Abstract. Empowered by Large Language Models (LLMs), recent advancements in VideoLLMs have driven progress in various video understanding tasks. These models encode video representations through pooling or query aggregation over a vast number of visual tokens, making computational and memory costs affordable. Despite successfully providing an overall comprehension of video content, existing VideoLLMs still face challenges in achieving detailed understanding in videos due to overlooking local information in long-term videos. To tackle this challenge, we introduce LongVLM, a straightforward yet powerful VideoLLM for long video understanding, building upon the observation that long videos often consist of sequential key events, complex actions, and camera movements. Our approach proposes to decompose long videos into multiple short-term segments and encode local features for each local segment via a hierarchical token merging module. These features are concatenated in temporal order to maintain the storyline across sequential short-term segments. Additionally, we propose to integrate global semantics into each local feature to enhance context understanding. In this way, we encode video representations that incorporate both local and global information, enabling the LLM to generate comprehensive responses for long-term videos. Experimental results on the VideoChatGPT benchmark and zero-shot video question-answering datasets demonstrate the superior capabilities of our model over the previous state-of-the-art methods. Qualitative examples demonstrate that our model produces more precise responses for long videos understanding. Code will be available at <https://github.com/ziplab/LongVLM>.

1 Introduction

Large language models (LLMs) [7, 36, 37, 43, 45, 46] have revolutionized natural language understanding tasks and have demonstrated a remarkable capability to follow human instructions and intentions, emerging as a universal agent for general-purpose assistants. Drawing from the development of LLMs, Multimodal Large Language Models (MLLMs) [8, 15, 30, 65] have driven the advance in vision-language learning by integrating visual encoders with LLMs and finetuning on language-image instruction-following data. However, developing Video-based Large Language Models (VideoLLMs) still poses a significant challenge

Fig. 1: Previous approaches employ pooling operation or query aggregation for visual representations, focusing primarily on modeling global semantics and potentially overlooking detailed information in long-term videos. In contrast, our LongVLM proposes to aggregate local features for short-term segments and integrate global semantics into segment-level local feature sequence. Text highlighted in bold green denotes correct content, while text in red indicates errors. The video duration is 1 minute and 20 seconds.

due to the necessity of processing a large number of tokens for jointly modeling spatial-temporal dependencies across consecutive video frames. For instance, employing OpenAI CLIP-ViT-L/14 [40] as a visual encoder for a 100-frame video clip necessitates handling 25.6K visual tokens, leading to impractical computational costs with existing LLMs. To address this, recent approaches propose to extract video representation via precompression over visual tokens, utilizing pooling operation [34, 35] or query aggregation [24, 42, 61] over the video token sequence before feeding them into the LLM, as shown in Fig. 1a. While these models showcase impressive capabilities in providing a meaningful understanding of video content, they still face challenges in achieving a significant advantage in fine-grained understanding of long-term videos. For example, as shown in Fig. 1b, while all models recognize the overall environment (*workshop*), the object (*bike*), and the action (*fixing*), previous methods may fail to correctly identify details such as the color of the clothes (*brown*), or the specific component being fixed (*bicycle chain*).

The main reason is that long-term videos typically involve numerous key actions, complex activities, and camera movements. Consequently, a long video can be divided into a sequence of short-term segments. For instance, in the example depicted in Fig. 1b, various short-term actions occur, *e.g.* speaking, displaying spare components, grabbing the bicycle chain, along with the camera moving from the human to the bicycle wheel, and eventually focusing on the broken

chain. Similarly, prior methods in video recognition task suggest to decompose complex activities into sequences of sub-activities [14, 19, 47]. These approaches treat the features of each short-range activity as the local information within the videos and emphasize the importance of reasoning over local features to develop a temporal-structural understanding [14, 19, 47–49, 60] within long-term videos for comprehending fine-grained information. From this perspective, existing VideoLLMs treat all visual tokens equally and aggregate them into compact representations through pooling operations [34, 35] and query aggregation [24, 42, 61]. While they successfully capture the global semantic context spanning the entire long-term videos, they often overlook preserving the local information for the short-term segments and the temporal structure of different short-term components, *e.g.*, the order of events or sub-actions. However, exclusively modeling the temporal structure through the sequence of local features may still lead to inconsistent recognition across different segments and impede the overall understanding of the videos. To comprehend the content in long videos, the human visual system relies on a blend of local and global information [44]. Building on this insight, earlier approaches in video object detection [52, 54] suggest integrating global semantics into local localization descriptors, motivating us to include global semantic information into the sequence of local features for enriching the context understanding for each short-term segment.

In this paper, we present LongVLM, a simple yet effective VideoLLM for efficient long video understanding, as illustrated in Fig. 2. We propose to extract video representations as sequences of short-term local features, and integrate global semantics into each short-term segment feature. Specifically, we begin by uniformly sampling a sequence of video frames from long-term videos and utilize a pretrained visual encoder, *e.g.*, CLIP-ViT-L/14 [40], to extract visual features for each individual video frame. These frame-level features include the [CLS] tokens from a range of encoder layers and the patch features from the last second layer of the visual encoder. Then, we divide the sequence of patch features along the temporal dimension, resulting in a sequence of short-term segments. Each segment is considered as a local unit in the videos and includes patch features of the video frames within that segment. To reduce computational costs and obtain the compact features for each segment, a token merging module is employed to aggregate these patch features for the specific segment into a condensed set of tokens. In this way, we obtain the local features for each segment. We next concatenate these features sequentially to explicitly preserve the temporal order of the short-term segments in long-term videos. Moreover, we average the [CLS] tokens from each video frame along the temporal dimension to represent the global semantic information of the entire video. To integrate the global information, we sequentially arrange the averaged [CLS] tokens and the segment-level features, and then feed them into the LLM after passing through a projection layer. Benefiting from the causal attention mechanism in the LLM, we simultaneously achieve temporal structure modeling over the sequence of short-term segments and inject global semantics into the local features. Finally, the LLM generates responses based on the input sequence, which is composed of the ob-

tained video representation and the designed system command with the specific user queries.

Overall, our main contributions is threefold:

- We propose LongVLM, a simple yet effective VideoLLM for efficient long-term video understanding at a fine-grained level while maintaining affordable computational cost.
- We propose decomposing long videos into short segments and extracting local features for each segment to preserve their temporal order. To compactly represent each segment, we propose a hierarchical token merging module to aggregate visual tokens. Additionally, we integrate global semantics into each segment to enhance context understanding.
- Extensive experiments on VideoChatGPT benchmark [35] and zero-shot video question-answering datasets [55, 59] demonstrate that our LongVLM surpasses the previous state-of-the-art methods by a significant margin while generating more precise and accurate response at fine-grained level for long-term videos.

2 Related Work

2.1 Large Language Models

Large Language Models (LLMs) have revolutionized natural language processing in recent years. Pretrained on large text corpora, LLMs like GPT [2], OPT [62], and LLaMA [45, 46] utilize auto-regressive Transformer models to predict subsequent tokens, showcasing remarkable adaptability and generalization. Models such as InstructGPT [38], ChatGPT [36], and GPT-4 [37] benefit from instruction-tuning techeque [51] on instructional datasets, leveraging the knowledge of pretrained LLMs and demonstrating improvements in diverse conversational interaction capabilities. This strategy is widely adopted in open-source models like Alpaca [43] and Vicuna [7], which build upon the advancements made by LLaMA [45] using specially designed instruction pairs. Drawing from the advancement of LLMs, recent Multi-modal Large Language Models (MLLMs), *e.g.*, BLIP-2 [23], Mini-GPT4 [65], LLaVA [30], LLama Adapter v2 [15], have demonstrated the feasibility of enabling visual conversation capabilities of LLMs over input images through instruction tuning on image-text instruction datasets. Our model aims to utilize existing MLLMs to develop efficient video dialogue model for long-term video understanding.

2.2 Video-based Large Language Models

Building upon pretrained image-language models, traditional approaches [6, 11, 13, 22, 26, 28, 33, 50] are proposed to address various video-language learning tasks. With the advent of LLMs, recent approaches are exploring the potential of developing Video-based Large Language Models (VideoLLMs) to unify various video-language understanding scenarios through human-video dialogue

interactions. Existing VideoLLMs typically follow a common paradigm, which involves using a pretrained visual encoder to encode visual features, a projection layer to convert visual representations into the text latent space of LLMs, and a pretrained LLM for response generation. VideoChatGPT [35] and Valley [34] rely on pooling over visual tokens to obtain compact visual representations. VideoChat [24] utilizes pretrained video foundation models [25,50] and Q-Former from BLIP-2 [23] to aggregate video representations. Video-LLaMA [61] proposes a Video Q-Former and an Audio Q-Former, enabling multiple modalities for video comprehension, while Video-ChatCaptioner [5] employs ChatGPT [36] to summarize video descriptions in multiple rounds of interactive question-and-answer conversation. Recently, MovieChat [42] proposes an effective memory management mechanism to enable LLMs to reason over hour-long videos. Multiple video-centric instruction datasets [24, 34, 35, 42] have also been proposed to finetune VideoLLMs for better video understanding capacity. Moreover, BT-Adapter [31] proposes a temporal adapter alongside the visual encoder for post-pretraining, while Video-Teller [29] highlights the importance of modality alignment in pretraining. Overall, these VideoLLMs rely on pooling and query aggregation on the whole long videos to extract visual representation for developing VideoLLMs, which lack of local information for fine-grained understanding in long videos. In contrast to existing VideoLLMs, we propose a simple yet effective framework that is feasible for aggregating both local and global information in long-term videos and preserves fine-grained content understanding.

2.3 Long-term Video Processing

Long-term video understanding poses several challenges due to the need to exploit complicated spatial-temporal dependencies while removing temporal redundancy over extended time duration. Previous studies propose efficient architectures [9, 20], temporal pooling/aggregation [12, 41, 53, 64], dynamic clip selection [16, 17, 21] to aggregate video representation while removing redundant information in videos. Other methods in video-language understanding tasks suggest to capture event temporality, causality, and dynamics in long-term videos by designing temporal alignment modules [3, 18]. Memory mechanism is also widely adopted in video dense prediction tasks [32, 52, 52, 54, 58, 63] to capture historical information and maintain temporal coherence, which results in more accurate and consistent prediction over time in long-term videos. In contrast to previous methods, we investigate the techniques for long-term video understanding in VideoLLMs. We propose to aggregate both local segment-level information and global semantic information, empowering MLLMs enhanced fine-grained understanding for long-term videos.

3 Method

In Sec. 3.1, we introduce the overall architecture and generation pipeline of the proposed LongVLM. In Sec. 3.2, we introduce the process of constructing local

Fig. 2: Overall architecture of the proposed LongVLM. We start by uniformly sampling T frames from a video and employing a visual encoder to extract frame-level features. We divide the input video into S segments, each with K frames. To obtain compact local features, we apply a hierarchical token merging module within each segment. These segment-level features are concatenated sequentially to explicitly preserve the temporal order of multiple short-term segments in long videos. Additionally, we incorporate [CLS] tokens to aggregate global semantic features. The global features and the sequence of local features are concatenated to form the video representations. Finally, the projected visual features are combined with the tokenized system command and user queries and inputted into the LLM to generate the responses.

representation via short-term feature aggregation. In Sec. 3.3, we discuss the integration of both local segment-level feature and global semantic feature for the video representation.

3.1 Overall Architecture

The overall architecture consists of three components: a visual encoder, a projection layer, and a large language model, as illustrated in Fig. 2.

Given an input video $\mathcal{V} \in \mathbb{R}^{T \times H \times W \times 3}$, we employ a visual encoder to extract frame-level features $\{\mathbf{X}^t, \mathbf{P}^t\}_{t=1}^T$ for each video frame independently. Following previous methods [30, 35], we utilize the patch feature $\mathbf{P}^t \in \mathbb{R}^{N \times d}$ from the penultimate encoder layer for each video frame, where N, d are the number of patch tokens and the channel dimension of the visual encoder, respectively. Additionally, we gather the [CLS] tokens $\mathbf{X}^t \in \mathbb{R}^{E \times d}$ from E selected encoder layers for each individual video frame.

To enable fine-grained understanding in long videos, we propose to divide long videos into a sequence of short-term segments, where each segment corresponds to the local features in the long videos. Without loss of generality, the input video \mathcal{V} is divided into S segments, where each segment includes K frames, *i.e.*, $K = \frac{T}{S}$. We collect patch features within the s^{th} segment, *i.e.*, $\mathbf{V}^s = \{\mathbf{P}^t\}_{t=(s-1)K}^{sK}$, and apply a token merging module $\mathcal{G}(\cdot)$ to aggregate \mathbf{V}^s into the compact segment-level feature $\mathbf{Z}^s = \mathcal{G}(\mathbf{V}^s)$. These segment-level features are sequentially concatenated as the sequence of local representation \mathbf{L} , explicitly preserving temporal order of short-term segments in long videos. Furthermore,

to integrate global semantic information, we propose to collect the [CLS] tokens for each frame from E encoder layers and average them in the time dimension, resulting in our global feature \mathbf{G} .

We forward the concatenated global features and the sequence of local features into a projection layer $\mathcal{F}_V(\cdot; \mathbf{W})$ to obtain the projected visual feature, *i.e.*, $\mathbf{H}_V = [\hat{\mathbf{G}}, \hat{\mathbf{L}}] = [\mathcal{F}_V(\mathbf{G}; \mathbf{W}), \mathcal{F}_V(\mathbf{L}; \mathbf{W})]$. The projected visual feature \mathbf{H}_V are concatenated with the tokenized system command and user queries \mathbf{H}_q , which are inputted into LLM for response generation \mathbf{H}_a , *i.e.*, $\mathbf{H}_a = \mathcal{F}_{LLM}([\mathbf{H}_V, \mathbf{H}_q])$, where $\mathcal{F}_{LLM}(\cdot)$ denotes an LLM model.

3.2 Local Feature Aggregation

After obtaining the frame-level patch feature $\{\mathbf{P}^t\}_{t=1}^T$ from the last second layer of visual encoder, previous methods either apply factorized spatio-temporal pooling [34, 35], or utilize query aggregation [24, 42, 61] over all visual tokens, which may miss local information referring to the short-term events or actions. Nevertheless, videos have heavy spatio-temporal redundancy, which results in redundant computational costs by directly considering all the patch features as the local representation for each segment. Therefore, we propose to aggregate compact visual features within each short-term segment. Specifically, we collect the patch feature for the s^{th} segment $\mathbf{V}^s = \{\mathbf{P}^t\}_{t=(s-1)K}^{sK} \in \mathbb{R}^{KN \times d}$ and apply a hierarchical token merging module to aggregate the local feature while reducing the number of visual tokens. Inspired by ToMe [1], we resort to the bipartite soft matching method and gradually merge the visual tokens for each short-term segment. At the i^{th} step, we randomly partition the R_i tokens into two non-overlap token sets \mathbb{P}_i with r_i tokens and \mathbb{Q}_i with $R_i - r_i$ tokens, where initial $R_0 = KN$. Then we calculate the similarity scores between the tokens in set \mathbb{P}_i and \mathbb{Q}_i based on the patch features. To obtain the similarity scores, each visual token is divided into C heads along channel dimension, each with $\frac{d}{C}$ channels. The similarity score for each token pair is obtained by averaging the cosine similarity scores over all heads following

$$a^{p_i q_i} = \frac{1}{C} \left[\sum_{c=1}^C \cos(\mathbf{p}_c^{(p_i)}, \mathbf{p}_c^{(q_i)}) \right],$$

where $p_i \in \{1, \dots, r_i\}$ and $q_i \in \{1, \dots, (R_i - r_i)\}$ are the indexes of patch feature \mathbf{p} in set \mathbb{P}_i and set \mathbb{Q}_i , respectively. We select the top- r_i token pairs with the highest similarity scores and merge the paired tokens by average pooling. Finally, the remaining tokens in the two sets are concatenated back together, resulting in $R_i - r_i$ tokens after the i^{th} merging step. We iteratively merge the tokens within each short-term segment, until the number of visual tokens reaches M , where $M \ll K \times N$. The compact local feature for the s^{th} segment is denoted as $\mathbf{Z}^s = \{\mathbf{z}_m\}_{m=1}^M \in \mathbb{R}^{M \times d}$. These segment-level features are concatenated sequentially as the sequence of local features $\mathbf{L} = \{\mathbf{Z}^s\}_{s=1}^S = [\mathbf{z}_1^1, \dots, \mathbf{z}_M^1, \dots, \mathbf{z}_1^S, \dots, \mathbf{z}_M^S] \in \mathbb{R}^{MS \times d}$. Thanks to the positional encoding in the LLM, the sequence of local representation \mathbf{L} explicitly preserves the order of short-term segments in long-term

videos, enabling LLMs to be aware of the temporal structure of multiple event occurrences in long videos. By utilizing the token merging module, we efficiently encode compact local features for each segment while eliminating redundancy in the visual token sequence.

3.3 Global Semantics Integration

The local feature provides fine-grained information about different events or actions in the generation process of VideoLLMs, enhancing the detailed understanding capabilities of the LongVLM. However, the local feature for each segment may be insufficient for the model to reason the relationship between different segments and generate reasonable response over the entire videos. Therefore, we additionally introduce global semantic features to enrich the local feature sequence with contextual information. Specifically, we collect the [CLS] tokens from E encoder layers from each video frame, *i.e.*, $\{\mathbf{x}_e^t\}_{e=1, t=1}^{e=E, t=T}$, and then average the [CLS] tokens along temporal dimension, resulting in $\bar{\mathbf{X}}_e = \text{AvgPool}(\{\mathbf{x}_e^t\}_{t=1}^T) \in \mathbb{R}^d, e \in [1, \dots, E]$. By default, E can be the number of layers in the visual encoder. However, previous studies demonstrate different properties between intermediate features from the shallow layers and deeper layers in ViT models [27, 39], and showcase the deeper layers tend to aggregate global semantics. Thus, we concatenate the E -scale features along sequentially, resulting in the global semantic feature for the entire video, *i.e.*, $\mathbf{G} = \{\bar{\mathbf{X}}_e\}_{e=1}^E \in \mathbb{R}^{E \times d}$.

Following the previous studies, a projection layer converts the visual features into the language space, and then the visual features are concatenated with the instruction as the input of LLM. By utilizing the attention mechanism in the LLM, we can easily enable each token in the local feature to attend to the global semantic feature, thereby achieving straightforward injection of global semantics into the local feature.

Remark. To address the risk of overlooking detailed understanding in long-term videos, we propose to divide long videos into multiple short-term segments and aggregate local spatial-temporal representation for each segment and preserving the temporal structure over the sequence of local feature vectors. Moreover, we enrich the local features with context information for better response generation by integrating global semantic information into short-term features. Different from previous approaches that rely solely on global semantics for long video understanding, we present a straightforward yet effective VideoLLM for achieving fine-grained understanding in long-term videos.

ActivityNet-v1.3 dataset [10], with 2000, 2000, 2000, 500, and 1000 questions in terms of five evaluation aspects: Correctness Information(CI), Detail Orientation(DO), Contextual Understanding(CU), Temporal Understanding(TU) and Consistency(C). Additionally, we evaluate the model on the zero-shot question-answering task using the ANET-QA [59] dataset, which contains 8000 QA pairs for 800 videos sampled from ActivityNet-v1.3 dataset [10]. The videos range from several seconds to minutes long and cover a wide range of daily human activities. We also utilize MSRVTT-QA [55,56](72821 QA pairs for 2990 videos) and MSVD-QA [4,55](13157 QA pairs for 520 videos) to evaluate the model performance, derived from publicly available video captioning, MSRVTT [56], and MRVDC [4], respectively. Following the evaluation protocol outlined in VideoChatGPT [35], we employ ChatGPT [36] for response evaluation and report the generation quality scores on VideoChatGPT benchmark and the answer accuracy and quality scores of models on zero-shot video QA tasks.

Implementation details. We employ CLIP-ViT-L/14 [40] as the visual encoder and Vicuna-7B-v1.1 [7] as the LLM. We initialize them with the pretrained weights in LLaVA-7B-v1.1 [30]. We finetune the model on the Video-ChatGPT-

100K instruction dataset [35] for 3 epochs, with a learning rate of $2 \times e^{-5}$ and a batch size of 32. We only finetune the linear projection layer to align the visual features into the input space of the LLM, keeping both the visual encoder and LLM frozen. It takes three hours to train three epochs on 4 A100 80GB GPUs. During training and inference, we sample $T = 100$ video frames for each video, and resize the frames to 224×224 resolutions. We set $S = 10$ for each video, and the number of tokens in each segment-level feature is $M = 30$. We collect the $[CLS]$ tokens from the last five encoder layers and average them along the temporal axis, resulting in $E = 5$ tokens as the global semantic features. Therefore, the length of visual tokens for a video sequence is $M \times S + E = 305$.

4.2 Main Results

Results on the video-based generation benchmark. In Tab. 1, we present a comprehensive evaluation of our LongVLM against state-of-the-art models on the video-based generation benchmark [35]. Our LongVLM outperforms all other models across all the evaluation aspects. Particularly noteworthy is its significant advantage in Detail Orientation (DO) and Consistency (C), showing improvements of +0.17 and +0.65, respectively, over BT-Adapter [31]. These results underscore superior capability of LongVLM in fine-grained video understanding and robust generation performance.

Results on zero-shot video question-answering. In Tab. 2, we compare the performance of LongVLM against various existing methods on three zero-shot video QA datasets: ANET-QA [10, 59], MSRVTT-QA [55, 56] and MSVD-QA [4, 55]. Our model achieves the highest accuracy of 47.6%, 59.8%, and 70.0% on the three QA datasets, surpassing the previous SOTA approach BT-Adapter [31] by 1.9%, 2.8% and 2.5%, respectively. Furthermore, we achieve the highest score in terms of generation quality over the three datasets.

4.3 Ablation Study

Effects of local feature aggregation. As discussed in Sec. 1, pooling operations or query aggregation might overlook local information in achieving fine-grained understanding in long-term videos. To this end, we introduce short-term segment-level features to retain local information and temporal structure within long-term videos. The first two rows in Tab. 3 present the effects for the design of using local features as the visual representations for videos. We compare the token merging module with local pooling operation using a pooling kernel and stride of $[5, 4, 4]$ within each short-term segment. The proposed hierarchical merging module achieves higher scores over spatial-temporal pooling operation. This could be attributed to the dynamic aggregation mechanism via the token similarity in the merging module, while averaging pooling statically aggregates visual tokens within each small 3D window. Additionally, we observe that aggregating local features for short-term segments either improves or maintains comparable performance across all evaluation metrics compared to the SOTA models which

Table 3: Ablation of the local and global aggregation design. Pooling: Using local 3D pooling kernel to obtain local features; Merging: Using the proposed hierarchical token merging to obtain local features; [L, G]: Concatenating local feature then global feature; [G, L]: Concatenating global feature then local feature.

extract global semantics only, highlighting the significance of preserving local features for short-term segments in long-term video understanding.

Effects of global semantics integration. Inspired by the human visual system that using a combination of local and global information for recognizing video content [44], we propose to enhance visual representation by injecting global semantic features into local features. The last two rows in Tab. 3 demonstrate the effects of integrating global semantics. Compared to the first two rows, introducing global semantic features significantly enhances performance compared to models using local features only across all evaluation aspects. The notable improvements in Contextual Understanding (CU) and Consistency (C) underscore the significance of integrating global semantic information with local short-term features. Moreover, concatenating global features before local features yields better results than the opposite concatenation order. This arrangement allows each the local feature to access the global semantic information across the entire video by leveraging the causal attention mechanism in the LLM. Consequently, this enriches the contextual information of the local features and enhances the response consistency of the model.

Effects of M . We report the model performance on VideoChatGPT benchmark and ANET-QA task on the selection of M , *i.e.*, $M = \{10, 20, 30, 40\}$, keeping

(a) Quantitative results on Video-ChatGPT-100K [35] benchmark and the task of zero-shot question answering on ANet-QA [59], MSRVTT-QA [55, 56] and MSVD-QA [4, 55]. Our model delivers the best performance on multiple evaluation aspects, compared with the state-of-the-art video dialogue models: Video Chat [24], LLaMA Adapter [15], Video LLaMA [61], Video-ChatGPT [35], and BT-Adapter [31]. Evaluation metrics and comparison details are given in Section 4.2.

(b) An example of zero-shot question answering. Video duration is 3 minutes and 46 seconds.

Fig. 3: Quantitative results and qualitative examples of our LongVLM.

Fig. 4: Two examples from Video-ChatGPT benchmark [35]. Text highlighted in bold green denotes correct content, while text in red indicates errors. The video durations are 42 seconds and 1 minute 39 seconds, respectively.

the same number of global semantic tokens in Tab. 4. For ANET-QA task, we also report the averaging GPU memory usage for generating each response. In general, the token length involves a trade-off between memory costs and performance. A shorter token sequence reduces computational costs for generating a single new token using LLM, thereby lowering memory costs for generating responses to individual user queries. However, it may also lead to insufficient visual information for generating accurate responses. The performance of our model is beneficial from the suitable length of visual tokens. Specifically, using $M = 10$

Question What is the scenery like along the stream?

LongVLM The scenery along the stream is **beautiful and picturesque**. The stream is **surrounded by lush green trees**, which create a **serene and natural** environment. The water appears to be **clear**, making it an attractive spot for **kayaking and canoeing**.

Question Can you describe the video in detail?

LongVLM The video shows a man **playing the bagpipes in a public square**, surrounded by a **crowd of people**. The man is **dressed in a kilt** and is playing the bagpipes while standing in the middle of the square. There are several people in the background, some of whom are **taking pictures** of the man and the bagpipes. The scene is set in a city, with the man playing the bagpipes in a public space, attracting the attention of the people around him. The video captures the moment of the man playing the bagpipes, showcasing the **unique sound and the atmosphere** it creates in the public square.

Question Can you describe the video in detail?

LongVLM The video is a performance of a **ballet dance routine**, featuring a **group of dancers in white dresses**. They are performing **on a stage**, with the **stage lights shining on them**. The dancers are **moving gracefully and elegantly**, showcasing their skills and coordination. The performance is set to music, which adds to the overall atmosphere and impact of the dance routine. The dancers are well-coordinated, and **their movements are synchronized**, creating a visually appealing and captivating performance.

Question What happens in the video?

LongVLM In the video, a woman is seen **brushing a brown horse** with a brush. She is **standing next to the horse** and is seen **brushing its back**. The horse is **calmly standing** while the woman brushes it.

Question What color nail polish did the woman apply to her ring finger?

LongVLM The woman applied a **pink** nail polish to her ring finger.

Question What is the man wearing while playing the piano in the piano store?

LongVLM The man is wearing a **brown** jacket while playing the piano in the piano store.

Fig. 5: More generative examples from the Video-ChatGPT benchmark [35] of the proposed LongVLM. Text in bold denotes the correct content. The LongVLM is able to capture the detailed information videos.

leads to the lowest performance in both tasks, while it still shows a comparable performance compared to the SOTA models, indicating the effectiveness of our model design. Increasing M from 10 to 40 results in a significant improvement in terms of most evaluation aspects, while the setting of $M = 40$ leads to neglecting

improvement but requires more memory cost compared to $M = 30$. Therefore, we choose $M = 30$ for our model.

Effects of E . We evaluate the model performance on the VideoChatGPT benchmark with varying E by selecting the [CLS] tokens from the last 1, 5, 10, 15, 20, 24 visual encoder layers, while maintaining the same M for local features. As depicted in Tab. 5, increasing the number of global semantic tokens from 1 to 5 improves the generation quality scores in terms of all evaluation aspects. However, increasing E from 5 to 24 leads to degraded performance, possibly because the [CLS] tokens from earlier layers carry less semantic information for the model. Therefore, we choose $E = 5$ in our model.

4.4 Qualitative Results

As illustrated in Sec. 1, Fig. 1b demonstrates the advancement of our model in terms of fine-grained understanding in long-term videos. Despite taking the same number of video frames as input, our model excels in capturing detailed information within the videos, discerning nuances like *fixing chain* rather than *fixing wheel*. In comparison, Video-ChatGPT [35] can describe the overall video content but may inaccurately recognize detailed information. For instance, it might identify objects such as *helmets* and *gloves* in the scene but erroneously recognize the location for these objects. This emphasizes the importance of decomposing long videos into multiple short-term segments and aggregate local features to achieve fine-grained understanding in videos. The examples depicted in Fig. 4 ablate the effectiveness of integrating global semantic information into local short-term features. With global semantics integration, the model is able to recognize the actions (*long jump*) and objects (*axe*) compared to the variant that using local features only. We provide more generated examples in Fig. 3b and Fig. 5 from ANET-QA and Video-ChatGPT benchmark, respectively, which showcase the precise description of the video content generated by our LongVLM.

5 Conclusion

In this work, we have introduced LongVLM, an effective and efficient multimodal LLM designed for long-term video understanding. By extracting local features for short-term segments, we efficiently model local dependencies while preserving the temporal structure of sequential events in long-term video sequences. Through the integration of local and global information, LongVLM captures detailed information and provides consistent and accurate responses for long-term videos.

Limitations and Further work. While we introduce a novel video conversation model for fine-grained long-term video comprehension, our framework is specifically designed for video-to-text generation scenarios. Future work may include extending our framework into video-centric multimodal generation tasks and training the model on large-scale, extended-duration videos for long-context understanding.

Question What is the first maneuver the man performs on the parallel bars and what is the final maneuver he performs before attempting a backswing?

LongVLM The first maneuver the man performs on the parallel bars is a **handstand**. He then performs a backswing, which involves swinging his body backward and upward while holding onto the bars. The final maneuver he performs before attempting a backswing is a **handstand on the bars**.

Question What is the sequence of events in the cheer squad routine shown in the video?

LongVLM The **cheer squad** routine in the video consists of a series of movements and stunts, showcasing the team's synchronization and athleticism. The routine starts with the cheerleaders standing in a formation, and then they begin to perform various stunts, with some girls performing **jumps** and **flips** while others are holding hands. The routine culminates with the cheerleaders **performing a pyramid formation**, where they are stacked on top of each other. Throughout the routine, the cheerleaders maintain a high level of energy and enthusiasm, which is essential for a successful performance.

Question What happens after the tattoo artist marks the girl's ear?

LongVLM After the tattoo artist marks the girl's ear, they begin to **tattoo** her ear. The video shows the artist working on the girl's ear, and it appears that they are **using a needle to create the tattoo design**. The process involves the artist **making incisions** in the skin, **adding color**, and possibly **shading to create the desired tattoo**. The girl is **lying on her back**, and the artist is working on her ear, which is a common position for tattooing. The tattooing process **can be painful**, and the girl may need to endure some discomfort during the process. After the tattooing is complete, the artist will likely **clean the area and apply a bandage or dressing** to protect the tattoo and prevent infection.

Question How does the man iron the shirt and what does he do afterwards in the video?

LongVLM The man in the video is ironing a shirt using an ironing board. He **first places the shirt on the ironing board** and then **uses the iron to press it**. After ironing the shirt, he **takes it off the ironing board and hangs it up**. The entire process is captured in the video, providing a clear demonstration of how to iron a shirt using an ironing board.

Question What happens towards the end of the video?

LongVLM At the end of the video, the windsurfer **falls off the board and into the water**.

Fig. 6: Additional response examples from the Video-ChatGPT benchmark [35] generated by our LongVLM, focusing on temporal understanding (TU) evaluation perspective. Text in bold indicates the correct content.

- Q** What is the name of the sport in the video?
- A** The sport in the video is **running**.
- Q** Is the person wearing a yellow dress at the beginning of the video?
- A** Yes.
- Q** Is this sport helpful for physical exercise?
- A** Yes, running is a highly beneficial sport for physical exercise. As seen in the video, a group of people are running down a street in a residential area, which indicates that they are engaging in a form of physical activity. Running is an excellent way to improve cardiovascular health, build muscle strength, and enhance overall fitness.

- Q** What is the person in the video doing?
- A** The person in the video is **changing a tire on a truck**. They are using a jack to lift the truck, and then using a tire iron to remove the old tire and put on a new one.
- Q** What is the color of the person's hair in the video?
- A** The person in the video has **blonde** hair.
- Q** What pants are the people wearing in the video
- A** The people in the video are wearing **jeans**.

- Q** What is the season in the video?
- A** The season in the video is **winter**, as evidenced by the snow and ice on the car and the woman's winter clothing.
- Q** What is the person in the video doing?
- A** The person in the video is **shoveling snow off** of a car.
- Q** Is the person in the video wearing a hat?
- A** Yes, the person in the video is wearing a hat.
- Q** What is in front of the person in the video?
- A** In front of the person in the video, there is a **car** covered in snow.

- Q** What happened to the person in the orange pants before he fell?
- A** The person in the orange pants was **skiing down** the snowy slope and lost control, causing him to fall.
- Q** What is under the foot of the person wearing orange pants?
- A** The person wearing orange pants is standing on a snowy hill or mountain slope. They are wearing **skis** and are skiing down the hill.

- Q** What is the color of the person's pants that pull the rope?
- A** The person pulling the rope is wearing **black** pants.
- Q** What does the person with the rope have on his hand?
- A** The person with the rope has a **glove** on his hand.

- Q** What is the person in the video doing?
- A** The person in the video is **dancing**.
- Q** Are the people in the video long hair?
- A** Yes, the people in the video have long hair.
- Q** What is behind the person in red
- A** Behind the person in red, there is a mirror.
- Q** How difficult is the dance
- A** The dance in the video appears to be relatively easy and suitable for beginners.

Fig. 7: Additional examples from Zero-shot ANET-QA [59] generated by the proposed LongVLM. Text in bold indicates the correct content.

Q What is a sitting boy playing?

A The sitting boy is playing a **guitar**.

Q What is a young boy doing?

A The young boy is **playing a guitar** in the video.

Q What is a woman peeling a papaya with?

A The woman is carving the skin off a papaya fruit using a **knife** in the video.

Q What is the woman peeling off a papaya?

A The woman is peeling off the **skin** of a papaya.

Q What is a cat knocking over blocks with?

A A cat is knocking over blocks with its **paw**.

Q What plays with a ball?

A A **cat** plays with a ball in the video.

Q What does a cat use to knock over some figurines?

A The cat uses its **paw** to knock over the figurines.

Q Who is jumping with the small bike?

A The video shows **a man** jumping with a small bike over a wooden ramp.

Q What is someone on a mini bike doing?

A In the video, a person on a mini bike is **riding** up a ramp and **jumping** over a wooden obstacle.

Q What is a person looking at during a wrestling event?

A A person is looking at the **camera** during the wrestling event.

Q What was the coach interviewed during?

A The coach is interviewed during a **wrestling match**.

Q Who was interviewed during a match?

A The video shows **a man** being interviewed during a wrestling match.

Q What is a person folding a piece of?

A The video shows a person folding a piece of **notebook paper**.

Q What is a woman cutting into small pieces?

A The woman is cutting **potatoes** into small pieces.

Q Who are fighting on the ground?

A **Two wrestlers** are fighting on the ground in the video.

Q How many men are wrestling each other?

A There are **two** men wrestling each other in the video.

Q What do two wrestlers compete in?

A The two wrestlers compete in a **wrestling match**, which involves grappling, throwing, and pinning each other down to score points.
