## Abstract

We explore and improve the capabilities of LLMs to generate data for grammatical error correction (GEC). When merely producing parallel sentences, their patterns are too simplistic to be valuable as a corpus. To address this issue, we propose an automated framework that includes a Subject Selector, Grammar Selector, Prompt Manager, and Evaluator. Additionally, we introduce a new dataset for GEC tasks, named **ChatLang-8**, which encompasses eight types of subject nouns and 23 types of grammar. It consists of 1 million pairs featuring human-like grammatical errors. Our experiments reveal that ChatLang-8 exhibits a more uniform pattern composition compared to existing GEC datasets. Furthermore, we observe improved model performance when using ChatLang-8 instead of existing GEC datasets. The experimental results suggest that our framework and ChatLang-8 are valuable resources for enhancing ChatGPT’s data generation capabilities.

## 1 Introduction

With the advent of large language models (LLM) (OpenAI, 2023a,c,b), fundamental paradigm shift is underway and many subfields of NLP such as machine translation (Jiao et al., 2023), summarization (Yang et al., 2023), question answering (Omar et al., 2023), and grammatical error correction (Wu et al., 2023; Fang et al., 2023) are being validated by LLM (Bang et al., 2023). However, there still lacks investigations into the ability of LLM to correct grammatical errors in text. For instance, ChatGPT gets much lower automatic evaluation scores (Wu et al., 2023) than GECToR (Omelianchuk et al., 2020), based on pretrained RoBERTa model, and GEC product (Grammarly, 2023). ChatGPT also suffers from *Overcorrection* problem (Fang et al., 2023) and shows much lower performance than TagGEC (Stahlberg and Kumar, 2021), T5 large,

and T5 xxl (Rothe et al., 2021), despite its cutting-edge prompting techniques.

In order to solve these problems, it is indispensable to improve the performance of existing methods or leverage a hybrid model consisting of a GEC model and LLM, using high-quality training datasets. However, these approaches require a lot of manually annotated sentence pairs and these pairs are very expensive and even hard to obtain. In addition, LLM’s data generation capabilities are not sufficiently corroborated and reinforced yet.

**Contributions.** In this paper, (i) we investigate LLM’s ability to generate synthetic data, (ii) propose an automatic framework to bolster up the quality of generated data, and (iii) leverage a new GEC dataset, ChatLang-8, which is composed of 1M pairs with a distribution of human-like grammat-

ical errors. We find that ChatLang-8 has a more uniform pattern composition than the existing GEC datasets. We also observe that the model performed better when trained with ChatLang-8 than with the existing GEC dataset with the same corpus size. To the best of our knowledge, we are the first to introduce a GEC dataset using LLM and to demonstrate it outperforms previous human-generated corpora.

## 2 ChatLang-8

The foremost goal is to generate data containing human-like grammatical mistakes. Thus, we aim to create parallel sentence pairs with a distribution of human-like grammatical errors, not unrealistic pairs (Grundkiewicz and Junczys-Dowmunt, 2014). When generating pairs, one of the most intuitive ways is to control all elements of the statement. However, because of productivity of language (O’Donnell et al., 2011), sentences can be infinitely long with recursive rules. It is impossible to control all elements of the generated pairs, and even this approach rather deteriorates the quality of data. Therefore, we first hypothesize that the main factors determining the quality of pairs are the subject types and grammatical error types, and then we diversify them based on our framework.

### 2.1 Subject Selector

One naive approach is to design the prompt to generate pairs without considering the subject element. However, as shown in Table 1, when simply generating parallel sentences, the type of subject of the sentence becomes too limited. To mitigate this risk, we propose *Subject Selector* (SS), a novel

algorithm for diversifying subject  $S$  of parallel sentences. First, we predefine the type of subject  $S_k$  to be created<sup>1</sup>. Then Subject Selector randomly choose a type of subject  $S_k$  among the predefined noun types and generate subject candidates as large as the window size. For example, if the noun type selected by Subject Selector is *proper noun* and the window size is 30, 30 proper nouns are created. Then, one of the candidates is randomly determine as a subject of a sentence.

### 2.2 Grammar Selector

Similar to the problem in Section 2.1, a vanilla prompt to generate pairs of wrong and correct sentences produces an extremely constrained set of sentences. Table 2 shows that the method just specifying the grammar type also could not ameliorate this problem. For instance, when generating data related to *Conjunction*, most of the outputs consist of *And*, and *But*. In this paper, we propose *Grammar Selector* (GS) to consider various grammar errors  $G$  and thereby improve the quality of generated data. We take into account the same grammatical error categories  $G_l$  in (Bryant et al., 2017, 2019). Unlike Subject Selector in Section 2.1, Grammar Selector first divides the grammar errors into two types: Errors that require diversification of grammar types and those that do not. For example, *Word Order* (WO) and *Spelling* (SPELL) don’t need to consider patterns as large as the window size: We can get good results just by instructing the LLM to create representative of real human errors.

### 2.3 Prompt Manager

Given a subject and grammatical error generated from Section 2.1 and Section 2.2 respectively, *Prompt Manager* combines them into one prompt. To improve production stability, we incorporate the CoT technique (Wei et al., 2022) into the Prompt Manager. To circumvent unnecessary errors, Prompt Manager matches a subject of wrong sentence to a subject of right sentence. Prompt Manager maintains the rest of the elements are the same, except for the grammatical error of parallel sentences.

### 2.4 Evaluator

Although generated pairs can be multifarious by exploiting Subject Selector, Grammar Selector, and

<sup>1</sup>Predefined types: Common Noun, Proper Noun, Collective Noun, Compound Noun, Concrete Noun, Abstract Noun, Countable Noun, and Uncountable Noun.

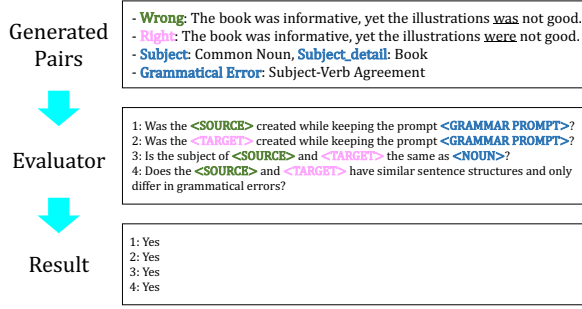

Figure 1: The pipeline of Evaluator.

Prompt Manager, due to uniform randomness of our method to encourage diversity, data that violates prompt instructions were generated occasionally. For example, a prompt *subject: Concrete Noun (car), and grammar\_type: Verb (swim)* created pairs "Wrong: *The car swims to the shore.*", "Right: *The car drives to the shore.*". They are the result of breaking the instruction to use the swim verb correctly (i.e., sentences related to verb tense or active/passive voice errors should have been output, not a semantic error). To alleviate this risk, we propose *Evaluator*, a simple LLM-based evaluator using four criteria  $C$  (Figure 1). Evaluator  $\mathcal{E}$  evaluates itself for compliance with the data creation process and employs a unanimous vote: If even a single criterion  $C_i$  is not met, the generated result is discarded:

$$\mathcal{E}(D) = \begin{cases} 1, & \text{if } C_1 \wedge C_2 \wedge C_3 \wedge C_4 \\ 0, & \text{otherwise} \end{cases} \quad (1)$$

## 2.5 Dataset Details

Our implementation utilizes GPT-3.5 Turbo. We gathered approximately 1M pairs that cover eight subject type and 23 grammar type. Table 3 shows statistics of *ChatLang-8* (ours), FCE (Yanakoudakis et al., 2011), Lang-8 (Mizumoto et al., 2012; Tajiri et al., 2012), NUCLE (Dahlmeier et al., 2013) and W&I+LOCNESS (Bryant et al., 2019). Note that we leverage ChatLang-8 that has a corpus size similar to Lang-8, one of the largest GEC corpora, and much larger than the other corpora.

## 3 Experiments

### 3.1 Statistical Analysis

Note that numerous studies show that the imbalance of a dataset causes performance degradation (Huang et al., 2021; Lin et al., 2023; Li and Shi, 2021). In order to demonstrate whether the dataset is created evenly, we conduct statistical analysis by

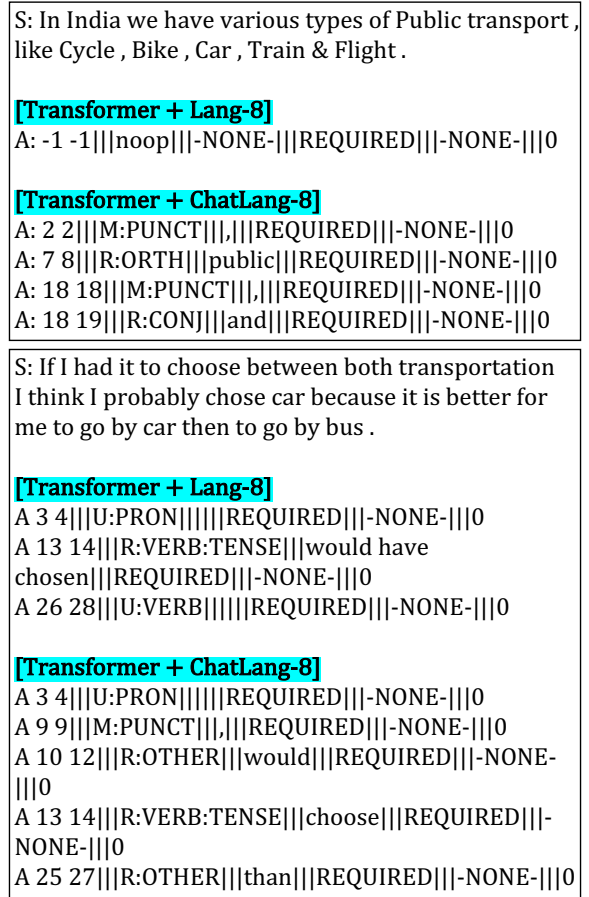

Figure 2: Comparison of  $M^2$  outputs of GEC models, trained on Lang-8 and ChatLang-8 respectively.

comparing ChatLang-8 with existing datasets. Figure 3 shows a subject distribution of ChatLang-8. We observe that the distribution of subject types in ChatLang-8 is evenly distributed. It suggests that the Subject Selector and evaluator affect data quality improvement even though the evaluator abandons all unsuitable data. In Figure 4 and Table 5, we find that the grammar types of ChatLang-8 are most evenly distributed while the other corpora have highly unbalanced grammar labels. For example, W&I+LOCNESS dataset has 10.7% (averaged) of Determiner (DET) errors, and 17.75% of Punctuation (PUNCT) errors, whereas 0.6133% of Conjunction (CONJ) and 0.21% of Adjective Form (ADJ:FORM). Existing datasets have a very small proportion of important grammatical patterns, which can cause performance degradation during model training. In addition, since ChatLang-8 excluded OTHER and UNK labels when generating data, while the other corpora have a great proportion of UNK label (e.g., NUCLE: 25.65%) and OTHER label (e.g., NUCLE: 2.57%), it is easier to handle dataset and to predict the model outputs.

	ChatLang-8	FCE	Lang-8	NUCLE	W&I+LOCNESS
Sentences	1,016,588	33,236	1,037,561	57,151	43,169

Table 3: ChatLang-8, FCE, Lang-8, NUCLE, and W&I+LOCNESS dataset statistics.

	ChatLang-8			Lang-8		
	P	R	F <sub>0.5</sub>	P	R	F <sub>0.5</sub>

GMEG-wiki						
Transformer	46.56	34.33	43.46	41.44	11.38	27.11
BART	49.09	41.77	47.42	23.54	15.68	21.39

Table 4: Evaluation results on English CoNLL-2014, BEA-2019, and GMEG-wiki.

### 3.2 Quantitative Results

To investigate whether ChatLang-8 has value as a dataset, we train a vanilla Transformer (Vaswani et al., 2017) and BART (Lewis et al., 2020), much larger model, on both ChatLang-8 and Lang-8 (Mizumoto et al., 2012; Tajiri et al., 2012). Note that for the fairness of the experiment, we choose Lang-8, which has a similar dataset structure and corpus size, and which effectively improve performance (Lichtarge et al., 2019, 2020; Flachs et al., 2021). In addition, though there is previous attempt to improve the Lang-8 (Flachs et al., 2021), it reports only five error types on BEA test while we considers 25 error types and three benchmarks. Thus, we employ Lang-8 to the experiments, instead of cLang-8. We evaluate performance on three popular GEC benchmarks: CoNLL-2014 (Ng et al., 2014), BEA-2019 (Bryant et al., 2019), and GMEG-wiki (Napoles et al., 2019). As evaluation metrics, we use M<sup>2</sup> scorer (Dahlmeier and Ng, 2012) for CoNLL-2014, and ERRANT (Bryant et al., 2017) for BEA-2019 and GMEG-wiki. Table 4 shows that GEC models trained on ChatLang-8 can surpass its counterparts which are trained on Lang-8 corpus, by a large margin in both recall (R) and F<sub>0.5</sub>. It represents that the GEC system trained with ChatLang-8 can simultaneously detect multiple types grammatical errors in a sentence and correct them, while system trained with Lang-8 can't.

Figure 3: Subject distribution of ChatLang-8.

Figure 4: Distributions of the ChatLang-8 and the other datasets with respect to 25 grammatical errors.

Simply a high R and a low F<sub>0.5</sub> indicate overcorrection. We observe that transformer learned with Lang-8 shows higher precision (P) than its counterpart on CoNLL-2014 and BEA-2019 benchmark evaluations, entailing much lower F<sub>0.5</sub>. This means that it corrects only very obvious grammatical errors and leaves the rest uncorrected. We also find that leveraging a high-quality GEC corpus is overarching problem, as merely enlarging the model does not always ensure improved performance.

### 3.3 Qualitative Results

Figure 2 shows an example and its corresponding M<sup>2</sup> outputs, which qualitatively demonstrate the effect of dataset used for training, as shown in Section 3.2. We observe that the learned model using ChatLang-8 can detect and correct multiple errors including punctuation (PUNCT), orthography (ORTH), and conjunction (CONJ) while its opponent can not find any errors. Indeed, the output of model learned with ChatLang-8 is *In India, we have various types of public transport, like Cycle, Bike, Car, Train, and Flight*. Results in Figure 2 demonstrates that ChatLang-8 has the error distribution shown in Table 5 very well, and thereby efficiently helps the learning of the GEC system.

## 4 Conclusion

We propose a framework with a hypothesis that determining the quality of dataset is the types of subject and grammatical error. We introduce that ChatLang-8, a high-quality dataset for GEC task that is composed of 1M pairs and covers eight subject type and 23 grammar type. We are the first to build a GEC dataset using ChatGPT and verify it outperforms existing corpora. We hope that our method and dataset can help researchers make a better-informed decision about their research.

## Limitations

**Factuality and Morality.** Though ChatLang-8 effectively can reflect a distribution of human-like grammatical errors in Figure 5 and guide a GEC model to perform well, due to uniform randomness of our method to encourage diversity, sometimes generated pairs have information that is literally not true. For instance, in Section 2.1, Subject Selector, of course, can generate celebrity (e.g., *Michael Jackson* or *Taylor Swift*), or even company name (e.g., *Google* or *Amazon*). By combining the selected subject and grammatical information, sentences that are not true can be generated as follows:

*Michael Jackson was known for his music career, in order that he could be more successful, he decided to try his hand at acting.*

*Taylor Swift is really good at using a computer.*

In addition, the generated sentences may contain biased information such as subjective opinions:

*Barack Obama's speeches were always inspiring the crowds.*

*Google is the best search engine in the world.*

Note that, although most of pairs are normal and fabricated information is found in some generated examples, this factuality problem must be resolved.

On the other hand, we also observed whether ChatLang-8 has a problem with moral deviations. Fortunately, no morality issue was found in most of the pairs constituting ChatLang-8:

*The equality between races, genders, and sexual orientations is important.*

*The importance of maintaining equality among all genders is evident in society.*

However, we found one sentence and removed from ChatLang-8:

*The equality of the sexes is not a big issue.*

These observations suggest that semantic information as well as grammatical information of the generated sentence should be added to the evaluation criteria of our Evaluator.

**Time and Cost.** As mentioned in Section 2.5, Our implementation utilizes gpt3.5-turbo version of ChatGPT. It took about two weeks to gather ChatLang-8. To collect 1M pairs dataset, we spent about 1.1K *dollars*. However, It should be noted that the cost was higher than expected because some pairs are discarded by Evaluator. Evaluator disposed of about 0.7M sentences out of a total of 1.7M generated sentences. We consider that though it is much more efficient than having annotators create the dataset, this a great waste of time and resources. Also, there is a trade-off in our framework: The larger window size, the more diverse and high-quality dataset can be obtained, but the time and cost to create dataset increases accordingly.

**Discussion and Future Works.** In this paper, we strived to validate the ability of LLM to generate datasets. Of course, efficient dataset acquisition and model training are important challenges in the GEC task, but in fact, we also wanted to know what information is important and should be considered in Natural language generation in order to improve quality of outputs generated by LLM. We hope that this study and its results will be helpful to researchers who have the same concerns as us.

Our direction of future work is threefold:

1. We will establish new criteria for factuality and morality, and improve the evaluator through methods such as giving penalties for the generated results that violate the criteria.
2. We also will devise methods such as soft alignment to minimize the amount of data discarded by Evaluator to prevent resource waste.
3. Though we conducted an in-depth analysis through statistical, quantitative, and qualitative methods, we relied on LLM for data collection, leaving human evaluation behind. We will experiment with more off-the-shelf baselines by increasing the size of the corpus, and human evaluation will also be conducted on the generated results.

## Ethics Statement

There are no ethical issues in this study. The data was collected through legitimate methods. Moreover, the experimental results were obtained through an objective comparison. The authors confirm that the research was conducted in accordance with the relevant ethical guidelines and principles.

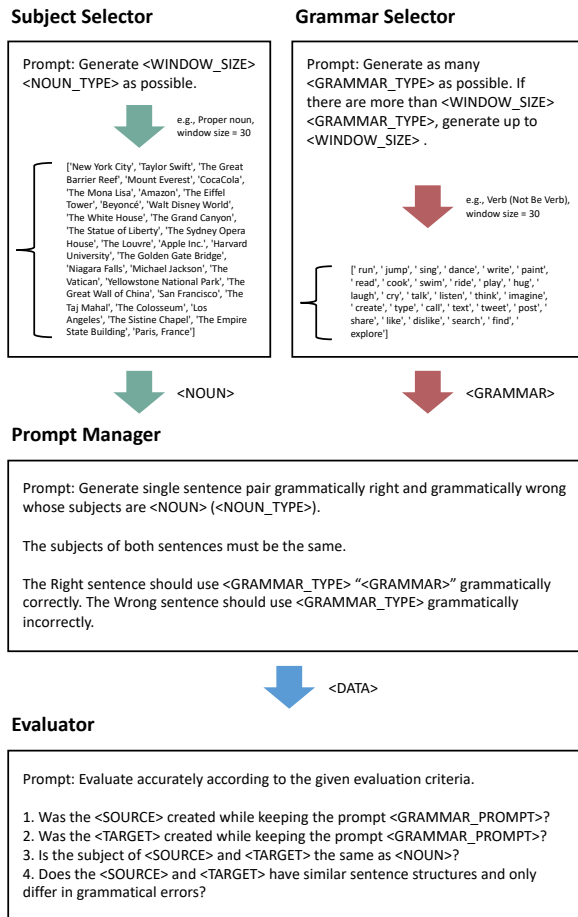

Figure 5: Schematic depiction of overall architecture

## A Statistical Analysis: Error Type Distributions

Table 5 shows the ERRANT error type distributions of ChatLang-8 and The Other Corpora. We find that ChatLang-8 are most evenly distributed while the other corpora have highly unbalanced grammar labels.

## B Architecture

As shown in Figure 5, our framework consists of Subject Selector, Grammar Selector, Prompt Manager, and Evaluator. Subject Selector and Grammar Selector ensure the diversity of the generated data, Prompt Manager maintains the format of the generated data, and Evaluator manages the quality of the generated data.

	ChatLang-8	FCE	Lang-8	NUCLE	W&I+LOCNESS (Train)	W&I+LOCNESS (Dev)	W&I+LOCNESS (Test)
