+1}}^1 \in \mathbb{P}^{d+1}(K) \cap$  $W_0^{1,1}(K)$ , where  $y_1, \ldots, y_{d+1} \in \mathcal{L}_1(K)$  are such that  $K = \operatorname{conv}\{y_1, \ldots, y_{d+1}\}$ , the corresponding bubble function. Then, the operator  $\mathcal{B}_h^{(2)} \colon C^0(\mathcal{T}_h)^n \to$  $\mathbb{P}^{k+d}(\mathcal{T}_h)^n \cap W_0^{1,1}(\Omega)^n$ , for every  $w_h \in C^0(\mathcal{T}_h)^n$ , is defined via

$$oldsymbol{\mathcal{B}}_h^{(2)}oldsymbol{w}_h\coloneqq\sum_{K\in\mathcal{T}_h}(oldsymbol{\mathcal{Q}}_Koldsymbol{w}_h)\,arphi_K\,,$$

where  $\mathbf{Q}_K : C^0(\mathcal{T}_h)^n \to \mathbb{P}^{k-1}(K)^n$  is the weighted  $L^2$ -projection, for every  $\mathbf{w}_h \in C^0(\mathcal{T}_h)^n$  and  $\mathbf{z}_h \in \mathbb{P}^{k-1}(K)^n$ , defined via

$$(\varphi_K \boldsymbol{\mathcal{Q}}_K \boldsymbol{w}_h, \boldsymbol{z}_h)_K = (\boldsymbol{w}_h, \boldsymbol{z}_h)_K.$$

Note that  $\boldsymbol{\mathcal{B}}_{h}^{(2)}$  is not needed when k = 1.

The idea in all these cases is that the bubble smoother helps with the preservation of moments, but as the bubble smoothers are not stable, a nodal averaging operator is added to recover stability. Namely, [39, (3.17), (3.18)] and  $|\llbracket \boldsymbol{v}_h \rrbracket| = |\llbracket \boldsymbol{v}_h \otimes \boldsymbol{n} \rrbracket|$ , for every  $\boldsymbol{v}_h \in \mathbb{P}^k(\mathcal{T}_h)^n$ , imply that

(3.1) 
$$\|\nabla_h (\boldsymbol{v}_h - \boldsymbol{\mathcal{E}}_h \boldsymbol{v}_h)\|_{2,K} \lesssim \sum_{F \in \Gamma_h(K)} \|h_{\Gamma}^{-1/2} [\![\boldsymbol{v}_h \otimes \boldsymbol{n}]\!]_F\|_{2,F},$$

where  $\Gamma_h(K) \coloneqq \{F \in \Gamma_h \mid K \cap F \neq \emptyset\}$  and the constants depend only on k and  $\omega_0$ . We now proceed to generalise the estimate (3.1) to the Orlicz setting.

PROPOSITION 3.1 (Interpolation estimate). Let  $\psi \colon \mathbb{R}^{\geq 0} \to \mathbb{R}^{\geq 0}$  be an N-function with  $\psi \in \Delta_2$ ,  $\psi^* \in \Delta_2$ , and let  $k \in \mathbb{N}$ . Then, for every  $\boldsymbol{v}_h \in \mathbb{P}^k(K)^n$  and  $K \in \mathcal{T}_h$ , it holds that

$$\frac{1}{|K|} \int_{K} \psi(h_{K} |\tilde{\nabla}_{h}(\boldsymbol{v}_{h} - \boldsymbol{\mathcal{E}}_{h} \boldsymbol{v}_{h})|) \, \mathrm{d}x \lesssim \sum_{F \in \Gamma_{h}(K)} \frac{1}{|F|} \int_{F} \psi(|\llbracket \boldsymbol{v}_{h} \otimes \boldsymbol{n}]]_{F}|) \, \mathrm{d}s$$

where either  $\tilde{\nabla}_h = \nabla_h$  or  $\tilde{\nabla}_h = \mathcal{G}_h$  and the constants depend only on k,  $\Delta_2(\psi)$ ,  $\Delta_2(\psi^*)$  and  $\omega_0$ .

*Proof.* We need to distinguish the cases  $\tilde{\nabla}_h = \nabla_h$  and  $\tilde{\nabla}_h = \boldsymbol{\mathcal{G}}_h$ : Case  $\tilde{\nabla}_h = \nabla_h$ . Owing to (3.1) together with [17, Lem. 12.1], we have that

(3.2) 
$$h_K \|\nabla (\boldsymbol{v}_h - \boldsymbol{\mathcal{E}}_h \boldsymbol{v}_h)\|_{\infty, K} \lesssim \sum_{F \in \Gamma_h(K)} \frac{1}{|F|} \int_F |[\![\boldsymbol{v}_h \otimes \boldsymbol{n}]\!]_F| \, \mathrm{d}s \, ds$$

where the constants depends only on k and  $\omega_0$ . Using (3.2), the  $\Delta_2$ -condition and convexity of  $\psi$ , in particular, Jensen's inequality, and that  $\sup_{h>0} \sup_{K \in \mathcal{T}_h} \operatorname{card}(\Gamma_h(K)) \leq c$ , where c > 0 depends only on  $\omega_0$ , we find that

$$\frac{1}{|K|} \int_{K} \psi(h_{K} |\nabla(\boldsymbol{v}_{h} - \boldsymbol{\mathcal{E}}_{h} \boldsymbol{v}_{h})|) \, \mathrm{d}x \lesssim \psi\left(\frac{1}{\operatorname{card}(\Gamma_{h}(K))} \sum_{F \in \Gamma_{h}(K)} \frac{1}{|F|} \int_{F} |\llbracket \boldsymbol{v}_{h} \otimes \boldsymbol{n} \rrbracket_{F}| \, \mathrm{d}s\right)$$

$$\lesssim \frac{1}{\operatorname{card}(\Gamma_{h}(K))} \sum_{F \in \Gamma_{h}(K)} \frac{1}{|F|} \int_{F} \psi(|\llbracket \boldsymbol{v}_{h} \otimes \boldsymbol{n} \rrbracket_{F}|) \, \mathrm{d}s$$

$$\lesssim \sum_{F \in \Gamma_{h}(K)} \frac{1}{|F|} \int_{F} \psi(|\llbracket \boldsymbol{v}_{h} \otimes \boldsymbol{n} \rrbracket_{F}|) \, \mathrm{d}s,$$

where the constants depend only on k,  $\Delta_2(\psi)$ ,  $\Delta_2(\psi^*)$  and  $\omega_0$ .

Case  $\dot{\nabla}_h = \mathcal{G}_h$ . Appealing to [14, (A.23)], for every  $F \in \Gamma_h$  and  $K \in \mathcal{T}_h$  with  $F \subseteq \partial K$ , it holds that

(3.4) 
$$\frac{1}{|K|} \int_{K} \psi(h_{K} |\boldsymbol{\mathcal{R}}_{h} \boldsymbol{v}_{h}|) \, \mathrm{d}x \lesssim \frac{1}{|F|} \int_{F} \psi(|\llbracket \boldsymbol{v}_{h} \otimes \boldsymbol{n} \rrbracket_{F}|) \, \mathrm{d}s \,,$$

where the constants depend only on k,  $\Delta_2(\psi)$ ,  $\Delta_2(\psi^*)$  and  $\omega_0$ . Thus, using (3.3), that

 $\mathcal{R}_h \mathcal{E}_h v_h = \mathbf{0}$ , and (3.4), we obtain

$$\begin{aligned} \frac{1}{|K|} \int_{K} \psi(h_{K} |\tilde{\nabla}_{h}(\boldsymbol{v}_{h} - \boldsymbol{\mathcal{E}}_{h} \boldsymbol{v}_{h})|) \, \mathrm{d}x &\lesssim \frac{1}{|K|} \int_{K} \psi(h_{K} |\nabla(\boldsymbol{v}_{h} - \boldsymbol{\mathcal{E}}_{h} \boldsymbol{v}_{h})|) \, \mathrm{d}x \\ &+ \frac{1}{|K|} \int_{K} \psi(h_{K} |\boldsymbol{\mathcal{R}}_{h} \boldsymbol{v}_{h}|) \, \mathrm{d}x \\ &\lesssim \sum_{F \in \Gamma_{h}(K)} \frac{1}{|F|} \int_{F} \psi(|\llbracket \boldsymbol{v}_{h} \otimes \boldsymbol{n}]]_{F}|) \, \mathrm{d}s \,,\end{aligned}$$

where the constants depend only on k,  $\Delta_2(\psi)$ ,  $\Delta_2(\psi^*)$  and  $\omega_0$ .

4. Primal formulation. In this section, we examine the primal formulation of the non-linear problem (1.1) and its discretization. In doing so, throughout the entire section, we assume that  $\boldsymbol{S}$  has  $(p, \delta)$ -structure in the sense of Definition 2.1.

## 4.1. Continuous primal formulation. We abbreviate

$$V \coloneqq W_0^{1,p}(\Omega)^n \, .$$

Then, for given right-hand side  $f \in V^*$ , the *primal formulation* of (1.1) seeks for a function (or vector field, respectively)  $u \in V$  such that for every  $z \in V$ , it holds that

(4.1) 
$$(\boldsymbol{\mathcal{S}}(\nabla \boldsymbol{u}), \nabla \boldsymbol{z})_{\Omega} = \langle \boldsymbol{f}, \boldsymbol{z} \rangle_{V}.$$

Resorting to the celebrated theory of monotone operators, cf. [42, 34], it is readily seen that the primal formulation admits a unique solution.

**4.2.** Discrete primal formulation. For given  $k \in \mathbb{N}$ , we abbreviate

$$V_h \coloneqq V_h^k \coloneqq \mathbb{P}^k(\mathcal{T}_h)^n$$

Then, for given right-hand side  $\mathbf{f} \in V^*$ , the discrete primal formulation of (1.1) seeks for a discrete function (or vector field, respectively)  $\mathbf{u}_h \in V_h$  such that for every  $\mathbf{z}_h \in V_h$ , it holds that

(4.2) 
$$(\boldsymbol{\mathcal{S}}(\tilde{\nabla}_{h}\boldsymbol{u}_{h}), \nabla \boldsymbol{\mathcal{E}}_{h}\boldsymbol{z}_{h})_{\Omega} + \alpha \langle \boldsymbol{\mathcal{S}}_{\boldsymbol{\beta}_{h}(\boldsymbol{u}_{h})}(h_{\Gamma}^{-1}\llbracket\boldsymbol{u}_{h}\otimes\boldsymbol{n}\rrbracket), \llbracket\boldsymbol{z}_{h}\otimes\boldsymbol{n}\rrbracket\rangle_{\Gamma_{h}} = \langle \boldsymbol{f}, \boldsymbol{\mathcal{E}}_{h}\boldsymbol{z}_{h}\rangle_{V},$$

where  $\alpha > 0$  is the stabilisation parameter,  $\beta_h : V_h \to \mathbb{R}^{\geq 0}$  is the max-shift functional, for every  $v_h \in V_h$ , defined via

(4.3) 
$$\boldsymbol{\beta}_h(\boldsymbol{v}_h) \coloneqq \begin{cases} 0 & \text{if } p \le 2, \\ \|\tilde{\nabla}_h \boldsymbol{v}_h\|_{\infty,\Omega} & \text{if } p > 2, \end{cases}$$

with  $\tilde{\nabla}_h \in \{\boldsymbol{\mathcal{G}}_h, \nabla_h\}$ , and  $\boldsymbol{\mathcal{S}}_{\boldsymbol{\beta}_h(\boldsymbol{u}_h)}$  is defined in (2.6). More precisely, setting  $\tilde{\nabla}_h = \boldsymbol{\mathcal{G}}_h$ , results in an LDG-type method and setting  $\tilde{\nabla}_h = \nabla_h$ , results is an IIDG-type method.

REMARK 4.1. Note that for each choice  $\tilde{\nabla}_h \in \{\boldsymbol{\mathcal{G}}_h, \nabla_h\}$  and for every  $\boldsymbol{w}_h \in C^0(\mathcal{T}_h)^n$ , we have that  $\tilde{\nabla}_h \boldsymbol{\mathcal{E}}_h \boldsymbol{w}_h = \nabla \boldsymbol{\mathcal{E}}_h \boldsymbol{w}_h$ . This enables us to replace the classical gradient in the primal formulation (4.2), by  $\tilde{\nabla}_h \in \{\boldsymbol{\mathcal{G}}_h, \nabla_h\}$ , which is of crucial importance in the proof of a best-approximation type result in Theorem 4.6; see also Lemma 4.4.

REMARK 4.2. It can be seen that if we add to the left-hand side of the LDG discretisation the term  $(\mathcal{S}(\mathcal{R}_h u_h), \nabla_h (\mathcal{E}_h z_h - z_h))_{\Omega}$ , then we arrive at a SIP-like method (in that it reduces to the usual Symmetric Interior Penalty method in the linear case). Thus, all results proved for the LDG method and the IIDG method can be carried over to this method.

REMARK 4.3. The max-shift functional is constructed in such a way that is has the following two properties. First, for the globally non-constant shift  $|\tilde{\nabla}_{h} \boldsymbol{u}_{h}| \in L^{p}(\Omega)^{n \times d}$  and the globally constant shift  $\beta_{h}(\boldsymbol{u}_{h}) \in \mathbb{R}$ , it holds that  $\varphi_{|\bar{\nabla}_{h} \boldsymbol{u}_{h}|}(t) \leq \varphi_{\beta_{h}(\boldsymbol{u}_{h})}(t)$  for all  $t \geq 0$ . To the latter N-function, the approximation properties of the smoothing operator  $\mathcal{E}_{h}: V_{h} \to V$  apply, cf. (4.5) (below). Second, for the conjugate N-function, the equivalences (2.8) apply, cf. (4.6) (below).

More precisely, the max-shift functional is precisely constructed in such a way that the following lemma applies.

LEMMA 4.4. For every  $\kappa > 0$ , there exists constant  $c_{\kappa} > 0$ , depending on the characteristics of  $\boldsymbol{S}$ , such that for every  $\boldsymbol{v}_h, \boldsymbol{z}_h \in V_h$  and  $\boldsymbol{v} \in V$ , it holds that

$$\begin{split} & (\boldsymbol{\mathcal{S}}(\tilde{\nabla}_{h}\boldsymbol{v}_{h}) - \boldsymbol{\mathcal{S}}(\nabla\boldsymbol{v}), \tilde{\nabla}_{h}(\boldsymbol{\mathcal{E}}_{h}\boldsymbol{z}_{h} - \boldsymbol{z}_{h}))_{\Omega} | \\ & \lesssim \kappa \left\| \boldsymbol{\mathcal{F}}(\tilde{\nabla}_{h}\boldsymbol{v}_{h}) - \boldsymbol{\mathcal{F}}(\nabla\boldsymbol{v}) \right\|_{2,\Omega}^{2} + c_{\kappa} \, m_{\varphi_{\boldsymbol{\mathcal{B}}_{h}}(\boldsymbol{v}_{h}),h}(\boldsymbol{z}_{h}) \end{split}$$

where the constants depend only on k,  $\omega_0$ , and the characteristics of  $\boldsymbol{S}$ .

*Proof.* Using (2.9) and the  $\varepsilon$ -Young inequality (2.2) with  $\psi = \varphi_{\beta_h(\boldsymbol{v}_h)}$ , we find that

(4.4) 
$$\frac{|(\boldsymbol{\mathcal{S}}(\nabla_{h}\boldsymbol{v}_{h}) - \boldsymbol{\mathcal{S}}(\nabla\boldsymbol{v}), \nabla_{h}(\boldsymbol{\mathcal{E}}_{h}\boldsymbol{z}_{h} - \boldsymbol{z}_{h}))_{\Omega}|}{\lesssim c_{\kappa} \rho_{\varphi_{\boldsymbol{\beta}_{h}}(\boldsymbol{v}_{h}), \Omega}(\tilde{\nabla}_{h}(\boldsymbol{\mathcal{E}}_{h}\boldsymbol{z}_{h} - \boldsymbol{z}_{h})) + \kappa \rho_{(\varphi_{\boldsymbol{\beta}_{h}}(\boldsymbol{v}_{h}))^{*}, \Omega}(\varphi'_{|\tilde{\nabla}_{h}\boldsymbol{v}_{h}|}(|\tilde{\nabla}_{h}\boldsymbol{v}_{h} - \nabla\boldsymbol{v}|)).$$

Due to  $\beta_h(u_h) \in \mathbb{R}$ , Proposition 3.1 is applicable and yields, also using  $h_F \sim h_K$ , that

(4.5) 
$$\rho_{\varphi_{\boldsymbol{\beta}_h(\boldsymbol{v}_h)},\Omega}(\tilde{\nabla}_h(\boldsymbol{\mathcal{E}}_h\boldsymbol{z}_h-\boldsymbol{z}_h)) \lesssim m_{\varphi_{\boldsymbol{\beta}_h(\boldsymbol{u}_h)},h}(\boldsymbol{z}_h) +$$

By definition of the max-shift functional and Remark 2.2 (iii), we obtain  $(\varphi_{\beta_h(\boldsymbol{v}_h)})^* \leq (\varphi_{|\tilde{\nabla}_h \boldsymbol{v}_h|})^*$ . Using this, the equivalence (2.1) for  $\psi = \varphi_{|\tilde{\nabla}_h \boldsymbol{v}_h|}$ , and (2.8), we obtain

(4.6) 
$$\begin{aligned} \rho_{(\varphi_{\beta_{h}(\boldsymbol{v}_{h})})^{*},\Omega}(\varphi_{|\tilde{\nabla}_{h}\boldsymbol{v}_{h}|}(|\tilde{\nabla}_{h}\boldsymbol{v}_{h}-\nabla\boldsymbol{v}|)) &\leq \rho_{(\varphi_{|\tilde{\nabla}_{h}\boldsymbol{v}_{h}|})^{*},\Omega}(\varphi_{|\tilde{\nabla}_{h}\boldsymbol{v}_{h}|}(|\tilde{\nabla}_{h}\boldsymbol{v}_{h}-\nabla\boldsymbol{v}|)) \\ &\lesssim \|\boldsymbol{\mathcal{F}}(\tilde{\nabla}_{h}\boldsymbol{v}_{h})-\boldsymbol{\mathcal{F}}(\nabla\boldsymbol{v})\|_{2,\Omega}^{2}. \end{aligned}$$

Eventually, combining (4.5) and (4.6) in (4.4), we conclude the claimed estimate.

In the linear case  $\boldsymbol{\mathcal{S}}(\tilde{\nabla}_h \boldsymbol{u}) = \tilde{\nabla}_h \boldsymbol{u}$ , non-degeneracy and existence of discrete solutions is a direct consequence of the construction of  $\boldsymbol{\mathcal{E}}_h$ , because then the preservation property (1.6) means that we can forget the operator  $\boldsymbol{\mathcal{E}}_h$  on the left-hand side and so the usual argument for proving coercivity works (note that, by construction,  $\tilde{\nabla}_h \boldsymbol{u}_h \in \mathbb{P}^{k-1}(\mathcal{T}_h)^{n \times d}$ ). In the non-linear case this argument only works for the lowest order DG ansatz for which the gradients are element-wise constant. Hence, in general, we would need to check that discrete solutions exist.

PROPOSITION 4.5. For  $\alpha > 0$  sufficiently large, the primal formulation (4.2) admits a solution.

*Proof.* We equip  $V_h$  with the norm  $\|\cdot\|_{V_h} \coloneqq \|\cdot\|_{h,p}$ , and consider the operator  $\mathcal{T}_h: V_h \to (V_h)^*$ , for every  $v_h \in V_h$  and  $z_h \in V_h$ , defined via

$$\langle \boldsymbol{\mathcal{T}}_h \boldsymbol{v}_h, \boldsymbol{z}_h \rangle_{V_h} \coloneqq (\boldsymbol{\mathcal{S}}(\tilde{\nabla}_h \boldsymbol{v}_h), \nabla \boldsymbol{\mathcal{E}}_h \boldsymbol{z}_h)_{\Omega} + \alpha \, \langle \boldsymbol{\mathcal{S}}_{\boldsymbol{\beta}_h(\boldsymbol{v}_h)}(h_{\Gamma}^{-1}\llbracket \boldsymbol{v}_h \otimes \boldsymbol{n} 
rbracket), \llbracket \boldsymbol{z}_h \otimes \boldsymbol{n} 
rbracket \rangle_{\Gamma_h}$$

Since  $V_h$  is finite dimensional, consists of broken polynomials, [5, Lem. 3.18], the properties of  $\boldsymbol{\mathcal{S}}$  and  $\boldsymbol{\mathcal{S}}_a$ ,  $a \geq 0$ , imply that the operator  $\boldsymbol{\mathcal{T}}_h: V_h \to (V_h)^*$ , for every fixed h > 0, is well-defined, continuous, and monotone. To prove the boundedness of  $\boldsymbol{\mathcal{T}}_h: V_h \to (V_h)^*$ , we use the properties of  $\boldsymbol{\mathcal{S}}, \boldsymbol{\mathcal{S}}_{\boldsymbol{\beta}_h(\boldsymbol{v}_h)}$  (cf. Proposition 2.3 and Remark 2.4), Young's inequality, (2.1), Proposition 3.1 with  $\psi = \varphi$ , the stability of  $\boldsymbol{\mathcal{R}}_h$  (cf. [14, (A.25)]), a shift change (cf. Lemma 2.5),  $\sum_{F \in \Gamma_h} h_F \mathscr{H}^{d-1}(F) \sim |\Omega|$ , [17, Lemma 12.1], Jensen's inequality, and  $\varphi(t) + t^p \sim t^p + \delta^p$  for all  $t \geq 0$  (cf. [5]), to find that

$$\begin{split} |\langle \boldsymbol{\mathcal{T}}_{h} \boldsymbol{v}_{h}, \boldsymbol{z}_{h} \rangle_{V_{h}}| &\lesssim \rho_{\varphi,\Omega}(\bar{\nabla}_{h} \boldsymbol{v}_{h}) + \rho_{\varphi,\Omega}(\bar{\nabla}_{h} (\boldsymbol{\mathcal{E}}_{h} \boldsymbol{z}_{h} - \boldsymbol{z}_{h})) + \rho_{\varphi,\Omega}(\bar{\nabla}_{h} \boldsymbol{z}_{h}) \\ &+ \alpha \, m_{\varphi_{\boldsymbol{\beta}_{h}(\boldsymbol{v}_{h}),h}(\boldsymbol{v}_{h}) + \alpha \, m_{\varphi_{\boldsymbol{\beta}_{h}(\boldsymbol{v}_{h}),h}(\boldsymbol{z}_{h}) \\ &\lesssim \rho_{\varphi,\Omega}(\nabla_{h} \boldsymbol{v}_{h}) + \rho_{\varphi,\Omega}(\nabla_{h} \boldsymbol{z}_{h}) + m_{\varphi,h}(\boldsymbol{v}_{h}) + m_{\varphi,h}(\boldsymbol{z}_{h}) + \varphi(\boldsymbol{\beta}_{h}(\boldsymbol{v}_{h})) \\ &\lesssim \|\boldsymbol{v}_{h}\|_{p,h}^{p} + \|\boldsymbol{z}_{h}\|_{p,h}^{p} + \delta^{p} \,. \end{split}$$

Thus,  $\mathcal{T}_h: V_h \to (V_h)^*$  is pseudo-monotone. If we can prove its coercivity, then, from pseudo-monotone operator theory (cf. [42, Thm. 27.A]), it follows that  $\mathcal{T}_h: V_h \to (V_h)^*$  is surjective. For every  $\boldsymbol{v}_h \in V_h$ , using first that  $\nabla \boldsymbol{\mathcal{E}}_h \boldsymbol{v}_h = \tilde{\nabla}_h \boldsymbol{\mathcal{E}}_h \boldsymbol{v}_h$ , then that  $\boldsymbol{\mathcal{S}}(\mathbf{Q}): \mathbf{Q} \sim \varphi(|\mathbf{Q}|)$  and  $\boldsymbol{\mathcal{S}}_{\beta_h(\boldsymbol{v}_h)}(\mathbf{Q}): \mathbf{Q} \sim \varphi_{\beta_h(\boldsymbol{v}_h)}(|\mathbf{Q}|)$  for all  $\mathbf{Q} \in \mathbb{R}^{n \times d}$  (cf. Proposition 2.3 and Remark 2.4),  $\varphi_{\beta_h(\boldsymbol{v}_h)} \geq \varphi$  (cf. Remark 2.2 (iii)), the  $\varepsilon$ -Young inequality (2.2) with  $\psi = \varphi$ , and Proposition 3.1 with  $\psi = \varphi$ , we find that

$$\begin{split} \langle \boldsymbol{\mathcal{T}}_{h} \boldsymbol{v}_{h}, \boldsymbol{v}_{h} \rangle_{V_{h}} &= (\boldsymbol{\mathcal{S}}(\nabla_{h} \boldsymbol{v}_{h}), \nabla_{h} \boldsymbol{v}_{h})_{\Omega} + \alpha \, \langle \boldsymbol{\mathcal{S}}_{\boldsymbol{\beta}_{h}(\boldsymbol{v}_{h})}(h_{\Gamma}^{-1}\llbracket \boldsymbol{v}_{h} \otimes \boldsymbol{n} \rrbracket), \llbracket \boldsymbol{v}_{h} \otimes \boldsymbol{n} \rrbracket \rangle_{\Gamma_{h}} \\ &+ (\boldsymbol{\mathcal{S}}(\tilde{\nabla}_{h} \boldsymbol{v}_{h}), \tilde{\nabla}_{h}(\boldsymbol{\mathcal{E}}_{h} \boldsymbol{v}_{h} - \boldsymbol{v}_{h}))_{\Omega} \\ &\geq (c - \varepsilon) \, \rho_{\varphi,\Omega}(\tilde{\nabla}_{h} \boldsymbol{v}_{h}) + \alpha \, c \, m_{\varphi_{\boldsymbol{\beta}_{h}(\boldsymbol{v}_{h}),h}(\boldsymbol{v}_{h}) - c_{\varepsilon} \, \rho_{\varphi,\Omega}(\tilde{\nabla}_{h}(\boldsymbol{\mathcal{E}}_{h} \boldsymbol{v}_{h} - \boldsymbol{v}_{h})) \\ &\geq (c - \varepsilon) \, \rho_{\varphi,\Omega}(\tilde{\nabla}_{h} \boldsymbol{v}_{h}) + (\alpha \, c - c_{\varepsilon}) \, m_{\varphi,h}(\boldsymbol{v}_{h}) \,. \end{split}$$

Consequently, choosing first  $\varepsilon > 0$  sufficiently small and, subsequently,  $\alpha > 0$  sufficiently large, also using  $\varphi(t) + t^p \sim t^p + \delta^p$  for all  $t \ge 0$  (cf. [5]),  $h \mathscr{H}^{d-1}(\Gamma_h) \sim |\Omega|$ , for every  $\boldsymbol{v}_h \in V_h$ , and the norm equivalence (2.12), we arrive at

$$egin{aligned} & \langle m{\mathcal{T}}_h m{v}_h, m{v}_h 
angle_{V_h} \gtrsim \| 
abla_h m{v}_h \|_{p,\Omega}^p + lpha \, \| h_{\Gamma}^{-1/p'} \llbracket m{v}_h \otimes m{n} 
brace \| \|_{p,\Gamma_h}^p - \delta^p \, |\Omega| \, (1+lpha) \ & \gtrsim \min\{1,lpha\} \, \| m{v}_h \|_{V_h}^p - \delta^p \, |\Omega| \, \max\{1,lpha\} \, . \end{aligned}$$

Putting everything together, we proved that the operator  $\mathcal{T}_h: V_h \to (V_h)^*$  is well-defined, bounded, pseudo-monotone, and coercive and, thus, surjective (cf. [42, Thm. 27.A]).

From (4.1) and (4.2), it follows that the error equation, for every  $\boldsymbol{z}_h \in V_h$ , takes the form

(4.7) 
$$(\boldsymbol{\mathcal{S}}(\tilde{\nabla}_{h}\boldsymbol{u}_{h}) - \boldsymbol{\mathcal{S}}(\nabla\boldsymbol{u}), \nabla \boldsymbol{\mathcal{E}}_{h}\boldsymbol{z}_{h})_{\Omega} + \alpha \langle \boldsymbol{\mathcal{S}}_{\boldsymbol{\beta}_{h}(\boldsymbol{u}_{h})}(h_{\Gamma}^{-1}\llbracket\boldsymbol{u}_{h}\otimes\boldsymbol{n}\rrbracket), \llbracket\boldsymbol{z}_{h}\otimes\boldsymbol{n}\rrbracket\rangle_{\Gamma_{h}} = 0.$$

THEOREM 4.6. Let  $\mathbf{u} \in V$  be a solution of (4.1) and  $\mathbf{u}_h \in V_h$  be a solution of (4.2). If  $\alpha > 0$  sufficiently large, we have that

$$\begin{split} \| \boldsymbol{\mathcal{F}}(\nabla_{h}\boldsymbol{u}_{h}) - \boldsymbol{\mathcal{F}}(\nabla \boldsymbol{u}) \|_{2,\Omega}^{2} + m_{\varphi_{\boldsymbol{\beta}_{h}(\boldsymbol{u}_{h})},h}(\boldsymbol{u}_{h}) \\ \lesssim \inf_{\boldsymbol{v}_{h} \in V_{h}} \left( \| \boldsymbol{\mathcal{F}}(\tilde{\nabla}_{h}\boldsymbol{v}_{h}) - \boldsymbol{\mathcal{F}}(\nabla \boldsymbol{u}) \|_{2,\Omega}^{2} + m_{\varphi_{\boldsymbol{\beta}_{h}(\boldsymbol{u}_{h})},h}(\boldsymbol{v}_{h}) \right) \end{split}$$

where the constant depends only on k,  $\omega_0$ , and the characteristics of  $\boldsymbol{S}$ .

*Proof.* Adding and subtracting  $\tilde{\nabla}_h \boldsymbol{z}_h \in \mathbb{P}^{k-1}(\mathcal{T}_h)^{n \times d}$  in (4.7) for arbitrary  $\boldsymbol{z}_h \in V_h$ , using that  $\tilde{\nabla}_h \boldsymbol{\mathcal{E}}_h \boldsymbol{z}_h = \nabla \boldsymbol{\mathcal{E}}_h \boldsymbol{z}_h$ , we get

(4.8)  
$$0 = (\boldsymbol{\mathcal{S}}(\tilde{\nabla}_{h}\boldsymbol{u}_{h}) - \boldsymbol{\mathcal{S}}(\nabla\boldsymbol{u}), \tilde{\nabla}_{h}\boldsymbol{z}_{h})_{\Omega} + \alpha \langle \boldsymbol{\mathcal{S}}_{\boldsymbol{\beta}_{h}(\boldsymbol{u}_{h})}(h_{\Gamma}^{-1}\llbracket\boldsymbol{u}_{h}\otimes\boldsymbol{n}\rrbracket), \llbracket\boldsymbol{z}_{h}\otimes\boldsymbol{n}\rrbracket\rangle_{\Gamma_{h}} + (\boldsymbol{\mathcal{S}}(\tilde{\nabla}_{h}\boldsymbol{u}_{h}) - \boldsymbol{\mathcal{S}}(\nabla\boldsymbol{u}), \tilde{\nabla}_{h}(\boldsymbol{\mathcal{E}}_{h}\boldsymbol{z}_{h} - \boldsymbol{z}_{h}))_{\Omega} =: \mathfrak{I}_{1} + \mathfrak{I}_{2} + \mathfrak{I}_{3}.$$

Next, we choose  $\boldsymbol{z}_h = \boldsymbol{u}_h - \boldsymbol{v}_h \in V_h$ , where  $\boldsymbol{v}_h \in V_h$  is arbitrary, and estimate  $\mathfrak{I}_1, \mathfrak{I}_2, \mathfrak{I}_3$ :

ad  $\mathfrak{I}_1$ . Using (2.8), and (2.9), the  $\varepsilon$ -Young inequality (2.2) with  $\psi = \varphi_{|\nabla u|}$ , we find that

$$(4.9) \qquad \begin{aligned} \mathfrak{I}_{1} &= (\boldsymbol{\mathcal{S}}(\bar{\nabla}_{h}\boldsymbol{u}_{h}) - \boldsymbol{\mathcal{S}}(\nabla\boldsymbol{u}), \bar{\nabla}_{h}\boldsymbol{u}_{h} - \nabla\boldsymbol{u} + \nabla\boldsymbol{u} - \bar{\nabla}_{h}\boldsymbol{v}_{h})_{\Omega} \\ &\geq c \, \|\boldsymbol{\mathcal{F}}(\bar{\nabla}_{h}\boldsymbol{u}_{h}) - \boldsymbol{\mathcal{F}}(\nabla\boldsymbol{u})\|_{2,\Omega}^{2} - |(\boldsymbol{\mathcal{S}}(\bar{\nabla}_{h}\boldsymbol{u}_{h}) - \boldsymbol{\mathcal{S}}(\nabla\boldsymbol{u}), \nabla\boldsymbol{u} - \bar{\nabla}_{h}\boldsymbol{v}_{h})_{\Omega}| \\ &\geq (c - \varepsilon) \, \|\boldsymbol{\mathcal{F}}(\bar{\nabla}_{h}\boldsymbol{u}_{h}) - \boldsymbol{\mathcal{F}}(\nabla\boldsymbol{u})\|_{2,\Omega}^{2} - c_{\varepsilon} \, \|\boldsymbol{\mathcal{F}}(\nabla\boldsymbol{u}) - \boldsymbol{\mathcal{F}}(\bar{\nabla}_{h}\boldsymbol{v}_{h})\|_{2,\Omega}^{2}. \end{aligned}$$

ad  $\mathfrak{I}_2$ . Using that  $\boldsymbol{\mathcal{S}}_{\boldsymbol{\beta}_h(\boldsymbol{u}_h)}(\mathbf{Q}) : \mathbf{Q} \sim \varphi_{\boldsymbol{\beta}_h(\boldsymbol{u}_h)}(\mathbf{Q})$  uniformly in  $\mathbf{Q} \in \mathbb{R}^{n \times d}$  (cf. Proposition 2.3 and Remark 2.4) and the  $\varepsilon$ -Young inequality (2.2) with  $\psi = \varphi_{|\boldsymbol{\beta}_h(\boldsymbol{u}_h)|}$ , we obtain

$$(4.10) \begin{aligned} \mathfrak{I}_{2} &= \alpha \, \langle \boldsymbol{\mathcal{S}}_{\boldsymbol{\beta}_{h}(\boldsymbol{u}_{h})}(h_{\Gamma}^{-1}\llbracket\boldsymbol{u}_{h}\otimes\boldsymbol{n}\rrbracket), \llbracket\boldsymbol{u}_{h}\otimes\boldsymbol{n}\rrbracket - \llbracket\boldsymbol{v}_{h}\otimes\boldsymbol{n}\rrbracket\rangle_{\Gamma_{h}} \\ &\geq \alpha \, c \, m_{\varphi_{\boldsymbol{\beta}_{h}(\boldsymbol{u}_{h})},h}(\boldsymbol{u}_{h}) - \alpha \, \langle h_{\Gamma}(\varphi_{\boldsymbol{\beta}_{h}(\boldsymbol{u}_{h})})'(h_{\Gamma}^{-1}\llbracket\boldsymbol{u}_{h}\otimes\boldsymbol{n}\rrbracket), h_{\Gamma}^{-1}\llbracket\boldsymbol{v}_{h}\otimes\boldsymbol{n}\rrbracket\rangle_{\Gamma_{h}} \\ &\geq \alpha \, (c-\varepsilon) \, m_{\varphi_{\boldsymbol{\beta}_{h}(\boldsymbol{u}_{h})},h}(\boldsymbol{u}_{h}) - \alpha \, c_{\varepsilon} \, m_{\varphi_{\boldsymbol{\beta}_{h}(\boldsymbol{u}_{h})},h}(\boldsymbol{v}_{h}) \,. \end{aligned}$$

ad  $\mathfrak{I}_3$ . Using Lemma 4.4, we find that

Combining (4.9)–(4.11), for  $\varepsilon, \kappa > 0$  sufficiently small and  $\alpha > 0$  sufficiently large, we arrive at the claimed best-approximation result.

As a first immediate consequence of the best-approximation result in Theorem 4.6, we obtain the convergence of the method under minimal regularity assumptions, i.e., merely  $\boldsymbol{u} \in V$  and  $\boldsymbol{f} \in V^*$ .

COROLLARY 4.7 (Convergence). For  $\alpha > 0$  sufficiently large, it holds that

$$\|\boldsymbol{\mathcal{F}}(\tilde{\nabla}_{h}\boldsymbol{u}_{h}) - \boldsymbol{\mathcal{F}}(\nabla\boldsymbol{u})\|_{2,\Omega}^{2} + m_{\varphi_{\boldsymbol{\beta}_{h}}(\boldsymbol{u}_{h}),h}(\boldsymbol{u}_{h}) \to 0 \quad (h \to 0)$$

*Proof.* Let  $\Pi_h^{SZ}: V \to V_h \cap V$  denote the Scott–Zhang quasi-interpolation operator (cf. [36]). Then, due to  $[\![\Pi_h^{SZ} \boldsymbol{u} \otimes \boldsymbol{n}]\!] = \boldsymbol{0}$  a.e. on  $\Gamma_h$ , we have that

(4.12) 
$$m_{\varphi_{\boldsymbol{\beta}_h(\boldsymbol{u}_h),h}}(\boldsymbol{\Pi}_h^{SZ}\boldsymbol{u}) = 0.$$

Therefore, using the stability and convergence properties of  $\Pi_h^{SZ}: V \to V_h \cap V$  (cf. [36]) and the density of smooth functions in V, we conclude that  $\Pi_h^{SZ} \boldsymbol{u} \to \boldsymbol{u}$  in V  $(h \to 0)$ . This, together with (2.8), Remark 2.2 (iii), Hölder's inequality implies that

(4.13) 
$$\|\boldsymbol{\mathcal{F}}(\nabla \boldsymbol{u}) - \boldsymbol{\mathcal{F}}(\nabla \Pi_h^{SZ} \boldsymbol{u})\|_{2,\Omega}^2 \lesssim \|\nabla \boldsymbol{u} - \nabla \Pi_h^{SZ} \boldsymbol{u}\|_p^{\min\{p,2\}} \to 0 \quad (h \to 0)$$

with a constant depending possibly on  $\delta$ ,  $\|\nabla \boldsymbol{u}\|_p$ . Putting everything together, choosing  $\boldsymbol{v}_h = \prod_h^{SZ} \boldsymbol{u} \in V_h$  in Theorem 4.6, using (4.12) and (4.13), we conclude that

$$\begin{split} \| \boldsymbol{\mathcal{F}}(\tilde{\nabla}_{h}\boldsymbol{u}_{h}) - \boldsymbol{\mathcal{F}}(\nabla \boldsymbol{u}) \|_{2,\Omega}^{2} + m_{\varphi_{\boldsymbol{\beta}_{h}(\boldsymbol{u}_{h})},h}(\boldsymbol{u}_{h}) \\ \lesssim \| \boldsymbol{\mathcal{F}}(\nabla \boldsymbol{u}) - \boldsymbol{\mathcal{F}}(\nabla \Pi_{h}^{SZ}\boldsymbol{u}) \|_{2,\Omega}^{2} \to 0 \quad (h \to 0) \,, \end{split}$$

which is the claimed convergence under minimal regularity assumptions.

As a second immediate consequence of the best-approximation result in Theorem 4.6, we obtain fractional convergence rates of the method given fractional regularity assumptions on the solution of the continuous primal problem (4.1). In order to express the fractional regularity of the solution of (4.1), we make use of Nikolskiĭ spaces. For given  $p \in [1, \infty)$ ,  $\beta \in (0, 1]$ , and  $v \in L^p(\Omega)$ , the Nikolskiĭ semi-norm is defined via

$$[v]_{N^{\beta,p}(\Omega)} \coloneqq \sup_{h \in \mathbb{R}^d \setminus \{0\}} |h|^{-\beta} \left( \int_{\Omega \cap (\Omega-h)} |v(x+h) - v(x)|^p \, \mathrm{d}x \right)^{\frac{1}{p}} < \infty \,.$$

Then, for  $p \in [1, \infty)$  and  $\beta \in (0, 1]$ , the Nikolskii space is defined via

$$N^{\beta,p}(\Omega) \coloneqq \left\{ v \in L^p(\Omega) \mid [v]_{N^{\beta,p}(\Omega)} < \infty \right\},$$

and the Nikolskii norm  $\|\cdot\|_{N^{\beta,p}(\Omega)} \coloneqq \|\cdot\|_{p,\Omega} + [v]_{N^{\beta,p}(\Omega)}$  turns  $N^{\beta,p}(\Omega)$  into a Banach space.

COROLLARY 4.8 (Fractional convergence rates). Assume that the family of triangulations  $\{\mathcal{T}_h\}_h$  is quasi-uniform, and that  $\mathcal{F}(\nabla \boldsymbol{u}) \in N^{\beta,2}(\Omega)^{n \times d}$  for some  $\beta \in (0,1]$ . Then, for  $\alpha > 0$  sufficiently large, it holds that

$$\|\boldsymbol{\mathcal{F}}(\tilde{\nabla}_{h}\boldsymbol{u}_{h}) - \boldsymbol{\mathcal{F}}(\nabla\boldsymbol{u})\|_{2,\Omega}^{2} + m_{\varphi_{\boldsymbol{\mathcal{G}}_{h}(\boldsymbol{u}_{h})},h}(\boldsymbol{u}_{h}) \lesssim h^{2\beta} \left[\boldsymbol{\mathcal{F}}(\nabla\boldsymbol{u})\right]_{N^{\beta,2}(\Omega)}^{2}$$

where the constant depends only on k,  $\omega_0$ , and the characteristics of S.

*Proof.* Thanks to the quasi-uniformity, appealing to [8, Thm. 4.2], we have that

(4.14) 
$$\|\boldsymbol{\mathcal{F}}(\nabla \boldsymbol{u}) - \boldsymbol{\mathcal{F}}(\nabla \Pi_h^{SZ} \boldsymbol{u})\|_{2,\Omega}^2 \lesssim h^{2\beta} [\boldsymbol{\mathcal{F}}(\nabla \boldsymbol{u})]_{N^{\beta,2}(\Omega)}^2$$

Thus, choosing  $\boldsymbol{v}_h = \Pi_h^{SZ} \boldsymbol{u} \in V_h \cap V$  in Theorem 4.6, due to  $\llbracket \Pi_h^{SZ} \boldsymbol{u} \otimes \boldsymbol{n} \rrbracket = 0$  on  $\Gamma_h$ , we obtain

$$\begin{split} \|\boldsymbol{\mathcal{F}}(\tilde{\nabla}_{h}\boldsymbol{u}_{h}) - \boldsymbol{\mathcal{F}}(\nabla\boldsymbol{u})\|_{2,\Omega}^{2} + m_{\varphi_{\boldsymbol{\beta}_{h}(\boldsymbol{u}_{h}),h}}(\boldsymbol{u}_{h}) \lesssim \|\boldsymbol{\mathcal{F}}(\nabla\boldsymbol{u}) - \boldsymbol{\mathcal{F}}(\nabla\Pi_{h}^{SZ}\boldsymbol{u})\|_{2,\Omega}^{2} \\ \lesssim h^{2\beta} \left[\boldsymbol{\mathcal{F}}(\nabla\boldsymbol{u})\right]_{N^{\beta,2}(\Omega)}^{2}, \end{split}$$

which is the claimed fractional a priori error estimate.

REMARK 4.9. In view of [15, Corollary 5.8] the assertion of Corollary 4.8 for  $\beta = 1$  is also valid if  $\mathcal{F}(\nabla u) \in W^{1,2}(\Omega)^{n \times d}$  without the additional assumption that the triangulation  $\{\mathcal{T}_h\}_h$  is quasi-uniform.

Eventually, resorting to the approximation properties of the node-averaging quasiinterpolation operator  $\mathcal{I}_h^{av}: C^0(\mathcal{T}_h) \to V_{h,c}$ , for every  $v_h \in \mathbb{P}(\mathcal{T}_h)$ , defined via

$${\mathcal I}_h^{av} {oldsymbol v}_h \coloneqq \sum_{y \in {\mathcal L}_k^{\mathrm{int}}({\mathcal T}_h)} \langle {oldsymbol v}_h 
angle_y arphi_y^k, \quad ext{where} \quad \langle {oldsymbol v}_h 
angle_y \coloneqq \sum_{T \in {\mathcal T}_h; y \in T} \left( {oldsymbol v}_h |_T 
ight)(y),$$

Theorem 4.6 allows to carry out an ansatz class competition, which reveals that the approximation capabilities of the LDG and IIDG approximations and continuous Lagrange approximation of the problem (1.1) are comparable.

COROLLARY 4.10 (Ansatz class competition). Let  $u_h^c \in V_{h,c} \coloneqq V_h \cap V$  be the continuous Lagrange solution of (1.1), i.e., for every  $v_h \in V_{h,c}$ , it holds that

(4.15) 
$$(\boldsymbol{\mathcal{S}}(\nabla \boldsymbol{u}_h^c), \nabla \boldsymbol{v}_h)_{\Omega} = (\boldsymbol{f}, \boldsymbol{v}_h)_{\Omega}.$$

Then, for  $\alpha > 0$  sufficiently large, it holds that

$$\|\boldsymbol{\mathcal{F}}(\tilde{\nabla}_{h}\boldsymbol{u}_{h})-\boldsymbol{\mathcal{F}}(\nabla\boldsymbol{u})\|_{2,\Omega}^{2}+m_{\varphi_{\boldsymbol{\mathcal{B}}_{h}}(\boldsymbol{u}_{h}),h}(\boldsymbol{u}_{h})\sim\|\boldsymbol{\mathcal{F}}(\nabla\boldsymbol{u}_{h}^{c})-\boldsymbol{\mathcal{F}}(\nabla\boldsymbol{u})\|_{2,\Omega}^{2},$$

with constants depending only on k,  $\omega_0$ , and the characteristics of  $\boldsymbol{S}$ .

*Proof.*  $ad \leq$ . Using Theorem 4.6 with  $\boldsymbol{v}_h = \boldsymbol{u}_h^c \in V_{h,c} \subseteq V_h$  and observing that  $m_{\varphi_{\boldsymbol{\beta}_h(\boldsymbol{u}_h)},h}(\boldsymbol{u}_h^c) = 0$ , we find that

$$\|\boldsymbol{\mathcal{F}}(\tilde{\nabla}_{h}\boldsymbol{u}_{h}) - \boldsymbol{\mathcal{F}}(\nabla\boldsymbol{u})\|_{2,\Omega}^{2} + m_{\varphi_{\boldsymbol{\mathcal{B}}_{h}}(\boldsymbol{u}_{h}),h}(\boldsymbol{u}_{h}) \lesssim \|\boldsymbol{\mathcal{F}}(\nabla\boldsymbol{u}_{h}^{c}) - \boldsymbol{\mathcal{F}}(\nabla\boldsymbol{u})\|_{2,\Omega}^{2}$$

 $ad \gtrsim$ . Using (2.8), that  $\varphi_{|\tilde{\nabla}_h \boldsymbol{u}_h|} \leq \varphi_{\boldsymbol{\beta}_h(\boldsymbol{u}_h)}$ , and [25, Prop. A.1], for every  $K \in \mathcal{T}_h$ , we find that

(4.16)  
$$\|\boldsymbol{\mathcal{F}}(\nabla \boldsymbol{\mathcal{I}}_{h}^{av}\boldsymbol{u}_{h}) - \boldsymbol{\mathcal{F}}(\tilde{\nabla}_{h}\boldsymbol{u}_{h})\|_{2,K}^{2} \lesssim \rho_{\varphi_{|\tilde{\nabla}_{h}\boldsymbol{u}_{h}|},K}(\tilde{\nabla}_{h}(\boldsymbol{u}_{h} - \boldsymbol{\mathcal{I}}_{h}^{av}\boldsymbol{u}_{h})) \\ \lesssim \rho_{\varphi_{\boldsymbol{\beta}_{h}(\boldsymbol{u}_{h})},K}(\tilde{\nabla}_{h}(\boldsymbol{u}_{h} - \boldsymbol{\mathcal{I}}_{h}^{av}\boldsymbol{u}_{h})) \\ \lesssim m_{\varphi_{\boldsymbol{\beta}_{h}(\boldsymbol{u}_{h})},h}(\boldsymbol{u}_{h}).$$

Eventually, using the best-approximation properties of  $\boldsymbol{u}_{h}^{c} \in V_{h,c}$  (cf. [15, Lem. 5.2]) and (4.16), we conclude that

$$\begin{aligned} \|\boldsymbol{\mathcal{F}}(\nabla\boldsymbol{u}_{h}^{c}) - \boldsymbol{\mathcal{F}}(\nabla\boldsymbol{u})\|_{2,\Omega}^{2} &\lesssim \|\boldsymbol{\mathcal{F}}(\nabla\boldsymbol{\mathcal{I}}_{h}^{av}\boldsymbol{u}_{h}) - \boldsymbol{\mathcal{F}}(\nabla\boldsymbol{u})\|_{2,\Omega}^{2} \\ (4.17) &\lesssim \|\boldsymbol{\mathcal{F}}(\tilde{\nabla}_{h}\boldsymbol{u}_{h}) - \boldsymbol{\mathcal{F}}(\nabla\boldsymbol{u})\|_{2,\Omega}^{2} + \|\boldsymbol{\mathcal{F}}(\nabla\boldsymbol{\mathcal{I}}_{h}^{av}\boldsymbol{u}_{h}) - \boldsymbol{\mathcal{F}}(\tilde{\nabla}_{h}\boldsymbol{u}_{h})\|_{2,\Omega}^{2} \\ &\lesssim \|\boldsymbol{\mathcal{F}}(\tilde{\nabla}_{h}\boldsymbol{u}_{h}) - \boldsymbol{\mathcal{F}}(\nabla\boldsymbol{u})\|_{2,\Omega}^{2} + m_{\varphi_{\boldsymbol{\mathcal{F}}_{h}}(\boldsymbol{u}_{h}),h}(\boldsymbol{u}_{h}) \,. \end{aligned}$$

Putting everything together, we arrive at the claimed equivalence.

REMARK 4.11 (Application to Crouzeix–Raviart element). If  $V_h := C\mathcal{R}^k(\mathcal{T}_h)$ , where  $C\mathcal{R}^k(\mathcal{T}_h)$  is the Crouzeix–Raviart element and its generalization to higher orders (cf. [40, Sec. 3.3 (3.17)]), and if we use the same primal formulation with  $\tilde{\nabla}_h = \nabla_h$ , then it is possible to prove the same results. However, omitting the stabilization terms in the primal formulation as in the linear case is still an open problem, since, in this case, one cannot simply absorb the term  $c_{\kappa} m_{\varphi_{\beta_h}(u_h),h}(v_h)$  in (4.11) in the term  $\alpha c_{\varepsilon} m_{\varphi_{\beta_h}(u_h),h}(v_h)$  in (4.10) via choosing  $\alpha > 0$  large enough.

5. Mixed formulation. Since  $\boldsymbol{S} \colon \mathbb{R}^{n \times d} \to \mathbb{R}^{n \times d}$  is bounded, continuous, and strictly monotone, by the Browder-Minty theorem (cf. [42, Thm. 26.A]), it is also bijective and its inverse  $\boldsymbol{\mathcal{D}} \coloneqq \boldsymbol{\mathcal{S}}^{-1} \colon \mathbb{R}^{n \times d} \to \mathbb{R}^{n \times d}$  is bounded, continuous, and strictly monotone as well. This motivates to consider the following mixed formulation and corresponding discrete mixed formulation. In doing so, throughout the entire section, we assume that  $\boldsymbol{\mathcal{S}} \colon \mathbb{R}^{n \times d} \to \mathbb{R}^{n \times d}$  has  $(p, \delta)$ -structure in the sense of Definition 2.1. To ensure the validity of the identity (1.6), in this formulation, it will be crucial to have that  $\tilde{\nabla}_h(V_h) \subseteq \Sigma_h$ .

#### 5.1. Continuous mixed formulation. We abbreviate

$$\Sigma \coloneqq L^{p'}(\Omega)^{n \times d}.$$

Then, for given  $\mathbf{f} \in V^*$ , the *(continuous) mixed formulation* of (1.1) seeks for  $(\mathbf{S}, \boldsymbol{u})^\top \in \Sigma \times V$  such that for every  $(\mathbf{T}, \boldsymbol{z})^\top \in \Sigma \times V$ , it holds that

(5.1a) 
$$(\mathcal{D}(\mathbf{S}),\mathbf{T})_{\Omega}-(\mathbf{T},\nabla \boldsymbol{u})_{\Omega}=0,$$

(5.1b) 
$$(\mathbf{S}, \nabla \boldsymbol{z})_{\Omega} = \langle \boldsymbol{f}, \boldsymbol{z} \rangle_{V}.$$

The unique solvability of the mixed formulation (5.1) is a consequence of the unique solvability of the primal formulation (4.1). In fact, both formulations are equivalent: If  $(\mathbf{S}, \boldsymbol{u})^{\top} \in \Sigma \times V$  is a solution of (5.1), then (5.1a) implies that  $\mathcal{D}(\mathbf{S}) = \nabla \boldsymbol{u}$ , which is equivalent to  $\mathbf{S} = \mathcal{S}(\nabla \boldsymbol{u})$ , and, thus, together with (5.1b) shows that  $\boldsymbol{u} \in V$  is a solution of (4.1). If, in turn,  $\boldsymbol{u} \in V$  is a solution of (4.1), then, setting  $\mathbf{S} := \mathcal{S}(\nabla \boldsymbol{u}) \in \Sigma$ , we have that  $\mathcal{D}(\mathbf{S}) = \nabla \boldsymbol{u}$  and, thus, (5.1a). In addition,  $\mathbf{S} \in \Sigma$  then satisfies (5.1b), so that  $(\mathbf{S}, \boldsymbol{u})^{\top} \in \Sigma \times V$  is a solution of (5.1). It is possible to prove the weak solvability of (5.1) directly using pseudo-monotone operator theory. For this, however, one first needs to ascertain that  $\mathcal{D}: \mathbb{R}^{n \times d} \to \mathbb{R}^{n \times d}$  has similar – but dual– growth conditions to  $\mathcal{S}: \mathbb{R}^{n \times d} \to \mathbb{R}^{n \times d}$ .

LEMMA 5.1. Let  $\boldsymbol{\mathcal{S}} \colon \mathbb{R}^{n \times d} \to \mathbb{R}^{n \times d}$  have  $(p, \delta)$ -structure in the sense of Definition 2.1. Then, its inverse  $\boldsymbol{\mathcal{D}} \coloneqq \boldsymbol{\mathcal{S}}^{-1} \colon \mathbb{R}^{n \times d} \to \mathbb{R}^{n \times d}$  has  $(p', \delta^{p-1})$ -structure in the sense of Definition 2.1.

*Proof.* Due to (2.8), for every  $\mathbf{Q}, \mathbf{P} \in \mathbb{R}^{n \times d}$ , it holds that

(5.2) 
$$(\mathcal{D}(\mathbf{Q}) - \mathcal{D}(\mathbf{P})) : (\mathbf{Q} - \mathbf{P}) = (\mathcal{S}(\mathcal{D}(\mathbf{Q})) - \mathcal{S}(\mathcal{D}(\mathbf{P}))) : (\mathcal{D}(\mathbf{Q}) - \mathcal{D}(\mathbf{P})) \\ \sim (\varphi^*)_{|\mathcal{S}(\mathcal{D}(\mathbf{Q}))|} (|\mathcal{S}(\mathcal{D}(\mathbf{Q})) - \mathcal{S}(\mathcal{D}(\mathbf{P}))|) \\ = (\varphi^*)_{|\mathbf{Q}|} (|\mathbf{Q} - \mathbf{P}|) .$$

Due to  $((\varphi_{|\mathcal{D}(\mathbf{Q})|})^*)' \circ \varphi'_{|\mathcal{D}(\mathbf{Q})|} = \mathrm{id}_{\mathbb{R}}, ((\varphi_{|\mathcal{D}(\mathbf{Q})|})^*)' \sim (\varphi^*)'_{|\mathcal{S}(\mathcal{D}(\mathbf{Q}))|}, \text{ and } (2.9), \text{ for every } \mathbf{Q}, \mathbf{P} \in \mathbb{R}^{n \times d}, \text{ it holds that}$ 

(5.3) 
$$\begin{aligned} |\mathcal{D}(\mathbf{Q}) - \mathcal{D}(\mathbf{P})| &= (((\varphi_{|\mathcal{D}(\mathbf{Q})|})^*)' \circ \varphi'_{|\mathcal{D}(\mathbf{Q})|})(|\mathcal{D}(\mathbf{Q}) - \mathcal{D}(\mathbf{P})|) \\ &\lesssim (\varphi^*)'_{|\mathcal{S}(\mathcal{D}(\mathbf{Q}))|}(|\mathcal{S}(\mathcal{D}(\mathbf{Q})) - \mathcal{S}(\mathcal{D}(\mathbf{P}))|) \\ &= (\varphi^*)'_{|\mathbf{Q}|}(|\mathbf{Q} - \mathbf{P}|) \,. \end{aligned}$$

In other words,  $\mathcal{D}: \mathbb{R}^{n \times d} \to \mathbb{R}^{n \times d}$  has  $(p', \delta^{p-1})$ -structure in the sense of Definition 2.1.

Since, appealing to Lemma 5.1,  $\mathcal{D}$  has  $(p', \delta^{p-1})$ -structure in the sense of Definition 2.1, similar to Proposition 2.3, we have the following connections between  $\mathcal{D}, \mathcal{F}, \mathcal{F}^* \colon \mathbb{R}^{n \times d} \to \mathbb{R}^{n \times d}$  and  $\varphi_a, (\varphi^*)_a, ((\varphi^*)_a)^* \colon \mathbb{R}^{\geq 0} \to \mathbb{R}^{\geq 0}, a \geq 0$ .

PROPOSITION 5.2. Let S satisfy Definition 2.1, let  $\varphi$  be defined in (2.3), and let  $\mathcal{F}, \mathcal{F}^*$  be defined in (2.7). Then, uniformly with respect to  $\mathbf{Q}, \mathbf{P} \in \mathbb{R}^{n \times d}$ , we have that

(5.4)  
$$(\mathcal{D}(\mathbf{Q}) - \mathcal{D}(\mathbf{P})) : (\mathbf{Q} - \mathbf{P}) \sim |\mathcal{F}^*(\mathbf{Q}) - \mathcal{F}^*(\mathbf{P})|^2 \\\sim ((\varphi^*)_{|\mathbf{Q}|})^* (|\mathcal{D}(\mathbf{Q}) - \mathcal{D}(\mathbf{P})|) \\\sim \varphi_{|\mathcal{D}(\mathbf{Q})|} (|\mathcal{D}(\mathbf{Q}) - \mathcal{D}(\mathbf{P})|),$$

(5.5) 
$$|\mathcal{D}(\mathbf{Q}) - \mathcal{D}(\mathbf{P})| \sim (\varphi^*)'_{|\mathbf{Q}|}(|\mathbf{Q} - \mathbf{P}|),$$

(5.6) 
$$|\mathcal{F}(\mathcal{D}(\mathbf{P})) - \mathcal{F}(\mathcal{D}(\mathbf{Q}))|^2 \sim |\mathcal{F}^*(\mathbf{P}) - \mathcal{F}^*(\mathbf{Q})|^2.$$

The constants in (5.4)–(5.6) depend only on the characteristics of  $\boldsymbol{S}$ .

### **5.2.** Discrete mixed formulation. For given $k \in \mathbb{N}$ , we abbreviate

$$\Sigma_h \coloneqq \Sigma_h^{k-1} \coloneqq \mathbb{P}^{k-1}(\mathcal{T}_h)^{n \times d}.$$

Then, for given  $\mathbf{f} \in V^*$ , the discrete mixed formulation of (1.1) seeks for  $(\mathbf{S}_h, \mathbf{u}_h) \in \Sigma_h \times V_h$  such that for every  $(\mathbf{T}_h, \mathbf{z}_h) \in \Sigma_h \times V_h$ , it holds that

(5.7) 
$$(\mathcal{D}(\mathbf{S}_h) - \nabla_h \boldsymbol{u}_h, \mathbf{T}_h)_{\Omega} = 0,$$
$$(\mathbf{S}_h, \boldsymbol{\mathcal{G}}_h \boldsymbol{z}_h)_{\Omega} + \alpha \langle \boldsymbol{\mathcal{S}}_{\boldsymbol{\beta}_h(\boldsymbol{u}_h)}(h_{\Gamma}^{-1} \llbracket \boldsymbol{u}_h \otimes \boldsymbol{n} \rrbracket), \llbracket \boldsymbol{z}_h \otimes \boldsymbol{n} \rrbracket \rangle_{\Gamma_h} = \langle \boldsymbol{f}, \boldsymbol{\mathcal{E}}_h \boldsymbol{z}_h \rangle_V.$$

**PROPOSITION 5.3.** The following statements apply:

- (i) If  $\nabla_h = \boldsymbol{\mathcal{G}}_h$ , then the mixed formulation (5.7) admits a solution.
- (ii) If  $\tilde{\nabla}_h = \nabla_h$ , then for sufficiently large  $\alpha > 0$ , the mixed formulation (5.7) admits a solution.

*Proof.* We equip  $\Sigma_h \times V_h$  with the norm

$$\|(\mathbf{T}_h, oldsymbol{z}_h)\|_{\Sigma_h imes V_h} \coloneqq \|\mathbf{T}_h\|_{p',\Omega} + \|oldsymbol{z}_h\|_{p,h} \, .$$

For every  $\varepsilon > 0$ , we consider the regularized operator  $\mathcal{T}_h^{\varepsilon} \colon \Sigma_h \times V_h \to (\Sigma_h \times V_h)^*$ , defined, for every  $(\mathbf{S}_h, \boldsymbol{u}_h) \in \Sigma_h \times V_h$  and  $(\mathbf{T}_h, \boldsymbol{v}_h) \in \Sigma_h \times V_h$ , via

$$egin{aligned} &\langle \mathcal{T}_h^arepsilon(\mathbf{S}_h,oldsymbol{u}_h),(\mathbf{T}_h,oldsymbol{v}_h)
angle_{\Sigma_h imes V_h}\coloneqq &(\mathcal{D}(\mathbf{S}_h)-
abla_holdsymbol{u}_h,\mathbf{T}_h)_\Omega+(\mathbf{S}_h,oldsymbol{u}_h,\mathbf{V}_holdsymbol{v}_h)_\Omega\ &+arepsilon(oldsymbol{\mathcal{S}}_{oldsymbol{eta}_h}(oldsymbol{u}_h),(h_\Gamma^{-1}[\![oldsymbol{u}_h\otimesoldsymbol{n}]\!]),[\![oldsymbol{v}_h\otimesoldsymbol{n}]\!]
angle_{\Gamma_h}\,. \end{aligned}$$

Since  $V_h$  is finite dimensional, consists of broken polynomials, [5, Lem. 3.18], the properties of  $\mathcal{D}$ ,  $\mathcal{S}$  and  $\mathcal{S}_a$ ,  $a \geq 0$ , imply that the operator  $\mathcal{T}_h^{\varepsilon} \colon \Sigma_h \times V_h \to (\Sigma_h \times V_h)^*$ , for every fixed  $h, \varepsilon > 0$ , is well-defined, continuous, and monotone. To prove the boundedness of  $\mathcal{T}_h^{\varepsilon} \colon \Sigma_h \times V_h \to (\Sigma_h \times V_h)^*$ , we use the properties of  $\mathcal{D}$ ,  $\mathcal{S}$ ,  $\mathcal{S}_{\beta_h(\boldsymbol{v}_h)}$  (cf. Proposition 2.3 and Remark 2.4), Young's inequality, (2.1), the stability of  $\mathcal{R}_h$  (cf. [14, (A.25)]), a shift change (cf. Lemma 2.5),  $\sum_{F \in \Gamma_h} h_F \mathscr{H}^{d-1}(F) \sim |\Omega|$ , [17, Lemma 12.1], Jensen's inequality,  $\varphi(t) + t^p \sim t^p + \delta^p$ , and  $\varphi^*(t) + t^{p'} \sim t^{p'} + \delta^{p'}$  for all  $t \geq 0$  (cf. [5]), to find that

$$\begin{split} |\langle \boldsymbol{\mathcal{T}}_{h}^{\varepsilon}(\mathbf{S}_{h},\boldsymbol{u}_{h}),(\mathbf{T}_{h},\boldsymbol{v}_{h})\rangle_{\Sigma_{h}\times V_{h}}| \\ \lesssim \rho_{\varphi^{*},\Omega}(\mathbf{S}_{h}) + \rho_{\varphi^{*},\Omega}(\mathbf{T}_{h}) + \rho_{\varphi,\Omega}(\tilde{\nabla}_{h}\boldsymbol{u}_{h}) + \rho_{\varphi,\Omega}(\nabla_{h}\boldsymbol{u}_{h}) + \rho_{\varphi,\Omega}(\nabla_{h}\boldsymbol{v}_{h}) \\ \lesssim \rho_{\varphi^{*},\Omega}(\mathbf{S}_{h}) + \rho_{\varphi^{*},\Omega}(\mathbf{T}_{h}) + \rho_{\varphi,\Omega}(\nabla_{h}\boldsymbol{u}_{h}) + \rho_{\varphi,\Omega}(\nabla_{h}\boldsymbol{v}_{h}) + m_{\varphi,h}(\boldsymbol{u}_{h}) + \varphi(\boldsymbol{\beta}_{h}(\boldsymbol{v}_{h})) \\ \lesssim \|\mathbf{S}_{h}\|_{p'}^{p'} + \|\mathbf{T}_{h}\|_{p'}^{p'} + \|\boldsymbol{u}_{h}\|_{p,h}^{p} + \|\boldsymbol{v}_{h}\|_{p,h}^{p} + \delta^{p} + \delta^{p'} \,. \end{split}$$

Thus,  $\mathcal{T}_{h}^{\varepsilon}: \Sigma_{h} \times V_{h} \to (\Sigma_{h} \times V_{h})^{*}$  is pseudo-monotone. If we can prove its coercivity, then, owing to the pseudo-monotone operator theory (cf. [42, Thm. 27.A]), it follows that  $\mathcal{T}_{h}^{\varepsilon}: \Sigma_{h} \times V_{h} \to (\Sigma_{h} \times V_{h})^{*}$  is surjective. To this end, we distinguish the cases  $\tilde{\nabla}_{h} = \mathcal{G}_{h}$  and  $\tilde{\nabla}_{h} = \nabla_{h}$ :

Case  $\tilde{\nabla}_h = \mathcal{G}_h$ . For every  $(\mathbf{S}_h, \mathbf{u}_h) \in \Sigma_h \times V_h$ , using that  $\mathcal{D}(\mathbf{Q}) : \mathbf{Q} \sim \varphi^*(|\mathbf{Q}|)$ (cf. (5.4)) and  $\mathcal{S}_{\beta_h(\mathbf{u}_h)}(\mathbf{Q}) : \mathbf{Q} \sim \varphi_{\beta_h(\mathbf{u}_h)}(|\mathbf{Q}|)$  for all  $\mathbf{Q} \in \mathbb{R}^{n \times d}$  (cf. Proposition 2.3 and Remark 2.4) as well as that  $\varphi_{\beta_h(\mathbf{u}_h)} \geq \varphi, \, \delta^{p'} + \varphi^*(t) \sim t^{p'} + \delta^{p'}$ , and  $\delta^p + \varphi(t) \sim$   $t^p + \delta^p$  for all  $t \ge 0$ , and  $\sum_{F \in \Gamma_h} h_F \, \mathscr{H}^{d-1}(F) \lesssim |\Omega|$ , we find that

$$\begin{aligned} \langle \mathcal{T}_{h}^{\varepsilon}(\mathbf{S}_{h},\boldsymbol{u}_{h}),(\mathbf{S}_{h},\boldsymbol{u}_{h})\rangle_{\Sigma_{h}\times V_{h}} \\ &= (\mathcal{D}(\mathbf{S}_{h}),\mathbf{S}_{h})_{\Omega} + \varepsilon \left(\mathcal{S}(\nabla_{h}\boldsymbol{u}_{h}),\nabla_{h}\boldsymbol{u}_{h}\right)_{\Omega} + \alpha \left\langle \mathcal{S}_{\boldsymbol{\beta}_{h}(\boldsymbol{u}_{h})}(h_{\Gamma}^{-1}\llbracket\boldsymbol{u}_{h}\otimes\boldsymbol{n}\rrbracket),\llbracket\boldsymbol{u}_{h}\otimes\boldsymbol{n}\rrbracket \right\rangle_{\Gamma_{h}} \\ &\gtrsim \rho_{\varphi^{*},\Omega}(\mathbf{S}_{h}) + \varepsilon \rho_{\varphi,\Omega}(\nabla_{h}\boldsymbol{u}_{h}) + \alpha m_{\varphi_{\boldsymbol{\beta}_{h}(\boldsymbol{u}_{h})},h}(\boldsymbol{u}_{h}) \\ &\gtrsim \|\mathbf{S}_{h}\|_{p',\Omega}^{p'} + \min\{\varepsilon,\alpha\} \|\boldsymbol{u}_{h}\|_{p,h}^{p} - \delta^{p} |\Omega| \left(\varepsilon + \alpha\right) - \delta^{p'} |\Omega| \,. \end{aligned}$$

Putting everything together,  $\mathcal{T}_{h}^{\varepsilon}: \Sigma_{h} \times V_{h} \to (\Sigma_{h} \times V_{h})^{*}$  is well-defined, continuous, and coercive and, thus, surjective (cf. [42, Thm. 27.A]).

Case  $\tilde{\nabla}_h = \nabla_h$ . For every  $(\mathbf{S}_h, \mathbf{u}_h) \in \Sigma_h \times V_h$ , proceeding as before, also using the  $\kappa$ -Young inequality (2.2) with  $\psi = |\cdot|^{p'}$  and that  $\|\mathcal{R}_h \mathbf{u}_h\|_{p,\Omega} \lesssim \|h_{\Gamma}^{1/p'}[\![\mathbf{u}_h \otimes \mathbf{n}]\!]\|_{p,\Gamma_h}$  (cf. [14, (A.25)]), it holds that

(5.8)  

$$\begin{aligned} \langle \boldsymbol{\mathcal{T}}_{h}^{\varepsilon}(\mathbf{S}_{h},\boldsymbol{u}_{h}),(\mathbf{S}_{h},\boldsymbol{u}_{h})\rangle_{\Sigma_{h}\times V_{h}} &= (\boldsymbol{\mathcal{D}}(\mathbf{S}_{h})-\boldsymbol{\mathcal{R}}_{h}\boldsymbol{u}_{h},\mathbf{S}_{h})_{\Omega}+\varepsilon\,(\boldsymbol{\mathcal{S}}_{\Gamma}\boldsymbol{u}_{h},\boldsymbol{u}_{h}),\nabla_{h}\boldsymbol{u}_{h})_{\Omega}\\ &+\alpha\,\langle \boldsymbol{\mathcal{S}}_{\boldsymbol{\beta}_{h}(\boldsymbol{u}_{h})}(h_{\Gamma}^{-1}\llbracket\boldsymbol{u}_{h}\otimes\boldsymbol{n}\rrbracket),\llbracket\boldsymbol{u}_{h}\otimes\boldsymbol{n}\rrbracket\rangle_{\Gamma_{h}}\\ &\geq (c-\kappa)\,\Vert \mathbf{S}_{h}\Vert_{p',\Omega}^{p'}+\min\{\varepsilon,\alpha-c_{\kappa}\}\,\Vert\boldsymbol{u}_{h}\Vert_{p,h}^{p}\\ &-c\,\delta^{p}\,\vert\Omega\vert\,(\varepsilon+\alpha)-c\,\delta^{p'}\,\vert\Omega|\,.
\end{aligned}$$

Therefore, choosing first  $\kappa > 0$  sufficiently small and, subsequently,  $\alpha > 0$  sufficiently large in (5.8), for every  $(\mathbf{S}_h, \mathbf{u}_h) \in \Sigma_h \times V_h$ , we conclude that

$$\begin{split} & \langle \boldsymbol{\mathcal{T}}_{h}^{\varepsilon}(\boldsymbol{\mathsf{S}}_{h},\boldsymbol{u}_{h}), (\boldsymbol{\mathsf{S}}_{h},\boldsymbol{u}_{h}) \rangle_{\Sigma_{h} \times V_{h}} \\ & \gtrsim \|\boldsymbol{\mathsf{S}}_{h}\|_{p',\Omega}^{p'} + \min\{\varepsilon,\alpha\} \|\boldsymbol{u}_{h}\|_{p,h}^{p} - \delta^{p} |\Omega| (\varepsilon + \alpha) - \delta^{p'} |\Omega| \end{split}$$

Putting everything together,  $\mathcal{T}_{h}^{\varepsilon} \colon \Sigma_{h} \times V_{h} \to (\Sigma_{h} \times V_{h})^{*}$  is well-defined, continuous, and coercive and, thus, surjective (cf. [42, Thm. 27.A]).

Therefore, for every  $\varepsilon, h > 0$  and  $\tilde{\nabla}_h \in \{\boldsymbol{\mathcal{G}}_h, \nabla_h\}$ , there exists  $(\mathbf{S}_h^{\varepsilon}, \boldsymbol{u}_h^{\varepsilon}) \in \Sigma_h \times V_h$ such that  $\mathcal{T}_h^{\varepsilon}(\mathbf{S}_h^{\varepsilon}, \boldsymbol{u}_h^{\varepsilon}) = (\mathbf{0}, \boldsymbol{\mathcal{E}}_h^* \boldsymbol{f})$  in  $(\Sigma_h \times V_h)^* \cong \Sigma_h^* \times V_h^*$ , i.e., for every  $(\mathbf{T}_h, \boldsymbol{z}_h) \in \Sigma_h \times V_h$ , it holds that

(5.9a)

$$(\mathcal{D}(\mathbf{S}_{h}^{\varepsilon}), \mathbf{T}_{h})_{\Omega} - (\mathbf{T}_{h}, \tilde{\nabla}_{h} \boldsymbol{u}_{h}^{\varepsilon})_{\Omega} = 0,$$

(5.9b) 
$$(\mathbf{S}_{h}^{\varepsilon}, \boldsymbol{\mathcal{G}}_{h} \boldsymbol{z}_{h})_{\Omega} + \varepsilon \left( \boldsymbol{\mathcal{S}}(\nabla_{h} \boldsymbol{u}_{h}^{\varepsilon}), \nabla_{h} \boldsymbol{z}_{h} \right)_{\Omega} + \alpha \left\langle \boldsymbol{\mathcal{S}}_{\boldsymbol{\beta}_{h}(\boldsymbol{u}_{h}^{\varepsilon})}(h_{\Gamma}^{-1} \llbracket \boldsymbol{u}_{h}^{\varepsilon} \otimes \boldsymbol{n} \rrbracket \right), \llbracket \boldsymbol{z}_{h} \otimes \boldsymbol{n} \rrbracket \right\rangle_{\Gamma_{h}} = \langle \boldsymbol{f}, \boldsymbol{\mathcal{E}}_{h} \boldsymbol{z}_{h} \rangle_{V} \,.$$

Then, choosing  $\boldsymbol{z}_h = \boldsymbol{u}_h^{\varepsilon} \in V_h$ ,  $\boldsymbol{\mathsf{T}}_h = \boldsymbol{\mathsf{S}}_h^{\varepsilon} \in \Sigma_h$  in (5.9), and using Remark 4.1, (1.6) we find that

(5.10) 
$$\langle \boldsymbol{f}, \boldsymbol{\mathcal{E}}_{h} \boldsymbol{u}_{h}^{\varepsilon} \rangle_{V} = (\boldsymbol{\mathcal{D}}(\boldsymbol{S}_{h}^{\varepsilon}), \boldsymbol{S}_{h}^{\varepsilon})_{\Omega} + \varepsilon \left(\boldsymbol{\mathcal{S}}(\nabla_{h} \boldsymbol{u}_{h}^{\varepsilon}), \nabla_{h} \boldsymbol{u}_{h}^{\varepsilon}\right)_{\Omega} + \alpha \left\langle \boldsymbol{\mathcal{S}}_{\boldsymbol{\beta}_{h}(\boldsymbol{u}_{h}^{\varepsilon})}(h_{\Gamma}^{-1}[\![\boldsymbol{u}_{h}^{\varepsilon} \otimes \boldsymbol{n}]\!]), [\![\boldsymbol{u}_{h}^{\varepsilon} \otimes \boldsymbol{n}]\!] \right\rangle_{\Gamma_{h}} \geq \rho_{\varphi^{*},\Omega}(\boldsymbol{S}_{h}^{\varepsilon}) + \varepsilon \rho_{\varphi,\Omega}(\nabla_{h} \boldsymbol{u}_{h}^{\varepsilon}) + \alpha m_{\varphi_{\boldsymbol{\beta}_{h}(\boldsymbol{u}_{h}^{\varepsilon})},h}(\boldsymbol{u}_{h}^{\varepsilon}) \,.$$

From (5.9a), we obtain  $\tilde{\nabla}_h \boldsymbol{u}_h^{\varepsilon} = \Pi_h^{k-1} \boldsymbol{\mathcal{D}}(\mathbf{S}_h^{\varepsilon})$ . Using this, the Orlicz stability of  $\Pi_h^{k-1}$  (cf. [14, (A.11)]), that  $\boldsymbol{\mathcal{D}}$  has  $(p', \delta^{p-1})$ -structure (cf. Lemma 5.1), and the equivalence (2.1), we obtain

(5.11) 
$$\rho_{\varphi,\Omega}(\nabla_{h}\boldsymbol{u}_{h}^{\varepsilon}) = \rho_{\varphi,\Omega}(\Pi_{h}^{\kappa-1}\mathcal{D}(\boldsymbol{\mathsf{S}}_{h}^{\varepsilon})) \\ \lesssim \rho_{\varphi,\Omega}((\varphi^{*})'(\boldsymbol{\mathsf{S}}_{h}^{\varepsilon})) \\ \lesssim \rho_{\varphi^{*},\Omega}(\boldsymbol{\mathsf{S}}_{h}^{\varepsilon}) .$$

Using (5.11) in (5.10) and  $\varphi_{\beta_h(u_h)} \ge \varphi, \, \delta^{p'} + \varphi^*(t) \sim t^{p'} + \delta^{p'}$ , and  $\delta^p + \varphi(t) \sim t^p + \delta^p$ for all  $t \ge 0$ ,  $\sum_{F \in \Gamma_h} h_F \mathscr{H}^{d-1}(F) \lesssim |\Omega|$ , and (2.12) if  $\tilde{\nabla}_h = \mathcal{G}_h$ , yields that

(5.12) 
$$\langle \boldsymbol{f}, \boldsymbol{\mathcal{E}}_{h} \boldsymbol{u}_{h}^{\varepsilon} \rangle_{V} \gtrsim \rho_{\varphi^{*},\Omega}(\boldsymbol{S}_{h}^{\varepsilon}) + (1+\varepsilon) \rho_{\varphi,\Omega}(\tilde{\nabla}_{h} \boldsymbol{u}_{h}^{\varepsilon}) + \alpha m_{\varphi_{\boldsymbol{\beta}_{h}}(\boldsymbol{u}_{h}^{\varepsilon}),h}(\boldsymbol{u}_{h}^{\varepsilon}) \\ \gtrsim \|\boldsymbol{S}_{h}^{\varepsilon}\|_{p',\Omega}^{p'} + \min\{1,\alpha\} \|\boldsymbol{u}_{h}^{\varepsilon}\|_{p,h}^{p} - \delta^{p} |\Omega| (1+\alpha) - \delta^{p'} |\Omega|$$

Crucially, the constant in the last inequality is independent of  $\varepsilon$ . On the other hand, using the  $\kappa$ -Young inequality (2.2) with  $\psi = |\cdot|^p$  and Proposition 3.1 with  $\psi = |\cdot|^p$ , we find that

(5.13) 
$$\begin{aligned} |\langle \boldsymbol{f}, \boldsymbol{\mathcal{E}}_{h} \boldsymbol{u}_{h}^{\varepsilon} \rangle_{V}| &\leq c_{\kappa} \|\boldsymbol{f}\|_{V^{*}}^{p} + \kappa \|\boldsymbol{\mathcal{E}}_{h} \boldsymbol{u}_{h}^{\varepsilon}\|_{V}^{p} \\ &\lesssim c_{\kappa} \|\boldsymbol{f}\|_{V^{*}}^{p'} + \kappa \|\boldsymbol{u}_{h}^{\varepsilon}\|_{p,h}^{p}. \end{aligned}$$

Therefore, combining (5.12) and (5.13) as well as choosing  $\kappa > 0$  sufficiently small, we conclude that

$$\|\mathbf{S}_{h}^{\varepsilon}\|_{p',\Omega}^{p'} + \min\{1,\alpha\} \|\boldsymbol{u}_{h}^{\varepsilon}\|_{p,h}^{p} \lesssim 1$$

Therefore, due to the finite dimensionality of  $\Sigma_h$  and  $V_h$ , the Bolzano–Weierstraß compactness theorem yields the existence of a not re-labeled subsequence as well as limits  $\mathbf{S}_h \in \Sigma_h$  and  $\boldsymbol{u}_h \in V_h$  such that

(5.14) 
$$\begin{aligned} \mathbf{S}_{h}^{\varepsilon} \to \mathbf{S}_{h} & \text{strongly in } \Sigma_{h} & (\varepsilon \to 0) , \\ \boldsymbol{u}_{h}^{\varepsilon} \to \boldsymbol{u}_{h} & \text{strongly in } V_{h} & (\varepsilon \to 0) . \end{aligned}$$

Using (5.14), by passing for  $\varepsilon \to 0$  in (5.9), we conclude that

$$(\mathcal{D}(\mathbf{S}_h), \mathbf{T}_h)_{\Omega} - (\mathbf{T}_h, \dot{\nabla}_h \boldsymbol{u}_h)_{\Omega} = 0,$$
  
$$(\mathbf{S}_h, \boldsymbol{\mathcal{G}}_h \boldsymbol{z}_h)_{\Omega} + \alpha \langle \boldsymbol{\mathcal{S}}_{\boldsymbol{\beta}_h(\boldsymbol{u}_h)}(h_{\Gamma}^{-1}\llbracket \boldsymbol{u}_h \otimes \boldsymbol{n} \rrbracket), \llbracket \boldsymbol{z}_h \otimes \boldsymbol{n} \rrbracket \rangle_{\Gamma_h} = \langle \boldsymbol{f}, \boldsymbol{\mathcal{E}}_h \boldsymbol{z}_h \rangle_V,$$

i.e.,  $(\mathbf{S}_h, \mathbf{u}_h) \in \Sigma_h \times V_h$  is a solution of the discrete mixed formulation (5.7). 

Let us next prove a best-approximation result similar to Theorem 4.6, but now for the mixed formulation (5.7). To this end, we need to restrict ourselves either to the case of element-wise affine functions or the case  $p \leq 2$  together with the assumption that  $(\delta + |\overline{\nabla u}|)^{2-p}$ , where  $\overline{\nabla u} \coloneqq \nabla u$  in  $\Omega$  and  $\overline{\nabla u} \coloneqq \mathbf{0}$  in  $\mathbb{R}^d \setminus \Omega$ , belongs to the Muckenhoupt class  $A_2(\mathbb{R}^d)$ . More precisely, given  $p \in [1, \infty)$ , a weight  $\sigma \colon \mathbb{R}^d \to (0, +\infty)$ , i.e.,  $\sigma \in L^1_{\text{loc}}(\mathbb{R}^d)$  and  $0 < \sigma(x) < +\infty$  for a.e.  $x \in \mathbb{R}^d$ , is said to satisfy the  $A_p$ -condition, if

$$[\sigma]_{A_p(\mathbb{R}^d)} \coloneqq \sup_{B \subseteq \mathbb{R}^d; B \text{ ball}} \langle \sigma \rangle_B (\langle \sigma^{1-p'} \rangle_B)^{p-1} < \infty.$$

We denote by  $A_p(\mathbb{R}^d)$  the class of all weights satisfying the  $A_p$ -condition and use weighted Lebesgue spaces  $L^p(\Omega; \sigma)$  equipped with the norm  $\|v\|_{p,\sigma,\Omega} \coloneqq (\int_{\Omega} |v|^p \sigma \, \mathrm{d}x)^{\frac{1}{p}}$ .

REMARK 5.4 (Comments on Muckenhoupt weights).

- (i) If  $\sigma \in L^1_{\text{loc}}(\mathbb{R}^d)$  is a weight and there exist c, C > 0 such that  $c \leq \sigma \leq C$  a.e. in  $\mathbb{R}^d$ , then  $\sigma \in A_p(\mathbb{R}^d)$  for all  $p \in [1, \infty)$ . (ii) If  $\sigma \coloneqq |\cdot|^\eta \in L^1_{\text{loc}}(\mathbb{R}^d)$ , then  $\sigma \in A_p(\mathbb{R}^d)$ ,  $p \in (1, \infty)$ , if  $-d < \eta < d(p-1)$ .

THEOREM 5.5. Assume that k = 1 or that  $p \leq 2$  and  $(\delta + |\overline{\nabla u}|)^{2-p} \in A_2(\mathbb{R}^d)$ , where  $\overline{\nabla u} \coloneqq \nabla u$  in  $\Omega$  and  $\overline{\nabla u} \coloneqq 0$  in  $\mathbb{R}^d \setminus \Omega$ . Then, for  $\alpha > 0$  sufficiently large, we have that

$$\begin{aligned} \|\boldsymbol{\mathcal{F}}(\tilde{\nabla}_{h}\boldsymbol{u}_{h}) - \boldsymbol{\mathcal{F}}(\nabla\boldsymbol{u})\|_{2,\Omega}^{2} + \|\boldsymbol{\mathcal{F}}^{*}(\boldsymbol{\mathsf{S}}_{h}) - \boldsymbol{\mathcal{F}}^{*}(\boldsymbol{\mathsf{S}})\|_{2,\Omega}^{2} + m_{\varphi_{\boldsymbol{\mathcal{B}}_{h}(\boldsymbol{u}_{h})},h}(\boldsymbol{u}_{h}) \\ \lesssim \inf_{\substack{(\boldsymbol{\mathsf{T}}_{h},\boldsymbol{v}_{h})\\\in\Sigma_{h}\times V_{h}}} \left(\|\boldsymbol{\mathcal{F}}(\nabla\boldsymbol{u}) - \boldsymbol{\mathcal{F}}(\tilde{\nabla}_{h}\boldsymbol{v}_{h})\|_{2,\Omega}^{2} + \|\boldsymbol{\mathcal{F}}^{*}(\boldsymbol{\mathsf{S}}) - \boldsymbol{\mathcal{F}}^{*}(\boldsymbol{\mathsf{T}}_{h})\|_{2,\Omega}^{2} + m_{\varphi_{\boldsymbol{\mathcal{B}}_{h}(\boldsymbol{u}_{h})},h}(\boldsymbol{v}_{h})\right). \end{aligned}$$

where the constant depends only on k,  $\omega_0$ ,  $[\sigma]_{A_2(\mathbb{R}^d)}$ , and the characteristics of S and  $\mathcal{D}$ .

Key ingredient in the proof of Theorem 5.5 is the following convex conjugation type inequality for the natural distance, which applies, if, e.g., k = 1 or if  $p \leq 2$  and  $(\delta + |\overline{\nabla u}|)^{2-p} \in A_2(\mathbb{R}^d)$ . In particular, note that if one is capable of establishing these convex conjugation formula for more general assumptions, then Theorem 5.5 immediately applies for these assumptions.

LEMMA 5.6. The following statements apply: (i) If k = 1, then for every  $\boldsymbol{v}_h, \boldsymbol{w}_h \in V_h$ , it holds that

$$\begin{split} & |\boldsymbol{\mathcal{F}}(\tilde{\nabla}_{h}\boldsymbol{v}_{h}) - \boldsymbol{\mathcal{F}}(\tilde{\nabla}_{h}\boldsymbol{w}_{h})\|_{2,\Omega}^{2} \\ &\lesssim \sup_{\boldsymbol{\mathsf{T}}_{h}\in\Sigma_{h}} \left[ (\tilde{\nabla}_{h}\boldsymbol{v}_{h} - \tilde{\nabla}_{h}\boldsymbol{w}_{h}, \boldsymbol{\mathsf{T}}_{h})_{\Omega} - \frac{1}{c}\rho_{(\varphi_{|\tilde{\nabla}_{h}\boldsymbol{v}_{h}|})^{*},\Omega}(\boldsymbol{\mathsf{T}}_{h}) \right], \end{split}$$

where the constants depend only on k,  $\omega_0$ ,  $[\sigma]_{A_2(\mathbb{R}^d)}$ , and the characteristics of  $\boldsymbol{S}$  and  $\boldsymbol{\mathcal{D}}$ .

(ii) If  $p \leq 2$ ,  $\mathcal{F}(\nabla u) \in L^2(\Omega)^{n \times d}$  and  $(\delta + |\overline{\nabla u}|)^{2-p} \in A_2(\mathbb{R}^d)$ , then for every  $v_h, w_h \in V_h$ , it holds that

$$\begin{split} \| \boldsymbol{\mathcal{F}}(\tilde{\nabla}_{h}\boldsymbol{v}_{h}) - \boldsymbol{\mathcal{F}}(\tilde{\nabla}_{h}\boldsymbol{w}_{h}) \|_{2,\Omega}^{2} \\ \lesssim \sup_{\boldsymbol{\mathsf{T}}_{h} \in \Sigma_{h}} \left[ (\tilde{\nabla}_{h}\boldsymbol{v}_{h} - \tilde{\nabla}_{h}\boldsymbol{w}_{h}, \boldsymbol{\mathsf{T}}_{h})_{\Omega} - \frac{1}{c}\rho_{(\varphi|\tilde{\nabla}_{h}\boldsymbol{v}_{h}|)^{*},\Omega}(\boldsymbol{\mathsf{T}}_{h}) \right] \\ + \| \boldsymbol{\mathcal{F}}(\tilde{\nabla}_{h}\boldsymbol{v}_{h}) - \boldsymbol{\mathcal{F}}(\nabla \boldsymbol{u}) \|_{2,\Omega}^{2} \,, \end{split}$$

where the constants depend only on k,  $\omega_0$ ,  $[\sigma]_{A_2(\mathbb{R}^d)}$ , and the characteristics of  $\boldsymbol{\mathcal{S}}$  and  $\boldsymbol{\mathcal{D}}$ .

Lemma 5.6(ii), in turn, is essentially based on the following (local) stability result for the  $L^2$ -projection in terms of weighted Lebesgue norms.

LEMMA 5.7. If  $\sigma \in A_p(\mathbb{R}^d)$ ,  $p \in (1,\infty)$ , then for every  $\mathbf{T} \in L^p(\Omega;\sigma)^{n \times d}$  and  $K \in \mathcal{T}_h$ , we have that

$$\|\Pi_h^{k-1}\mathbf{T}\|_{p,\sigma,K} \lesssim \|\mathbf{T}\|_{p,\sigma,K},$$

where the constant depends only on k,  $\omega_0$ , p, and  $[\sigma]_{A_n(\mathbb{R}^d)}$ .

*Proof.* Using Hölder's inequality, a local norm equivalence (cf. [17, Lem. 12.1]), the  $L^1$ -stability of  $\Pi_h^{k-1}$  (cf. [14]),  $|B_{h_K}(x_K)| \sim |K|$ , where  $x_K$  is the barycenter of K,

and  $\sigma \in A_p(\mathbb{R}^d)$ , we observe that

$$\begin{split} \|\Pi_{h}^{k-1}\mathbf{T}\|_{p,\sigma,K} &\leq \|\Pi_{h}^{k-1}\mathbf{T}\|_{\infty,K} \|\sigma\|_{1,K}^{1/p} \\ &\lesssim |K|^{-1} \|\Pi_{h}^{k-1}\mathbf{T}\|_{1,K} \|\sigma\|_{1,K}^{1/p} \\ &\lesssim |K|^{-1} \|\mathbf{T}\|_{1,K} \|\sigma\|_{1,K}^{1/p} \\ &= |K|^{-1} \|\mathbf{T}\sigma^{1/p}\sigma^{-1/p}\|_{1,K} \|\sigma\|_{1,K}^{1/p} \\ &\lesssim \|\mathbf{T}\|_{p,\sigma,K} \||K|^{-1}\sigma^{1-p'}\|_{1,K}^{1/p'} \||K|^{-1}\sigma\|_{1,K}^{1/p} \\ &\lesssim \|\mathbf{T}\|_{p,\sigma,K} \||B_{h_{K}}(x_{K})|^{-1}\sigma^{1-p'}\|_{1,B_{h_{K}}(x_{K})}^{1/p'} \||B_{R_{K}}(x_{K})|^{-1}\sigma\|_{1,B_{h_{K}}(x_{K})}^{1/p} \\ &\lesssim \|\mathbf{T}\|_{p,\sigma,K}, \end{split}$$

where the constants depend only on k,  $\omega_0$ , p, and  $[\sigma]_{A_n(\mathbb{R}^d)}$ .

Proof (of Lemma 5.6). ad (i). For  $\tilde{\nabla} \boldsymbol{v}_h \in \Sigma_h$ , the local Orlicz-stability of  $\Pi_h^{k-1}$  (cf. [14, (A.11)]), for every  $\mathbf{T} \in L^{(\varphi|\tilde{\nabla}_h \boldsymbol{v}_h|)^*}(\Omega)^{n \times d}$ , implies that

$$\rho_{(\varphi|\tilde{\nabla}_{h}\boldsymbol{v}_{h}|)^{*},\Omega}(\Pi_{h}^{k-1}\mathbf{T}) \leq \rho_{(\varphi|\tilde{\nabla}_{h}\boldsymbol{v}_{h}|)^{*},\Omega}(\mathbf{T}).$$

Using this, Proposition 2.3, that  $\varphi_{|\tilde{\nabla}_h \boldsymbol{v}_h|} = (\varphi_{|\tilde{\nabla}_h \boldsymbol{v}_h|})^{**} = ((\varphi_{|\tilde{\nabla}_h \boldsymbol{v}_h|})^*)^*$ , the convex conjugation formula for integral functionals (cf. [16, Prop. 1.2]), and  $\tilde{\nabla} \boldsymbol{v}_h, \tilde{\nabla} \boldsymbol{w}_h \in \Sigma_h$ , we find that

$$\begin{split} \| \mathcal{F}(\tilde{\nabla}_{h} \boldsymbol{v}_{h}) - \mathcal{F}(\tilde{\nabla}_{h} \boldsymbol{w}_{h}) \|_{2,\Omega}^{2} &\lesssim \rho_{\varphi|\tilde{\nabla}_{h} \boldsymbol{v}_{h}|,\Omega}(\tilde{\nabla}_{h} \boldsymbol{v}_{h} - \tilde{\nabla}_{h} \boldsymbol{w}_{h}) \\ &= \rho_{(\varphi|\tilde{\nabla}_{h} \boldsymbol{v}_{h}|)^{*},\Omega}(\tilde{\nabla}_{h} \boldsymbol{v}_{h} - \tilde{\nabla}_{h} \boldsymbol{w}_{h}) \\ &= \sup_{\mathbf{T} \in L^{(\varphi|\tilde{\nabla}_{h} \boldsymbol{v}_{h}|)^{*}}(\Omega)^{n \times d}} \left[ (\tilde{\nabla}_{h} \boldsymbol{v}_{h} - \tilde{\nabla}_{h} \boldsymbol{w}_{h}, \mathbf{T})_{\Omega} - \rho_{(\varphi|\tilde{\nabla}_{h} \boldsymbol{v}_{h}|)^{*},\Omega}(\mathbf{T}) \\ &= \sup_{\mathbf{T} \in L^{(\varphi|\tilde{\nabla}_{h} \boldsymbol{v}_{h}|)^{*}}(\Omega)^{n \times d}} \left[ (\tilde{\nabla}_{h} \boldsymbol{v}_{h} - \tilde{\nabla}_{h} \boldsymbol{w}_{h}, \Pi_{h}^{k-1}\mathbf{T})_{\Omega} - \rho_{(\varphi|\tilde{\nabla}_{h} \boldsymbol{v}_{h}|)^{*},\Omega}(\mathbf{T}) \\ &\lesssim \sup_{\mathbf{T} \in L^{(\varphi|\tilde{\nabla}_{h} \boldsymbol{v}_{h}|)^{*}}(\Omega)^{n \times d}} \left[ (\tilde{\nabla}_{h} \boldsymbol{v}_{h} - \tilde{\nabla}_{h} \boldsymbol{w}_{h}, \Pi_{h}^{k-1}\mathbf{T})_{\Omega} - \frac{1}{c}\rho_{(\varphi|\tilde{\nabla}_{h} \boldsymbol{v}_{h}|)^{*},\Omega}(\Pi_{h}^{k-1}\mathbf{T}) \\ &\lesssim \sup_{\mathbf{T}_{h} \in \Sigma_{h}} \left[ (\tilde{\nabla}_{h} \boldsymbol{v}_{h} - \tilde{\nabla}_{h} \boldsymbol{w}_{h}, \mathbf{T}_{h})_{\Omega} - \frac{1}{c}\rho_{(\varphi|\tilde{\nabla}_{h} \boldsymbol{v}_{h}|)^{*},\Omega}(\mathbf{T}_{h}) , \end{split} \right]$$

which is the claimed convex conjugation type inequality for the natural distance in the case k = 1.

ad (ii). Abbreviate  $\sigma := (\delta + |\overline{\nabla u}|)^{2-p}$ . Due  $p \leq 2$ , for a.e.  $x \in \Omega$  and every  $t \geq 0$ , it holds that

(5.15) 
$$((\delta + |\nabla \boldsymbol{u}(x)|)^{p-1} + t)^{p-2} t^{2} \leq 2^{p'-2} (\sigma(x) t^{2} + t^{p'}) \leq 2^{p'-2} ((\delta + |\nabla \boldsymbol{u}(x)|)^{p-1} + t)^{p'-2} t^{2}.$$

Therefore, using (5.15), the stability of  $\Pi_h^{k-1}$  in  $L^{p'}(\Omega)^{n \times d}$  (cf. [26, Cor. A.8]), and in  $L^2(\Omega, \sigma)^{n \times d}$  (cf. Lemma 5.7) together with  $(\delta + |\overline{\nabla u}|)^{2-p} \in A_2(\mathbb{R}^d)$ , for every  $\mathbf{T} \in L^{p'}(\Omega)^{n \times d} \cap L^2(\Omega; \sigma)^{n \times d} \sim L^{(\varphi_{|\nabla u|})^*}(\Omega)^{n \times d}$ , it holds that

(5.16)  

$$\rho_{(\varphi_{|\nabla \boldsymbol{u}|})^{*}}(\Pi_{h}^{k-1}\mathbf{T}) \lesssim \|\Pi_{h}^{k-1}\mathbf{T}\|_{2,\omega}^{2} + \|\Pi_{h}^{k-1}\mathbf{T}\|_{p'}^{p'}$$

$$\lesssim \|\mathbf{T}\|_{2,\omega}^{2} + \|\mathbf{T}\|_{p'}^{p'}$$

$$\lesssim \rho_{(\varphi_{|\nabla \boldsymbol{u}|})^{*}}(\mathbf{T}),$$

which, using a shift change in Lemma 2.5, implies that

(5.17)  

$$\begin{aligned} \rho_{(\varphi_{|\tilde{\nabla}_{h}\boldsymbol{v}_{h}|)^{*},\Omega}(\Pi_{h}^{k-1}\mathbf{T}) &\lesssim \rho_{(\varphi_{|\nabla\boldsymbol{u}|})^{*},\Omega}(\Pi_{h}^{k-1}\mathbf{T}) + \|\boldsymbol{\mathcal{F}}(\tilde{\nabla}_{h}\boldsymbol{v}_{h}) - \boldsymbol{\mathcal{F}}(\nabla\boldsymbol{u})\|_{2,\Omega}^{2} \\ &\lesssim \rho_{(\varphi_{|\nabla\boldsymbol{u}|})^{*},\Omega}(\mathbf{T}) + \|\boldsymbol{\mathcal{F}}(\tilde{\nabla}_{h}\boldsymbol{v}_{h}) - \boldsymbol{\mathcal{F}}(\nabla\boldsymbol{u})\|_{2,\Omega}^{2} \\ &\lesssim \rho_{(\varphi_{|\tilde{\nabla}_{h}\boldsymbol{v}_{h}|)^{*},\Omega}(\mathbf{T}) + \|\boldsymbol{\mathcal{F}}(\tilde{\nabla}_{h}\boldsymbol{v}_{h}) - \boldsymbol{\mathcal{F}}(\nabla\boldsymbol{u})\|_{2,\Omega}^{2}.
\end{aligned}$$

Using (5.17) and proceeding as in (i), we find that

$$\begin{split} \| \mathcal{F}(\tilde{\nabla}_{h}\boldsymbol{v}_{h}) - \mathcal{F}(\tilde{\nabla}_{h}\boldsymbol{w}_{h}) \|_{2,\Omega}^{2} &\lesssim \rho_{\varphi_{|\tilde{\nabla}_{h}\boldsymbol{v}_{h}|,\Omega}}(\tilde{\nabla}_{h}\boldsymbol{v}_{h} - \tilde{\nabla}_{h}\boldsymbol{w}_{h}) \\ &= \rho_{(\varphi_{|\tilde{\nabla}_{h}\boldsymbol{v}_{h}|})^{**},\Omega}(\tilde{\nabla}_{h}\boldsymbol{v}_{h} - \tilde{\nabla}_{h}\boldsymbol{w}_{h}) \\ &= \sup_{\mathbf{T}\in L^{(\varphi_{|\tilde{\nabla}_{h}\boldsymbol{v}_{h}|)^{*}}(\Omega)^{n\times d}} \left[ (\tilde{\nabla}_{h}\boldsymbol{v}_{h} - \tilde{\nabla}_{h}\boldsymbol{w}_{h}, \mathbf{T})_{\Omega} - \rho_{(\varphi_{|\tilde{\nabla}_{h}\boldsymbol{v}_{h}|})^{*},\Omega}(\mathbf{T}) \right] \\ &= \sup_{\mathbf{T}\in L^{(\varphi_{|\tilde{\nabla}_{h}\boldsymbol{v}_{h}|)^{*}}(\Omega)^{n\times d}} \left[ (\tilde{\nabla}_{h}\boldsymbol{v}_{h} - \tilde{\nabla}_{h}\boldsymbol{w}_{h}, \Pi_{h}^{k-1}\mathbf{T})_{\Omega} - \rho_{(\varphi_{|\tilde{\nabla}_{h}\boldsymbol{v}_{h}|})^{*},\Omega}(\mathbf{T}) \right] \\ &\lesssim \sup_{\mathbf{T}\in L^{(\varphi_{|\tilde{\nabla}_{h}\boldsymbol{v}_{h}|)^{*}}(\Omega)^{n\times d}} \left[ (\tilde{\nabla}_{h}\boldsymbol{v}_{h} - \tilde{\nabla}_{h}\boldsymbol{w}_{h}, \Pi_{h}^{k-1}\mathbf{T})_{\Omega} - \frac{1}{c}\rho_{(\varphi_{|\tilde{\nabla}_{h}\boldsymbol{v}_{h}|)^{*},\Omega}(\Pi_{h}^{k}\mathbf{T}) \right] \\ &+ \| \mathcal{F}(\tilde{\nabla}_{h}\boldsymbol{v}_{h}) - \mathcal{F}(\nabla\boldsymbol{u}) \|_{2,\Omega}^{2} \\ &\lesssim \sup_{\mathbf{T}_{h}\in\Sigma_{h}} \left[ (\tilde{\nabla}_{h}\boldsymbol{v}_{h} - \tilde{\nabla}_{h}\boldsymbol{w}_{h}, \mathbf{T}_{h})_{\Omega} - \frac{1}{c}\rho_{(\varphi_{|\tilde{\nabla}_{h}\boldsymbol{v}_{h}|)^{*},\Omega}(\mathbf{T}_{h}) \right] \\ &+ \| \mathcal{F}(\tilde{\nabla}_{h}\boldsymbol{v}_{h}) - \mathcal{F}(\nabla\boldsymbol{u}) \|_{2,\Omega}^{2}, \end{split}$$

which is the claimed convex conjugation type inequality for the natural distance in the case  $p \leq 2$  and  $\sigma \in A_2(\mathbb{R}^d)$ .

Proof (of Theorem 5.5). By the continuous mixed formulation (5.1), the discrete mixed formulation (5.7) and the crucial identity (1.6), for every  $(\mathbf{T}_h, \mathbf{z}_h) \in \Sigma_h \times V_h$ , we have that

(5.18) 
$$(\mathcal{D}(\mathbf{S}_h) - \mathcal{D}(\mathbf{S}), \mathbf{T}_h)_{\Omega} = (\tilde{\nabla}_h \boldsymbol{u}_h - \nabla \boldsymbol{u}, \mathbf{T}_h)_{\Omega} ,$$
  
(5.19) 
$$(\mathbf{S}_h - \mathbf{S}, \nabla_h \boldsymbol{\mathcal{E}}_h \boldsymbol{z}_h)_{\Omega} = -\alpha \langle \boldsymbol{\mathcal{S}}_{\boldsymbol{\beta}_h(\boldsymbol{u}_h)}(h_{\Gamma}^{-1} \llbracket \boldsymbol{u}_h \otimes \boldsymbol{n} \rrbracket), \llbracket \boldsymbol{z}_h \otimes \boldsymbol{n} \rrbracket \rangle_{\Gamma_h}$$

Therefore, taking an arbitrary  $\boldsymbol{v}_h \in V_h$ , using Lemma 5.6, (5.18), the  $\varepsilon$ -Young inequality (2.2) with  $\psi = \varphi_{|\tilde{\nabla}_h \boldsymbol{v}_h|}$ , (2.8), and a shift change in Lemma 2.5, choosing  $\varepsilon > 0$  sufficiently small, and using (5.4) with  $\nabla \boldsymbol{u} = \mathcal{D}(\boldsymbol{S})$ , we find that

$$\begin{split} \|\mathcal{F}(\tilde{\nabla}_{h}\boldsymbol{u}_{h}) - \mathcal{F}(\tilde{\nabla}_{h}\boldsymbol{v}_{h})\|_{2,\Omega}^{2} \\ \lesssim \sup_{\mathbf{T}_{h}\in\Sigma_{h}} \left[ (\tilde{\nabla}_{h}\boldsymbol{u}_{h} - \tilde{\nabla}_{h}\boldsymbol{v}_{h}, \mathbf{T}_{h})_{\Omega} - \frac{1}{c}\rho_{(\varphi_{|\tilde{\nabla}_{h}\boldsymbol{v}_{h}|})^{*},\Omega}(\mathbf{T}_{h}) \right] + \|\mathcal{F}(\nabla\boldsymbol{u}) - \mathcal{F}(\tilde{\nabla}_{h}\boldsymbol{v}_{h})\|_{2,\Omega}^{2} \\ = \sup_{\mathbf{T}_{h}\in\Sigma_{h}} \left[ (\mathcal{D}(\mathbf{S}_{h}) - \mathcal{D}(\mathbf{S}), \mathbf{T}_{h})_{\Omega} + (\nabla\boldsymbol{u} - \tilde{\nabla}_{h}\boldsymbol{v}_{h}, \mathbf{T}_{h})_{\Omega} - \frac{1}{c}\rho_{(\varphi_{|\tilde{\nabla}_{h}\boldsymbol{v}_{h}|})^{*},\Omega}(\mathbf{T}_{h}) \right] \\ + \|\mathcal{F}(\nabla\boldsymbol{u}) - \mathcal{F}(\tilde{\nabla}_{h}\boldsymbol{v}_{h})\|_{2,\Omega}^{2} \\ \leq c_{\varepsilon} \rho_{\varphi_{|\tilde{\nabla}_{h}\boldsymbol{v}_{h}|},\Omega}(\mathcal{D}(\mathbf{S}_{h}) - \mathcal{D}(\mathbf{S})) + (c_{\varepsilon} + 1) \|\mathcal{F}(\nabla\boldsymbol{u}) - \mathcal{F}(\tilde{\nabla}_{h}\boldsymbol{v}_{h})\|_{2,\Omega}^{2} \\ + \sup_{\mathbf{T}_{h}\in\Sigma_{h}} \left[ 2\varepsilon \rho_{(\varphi_{|\tilde{\nabla}_{h}\boldsymbol{v}_{h}|)^{*},\Omega}(\mathbf{T}_{h}) - \frac{1}{c}\rho_{(\varphi_{|\tilde{\nabla}_{h}\boldsymbol{v}_{h}|)^{*},\Omega}(\mathbf{T}_{h}) \right] \\ \lesssim \rho_{\varphi_{|\tilde{\nabla}_{h}\boldsymbol{v}_{h}|},\Omega}(\mathcal{D}(\mathbf{S}_{h}) - \mathcal{D}(\mathbf{S})) + \|\mathcal{F}(\nabla\boldsymbol{u}) - \mathcal{F}(\tilde{\nabla}_{h}\boldsymbol{v}_{h})\|_{2,\Omega}^{2} \\ \lesssim \rho_{\varphi_{|\tilde{\nabla}\boldsymbol{u}|},\Omega}(\mathcal{D}(\mathbf{S}_{h}) - \mathcal{D}(\mathbf{S})) + \|\mathcal{F}(\nabla\boldsymbol{u}) - \mathcal{F}(\tilde{\nabla}_{h}\boldsymbol{v}_{h})\|_{2,\Omega}^{2} \\ \lesssim \|\mathcal{F}^{*}(\mathbf{S}_{h}) - \mathcal{F}^{*}(\mathbf{S})\|_{2,\Omega}^{2} + \|\mathcal{F}(\nabla\boldsymbol{u}) - \mathcal{F}(\tilde{\nabla}_{h}\boldsymbol{v}_{h})\|_{2,\Omega}^{2} . \end{split}$$

As a direct consequence of this, we obtain

(5.20)  $\|\boldsymbol{\mathcal{F}}(\tilde{\nabla}_{h}\boldsymbol{u}_{h}) - \boldsymbol{\mathcal{F}}(\nabla \boldsymbol{u})\|_{2,\Omega}^{2} \lesssim \|\boldsymbol{\mathcal{F}}^{*}(\boldsymbol{\mathsf{S}}_{h}) - \boldsymbol{\mathcal{F}}^{*}(\boldsymbol{\mathsf{S}})\|_{2,\Omega}^{2} + \|\boldsymbol{\mathcal{F}}(\nabla \boldsymbol{u}) - \boldsymbol{\mathcal{F}}(\tilde{\nabla}_{h}\boldsymbol{v}_{h})\|_{2,\Omega}^{2}$ . On the other hand, for every  $(\boldsymbol{\mathsf{T}}_{h},\boldsymbol{v}_{h}) \in \Sigma_{h} \times V_{h}$ , using (5.4), (5.18), and the  $\varepsilon$ -Young inequality (2.2) with  $\psi = (\varphi^{*})_{|\boldsymbol{\mathsf{S}}|} \sim (\varphi_{|\nabla \boldsymbol{u}|})^{*}$  and  $\psi = \varphi_{|\nabla \boldsymbol{u}|}$ , we obtain

$$\begin{aligned} \|\mathcal{F}^{*}(\mathbf{S}_{h}) - \mathcal{F}^{*}(\mathbf{S})\|_{2,\Omega}^{2} \lesssim (\mathbf{D}(\mathbf{S}_{h}) - \mathbf{D}(\mathbf{S}), \mathbf{S}_{h} - \mathbf{S})_{\Omega} \\ &= (\mathbf{D}(\mathbf{S}_{h}) - \mathbf{D}(\mathbf{S}), \mathbf{S}_{h} - \mathbf{T}_{h})_{\Omega} + (\mathbf{D}(\mathbf{S}_{h}) - \mathbf{D}(\mathbf{S}), \mathbf{T}_{h} - \mathbf{S})_{\Omega} \\ &= (\tilde{\nabla}_{h}\boldsymbol{u}_{h} - \nabla\boldsymbol{u}, \mathbf{S}_{h} - \mathbf{T}_{h})_{\Omega} + (\mathbf{D}(\mathbf{S}_{h}) - \mathbf{D}(\mathbf{S}), \mathbf{T}_{h} - \mathbf{S})_{\Omega} \\ &= (\tilde{\nabla}_{h}\boldsymbol{u}_{h} - \nabla\boldsymbol{u}, \mathbf{S} - \mathbf{T}_{h})_{\Omega} + (\tilde{\nabla}_{h}\boldsymbol{u}_{h} - \nabla\boldsymbol{u}, \mathbf{S}_{h} - \mathbf{S})_{\Omega} \\ &+ (\mathbf{D}(\mathbf{S}_{h}) - \mathbf{D}(\mathbf{S}), \mathbf{T}_{h} - \mathbf{S})_{\Omega} \\ &+ (\mathbf{D}(\mathbf{S}_{h}) - \mathbf{D}(\mathbf{S}), \mathbf{T}_{h} - \mathbf{S})_{\Omega} \\ &\leq (\tilde{\nabla}_{h}\boldsymbol{u}_{h} - \tilde{\nabla}_{h}\boldsymbol{v}_{h}, \mathbf{S}_{h} - \mathbf{S})_{\Omega} + (\mathbf{D}(\mathbf{S}_{h}) - \mathbf{D}(\mathbf{S}), \mathbf{T}_{h} - \mathbf{S})_{\Omega} \\ &\leq \varepsilon \|\mathcal{F}(\tilde{\nabla}_{h}\boldsymbol{u}_{h}) - \mathcal{F}(\nabla\boldsymbol{u})\|_{2,\Omega}^{2} + c_{\varepsilon} \|\mathcal{F}^{*}(\mathbf{T}_{h}) - \mathcal{F}^{*}(\mathbf{S})\|_{2,\Omega}^{2} \\ &+ \varepsilon \|\mathcal{F}^{*}(\mathbf{S}_{h}) - \mathcal{F}^{*}(\mathbf{S})\|_{2,\Omega}^{2} + c_{\varepsilon} \|\mathcal{F}(\tilde{\nabla}_{h}\boldsymbol{v}_{h}) - \mathcal{F}(\nabla\boldsymbol{u})\|_{2,\Omega}^{2} \\ &+ (\tilde{\nabla}_{h}\boldsymbol{u}_{h} - \tilde{\nabla}_{h}\boldsymbol{v}_{h}, \mathbf{S}_{h} - \mathbf{S})_{\Omega}. \end{aligned}$$

Moreover, abbreviating  $\boldsymbol{z}_h \coloneqq \boldsymbol{u}_h - \boldsymbol{v}_h \in V_h$ , using (5.19) and  $\tilde{\nabla}_h \boldsymbol{\mathcal{E}}_h \boldsymbol{z}_h = \nabla \boldsymbol{\mathcal{E}}_h \boldsymbol{z}_h$  (cf. Remark 4.1), we have that

(5.22) 
$$\begin{aligned} & (\mathbf{S}_{h} - \mathbf{S}, \nabla_{h} \boldsymbol{z}_{h})_{\Omega} \\ & = (\mathbf{S}_{h} - \mathbf{S}, \tilde{\nabla}_{h} (\boldsymbol{z}_{h} - \boldsymbol{\mathcal{E}}_{h} \boldsymbol{z}_{h}))_{\Omega} + (\mathbf{S}_{h} - \mathbf{S}, \tilde{\nabla}_{h} \boldsymbol{\mathcal{E}}_{h} \boldsymbol{z}_{h})_{\Omega} \\ & = (\mathbf{S}_{h} - \mathbf{S}, \tilde{\nabla}_{h} (\boldsymbol{z}_{h} - \boldsymbol{\mathcal{E}}_{h} \boldsymbol{z}_{h}))_{\Omega} - \alpha \, \langle \boldsymbol{\mathcal{S}}_{\boldsymbol{\beta}_{h}(\boldsymbol{u}_{h})} (h_{\Gamma}^{-1} \llbracket \boldsymbol{u}_{h} \otimes \boldsymbol{n} \rrbracket), \llbracket \boldsymbol{z}_{h} \otimes \boldsymbol{n} \rrbracket \rangle_{\Gamma_{h}} \, . \end{aligned}$$

Using the  $\varepsilon$ -Young inequality (2.2) with  $\psi = \varphi_{|\tilde{\nabla}_h \boldsymbol{u}_h|}$ , that  $\varphi_{|\tilde{\nabla}_h \boldsymbol{u}_h|} \leq \varphi_{\boldsymbol{\beta}_h(\boldsymbol{u}_h)}$ , a shift change in Lemma 2.5, Proposition 3.1,  $\boldsymbol{z}_h = \boldsymbol{u}_h - \boldsymbol{v}_h \in V_h$ , and (5.4) with  $\nabla \boldsymbol{u} = \mathcal{D}(\boldsymbol{S})$ , we obtain  $(\boldsymbol{S}_h - \boldsymbol{S} \ \tilde{\nabla}_h (\boldsymbol{z}_h - \boldsymbol{\mathcal{E}}_h \boldsymbol{z}_h))_{\mathcal{O}}$ 

$$(5.23) \qquad \begin{aligned} (\mathbf{S}_{h} - \mathbf{S}, \mathbf{v}_{h}(\mathbf{z}_{h} - \mathbf{C}_{h}\mathbf{z}_{h}))_{\Omega} \\ &\leq \varepsilon \,\rho_{(\varphi_{|\bar{\nabla}_{h}\mathbf{u}_{h}|)^{*},\Omega}(\mathbf{S}_{h} - \mathbf{S}) + c_{\varepsilon} \,\rho_{\varphi_{|\bar{\nabla}_{h}\mathbf{u}_{h}|,\Omega}(\bar{\nabla}_{h}(\mathbf{z}_{h} - \boldsymbol{\mathcal{E}}_{h}\mathbf{z}_{h})) \\ &\leq \varepsilon \,\rho_{(\varphi_{|\bar{\nabla}_{h}\mathbf{u}_{h}|)^{*},\Omega}(\mathbf{S}_{h} - \mathbf{S}) + c_{\varepsilon} \,\rho_{\varphi_{\beta_{h}(\mathbf{u}_{h}),\Omega}}(\bar{\nabla}_{h}(\mathbf{z}_{h} - \boldsymbol{\mathcal{E}}_{h}\mathbf{z}_{h})) \\ &\lesssim \varepsilon \,\rho_{(\varphi_{|\nabla \mathbf{u}|})^{*},\Omega}(\mathbf{S}_{h} - \mathbf{S}) + \varepsilon \, \|\boldsymbol{\mathcal{F}}(\bar{\nabla}_{h}\mathbf{u}_{h}) - \boldsymbol{\mathcal{F}}(\nabla \mathbf{u})\|_{2,\Omega}^{2} \\ &+ c_{\varepsilon} \,m_{\varphi_{\beta_{h}(\mathbf{u}_{h}),h}(\mathbf{u}_{h}) + c_{\varepsilon} \,m_{\varphi_{\beta_{h}(\mathbf{u}_{h}),h}(\mathbf{v}_{h}) \\ &\lesssim \varepsilon \, \|\boldsymbol{\mathcal{F}}^{*}(\mathbf{S}_{h}) - \boldsymbol{\mathcal{F}}^{*}(\mathbf{S})\|_{2,\Omega}^{2} + \varepsilon \, \|\boldsymbol{\mathcal{F}}(\bar{\nabla}_{h}\mathbf{u}_{h}) - \boldsymbol{\mathcal{F}}(\nabla \mathbf{u})\|_{2,\Omega}^{2} \end{aligned}$$

+  $c_{\varepsilon} m_{\varphi_{\beta_h(\boldsymbol{u}_h)},h}(\boldsymbol{u}_h)$  +  $c_{\varepsilon} m_{\varphi_{\beta_h(\boldsymbol{u}_h)},h}(\boldsymbol{v}_h)$ ,

and

(5.24) 
$$(\boldsymbol{\mathcal{S}}_{\boldsymbol{\beta}_{h}(\boldsymbol{u}_{h})}(h_{\Gamma}^{-1}\llbracket\boldsymbol{u}_{h}\otimes\boldsymbol{n}\rrbracket), \llbracket\boldsymbol{z}_{h}\otimes\boldsymbol{n}\rrbracket)_{\Omega} \\ \geq (1-\varepsilon) m_{\varphi_{\boldsymbol{\beta}_{h}(\boldsymbol{u}_{h})},h}(\boldsymbol{u}_{h}) - c_{\varepsilon} m_{\varphi_{\boldsymbol{\beta}_{h}(\boldsymbol{u}_{h})},h}(\boldsymbol{v}_{h})$$

Combining (5.20)–(5.24), choosing  $\varepsilon > 0$  sufficiently small, we arrive at

$$\begin{aligned} \|\boldsymbol{\mathcal{F}}(\nabla_{h}\boldsymbol{u}_{h}) - \boldsymbol{\mathcal{F}}(\nabla\boldsymbol{u})\|_{2,\Omega}^{2} + \|\boldsymbol{\mathcal{F}}^{*}(\boldsymbol{S}_{h}) - \boldsymbol{\mathcal{F}}^{*}(\boldsymbol{S})\|_{2,\Omega}^{2} + (\alpha - c) \, m_{\varphi_{\boldsymbol{\beta}_{h}(\boldsymbol{u}_{h}),h}(\boldsymbol{u}_{h}) \\ \lesssim \inf_{(\boldsymbol{\mathsf{T}}_{h},\boldsymbol{v}_{h})\in\Sigma_{h}\times V_{h}} \left( \|\boldsymbol{\mathcal{F}}^{*}(\boldsymbol{S}) - \boldsymbol{\mathcal{F}}^{*}(\boldsymbol{\mathsf{T}}_{h})\|_{2,\Omega}^{2} + \|\boldsymbol{\mathcal{F}}(\nabla\boldsymbol{u}) - \boldsymbol{\mathcal{F}}(\tilde{\nabla}_{h}\boldsymbol{v}_{h})\|_{2,\Omega}^{2} \\ + (\alpha + c) \, m_{\varphi_{\boldsymbol{\beta}_{h}(\boldsymbol{u}_{h}),h}(\boldsymbol{v}_{h}) \right). \end{aligned}$$

Eventually, for  $\alpha > 0$  sufficiently large, we obtain the desired best-approximation result.

As a first immediate consequence of the best-approximation result in Theorem 5.5, we obtain the convergence of the method under minimal regularity assumptions, i.e., merely  $\boldsymbol{u} \in V, \boldsymbol{S} \in \Sigma$ , and  $\boldsymbol{f} \in V^*$ .

COROLLARY 5.8 (Convergence). For  $\alpha > 0$  sufficiently large, it holds that

$$\|\boldsymbol{\mathcal{F}}(\tilde{\nabla}_{h}\boldsymbol{u}_{h}) - \boldsymbol{\mathcal{F}}(\nabla\boldsymbol{u})\|_{2,\Omega}^{2} + \|\boldsymbol{\mathcal{F}}^{*}(\boldsymbol{\mathsf{S}}_{h}) - \boldsymbol{\mathcal{F}}^{*}(\boldsymbol{\mathsf{S}})\|_{2,\Omega}^{2} + m_{\varphi_{\boldsymbol{\mathcal{B}}_{h}(\boldsymbol{u}_{h})},h}(\boldsymbol{u}_{h}) \to 0 \quad (h \to 0).$$

*Proof.* Using the stability and approximation properties of  $\Pi_h^{k-1}$ , and the density of smooth functions, we obtain  $\Pi_h^{k-1} \mathbf{S} \to \mathbf{S}$  in  $L^{p'}(\Omega)^{n \times d}$   $(h \to 0)$ , which implies that

(5.25) 
$$\|\boldsymbol{\mathcal{F}}^*(\mathbf{S}) - \boldsymbol{\mathcal{F}}^*(\Pi_h^{k-1}\mathbf{S})\|_{2,\Omega}^2 \lesssim \|\mathbf{S} - \Pi_h^{k-1}\mathbf{S}\|_{p'}^{\min\{p',2\}} \to 0 \quad (h \to 0)$$

with a constant depending possibly on  $\delta$ ,  $\|\mathbf{S}\|_{p'}$ . Therefore, choosing  $(\mathbf{T}_h, \boldsymbol{v}_h) = (\Pi_h^{k-1} \mathbf{S}, \Pi_h^{SZ} \boldsymbol{u}) \in \Sigma_h \times V_h$  in Theorem 5.5, using (5.25), (4.12), and (4.13), we conclude that

$$\begin{aligned} \|\boldsymbol{\mathcal{F}}(\nabla_{h}\boldsymbol{u}_{h}) - \boldsymbol{\mathcal{F}}(\nabla\boldsymbol{u})\|_{2,\Omega}^{2} + \|\boldsymbol{\mathcal{F}}^{*}(\boldsymbol{\mathsf{S}}_{h}) - \boldsymbol{\mathcal{F}}^{*}(\boldsymbol{\mathsf{S}})\|_{2,\Omega}^{2} + m_{\varphi_{\boldsymbol{\mathcal{F}}_{h}}(\boldsymbol{u}_{h}),h}(\boldsymbol{u}_{h}) \\ \lesssim \|\boldsymbol{\mathcal{F}}(\nabla\boldsymbol{u}) - \boldsymbol{\mathcal{F}}(\nabla\Pi_{h}^{SZ}\boldsymbol{u})\|_{2,\Omega}^{2} + \|\boldsymbol{\mathcal{F}}^{*}(\boldsymbol{\mathsf{S}}) - \boldsymbol{\mathcal{F}}^{*}(\Pi_{h}^{k-1}\boldsymbol{\mathsf{S}})\|_{2,\Omega}^{2} \to 0 \quad (h \to 0) \,, \end{aligned}$$

Π

which is the claimed convergence under minimal regularity assumptions.

COROLLARY 5.9 (Fractional convergence rates). Assume that the family of triangulations  $\{\mathcal{T}_h\}_h$  is quasi-uniform, and that  $\mathcal{F}(\nabla \boldsymbol{u}) \in N^{\beta,2}(\Omega)^{n \times d}$  for some  $\beta \in (0,1]$ . Then, for  $\alpha > 0$  sufficiently large, it holds that

$$\begin{split} \|\boldsymbol{\mathcal{F}}(\tilde{\nabla}_{h}\boldsymbol{u}_{h}) - \boldsymbol{\mathcal{F}}(\nabla\boldsymbol{u})\|_{2,\Omega}^{2} + \|\boldsymbol{\mathcal{F}}^{*}(\boldsymbol{\mathsf{S}}_{h}) - \boldsymbol{\mathcal{F}}^{*}(\boldsymbol{\mathsf{S}})\|_{2,\Omega}^{2} + m_{\varphi_{\boldsymbol{\beta}_{h}(\boldsymbol{u}_{h})},h}(\boldsymbol{u}_{h}) \\ \lesssim h^{2\beta} \left[\boldsymbol{\mathcal{F}}(\nabla\boldsymbol{u})\right]_{N^{\beta,2}(\Omega)}^{2}. \end{split}$$

*Proof.* First, we note that  $\mathcal{F}(\nabla u) \in N^{\beta,2}(\Omega)^{n \times d}$  for  $\beta \in (0,1]$  is equivalent to  $\mathcal{F}^*(\mathbf{S}) \in N^{\beta,2}(\Omega)^{n \times d}$  for  $\beta \in (0,1]$  and that  $[\mathcal{F}(\nabla u)]_{N^{\beta,2}(\Omega)} \sim [\mathcal{F}^*(\mathbf{S})]_{N^{\beta,2}(\Omega)}$ . This is an immediate consequence of the fact that, due to (2.11), for every  $h \in \mathbb{R}^d \setminus \{\mathbf{0}\}$  and  $x \in \Omega \cap (\Omega - h)$ , we have that

$$|\mathcal{F}(\nabla u(x+h)) - \mathcal{F}(\nabla u(x))|^2 \sim |\mathcal{F}^*(\mathbf{S}(x+h)) - \mathcal{F}^*(\mathbf{S}(x))|^2$$

Using that  $\Pi_h^0 \mathbf{S} = \Pi_h^{k-1} \Pi_h^0 \mathbf{S}$ , (2.10), the Orlicz-stability of  $\Pi_h^{k-1}$  (cf. [26, Cor. A.8]), (2.10), [14, Lem. 4.4], and [8, (4.6), (4.7)], we obtain

$$\begin{aligned} \|\boldsymbol{\mathcal{F}}^{*}(\mathbf{S}) - \boldsymbol{\mathcal{F}}^{*}(\Pi_{h}^{k-1}\mathbf{S})\|_{2,\Omega}^{2} &\lesssim \|\boldsymbol{\mathcal{F}}^{*}(\mathbf{S}) - \boldsymbol{\mathcal{F}}^{*}(\Pi_{h}^{0}\mathbf{S})\|_{2,\Omega}^{2} + \|\boldsymbol{\mathcal{F}}^{*}(\Pi_{h}^{0}\mathbf{S}) - \boldsymbol{\mathcal{F}}^{*}(\Pi_{h}^{k-1}\mathbf{S})\|_{2,\Omega}^{2} \\ &\lesssim \|\boldsymbol{\mathcal{F}}^{*}(\mathbf{S}) - \boldsymbol{\mathcal{F}}^{*}(\Pi_{h}^{0}\mathbf{S})\|_{2,\Omega}^{2} + \rho_{\varphi_{|\Pi_{h}^{0}\mathbf{S}|}^{*}}(\Pi_{h}^{k-1}(\Pi_{h}^{0}\mathbf{S} - \mathbf{S})) \\ &\lesssim \|\boldsymbol{\mathcal{F}}^{*}(\mathbf{S}) - \boldsymbol{\mathcal{F}}^{*}(\Pi_{h}^{0}\mathbf{S})\|_{2,\Omega}^{2} + \rho_{\varphi_{|\Pi_{h}^{0}\mathbf{S}|}^{*}}(\Pi_{h}^{0}\mathbf{S} - \mathbf{S}) \\ &\lesssim \|\boldsymbol{\mathcal{F}}^{*}(\mathbf{S}) - \boldsymbol{\mathcal{F}}^{*}(\Pi_{h}^{0}\mathbf{S})\|_{2,\Omega}^{2} \\ &\lesssim \|\boldsymbol{\mathcal{F}}^{*}(\mathbf{S}) - \Pi_{h}^{0}\boldsymbol{\mathcal{F}}^{*}(\mathbf{S})\|_{2,\Omega}^{2} \\ &\lesssim h^{2\beta} \left[\boldsymbol{\mathcal{F}}^{*}(\mathbf{S})\right]_{N^{\beta,2}(\Omega)}^{2} \\ &\sim h^{2\beta} \left[\boldsymbol{\mathcal{F}}(\nabla\boldsymbol{u})\right]_{N^{\beta,2}(\Omega)}^{2}. \end{aligned}$$

Therefore, choosing  $(\mathbf{T}_h, \boldsymbol{v}_h) = (\Pi_h^{k-1} \mathbf{S}, \Pi_h^{SZ} \boldsymbol{u}) \in \Sigma_h \times V_h$  in Theorem 5.5, using (5.26), (4.12), and (4.14), we conclude that

$$\begin{split} \| \boldsymbol{\mathcal{F}}(\tilde{\nabla}_{h}\boldsymbol{u}_{h}) - \boldsymbol{\mathcal{F}}(\nabla \boldsymbol{u}) \|_{2,\Omega}^{2} + \| \boldsymbol{\mathcal{F}}^{*}(\boldsymbol{\mathsf{S}}_{h}) - \boldsymbol{\mathcal{F}}^{*}(\boldsymbol{\mathsf{S}}) \|_{2,\Omega}^{2} + m_{\varphi_{\boldsymbol{\beta}_{h}}(\boldsymbol{u}_{h}),h}(\boldsymbol{u}_{h}) \\ \lesssim \| \boldsymbol{\mathcal{F}}(\nabla \boldsymbol{u}) - \boldsymbol{\mathcal{F}}(\nabla \Pi_{h}^{SZ}\boldsymbol{u}) \|_{2,\Omega}^{2} + \| \boldsymbol{\mathcal{F}}^{*}(\boldsymbol{\mathsf{S}}) - \boldsymbol{\mathcal{F}}^{*}(\Pi_{h}^{k-1}\boldsymbol{\mathsf{S}}) \|_{2,\Omega}^{2} \\ \lesssim h^{2\beta} \left[ \boldsymbol{\mathcal{F}}(\nabla \boldsymbol{u}) \right]_{N^{\beta,2}(\Omega)}^{2}, \end{split}$$

which is the claimed fractional a priori error estimate.

REMARK 5.10. In view of [15, Corollary 5.8] the assertion of Corollary 5.9 for  $\beta = 1$  is also valid if  $\mathcal{F}(\nabla u) \in W^{1,2}(\Omega)^{n \times d}$  without the additional assumption that the triangulation  $\{\mathcal{T}_h\}_h$  is quasi-uniform.

COROLLARY 5.11 (Ansatz class competition). Let k = 1 and  $\boldsymbol{u}_h^c \in V_{h,c} \coloneqq V_h \cap W_0^{1,p}(\Omega)$  the continuous Lagrange solution of (1.1), cf. (4.15). Then, for  $\alpha > 0$  sufficiently large, it holds that

$$\begin{aligned} \|\boldsymbol{\mathcal{F}}(\tilde{\nabla}_{h}\boldsymbol{u}_{h}) - \boldsymbol{\mathcal{F}}(\nabla\boldsymbol{u})\|_{2,\Omega}^{2} + \|\boldsymbol{\mathcal{F}}^{*}(\boldsymbol{\mathsf{S}}_{h}) - \boldsymbol{\mathcal{F}}^{*}(\boldsymbol{\mathsf{S}})\|_{2,\Omega}^{2} + m_{\varphi_{\boldsymbol{\mathcal{B}}_{h}(\boldsymbol{u}_{h})},h}(\boldsymbol{u}_{h}) \\ &\sim \|\boldsymbol{\mathcal{F}}(\nabla\boldsymbol{u}_{h}^{c}) - \boldsymbol{\mathcal{F}}(\nabla\boldsymbol{u})\|_{2,\Omega}^{2}, \end{aligned}$$

*i.e.*, the approximation capabilities of the discrete mixed formulation (5.7) and the continuous Lagrange approximation (4.15) of (1.1) are comparable.

*Proof.*  $ad \leq$ . Using Theorem 5.5 with  $(\mathbf{T}_h, \mathbf{v}_h) = (\mathbf{S}(\nabla \mathbf{u}_h^c), \mathbf{u}_h^c) \in \Sigma_h \times V_{h,c} \subseteq \Sigma_h \times V_h$ , that  $m_{\varphi_{\boldsymbol{\beta}_h}(\mathbf{u}_h), h}(\mathbf{u}_h^c) = 0$ , and (2.8), we find that

 $ad \gtrsim$ . This is proved in (4.17).

Putting everything together, we arrive at the claimed equivalence.

6. Numerical experiments. In this section, we show numerical results that confirm our theoretical findings, in particular, Corollaries 4.8 and 5.9. In our implementation, the max-shift in the jump penalisation is handled through a fixed point iteration, i.e., when solving the discrete primal formulation (4.2) starting from a solution guess  $\boldsymbol{u}_h^{(k-1)} \in V_h$ , we define the residual  $\mathfrak{F}(\boldsymbol{u}_h^{(k-1)}; \cdot) \in (V_h)^*$ , for every  $\boldsymbol{v}_h, \boldsymbol{z}_h \in V_h$ , via

$$egin{aligned} &\langle \boldsymbol{\mathfrak{F}}(\boldsymbol{u}_h^{k-1}; \boldsymbol{v}_h), \boldsymbol{z}_h 
angle_{V_h} \coloneqq (\boldsymbol{\mathcal{S}}( ilde{
abla}_h \boldsymbol{v}_h), 
abla \boldsymbol{\mathcal{E}}_h \boldsymbol{z}_h)_\Omega \ &+ lpha \langle \boldsymbol{\mathcal{S}}_{eta_h}(\boldsymbol{u}_h^{k-1})(h_\Gamma^{-1}\llbracket \boldsymbol{v}_h \otimes \boldsymbol{n} 
rbrack), \llbracket \boldsymbol{z}_h \otimes \boldsymbol{n} 
rbrack )_{\Gamma_h} - \langle \boldsymbol{f}, \boldsymbol{\mathcal{E}}_h \boldsymbol{v}_h 
angle_V, \end{aligned}$$

and, then, apply Newton's method to find the next guess  $\boldsymbol{u}_{h}^{(k)} \in V_{h}$ . At a given Newton step, the linear systems are solved using the sparse direct solver MUMPS [1]. All the examples were implemented using Firedrake [23] and PETSc [4]. The complete code for reproducing the experiments can be found at [6] with exact version of its dependencies being recorded at [43], additionally using Gmsh version 4.8.4 [19].

Only polynomial degree k = 1 is considered. Note that, in this case, the smoothing operator only needs to be applied on the forcing term, since  $\boldsymbol{\mathcal{S}}(\tilde{\nabla}_h \boldsymbol{u}_h) \in \mathbb{P}^0(\mathcal{T}_h)^{n \times d}$ . In addition, in all the examples, we restrict to the case d = 2 and n = 1.

FIG. 1. Initial mesh  $\mathcal{T}_{h_0}$ 

**6.1. Primal formulation.** For the experiments based on the discrete primal formulation (4.2), we employ the non-linear term  $\mathcal{S} \colon \mathbb{R}^{1 \times 2} \to \mathbb{R}^{1 \times 2}$ , for every  $\mathbf{D} \in \mathbb{R}^{1 \times 2}$ , defined via

(6.1) 
$$\boldsymbol{\mathcal{S}}(\mathbf{D}) \coloneqq (\delta + |\mathbf{D}|)^{p-2} \mathbf{D},$$

which has  $(p, \delta)$ -structure according to Definition 2.1. We choose  $\delta \coloneqq 0.01$  and various values of  $p \in [1.5, 4.5]$ . The shifted constitutive relation  $\boldsymbol{S}_a$  in the jump penalty term in (4.2) is then (2.6) and  $\alpha = 10$  is chosen. The computational domain is defined via  $\Omega \coloneqq (-1, 1)^2$  and, for  $\beta > 1 - \frac{2}{p}$ , the exact solution  $\boldsymbol{u} \in V$  with a point singularity at the origin, for every  $\boldsymbol{x} \coloneqq (x_1, x_2)^\top \in \Omega$ , is defined via

$$\boldsymbol{u}(x) = (1 - x_1^2)(1 - x_2^2)|x|^{\beta}$$

Note that  $\beta > 1 - \frac{2}{p}$  guarantees that at least  $\boldsymbol{u} \in V$ . We start with an initial unstructured mesh  $\mathcal{T}_{h_0}$  with 517 elements, 257 vertices, of which one is at the origin, and  $h_0 \approx 0.1668$ ; see Figure 1. We consider six additional levels of uniform refinement, i.e.,  $\mathcal{T}_{h_l}$ ,  $l \in \{1, \ldots, 6\}$ , where  $h_l = \frac{h_{l-1}}{2}$  for all  $l \in \{1, \ldots, 6\}$ . The error corresponding to the discrete solution  $\boldsymbol{u}_{h_\ell} \in V_{h_\ell}$  of (4.2), associated to a given refinement level  $\ell \in \{0, \ldots, 6\}$ , is defined via

$$e_{\ell} \coloneqq \|\boldsymbol{\mathcal{F}}(\nabla_{h_{\ell}}\boldsymbol{u}_{h_{\ell}}) - \boldsymbol{\mathcal{F}}(\nabla \boldsymbol{u})\|_{2,\Omega} + \left(\alpha \, m_{\varphi_{\beta_{h}}}(\boldsymbol{u}_{h_{\ell}}), h(\boldsymbol{u}_{h_{\ell}})\right)^{\frac{1}{2}}.$$

The experimental rate of convergence is then set to

(6.2) 
$$\operatorname{EOC}_{\ell} \coloneqq \frac{\log(e_{\ell}/e_{\ell-1})}{\log(h_{\ell}/h_{\ell-1})}$$

An important observation is that  $\beta > 0$  determines the regularity of the exact solution and, thus, also the expected rate of convergence. More precisely, to obtain a rate of convergence  $\rho \in (0, 1]$ , one needs to choose  $\beta > 1 - \frac{2(1-\rho)}{p}$ . Tables 1, 3, and 5 show the results for the IIDG formulation for expected rates of convergence of 1, 0.5, and 0.2, respectively; Tables 2, 4, and 6 show the same for the LDG formulation. It can be observed that the values are in agreement with the theoretical predictions.

As mentioned in Remark 4.11, our results do not cover the case of a Crouzeix– Raviart discretisation without jump stabilisation terms. However, as seen in Tables 7 to 9, the rates are roughly in agreement with the same rates as the DG discretisation, suggesting that there might be a proof strategy that also covers this case.

6.2. Mixed formulation. For the experiments based on the discrete mixed formulation (5.7), for which now the following nonlinear term is employed:

$$\mathcal{D}(\mathsf{S}) := \left(\delta^{2(p-1)} + |\mathsf{S}|^2\right)^{\frac{p'-2}{2}}\mathsf{S},$$

which has  $(p', \delta^{p-1})$ -structure in the sense of Definition 2.1. Note that this relation is the inverse of (6.1) when  $\delta = 0$ . In the experiments, we set  $\delta = 0.01$ . The jump penalty term in (5.7) is again defined using (2.6) and  $\alpha = 10$ . The computational domain, once again,  $\Omega = (-1, 1)^2$  and we choose the exact flux  $\mathbf{S} \in \Sigma$  as

$$\mathbf{S} \coloneqq (\delta^2 + |\nabla \tilde{\boldsymbol{u}}|^2)^{\frac{p-2}{2}} \nabla \tilde{\boldsymbol{u}}, \qquad \tilde{\boldsymbol{u}}(x) = (1 - x_1^2)(1 - x_2^2)|x|^{\beta}$$

where p > 1 is specified beforehand, and  $\beta \in \mathbb{R}$ . The gradient of the exact solution can, then, be computed as  $\nabla \boldsymbol{u} \coloneqq \boldsymbol{\mathcal{D}}(\boldsymbol{\mathsf{S}})$ . In the implementation, we set  $\tilde{\nabla}_h = \mathcal{G}_h$  in the discrete formulation (5.7), which corresponds to an LDG method. For the mixed formulation, we define the error corresponding to a solution  $(\boldsymbol{\mathsf{S}}_{h_\ell}, \boldsymbol{u}_{h_\ell}) \in \Sigma_{h_\ell} \times V_{h_\ell}$ associated to a refinement level  $\ell \in \{0, \ldots, 6\}$  as:

$$e_{\ell} \coloneqq \|\boldsymbol{\mathcal{F}}^*(\boldsymbol{\mathsf{S}}_{h_{\ell}}) - \boldsymbol{\mathcal{F}}^*(\boldsymbol{\mathsf{S}})\|_{2,\Omega} + \|\boldsymbol{\mathcal{F}}(\nabla_{h_{\ell}}\boldsymbol{u}_{h_{\ell}}) - \boldsymbol{\mathcal{F}}(\nabla\boldsymbol{u})\|_{2,\Omega} + \left(\alpha \, m_{\varphi_{\beta_h}(\boldsymbol{u}_{h_{\ell}}),h}(\boldsymbol{u}_{h_{\ell}})\right)^{\frac{1}{2}}.$$

The experimental order of convergence is then defined analogously to (6.2). The results in this case can be found in Tables 10 to 12.

Table 10

Experimental order of convergence  $EOC_{\ell}$ ,  $\ell \in \{1, \ldots, 6\}$ , for the mixed LDG formulation, with  $\beta = 1.01$  and, thus,  $\rho = 1.0$ .
