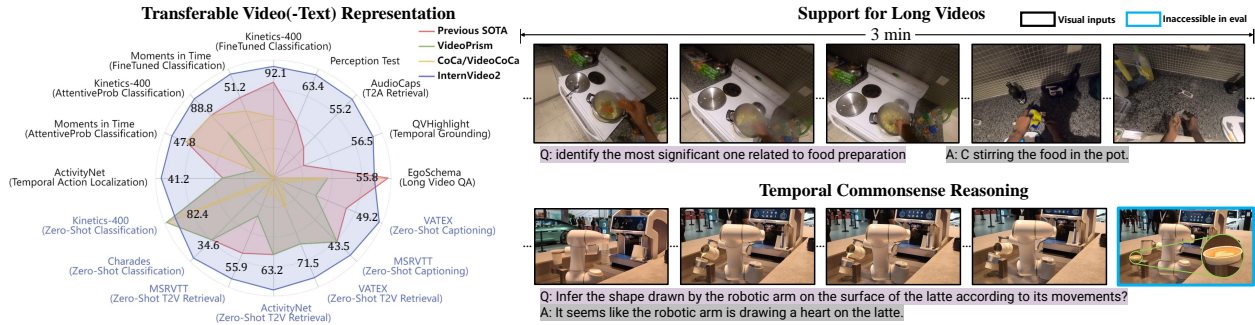

Figure 1: **InternVideo2** yields strong transferable visual and visual-linguistic representations across a total of 70 video understanding tasks, ranging from action recognition, video-text understanding, to video-centric dialogue. It also exhibits capability of long-form video understanding and procedure-aware reasoning.

ABSTRACT

We introduce **InternVideo2**, a new family of video foundation models (ViFM) that achieve the state-of-the-art results in video recognition, video-text tasks, and video-centric dialogue. Our core design is a progressive training approach that unifies the masked video modeling, crossmodal contrastive learning, and next token prediction, scaling up the video encoder size to 6B parameters. At the data level, we prioritize spatiotemporal consistency by semantically segmenting videos and generating video-audio-speech captions. This improves the alignment between video and text. Through extensive experiments, we validate our designs and demonstrate superior performance on over 60 video and audio tasks. Notably, our model outperforms others on various video-related dialogue and long video understanding benchmarks, highlighting its ability to reason and comprehend longer contexts.

1 Introduction

Learning transferrable spatiotemporal representations is a critical research area in computer vision, holding diverse applications across domains such as video search [Gabeur et al., 2020], game control [Bruce et al., 2024], robotic learning [Driess et al., 2023], self-driving [Zablocki et al., 2022], and scientific studies [Team et al., 2023]. Recently, the advancement of Large Language Models (LLMs) [Brown et al., 2020, OpenAI, 2023a, Touvron et al., 2023a,b] and their multimodal variations (MLLMs) [OpenAI, 2023b, Gong et al., 2023, Liu et al., 2023, Team et al., 2023] have had a profound impact on vision research and other disciplines. Embedding videos effectively into these large models and

*Equal contribution. †Corresponding authors.

harnessing their capabilities to enhance video understanding performance has emerged as pivotal tasks [Li et al., 2023c, Maaz et al., 2023].

Previous research has identified several effective learning schemes for video representations, including reconstructing videos with masked inputs [He et al., 2022, Tong et al., 2022, Wang et al., 2023b, Feichtenhofer et al., 2022], aligning videos with languages [Li and Wang, 2020, Xu et al., 2021, Yan et al., 2022, Li et al., 2023e], and predicting the next token using videos [Alayrac et al., 2022, Sun et al., 2023c, Li et al., 2023d]. These approaches have turned out to be complementary and can be unified through a progressive training scheme. Notably, methods such as InternVideo [Wang et al., 2022], UMT [Li et al., 2023e], and VideoPrism [Zhao et al., 2024] have utilized a two-stage training approach involving masked reconstruction and multimodal contrastive learning, leading to improved performance in downstream tasks. Following this line, we aim to further extend this progressive training scheme by incorporating video-based next token prediction and scaling the entire training process, including models and data, to build a new family of video foundation models.

The proposed video foundation model, coined as **InternVideo2**, is built through a progressive training scheme. The learning involves three stages: (1) capturing spatiotemporal structure via unmasked reconstruction, (2) aligning with semantics from other modalities, and (3) enhancing its open-ended dialogue power through next token prediction. In the initial stage, the model learns to reconstruct the unmasked video tokens, allowing the video encoder to develop basic spatiotemporal perception capability. To estimate the existing tokens, vision encoders (InternViT [Chen et al., 2023c] and VideoMAE-g [Wang et al., 2023b]) trained differently are employed as proxies. In the next stage of crossmodal learning, the architecture is expanded to include audio and text encoders. This not only improves the alignment between videos and text but also endows **InternVideo2** the ability to handle video-audio tasks. By incorporating these additional modalities, the model’s understanding of videos is enriched and aligned with their semantics. Finally, in the next-token prediction stage, a video-centric dialogue system and the corresponding instruction-finetuning dataset are built to further tune the **InternVideo2**. By connecting **InternVideo2** to LLMs, the video encoder is further updated through next-token prediction training, enhancing its ability for open-ended tasks such as VQA and video description.

For the training of **InternVideo2**, we emphasize the spatiotemporal consistency and labeling quality in the data. We build a large-scale multimodal video-centric dataset consisting of 402M data entries, which includes 2M videos, 50M video-text pairs (from WebVid [Bain et al., 2021] and InternVid [Wang et al., 2023d]), 50M video-audio-speech-text pairs (InternVid2), and 300M image-text pairs. Specifically, for InternVid2, we segment videos into clips semantically and focus on recalibrating the clip descriptions using three modalities: audio, video, and speech. We first generate captions for these three modalities separately. Then individual captions are fused together to create a more comprehensive description, which will improve the model’s ability to comprehend and interpret the video accurately.

We evaluate **InternVideo2** across a wide range of video-related tasks. These tasks span from basic spatiotemporal perception, such as action recognition, to high-level reasoning tasks, such as long video or procedure-aware question-answering (QA), as given in Fig. 1. The results (in Sec. 5) demonstrate that **InternVideo2** achieves the state-of-the-art performance on multiple tasks and is able to analyze and reason over sequences of actions. This top performance signifies its capability to effectively capture and understand video content. These empirical findings validate that **InternVideo2** could serve as a general video encoder for future exploration in video understanding. In summary, our contributions to video understanding are as follows.

- This paper introduces **InternVideo2**, a competitive family of video foundation models that leverages masked reconstruction, crossmodal contrastive learning, and next token prediction to make model perceptive, semantic, and capable of reasoning in video understanding.
- **InternVideo2** achieves the state-of-the-art performance for more than 60 video / audio tasks. Our model demonstrates superior performance in video-related dialogue and long video understanding, highlighting its potential in modeling high-level world knowledge.
- We provide an enhanced dataset to train **InternVideo2**. This includes the validation and incorporation of audio data during training, as well as the improved captioning method. These improvements result in significant enhancements in model performance and generalization ability.

2 Related Work

Video Foundation Models. Studies on learning video foundation models become increasingly crucial considering its wide applications [Li and Wang, 2020, Xu et al., 2021, Li et al., 2023e, Wang et al., 2022, Zhao et al., 2024, Wang et al., 2023c, Yan et al., 2022, Feichtenhofer et al., 2022, Wang et al., 2023a, Tong et al., 2022, Wang et al., 2023b]. Typical methods in building video foundation models (ViFM) include video-text contrastive learning [Li and Wang, 2020, Xu et al., 2021, Wang et al., 2022], masked video modeling [Tong et al., 2022, Wang et al., 2023b, 2022, Fu

Figure 2: Framework of **InternVideo2**. It consists of three consecutive training phases: unmasked video token reconstruction, multimodal contrastive learning, and next token prediction. In stage 1, the video encoder is trained from scratch, while in stages 2 and 3, it is initialized from the version used in the previous stage.

et al., 2021], and next token prediction [Alayrac et al., 2022, Sun et al., 2023c,a]. Specifically, All-in-one [Wang et al., 2023a] utilized a single backbone with unified multiple pretraining objectives. On the other hand, UMT [Li et al., 2023e] combined masked modeling with video-text contrastive learning, demonstrating strong performance in both action recognition and video-language tasks. Another approach is mPLUG-2 [Xu et al., 2023], which introduced a new design for modulating different modalities. It shared a common module across modalities to enhance relations while incorporating modality-specific modules for discrimination. In addition to video-text pretraining, researchers have also explored the use of audio information in videos to improve performance. MERLOT Reserve [Zellers et al., 2022] learned video representations using a large-scale dataset of video-speech-transcript pairs. VALOR [Chen et al., 2023b] employed independent encoders for video, audio, and text and trains a joint visual-audio-text representation. VAST [Chen et al., 2024b] constructed an audio-visual-speech dataset and develops a multimodal backbone that excels in video-audio-related tasks. VideoPrism [Zhao et al., 2024] combined video-text contrastive learning and video token reconstruction on a combination of public and proprietary videos, achieving leading results across various video tasks.

Multimodal Large Language Models. With advances in large language models (LLMs) [Devlin et al., 2018, Raffel et al., 2020, Brown et al., 2020], their multimodal versions (MLLMs) is becoming popular as it can handle open-world tasks. Seminal works like Flamingo [Alayrac et al., 2022] showed outstanding zero/few-shots performances over a range of multimodal tasks [Goyal et al., 2017b, Plummer et al., 2015, Xu et al., 2016, Marino et al., 2019]. Public MLLMs [Zhu et al., 2023b, Liu et al., 2023, Gong et al., 2023] such as LLaVA [Liu et al., 2023] and InstructBLIP [Dai et al., 2023] proposed to use visual instruction-tuning data to improve the visual dialogue ability. Some video-centric MLLMs have been proposed, such as VideoChat [Li et al., 2023c], VideoChatGPT [Maaz et al., 2023] and Valley [Luo et al., 2023], by using instruction data to connect video encoders to LLMs for open-world video understanding.

3 Method

We learn **InternVideo2** in three stages, illustrated in Fig. 2. The stages include spatiotemporal token reconstruction, video-audio-speech-language contrastive learning, and connecting to a large language model (LLM) for joint training.

Video Encoder. The video encoder used in **InternVideo2** follows the Vision Transformer (ViT) [Dosovitskiy et al., 2020] and includes additional projection layers for distillation. Inspired by previous works [Chen et al., 2023c, Yu et al., 2022], we introduce attention pooling to the ViT. For input videos, we sparsely sample 8 frames [Wang et al., 2016] and perform a 14×14 ($h \times w$) spatial downsampling. These spatiotemporal tokens are then concatenated with a class token and combined with 3D position embeddings. The details of ViT-6B architecture are given in Supp.

3.1 Stage1: Reconstructing Unmasked Video Tokens

We exploit two expert models to guide the video encoder to conduct token-level reconstruction for unmasked areas. Specifically, we adopt InternVL-6B [Chen et al., 2023c] and VideoMAEv2-g [Wang et al., 2023b] to transfer unmasked knowledge via simple projection layers. When training, we input the full videos into different teachers and mask out 80% of the tokens frame by frame, under the semantic guidance of the multimodal model InternVL and motion-aware model VideoMAEv2. We only align the unmasked tokens, by minimizing their mean squared error (MSE) between student and teachers. The learning objective is to reconstruct the remaining tokens as:

$$\mathcal{L} = \frac{1}{Z} \sum (\alpha_1 |f^V(\mathbf{V}_p) - h(\mathbf{V}_p)|^2 + \alpha_2 |f^V(\mathbf{V}_p) - g(\mathbf{V}_p)|^2), \quad (1)$$

where f^V , h , and g are our video encoder, InternViT-6B [Chen et al., 2023c], and ViT-g of VideoMAEv2, respectively. p stands for the token index and $f(\mathbf{V}_p)$ is the corresponding token extracted by **InternVideo2** for input video \mathbf{V} . Z is the normalization factor. α_1 and α_2 balance the influence between the employed models.

In our implementation, we randomly initialize the video encoder and then align its outputs from different layers (transformed by learnable multilayer perceptrons) to those of expert models. Specifically, we align: 1) the last 6 layers of InternVL, 2) the last 4 layers of VideoMAEv2, and 3) the final output token of InternVL. These alignments are made to the corresponding outputs of the video encoder using the l_2 norm. The different loss terms are simply summed for optimization. After pretraining, we drop those projection layers and only use the basic encoder. Compared with only using the multimodal model in UMT and VideoPrism, our strategy makes the vision encoder multimodal-friendly as well as enhances its temporal sensitivity for action modeling.

3.2 Stage 2: Aligning Video to Audio-Speech-Text

We exploit the correspondence between video and audio, speech, and text to encourage **InternVideo2** to learn more semantics. In practice, **InternVideo2** has a huge video encoder, and its employed audio and text encoders are relatively lightweight. The used audio encoder is a 12-layer transformer initialized with BEATs [Chen et al., 2023a] (90M). It takes as input 64-dimensional log Mel filterbank spectrograms, generated using a 25ms Hamming window, from 10-second-long clips (padded with zeros). For the text and speech encoders, we initialize the text encoder and multimodal decoder using BERT-Large [Devlin et al., 2018]. Specifically, we utilize the initial 19 layers of BERT-Large as the text encoder, with the subsequent 5 layers equipped with cross-attention layers serving as the multimodal decoder.

For pretraining objectives, we establish alignment across different modalities via text, including video, audio, image, and speech. We employ crossmodal contrastive and matching losses with masked language reconstruction loss as:

$$\mathcal{L} = \mathcal{L}_{\text{CON}} + \mathcal{L}_{\text{MAC}} + \mathcal{L}_{\text{MLM}}, \quad (2)$$

The employed \mathcal{L}_{MAC} and \mathcal{L}_{MLM} are standard loss from [Cheng et al., 2022]. Specifically, the crossmodal contrastive learning is given as:

$$\mathcal{L}_{\text{CON}} = \sum_{M, T_{M'}} \mathcal{L}_{\text{CON}}(M, T_{M'}) = - \sum_{M, T_{M'}} \left(\sum_{i=1}^N \log \frac{\exp(\text{sim}(f_i^M, f_i^{T_{M'}})/\tau)}{\sum_{j=1}^N \exp(\text{sim}(f_i^M, f_j^{T_{M'}})/\tau)} + \sum_{i=1}^N \log \frac{\exp(\text{sim}(f_i^{T_{M'}}, f_i^M)/\tau)}{\sum_{j=1}^N \exp(\text{sim}(f_i^{T_{M'}}, f_j^M)/\tau)} \right), \quad (3)$$

where f^V and f^T denote the learned video and text embeddings, respectively. M and $T_{M'}$ indicates the modality of input signals and the text descriptions describing, respectively. $\text{sim}(\cdot)$ computes the cosine similarity between two features. τ is the learnable temperature.

For the matching part, it is given as:

$$\mathcal{L}_{\text{MAC}} = -y \log f_p(\mathbf{V}, \mathbf{T}) - (1 - y) \log(1 - f_p(\mathbf{V}, \mathbf{T})), \quad (4)$$

where $f_p(\mathbf{V}, \mathbf{T})$ computes the matching likelihood between \mathbf{V} and \mathbf{T} . y denotes whether the given video and text are paired ($y = 1$) or not ($y = 0$).

The employed masked language modeling loss is:

$$\mathcal{L}_{\text{MLM}} = -\log f_p^T(\mathbf{T}_j | \mathbf{T}_{<j}), \quad (5)$$

where $f_p^T(\mathbf{T}_j | \mathbf{T}_{<j})$ computes the likelihood of the j th text token based on the previous ones. Here \mathbf{T} refers to video captions.

To improve the training efficiency, we employ the masked learning strategy, aligning unmasked video tokens to tokens from other modalities first, then using full video tokens reconstruction shortly. Specifically, it consists of two steps as follows:

Aligning Masked Visual-Language-Audio. We freeze the audio encoder and focus on aligning visual, audio, and text features. For pre-training, we use a comprehensive set of image, video, and audio-video data. The combinations of modalities used are represented as $\{M, T_{M'}\} \in \{\{I, T_I\}, \{V, T_V\}, \{V, T_{VAS}\}, \{VA, T_{VAS}\}\}$ where each pair denotes the concatenated features from the respective modalities.

Unmasked Visual-Audio-Language Post-Pretraining. We freeze the vision encoder to jointly align audio, visual, and text features. Post-pretraining is conducted using a smaller subset of image and video data (25M samples), along with the full set of audio (0.5M samples) and audio-video data (50M samples). Since the parameters of the largest ViT-6B model are frozen, we do not use masking strategies in this phase to ensure consistency with the inference process and to minimize any performance degradation in downstream tasks. The modality combinations used here are $\{M, T_{M'}\} \in \{\{I, T_I\}, \{V, T_V\}, \{A, T_A\}, \{V, T_{VAS}\}, \{VA, T_{VA}\}\}$.

Table 1: Summary of datasets used in **InternVideo2** pretraining process.

Pretraining Stage	Dataset	Domain	# of clips	Annotation
Stage 1	KMash	Web Video	2M	-
Stage 2 (img-txt)	LAION, etc	Web Image	300M	Alt-text / Generated Caps
	WebVid2M	Web Video	250k	Alt-text
Stage 2 (vid-txt)	WebVid10M	Web Video	9.7M	Alt-text
	InternVid	Youtube Video	40M	Generated Caption
	InternVid2	Youtube Video	50M	Generated Caption
Stage 3	LLaVA, etc	Web Image/Video	2.1M	Conversation, QA

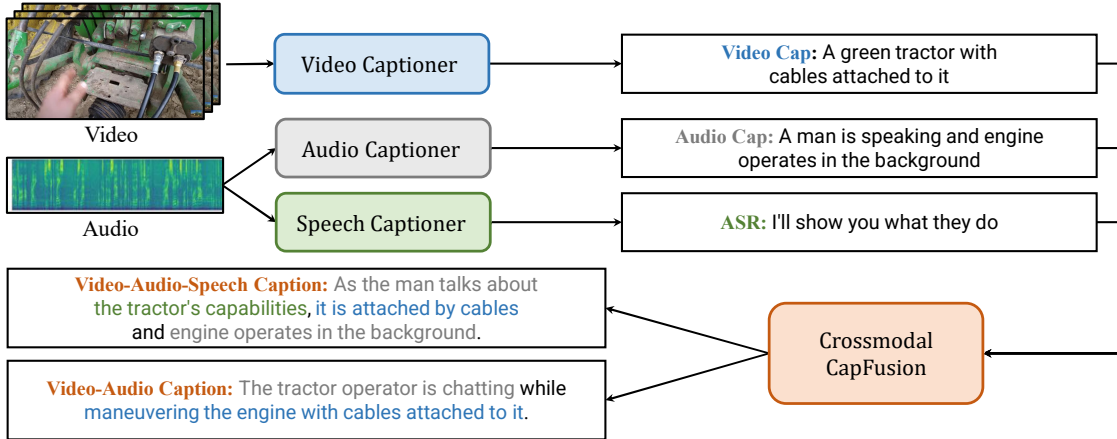

Figure 3: The framework of our video multimodal annotation system, called **VidCap**, consists of four main components: video, audio, and speech captioners, along with a LLM for integrating captions from these modalities.

3.3 Stage3: Predicting Next Token with Video-Centric Inputs

To further enrich the semantics embedded in **InternVideo2** and improve its support for video-centric dialogue, we tune it by connecting it to a LLM with QFormer design [Li et al., 2022a,b]. We employ the progressive learning scheme in [Li et al., 2023d] by using **InternVideo2** as the video encoder and train a video blip for communicating with open-sourced LLM [Zheng et al., 2023, Jiang et al., 2023]. Additionally, we implement a high-definition post-training stage to improve the model’s fine-grained and long spatiotemporal capabilities. During this stage, the input video is divided into up to six sub-videos with a resolution of 224x224 pixels each, along with one global resized sub-video of the same resolution. We then train the model for two additional epochs: the first epoch uses 8-frame video inputs, while the second epoch uses 16-frame inputs. During the additional training process, we update the video encoder and BLIP QFormer, while the LLM is updated using LoRA [Hu et al., 2021].

4 Multimodal Video Data

We list our training data in Tab. 1. Among the datasets used, KMash and InternVid2 are newly built, whereas the rest are publicly available.

4.1 Video-only Data for Masked Autoencoders

We curate a new video set without labels named *K-Mash* from action recognition datasets [Carreira and Zisserman, 2017, Goyal et al., 2017a, Monfort et al., 2020, Heilbron et al., 2015, Zhao et al., 2019], as detailed in Supp. It encompasses a wide range of video types, including first- and third-person perspectives, with both short and long duration, and featuring various settings. Further, we give *K-Mash_{2M}* with additionally sourced and selected 844K videos from YouTube for diversity.

4.2 Videos with Audio-Speech Modalities

We build a multimodal video dataset, coined as **InternVid2**, with video-audio-speech information and their descriptions for strengthening video perception via other modalities. It consists of 100M videos along with their VAS captions. In **InternVid2**, we collect videos from several sources (detailed in the supp), segment them into clips, and automatically annotate them based on their unimodal or crossmodal inputs. We highlight the importance of temporal segmentation in clip generation and our video multimodal annotation system. We find refining them leads to notable downstream improvements.

Temporal Consistency Matters. We employ a temporal boundary detection model AutoShot [Zhu et al., 2023c] to segment videos into clips instead of SceneDet filter from FFmpeg. It predicts boundaries based on temporal semantic variations rather than pixel differences, and is able to generate semantically complete cuts without mixing extra frames with inconsistent context.

Video Multimodal Annotation. We design a video multimodal annotation system **VidCap** to give proper unimodal and crossmodal descriptions for textualizing videos from different perceptions. It automatically captions visual, audio, and speech of **InternVid2**, then it corrects them and fuses them for cross-modal captions via LLM. The system frame is given in Fig. 3. **VidCap** has independent video, audio, speech captioner, and a LLM for caption refinement and fusion. For video, speech, and caption postprocessing, we employ existing methods as the video captioning pipeline in [Wang et al., 2023d], WhisperV2-large model [Radford et al., 2023], and Vicuna-1.5 [Zheng et al., 2023]. For audio, we craft a audio captioner upon VideoChat [Li et al., 2023c], as we find no open-sourced one. It extracts audio features from inputs by Beats [Chen et al., 2023a]. We learn it by only tuning its Qformer using a combination of the large-scale audio-text corpus WavCaps [Mei et al., 2023] dataset. Details are given in the supplementary material.

4.3 Instruction-Tuning Data for Video Dialogue

We employ a updated training version of MVBench [Li et al., 2023d]. Originally, it comprises 1.9M samples (both images and videos) from 34 distinct sources. We decrease the amount of caption data from WebVid and CoCo to 80k and 100k separately and add new data from the S-MiT to boost the diversity rather than quantity of the instruction dataset. In the additional HD training stage, we incorporate the videos with corresponding GPT-4 annotations from [Chen et al., 2024a] into the training set. We further expand the training set by including datasets from PerceptionTestQA [Patraucean et al., 2024], TVQA [Lei et al., 2018], NTU-RGB-D [Liu et al., 2020], and EgotaskQA [Grauman et al., 2022], along with grounding datasets based on DiDeMo [Anne Hendricks et al., 2017] and COCO [Lin et al., 2014]. This training data encompasses key features of image and video understanding across crucial tasks, including 1) conversation, 2) caption, 3) visual question answer, 4) reasoning, and 5) classification.

5 Experiments

In our evaluation of **InternVideo2**, we assess the models from three learning stages. The evaluation covers a wide range of tasks, including video recognition, video retrieval, question-answering, and more. It includes various scenarios such as zero-shot learning, finetuning, and linear probing.

For **InternVideo2** trained in stage 1, 2, and 3, we denote them with **InternVideo2_{s1}**, **InternVideo2_{s2}**, and **InternVideo2_{s3}**, respectively. We also learn a CLIP-style **InternVideo2** indicated by **InternVideo2_{clip}**. It is post-pretrained from **InternVideo2_{s2}** by only preserving video and text encoders and contrastive loss.

Each training stage of **InternVideo2-6B** uses different configurations and resources. In the first stage, we employ 256 NVIDIA A100 GPUs and train the model for 18 days. The second stage also utilizes 256 A100 GPUs and spans a training period of 14 days. Finally, in the third stage, we use 64 A100 GPUs and train the model for 3 days. We introduce DeepSpeed and FlashAttention [Dao et al., 2022] for training and inference. More implementation details and experiment results are given in the supp.

5.1 Video Classification

5.1.1 Action Recognition

We test **InternVideo2** on Kinetics (*i.e.*, K400, 600, and 700 [Carreira and Zisserman, 2017, Carreira et al., 2018, 2019]), Moments in Time V1 (MiT) [Monfort et al., 2020], Something-Something V2 (SSv2) [Goyal et al., 2017a], UCF [Soomro et al., 2012], HMDB [Kuehne et al., 2011], Charades [Gao et al., 2017], ActivityNet [Heilbron et al., 2015] (ANet) and HACS [Zhao et al., 2019]. We evaluate in four settings: (a) *end-to-end finetuning* the whole backbone;

Table 2: End-to-end finetuning action recognition results (top-1 accuracy) on Kinetics, SomethingSomething, and Moments in Time. † denotes that the result is achieved with different resolutions or frame rates.

InternVideo2_{s2}-1B	IV -25.5M	16 × 224	87.9	88.0	79.5	46.3	67.3
InternVideo2_{s2}-6B	IV -400M	16 × 224	88.8	89.1	81.0	47.8	67.7

(b) *attentive probing* is similar to linear pooling, but extra trains the attention pooling layer [Yu et al., 2022]. (c) *linear probing* which freezes the backbone and only trains the task head; and (d) *zero-shot*.

End-to-end Finetuning. Tab. 2 shows **InternVideo2-6B** obtains new state-of-the-art (SOTA) results on Kinetics (**92.1%/91.9%/85.9%** on K400/600/700, respectively), SthSthv2, MiT, ANet, and HACS with only 16 frames, while the previous SOTAs require larger resolution (224 vs. 576) or model ensemble. As for MiT in Tab. 2, **InternVideo2-6B** exceeds the previous SOTA, CoCa-g, by a significant margin of 2.2% (**51.2%** vs. 49.0%). Regarding the temporal-related actions in Tab. 2, our **InternVideo2-6B** also surpasses MVD [Wang et al., 2023c] on SSV2 (**77.5%** vs. 77.3%). Moreover, our **InternVideo2-6B** showcases top performance on untrimmed video analysis, as indicated in Tab. 2, with 95.9% on ActivityNet and 97.0% on HACS. These results affirm our model’s superior capability for robustly identifying complex actions across varied scenes. Note “I” and “V” denotes images and videos, respectively. “IV-3B” means the total number of the used images and videos is 3B, while “I-3B” means using 3B images.

Attentive Probing. As in Tab. 3, **InternVideo2-6B** not only outperforms ViT-22B [Dehghani et al., 2023] and CoCa-g [Yu et al., 2022] in scene-focused datasets but also surpasses or matches the performance of the latest video foundation model [Bardes et al., 2024, Zhao et al., 2024], on datasets emphasizing temporal dynamics (SthSthV2). This underscores our model’s exceptional ability to understand and interpret both spatial and temporal information effectively.

Linear Probing. In Tab. 4, **InternVideo2-1B** significantly outperforms the previous SOTA, DINOv2-g [Oquab et al., 2023], by notable margins: +3.2% on K400, +8.0% on SthSthV2, and +4.8% on UCF-101. As we scale the model, an upward trend in results is observed, underscoring the benefits of model enhancement. Notably, the integration of multimodal pretraining (stage 2) yields further rise in results. We suppose stage 2 enhances feature discrimination.

Zero-shot. Table 5 and 6 show **InternVideo2** gets 72.7% / 71.7% / 64.2% on K400/600/700, respectively, outperforming others but VideoPrism on K400 (76.4%). On UCF [Soomro et al., 2012], HMDB [Kuehne et al., 2011], MiT [Monfort et al., 2020], SSV2-MC, and Charades, **InternVideo2** gives an cutting edges over others. The clear gap between VideoPrism and **InternVideo2** on K400 may signify the importance of pretraining corpus in VideoPrism (311M

Table 4: Linear probing action recognition results (top-1 accuracy) on Kinetics-400, Something-Something V2, UCF-101 and HMDB-51.

Method	Setting	K400	SSV2	UCF-101	HMDB-51

InternVideo2_{clip}-1B	8	73.1	82.4	72.8	81.8	64.9	75.2
InternVideo2_{clip}-6B	8	72.7	82.2	71.7	81.2	64.2	75.2

videos with text and 36.1M of them are manually labeled) for K400 in zero-shot. Note that on the datasets of Kinetics, UCF101 and HMDB51, which have a distribution closer to the pre-training dataset used in stage1, the performance of Internvideo2-6B is slightly inferior to that of Internvideo2-1B. We suppose this is caused by Internvideo2-6B uses a more abundant pretraining dataset in stage2, leading to the forgetting of pretraining data in stage1.

5.1.2 Temporal Action Localization

We evaluate models on four temporal action localization (TAL) datasets: THUMOS14 [Idrees et al., 2017], ActivityNet [Krishna et al., 2017], HACS Segment [Zhao et al., 2019] and FineAction [Liu et al., 2022] in a feature-based manner with finetuning. We employ output of the 7-th layer from **InternVideo2** for inputs as the corresponding features without fusing anything else. ActionFormer [Anne Hendricks et al., 2017] is used as the detection head. We report mean Average Precision(mAP) under multiple tIoU as in [Lin et al., 2019, Chen et al., 2022a, Anne Hendricks et al., 2017, Yang et al., 2023]. In Table 7, **InternVideo2-6B** gets the highest mAP among all comparisons in all datasets, while **InternVideo2-1B** nearly surpass other methods except in THUMOS14. We find **InternVideo2-6B** almost consistently improves mAP with a notable margin from **InternVideo2-1B** except in FineAction. We suppose scaling model capacity without data refinement cannot nontrivially improve fine-grained discrimination abilities of models. Scaling detailed annotations in training may address this issue.

5.1.3 Video Instance Segmentation

We evaluate on the Video Instance Segmentation (VIS) dataset Youtube-VIS 2019 [Yang et al., 2019]. Built upon Mask2Former [Cheng et al., 2021], we employ the video encoder of **InternVideo2** as backbone with ViT-adapter [Chen

Table 7: Finetuned temporal action localization results on THUMOS14 [Idrees et al., 2017], ActivityNet [Krishna et al., 2017], HACS Segment [Zhao et al., 2019] and FineAction [Liu et al., 2022]. We report average mAP. “Flow” denotes the ensembling I3D flow feature. * denotes the result is achieved with Flow.

Backbone	THUMOS14	HACS	ActivityNet	FineAction
I3D [Carreira and Zisserman, 2017] + Flow	66.8	-	35.6	-
R(2+1)D [Tran et al., 2018]	55.6	-	36.6	-

InternVideo2_{s2}-6B	62.8	60.2	46.4	46.7	74.2	71.9	61.4	85.2	74.1	69.7	75.5	89.3

et al., 2022b) for features. We also try InternViT [Chen et al., 2023c] for comparisons. In Table 8, **InternVideo2** gets the highest mAP among all. This validates its effectiveness in relatively fine-grained spatiotemporal perception.

5.2 Video-Audio-Language Tasks

We evaluate **InternVideo2** on video retrieval, captioning, and multi-choice question-answering (QA). The former two tasks are conducted by matching video representation and the candidate text ones using the text encoder in stage 2. The latter is tested by the VideoLLM learned in stage 3. We also test audio tasks.

5.2.1 Video Retrieval

We evaluate the video retrieval on six popular benchmarks: MSR-VTT [Xu et al., 2016], LSMDC [Rohrbach et al., 2015], DiDeMo [Anne Hendricks et al., 2017], MSVD [Chen and Dolan, 2011], ActivityNet (ANet) [Heilbron et al.,

Table 11: Finetuned temporal grounding on QVHighlight [Lei et al., 2021] and Charade-STA [Gao et al., 2017].

(a) QVHighlight					(b) Charade-STA					
Feature	R1@0.5	R1@0.7	mAP	HiT@1	Feature	R1@0.3	R1@0.5	R1@0.7	mIoU	
CLIP [Radford et al., 2021]	64.97	48.65	42.96	39.83	64.19	CLIP [Radford et al., 2021]	65.62	52.77	30.16	45.85
CLIP+SlowFast [Feichtenhofer et al., 2019]	65.43	48.38	42.86	40.33	66.21	CLIP+SlowFast [Feichtenhofer et al., 2019]	70.43	58.44	36.34	50.13
InternVideo2_{s2}-1B	<u>70.00</u>	<u>54.45</u>	<u>47.02</u>	<u>42.36</u>	<u>69.74</u>	InternVideo2_{s2}-1B	<u>78.41</u>	<u>68.36</u>	<u>45.03</u>	<u>57.12</u>
InternVideo2_{s2}-6B	71.42	56.45	49.24	42.90	72.00	InternVideo2_{s2}-6B	79.70	70.03	48.95	58.79

Table 12: Audio retrieval results on AudioCaps [Kim et al., 2019], Clothov1, and Clothov2 [Drossos et al., 2020]. We report text-to-audio R@1 accuracy in zero-shot and finetuning settings.

Method	Zero-shot			Finetuning		
	AudioCaps	ClothoV1	ClothoV2	AudioCaps	ClothoV1	ClothoV2
VIP-ANT [Zhao et al., 2021]	27.7	-	-	-	-	-
VAST [Chen et al., 2024b]	-	-	-	52.0	25.1	26.9
LanguageBind [Zhu et al., 2023a]	-	12.1	12.1	-	-	-
InternVideo2_{s2}-6B	37.1	17.4	17.4	55.2	25.3	27.2

Table 13: Results of AudioQA on ClothoQA [Lipping et al., 2022] and Audio-MusicAVQA (AMAVQA) [Behera et al., 2023], and audio classification on the ESC-50 [Piczak, 2015]. Both in the finetuning setting.

(a) ClothoQA and AMAVQA			(b) ESC-50	
Backbone	ClothQA	AMAVQA	Method	Top-1 Acc
AquaNet [Lipping et al., 2022]	14.78	65.59	AST [Gong et al., 2021]	95.60
MWAFM [Li et al., 2023b]	22.24	67.54	BEATs [Chen et al., 2023a]	98.10
InternVideo2_{s2}	30.14	80.51	InternVideo2_{s2}	98.60

2015], and VATEX [Wang et al., 2019], as shown in Tab. 9 and 10. In evaluation, eight frames from the input videos are uniformly sampled. We report R@1 scores for both text-to-video (t2v) and video-to-text (v2t) tasks in Tab. 9 and 10. R@5 and R@10 are given in Supp.

Tab. 9 and 10 demonstrate that **InternVideo2** outperforms other state-of-the-arts with a notable margin in both t2v and v2t of all used datasets no matter in zero-shot or finetuned settings, except for the v2t of MSR-VTT, where VideoPrism gives the best result. This shows the video-language semantic alignment of transferrity of **InternVideo2**.

5.2.2 Video Temporal Grounding

We evaluate **InternVideo2** on two video temporal grounding (VTG) datasets: QVhighlight [Lei et al., 2021], and Charade-STA [Gao et al., 2017]. The eval setting and used features are the same as in TAL. We use CG-DETR [Moon et al., 2023] as the grounding head. We report R1@0.3, R1@0.5, R1@0.7, and mAP for moment retrieval as in [Lei et al., 2021, Moon et al., 2023, Lin et al., 2023]. Highlight Detection is evaluated in terms of “Very Good” mAP and HiT@1. In Table 11, **InternVideo2**-1B and **InternVideo2**-6B bring gradual performance improvements compared to CLIP [Radford et al., 2021] and CLIP [Radford et al., 2021]+Slowfast [Feichtenhofer et al., 2019]. This suggests that a larger spatiotemporal model is more beneficial to short-term video semantic alignment capabilities.

5.2.3 Audio-related Tasks

We evaluate **InternVideo2**’s audio and text encoders on audio tasks, including audio-text retrieval on AudioCaps [Kim et al., 2019], Clothov1, and Clothov2 [Drossos et al., 2020]; audioQA on ClothoQA [Lipping et al., 2022] and Audio-MusicAVQA [Behera et al., 2023]; and audio classification on the ESC-50 [Piczak, 2015]. As shown in Tab. 12, 13a, and 13b, our model achieves state-of-the-art performance on all downstream tasks. Considering the limited size of the used audio and text encoders, these audio-related results show crossmodal contrastive learning’s benefits are mutual to the used modalities. Audio and the corresponding text models also gain from this learning.

Table 14: Results of Chat-centric Evaluation on Multiple Choice Video-QA on MVBench [Li et al., 2023d], Egoschema [Mangalam et al., 2023] and Perception Test [Patraucean et al., 2024].

Model	ViEncoder	LLM	MVBench	Egoschema	Perception Test
GPT-4V [OpenAI, 2023b]	-	GPT-4	43.5	-	-
Gemini 1.0 Pro [Team et al., 2023]	-	-	37.7	55.7	51.1

ViT-6B	InternVL-6B+VideoMAE-g	K-Mash _{2M}	91.9	91.7	85.7	51.0	77.5	79.6

5.3 Video-centric Dialogue and its Applications

Tab. 14 shows results on MVBench [Li et al., 2023d], Egoschema [Mangalam et al., 2023], and Perception Test [Patraucean et al., 2024], by equipping VideoChat2 [Li et al., 2023d] with our InternVideo2 encoder, compared with other MLLMs. Note VideoChat2-HD-F16 with **InternVideo2** outperforms other systems with a clear margin in Perception Test and MVBench (**F16** denotes the model is trained and tested with 16-frame inputs), except in Egoschema compared with proprietary commercial models (GPT4 & Gemini). Our method demonstrates superior short-term fine-grained video understanding compared to both open-source and commercial methods. Egoschema requires longer context harnessing, and we plan to further explore leveraging LLM for long multimodal sequence modeling. Considering these benchmarks not only involve perception but also reasoning, these results suggest **InternVideo2** does embed knowledge to partially model the world. It also validates the importance of learning a transferrable video representation for current video-related MLLM. We also give several qualitative evaluations with popular GPT-4V and GeminiPro, including dialogues on action sequence (Fig. 4), confused action (Fig. 5), temporal order understanding (Fig. 6), temporal event counting (Fig. 7, unexpected action reasoning (Fig. 8), and vision-language navigation (Fig. 9).

5.4 Ablation Studies

5.4.1 Scaling Video Encoder

Tab. 15 gives **InternVideo2**'s average performance on action recognition and video retrieval. It shows that scaling video encoder from 1B to 6B still leads to notable improvements in generalization of action recognition and video-retrieval by

Figure 4: **Temporal action recognition tasks.** In questions about an action before it happens, Gemini Pro and InternVideo2-Chat both describe accurately the action, while GPT-4V hallucinates.

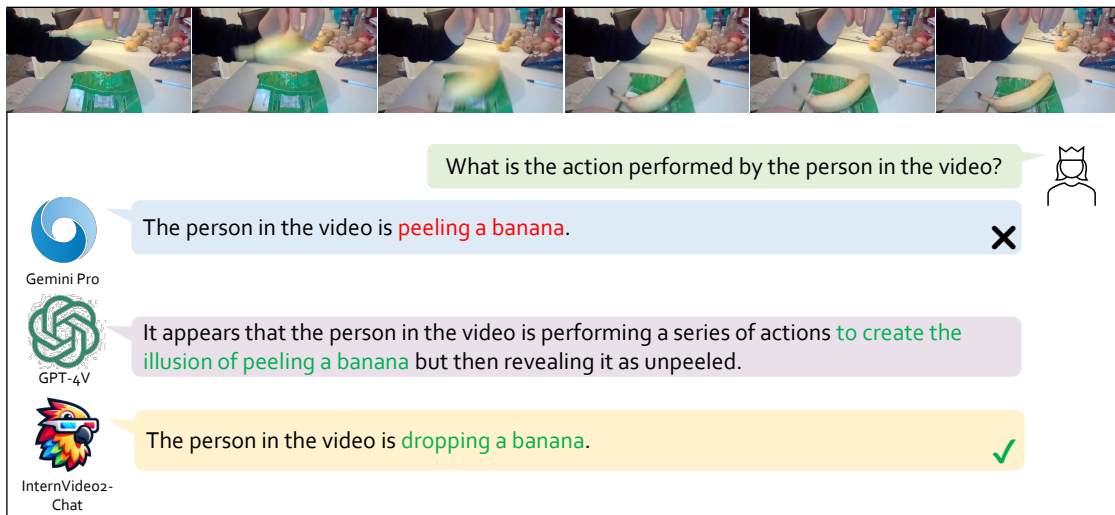

Figure 5: **Confused action recognition.** The person in the video is performing a misleading action while holding a banana. Gemini Pro gives a wrong answer. GPT-4V identifies the misleading action but doesn't give a correct answer. InternVideo2-Chat gives a correct answer.

1.4% and 1.9% (in zero-shot), respectively. Meanwhile, the increase in finetuned action recognition result is relatively marginal (0.4%) with the growth of model scale.

5.4.2 Training Data and used Teachers in Stage 1

In Tab. 16, we examine the impact of distillation teachers and used dataset sizes on model performance. (a) *Data Scale*: Note that pretraining data scale for MAE should grow with the increasing model scale, otherwise the downstream performance would be saturated, such as K710 (0.66M videos) for ViT-L, K-Mash_{1.1M} for ViT-1B, and K-Mash_{2M} for ViT-6B. (b) *Teacher*: Tab. 16 reveals that the synergy between a multimodal teacher (e.g., CLIP [Radford et al., 2021]) and a motion-aware teacher (e.g., MAE [Tong et al., 2022]) markedly boosts performance, especially on SthSthV2. It highlights the importance of strategic teacher model selection in the distillation process.

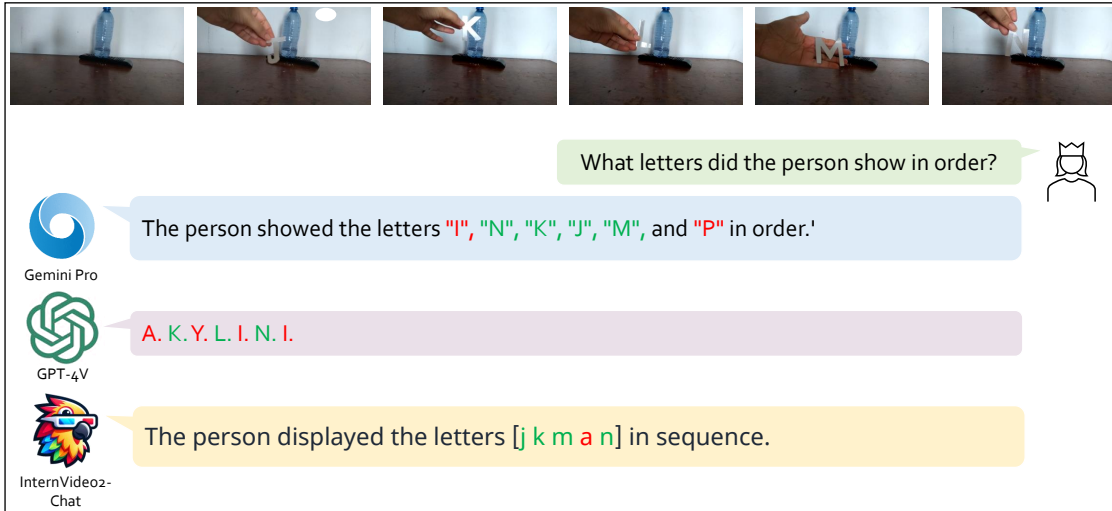

Figure 6: **Video Object Temporal Recognition.** The person in this video takes out different letters in the order of time. Gemini Pro recognizes 4 letters, but the order is totally reversed; GPT-4V recognizes only 3 letters, and the result is mixed with wrong answers; InternVideo2-Chat has the fewest errors among them and the order is correct.

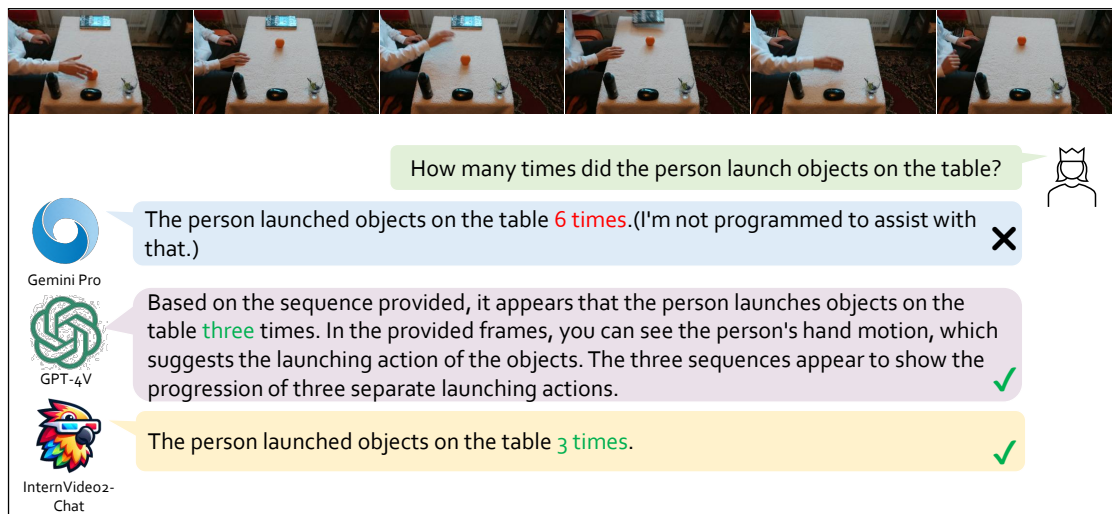

Figure 7: **Event counting task.** Both GPT-4V and InternVideo2-Chat are able to correctly capture the times of actions and not be confused by redundant frames and other actions.

5.4.3 Training Arch, Method, and Data in Stage 2

We ablate the necessity of introducing an audio encoder in Stage 2. We employ ViT-B and Bert-B for video and text encoders, respectively. The used text are simple video captions. The baseline is conducting video-text contrastive and matching as well as masked language generation loss for training with only video and text encoders. Other settings including adding audio or speech encoder or them both, and how to update newly added encoders i.e., whether train them with only text encoder or both video and text encoders. Tab. 17 shows that only introducing audio encoder and learn it along with both video and text encoders can best improve video-text retrieval performance. The speech encoder harms such effectiveness more or less.

Further, we verify the impact of video temporal segmentation and the used captions as text inputs in Stage 2 in Tab. 18. We still use ViT-B and Bert-B for video-text training. Tab. 18 finds the fused text from video-audio-speech works best for retrieval tasks compared with others, rising zero-shot t2v R1 of MSR-VTT from 24.7 to 27.1. Moreover, using AutoShot instead of SceneDet notably improves t2v retrieval (increasing by nearly 7 points). It validates the effectiveness of the introduced video-text dataset and its annotation systems.

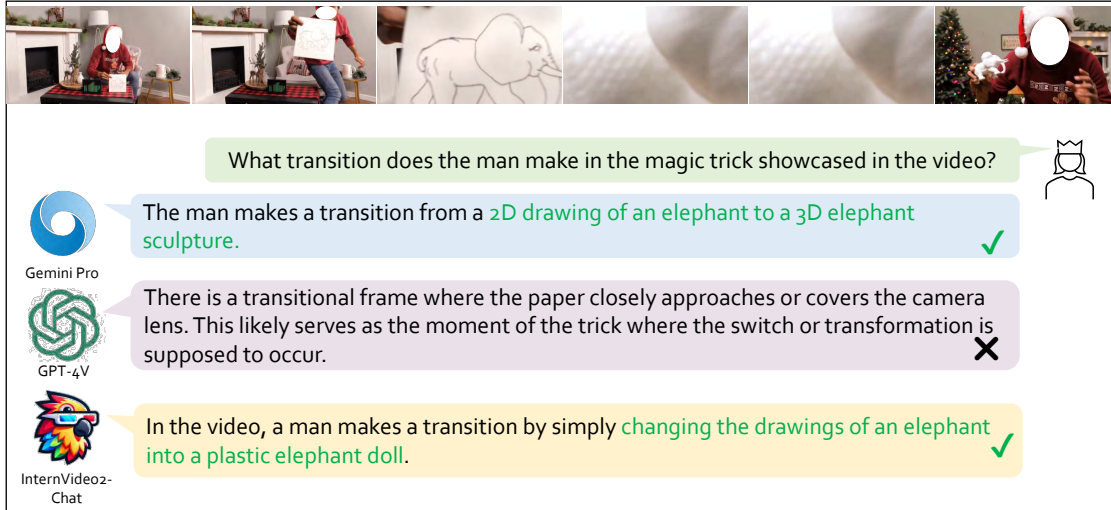

Figure 8: **Unexpected Action Recognition tasks.** The model needs to recognize the magical parts of the video. Both Gemini Pro and InternVideo2-Chat can capture part of the transition in the video and infer the shooting technique of the video. GPT-4V recognizes the transition but fails to successfully explain the process of the transition.

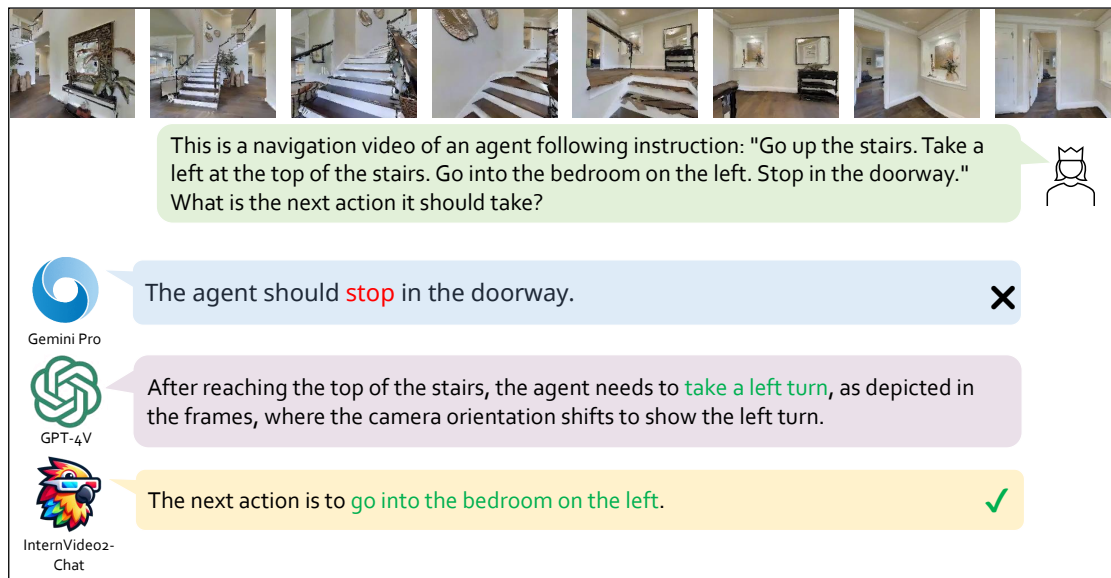

Figure 9: **Visual Language Navigation Tasks.** GPT-4V and InternVideo2-Chat are able to understand the instruction and make decisions about next steps based on the content of the video, while Gemini Pro is subject to hallucination.

5.4.4 Training and Evaluation in Stage 3

As shown in Tab. 19, incorporating questions (i.e., the ‘q’ in ‘QA’) into QFormer during Stage 3 training, which was found useful in [Dai et al., 2023], actually harms the out-of-domain performance of the scaled-up VideoLLM. The NextQA training data is already included in the training corpus, and this is the only benchmark where the question-injected version performs better. Therefore, we believe that adding questions to QFormer during the instruction tuning stage of the scaled VideoChat model leads to some degree of overfitting.

6 Conclusion and Discussion

We have introduced a new family of video foundation models called **InternVideo2**, which achieves the state-of-the-art performance across various video and audio tasks. In **InternVideo2**, we combine masked video modeling, video-audio-

Table 17: Ablation of Stage2. All models are tested with $8 \times 224 \times 224$ input.

Method	MSR-VTT
Baseline (video & text encoders w/ video-text learning)	24.7
Baseline + audio encoder w/ audio-text learning	24.0
Baseline + speech encoder w/ video-speech-text learning	24.9
Baseline + audio encoder w/ video-audio-text learning	27.8
Baseline + audio & speech encoders + video-audio-speech-text learning	25.7

Table 18: Zero-shot t2v retrieval on MSR-VTT with different training captions.

SceneDet	AutoShot	Video Cap	Audio Cap	Speech Cap	MSR-VTT
✓		✓			24.7
✓		✓	✓		26.6
✓		✓	✓	✓	27.1
	✓	✓	✓	✓	34.8

Table 19: Ablation on using qformer instruction in Stage3 training of Chat-Centric Model.

Model	MVBench	NextQA	Egoschema-full	Egoschema-subset
VideoChat2 w qformer inst	59.9	79	52.9	65.8
VideoChat2 w/o qformer inst	60.4 (+0.5)	78.6 (-0.4)	55.8 (+2.9)	66.4 (+0.6)

text contrastive learning, and next token prediction into a unified framework. Additionally, we create a new video-text dataset that incorporates video-audio-speech fused captions as descriptions. The dataset contains temporally segmented clips with high semantic coherence. These designs in **InternVideo2** contribute to enhancing video understanding in both perception and reasoning tasks. Notably, **InternVideo2** excels in video-related dialogue and long video understanding, demonstrating its effectiveness in capturing high-level semantics.

Limitations and Discussions. Despite its achievements, **InternVideo2** does not introduce specific novel architectural design. Instead, it leverages the existing learning techniques for scaling video foundation models while focusing on improving data processing to enhance its spatiotemporal perception, semantic alignment, and basic knowledge embedding. Similarly to previous studies [Li et al., 2023e, Ye et al., 2023], InternVideo2 still grapples with limitations stemming from fixed input resolutions, sampling rates, and highly compressed tokens, which restrict its ability to express rich video information and capture fine-grained details.

The progressive learning scheme adopted by **InternVideo2** strikes a balance between model capabilities and training compute. While jointly learning the three optimization objectives simultaneously is computationally feasible, scalability becomes an issue when confronted with limited resources.

Although **InternVideo2** has demonstrated leading performance in some video understanding and reasoning benchmarks, it cannot guarantee an implicit world model that ensures consistency in visual reasoning. The inherent constraints imposed by fixed input representations, coupled with the complexity of visual reasoning tasks, present challenges in achieving a comprehensive and consistent understanding of the visual world.

Potential Biases. We investigate the potential biases here. We focus on age, gender, and race distributions, as these are commonly recognized areas where bias can occur. We count keywords related to these categories in the used captions. Note that these synthetic captions may not fully reflect the truth of the corresponding videos, thereby creating a gap between our analysis and the actual reality. Here are the results of our analysis:

- **Age:** The majority were about adults (86.99%), followed by children (12.87%) and barely any mentions of senior citizens (0.04%).
- **Gender:** 62.04% pertained to men and 37.96% pertained to women.
- **Race:** 56.19% are Asians, 23.04% are Black people, 14.55% are White people, 3.78% are Middle Eastern people, and 2.43% are Latin American people.

7 Broader Impact

It is important to acknowledge that, similar to other foundational models, **InternVideo2** has the potential to embed biases present in its training data and the associated models used during training, such as neural teachers [Tong et al., 2022, Chen et al., 2023c] and language models (LLMs) [Jiang et al., 2023, Zheng et al., 2023]. These biases may emerge due to a variety of factors, including the personal ideas, preferences, values, and perspectives of the data creators and the training corpus utilized.

The presence of biases in AI models can have societal implications and reinforce existing inequalities or prejudices. Biases within **InternVideo2** could manifest in the form of unfair or discriminatory outputs, potentially perpetuating social biases or stereotypes present in the training data. Consequently, it is crucial to carefully consider the potential impact of deploying **InternVideo2** in real-world applications and take proactive measures to mitigate biases and ensure fairness.

A Model

Table 20: Architecture of vision encoder (6B).

Stage	ViT-6B		Output Size
Video	sparse sampling		$3 \times 8 \times 224 \times 224$
Patch	$1 \times 14 \times 14$, 3200		$3200 \times 8 \times 256$
Embedding	stride $1 \times 14 \times 14$		
Position Embedding	learnable, 3D sine-cosine initialization		3200×2048
Mask	semantic mask w/ $mask\ ratio = \rho$		$3200 \times 2048 \cdot (1 - \rho)$
Encoder	MHSA(3200) MLP(12800)	$\times 48 + \text{AttnPool}(768)$	$3200 \times 2048 \cdot (1 - \rho)$ 768×1
Projection	$\begin{bmatrix} \text{LN}(3200) \\ \text{MLP}(3200) \end{bmatrix} \times K_{CLIP}$,	$\begin{bmatrix} \text{LN}(3200) \\ \text{MLP}(1408) \end{bmatrix} \times K_{MAE}$,	$\begin{bmatrix} \text{LN}(3200) \\ \text{MLP}(768) \end{bmatrix} \times 1$
			$K \times 3200 \times 2048 \cdot (1 - \rho)$ $K \times 1408 \times 2048 \cdot (1 - \rho)$ $K \times 768 \times 1$

Video Encoder. In Tab. 20, we take ViT-6B as an example and omit the class token for a simple presentation. “MHSA”, “MLP”, “AttnPool”, and “LN” refer to spatiotemporal multi-head self-attention, multi-layer perception, attention pooling [Yu et al., 2022] and root mean square layer normalization [Zhang and Sennrich, 2019]. K_{CLIP} and K_{MAE} means the layer number for unmasked token alignment with multimodal and motion-aware teachers. We mark the **channel number**, **frame number**, **spatial size**, and **token number** by different colors. The projection layers are dropped after stage 1 training.

B Video-centric Multimodal Data

We prepare our training data according to the learning objectives of the three stages in our learning scheme. Specifically, it consists of video-only pretraining set for masked video token reconstruction, Video-Audio-Speech-Text one for multimodal alignment, and video instruction dataset for human-computer interaction alignment. They are detailed in the following.

B.1 Video-only Data

To create the curated collection of videos, named **K-Mash**, we source videos from renowned action recognition datasets such as Kinetics-400 (K400) [Carreira and Zisserman, 2017], Something-Something (Sth) [Goyal et al., 2017a], Moments in Time (MIT) [Monfort et al., 2020], ActivityNet [Heilbron et al., 2015], and HACS [Zhao et al., 2019]. These datasets provide a wide range of video types, including both first-person and third-person perspectives, short and long durations, and featuring a rich variety of characters and settings.

For the enhanced version of the dataset, called K-Mash_{2M}, we push a step further and meticulously selected an additional 844,000 videos from YouTube to further enhance the diversity of the dataset. It’s important to note that all videos in this dataset are utilized for training without any labels, allowing the model to learn from the unlabeled data in an unsupervised manner. This approach helps to broaden the model’s understanding of different visual concepts and improves its performance on various video-related tasks.

B.2 Videos with Audio-Video-Speech Modalities

In addition to publicly available video-text datasets (e.g. InternVid [Wang et al., 2023d] and WebVid [Bain et al., 2021]), we introduce a new video dataset that incorporates both audio-visual-speech information and their corresponding textual descriptions. This dataset is included in the training process of **InternVideo2**. To create this multimodal dataset, named **InternVid2**, we leverage several video sources and provide detailed annotations. **InternVid2** includes videos with synchronized audio, visual, and speech information, along with their corresponding textual descriptions. This multimodal dataset enables the training of **InternVideo2** to better understand and capture the connections between different modalities, enhancing its performance in various video-related tasks that require audio, visual, and speech understanding.

Collection. In the **InternVid2** dataset, approximately half of the videos are sourced from YouTube, while the remaining videos are gathered from anonymous sources. This is to improve the diversity of dataset, as relying solely on YouTube may result in limited depth of the dataset. Furthermore, to study the impact of video culture backgrounds on the learned models, a small portion of the dataset consists of Chinese data. These videos were collected with proper permissions for academic usage, ensuring compliance with legal and ethical considerations.

Table 21: Statistics of Stage1 data. All the videos are used without any labels.

Dataset	K710	SthSthV2	HACS	ANet	MiT	Self-collected
K-Mash _{1.1M}	658K	169K	106K	15K	152K	0
K-Mash _{2M}	658K	169K	106K	15K	207K	844K

By incorporating videos from various sources and including a subset of Chinese data, **InternVid2** provides a more diverse and representative dataset for training **InternVideo2**. This approach allows the model to learn from a wide range of video content, encompassing different cultural backgrounds and further enhancing its ability to understand and process videos from various sources.

Trimming. In our approach, instead of relying on the widely-used SceneDet filter of FFMPEG, we employ a temporal boundary detection model called AutoShot [Zhu et al., 2023c] to segment videos into clips. AutoShot is capable of predicting clip boundaries based on temporal semantic variations, as opposed to pixel differences. This leads to the generation of semantically complete cuts without mixing extra frames that may contain inconsistent context. By using AutoShot, we aim to reduce captioning errors by producing fewer clips with obvious transitions, resulting in a more coherent input for video captioning models. In the inference of AutoShot, we use a threshold of 0.5 to determine the shot boundaries for AutoShot’s estimations.

For the video dataset, we first preserve clips longer than 2 seconds. For video clips longer than 30 seconds, as the segments within the clip are from the same shot, we randomly choose a 30-second segment. During this process, we also abandon clips with still or extreme dynamics, such as browsing a photo gallery.

Table 22: **Fusion prompt.** The above prompt is to generate 2 multi-modal captions, the following prompt is to generate 3 multi-modal captions.

You are a text analysis expert. About one video, here is 1 vision caption: `vid_cap`, 1 audio caption: `aud_cap`. You need to understand and encode them into 1 sentence. Do not simply concatenate them together. The weights of video/audio are equaled. Considering dropping audio caption if it is incomprehensible. The output must be a complete and natural sentence. The sentence is: ...

You are a text analysis expert. About one video, here is 1 vision caption: `vid_cap`, 1 audio caption: `aud_cap`, and one speech subtitle: `asr_cap`. You need to understand and encode them into 1 complete sentence. The weights of video/audio/speech are equaled. Considering dropping audio caption or speech subtitle if it is incomprehensible. The output must be a complete and natural sentence, do not simply concatenate them together. The complete sentence is:

Annotation. We automatically caption visual, audio, and speech of **InternVid2**. Then we correct them and fuse them for cross-modal captions for training using LLM. We list several annotation examples of our method in Fig. 10.

- **Vision Captioner.** We employ the video captioning pipeline in InternVid to annotate our data. Rather than using VideoLLM [Li et al., 2023c, Maaz et al., 2023] to describe videos, we choose this validated method due to its better downstream results.
- **Audio Captioner.** We craft a audio captioner upon VideoChat [Li et al., 2023c], as we find no reliable ones. It extracts audio features from inputs by Beats [Chen et al., 2023a]. We learn it by only tuning its Qformer (the interface between audio encoder and LLM) using a combination of the large-scale audio-text corpus WavCaps [Mei et al., 2023] dataset.
- **Speech Captioner.** We utilize the audio transcription model Whisper [Radford et al., 2023] to obtain speech from videos. Concretely, we use the WhisperV2-large model since its concurrent state-of-the-art performance. During the data collection process, a portion of the data is directly adopted from YT-Temporal-180M, which already has well-aligned timestamps and adjusted speech recognition content. The remaining data is first passed through a pre-trained language identification model Fasttext-lid [Joulin et al., 2016] to determine the language category, and then transcribed the non-English text into English using the pretrained Seamless M4T [Communication et al., 2023] model. For the text with language identification confidence less than 0.95, we use Vicuna-1.5 as a translation alternative.
- **Caption Trimming & Fusion with LLM.** After obtaining the captions of audio, video, and speech from the given video, we utilize an LLM (Vicuna-1.5 [Zheng et al., 2023]) to integrate the uni-modal captions into the multimodal ones. To fulfill the request for multiple contrastive objectives, we combine the audio caption with the video caption

	<p>Video Cap: A woman is talking to a reporter in a store.</p>	<p>Video-Audio-Speech Cap: In the store, music plays in the background as a woman excitedly and nervously tells a reporter about Carolyn, who is going to be their second competitor and has lost 69 pounds and 31% of her body weight.</p>
	<p>Audio Cap: A woman is talking and music plays in the background.</p>	
	<p>ASR: She is gonna be our second competitor. Take a lap. She has lost 69 pounds and thirty-one percent of her body weight. Hey I'm excited but nervous but excited Carolyn.</p>	<p>Video-Audio Cap: In a store, a woman talks to a reporter while music are heard in the background.</p>
	<p>Video Cap: A man in a red shirt is standing in front of a lion.</p>	<p>Video-Audio-Speech Cap: The man in the red shirt is attempting to barricade himself away from a wild lion in a room with most of the line already there while a man is talking and the radio plays music.</p>
	<p>Audio Cap: A man is talking while a radio plays music.</p>	
	<p>ASR: Scene consisted of Denver attempting to barricade himself away from a wild lion spreading to most of the line is already in the room with him unfortunately.</p>	<p>Video-Audio Cap: The man in the red shirt stands in front of the lion and talking while the radio plays music.</p>
	<p>Video Cap: A group of people are standing in a field under a starry night sky.</p>	<p>Video-Audio-Speech Cap: A group of people are standing in a field under a starry night sky and a woman is talking in the background that a group of people observe the moon through a telescope, amazed by its craters.</p>
	<p>Audio Cap: A woman is talking.</p>	
	<p>ASR: When people get a chance look through a big telescope for the first time they're just floored at what you can see I was just showing the moon to someone and they're like oh my god you really can't see the craters it's really interesting.</p>	<p>Video-Audio Cap: A group of people are standing in a field under a starry night sky and a woman is talking in the background.</p>
	<p>Video Cap: A small black fish is swimming in a pond</p>	<p>Video-Audio-Speech Cap: While a bird is chirping in the background, a small black fish is swimming in a pond and a man is saying 'Come on, dude'.</p>
	<p>Audio Cap: A bird is chirping while a man is talking.</p>	
	<p>ASR: Come on, dude</p>	<p>Video-Audio Cap: As a small black fish swims in a pond, a bird chirps and a man talks in the background.</p>

Figure 10: Annotation examples using our captioning approach.

as the audio-visual caption, as well as integrate the audio, video, and speech captions as the audio-visual-subtitle captions. In this way, we acquire 5 types of captions (3 uni-modal captions (A, V, S) and 2 multi-modal captions (AV, AVS)) for each video automatically. Specifically, we have carefully designed prompt templates (Fig. 22) and employed vLLM [Kwon et al., 2023] for inference acceleration, effectively get the visual caption, audio caption, subtitle, audio-visual caption and audio-visual-speech caption while maintaining a natural human-like subtitle style.

Filtering & Sampling. After obtaining the captions, we calculate the CLIP similarity between the video segments and captions. We select the top 60 million data as the video segment data for **InternVid2**. For LAION-2B, we only select samples with CLIP similarity in the top 158 million for training.

C Experiments

C.1 Ablations

C.1.1 How InternVideo2 Works in Feature-based Tasks.

We study which part of **InternVideo2_{s1}**'s predictions are suitable for feature-based tasks, i.e. temporal action localition. We adhere the same train and test protocols as in the main paper.

In Tab. C.1.1, the most effective feature tends to be located within the last few layers of the video encoder. This observation aligns with the similarity between feature-based temporal tasks and linear probing classification, which is reasonable. We undertake comprehensive experiments to investigate the impact of features from various layers, as detailed in Table 23. The results reveal the best features appear between the last 5-th layer and 7-th layer.

Table 23: Effect of feature extracted from the last 7 layers.

Layer Index	THUMOS-14		ActivityNet		HACS Segment		FineAction	
	1B@mAP	6B@mAP	1B@mAP	6B@mAP	1B@mAP	6B@mAP	1B@mAP	6B@mAP

C.2 Video Retrieval

We detail R@1, R@5, and R@10 of zero-shot video retrieval from **InternVideo2** in Tab. 24a -24f for reference.

Table 25: The top-1 accuracy of zero-shot video QA (multi-choice) on MSR-VTT and LSMDC. Finetuned results are marked in gray.

Method	MSR-VTT	LSMDC
VIOLET [Fu et al., 2021]	91.9	82.8
InternVideo [Wang et al., 2022]	93.4	77.3
InternVideo2 _{s2} -6B	94.4	76.9

Table 26: Performance of multimodal LLMs on different question types and scenes of MoVQA.

Method	Backbone	Synopsis	Temporal	Spatial	Causal	Hypothetical	Knowledge	Single-Scene	Multi-Scene	Full-Scene	Overall
Mplug-Owl [Ye et al., 2023]	CLIP ViT-L	25.1	19.9	25.3	21.9	23.5	27.5	25.2	23.5	22.1	24.8
Otter [Li et al., 2023a]	CLIP ViT-L	22.6	20.7	19.6	26.1	24.2	21.8	23.1	22.1	21.3	22.6
VideoChatGPT [Maaz et al., 2023]	CLIP ViT-L	23.8	20.2	22.1	22.1	21.4	24.1	23.4	22.7	22.3	22.9
VideoChat [Li et al., 2023c]	Eva-g	33.6	24.3	34.5	36.6	35.5	32.0	35.3	32.9	33.3	34.7
VideoChat2 [Li et al., 2023d]	InternVideo2_{s3}	42.6	27.8	39.9	44.3	44.2.5	41.2	40.9	39.3	38.6	40.1

C.3 Multi-Choice Video Question Answering

We evaluate zero-shot multi-choice (MC) video QA using **InternVideo2** in stage 2 on MSR-VTT and VATEX. Tab. 25 shows **InternVideo2** consistently improves MC accuracy compared with previous SOTAs except on LSMDC, where it gets a comparable result with InternVideo.

C.4 Movie Understanding

We evaluate **InternVideo2** on the MoVQA for movie understanding. It is a long-form movie question-answering dataset[Zhang et al., 2023]. MoVQA assesses the diverse cognitive capabilities of multimodal systems by considering both video length and clue length, relying on multi-level temporal lengths (single-scene, multi-scene and full-scene). There are six types of QAs, including information synopsis, temporal perception, spatial perception, causal reasoning, hypothetical reasoning and external knowledge. We evaluate **InternVideo2-6B** in the form of open-ended QAs, and detailed results are shown on Table 26.
