Abstract

The mirror energy difference (MED) of the mirror state, especially for states bearing the Thomas-Erhman shift, serves as a source of isospin symmetry breaking. We employ the Gamow shell model, which includes the inter-nucleon correlation and continuum coupling, to investigate the MED for *sd*-shell nuclei by taking the ${}^{18}Ne{}^{18}O$ and ${}^{19}Na{}^{19}O$. Moreover, our calculations also provides good descriptions for the excitation energies and MEDs for the ${}^{18}Ne{}^{18}O$ and ${}^{19}Na{}^{19}O$. Moreover, our calculations also provides good descriptions for the excitation energies and MEDs for the ${}^{18}Ne{}^{14}O$ and ${}^{19}Na{}^{19}O$. Moreover, our calculations also provides good descriptions for the excitation energies and MEDs for the ${}^{18}Ne{}^{14}O$ and ${}^{19}Na{}^{19}O$. Moreover, our calculations also provides good descriptions for the excitation energies and MEDs for the ${}^{18}Ne{}^{14}O$ and ${}^{19}Na{}^{19}O$. Moreover, our calculations also function interaction are different for the mirror states in deeply-bound in proton-rich nuclei bearing the Thomas-Erhman shift, which also contributes to the significant ty contributes to MEDs of mirror states. Moreover, the contributions of the nucleon-nucleon interaction are different for the mirror state, especially for the state of proton-rich nuclei bearing the Thomas-Erhman shift, which also contributes to the significant type properties that exhibit significant generates as the excitation energies in these systems is the fore output of the states of stable nuclei. One of the most significant phenomena observed in these systems is the inounced in nuclei close to the proton drip lines, where the balance between the strong force and the Coulomb force is most acce, the extended wave function is given via the '6'F and '16'N mirror nuclei is primarily due to the unbound proton 16 from 16 for mirror nuclei is primarily due to the unbound proton 16 from 16 main for mirror energed in GSM calculation within the The mirror energy difference (MED) of the mirror state, especially for states bearing the Thomas-Erhman shift, serves as a

of weakly bound and unbound nuclear systems and understanding the mechanisms underlying isospin symmetry breaking in mirror nuclei.

Two possible reasons exist for the states with large MED, of external or internal character. If extended single-particle wave functions of weakly- or unbound s- or p-waves are significantly occupied in the considered states, the large MED is of external nature, as in the TES states [4, 7, 8]. The second possibility,

ing significant TES effects have been identified [3-5, 16]. For instance, the mirror pairs ¹⁸Ne/¹⁸O [3, 17] and ¹⁹Na/¹⁹O [16] serve as notable examples. For the sd-shell nuclei, TES is mainly driven by s-waves. Indeed, the proton $1s_{1/2}$ orbital is weakly bound or unbound in proton drip-line nuclei, whereas the neutron $1s_{1/2}$ is well-bound in their mirror neutron-rich nuclei.

Several theoretical models have been developed to probe the isospin asymmetry for mirror nuclei, especially the MEDs of sd-shell nuclei, such as the standard shell model (SM) [18-21], mean-field calculations [22, 23], and *ab initio* approaches [17, 24–27]. Within the standard SM calculations, weakly bound and

unbound wave functions on eigenenergies are indirectly considered via phenomenologically adjusting the matrix element related to $1s_{1/2}$ orbit [4, 7]. Mean-field calculations, such as the Skyrme-Hartree-Fock, have also been extensively employed in MED studies [22, 23]. However, these models involve parameters that are constrained by data [18, 22, 28]. In recent years, ab initio approaches, such as the ab initio valence-space in-medium similarity renormalization group have also been applied to study MEDs of sd-shell nuclei [5, 6, 17, 24-27, 29], in which, the extended many-body wavefunctions are partially described by using a large number of HO spaces. Moreover, current theoretical calculations have pointed out that the TES is caused by the repulsive Coulomb interaction and the occupations of weakly bound or unbound s- or p-waves for valence protons. However, detailed studies on the mechanism of the TES are also lacking.

One of the major challenges in studying drip line nuclei is accounting for the interplay between configuration-mixing and continuum effects. The Gamow shell model (GSM) [9, 10, 17, 24, 30–35] has emerged as a powerful tool in this regard, as it provides a unified framework to describe the structure of nuclei close to the particle emission threshold and allows for a accurate understanding of the exotic properties in drip line nuclei. Based on the above situation, we employ the GSM to investigate the significant isospin symmetry breaking with large MED values and behind mechanism for the *sd*-shell nuclei, taking the 18 Ne/ 18 O and 19 Na/ 19 O mirror partner as examples.

Method.— GSM is a multiconfiguration shell model framework, which works in the picture of a core plus valence nucleons [32, 36-39]. At the heart of GSM lies the utilization of the one-body Berggren basis [40], which possesses bound, resonance, and scattering states, generated by a finite-range potential, typically of Woods-Saxon (WS) types (see details in Ref. [32, 36, 40]). Contrary to the traditional SM, the GSM Hamiltonian matrix is characterized as complex symmetric [32, 36]. Moreover, the GSM Hamiltonian possesses numerous many-body scattering states, so that the bound or resonance eigenstates are embedded among scattering eigenstates. Thus, one developed the overlap method along with the Jacobi-Davidson method extended to complex-symmetric matrices to diagonalize and identify many-body resonance eigenstates [32, 36, 41]. In the case of well-bound states in traditional SM calculations, the use of the Lanczos method is optimal [13]. As a consequence, the GSM calculation includes both the internucleon correlations and continuum coupling [32, 36, 37].

The many-body Schrödinger equation of GSM Hamiltonian can be solved within the so-called cluster orbital shell model (COSM) formalism [42] (see Refs. [36, 43, 44]). The GSM Hamiltonian in COSM coordinates reads [36, 43, 44]:

$$\hat{H}_{\text{GSM}} = \sum_{i=1}^{A_{val}} \left(\frac{\mathbf{p}_i^2}{2\mu_i} + \hat{U}_i^{(c)} \right) + \sum_{i$$

where A_{val} is the number of valence nucleons, μ_i is the effective mass of the nucleon, $\hat{U}_i^{(c)}$ is represented by a one-body WS potential mimicking the inert core. \hat{V}_{ij} is the residual inter-nucleon interaction, which is modeled by a pionless effective field the-

ory (EFT) interaction [45, 46], and the last term embodies the recoil effects induced by the finite mass of the core M_c . Concerning the used pionless EFT interaction [45, 46], only twobody contact terms up to next-to-next leading-order are considered in the present calculations, and EFT interaction is optimized to reproduce the low-lying states of selected nuclei. The harmonic oscillator (HO) basis used for the representation of the EFT interaction is limited to a few shells. This regularization approach has been recently utilized in Refs. [47–50], and in particular in GSM calculation of unbound neutron-rich oxygen isotopes [38].

In the present work, the ¹⁸Ne/¹⁸O and ¹⁹Na/¹⁹O mirror partners are taken as examples. The doubly magic nucleus ¹⁶O is chosen as the inert core, and the $s_{1/2}$, $p_{1/2,3/2}$ and $d_{3/2,5/2}$ partial waves are represented by the Berggren basis, in which 40 discretization points are used in total for continuum states in each partial wave, and the $f_{5/2.7/2}$ partial waves are treated using the HO basis, in which 6 HO states are adopted for each partial wave. Only the Coulomb force is considered for the isospin non-conserving part of the GSM Hamiltonian. The contribution of the isospin-dependent part of nuclear interaction to TES is small, which is neglected in the present GSM calculations. The adopted Hamiltonian is optimized to produce the selected experimental data of sd-shell nuclei. The calculated excitation energies of ¹⁸Ne/¹⁸O and ¹⁹Na/¹⁹O mirror partners are presented in Tables. 1 and 2, which show good agreements with experimental data [51]. In the following section, the mechanics of mirror energies difference for the ¹⁸Ne/¹⁸O and ¹⁹Na/¹⁹O mirror partners are detail investigated.

Results.— Our GSM calculations accurately describe the excitation energies of low-lying states for the mirror partners ¹⁸Ne/¹⁸O and ¹⁹Na/¹⁹O. To delve deeper into the significant isospin symmetry breaking observed in these mirror nu-

clei, we define the MED for a given state J^{π} as $\text{MED}(J^{\pi}) = E_x(T_z^<, J^{\pi}) - E_x(T_z^>, J^{\pi})$, where $T_z^<$ and $T_z^>$ denote the negative and positive isospin projection $T_z = (N-Z)/2$, respectively, for a mirror pair. We have calculated MED values for mirror states in ¹⁸Ne/¹⁸O and ¹⁹Na/¹⁹O, as presented in Tables 1 and 2, along with experimental data. It is observed that the calculated MED values for low-lying states in the mirror partners ¹⁸Ne/¹⁸O and ¹⁹Na/¹⁹O, align well with the experimental data. However, an exception is noted for the 0⁺₂ state in the ¹⁸Ne/¹⁸O mirror nuclei, where our GSM calculations yield larger values than the experimental data. Both our GSM calculations and the experimental data highlight significant isospin symmetry breaking in the 3⁺₁ state of the ¹⁸Ne/¹⁸O mirror nuclei and the 1/2⁺₁ state of the ¹⁹Na/¹⁹O mirror nuclei, evidenced by their large MED values.

Figure 1: The average occupation numbers for the $s_{1/2}$ and $d_{5/2}$ partial waves in the low-lying states of the ¹⁸Ne/¹⁸O mirror pair, calculated using the GSM above the ¹⁶O core.

Figure 2: Similar to Fig. 1, but for low-lying states in ¹⁹Na/¹⁹O.

To investigate the significant isospin symmetry breaking and

the associated large MEDs, we begin with calculating the average occupations of low-lying states through the GSM. The focus is particularly on the $s_{1/2}$ and $d_{5/2}$ partial waves above the ¹⁶O core for the ¹⁸Ne/¹⁸O and ¹⁹Na/¹⁹O mirror nuclei, as illustrated in Figs. 1 and 2. Notably, other partial waves like $d_{3/2}$, $f_{5/2,7/2}$ exhibit negligible occupations and are, therefore, excluded from these figures. The calculated average occupations reveal almost identical patterns for mirror states within the ¹⁸Ne/¹⁸O and ¹⁹Na/¹⁹O pairs. Our GSM calculations further indicate that states exhibiting significant isospin symmetry breaking with large MED values also show significant occupancy in the $s_{1/2}$ partial waves—markedly higher than in their respective ground states. For instance, the occupations of the $s_{1/2}$ partial wave for the 3_1^+ and $1/2_1^+$ states in the ¹⁸Ne/¹⁸O and ¹⁹Na/¹⁹O mirror pairs, respectively, are substantially greater than those of the ground states. Additionally, our calculations give that the 0^+_2 of ¹⁸Ne/¹⁸O demonstrate a notable $s_{1/2}$ partial wave occupations compared to the ground states, resulting in a large MED. Contrastingly, experimental data give a smaller MED value, hinting at a complex structure of the 0^+_2 states in ${}^{18}\text{Ne}/{}^{18}\text{O}$ that might not be fully captured by ¹⁶O plus valence particles picture.

Figure 3: The calculated radial density distribution of valence protons and valence neutrons for low-lying mirror states in ¹⁸Ne/¹⁸O, respectively, above ¹⁶O inner core, using GSM.

Aligned with results from other theoretical frameworks, such as the standard shell model and the *ab initio* VS-IMSRG approach, our results indicate that the significant isospin symmetry breaking with large MEDs observed in mirror states stem primarily from the extensive occupation of the $s_{1/2}$ partial waves, which is weakly bound or unbound in the protonrich nucleus but deeply bound in its mirror neutron-rich nucleus, called TES. However, a further deep understanding of the mirror state bearing significant isospin symmetry breaking with large MED value is lacking. The GSM is a very suitable model, which properly treats both the inter-nucleon correlations and continuum coupling, to describe the properties of dripline nuclei, including a precious description of the many-body wave

Figure 4: Similar to Fig. 3, but for low-lying states in ¹⁹Na/¹⁹O.

function in the asymptotic regions [38, 52–54].

To elucidate the underlying mechanism of large MEDs, we conduct a detailed analysis of the radial density distributions of mirror states in ¹⁸Ne/¹⁸O and ¹⁹Na/¹⁹O pairs using the GSM. The results allow us to systematically compare the radial distributions of valence protons in proton-rich nuclei and valence neutrons in their neutron-rich mirror counterparts. The results are presented in Figs. 3 and 4 for ¹⁸Ne/¹⁸O and ¹⁹Na/¹⁹O mirror partners, respectively. Our GSM results reveal that the states characterized by minor isospin symmetry breaking with small MEDs exhibit almost identical radial density distributions, which decline sharply in the asymptotic regions, such as the ground states of both ¹⁸Ne/¹⁸O and ¹⁹Na/¹⁹O. This phenomenon is largely attributed to the dominance of $d_{5/2}$ partial waves, which are constrained within the nuclear region by high centrifugal and Coulomb barriers, despite the state being unbound. Conversely, GSM calculations depict the radial density distributions of the 3_1^+ state of 18 Ne and the $1/2_1^+$ state of ¹⁹Na as more extended in the asymptotic region than their neutron-rich counterparts, ¹⁸O and ¹⁹O, respectively. This disparity stems from the non-existent centrifugal barrier for the $s_{1/2}$ partial wave, leading to a more pronounced distribution in the proton-rich nucleus due to the weakly bound or unbound nature of the $s_{1/2}$ partial wave. A similar mechanism underlies the formation of halo nuclei, where the valence nucleons occupy weakly bound s- or p- partial waves, resulting in an extended density distribution due to the minimal or absent centrifugal barrier [9, 43, 55]. Consequently, our GSM calculations provide direct calculations for radial density distribution and unveil that the mirror states demonstrating significant isospin symmetry breaking with large MEDs possess many-body wave functions in proton-rich nuclei that are more extended than those in their neutron-rich mirror states, which add a new dimension to our understanding of the role of isospin symmetry breaking in shaping their properties.

Within the present GSM calculations, the GSM Hamiltonian,

Figure 5: Upper panel: calculated energies (GSM), energies minus the twobody Coulomb contribution (GSM-2BC), and energies minus one- and twobody Coulomb total contributions (GSM-1BC-2BC) of low-lying states of ¹⁸Ne using GSM, along with the energies of mirror states in ¹⁸O, with respect to the ¹⁶O inner core. The GSM results are also compared with experimental data. Lower panel: the contribution for the calculated energy difference between the mirror states.

Figure 6: Similar to Fig. 5, but for low-lying states in ¹⁹Na/¹⁹O.

as shown in Eq. (1), can be divided into nuclear interaction (encompassing core-nucleons and nucleon-nucleon interaction) and Coulomb interaction (including one-body Coulomb (1BC)

interaction between the inner core and valence protons, twobody Coulomb (2BC) interaction between valence protons). We delve into further calculations to dissect the contributions from different parts of the Hamiltonian, aiming to shed light on the underlying mechanisms in mirror states exhibiting significant isospin symmetry breaking with large MED.

The computed energies for the low-lying mirror states in the pairs ¹⁸Ne/¹⁸O and ¹⁹Na/¹⁹O, along with experimental data [51], are showcased in Figs. 5 and 6, respectively. To gain deeper insights, we also present the energy minus 2BC contribution (GSM-2BC) and energy minus 1BC and 2BC contribution (GSM-1BC-2BC) in proton-rich nuclei ¹⁸Ne and ¹⁹Na. Indeed, the GSM-1BC-2BC also corresponds to the contribution of nuclear interaction. Within the isospin symmetry picture, the difference in mirror state energies should solely stem from Coulomb interactions, implying that the GSM-1BC-2BC values for a state in a proton-rich nucleus would be the same as its mirror state in the neutron-rich nucleus.

Our GSM calculation gives that the GSM-1BC-2BC values for the ground states of ¹⁸Ne and ¹⁹Na closely align with the computed ground-state energies of their neutron-rich counterparts, ¹⁸O and ¹⁹O, respectively. The results indicate the preservation of isospin symmetry for these ground states. Conversely, for the excited 3_1^+ state in ${}^{18}\text{Ne}/{}^{18}\text{O}$ and the $1/2_1^+$ state in ${}^{19}\text{Na}/{}^{19}\text{O}$, our GSM calculations showcase a deviation from this symmetry. Specifically, the GSM-1BC-2BC values for the 3_1^+ state of ¹⁸Ne and the $1/2_1^+$ state of ¹⁹Na are more unbound compared to their computed energies of mirror states. To quantitatively examine this discrepancy, we introduce ΔE as the differential metric. ΔE encapsulates the disparity between the GSM-1BC-2BC values in the state of the protonrich nucleus and the energy calculated for the corresponding state in the neutron-rich mirror nucleus, which read as $\Delta E =$ $\langle \Psi_{\text{proton}} | H_{NN} | \Psi_{\text{proton}} \rangle - \langle \Psi_{\text{neutron}} | H_{NN} | \Psi_{\text{neutron}} \rangle$, the Ψ_{proton} and $\Psi_{neutron}$ correspond to the many-body wave function of protonrich and neutron-rich nuclei, respectively. The ΔE corresponds to the difference in the contribution of nuclear interactions in the mirror state.

Our GSM calculations show that both ΔE and Coulomb interactions, including 1BC and 2BC, significantly influence the energy discrepancies observed in mirror states. Predominantly, the Coulomb interaction emerges as the dominant factor contributing to these differences. Illustrated in the lower panels of Figs. 5 and 6, we detail the ΔE , 1BC, and 2BC contributions to the energy differences in the low-lying mirror states of ¹⁸Ne/¹⁸O and ¹⁹Na/¹⁹O mirror pairs. Our GSM results indicate that the energy differences in the ground states of ¹⁸Ne/¹⁸O primarily stem from Coulomb interactions, with ΔE making a minimal contribution. Furthermore, for 19 Na/ 19 O, the ΔE contribution is noted to be around 100 keV. Interestingly, we find varying contributions of ΔE , 1BC, and 2BC across different mirror states within each state. For instance, the 3_1^+ states in ${}^{18}\text{Ne}/{}^{18}\text{O}$ exhibit a higher ΔE contribution and lower Coulomb interactions, relative to their ground states. The heightened ΔE values underscore the distinct nuclear interaction contributions to isospin symmetry breaking in these systems, showcasing the complex interplay of forces that shape the energy landscapes of mirror

nuclei.

In evaluating the MED, the ground state energy of mirror nuclei serves as the baseline, with MED being determined by the discrepancy in excitation energies of corresponding mirror states. Adopting the energy difference of the ground states of mirror nuclei as a reference—illustrated by red dashed lines in Figs. 5 and 6. The difference between the values of ground and excited mirror states corresponds to the MED, highlighted by the red arrows in these figures. The results reveal that both the ΔE values and the Coulomb interaction exhibit significant variations across different mirror states, both contributing to the MED.

Summary.—Based on the GSM calculations, in which both the inter-nucleon correlation and continuum coupling are properly treated, we deduce that significant isospin symmetry breaking in mirror states, leading to large MED values, arises from the occupation of weakly-bound or unbound $s_{1/2}$ partial waves in the proton-rich nucleus, while its counterpart in the neutronrich nucleus remains deeply bound. This dichotomy culminates in a more expansive radial density distribution for states within the proton-rich nucleus, as opposed to their mirror counterparts. Additionally, the difference in radial density distributions between mirror states implies disparate contributions from nuclear interactions, underscored by significant ΔE values, which further highlight the presence of isospin symmetry breaking. Moreover, states with an extended radial density distribution tend to yield smaller Coulomb contributions compared to ground states characterized by more localized distributions. This factor chiefly accounts for the reduced excitation energies in states influenced by the Thomas-Ehrman shift effect, thereby engendering substantial negative MED values in mirror states. Our GSM calculations corroborate that both nuclear and Coulomb interactions play crucial roles in manifesting the significant isospin symmetry breaking associated with significant MED values.
