Abstract

Uncertainty in medical image segmentation tasks, especially inter-rater variability, arising from differences in interpretations and annotations by various experts, presents a significant challenge in achieving consistent and reliable image segmentation. This variability not only reflects the inherent complexity and subjective nature of medical image interpretation but also directly impacts the development and evaluation of automated segmentation algorithms. Accurately modeling and quantifying this variability is essential for enhancing the robustness and clinical applicability of these algorithms. We report the set-up and summarize the benchmark results of the Quantification of Uncertainties in Biomedical Image Quantification Challenge (QUBIQ), which was organized in conjunction with International Conferences on Medical Image Computing and Computer-Assisted Intervention (MICCAI) 2020 and 2021. The challenge focuses on the uncertainty quantification of medical image segmentation which considers the omnipresence of inter-rater variability in imaging datasets. The large collection of images with multi-rater annotations features various modalities such as MRI and CT; various organs such as the brain, prostate, kidney, and pancreas; and different image dimensions 2D-vs-3D. A total of 24 teams submitted different solutions to the problem, combining various baseline models, Bayesian neural networks, and ensemble model techniques. The obtained results indicate the importance of the ensemble models, as well as the need for further research to develop efficient 3D methods for uncertainty quantification methods in 3D segmentation tasks.

1. Introduction

Background. The segmentation of anatomical structures and pathologies in medical images frequently encounters substantial inter-rater variability (Lazarus et al., 2006; Watadani et al., 2013), which in turn significantly impacts downstream supervised-learning tasks and clinical decision-making processes. This variability becomes especially pronounced in the context of medical imaging, where manual annotations are often limited and costly to acquire (Kofler et al., 2023). A notable example of this challenge is the segmentation of liver lesions in CT scans, which is inherently complex even for experienced experts, due to the

June 25, 2024

variability in lesion location, contrast, and size among different patients (Joskowicz et al., 2019). It has been observed that the range of variability in manual delineations for various structures and observers is extensive, encompassing a wide spectrum of structures and pathologies, as shown in Figure 1. The involvement of only two or three observers may be inadequate to capture the full breadth of potential variability in the outlines of the targeted structures. This variability, intrinsic to the biological problem, the imaging modality, and the expertise of the annotators has not yet been adequately addressed in the design of computerized algorithms for medical image quantification (Kofler et al., 2021b).

Figure 1: Visualisation of the multi-rater segmentation masks on brain and prostate MRI scans and their derived uncertainty map.

Uncertainty quantification. Current methods for modeling uncertainty in predicted image segmentations primarily stem from general statistical model considerations, ensemble approaches involving resampling of training datasets, and aggregating multiple segmentation results, or systematic modifications to the predictive algorithm, as seen in techniques like Monte Carlo (MC) dropout. Yet, the exact delineation of segmented structures within an image inherently carries uncertainty, which is both task-specific and dependent on the dataset. Importantly, this uncertainty can be directly extrapolated from annotations made by multiple human experts. To our knowledge, there are currently no datasets available specifically for evaluating the accuracy of probabilistic model predictions against such multi-expert ground truths. Furthermore, there is a lack of consensus on which uncertainty quantification procedures yield realistic estimates and which do not. *Objective.* The primary goal of the challenge is to establish a benchmark for algorithms that generate uncertainty estimates (such as probability scores and variability regions) in medical imaging segmentation tasks. The focus is to compare these algorithmic outputs against the uncertainties ascribed by human annotators in the local delineation of structures across various biomedical imaging segmentation tasks. These tasks include, but are not limited to, the segmentation of lesions (such as brain, pancreas, or prostate tumors) and anatomical structures (like brain, kidney, prostate, and pancreas). Multiple expert annotations have been gathered for several CT and MR image datasets to quantify boundary delineation variability.

Contributions. In an effort to assess the latest methods in uncertainty quantification for medical image segmentation, we organized the Uncertainty Quantification of Biomedical Image Quantification Challenge (QUBIQ) at MICCAI-2020 and MICCAI-2021. This paper highlights three major contributions to this field. Firstly, we introduce a new, publicly available multi-rater, multi-center, multi-modality dataset that includes both 2D and 3D segmentation tasks. Secondly, we present the setup and summarize the findings of our QUBIQ uncertainty quantification benchmarks held at two grand challenges. Lastly, we review, evaluate, rank, and analyze the state-of-the-art algorithms that emerged from these benchmarks.

2. Prior Work on Approaches and Datasets

2.1. Prior work.

There is a body of literature that models uncertainty and inter-rater variability in biomedical image segmentation (Lê et al., 2016; Sabuncu et al., 2010; Kwon et al., 2020; Roy et al., 2019; Ilg et al., 2018). Some of the prior methods directly extract uncertainty estimates from trained models, either by augmenting the input image Wang et al. (2019) or by generating multiple potential segmentations using MC dropout Nair et al. (2020). Others modify techniques into ensemble methods that generate multiple parallel predictions Ilg et al. (2018) or by running multiple models in parallel Calisto & Lai-Yuen (2020). Koffer et al. (2021a) extend this further to create an ensemble of multiple approaches from the literature and create a system to alert the user if there is low segmentation agreement within the ensemble. In contrast, others explicitly model interrater uncertainty. In Probabilistic U-Net, Kohl et al. Kohl et al. (2018) use variational inference to learn a prior distribution of variability, from which they sample plausible segmentations, while Baumgartner et al. Baumgartner et al. (2019) extend this to a hierarchical model capable of modeling uncertainty at different levels of abstraction within the U-Net architecture. Monteiro et al. Monteiro et al. (2020) explicitly model uncertainty by learning a low-rank pixel-wise covariance matrix.

2.2. Publicly available datasets.

Table 1 showcases available datasets for uncertainty quantification task. Most of the datasets feature multi-rater labeling. Each focuses on a particular pathological or healthy anatomy segmentation task.

Therefore, the datasets contain either contain 2D or 3D images, CT or MRI modality. The QUBIQ challenge offers a dataset composed of multiple tasks for both image dimensions and imaging modalities.

Table 1: Overview of publicly available medical datasets for uncertainty quantification in image segmentation tasks. (to be updated)

Dataset	Modality	Target	$2\mathrm{D}$	3D	#Images	multi-rater
LIDC-IDRI (Armato III et al., 2011)	CT	Lung nodule	1	×	1,018	1
MICCAI-2012 (Litjens et al., 2012)	MRI	Prostate	1	×	48	1
ISBI-2015 (Styner et al., 2008)	MRI	MS lesion	×	1	21	1
BraTS (Mehta et al., 2020)	MRI	brain tumor	×	1	335	×
QUBIQ	CT,MRI	six tasks	1	1	**	1

3. QUBIQ challenge

3.1. QUBIQ datasets

3.1.1. Dataset creation.

For the adult glioma segmentation task, we employ three label sets. The first label set is the original label from the BraTS adult glioma segmentation challenge (Bakas et al., 2019). Additionally, we use two algorithm-based labels obtained from BraTS Toolkit (Kofler et al., 2020). To generate these, we first generate five algorithmic (Isensee et al., 2019; McKinley et al., 2019; Feng et al., 2020,?; Zhao et al., 2019; McKinley et al., 2020) glioma segmentations. Subsequently, we fuse these using basic majority voting and SIMPLE fusion (Langerak et al., 2010).

Table 2: Overview of QUBIQ datasets and the sub-tasks

Dataset	Modality	[2020, 2021]	$^{2\mathrm{D}}$	3D	#Images	#Tasks	Source (NEED to double check
Prostate segmentation	MRI	[✔,✔]	1	×	55	2	ETH Zrich
Brain growth segmentation	MRI	[✔,✔]	1	×	39	1	University of Zrich
Brain tumor segmentation	multimodal MRI	[✔,✔]	1	×	32	3	University of Pennsylvania
Kidney segmentation	CT	[✔,✔]	1	×	24	1	Technical University of Munich
Pancreas segmentation	CT	[<mark>×</mark> , √]	×	1	38	1	University of Pennsylvania
Pancreatic lesion segmentation	CT	[× , √]	×	1	21	1	University of Pennsylvania

3.2. Evaluation metrics and ranking

For the evaluation, each participant had to segment the given binary structures and predict the distribution of the experts' labels by returning one mask with continuous values between 0 and 1 which is supposed to reproduce the average segmentations of the experts.

Predictions and continuous ground truth labels are compared by thresholding the continuous labels at predefined thresholds and calculating the volumetric overlap of the resulting binary volumes using the Dice score (the continuous ground truth labels are obtained by averaging multiple experts' annotations). To this end, both the ground truth and prediction are binarized at ten probability levels (0.1, 0.2, ..., 0.8, 0.9). Dice scores for all thresholds are averaged.

The Q-Dice, a staged Dice score, is used to quantify the quality of the predicted probability map p against the ground truth y in L discrete probability levels, formulated as:

$$T_{L}(p,l) = \begin{cases} \mathbb{1}\left\{\frac{l}{L} \le p < \frac{l+1}{L}\right\}, & \text{if } 0 \le l < L-1\\ \mathbb{1}\left\{\frac{l}{L} \le p \le \frac{l+1}{L}\right\}, & \text{if } l = L-1 \end{cases}$$
(1)

Compared to the original Dice score, Q-score quantifies the uncertainty by comparing the prediction and ground truth maps at different confidence levels. Since in most cases experts agree on most parts of the annotations, the variance of different Q-score demonstrates how well the prediction modeled the uncertainty on the borders of the structure of interest.

3.3. Challenge events

The QUBIQ challenge was organized within the MICCAI conference using the Grand Challenge platform. Below in Tables 3, 4, and 5, we provide descriptions of algorithms across the two iterations of the QUBIQ challenge (QUBIQ2020 and QUBIQ2021). Fig. 2 quantitatively compares the algorithms over the two iterations of the challenge.

3.4. Results

In Tables 3 and 4, we show the leaderboard for both iterations of the challenge.

Table 3: Results QUIBIQ 2020 ordered according to the ranking score. The top 3 performing teams are highlighted in blue color. Notice that only teams participating in all tasks are considered for the overall ranking.

4. Conclusion

In this paper, we report on the results of the QUBIQ challenge (Quantification of Uncertainties in Biomedical Image Quantification Challenge), which was organized in conjunction with International Conferences on Medical Image Computing and Computer-Assisted Intervention (MICCAI). Quantifying uncertainty in medical imaging is paramount for image analysis, as inter-rater variability is omnipresent in imaging datasets. Such quantification could reduce barriers to adopting learnable algorithms into clinical practice. With the QUBIQ challenge, we aim to fill the empty space among the medical imaging challenges, which are dominated by competition in deterministic segmentation, ignoring the importance of uncertainty prediction.

Lead Author & Team Members	Method, Architecture $\&$ Modifications	Data Augmentation	Loss Function	Pre-processing	Label Processing	Ensemble strategy
Dewen Zeng ; Yukun Ding Yiyu Shi	2D U-Net with multiple loss functions (one each for individual annotators, aggregated label & multi-scale threshold).	None	Cross-entropy	z-Score normalization, resizing	Averaging	None
■ Yanwu Yang; Xutao Guo Yiwei Pan Pengcheng Shi Haiyan Lv Ting Ma	2D U-Net with one decoder per annotator and Layer Norm and skip-connections.	None	Cross-entropy & Dice loss on individual decoders A cross loss between different decoders & an auxiliary loss between average prediction & average ground truth	z-Score normalization, resizing	Averaging different labels	Deep ensemble (averaging)
Stephan Huschauer	High-Resolution Network (HRNet) with stem layers replaced by 2D wavelet scattering transformation.	None	None	Resizing to 512×512	Averaging annotations	Deep ensemble (averaging)
Xiaofeng Liu; Fangxu Xing Georges El Fakhri Jonghye Woo	Variational Inference encoding multi-annotator variability with a latent variable model.	None	Cross-entropy & L2 reconstruction loss	None	Averaging annotations	Deep ensemble (averaging)
Yucong Chen ; Guanqi He Zhitong Gao Xuming He	2D U-Net with multiple decoders, one for each annotator.	Random cropping (training), sliding window (inference)	None	None	None	Deep ensemble (averaging)
Mohammad Eslami ; Farzin Soleymani Anirudh Ashok Bernd Bischl Mina Rezaei	Uncertainty-aware progressive GAN. Encoder modeled using 2D U-Net & Patch Discriminators from Pix2Pix	None	Multi-stage GAN loss and Soft Dice loss	Intensity values noramlized between 0-255	Averaging	None
Timothy Sum Hon Mun; Simon J Doran Paul Huang Christina Messiou Matthew D Blackledge	2D U-Net with Monte Carlo dropout.	None	Dice loss	None	None	None

Table 7: Details of the participating teams methods in QUBIQ-Challenge-2021 (part 2).
