Abstract

The double pion photoproduction off nucleons near threshold is analyzed in a covariant baryon chiral perturbation theory up to next to leading order, where the $\Delta(1232)$, $N^*(1400)$ and $\rho(770)$ resonances are included as explicit degrees of freedom. For the process $\gamma p \rightarrow \pi^+ \pi^0 n$, the chiral results of total cross sections, invariant-mass distributions and beam-helicity asymmetry are in good agreement with the experimental data within uncertainties. For the process $\gamma p \rightarrow \pi^0 \pi^0 p$, the prediction of total cross section deviates from the existing experimental data. Once the final-state interaction of $\pi\pi$ in the isoscalar S-wave channel is taken into account, a good description of the cross section is achieved. The effect of the Roper resonance always turns out to be negligible, and hence can be thrown away in future study of this process.

1 Introduction

Single and double pion photoproduction has been studied for decades, mainly aiming at solving the so-called missing resonance problem. That is, some of the resonances predicted by the quark model and lattice QCD were not found in πN scattering [1–3]. An explanation is that these resonances are weakly coupled to πN , and need to be further explored through the photoproduction processes. The photoproduction processes also play an important role in deciphering the electromagnetic properties of resonances from experimental data. For instance, the single π photo- and electroproduction off the nucleon near threshold are investigated in Refs [4, 5] to extract the $\gamma^{(*)}N$ coupling to the sub-threshold resonance [6–9] in the S_{11} channel.

High-energy nucleon intermediate excitations prefer sequential decays into many meson states, where the double pion production is considered to dominate [10, 11]. Plenty of experimental results for double pion photoproduction on the nucleon have been accumulated so far, including total cross sections, invariant-mass distributions, angle differential cross sections and the asymmetry related to the polarization of photons and initial nucleons [12–24]. However, data near the threshold are scarce. It is therefore challenging to decode resonant information in the low-energy region.

Various effective models have been proposed in previous theoretical works in order to analyze the contributions of different resonances. The Bonn-Gatchina model [25] performed partial wave analysis to fit experimental cross sections of $\gamma p \rightarrow \pi^0 \pi^0 p$, finding that the $D_{33}(1700)$ wave makes the most sizeable contribution and $D_{13}(1520)$ accounts for a large part of the first bump. The Valencia model [26] employed phenomenological Lagrangian approach, where the Born term and the resonance contributions of $P_{33}(1232)$, $P_{11}(1440)$, $D_{13}(1520)$, $D_{33}(1700)$ and $\rho(770)$ are considered at tree level. A good description is achieved for cross sections of $\gamma p \rightarrow \pi^0 \pi^0 p$, $\gamma p \rightarrow \pi^+ \pi^- p$, $\gamma p \rightarrow \pi^+ \pi^0 n$. It is also found that the $D_{13}(1520)$ state is the dominant contribution amongst the resonant terms and a strong $P_{11}(1440)$ contribution was ruled out therein. The MAID model [27] is very similar to the Valencia model, but more higher lying states, such as $F_{15}(1680)$, $D_{15}(1570)$, are also taken into account. Although it yields a satisfactory description for total cross sections of $\gamma p \rightarrow \pi^+ \pi^- p$, $\gamma p \rightarrow \pi^+ \pi^0 n$, the $\pi^0 \pi^0$ production on the proton near the threshold is underestimated. In the MAID model, the $D_{13}(1520)$ excitation turns out to be dominant in resonant region and at higher energies $F_{15}(1680)$ plays an important

§zhenghq@scu.edu.cn (corresponding author)

role. The influence owing to the rescattering mechanism of $\pi^+\pi^- \rightarrow \pi^0\pi^0$ in the neutral channel has been investigated in Ref. [28].

Besides, hitting longitudinally polarized nuclei by circularly polarized photons, the beam-target helicity asymmetry $\sigma_{3/2} - \sigma_{1/2}$ can be obtained. It is the difference between the total cross sections that the spins of photons and nucleons are oriented parallel and anti-parallel. The beam-target helicity asymmetry can be related to the anomalous magnetic moment of the nucleon through the Gerasimov-Drell-Hearn (GDH) sum rule [29]. It is pointed out that the double pion photoproduction process has a non-negligible contribution to the overall GDH sum rule [18].

Double pion photoproduction amplitudes at threshold have been calculated within chiral perturbation theory (ChPT) in the 1990s [30, 31]. Among them, Ref. [30] employed covariant formalism and calculated the leading order (LO) amplitude with explicit inclusion of the $\Delta(1232)$ resonance. Therein, the neutral channels $\gamma p \rightarrow \pi^0\pi^0 p, \gamma n \rightarrow \pi^0\pi^0 n$ are zero in the chiral limit, while the $\Delta(1232)$ does not contribute to $\gamma n \rightarrow \pi^0\pi^0 n$ channel and its contribution to other channels is not as pronounced as expected. On the other hand, calculation was done in heavy baryon (HB) formalism up to $\mathcal{O}(p^3)$ in Ref. [31]. The amplitudes are derived exactly at threshold, where most of the Feynman diagrams do not contribute. It is found that, for the neutral channel, the loop diagrams play a major role and $\Delta(1232)$ has no contribution. For the channels with one charged pion, i.e., $\gamma p \rightarrow \pi^+\pi^0 n, \gamma n \rightarrow \pi^-\pi^0 p$, the $\mathcal{O}(p^2)$ diagrams are of crucial importance, while the loop contribution is negligible. For the double-charged channel $\gamma p \rightarrow \pi^+\pi^- p, \gamma n \rightarrow \pi^+\pi^- n$, major contribution stems from the loop diagrams. The obtained HB results of cross sections of $\gamma p \rightarrow \pi^0\pi^0 p$ are in good agreement with the experimental data [13], however, only up to the energy point ~ 40 MeV above the threshold. In addition, for the $\gamma p \rightarrow \pi^+\pi^0 n$ channel, it is found that the HB ChPT predictions are much lower than existing data.

The main purpose of this work is to extend the calculation of $\gamma N \rightarrow \pi\pi N$ process beyond the threshold by imposing a covariant chiral perturbation theory scheme, in which the resonances $\Delta(1232), N^*(1440)$ and $\rho(770)$ are considered as explicit degrees of freedom. The importance of various contributions from the Born terms and resonances is discussed. The cross sections for $\gamma p \rightarrow \pi^0\pi^0 p$ and $\gamma p \rightarrow \pi^+\pi^0 n$ channel are calculated, which are then confronted with the available data so as to test the validity of chiral perturbation theory. For the $\gamma p \rightarrow \pi^0\pi^0 n$ channel, the effect of final-state interaction (FSI) of $\pi\pi$ with $IJ = 00$ is taken into account. In consequence, a good description of the existing experimental data can be obtained, even though the contribution of chiral loop diagrams is absent.

The structure of this manuscript is as follows. Section 2 represents the theoretical formalism, comprising the required chiral effective Lagrangian, basic formulae for the amplitude structure as well as observables, and the obtained chiral amplitudes. Section 3 shows the numerical results of total cross sections, the $\pi\pi$ invariant mass distribution and the beam-target helicity asymmetry. Comparison with the available experimental data is also discussed. We summarize in Section 4. Correspondence between the theories with and without the ρ meson is discussed in Appendix A. Explicit expressions of the $\mathcal{O}(p)$ and $\mathcal{O}(p^2)$ non-resonant chiral amplitudes are relegated to Appendix B.

2 Theoretical formalism

2.1 Covariant chiral effective Lagrangian

ChPT is a low-energy effective theory of Quantum Chromodynamics (QCD) describing the interaction between Goldstone-bosons and matter [32–34]. Its calculations are organized as a perturbative expansion in terms of the Goldstone-boson masses and external momentum, denoted collectively by p hereafter. The chiral order of a given diagram, with L loops, I_ϕ internal pion lines, I_N internal nucleon lines and $N^{(k)}$ vertices from $\mathcal{O}(p^k)$ Lagrangian, is assigned to be [35]

$$D = 4L - 2I_\phi - I_N + \sum_k^\infty kN^{(k)}. \quad (1)$$

The leading order chiral Lagrangian for purely pionic interaction reads [36]

$$\mathcal{L}_{\pi\pi}^{(2)} = \frac{F^2}{4} \text{Tr} \left[\nabla_\mu U (\nabla^\mu U)^\dagger \right] + \frac{F^2}{4} \text{Tr} \left[\chi U^\dagger + U \chi^\dagger \right], \quad (2)$$

where the superscript represents the chiral order and F is the meson decay constant in chiral limit. The pion field in this Lagrangian is parameterized in the SU(2) matrix

$$U = \exp \left(i \frac{\phi}{F} \right), \quad \phi = \vec{\phi} \cdot \vec{\tau} = \begin{pmatrix} \pi_0 & \sqrt{2}\pi^+ \\ \sqrt{2}\pi^- & -\pi_0 \end{pmatrix}, \quad (3)$$

with $\tau_i (i = 1, 2, 3)$ being the Pauli matrix. The covariant derivative acting on the pion fields is defined as $\nabla_\mu U = \partial_\mu U - ir_\mu \cdot U + iU \cdot l_\mu$. The photon field A_μ enters through the external fields by setting $r_\mu = l_\mu = -eA_\mu Q$,

where $e > 0$ is the elementary charge and $Q = (\mathbf{1} + \tau_3)/2$. In addition, $\chi = M^2 \mathbf{1}$ in the isospin symmetric limit, with M the mass of pions. The required Lagrangian describing the interaction with nucleon is [37]

$$\begin{aligned}\mathcal{L}_{\pi N}^{(1)} &= \bar{\Psi} \left(i \not{D} - m + \frac{g}{2} \gamma^\mu \gamma_5 u_\mu \right) \Psi, \\ \mathcal{L}_{\pi N}^{(2)} &= c_1 \text{Tr}[\chi_+] \bar{\Psi} \Psi - \frac{c_2}{4m^2} \text{Tr}[u_\mu u_\nu] (\bar{\Psi} D^\mu D^\nu \Psi + \text{h.c.}) + \frac{c_3}{2} \text{Tr}[u^\mu u_\mu] \bar{\Psi} \Psi \\ &\quad - \frac{c_4}{4} \bar{\Psi} \gamma^\mu \gamma^\nu [u_\mu, u_\nu] \Psi + c_5 \bar{\Psi} \left[\chi_+ - \frac{1}{2} \text{Tr}[\chi_+] \right] \Psi + \bar{\Psi} \sigma^{\mu\nu} \left[\frac{c_6}{8m} f_{\mu\nu}^+ + \frac{c_7}{8m} \text{Tr}[f_{\mu\nu}^+] \right] \Psi.\end{aligned}\quad (4)$$

The nucleon is contained in the isospin doublet: $\Psi = \begin{pmatrix} p \\ n \end{pmatrix}$. Here m is the nucleon mass, g is the axial coupling constant, and c_i 's are $\mathcal{O}(p^2)$ low-energy constants (LECs). The covariant derivative with respect to the nucleon field is given by:

$$\begin{aligned}D_\mu &= \partial_\mu + \Gamma_\mu, \\ \Gamma_\mu &= \frac{1}{2} [u^\dagger (\partial_\mu - i r_\mu) u + u (\partial_\mu - i l_\mu) u^\dagger], \\ u &= \sqrt{U} = \exp\left(\frac{i\phi}{2F}\right).\end{aligned}\quad (5)$$

Furthermore, the chiral vielbein is defined as $u_\mu = i [u^\dagger (\partial_\mu - i r_\mu) u - u (\partial_\mu - i l_\mu) u^\dagger]$ and the chiral operator χ_+ reads $\chi_+ = u^\dagger \chi u^\dagger + u \chi^\dagger u$. For convenience, we also need the electromagnetic tensor $f_{\mu\nu}^+ = u f_{L\mu\nu} u^\dagger + u^\dagger f_{R\mu\nu} u$ with $f_{L\mu\nu} = f_{R\mu\nu} = -eQ(\partial_\mu A_\nu - \partial_\nu A_\mu)$. Due to the closeness of the $\Delta(1232)$ to the nucleon, including it in ChPT will lead to a faster convergence property and generate more accurate predictions in the description of the γN and πN processes [38, 39]. Hence, we ought to take the $\Delta(1232)$ excitations as explicit degrees freedom. The spin of $\Delta(1232)$ is $3/2$, which can be described using the vector-spinor field of the Rarita-Schwinger formalism [40]. Its isospin is also $3/2$, and can be described in the form of isovector-isospinor. With explicit $\Delta(1232)$ in ChPT, the Lagrangian for its interaction with pions can be constructed as [41]

$$\begin{aligned}\mathcal{L}_{\pi\Delta}^{(1)} &= -\bar{\Psi}_\mu^i \xi_{ij}^{\frac{3}{2}} \left[(i \not{D}_{jk} - m_\Delta \delta_{jk}) g_{\mu\nu} + iA(\gamma^\mu D_{jk}^\nu + \gamma^\nu D_{jk}^\mu) \right. \\ &\quad + \frac{i}{2} (3A^2 + 2A + 1) \gamma^\mu \not{D}_{jk} \gamma^\nu + m_\Delta \gamma^\mu \delta_{jk} \gamma^\nu \\ &\quad \left. + \frac{g_1}{2} \not{D}_{jk} \gamma_5 g^{\mu\nu} + \frac{g_2}{2} (\gamma^\mu u_{jk}^\nu + \gamma^\nu u_{jk}^\mu) \gamma_5 + \frac{g_3}{2} \gamma^\mu \not{D}_{jk} \gamma_5 \gamma^\nu \right] \xi_{kl}^{\frac{3}{2}} \Psi_{\nu,l},\end{aligned}\quad (6)$$

where m_Δ and g_1, g_2, g_3 are the mass and coupling constants of the $\Delta(1232)$, respectively. Here, $A \neq -\frac{1}{2}$ is an arbitrary real parameter and we take $A = -1$ in the calculation throughout this work. Ψ_μ^i represents the field corresponding to $\Delta(1232)$, where $\mu = 0, 1, 2, 3$ are the Lorentz vector indices and $i = 1, 2, 3$ are the isovector indices. Furthermore, $\xi_{ij}^{\frac{3}{2}} = \delta_{ij} - \frac{1}{3} \tau_i \tau_j$ is the matrix form of the projection operator of the isospin-3/2 component, e.g., $u_{\mu,ij} = \xi_{ik}^{\frac{3}{2}} u_\mu \xi_{kj}^{\frac{3}{2}}$. The covariant derivative acting on Ψ_μ^i is defined by $D_{\mu,ij} = \delta_{ij} \partial_\mu - 2i \epsilon_{ijk} \Gamma_{\mu,k} + \delta_{ij} \Gamma_\mu$. The leading order Lagrangian describing the $\pi N \Delta$ interaction is

$$\mathcal{L}_{\pi N \Delta}^{(1)} = h \bar{\Psi} u_j^\mu \Theta_{\mu\alpha}(z_0) \xi_{ji}^{\frac{3}{2}} \Psi_i^\alpha + \text{h.c.}\quad (7)$$

where h is the pion-nucleon-delta coupling constant. $\Theta_{\mu\alpha}(z_0) = g_{\mu\alpha} + z_0 \gamma_\mu \gamma_\alpha$, here z_0 is an off-shell parameter. The parameters of g_2, g_3, z_0 can be absorbed by a redefinition of other LECs as done in Ref. [42], therefore we can simply set $g_2 = g_3 = z_0 = 0$ for convenience.

In addition to $\Delta(1232)$, we also consider the lowest-order contribution of the $N^*(1440)$ resonance, i.e. the Roper resonance. The relevant Lagrangian reads [43],

$$\mathcal{L}_{\pi NR}^{(1)} = \frac{g_{\pi NR}}{2} \bar{\Psi}_R \gamma^\mu \gamma_5 u_\mu \Psi + \text{h.c.}\quad (8)$$

As for the vector meson resonance $\rho(770)$, following Ref. [44], we adopt the so-called massive Yang-Mills approach [45], which was suggested as a general one by demanding the self-consistency in the sense of constraints and perturbative renormalizability [46].

$$\begin{aligned}\mathcal{L}_{\pi\rho} &= -\frac{1}{2} \text{Tr}(\rho_{\mu\nu} \rho^{\mu\nu}) + M_\rho^2 \text{Tr} \left[\left(\rho_\mu - \frac{i}{g_\rho} \tilde{\Gamma}_\mu \right) \left(\rho^\mu - \frac{i}{g_\rho} \tilde{\Gamma}^\mu \right) \right] \\ \mathcal{L}_{\pi\rho N} &= g_\rho \bar{\Psi} \left[\rho_\mu - \frac{i}{g_\rho} \tilde{\Gamma}_\mu \right] \gamma^\mu \Psi + \frac{G_\rho}{2} \bar{\Psi} \rho_{\mu\nu} \sigma^{\mu\nu} \Psi,\end{aligned}\quad (9)$$

where $\tilde{\Gamma}_\mu = \Gamma_\mu - \frac{1}{2}\text{Tr}(\Gamma_\mu)$, $\rho_\mu = \rho_{i\mu}\frac{\tau_i}{2}$, $\rho_{\mu\nu} = \partial_\mu\rho_\nu - \partial_\nu\rho_\mu - ig_\rho[\rho_\mu, \rho_\nu]$, $g_\rho^2 = \frac{M_\rho^2}{2F^2}$ [47].¹ We can get $\mathcal{O}(p^0)$ three- ρ and four- ρ interaction terms, and $\mathcal{O}(p^1)$ ρ -photon, ρ - π - π and ρ -photon- π - π interaction terms from $\mathcal{L}_{\pi\rho}$. $\mathcal{L}_{\pi\rho N}$ will give $\mathcal{O}(p^0)$ and $\mathcal{O}(p^1)$ interactions between ρ and nucleons.

2.2 Amplitude structure and observables

The amplitude of the $\gamma(k)N(p_1) \rightarrow \pi^a(q_1)\pi^b(q_2)N(p_2)$ process can be decomposed into 6 parts according to the isospin structure:

$$\mathcal{M}_{ab} = \mathcal{M}^1\delta_{ab} + \mathcal{M}^2\delta_{ab}\tau_3 + \mathcal{M}^3\delta_{a3}\tau_b + \mathcal{M}^4\delta_{b3}\tau_a + \mathcal{M}^5\epsilon_{abc}\tau_c + \mathcal{M}^6\epsilon_{3ab}\mathbf{1}. \quad (10)$$

The amplitude should satisfy the Bose symmetry due to the presence of two π in the final states. That is, by exchanging a, b and q_1, q_2 simultaneously, the amplitude should remain unchanged. Consequently, the exchange of $q_1 \leftrightarrow q_2$ leads to the interchanging between the isospin amplitudes \mathcal{M}^i 's:²

$$\mathcal{M}^1 \leftrightarrow \mathcal{M}^1, \mathcal{M}^2 \leftrightarrow \mathcal{M}^2, \mathcal{M}^3 \leftrightarrow \mathcal{M}^4, \mathcal{M}^4 \leftrightarrow \mathcal{M}^3, \mathcal{M}^5 \leftrightarrow -\mathcal{M}^5, \mathcal{M}^6 \leftrightarrow -\mathcal{M}^6 \quad (11)$$

The isospin amplitudes can be further decomposed according to the Lorentz structure as

$$\mathcal{M}^i = \epsilon_\mu(k)\bar{u}(p_2) \left[\sum_{j=1}^{12} \mathcal{M}_j^i l_j^\mu \right] u(p_1) \equiv \epsilon_\mu(k)\bar{u}(p_2)\mathcal{M}^{i,\mu}u(p_1), \quad (12)$$

where the Lorentz operators are defined by

$$\begin{aligned} l_1^\mu &= P \cdot k \gamma^\mu - P^\mu \not{k}, & l_2^\mu &= \gamma^\mu \not{k}, & l_3^\mu &= P \cdot k \gamma^\mu \not{Q}_- - P^\mu \not{k} \not{Q}_-, & l_4^\mu &= \gamma^\mu \not{k} \not{Q}_-, \\ l_5^\mu &= P \cdot k Q_+^\mu - P^\mu Q_+ \cdot k, & l_6^\mu &= Q_+^\mu \not{k} - Q_+ \cdot k \gamma^\mu, & l_7^\mu &= P \cdot k Q_+^\mu \not{Q}_- - P^\mu Q_+ \cdot k \not{Q}_-, \\ l_8^\mu &= Q_+^\mu \not{k} \not{Q}_- - Q_+ \cdot k \gamma^\mu \not{Q}_-, & l_9^\mu &= P \cdot k Q_-^\mu - P^\mu Q_- \cdot k, & l_{10}^\mu &= Q_-^\mu \not{k} - Q_- \cdot k \gamma^\mu, \\ l_{11}^\mu &= P \cdot k Q_-^\mu \not{Q}_- - P^\mu Q_- \cdot k \not{Q}_-, & l_{12}^\mu &= Q_-^\mu \not{k} \not{Q}_- - Q_- \cdot k \gamma^\mu \not{Q}_-, \end{aligned} \quad (13)$$

with $Q_+ = (q_1 + q_2)/2$, $Q_- = (q_1 - q_2)/2$, $P = (p_1 + p_2)/2$. It should be stressed that each Lorentz structure above obeys gauge invariance separately. In Eq. (12), \mathcal{M}_j^i are scalar functions of Mandelstam variables. For a process of with 2 initial and 3 final states, there are 5 independent Mandelstam variables in total. In this work, they are chosen to be:

$$s = (k + p_1)^2, \quad s_1 = (p_2 + q_1)^2, \quad s_2 = (p_2 + q_2)^2, \quad t_1 = (k - q_1)^2, \quad t_2 = (k - q_2)^2. \quad (14)$$

At threshold, the 3-momenta of final states in the center-of-mass (CM) frame are zero, so $s^{\text{thr}} = (m + 2M)^2$ with the superscript denoting the threshold for short. In the laboratory reference frame, the energy of the incident photon is $E_\gamma = (s - m^2)/(2m)$. Taking $m = 938.27$ MeV, $M = 139.57$ MeV, we can get for the threshold $\sqrt{s}^{\text{thr}} = 1217.5$ MeV and $E_\gamma^{\text{thr}} = 320.7$ MeV.

We denote the amplitude for the physical process P_i by $\mathcal{N}(P_i)$, which can be expressed in terms of the above isospin amplitudes \mathcal{M}^i via

$$\begin{aligned} P_1 \quad \gamma p \rightarrow \pi^+ \pi^0 n : & \quad \mathcal{N}(P_1) = \sqrt{2}\mathcal{M}^4 - i\sqrt{2}\mathcal{M}^5, \\ P_2 \quad \gamma n \rightarrow \pi^- \pi^0 p : & \quad \mathcal{N}(P_2) = \sqrt{2}\mathcal{M}^4 + i\sqrt{2}\mathcal{M}^5, \\ P_3 \quad \gamma p \rightarrow \pi^0 \pi^0 p : & \quad \mathcal{N}(P_3) = \mathcal{M}^1 + \mathcal{M}^2 + \mathcal{M}^3 + \mathcal{M}^4, \\ P_4 \quad \gamma n \rightarrow \pi^0 \pi^0 n : & \quad \mathcal{N}(P_4) = \mathcal{M}^1 - \mathcal{M}^2 - \mathcal{M}^3 - \mathcal{M}^4, \\ P_5 \quad \gamma p \rightarrow \pi^+ \pi^- p : & \quad \mathcal{N}(P_5) = \mathcal{M}^1 + \mathcal{M}^2 + i\mathcal{M}^5 + i\mathcal{M}^6, \\ P_6 \quad \gamma n \rightarrow \pi^+ \pi^- n : & \quad \mathcal{N}(P_6) = \mathcal{M}^1 - \mathcal{M}^2 - i\mathcal{M}^5 + i\mathcal{M}^6. \end{aligned} \quad (15)$$

It can be checked that at threshold one has

$$\mathcal{N}(P_3) - \mathcal{N}(P_5) = \mathcal{N}(P_6) - \mathcal{N}(P_4) = \sqrt{2}\mathcal{N}(P_1) = \sqrt{2}\mathcal{N}(P_2). \quad (16)$$

The modular square of the amplitude for the physical process, that is averaged for the initial state polarizations and summed for the final state polarizations, is denoted by $|\overline{\mathcal{N}}|^2$. Then, the unpolarized cross section can be obtained by performing the three-body phase space integration over Φ_3 ,

$$\sigma = \frac{S}{4p_1 \cdot k} \int |\overline{\mathcal{N}}|^2 d\Phi_3. \quad (17)$$

¹In fact, this equation is the so-called (Kawarabayashi-Suzuki-Riadzuddin-Fayyazuddin) KSRF relation [48, 49]. The KSRF relation can be generalized by including the contributions of the crossed channel resonance exchange, as pointed out, e.g. in Ref. [50], and discussed in details in Ref. [51].

²Note that, in the isospin limit, one further has $q_1 = q_2$ at threshold. In this case, the threshold amplitude is symmetric in q_1 and q_2 , which leads to $\mathcal{M}^3 = \mathcal{M}^4, \mathcal{M}^5 = \mathcal{M}^6 = 0$.

Figure 1: Kinematics in the CM frame of the initial γN system. The z -axis is oriented in the direction of the three-momentum of the incoming photon.

Here S is a symmetry factor for the identical particles in the final states, which is $1/2$ for the neutral channels and 1 for the charged channels. The kinematics of double-pion photoproduction on the nucleon in the CM frame is shown in Fig. 1. The polar and azimuth angles of \vec{p}_2 are denoted by $(\pi - \theta)$ and φ , respectively. The dihedral angle ϕ is spanned by the (\vec{k}, \vec{p}_2) plane and the (\vec{q}_1, \vec{q}_2) plane. The phase space integration can be written as a multidimensional integral over the angles θ, φ, ϕ and the Dalitz variables s_1, s_{23} via

$$d\Phi_3 = \frac{ds_1 ds_{23}}{(2\pi)^5 \cdot 32s} d\cos\theta d\varphi d\phi. \quad (18)$$

Note that s_{23} is related to the Mandelstam variables through $s_{23} = m^2 + 2M^2 + s - s_1 - s_2$. The integration range for θ is $[0, \pi]$, while for φ and ϕ one has $(0, 2\pi]$. The upper and lower limits of the Dalitz variables s_1, s_{23} are given by

$$\begin{aligned} (s_{23})_{\max} &= (\sqrt{s} - m)^2, & (s_{23})_{\min} &= 4M^2, \\ (s_1)_{\max} &= (\hat{E}_{p_2} + \hat{E}_{q_1})^2 - \left(\sqrt{(\hat{E}_{p_2})^2 - m^2} - \sqrt{(\hat{E}_{q_1})^2 - M^2} \right)^2, \\ (s_1)_{\min} &= (\hat{E}_{p_2} + \hat{E}_{q_1})^2 - \left(\sqrt{(\hat{E}_{p_2})^2 - m^2} + \sqrt{(\hat{E}_{q_1})^2 - M^2} \right)^2, \end{aligned} \quad (19)$$

where \hat{E}_{p_2} and \hat{E}_{q_1} are the energies of the nucleon and the pion (with momentum q_1) in the two-pion CM frame, respectively:

$$\hat{E}_{p_2} = \frac{s - m^2 - s_{23}}{2\sqrt{s_{23}}}, \quad \hat{E}_{q_1} = \frac{\sqrt{s_{23}}}{2}, \quad (20)$$

with $\sqrt{s_{23}}$ being the invariant mass of the pion pair. By substituting Eq. (18) into Eq. (17) and performing the integration over all the involved variables except s_{23} , one can derive the differential cross section with respect to $\sqrt{s_{23}}$:

$$\frac{d\sigma}{d\sqrt{s_{23}}} = \frac{S}{2(s - m_N^2)} \int |\bar{\mathcal{N}}|^2 2\sqrt{s_{23}} \frac{ds_1}{(2\pi)^5 \cdot 32s} d\cos\theta d\varphi d\phi \quad (21)$$

The spinor for a nucleon polarized along the momentum $\vec{p} = |\vec{p}|(\sin\theta\cos\varphi, \sin\theta\sin\varphi, \cos\theta)$ reads

$$u_\lambda(p) = \begin{pmatrix} \sqrt{p \cdot \sigma} \xi_\lambda \\ \sqrt{p \cdot \bar{\sigma}} \xi_\lambda \end{pmatrix}. \quad (22)$$

where $\sigma^\mu = (\mathbf{1}, \vec{\tau})$, $\bar{\sigma}^\mu = (\mathbf{1}, -\vec{\tau})$. $\xi_+ = \begin{pmatrix} \cos\frac{\theta}{2} \\ e^{i\varphi} \sin\frac{\theta}{2} \end{pmatrix}$ and $\xi_- = \begin{pmatrix} -e^{-i\varphi} \sin\frac{\theta}{2} \\ \cos\frac{\theta}{2} \end{pmatrix}$ represent the helicity $+\frac{1}{2}$ and $-\frac{1}{2}$ respectively. On the other hand, the polarization vector for a circularly polarized photon with helicity $+, -$ are

$$\epsilon_\pm^\mu(k, n) = \left(0, \frac{1}{\sqrt{2}}, \frac{i}{\sqrt{2}}, 0 \right), \quad (23)$$

$$\epsilon_-^\mu(k, n) = (0, \frac{1}{\sqrt{2}}, -\frac{i}{\sqrt{2}}, 0), \quad (24)$$

respectively. Consequently, the helicity amplitude for the physical process P^i of $\gamma N \rightarrow \pi\pi N$ can be defined through

$$\mathcal{N}_{\lambda_1\lambda_2\lambda_3} = \epsilon_{\lambda_1}^\mu(k) \bar{u}_{\lambda_3}(p_2) \mathcal{N}_\mu u_{\lambda_2}(p_1) \quad (25)$$

where \mathcal{N}_μ can be expressed in terms of \mathcal{M}_μ^i with the help of Eq. (15) and Eq. (12). Ignoring the influence of resonance width, some relations among $\mathcal{N}_{\lambda_1\lambda_2\lambda_3}^i$'s can be found

$$\begin{aligned} \mathcal{N}_{+++} &= (\mathcal{N}_{---})^* , & \mathcal{N}_{+--} &= (\mathcal{N}_{-++})^* , \\ \mathcal{N}_{++-} &= -(\mathcal{N}_{--+})^* , & \mathcal{N}_{-+-} &= -(\mathcal{N}_{+-+})^* . \end{aligned} \quad (26)$$

And at threshold, we have

$$\begin{aligned} \mathcal{N}_{+++} &= \mathcal{N}_{---} , \\ \mathcal{N}_{+--} &= \mathcal{N}_{++-}^i = \mathcal{N}_{-+-} = 0 . \end{aligned} \quad (27)$$

Eventually, the total cross section for the scattering of a circularly polarized photon by a proton polarized with its spin parallel ($\sigma_{3/2}$) and anti-parallel ($\sigma_{1/2}$) to the photon spin are

$$\begin{aligned} \sigma_{\frac{3}{2}} &\equiv \frac{S}{4\sqrt{(p_1 \cdot k)^2 - m_{p_1}^2 \cdot m_k^2}} \int \sum_{\lambda_3} |\mathcal{N}_{+-\lambda_3}|^2 d\Phi_3 , \\ \sigma_{\frac{1}{2}} &\equiv \frac{S}{4\sqrt{(p_1 \cdot k)^2 - m_{p_1}^2 \cdot m_k^2}} \int \sum_{\lambda_3} |\mathcal{N}_{++\lambda_3}|^2 d\Phi_3 , \end{aligned} \quad (28)$$

respectively. The beam-target helicity asymmetry of the total cross section is defined to be

$$\Delta\sigma = \sigma_{3/2} - \sigma_{1/2} . \quad (29)$$

2.3 Chiral amplitudes

Figure 2: Topologies of tree-level diagrams of $\gamma N \rightarrow \pi\pi N$ without resonances. The wavy, dashed, and solid lines represent photons, pions and nucleons, respectively. Circled numbers mark the chiral orders of the vertices. Crossed diagrams are not shown.

Topologies of tree-level diagrams for the double pion photoproduction without resonances are displayed in Fig. 2, where i, j, k refer to the chiral orders of the vertices. For the calculation up to $\mathcal{O}(p^2)$, it is worthy noting that the vertex for the interaction between photon and mesons must be $\mathcal{O}(p^2)$. In consequence, one can get all the $\mathcal{O}(p)$ diagrams by uniformly setting the chiral orders of the vertices involving nucleons to be 1. Similarly, all the $\mathcal{O}(p^2)$ diagrams can be obtained by merely setting one of the vertices containing nucleons to $\mathcal{O}(p^2)$, while the remaining ones to $\mathcal{O}(p)$. Expressions of the $\mathcal{O}(p)$ and $\mathcal{O}(p^2)$ non-resonant chiral amplitudes are shown in Appendix B.

Figure 3: Tree diagrams of $\gamma N \rightarrow \pi\pi N$ with $\Delta(1232)$. The wavy, dashed, solid and thick lines represent photons, pions, nucleons and deltas, in order. Circled numbers mark the chiral orders of the vertices. Crossed diagrams are not shown.

Figure 4: Tree diagrams of $\gamma N \rightarrow \pi\pi N$ with Roper resonances. The wavy, dashed, solid and double lines represent photons, pions, nucleons and Ropers, in order. Circled numbers mark the chiral orders of the vertices. Crossed diagrams are not shown.

Figure 5: Tree diagrams of $\gamma N \rightarrow \pi\pi N$ with ρ meson. The wavy, dashed, solid and double wavy lines represent photons, pions, nucleons and ρ mesons, in order. Circled numbers mark the chiral order of the vertices. Crossed diagrams are not shown.

Figure 6: Tree diagrams of $\gamma N \rightarrow \pi\pi N$ with both ρ meson and baryon resonance. The wavy, dashed, solid, double wavy and thick lines represent photons, pions, nucleons, ρ mesons and baryon resonance ($\Delta(1232)$ or Roper) in order. Circled numbers mark the chiral orders of the vertices. Crossed diagrams are not shown.

The tree diagrams with explicit $\Delta(1232)$, $N^*(1440)$, $\rho(770)$ resonances are shown in Figs. 3, 4, 5 and 6, in order. Note that, if the ρ mesons are explicitly included via the Yang-Mills approach, those diagrams of Fig 2, containing the LO photon- π - π , LO π - π -N-N, LO photon- π - π -N-N vertices and $e\bar{\Psi}A\frac{\tau_3}{2}\Psi$, do not show up. As illustrated in Appendix A, their contributions are actually incorporated by the exchange of ρ meson. The expressions of the amplitudes with explicit resonant contributions are too lengthy to be shown here.³

3 Numerical results and discussions

At present, there are few experimental data for double pion photoproduction near threshold with the photon energy $E_\gamma \leq 450$ MeV. The available data we can use are total cross sections of $\gamma p \rightarrow \pi^0\pi^0 p$. For $\gamma p \rightarrow \pi^+\pi^0 n$, one has data on total cross sections, pion-pair invariant-mass distributions and beam-target helicity asymmetry. In what follows, comparisons between our model and the above-mentioned experimental results will be discussed.

3.1 Parameters

In our numerical computation, the parameters m , g , F and M , stemming from the chiral Lagrangians, can be replaced by the corresponding physical ones m_N , g_A , F_π and M_π , respectively. The error caused by such a replacement is of higher order beyond the accuracy we are considering. In the SU(2) isospin limit, the values of the physical quantities are taken to be

$$m_N = 938.27 \text{ MeV}, \quad F_\pi = 92.42 \text{ MeV}, \quad g_A = 1.267, \quad e = 0.303. \quad (30)$$

The pion mass is set as $M_\pi = 139.57$ MeV for the charged channels and $M_\pi = 135$ MeV for the neutral ones. For the $O(p^2)$ πN LECs, we choose the determinations given in Refs. [52]:

$$\begin{aligned} c_1 &= -0.99 \pm 0.02 \text{ GeV}^{-1}, & c_2 &= 1.38 \pm 0.03 \text{ GeV}^{-1}, \\ c_3 &= -2.33 \pm 0.03 \text{ GeV}^{-1}, & c_4 &= 1.71 \pm 0.02 \text{ GeV}^{-1}. \end{aligned} \quad (31)$$

The LECs c_6 and c_7 can be determined by the anomalous magnetic moment of the nucleon $\kappa_p = 1.793$, $\kappa_n = -1.913$ with the help of the following relations [44, 53]

$$c_6 = \kappa_p - \kappa_n + 2m_N \frac{G_\rho}{g_\rho}, \quad c_7 = \kappa_n - m_N \frac{G_\rho}{g_\rho}. \quad (32)$$

For the $\Delta(1232)$, we use $m_\Delta = 1210$ MeV and $h = 1.28 \pm 0.01$ [52]. For the Roper, we take $m_R = 1396$ MeV, $g_{\pi NR} = \pm 0.47$, following Ref. [43]. As for the ρ parameters, $M_\rho = 775$ MeV, $g_\rho = \frac{M_\rho}{\sqrt{2}F_\pi} = 5.93$, and $G_\rho = -16.9 \text{ GeV}^{-1}$ are used [44].

To compare the contributions of different types, we compute the moduli of the helicity amplitude $|\mathcal{N}_{+++}^i|$, defined in Eq. (25), at threshold. Results are shown in Table 1. The resonant width effect have been incorporated by replacing the propagator in the following way,

$$\frac{1}{s - m_\xi^2} \rightarrow \frac{1}{s - m_\xi^2 + im_\xi \Gamma_\xi} \quad (33)$$

where ξ represents $\Delta(1232)$, $N^*(1440)$ or $\rho(770)$. The width of Roper is taken as constant $\Gamma_R = 175$ MeV, but for Δ and ρ we use the energy-dependent results of Ref. [54, 55].

$$\begin{aligned} \Gamma_\Delta(s) &= \frac{h^2 \lambda^{\frac{3}{2}}(s, M^2, m^2)}{192\pi F^2 s^3} [(s - M^2 + m^2)m_\Delta + 2sm], \\ \Gamma_\rho(s) &= \frac{M_\rho s}{96\pi F^2} \left(1 - \frac{4M^2}{s}\right)^{\frac{3}{2}}, \end{aligned} \quad (34)$$

³The expressions of the amplitudes are obtainable from the authors.

where $\lambda(a, b, c) = a^2 + b^2 + c^2 - 2ab - 2ac - 2bc$ is the Källén function.

The effects of the resonances are as follows. It can be seen from the fourth column of Table 1 that, the $\Delta(1232)$ does not contribute to the $\gamma n \rightarrow \pi^0 \pi^0 n$ channel, but makes a small contribution to the $\gamma p \rightarrow \pi^0 \pi^0 p$ channel. As for the other channels, the inclusion of $\Delta(1232)$ leads to sizeable changes in the results. It can also be found that the contributions of Roper are negligible in all the channels. The impact of ρ on the neutral channel is also negligible, but it changes the amplitude of other channels greatly at threshold.

As for non-resonant contributions, the HB ChPT results from Ref. [31] are shown for comparison in Table 1. It should be noted that, in the HB formalism, all the $\mathcal{O}(p^1)$ amplitudes at threshold are zero due to the selection rules. In fact, the $\mathcal{O}(p^1)$ amplitudes are sizable in covariant ChPT for almost all the channels except $\gamma n \rightarrow \pi^0 \pi^0 n$, as can be seen from the second column of Table 1. The $\mathcal{O}(p^2)$ HB results are comparable with our predictions (third column) except for the $\gamma p \rightarrow \pi^0 \pi^0 p$ channel and $\gamma p \rightarrow \pi^+ \pi^- p$ channel.

$ \mathcal{N}_{+++}(P_i) $	Process	$\mathcal{O}(p^1)$	$+\mathcal{O}(p^2)$	$+\Delta$	$+\text{Roper}$	$+\rho$	$\mathcal{O}(p^2)$ in HB ChPT [31]
P ₁ :	$\gamma p \rightarrow \pi^+ \pi^0 n$	9.39	4.55	2.03	1.58	45.47	5.10

3.2 The $\gamma p \rightarrow \pi^0 \pi^0 p$ process

Figure 7: Total cross sections for $\gamma p \rightarrow \pi^0 \pi^0 p$. Data are taken from Ref. [22]. Red short-dashed line represents the sum of various contributions: non-resonant terms up to $\mathcal{O}(p^2)$ (denoted by $\mathcal{O}(p^2)$ for short in the figure), Δ , Roper and ρ resonances. The inner red band stands for the statistical uncertainty propagating from the errors of LECs. The outer red band is obtained by quadratically adding the theoretical error, due to the chiral truncation, to the statistical one. Blue dashed line with bands stands for the result obtained by taking the FSI effect into account. The meaning of the green solid, black dotted and purple dash-dotted lines can be read from the legends.

For $\gamma p \rightarrow \pi^0 \pi^0 p$, we take $M_\pi = 135$ MeV for the neutral pion in the numerical computation. Results of the cross section are shown in Fig. 7. In Fig. 7, the inner bands represent the uncertainties propagated from the errors of the parameters. Specifically, 1000 groups of random numbers for the LECs, c_i and h , are generated with a normal distribution. Then, observables such as cross sections are computed for 1000 times, from which the standard deviations can be determined. The outer bands are obtained by quadratically adding the systematical errors, which are responsible for higher-order contribution due to the truncation in the chiral

series. We follow the method of Ref. [17] to estimate such errors due to the chiral truncation at $\mathcal{O}(p^2)$. Namely, for a given observable X , one has

$$\delta X^{(2)} = \max \left(|X^{(1)}|Q^2, |X^{(2)} - X^{(1)}|Q \right) \quad (35)$$

with $Q = E_\gamma^{\text{CM}}/\Lambda_b$. Here E_γ^{CM} and Λ_b are the photon energy in the CM frame and the breakdown scale of the chiral expansion, respectively. We set $\Lambda_b \sim 4\pi F_\pi \sim 1$ GeV. Appropriate powering counting rules for the resonances are needed for a reasonable estimation with Eq. (35). The inclusion of resonances introduces relevant extra mass scales. Following the treatment in Ref. [43], here we assign $(m_\Delta - m_N) \sim \delta$, $m_R - m_N \sim \delta$ and $\delta^2 \sim M_\pi \sim \mathcal{O}(p^1)$. This counting rule is actually a generalization of the so-called δ counting proposed in Ref. [56], where only the Δ resonance is incorporated. As a result, the contributions of diagrams with explicit Delta and Roper are either $\mathcal{O}(p^{1.5})$ or $\mathcal{O}(p^2)$. As for ρ , we employ the power counting scheme in Ref. [57] and count the ρ meson propagator as $\mathcal{O}(p^0)$.

It can be seen from Fig. 7 that the ChPT predictions are far away from the experimental data. Even in the vicinity of the threshold, large deviation is observed. We have further checked the influence of the $\mathcal{O}(p^3)$ trees, by using the values of the involved $\mathcal{O}(p^3)$ LECs from Ref. [39, 52]. We found that the inclusion of $\mathcal{O}(p^3)$ tree can not make the situation better. On the other hand, it is pointed out in Ref. [58] that there exists strong FSI between the final di-pions in the isospin-zero S-wave channel, corresponding to $IJ = 00$. Since the isospin-zero S-wave FSI is expected to yield sizeable contribution to the $\gamma p \rightarrow \pi^0 \pi^0 p$ process, we proceed with the discussion of the effect of FSI of $\pi^0 \pi^0$.

According to Watson's final-state theorem [59], we incorporate the $\pi\pi$ FSI by means of [60]

$$\mathcal{N}(\gamma p \rightarrow \pi^0 \pi^0 p) = \mathcal{N}_{\text{tree}} \mathcal{P}(s_{23}) \Omega_{00}(s_{23}) . \quad (36)$$

We refer the readers to, e.g. Ref. [61], for review of various approaches of implementing FSI effects. Here, $\mathcal{N}_{\text{tree}}$ denotes the tree-level chiral amplitude, which has already been derived above. The $\Omega_{00}(s_{23})$ is the Omnès function [62] in the $IJ = 00$ channel. Its explicit expression reads

$$\Omega_{00}(s_{23}) = \exp \left[\frac{s_{23} - s_{23}^{\text{th}}}{\pi} \int_{s_{23}^{\text{th}}}^{\infty} \frac{ds'_{23}}{s'_{23} - s_{23}^{\text{th}}} \frac{\delta_{00}(s'_{23})}{s'_{23} - s_{23}} \right] , \quad (37)$$

where $s_{23}^{\text{th}} = 4M_\pi^2$ and the phase shift δ_{00} is taken from the Roy-type equations presented in Ref. [63]. It is sufficient to take $\mathcal{P}(s_{23})$ in Eq. (36) to be a second-order polynomial, i.e.,

$$\mathcal{P}(s_{23}) = 1 + \alpha_1 (s_{23} - 4M_\pi^2) + \alpha_2 (s_{23} - 4M_\pi^2)^2 . \quad (38)$$

The coefficients α_1 and α_2 are free parameters to be determined by fitting experimental data. The fit results are

$$\alpha_1 = (2.16 \pm 0.23) \times 10^2 \text{GeV}^{-2} , \quad \alpha_2 = (-1.05 \pm 0.18) \times 10^4 \text{GeV}^{-4} , \quad (39)$$

with $\chi^2/\text{d.o.f} = 1.96$. The FSI-improved ChPT prediction of cross section is shown by the blue line in Fig. 7. The blue narrow band stands for the statistical errors due to the uncertainties of the parameters including the α_i 's, while the broad band is obtained by taking into account the influence of the theoretical uncertainties due to chiral truncation. Generally speaking, a good description of data is now achieved for $E_\gamma > 340$ MeV, indicating the $IJ = 00$ FSI effect is indeed sizeable. For the energy $E_\gamma < 340$ MeV, deviation still exists. Such deviation is attributed to the absence of the chiral loop contributions, as concluded in Ref. [31].

3.3 The $\gamma p \rightarrow \pi^+ \pi^0 n$ process

For $\gamma p \rightarrow \pi^+ \pi^0 n$, we take $M_\pi = 139.6$ MeV for both charged and neutral pions. Results of total cross section are shown in Fig. 8. It can be seen that the ChPT prediction with only non-resonant $\mathcal{O}(p) + \mathcal{O}(p^2)$ contributions is not adequate to describe the data from Ref. [22, 24]; see the purple dash-dotted curve in Fig. 8. As the incident photon energy increases, the deviation becomes larger and larger. The $\Delta(1232)$ resonance contributes largely, which is necessary for a good agreement with the data in the energy region below 440 MeV. The contribution of the Roper resonance is negligible. The ρ meson increases the modulus of cross section obviously, especially near the threshold. The incorporation of the ρ meson makes the theoretical result well consistent with the experimental data of Ref. [24], but not with the one of Ref. [22]. For the $\gamma p \rightarrow \pi^+ \pi^0 n$ process, there is no need to consider higher-order tree and loop contributions, in the sense that it is already sufficient to establish a good description of data by using the $\mathcal{O}(p^2)$ ChPT result with explicit Δ , Roper and ρ resonances. It is also worthy noting that the FSI of the $\pi^+ \pi^0$ system is dominated by the $IJ = 11$ partial wave, which is actually compensated by the explicit inclusion of the ρ meson.

Figure 8: Cross sections for $\gamma p \rightarrow \pi^+ \pi^0 n$. Data are taken from Ref. [22, 24]. The description of the curves is the same as in Fig. 7.

Besides the total cross section, invariant-mass distribution of pion pair can also be computed with the help of Eq. (21). To confront our model with the experimental measurement in a given energy bin $[E_{\gamma\min}, E_{\gamma\max}]$, we perform a convolution on the differential cross section in the following way,

$$\frac{d\sigma}{d\sqrt{s_{23}}} = \frac{1}{E_{\gamma\max} - E_{\gamma\min}} \int_{E_{\gamma\min}}^{E_{\gamma\max}} \frac{d\sigma(E_\gamma)}{d\sqrt{s_{23}}} dE_\gamma \quad (40)$$

For the photon energy interval [400, 430] MeV, our result of the di-pion invariant mass distribution is shown in Fig. 9. The $\mathcal{O}(p) + \mathcal{O}(p^2)$ non-resonant contribution does not agree with the data, even near the pion-pair production threshold. The $\Delta(1232)$ resonance improves the result significantly, and the theoretical curve with Δ contribution tends to be comparable with some of the data points. Similar to the case of total cross section, the impact of the Roper resonance remains negligible. The effect of the ρ meson is to deform the shape of the curve, leading to a good agreement with data within 1- σ uncertainty. For comparison, we also show the result obtained by an effective model (i.e. MAID model) calculation [27]. It can be seen from the figure that the chiral prediction, up to $\mathcal{O}(p^2)$ with explicit resonances, is much better than the MAID-model determination. However, it should be mentioned that inconsistency occurs for low di-pion invariant masses close to the threshold. That is, the experimental data rise slowly, while the ChPT result grows sharply. The MAID-model calculation suffers from the same problem [27]. This problem is expected to be addressed, in future, by further incorporating leading one-loop contribution with more complicated analytical structure.

We have also calculated the invariant-mass distribution for the energy bin of [430, 460] MeV, which is shown in Fig. 10. Effect of each resonance is similar to the case with energy bin [400, 430] MeV. However, it can be seen from Fig. 10 that the ChPT result starts to fail in describing the data, since the 1- σ error band merely overlaps with the experimental data marginally.

Finally, by making use of Eq. (28), the beam-target helicity asymmetry $\sigma_{3/2} - \sigma_{1/2}$ for $\gamma p \rightarrow \pi^+ \pi^0 n$ is predicted as well. Result is shown in Fig. 11. The available experimental data are close to zero with large error bars [18]. The contribution from the non-resonant terms is identical to zero, so is the Roper resonance. The $\Delta(1232)$ yields a positive value of the asymmetry, due to the fact that it mainly contributes to the total cross section $\sigma_{3/2}$ rather than $\sigma_{1/2}$. On the contrary, the influence of the ρ meson is opposite to that of the $\Delta(1232)$. It contributes much more to $\sigma_{1/2}$ than to $\sigma_{3/2}$, leading to a negative asymmetry eventually.

4 Summary

The double pion photoproduction off nucleons is analyzed in a covariant chiral perturbation theory with pions, nucleons, the $\Delta(1232)$, the $N^*(1440)$ and the ρ resonances as explicit degrees of freedoms. The production amplitudes for all the 6 physical processes are obtained up to $\mathcal{O}(p^2)$. All the parameters involved in the chiral amplitudes have been determined elsewhere, which allows us to make numerical predictions. The findings are as follows.

Figure 9: Pion-pion invariant-mass distribution for $\gamma p \rightarrow \pi^+\pi^0 n$ with incident photon energy bin of 400 – 430 MeV. Data are taken from [22]. The long black dashed line stands for the result by the MAID model [27]. The description of other curves is the same as in Fig. 8.

Figure 10: Pion-pion invariant-mass distribution for $\gamma p \rightarrow \pi^+\pi^0 n$ with incident photon energy bin of 430 – 460 MeV. Data are taken from [22]. The description of the curves is the same as in Fig. 9.

- It is found that, at threshold, all the considered resonances have little contribution to the neutral channels $\gamma N \rightarrow \pi^0\pi^0 N$ with N being proton or neutron, while the $\Delta(1232)$ and ρ resonances contribute largely to the other channels. The effect of the Roper resonance is negligible for all the channels.
- For $\gamma p \rightarrow \pi^0\pi^0 p$, our ChPT prediction of the total cross section is far below the corresponding experimental data. Even if the $\mathcal{O}(p^3)$ tree contribution is taken into account, the large discrepancy persists. The deviation can be remedied by implementing the isoscalar S-wave FSI of the $\pi^0\pi^0$ system, and a good description of data is established.
- For $\gamma p \rightarrow \pi^+\pi^0 n$, our results of total cross section, pion-pair invariant-mass distribution and beam-target helicity asymmetry are in good agreement with the existing experimental data. Sizeable contributions are from the $\mathcal{O}(p) + \mathcal{O}(p^2)$ non-resonant terms, the Δ and the ρ resonances. The impact of the Roper

Figure 11: Beam-target helicity asymmetry for $\gamma p \rightarrow \pi^+ \pi^0 n$. Data are taken from Ref. [18].

resonance is slight and can be neglected. The explicit inclusion of the ρ meson actually accounts for the FSI of the $\pi^+ \pi^0$ system in the $IJ = 11$ channel.

A more comprehensive ChPT analysis can be done at loop-level in the future to achieve better agreement with experimental data. The Roper resonance can be omitted due to its negligible contribution. On the other hand, more data near threshold are required from experiments to pin down the involved LECs that will show up in higher-order ChPT calculations.

A Correspondence between theories with and without the ρ meson

The leading order photon- π - π , π - π -N-N, photon- π - π -N-N interaction terms and $e\bar{\Psi}A\frac{\tau_3}{2}\Psi$ term from $\mathcal{L}_{\pi\pi}^{(2)}$ and $\mathcal{L}_{\pi N}^{(1)}$ will be canceled by the corresponding terms generated from Eq. (9). Their vertices will be replaced by the ones with an internal ρ line inserted, as shown in Fig. 12. The effective theory with ρ as explicit degree of freedom reduces to the ρ -less one by integrating out the ρ meson. Specifically, for the vertices in Fig. 12, one

can expand the ρ propagators and keep the leading term, which leads to the following correspondences:

$$\begin{aligned}
\text{Vertex}_{(2)} &= \left(\frac{ie}{g_\rho} M_\rho^2 \delta^{i3} g^{\mu\alpha} \right) \left[\frac{i\delta^{ij}}{k^2 - M_\rho^2} \left(-g_{\alpha\beta} + \frac{k_\alpha k_\beta}{M_\rho^2} \right) \right] \left[g_\rho \varepsilon^{abj} (q_2^\beta - q_1^\beta) \right] \\
&= e \varepsilon^{ab3} (q_1^\mu - q_2^\mu) + \mathcal{O}(p^3) = \text{Vertex}_{(1)} + \mathcal{O}(p^3) , \\
\text{Vertex}_{(4)} &= [g_\rho \varepsilon^{abi} (q_2^\mu - q_1^\mu)] \left[\frac{i\delta^{ij}}{(q_1 + q_2)^2 - M_\rho^2} \left(-g_{\mu\nu} + \frac{(q_{1\mu} + q_{2\mu})(q_{1\nu} + q_{2\nu})}{M_\rho^2} \right) \right] \left(ig_\rho \gamma^\nu \frac{\tau_j}{2} \right) \\
&= \frac{1}{2F^2} \varepsilon^{abi} \frac{\tau_i}{2} (q_1 - q_2) + \mathcal{O}(p^3) = \text{Vertex}_{(3)} + \mathcal{O}(p^3) , \\
\text{Vertex}_{(6)} &= \left[-\frac{ieM_\rho^2}{2F^2 g_\rho} g^{\mu\alpha} (2\delta_{ab}\delta_{i3} - \delta_{b3}\delta_{ia} - \delta_{a3}\delta_{ib}) \right] \left[\frac{i\delta^{ij}}{q^2 - M_\rho^2} \left(-g_{\alpha\beta} + \frac{q_\alpha q_\beta}{M_\rho^2} \right) \right] \left(ig_\rho \gamma^\beta \frac{\tau_j}{2} \right) \\
&= \frac{ie}{4F^2} \gamma^\mu (2\delta_{ab}\tau_3 - \delta_{a3}\tau_b - \delta_{b3}\tau_a) + \mathcal{O}(p^2) = \text{Vertex}_{(5)} + \mathcal{O}(p^2) , \\
\text{Vertex}_{(8)} + \text{Vertex}_{(9)} &= -ie \frac{1}{2} \gamma^\mu + \left(\frac{ie}{g_\rho} M_\rho^2 \delta^{i3} g^{\mu\alpha} \right) \left[\frac{i\delta^{ij}}{k^2 - M_\rho^2} \left(-g_{\alpha\beta} + \frac{k_\alpha k_\beta}{M_\rho^2} \right) \right] \left(ig_\rho \gamma^\beta \frac{\tau_j}{2} \right) \\
&= -ie Q \gamma^\mu + \mathcal{O}(p^2) = \text{Vertex}_{(7)} + \mathcal{O}(p^2) .
\end{aligned} \tag{41}$$

The difference between the left- and right-hand sides (with and without ρ , respectively) of each equation is of higher order. In another word, the inclusion of the ρ meson accounts for a resummation of higher-order contributions.

Figure 12: Correspondence between the vertices with and without $\rho(770)$. The dashed, solid, wavy, and double wavy lines represent pions, nucleons, photons, and ρ , respectively. Circled numbers mark the chiral orders of the vertices. Q in diagram(g) and $\mathbf{1}$ in diagram(i) represent terms proportional to matrices Q and $\mathbf{1}$, respectively.

B Expressions of non-resonant amplitudes

In this appendix, the $\mathcal{O}(p^1)$ and $\mathcal{O}(p^2)$ non-resonant amplitudes \mathcal{M}_j^i are shown for easy reference. The definition of \mathcal{M}_j^i can be found in Eq. (10) and Eq. (12). The expressions in subsection B.1 (B.2) correspond to the sum of the contributions of the $\mathcal{O}(p^1)$ ($\mathcal{O}(p^2)$) Feynman diagrams in Fig. 2 and their crossed partners.
