Abstract

Recently, Large Language Models (LLMs) with their strong task-handling capabilities have shown remarkable advancements across a spectrum of fields, moving beyond natural language understanding. However, their proficiency within the chemistry domain remains restricted, especially in solving professional moleculerelated tasks. This challenge is attributed to their inherent limitations in comprehending molecules using only common textual representations, i.e., SMILES strings. In this study, we seek to enhance the ability of LLMs to comprehend molecules by designing and equipping them with a multi-modal external module, namely MolX. In particular, instead of directly using a SMILES string to represent a molecule, we utilize specific encoders to extract fine-grained features from both SMILES string and 2D molecular graph representations for feeding into an LLM. Moreover, a human-defined molecular fingerprint is incorporated to leverage its embedded domain knowledge. Then, to establish an alignment between MolX and the LLM's textual input space, the whole model in which the LLM is frozen, is pre-trained with a versatile strategy including a diverse set of tasks. Extensive experimental evaluations demonstrate that our proposed method only introduces a small number of trainable parameters while outperforming baselines on various downstream molecule-related tasks ranging from molecule-to-text translation to retrosynthesis, with and without fine-tuning the LLM.

1 Introduction

In the last few years, Large Language Models (LLMs) have demonstrated impressive performances across a wide array of fields. Extending beyond the boundaries of natural language understanding, LLMs have facilitated various scientific disciplines [1]. Without exception, with a high-level understanding of chemical concepts obtained from the wealth of chemical literature in pre-training data, LLMs have recently been investigated for augmenting research in the chemistry domain as an alternative approach to the traditional supervised learning approach [2, 3].

Although owning strong task-handling capabilities, LLMs still struggle with the chemistry domain, reflected by their limited performances on a range of professional molecule-related tasks [4, 5]. For instance, the capable LLM, Llama-2 [6], performs unsatisfactorily on the molecule-to-text translation tasks such as molecule description generation and IUPAC name generation, being more than twice as inferior compared to the supervised learning models. Additionally, such LLM fails to predict molecule activity for high-level properties even using expert-designed prompts. One potential cause of this challenge has been figured out that most existing LLMs represent molecules only by their common textual representations, i.e., SMILES strings [7], and process them in a paradigm similar to

Figure 1: Current paradigm of using an LLM for molecule-related tasks and its issues.

texts [5, 8], as illustrated in Figure 1a. While convenient, several issues make it challenging for LLMs to comprehend molecules by solely interpreting SMILES strings. Firstly, LLMs lack an inherent understanding of SMILES strings and blindly treat them as sequences of separate characters relying on their byte-pair encoding tokenizers [9], which break SMILES strings into smaller pieces in ways that do not represent chemical laws behind these strings. Furthermore, without an understanding of chemical laws, it is difficult for LLMs to capture molecules' topological structures from SMILES strings due to potential inaccuracies such as incorrect transcription of complex aromatic systems or the absence of hydrogens and other atoms [10], as shown in Figure 1c.

In light of these issues, there have been some early attempts to enhance LLMs for solving moleculerelated tasks. For instance, Su et al. [11] attempt to employ a GNN-based graph encoder to extract features from the molecule's 2D molecular graph and directly input such features into the LLM to perform molecule-to-text translation tasks. Developed from that idea, Li et al. [8] input features extracted from the 2D or 3D molecular graph into the LLM through an intermediate projector, which is previously aligned with the LLM's textual input space by a pre-training stage. Although bridging the gap between the 2D or 3D molecular graph and the LLMs, previous works still ineffectively make use of another essential representation, i.e., SMILES string, as well as human-defined molecular descriptors, which have their own advantages over 2D or 3D molecular graph [12, 13], hence, might lead to suboptimal performances. Furthermore, existing methods are only applied to a limited number of molecule-related tasks, omitting other crucial tasks such as molecule property prediction, molecule optimization, or retrosynthesis.

In this study, we introduce a novel framework for enhancing LLMs to extensively comprehend molecules from multiple representations, thus, improving their performances on various moleculerelated tasks. Our proposed framework consists of two main components which are a multi-modal external module, namely MolX, equipped with the LLMs, and a versatile pre-training strategy for aligning MolX into the LLMs' textual input space. To be more precise, we first utilize a pre-trained BERT-like [14] SMILES encoder to extract features from the SMILES string instead of directly using it to represent a molecule. Because of its initial pre-training stage, the SMILES encoder has been enabled to work with its tokenizer to capture long-range dependencies identified in the SMILES string. Besides that, we simultaneously utilize a pre-trained GNN-based graph encoder to extract features from the molecule's 2D molecular graph, capturing its topological structures. To accomplish MolX, in addition to features extracted from raw representations, i.e., SMILES string and 2D molecular graph, a human-defined molecular fingerprint [15] containing abundant domain knowledge is further incorporated in a weighted scheme. Eventually, the whole model, in which the LLM is frozen, undergoes an instruction-based pre-training strategy with a diverse set of tasks, providing the model with comprehensive information of the molecules. This process encourages an alignment between MolX and the LLM's textual input space. Figure 2 provides an overview of our proposed method.

Our experimental results show that the proposed method outperforms baselines by a substantial margin on various downstream molecule-related tasks in two different model configurations, with and without fine-tuning the LLM. It is worth noting that MolX can flexibly act as a plug-in module to the LLM for enhancing the performances on molecule-related tasks while fully preserving its general-purpose usage on other domains.

To summarize, our main contributions are outlined as follows:

- We introduce a novel framework enhancing LLMs to comprehend molecules, thus, improving their performances on various molecule-related tasks. The LLMs are equipped with a multi-modal external module, MolX, to extract features from both SMILES string and 2D molecular graph representations, as well as leverage a human-defined molecular fingerprint.
- A versatile instruction-based pre-training strategy including a diverse set of tasks, is applied to establish an alignment between MolX and the LLMs' textual input space. This process parallelly advances the models' ability of molecular understanding, as well as instruction following.
- Extensive experimental evaluations demonstrate that our proposed method outperforms baselines by a substantial margin on a diverse range of downstream molecule-related tasks in two different model configurations, with and without fine-tuning the LLM.

2 Related Work

In this section, we provide a review of the literature related to molecular learning via language modeling and leveraging LLMs for solving molecule-related tasks.

2.1 Molecular Learning via Language Modeling

Molecules form the basis of chemistry and molecular learning has been a long-standing problem in cheminformatics [16]. Traditionally, molecular fingerprints serve as one of the most important descriptors for molecules. Typical examples include Morgan fingerprint [15] and ECFP [17], which encode a molecule into a fixed bit string with a hash function, where each bit indicates whether a certain substructure is present in the molecule. In the last decade, with the rapid development of language modeling, another representation has become more widely used due to its textual nature, i.e., SMILES strings [7]. Studying the molecule property prediction task, Wang et al. [18] introduce SMILES-BERT, a BERT-like model [14] and is pre-trained with the masked language modeling mechanism on a large-scale set of unlabeled molecules. Following that, while Wang et al. [19] propose using chemical reactions to assist the pre-training, Ahmad et al. [20] on the other hand propose using auxiliary tasks with more domain relevance for chemistry such as predicting computed properties of molecules, supporting masked language modeling. Irwin et al. [21] investigate the challenging sequence-to-sequence tasks such as retrosynthesis, and then introduce Chemformer which is built based on the BART model [22]. Notably, Chemformer applies an enumeration technique [23] to further augment masked language modeling. Parallelly, Edwards et al. [24] are interested in molecule-to-text translation tasks and vice versa. To solve those tasks, MoIT5 is proposed, which is built based on the T5 model [25] and is pre-trained with the multi-lingual masked language modeling mechanism, considering SMILES strings as a conventional language. In recent years, with their rising advancements across a wide array of fields, including chemistry [2, 3], LLMs have emerged as an evolution of the traditional language modeling approach for molecular learning.

2.2 LLMs for Molecule-Related Tasks

Due to their demonstrated strong capabilities, several studies have attempted to evaluate LLMs regarding the knowledge of chemistry. Castro et al. [2] have early explored how well ChatGPT understands chemistry by posing five student-level tasks in different subareas of chemistry and noticed moderate performances. Zhao et al. [4] investigate the molecule property prediction task and discover that LLMs tend to rely on memorized information for making predictions, which may significantly limit their applications in practice. After that, Guo et al. [5] conduct a more comprehensive evaluation by benchmarking various existing LLMs on 8 practical molecule-related tasks. Empirical results reveal that capable LLMs such as Llama-2 [6] typically fail to perform challenging tasks of molecule-to-text translation or predict molecule activity for high-level properties even using expert-designed prompts. A potential reason behind this challenge has been identified that most existing LLMs have a limited understanding of. In response to such findings, Su et al. [11] propose MoMu to enhance LLMs by applying a GNN-based graph encoder to extract features from the molecule's 2D molecular graph and input such features into the LLM for performing molecule-to-text translation tasks. Following that, Li et al. [8] proposed 2D and 3D MoLM to leverage an intermediate projector

for feeding features extracted from the 2D or 3D molecular graph into the LLM, which is previously aligned with the LLM's textual input space by a pre-training stage. Although showing improvements by bridging the gap between the 2D or 3D molecular graph and the LLMs, the importance of another essential representation, i.e., SMILES string, as well as human-defined molecular descriptors has been neglected in previous works. Additionally, existing methods are only applied to a limited set of molecule-related tasks, how well the enhanced LLMs can perform other crucial tasks such as molecule property prediction, molecule optimization, or retrosynthesis is underexplored.

3 Methodology

We propose a framework enhancing LLMs to comprehend molecules from multiple representations, consisting of two main components, a multi-modal external module and a novel pre-training strategy. Here we delve into the details of these components.

3.1 Model Architecture

The proposed MolX, which is equipped with a base LLM, consists of two key designs: 1) Trainable encoders, focusing on encoding raw representations of a molecule, i.e., SMILES string and 2D molecular graph; 2) A weighted scheme to further incorporate a human-defined molecular fingerprint.

Trainable Encoders. First of all, we formulate a molecule as m and consider m_S and m_G to depict its SMILES string and 2D molecular graph, respectively. While m_S is simply a sequence of ASCII characters, m_G is further considered as $m_G = \{\mathcal{V}, \mathcal{E}\}$, where each node in \mathcal{V} indicates an atom and each edge in \mathcal{E} indicates a chemical bond. Additionally, $\mathbf{X} \in \mathbb{R}^{|\mathcal{V}| \times N}$ is the attribute matrix of m_G where $x_n = \mathbf{X}[n, :]^T$ is the N-dimensional attribute vector of the node $v_n \in \mathcal{V}$.

To encode the SMILES string m_S , we adopt a pre-trained BERT-like [14] SMILES encoder, Chem-BERTa [20], which is constructed by stacking multiple Transformer layers. Notably, ChemBERTa, denoted as E_S is pre-trained on a large-scale set of unlabeled molecules with the masked language modeling mechanism, enabling it to capture long-range dependencies identified in the SMILES string. In more detail, an average is taken over outputs of E_S to obtain an embedding vector for m_S , which is then projected to the hidden dimension d of the base LLM by a multi-layer perceptron f_S :

$$e_S = f_S(\operatorname{Average}(\{t_i, t_i \in E_S(m_S)\})) \in \mathbb{R}^d.$$
(1)

To encode the 2D molecular graph m_G , we adopt a pre-trained GNN-based graph encoder, Chem-GraphCL [26], which is constructed based on an emerging powerful message-passing GNN model, Graph Isomorphism Network [27]. Notably, ChemGraphCL, denoted as E_G is pre-trained on a large-scale set of unlabeled molecules with a contrastive learning strategy [28], thus, being able to capture the topological structures of the molecule from its 2D molecular graph. In more detail, started from initial x_n , after multiple layers of message propagation, E_G produces an updated attribute vector h_n for the node $v_n \in \mathcal{V}$. Then an average is taken over all node-level attribute vectors to obtain an embedding vector for m_G , which is then projected to the hidden dimension d of the base LLM by a multi-layer perceptron f_G :

$$e_G = f_G(\operatorname{Average}(\{h_n, h_n \in E_G(m_G)\})) \in \mathbb{R}^d.$$
⁽²⁾

After that, e_S and e_G are averaged to form a unified embedding vector $e \in \mathbb{R}^d$.

Molecular Fingerprint Incorporation. Human-defined molecular fingerprints are one of the most important descriptors of molecules due to containing abundant domain knowledge. Nevertheless, molecular fingerprints are typically disregarded by using deep learning models despite that they have been shown to be extremely valuable for specific tasks such as molecule property prediction [29]. Therefore, here we seek to bring their benefits by incorporating the popular Morgan fingerprint [15] into the unified embedding vector e from trainable encoders described above. Specifically, a computational tool RDKit [30] is used to compute the Morgan fingerprint with a radius of 2 from the molecule m, which is then also projected to the hidden dimension d of the base LLM by a multi-layer perceptron f_F . The incorporation scheme works as follows:

$$e = w_e \cdot e + w_{e_F} \cdot e_F, \qquad e_F = f_F(\text{MorganFP}(m)), \tag{3}$$

where w_e and w_{e_F} are trainable parameters introduced for providing the model sufficient flexibility to incorporate the Morgan fingerprint into e.

3.2 Pre-training Strategy

There is a noticeable misalignment in the latent spaces of MolX and the base LLM where the former encodes molecules while the latter has a textual input space, hence, a cross-space alignment stage is needed. To this end, after feeding the embedding vector from MolX into the LLM as a soft token, we propose to pre-train the MolX-enhanced LLM with a diverse set of tasks including a molecule-to-text translation, i.e., molecule description generation, accompanied by a couple of auxiliary tasks. It is worth noting that while MolX is trainable, the base LLM is kept frozen during pre-training. This setting maintains the LLM's inherent generalizability, forcing MolX to produce embedding vectors that are well-suited in the LLM's textual input space, as well as can be effectively understood by the LLM to generate accurate answers. Besides, this allows the LLM to function normally on general domains by flexibly using MolX as a plug-in module for handling molecule-related tasks.

A Multi-Task Dataset. To conduct the pre-training stage, we first utilize the pre-train subset of the PubChem dataset [8], a dataset that contains approximately 300k molecule-description pairs collected from the PubChem database ¹ for the molecule description generation task. By using this task as an objective, MolX is encouraged to produce meaningful embedding vectors, so that the LLM can caption molecules with their substructures and properties accurately, as illustrated in Figure 2. Although a valuable dataset that collected from a reliable source, the descriptions in the dataset retain several limitations that might hinder the model's ability of molecular understanding. For instance, the average number of words in the dataset's descriptions is roughly 20, which is not capacity sufficient to describe a molecule. Additionally, a certain amount of the dataset's description generation objective, we design a set of auxiliary tasks including predicting the basic chemical and physical properties of molecules such as the number of heavy atoms or the molecular weight. We select a set of 10 low-level properties that are available for easy collection from PubChem and present comprehensive information of the molecules. Furthermore, leveraging the fact that a molecule can be represented by

multiple valid SMILES strings [23], we utilize one more special auxiliary task which is canonicalizing the molecule's SMILES string. This objective enhances the model's understanding of chemical laws behind SMILES strings. Notably, to keep the pre-training stage controllable, a subset of 10% of the dataset is used for each auxiliary task. Examples of proposed auxiliary tasks are shown in Figure 3 and details are provided in Appendix A.

Instruction-Based Pre-training. Despite demonstrated strong capabilities, LLMs tend to exhibit hallucinations in the domain of chemistry [5], generating unexpected answers regarding a molecule. Hence, we enrich our pre-training dataset by designing an informative instruction for each task, then employ instruction-based pre-training [31, 32], enhancing the model's ability of instruction following. Formally, we first define p(.) as the textual distribution parameterized by the base LLM. The base LLM is decomposed into two subparts, the text embedder F_{emb} and self-attention layers F_{att} , in which the text embedder F_{emb} converts an instruction of a task into a list of T tokens $Z = [z_1, z_2, ..., z_T]$. Given a molecule m and its label y for the given task, after the embedding vector e is extracted from MolX, the auto-regressive loss for pre-training is defined as:

$$= -\log p(y|F_{att}(z_1, z_2, .., z_T, e))$$
(4)

$$= -\sum_{l=1}^{L} \log p(y_l | F_{att}(z_1, z_2, ..., z_T, e), y_1, ..., y_{l-1}),$$
(5)

where L is the length of the label y for the given task.

4 Experiment

In this section, we conduct an extensive set of experiments on various downstream molecule-related tasks including molecule-to-text translation, molecule property prediction, molecule optimization, and retrosynthesis, to demonstrate the effectiveness of our proposed method. Throughout experiments, we utilize a capable open-sourced Llama-2 model [6] with 7B parameters as our base LLM to leverage its powerful text generation capability and internal chemistry knowledge. We consider two different model configurations for the evaluation: I) Inference-only: The model is frozen after pre-training for direct question answering on downstream tasks, evaluating the model's generalizability without fine-tuning; II) LoRA fine-tuning: The model is fine-tuned on downstream tasks using a parameter-efficient technique, LoRA [33], verifying the model's adaptability in scenarios where downstream data are available. In addition to comparing with discussed previous works including MoMu [11], as well as 2D and 3D MoLM [8], we also compare with competitive supervised learning models in each task. The details of experimental settings and hyper-parameters are provided in Appendix B.

4.1 Molecule-to-Text Translation

We first consider the molecule-to-text translation tasks, i.e., molecule description generation and IUPAC name generation. These kinds of tasks reflect the general molecular understanding of the model and have crucial applications in practice, enabling humans to gain an overview of a molecule. We conduct experiments on the downstream subset of the PubChem dataset [8], which has 15k high-quality molecule-description pairs and is separate from the pre-train one. Following [24, 34], we adopt BLEU-2, BLEU-4, ROUGE-1, ROUGE-2, ROUGE-L, and METEOR as evaluation metrics.

Table 2: Experimental results for molecule property prediction on the MoleculeNet dataset.

Figure 4: An example of molecule property prediction with Inference-only.

Answer: -2.3479

Table 1 presents experimental results for these tasks across 6 different metrics. Firstly, based on the Inference-only results, we observe the proposed framework significantly enhances the base LLM for direct question answering on both tasks without fine-tuning. In the scenario of LoRA fine-tuning, the MolX-enhanced LLM demonstrates superior performances compared to baselines across the board with the highest scores on all metrics, especially for ROUGE-based and METEOR metrics which might be attributed to the proposed versatile pre-training strategy that provides the model with comprehensive information of the molecules. Generally, due to its powerful text generation capability, the approach of fine-tuning the LLM shows better performances than competitive supervised learning models like MoIT5 [24] and its MoMu-enhanced one [11]. Additionally, the LoRA fine-tuning results also reveal that leveraging the 3D molecular graph seems to be valuable for the molecule-to-text translation tasks, which calls for further exploration.

4.2 Molecule Property Prediction

GT : -2.44

Besides the overall understanding, we further assess the model's perception of molecular properties by conducting experiments on molecule property prediction, a fundamental task in chemistry. Molecule property prediction involves approximating quantitative attributes such as solubility or determining the activity for high-level assays such as toxicity of a molecule, holding important potential for drug discovery. Here we employ the popular MoleculeNet dataset [35] with 8 different subsets including ESOL, FreeSolv, Lipophilicity, MUV, HIV, BACE, BBBP, and Tox21. As evaluation metrics, RMSE is used for regression subsets and Accuracy and F1-score are used for classification ones. Figure 4 illustrates an example of this task and more examples can be found in Appendix C.

Experimental results in Table 2 show that MolX improves performances of the base LLM in both model configurations, especially for Inference-only results, MolX remarkably narrows approximation errors. Additionally, MolX enhances the model's ability of instruction following, generating expected answers without LLMs's favorite phrases. This advantage is highly important for answer cleaning in cases where LLMs are required to reply with a numerical value. In addition to LoRA fine-tuned models, we consider ChemGraphCL [26] which serves as the GNN-based graph encoder in MolX, ensuring an adequate comparison. We observe that the MolX-enhanced LLM achieves the best scores in 6 out of 8 subsets of the MoleculeNet dataset and is the second-best in the other two. Notably, properties in the MoleculeNet dataset are high-level properties and unseen from the pre-training stage, showing the strong adaptability of our proposed method on unseen downstream tasks.

4.3 Molecule Optimization

Molecule optimization [36] is a more challenging task to assess the model's perception of molecular properties and the understanding of chemical laws behind SMILES strings. Specifically, this task aims to modify a molecule toward a desirable property profile and the model is expected to generate the SMILES string of the modified molecule. The used dataset, ChEMBL-02 [36], consists of

Table 4: Experimental results for retrosynthesis on the USPTO-50k dataset.

Instruction and Answer Provide SMILES strings of possible reactants used in the molecule's synthesis. The reactants should be split by '.' Molecule: O=C(NCCCI)Nc1ccc(Br)n1 Answer: As an assistant.... Here are some possible reactants: C6H5Br + NH3 + NaCN + HCI + NaN3 + H2O Provide SMILES strings of possible reactants used in the molecule's synthesis. The reactants should be split by '.' Molecule: O=C(NCCC()NC1cccc(Br)n1 GT : Nc1cccc(Br)n1.0=C=NCCCI Answer: Nc1cccc(Br)n1.0=C(NCCCI)N

200k matched molecule pairs extracted from the ChEMBL database [37], together with the property changes. Three molecular properties which are solubility, clearance, and LogD are optimized simultaneously. Following [24], we adopt Exact Match, BLEU, METEOR, Levenshtein distance, 2 molecular fingerprint-based similarities [38, 15], and Validity score as evaluation metrics. Figure 5 illustrates an example of this task and more examples can be found in Appendix C.

Experiential results for molecule optimization are shown in Table 3. For Inference-only results, not only increase the performances of the base LLM to an acceptable level, but MolX also reduces the hallucination with wordy answers and chemically unreasonable SMILES strings, which is typically found when the LLMs are required to generate a SMILES string [5]. As an example in Figure 5, although still imperfect, the MolX-enhanced LLM recognized that the Fluorine atom is the key modification. Considering the LoRA fine-tuning scenario, the MolX-enhanced LLM outperforms baselines including a powerful supervised learning model, Chemformer [21] in most metrics, except the Validity where Chemformer has a nearly perfect score.

4.4 Retrosynthesis

Retrosynthesis is a crucial task in chemistry and is well-known as a bottleneck in modern drug design [39], however, it is underexplored in considered literature. This task involves a reverse extrapolation from a molecule to identify possible reactants used in its synthesis. The model is expected to generate SMILES strings of reactants separated by a '.'. We use the USPTO-50k dataset [40], containing 50k reactions for conducting experiments. Evaluation metrics are similar to the molecule optimization task. Figure 6 illustrates an example of this task and more examples can be found in Appendix C.

Table 5: Ablation study results for molecule description generation on PubChem dataset.

Model	# Trainab	Description Generation						
	Pre-training	Downstream	BLEU-2↑	BLEU-4↑	ROUGE-1↑	ROUGE-2↑	ROUGE-L↑	METEOR↑
Llama-2-7B + MolX w/o ChemInit	36.1M (0.53%)	56.6M (0.82%)	30.21	22.67	43.64	28.80	38.47	38.43
Llama-2-7B + MolX w/o MorganFP	23.5M (0.35%)	44.0M (0.64%)	29.33	22.01	42.37	27.96	37.35	37.31
Llama-2-7B + MolX w/o WeightedInc	36.1M (0.53%)	56.6M (0.82%)	31.13	24.01	44.16	28.50	38.56	39.34
Llama-2-7B + MolX w/o Auxiliaries	36.1M (0.53%)	56.6M (0.82%)	30.71	23.06	40.29	24.33	33.62	35.37
Llama-2-7B + MolX w/o Pre-training	00.0M (0.00%)	56.6M (0.82%)	28.79	22.36	38.23	22.28	30.40	33.13
Llama-2-7B + MolX	36.1M (0.53%)	56.6M (0.82%)	31.40	24.25	44.20	28.96	38.76	39.55

From experiential results presented in Table 4, we can observe that MolX improves the Inferenceonly results of the base LLM and alleviates the hallucination with a similar effect as the molecule optimization task. As an example in Figure 6, the MolX-enhanced LLM correctly recognized the first reactant while slightly erring the second one with the lack of the isocyanate group O=C=N. Notably, for the scenario of LoRA fine-tuning, the MolX-enhanced LLM also surpasses baselines and the powerful supervised learning model, Chemformer [21] in most metrics, except for the Validity where Chemformer has an impressive score. Interestingly, in contrast to the previous task, leveraging the 3D molecular graph is not beneficial for retrosynthesis.

5 Ablation Study

Here we study the influence of building components in our proposed framework. Firstly, we use random initializations for trainable encoders, exploring the possibility of eliminating reliance on robust pre-trained weights. Next, we investigate the contributions of incorporating the Morgan fingerprint, as well as the weighted scheme by removing them from the framework. Moreover, to demonstrate the effectiveness of our versatile pre-training strategy, we discard auxiliary tasks and only use the molecule description generation objective during pre-training. Lastly, by totally skipping the pre-training stage, we aim to understand its alignment impact on the framework. Experiments are conducted on molecule description generation on the PubChem dataset [8] under the LoRA fine-tuning scenario, simultaneously highlighting the proposed framework's efficiency regarding the number of trainable parameters during pre-training and fine-tuning on downstream tasks.

Table 5 shows experimental results for the described ablation study. Firstly, a drop in performances of MolX without chemical initializations for encoders indicates the role of robust pre-trained weights. Next, while the weighted scheme brings a modest improvement, incorporating the Morgan fingerprint contributed to the performances of MolX significantly. Moreover, without proposed auxiliary tasks, a noticeable decrease in performances can be viewed, especially for ROUGE-based and METEOR metrics, demonstrating their effectiveness in providing the model with comprehensive information of the molecules. Lastly, it is not surprising that the pre-training stage which establishes an alignment between MolX and the LLMs' textual input space, has a large impact. In terms of efficiency, our proposed framework only introduces a small number of trainable parameters, accounting for 0.53% of the entire parameters during pre-training and 0.82% with fine-tuning on downstream tasks.

6 Conclusion

In this paper, we study the challenging problem of applying LLMs in chemistry and propose a novel framework enhancing LLMs to comprehend molecules, thus, improving their performances on molecule-related tasks. The LLMs are equipped with a multi-modal external module, MolX, which is aligned into their textual input space by a versatile pre-training strategy. Experimental evaluations demonstrate that our proposed method outperforms baselines on a diverse range of downstream molecule-related tasks, with and without fine-tuning the LLM. Especially, MolX can be viewed as a plug-in module, enabling the LLM to function normally on general domains.

Limitations and Future Work. Despite the promising results, our work has a few limitations. Firstly, although experiments are conducted on various molecule-related tasks, reaction-related tasks in chemistry such as reaction outcome prediction or yield prediction have not been considered. On the other hand, other capable LLMs should be taken into consideration. Looking forward, LLMs have been demonstrated to have intriguing abilities like In-context Learning [41] or Chain-of-Thought reasoning [42]. Leveraging these advanced abilities for molecule-related tasks is a potential direction.

A Pre-training Strategy

Here we elaborate the pre-training strategy by clearly describing the proposed pre-training tasks. A molecule-to-text translation, i.e., molecule description generation, serves as the main task, accompanied by a couple of auxiliary tasks. We select a set of 10 low-level properties that are available for easy collection from PubChem and present comprehensive information of the molecules. Furthermore, we utilize one more special auxiliary task which is canonicalizing the molecule's SMILES string. Examples of these tasks and the instructions for each task are illustrated in Figure A.1.

Molecule description generation	
Provide a detailed description of the molecule.	\bigcap
Molecule: C1=CC(=CC=C1C[C@H]2C(=0)N[C@H](C(=0)N2)CC3=CC=C(C=C3)0)0 Answer : The molecule is a cyclo(tyrosyl-tyrosyl) in which both stereocentres have L-configuration. Synthesized by Mycobacterium tuberculosis. It has a role as a metabolite.	100%
Predicting the basic chemical and physical properties	
Heavy Atom	~
A neary atom refers to any atom that is not hydrogen. How many heavy atoms are there in this molecule?	(
Molecule: C1=CC(=CC=C1C[C@H]2C(=0)N[C@H](C(=0)N2)CC3=CC=C(C=C3)0)0	(10%)
Answer: 24	\smile
Hydrogen Bond Acceptor	_
A hydrogen bond acceptor has tone electron pars that help form hydrogen bonds. How many bydrogen bond acceptor risk for en this molecule?	
Molecule: C1=CC=CC=C1C[C@H]2C(=0)N[C@H](C(=0)N2)CC3=CC=C(C=C3)0)0	(10%)
Answer: 4	\bigcirc
Hydrogen Bond Donor	-
A hydrogen bond donor is a compound that donates protons (hydrogen atoms) covalently bound to itself, allowing it to form hydrogen bonds. How many bydrogen bond donors are there in this molecule?	
Notecute: C1=CC(=CC)CC@H]2C(=0)N(C@H)(C(=0)N2)CC3=CC=C(C=C3)0)0	(10%)
Answer: 4	\smile
Rotatable Bond	
A rotatable bond is any single non-ring bond, attached to a non-terminal, non-hydrogen atom. How many rotatable honds are there in this molecule?	\bigcap
Molecule: C1=CC[=CC=C1C[C@H]2C[=0)N2)CC3=CC=C(C=C3)0)0	(10%)
Answer: 4	\bigcirc
Aromatic Ring	
Aromatic rings are hydrocarbons with a benzene or related ring.	\bigcap
Molecule: C1=CC=CCCCCCC[C@H]2C(=0)N(C@H](C(=0)N2)CC3=CC=C(C=C3)0)0	(10%)
Answer: 2	\smile
Complexity	
The complexity rating of a compound estimates its structural complexity based on its elements and structural features, including symmetry.	\bigcap
Molecule: C1=CC=CCC=CLC[C@H]2C(=0)N(C@H](C(=0)N2)CC3=CC=C(C=C3)0)0	(10%)
Answer: 412	\smile
Topological Polar Surface Area	
The topological polar surface area (TPSA) is the surface sum of all polar atoms or molecules, primarily oxygen and nitrogen, also including their attached hydrogen atoms.	\frown
Molecule: C1=CC[=CC=C1C[C@H]2C(=0)N[C@H](C(=0)N2)CC3=CC=C(C=C3)0)0	(10%)
Answer: 98.66	\smile
Molecular weight	
The molecular weight is the sum of the atomic weights of all the atoms in the molecule.	\bigcap
What is the indicated weight of this indicate: Molecule: C1=CC[=CC=C1C]C@H]2C[=0]N[C@H](C(=0)N2)CC3=CC=C(C=C3)0]0	(10%)
Answer: 326.352	\bigcirc
LogP	
LogP, or octanol-water partition coefficient, is a measure of how hydrophilic or hydrophobic a molecule is.	\frown
What is the Log Value of its Indecuel: Molecule: C1=CC[=CC=C1C]C@H12C(=0)N2)CC=1C(C=C3)0)0	(10%)
Answer: 0.8662	\smile
Quantitative Estimate of Druglikeness	
The quantitative estimate of druglikeness (QED) is a measure of how drug-like a molecule is, based on various molecular properties associated with druglikeness.	\bigcirc
What is the QED value of this inforeculer Moleculer: Inforeculer: Inforeculer: <td>(10%)</td>	(10%)
Answer: 0.669781	\bigcirc
Canonicalizing the molecule's SMILES string	_
Provide the molecule's canonical SMILES string, which is a unique representation of this molecule.	(100)
Molecule: C1=CC1=CC=C1CL@m12C1=O/NL(@m11C1=O/N2)CC3=CL=CL(=CC3)O/O Answer: 0=C1N1C@m0H1(C2)Cc(0)Ca2)(C1=O)NL(@m11C1Ca(0)Cc1	10%
	\sim

Figure A.1: Examples of all pre-training tasks in our instruction-based pre-training strategy.

The MolX-enhanced LLM is pre-trained with the above tasks in a multi-task learning setting for 5 epochs. AdamW optimizer [43] is adopted with a weight decay of 0.05 and a learning rate scheduler of a combination of linear warmup with 1000 steps and cosine decay, in which the peak and minimal learning rates are 1e-5 and 5e-6, respectively. The batch size is 12 and the maximal text length is set to be 256. The computation time is 72 hours on 2 A100 GPUs with BFloat16 Mixed precision.

B Experiments on Downstream Tasks

In this section, we provide the details of datasets and experimental settings used in our experiments on downstream molecule-related tasks including molecule-to-text translation, molecule property prediction, molecule optimization, and retrosynthesis.

B.1 Details of Datasets

First, Table A1 presents an overview including the number of samples of used datasets. It should be noted that each dataset comes with availably divided train, validation, and test sets, and these subsets are used in our experiments. The instructions for each task are provided below.

Dataset	Subset	No. Samples	Task Type	Task Metrics
PubChem	Downstream	15000	Text Generation	BLEU-2, BLEU-4, ROUGE-1, ROUGE-2, ROUGE-L, METEOR
MoleculeNet	ESOL FreeSolv Lipophilicity MUV HIV BACE BBBP Tox21	1128 642 4200 249886 41127 1513 2039 77946	Regression Regression Classification Classification Classification Classification Classification	RMSE RMSE RMSE Accuracy, F1-score Accuracy, F1-score Accuracy, F1-score Accuracy, F1-score Accuracy, F1-score Accuracy, F1-score
ChEMBL-02	-	198558	Text Generation	Exact Match, BLEU-2, METEOR, Levenshtein, MACCS FTS, Morgan FTS, Validity
USPTO-50k	-	50037	Text Generation	Exact Match, BLEU-2, METEOR, Levenshtein, MACCS FTS, Morgan FTS, Validity

Table A1: An overview of used datasets.

B.1.1 MoleculeNet

For the MoleculeNet dataset, each subset with a different property has a different instruction, which is followed [44].

ESOL

Solubility (logS) can be approximated by negative LogP -0.01 * (MPt – 25) + 0.5 . What is the logS of this molecule?

FreeSolv

The free energy of hydration ($\Delta \mu h$) is defined as the change in free energy associated with transferring the solute of interest from a dilute vapor phase into water. What is the free energy of hydration ($\Delta \mu h$) of this molecule?

Lipophilicity

Lipophilicity is an important feature of drug molecules that affects both membrane permeability and solubility, measured by octanol/water distribution coefficient (LogD at pH 7.4). What's the octanol/water distribution coefficient (LogD at pH 7.4) of this molecule?

MUV

The M1 muscarinic receptor is thought to be an important therapeutic target in schizophrenia. Is this molecule allosteric modulators of M1 muscarinic receptors?

HIV

Human immunodeficiency viruses (HIV) are a type of retrovirus, which induces acquired immune deficiency syndrome (AIDs). Is this molecule effective for inhibiting Human immunodeficiency viruses (HIV) replication?

BACE

BACE1 is an aspartic-acid protease important in the pathogenesis of Alzheimer's disease, and in the formation of myelin sheaths. Can this molecule bind to BACE1?

BBBP

In general, molecules that passively diffuse across the brain blood barrier have the molecular weight less than 500, with a LogP of 2-4, and no more than five hydrogen bond donors or acceptors. Can this molecule pass brain blood barrier?

Tox21

Estrogen receptor alpha (ER aplha) is Nuclear hormone receptor. The steroid hormones and their receptors are involved in the regulation of eukaryotic gene expression and affect cellular proliferation and differentiation in target tissues. Ligand-dependent nuclear transactivation involves either direct homodimer binding to a palindromic estrogen response element (ERE) sequence or association with other DNA-binding transcription factors, such as AP-1/c-Jun, c-Fos, ATF-2, Sp1 and Sp3, to mediate ERE-independent signaling. Is this molecule agonists of the estrogen receptor alpha (ER-alpha) signaling pathway?

B.1.2 ChEMBL-02

An example of the instruction for the molecule optimization task.

Modify the molecule to create a new one such that the solubility is unchanged, the clearance is unchanged, and a change in LogD (distribution coefficient) within the interval (0.1, 0.3]. Molecule: Fc1ccc(C2(c3nnc4n3CCCCCC4)CCCC2)cc1

B.1.3 USPTO-50k

An example of the instruction for the retrosynthesis task.

Provide SMILES strings of possible reactants used in the molecule's synthesis. The reactants should be split by '.'.

Molecule: O=C(NCCCl)Nc1cccc(Br)n1

B.2 Experimental Settings

Throughout experiments, we consider two different model configurations for the evaluation: I) Inference-only: The model is frozen after pre-training for direct question answering on downstream tasks, evaluating the model's generalizability without fine-tuning; II) LoRA fine-tuning: The model is fine-tuned on downstream tasks using a parameter-efficient technique, LoRA [33], verifying the model's adaptability in scenarios where downstream data are available. For LoRA fine-tuning, the model is fine-tuned on train sets of downstream tasks for 50 epochs, using the same settings of optimizer and learning rate scheduler as pre-training. LoRA is applied with the same hyper-parameters as the baselines 2D and 3D MoLM [8], factorizing all *_proj modules of LlamaSdpaAttention and LlamaMLP layers with a rank r = 8, $\alpha = 32$, and dropout = 0.1. Notably, for all tasks, the loss function employed is the auto-regressive loss as described in Equation 4. We report performances on the test sets selected by the corresponding validation sets.

C Additional Examples

In this section, we provide additional examples as mentioned in the main paper.

C.1 Molecule property prediction on MoleculeNet with Inference-only

For the MoleculeNet dataset, we provide an example for each subset with the instructions described in the previous section.

ESOL

Solubility (logS) can be approximated by negative LogP -0.01 * (MPt – 25) + 0.5. What is the logS of this molecule?

Molecule: Cc1occc1C(=O)Nc2ccccc2. Please answer the question with a numerical value only. Answer: -2.2663 GT: -3.30

FreeSolv

The free energy of hydration ($\Delta \mu h$) is defined as the change in free energy associated with transferring the solute of interest from a dilute vapor phase into water. What is the free energy of hydration ($\Delta \mu h$) of this molecule?

Molecule: c1ccc2c(c1)ccc3c2cccc3. Please answer the question with a numerical value only. Answer: -3.5142 GT : -3.88

Lipophilicity

Lipophilicity is an important feature of drug molecules that affects both membrane permeability and solubility, measured by octanol/water distribution coefficient (LogD at pH 7.4). What's the octanol/water distribution coefficient (LogD at pH 7.4) of this molecule?

Molecule: Clc1ccccc1c2cnn[nH]2. Please answer the question with a numerical value only. Answer: 1.4344 GT : 2.68

MUV

The M1 muscarinic receptor is thought to be an important therapeutic target in schizophrenia. Is this molecule allosteric modulators of M1 muscarinic receptors?

Molecule: O=C(O)c1cn[nH]c1-n1cnnn1. Please answer the question with only Yes or No. Answer: No GT: No

HIV

Human immunodeficiency viruses (HIV) are a type of retrovirus, which induces acquired immune deficiency syndrome (AIDs). Is this molecule effective for inhibiting Human immunodeficiency viruses (HIV) replication?

Molecule: C1C[S+]2CC[S+]1CC2. Please answer the question with only Yes or No. Answer: No GT: No

BACE

BACE1 is an aspartic-acid protease important in the pathogenesis of Alzheimer's disease, and in the formation of myelin sheaths. Can this molecule bind to BACE1?

Molecule: $n_{1c2c(nc(N)c1N1CCCC1)cccc2}$. Please answer the question with only Yes or No. Answer: Yes GT: Yes

BBBP

In general, molecules that passively diffuse across the brain blood barrier have the molecular weight less than 500, with a LogP of 2-4, and no more than five hydrogen bond donors or acceptors. Can this molecule pass brain blood barrier?

Molecule: Nc1nnc(c(N)n1)c2cccc(Cl)c2Cl. Please answer the question with only Yes or No. Answer: Yes GT: Yes

Tox21

Estrogen receptor alpha (ER aplha) is Nuclear hormone receptor. The steroid hormones and their receptors are involved in the regulation of eukaryotic gene expression and affect cellular proliferation and differentiation in target tissues. Ligand-dependent nuclear transactivation involves either direct homodimer binding to a palindromic estrogen response element (ERE) sequence or association with other DNA-binding transcription factors, such as AP-1/c-Jun, c-Fos, ATF-2, Sp1 and Sp3, to mediate ERE-independent signaling. Is this molecule agonists of the estrogen receptor alpha (ER-alpha) signaling pathway?

Molecule: N=C1NC(=N)c2cccc21. Please answer the question with only Yes or No. Answer: No GT: No

C.2 Molecule optimization on ChEMBL-02 with Inference-only

Molecule	Model	Instruction and Answer
H ₃ c OH	Llama-2-7B	Modify the molecule to create a new one such that the solubility is unchanged, the clearance is increased, and a change in logD (distribution coefficient) within the interval $(1.9, 2.1]$. Molecule: $CC(=0)c1c(0)c2cccc2oc1=0$ Answer: As an assistant Here is a modified molecule: $CC(=0)c1c(0)$
67 : CC(C)=CCc1c(0)c2cccc2oc1=0	Llama-2-7B + MolX	Modify the molecule to create a new one such that the solubility is unchanged, the clearance is increased, and a change in logD (distribution coefficient) within the interval (1.9, 2.1]. Molecule: $CC(=0)c1c(O)c2cccc2cc1=0$ Answer : $O=c1c(O)c2cccc2cc1=0$
	Llama-2-7B	Modify the molecule to create a new one such that the solubility is unchanged, the clearance is unchanged, and a change in logD (distribution coefficient) within the interval (-0.9, -0.7). Molecule: CCN(CC)CCCCCCcccccc2cc(C))ccc12 Answer: As an assistant Here is a modified molecule: CCN(CC)CCCLcccn2cc(F)ccc12
67 : CC(C)NCCCNc1ccnc2cc(Cl)ccc12	Llama-2-7B + MolX	Modify the molecule to create a new one such that the solubility is unchanged, the clearance is unchanged, and a change in logD (distribution coefficient) within the interval (-0.9, -0.7). Molecule: CCN(CC)CCCNc1ccn2cc(C)ccc12 Answer: CCN(CC)CCCNc1ccn2ccc(C)ccc120
	Llama-2-7B	Modify the molecule to create a new one such that the solubility is increased, the clearance is decreased, and a change in logD (distribution coefficient) within the interval $(-1.5, -1.3]$. Molecule: $CCCCC(=0)NC(=S)NC(=0)CCc1ccccc1$ Answer: As an assistant Here is a modified molecule: $CCCCC(=S)NC(=S)NC(=O)CCc1$
67 : CCCCC(=0)NC(=S)NNC(=0)CC	Llama-2-7B + MolX	Modify the molecule to create a new one such that the solubility is increased, the clearance is decreased, and a change in logD (distribution coefficient) within the interval (-1.5, -1.3]. Molecule: $CCCCC(=0)MC(=5)MNC(=0)CCcIccccCI$ Answer: $CCCCC(=0)NC(=5)MNC(=0)CCcIccccCI$
н.м	Llama-2-7B	Modify the molecule to create a new one such that the solubility is unchanged, the clearance is increased, and a change in logD (distribution coefficient) within the interval (-0.1, 0.1]. Molecule: N#SCLinc(C=CC2cccc2)ocIN(Answer: As an assistant Here is a modified molecule: N#CCInc(C=C2cccc2)ocIN(OH)
GT : N#Cc1nc(C=Cc2ccccc2)oc1NCc1cccnc1	Llama-2-7B + MolX	Modify the molecule to create a new one such that the solubility is unchanged, the clearance is increased, and a change in logD (distribution coefficient) within the interval (-0.1, 0.1]. Molecule: N#Cclnc(C=Cc2cccc2)oc1N Answer: N#Cclnc(C=Cc2ccc2)oc1N=CcClccl

C.3 Retrosynthesis on USPTO-50k with Inference-only

D Broader Impacts

Our work has broader impacts across multiple dimensions. First, for chemistry professionals, our enhanced LLM could be used as a computational tool, potentially speeding up their research process. For individuals without expertise in chemistry, our enhanced LLM could provide a more affordable way to handle molecule-related tasks, benefitting education in chemistry. However, our enhanced LLM shares the risks of most LLMs, it can generate inaccurate answers and could be abused to produce biased content. Additionally, concerns about job displacement in the chemical industry may arise, and efforts should be made to address these challenges and ensure a responsible and equitable adoption of AI technologies.
