SUNFLOWERS IN SET SYSTEMS WITH SMALL VC-DIMENSION

JÓZSEF BALOGH, ANTON BERNSHTEYN, MICHELLE DELCOURT, ASAF FERBER, AND HUY TUAN PHAM

ABSTRACT. A family of *r* distinct sets $\{A_1, \ldots, A_r\}$ is an *r*-sunflower if for all $1 \leq i \leq j \leq r$ and $1 \leq i' < j' \leq r$, we have $A_i \cap A_j = A_{i'} \cap A_{j'}$. Erdős and Rado conjectured in 1960 that every family H of ℓ -element sets of size at least $K(r)$ ^{ℓ} contains an *r*-sunflower, where $K(r)$ is some function that depends only on *r*. We prove that if H is a family of ℓ -element sets of VC-dimension at most *d* and $|\mathcal{H}| > (Cr(\log d + \log^* \ell))^{\ell}$ for some absolute constant $C > 0$, then H contains an *r*-sunflower. This improves a recent result of Fox, Pach, and Suk. When $d = 1$, we obtain a sharp bound, namely that $|\mathcal{H}| > (r - 1)^{\ell}$ is sufficient. Along the way, we establish a strengthening of the Kahn–Kalai conjecture for set families of bounded VC-dimension, which is of independent interest.

1. Introduction

All logarithms in this paper are binary and all set systems are finite. A family of *r* distinct sets $\{A_1, \ldots, A_r\}$ is called an *r***-sunflower** (also known as a Δ -system) if for all $1 \leq i \leq j \leq r$ and $1 \leq i' < j' \leq r$, we have $A_i \cap A_j = A_{i'} \cap A_{j'}$. The intersection $A_i \cap A_j$, common to all pairs $1 \leq i \leq j \leq r$, is called the **kernel** of the sunflower. We say that a set family H is *ℓ***-bounded** if all sets in H have size at most ℓ . Let $f_r(\ell)$ denote the maximum size of an *ℓ*-bounded set family H that does not contain an *r*-sunflower. Erdős and Rado [\[ER60\]](#page-12-0) proved the so-called **sunflower lemma**, which states that $f_r(\ell) \leq (r-1)^{\ell} \ell!$, and hence

$$
f_r(\ell)^{1/\ell} = O(r\ell). \tag{1.1}
$$

They also conjectured that $f_r(\ell)^{1/\ell} \leq K(r)$ for some function $K(r)$ that depends only on *r*. In a recent breakthrough, Alweiss, Lovett, Wu, and Zhang [\[Alw+21\]](#page-12-1) improved [\(1.1\)](#page-0-0) to

$$
f_r(\ell)^{1/\ell} = O(r^3 \log \ell \log \log \ell).
$$

The best currently known bound is

$$
f_r(\ell)^{1/\ell} = O(r \log \ell),\tag{1.2}
$$

due to Bell, Chueluecha, and Warnke [\[BCW21\]](#page-12-2) (see also [\[Rao20\]](#page-13-0) for an intermediate result by Rao). Perhaps even more importantly than making progress on the Erdős–Rado sunflower

conjecture, Alweiss, Lovett, Wu, and Zhang [\[Alw+21\]](#page-12-1) invented the so-called **spread method**, which was further developed by Frankston, Kahn, Narayanan, and Park [\[Fra+21\]](#page-12-3), leading to the proof of the Kahn–Kalai conjecture [\[KK07\]](#page-12-4) and Talagrand's selector process conjecture [\[Tal06;](#page-13-1) [Tal10;](#page-13-2) [Tal22\]](#page-13-3) by Park and Pham [\[PP24a;](#page-13-4) [PP24b\]](#page-13-5) and a number of other groundbreaking developments in probabilistic and extremal combinatorics [\[AC23;](#page-12-5) [BFM23;](#page-12-6) [DKP24;](#page-12-7) [DP23;](#page-12-8) [JP24a;](#page-12-9) [JLS23;](#page-12-10) [KNP21;](#page-12-11) [Kan+23;](#page-13-6) [Kan+24;](#page-13-7) [Kee22;](#page-13-8) [KMP23;](#page-13-9) [Pha+23;](#page-13-10) [SSS23;](#page-13-11) [Spi23\]](#page-13-12). We direct the reader to the surveys [\[Par23\]](#page-13-13) by Park and [\[Per24\]](#page-13-14) by Perkins and to Pham's PhD thesis [\[Pha23\]](#page-13-15) for an overview of the area and further references.

The **Vapnik–Chervonenkis dimension**, or **VC-dimension** for short, of a set family H on a ground set X is the maximum d for which there exists a subset $T \subseteq X$ of size d such that for all $A \subseteq T$, there is some $S \in \mathcal{H}$ with $T \cap S = A$. We denote the VC-dimension of a set family H by $VC(H)$. This notion was developed by Vapnik and Chervonenkis [\[VC71\]](#page-13-16) and plays an important role in statistical learning theory [\[SB14;](#page-13-17) [Vap99\]](#page-13-18), discrete and computational geometry [\[CW89;](#page-12-12) [HW87;](#page-12-13) [KPW92\]](#page-13-19), and model theory [\[Sim15\]](#page-13-20). In recent years, it has also found applications in extremal combinatorics, wherein a bound on VC-dimension is used to obtain improved extremal results; see [\[AFN07;](#page-12-14) [CS21;](#page-12-15) [CT20;](#page-12-16) [FPS19;](#page-12-17) [FPS21;](#page-12-18) [JP24b;](#page-12-19) [LS10;](#page-13-21) [TW22\]](#page-13-22) for a selection of papers belonging to this research stream. One such application is an improved bound on the sunflower problem for set families of bounded VC-dimension, recently established by Fox, Pach, and Suk [\[FPS23\]](#page-12-20):

Theorem 1.1 (Fox-Pach–Suk [\[FPS23,](#page-12-20) Theorem 1.3]). The following holds with $C = 2^{10}$. Let H be an *ℓ*-bounded set system with $VC(H) \le d$, where $d \ge 2$. If

$$
|\mathcal{H}|^{1/\ell} \geqslant C^{(dr)^{2\log^* \ell}},
$$

then H contains an *r*-sunflower.

Here $\log^* \ell$ is the **iterated logarithm** of ℓ , i.e., the number of times the binary logarithm function needs to be applied to ℓ before the result becomes at most 1. For constant *d* and *r*, the bound on $|\mathcal{H}|^{1/\ell}$ given by Theorem [1.1](#page-1-0) is doubly-exponential in $\log^* \ell$. In our main result we replace this doubly-exponential dependence by a linear one:

Theorem 1.2 (Main result: a sunflower lemma for set families of bounded VC-dimension)**.** There exists a universal constant $C > 0$ such that the following holds. Let H be an ℓ -bounded set system with $VC(\mathcal{H}) \leq d$, where $d \geq 2$. If

$$
|\mathcal{H}|^{1/\ell} \geqslant Cr(\log d + \log^* \ell),
$$

then H contains an r -sunflower.

Notice that our result also improves Theorem [1.1](#page-1-0) in its dependence on *r* and *d*. In particular, since every *ℓ*-bounded set family H satisfies $VC(H) \leq \ell$, the bound given by our theorem is always at least as good as the general result [\(1.2\)](#page-0-1), up to a constant factor. Furthermore, for $d = \ell^{\circ(1)}$, we get a strict asymptotic improvement on [\(1.2\)](#page-0-1). By contrast, the bound in Theorem [1.1](#page-1-0) can only be better than (1.2) when $d \ll \log \log \ell$. A preliminary version of Theorem [1.2](#page-1-1) with a looser (namely, exponential) dependence on *d* appeared previously in the fifth author's PhD thesis [\[Pha23,](#page-13-15) §4].

In the special case $VC(\mathcal{H}) = 1$ we can be even more precise. In [\[FPS23\]](#page-12-20) the following construction was described to show that there exists an ℓ -bounded set family of size $(r-1)^{\ell}$ with VC-dimension 1 and no *r*-sunflower. Fix a rooted complete $(r - 1)$ -ary tree *T* with the root on level 0 and with $(r-1)^{\ell}$ leaves on level ℓ . Let $\mathcal H$ be the family of the edge sets of

the leaf-to-root paths in T . It is straightforward to check that \mathcal{H} has the required properties. Fox, Pach, and Suk complemented this construction by the following bound:

Theorem 1.3 (Fox–Pach–Suk [\[FPS23,](#page-12-20) Theorem 1.2]). Let H be an ℓ -bounded set system with $VC(\mathcal{H}) \leq 1$. If $|\mathcal{H}| > r^{10\ell}$, then H contains an *r*-sunflower.

In our second result, we improve this by showing that the tree construction is optimal:

Theorem 1.4 (Sharp bound for 1-dimensional families). Let H be an ℓ -bounded set system with $\mathsf{VC}(\mathcal{H}) \leq 1$. If $|\mathcal{H}| > (r-1)^{\ell}$, then \mathcal{H} contains an *r*-sunflower.

Let us now say a few words about the machinery employed in the proof of Theorem [1.2.](#page-1-1) To begin with, we need some notation. For a set system H on a ground set *X*, define

$$
\langle \mathcal{H} \rangle := \{ A \subseteq X : \exists S \in \mathcal{H} \text{ such that } A \supseteq S \}.
$$

For $p \in [0,1]$, let X_p be the probability distribution on $\mathcal{P}(X)$, the power set of X, where a random subset of *X* is generated by including each element independently with probability *p*. For convenience, if $p > 1$, we let $X_p := X_1$ (i.e., if $W \sim X_p$, then $\mathbb{P}[W = X] = 1$). The following result (without explicit constants) was conjectured by Kahn and Kalai [\[KK07\]](#page-12-4). Their conjecture was recently verified by Park and Pham [\[PP24a\]](#page-13-4) (a weaker, fractional variant was established earlier by Frankston, Kahn, Narayanan, and Park [\[Fra+21\]](#page-12-3)). The version we state below is due to Bell [\[Bel23\]](#page-12-21) and includes a refinement of the dependence on *ε*.

Theorem 1.5 (Kahn–Kalai conjecture [\[KK07\]](#page-12-4); Park–Pham [\[PP24a\]](#page-13-4), Bell [\[Bel23\]](#page-12-21))**.** Let H be an ℓ -bounded set system on a ground set X and let $q \in [0,1]$. Then at least one of the following statements holds.

(KK₁) There is a set system
$$
\mathcal{F}
$$
 with $\mathcal{H} \subseteq \langle \mathcal{F} \rangle$ and $\sum_{F \in \mathcal{F}} q^{|F|} \leq \frac{1}{2}$.

(KK₂) For all $\varepsilon \in (0, \frac{1}{2})$ $\frac{1}{2}$, if $p = 48q \log(\ell/\varepsilon)$ and $W \sim X_p$, then $\mathbb{P}[W \in \langle \mathcal{H} \rangle] > 1 - \varepsilon$.

An important general problem is to determine when the logarithmic factor in the definition of p in (KK_2) (KK_2) (KK_2) can be removed; see, e.g., [\[DP23;](#page-12-8) [KNP21;](#page-12-11) [Spi23\]](#page-13-12). We show that for families $\mathcal H$ of bounded VC-dimension, the logarithmic dependence on *ℓ* can be reduced to just log˚ *ℓ*:

Theorem 1.6 (Kahn–Kalai for set families of bounded VC-dimension)**.** There is a universal constant $A > 0$ with the following property. Let H be an ℓ -bounded set system on a ground set X with $VC(\mathcal{H}) \leq d$ and let $q \in [0,1]$. Then at least one of the following statements holds.

(VC₁) There is a set system \mathcal{F} with $\mathcal{H} \subseteq \langle \mathcal{F} \rangle$ and \sum $F \in \mathcal{F}$ $q^{|F|} \leqslant \frac{2}{2}$ 3 .

(VC₂) For all
$$
\varepsilon \in (0, \frac{1}{2}]
$$
, if $p = Aq(\log(d/\varepsilon) + \log^* \ell)$ and $W \sim X_p$, then $\mathbb{P}[W \in \langle \mathcal{H} \rangle] > 1 - \varepsilon$.

For families of VC-dimension 1, Theorem [1.6](#page-2-1) can be further improved by completely eliminating the dependence on *ℓ*:

Theorem 1.7 (Kahn–Kalai for set families of VC-dimension 1)**.** There is a universal constant $A > 0$ with the following property. Let H be a set system on a ground set X with $VC(H) \leq 1$ and let $q \in [0, 1]$. Then at least one of the following statements holds.

(1d₁) There is a set system F with $\mathcal{H} \subseteq \langle \mathcal{F} \rangle$ and $\sum_{i=1}^{n}$ $F \in \mathcal{F}$ $q^{|F|} \leqslant \frac{2}{2}$ 3 . (1d₂) For all $\varepsilon \in (0, \frac{1}{2})$ $\frac{1}{2}$, if $p = Aq \log(1/\varepsilon)$ and $W \sim X_p$, then $\mathbb{P}[W \in \langle \mathcal{H} \rangle] > 1 - \varepsilon$.

The rest of the paper is organized as follows. Theorem [1.4](#page-2-2) is proved in [§2.](#page-3-0) Then, in [§3,](#page-4-0) we prove Theorem [1.6.](#page-2-1) Theorem [1.2](#page-1-1) follows from Theorem [1.6](#page-2-1) in a fairly straightforward manner, inspired by the proof of [\(1.2\)](#page-0-1) due to Bell, Chueluecha, and Warnke [\[BCW21\]](#page-12-2). We present this argument in [§4.](#page-9-0) Finally, in [§5](#page-10-0) we show how to modify the proof of Theorem [1.6](#page-2-1) in the case $d = 1$ to establish Theorem [1.7.](#page-2-3)

Acknowledgments. They also thank Caroline Terry and Anush Tserunyan for useful discussions on the project. The first author is grateful to Robert Krueger for fruitful discussions on the Kahn–Kalai conjecture/Park–Pham theorem. The third author would like to thank Luke Postle and Tom Kelly for a number of enlightening conversations on related topics. The fourth author is grateful to Marcelo Sales for fruitful discussions.

2. Sunflowers in 1-dimensional families: Proof of Theorem [1.4](#page-2-2)

The main part of the proof of Theorem [1.4](#page-2-2) is the following lemma:

Lemma 2.1. Let H be an ℓ -bounded family of sets on a ground set X with $|\mathcal{H}| > (r-1)^{\ell}$. If H contains no *r*-sunflower, then there exist distinct elements $x, y \in X$ and sets S_x, S_y , $S_{xy} \in \mathcal{H}$ such that $\{x, y\} \cap S_x = \{x\}, \{x, y\} \cap S_y = \{y\}, \text{ and } \{x, y\} \cap S_{xy} = \{x, y\}.$

PROOF. We proceed by induction on ℓ . The base case $\ell = 1$ holds vacuously as every 1-bounded set family with at least *r* members contains an *r*-sunflower with an empty kernel. Now suppose $\ell \geq 2$ and the statement holds when ℓ is replaced by $\ell - 1$. Without loss of generality, we assume that every set in $\mathcal H$ has exactly ℓ elements (otherwise we may add $|S| - \ell$ unique new elements to each set $S \in \mathcal{H}$). In particular, the sets in \mathcal{H} are nonempty.

Let $F_1, \ldots, F_t \subseteq \mathcal{H}$ be a maximal sequence of pairwise disjoint sets in \mathcal{H} (it is possible that $t = 1$). Note that $t \leq r - 1$, since otherwise $\{F_1, \ldots, F_t\}$ would be a sunflower (with an empty kernel) of size at least *r*. By the choice of F_1, \ldots, F_t , every set $F \in \mathcal{H}$ intersects at least one of these sets. Therefore, there exists an index $i^* \in [t]$ such that the family $\mathcal{H}_{i^*} := \{ F \in \mathcal{H} : F \cap F_{i^*} \neq \emptyset \}$ satisfies $|\mathcal{H}_{i^*}| \geq |\mathcal{H}|/t > (r-1)^{\ell-1}$.

If there exist $F, F' \in \mathcal{H}_{i^*}$ such that the sets $E := F \cap F_{i^*}$ and $E' := F' \cap F_{i^*}$ are not comparable with respect to inclusion, then choosing any $x \in E \backslash E'$ and $y \in E' \backslash E$ and letting $S_x := F$, $S_y := F'$, and $S_{xy} := F_{i^*}$ completes the proof. Therefore, we may assume that the family of intersections $\mathcal{E} := \{F \cap F_{i^*} : F \in \mathcal{H}_{i^*}\}\)$ forms a chain under inclusion.

Let $E \in \mathcal{E}$ be the minimal element in the chain \mathcal{E} . Then $\emptyset \neq E \subseteq F$ for all $F \in \mathcal{H}_{i^*}$. Consider the set system $\mathcal{H}' := \{ F \setminus E : F \in \mathcal{H}_{i^*} \}$. Since $E \neq \emptyset$, \mathcal{H}' is $(\ell - 1)$ -bounded and satisfies $|\mathcal{H}'| = |\mathcal{H}_{i^*}| > (r-1)^{\ell-1}$. Moreover, it does not contain an *r*-sunflower, since an *r*-sunflower in \mathcal{H}' corresponds to an *r*-sunflower in \mathcal{H} (with a kernel including E). Therefore, by the inductive hypothesis, the conclusion of the lemma holds for \mathcal{H}' , which implies that it also holds for \mathcal{H} .

We are now ready to prove Theorem [1.4,](#page-2-2) which we restate here for convenience.

Theorem [1.4.](#page-2-2) Let H be an *l*-bounded set system on a ground set X with $VC(H) \leq 1$. If $|\mathcal{H}| > (r-1)^{\ell}$, then \mathcal{H} contains an *r*-sunflower.

PROOF. We may assume that $r \geq 3$, as for $r \in \{1, 2\}$ the theorem holds trivially. The proof is by induction on ℓ . If $\ell = 1$, then $\mathcal H$ contains an *r*-sunflower with an empty kernel. Now suppose that $\ell \geq 2$ and the theorem holds when ℓ is replaced by $\ell - 1$.

Suppose that H contains no *r*-sunflower. By Lemma [2.1,](#page-3-1) there exist elements $x, y \in X$ and sets S_x , S_y , $S_{xy} \in \mathcal{H}$ such that $\{x, y\} \cap S_x = \{x\}$, $\{x, y\} \cap S_y = \{y\}$, and $\{x, y\} \cap S_{xy} = \{x, y\}$. Since $VC(H) \le 1$, there must be some $A \subseteq \{x, y\}$ such that $A \ne \{x, y\} \cap S$ for all $S \in \mathcal{H}$. Due to the existence of the sets S_x , S_y , S_{xy} , the only option for *A* is $A = \emptyset$. In other words, every set $S \in \mathcal{H}$ has a nonempty intersection with $\{x, y\}$. It follows that there exists $z \in \{x, y\}$ such that the subfamily $\mathcal{H}_z \coloneqq \{ S \in \mathcal{H} : z \in S \}$ satisfies $|\mathcal{H}_z| \geq |\mathcal{H}|/2 > (r-1)^{\ell-1}$ (here we use our assumption that $r \geq 3$).

Consider the $(\ell - 1)$ -bounded family $\mathcal{H}' := \{ S \setminus \{ z \} : S \in \mathcal{H}_z \}$. It is clear that $\mathsf{VC}(\mathcal{H}') \leq$ $\mathsf{VC}(\mathcal{H}) \leq 1$. As $|\mathcal{H}'| = |\mathcal{H}_z| > (r-1)^{\ell-1}$, we conclude that \mathcal{H}' contains an *r*-sunflower by the inductive hypothesis. But an *r*-sunflower in \mathcal{H}' corresponds to an *r*-sunflower in \mathcal{H} (with a kernel containing *z*), so H has an *r*-sunflower as well, and we are done.

3. Kahn–Kalai for low-dimensional families: Proof of Theorem [1.6](#page-2-1)

3.1. Preliminaries

Throughout the proof of Theorem [1.6,](#page-2-1) we will frequently invoke the following simple observation, which follows immediately from the definition of VC-dimension:

Observation 3.1. Let H be a set system on a ground set X and let $U \subseteq X$. Define the **trace** of H on *U* by $\mathcal{H}|_U := \{ S \cap U : S \in \mathcal{H} \}$. Then $VC(\mathcal{H}|_U) \le VC(\mathcal{H})$.

The following famous result of Sauer [\[Sau72\]](#page-13-23), Perles and Shelah [\[She72\]](#page-13-24), and Vapnik and Chervonenkis [\[VC71\]](#page-13-16) bounds the cardinality of a set family in terms of its VC-dimension:

Lemma 3.2 (Sauer–Shelah lemma [\[Sau72;](#page-13-23) [She72;](#page-13-24) [VC71\]](#page-13-16); see [\[SB14,](#page-13-17) Lemma 6.10])**.** Let H be a set system on a ground set *X* with $VC(\mathcal{H}) \le d \le |X|$. Then

$$
|\mathcal{H}| \leq \sum_{i=0}^d \binom{|X|}{i} \leq \left(\frac{e|X|}{d}\right)^d.
$$

Importantly, due to Observation [3.1,](#page-4-1) the bound given by Lemma [3.2](#page-4-2) also applies to the trace of H on any subset of X . This fact is the only property of VC-dimension we shall rely on in our proof of Theorem [1.6.](#page-2-1)

Before moving on, we make a technical remark regarding the log^* function. Our proof of Theorem [1.6](#page-2-1) will proceed by induction on *ℓ*. As a result, it is somewhat inconvenient for our purposes that \log^* is piecewise constant, as we would like to use the inequality $\log^* \ell' < \log^* \ell$ for the value $\ell' < \ell$ to which the inductive hypothesis is applied. To solve this issue, we slightly alter the definition of log^{*} to "smooth it out," as follows. The usual definition is that $\log^* \ell = t$ if ℓ is between the towers of 2s of heights $t - 1$ and t . For example, $\log^* \ell = 4$ for

$$
16 = 2^{2^2} < \ell \leq 2^{2^{2^2}} = 65536.
$$

We modify this by splitting the interval between the two towers of 2s at the point where the top 2 in the first tower is replaced by a 3 and letting $\log^* \ell := t$ in the first half of the interval and $\log^* \ell := t + 1/2$ in the second half. For example, we have

$$
\log^* \ell = 4 \iff 2^{2^2} < \ell \leq 2^{2^3} \text{ and } \log^* \ell = 4.5 \iff 2^{2^3} < \ell \leq 2^{2^{2^2}}.
$$

With this convention, the following holds (we omit the routine proof):

Claim 3.3. For $x > 8$, the following relation holds: $\log^*(x^2) + \frac{1}{2} \leq \log^*(2^x)$.

Clearly, since we may adjust the values of the constant factors in our results, it does not matter whether we use our definition of log˚ or the standard one.

3.2. A double counting argument

The heart of the proof of Theorem [1.6](#page-2-1) is in a certain double counting argument, analogous to the one employed by Park and Pham in their proof of the Kahn–Kalai conjecture [\[PP24a,](#page-13-4) Lemma 2.1, but using the VC-dimension of H to strengthen the bound.

Let H be a set system on a ground set X. For a set system S , we define S^{\downarrow} to be the set of all inclusion-minimal members of S. Given a subset $W \subseteq X$, we let

$$
\mathcal{H}_W := \{S \setminus W : S \in \mathcal{H}\}^{\downarrow} = (\mathcal{H}|_{X \setminus W})^{\downarrow},
$$

where $\mathcal{H}|_{X\setminus W}$ is the trace of H on $X\setminus W$ (as defined in Observation [3.1\)](#page-4-1). For a set $A \in \langle \mathcal{H} \rangle$, the H-core of A, denoted by core $\mathcal{H}(A)$, is the intersection of all sets $S \in \mathcal{H}$ such that $S \subseteq A$ (note that there exists at least one such set *S* because $A \in \langle \mathcal{H} \rangle$).

Lemma 3.4. For any $W \subseteq X$ and $F \in \mathcal{H}_W$, we have $W \cup F \in \langle \mathcal{H} \rangle$ and $F \subseteq \text{core}_{\mathcal{H}}(W \cup F)$.

PROOF. Since $F \in \mathcal{H}_W$, there is some $S \in \mathcal{H}$ such that $F = S \backslash W$, from which it follows that $S \subseteq W \cup F$ and hence $W \cup F \in \langle \mathcal{H} \rangle$. The minimality of *F* implies that *F* is contained in every set $S \in \mathcal{H}$ with $S \subseteq W \cup F$, therefore $F \subseteq \mathsf{core}_{\mathcal{H}}(W \cup F)$.

Given a set $W \subseteq X$, for each $S \in \mathcal{H}$, we let $F_{\mathcal{H},W}(S)$ be an arbitrary fixed set $F \in \mathcal{H}_W$ such that $F \subseteq S \backslash W$, which exists by the definition of \mathcal{H}_W . We also let

$$
F_{\mathcal{H},W}^*(S) \ := \ S \cap \mathsf{core}_{\mathcal{H}}(W \cup F_{\mathcal{H},W}(S)).
$$

It follows from the definitions and Lemma [3.4](#page-5-0) that

$$
F_{\mathcal{H},W}(S) \subseteq F_{\mathcal{H},W}^*(S) \subseteq S \quad \text{and} \quad F_{\mathcal{H},W}^*(S) \backslash W = F_{\mathcal{H},W}(S). \tag{3.1}
$$

For $t \geqslant 0$ we define

$$
\mathcal{H}_{W,t}^{\text{small}} := \{ F_{\mathcal{H},W}(S) : S \in \mathcal{H}, |F_{\mathcal{H},W}(S)| < t \}
$$

$$
\mathcal{H}_{W,t}^{\text{large}} := \{ F_{\mathcal{H},W}^*(S) : S \in \mathcal{H}, |F_{\mathcal{H},W}(S)| \ge t \}.
$$

The following lemma records some basic properties of $\mathcal{H}_{W,t}^{\text{small}}$ and $\mathcal{H}_{W,t}^{\text{large}}$.

Lemma 3.5. For all $W \subseteq X$ and $t \geq 0$, the following holds.

- (1) $\mathcal{H} \subseteq \langle \mathcal{H}_{W,t}^{\text{small}} \cup \mathcal{H}_{W,t}^{\text{large}} \rangle.$
- (2) The set system $\mathcal{H}_{W,t}^{\text{small}}$ is *t*-bounded.
- (3) If for some set $W' \subseteq X$, we have $W' \in \langle \mathcal{H}_{W,t}^{\text{small}} \rangle$, then $W \cup W' \in \langle \mathcal{H} \rangle$.
- (4) $\mathsf{VC}(\mathcal{H}_{W,t}^{\textsf{small}}) \leq \mathsf{VC}(\mathcal{H})$.
- (5) For all $F \in \mathcal{H}_{W,t}^{\text{large}}$, we have $|F \setminus W| \geq t$.

PROOF. Follows immediately from the definitions, relations [\(3.1\)](#page-5-1), and Observation [3.1.](#page-4-1) ■

We are now ready to state our main double counting lemma:

Lemma 3.6. Suppose the VC-dimension of H is at most $d \leq \ell$. Let p, $q \in [0,1]$ be such that $p \ge 2q$ and let $W \sim X_p$ be a random subset of *X*. Then, for all $t \ge 0$,

$$
\mathbb{E}\left[\sum_{F \,\in\, \mathcal{H}^{\text{large}}_{W,t}} q^{|F|} \right] \,\leqslant\, 2\,\left(\frac{e\ell}{d}\right)^d \,\left(\frac{q}{p}\right)^t.
$$

PROOF. Let $n \coloneqq |X|$ and write

$$
\mathbb{E}\left[\sum_{F \in \mathcal{H}_{W,t}^{\text{large}}} q^{|F|}\right] = \sum_{W \subseteq X} \sum_{F \in \mathcal{H}_{W,t}^{\text{large}}} q^{|F|} p^{|W|} (1-p)^{n-|W|}
$$

=
$$
\sum_{w=0}^{n} \sum_{k=t}^{\ell} q^k p^w (1-p)^{n-w} \cdot \left| \left\{ (W,F) : |W| = w, F \in \mathcal{H}_{W,t}^{\text{large}}, |F| = k \right\} \right|.
$$

Fix $k \in [t, \ell]$ and let us count the pairs (W, F) as above (this step is the crux of the proof). Say $|F\backslash W| = j$, so $t \leq j \leq k$ by Lemma [3.5](#page-5-2)[\(5\).](#page-5-3) Following Park and Pham's proof of [\[PP24a,](#page-13-4) Say $|F \setminus W| = j$, so $t \le j \le k$ by Lemma 3.5(5). Following Park and Pham's proof Lemma 2.1], we first fix the union $Z := W \cup F$, for which there are at most ${n \choose m+1}$ $\binom{n}{w+j}$ choices. Importantly, the H-core $\mathsf{core}_{\mathcal{H}}(Z)$ is uniquely determined by *Z* and has size at most ℓ . Since $F \in \mathcal{H}_{W,t}^{\text{large}}$, we have $F = S \cap \text{core}_{\mathcal{H}}(Z)$ for some $S \in \mathcal{H}$ by definition. Thus, as $\mathsf{VC}(\mathcal{H}) \leq d \leq \ell$, the Sauer–Shelah lemma (Lemma [3.2\)](#page-4-2) applied to $\mathcal{H}|_{\mathsf{core}_{\mathcal{H}}(Z)}$ in place of \mathcal{H} implies that there are at most $(e\ell/d)^d$ choices for *F* given *Z*. Finally, given *F* with $|F| = k$, there are at most *k* f_j^k choices for the subset $F\backslash W \subseteq F$ of size *j*, which, together with *Z*, determines *W*. Putting everything together, the quantity we want to bound is at most

$$
\sum_{w=0}^{n} \sum_{k=t}^{\ell} q^k p^w (1-p)^{n-w} \sum_{j=t}^{k} {n \choose w+j} \left(\frac{e\ell}{d}\right)^d {k \choose j}
$$

$$
= \left(\frac{e\ell}{d}\right)^d \sum_{w=0}^{n} p^w (1-p)^{n-w} \sum_{j=t}^{\ell} {n \choose w+j} \sum_{k=j}^{\ell} q^k {k \choose j}. \tag{3.2}
$$

Next we notice that

$$
\sum_{k=j}^{\infty} q^k \binom{k}{j} = \frac{q^j}{(1-q)^{j+1}},
$$

so the last expression in [\(3.2\)](#page-6-0) is bounded above by

$$
\left(\frac{e\ell}{d}\right)^d \sum_{w=0}^n p^w (1-p)^{n-w} \sum_{j=t}^\ell {n \choose w+j} \frac{q^j}{(1-q)^{j+1}}
$$
\n
$$
= \left(\frac{e\ell}{d}\right)^d \sum_{j=t}^\ell \frac{q^j}{(1-q)^{j+1}} \sum_{w=0}^n {n \choose w+j} p^w (1-p)^{n-w}
$$
\n
$$
= \left(\frac{e\ell}{d}\right)^d \sum_{j=t}^\ell \frac{q^j (1-p)^j}{(1-q)^{j+1} p^j} \sum_{w=0}^n {n \choose w+j} p^{w+j} (1-p)^{n-w-j}.
$$
\n(3.3)

Observe that

$$
\sum_{w=0}^{n} {n \choose w+j} p^{w+j} (1-p)^{n-w-j} \leq \sum_{s \in \mathbb{Z}} {n \choose s} p^{s} (1-p)^{n-s} = 1,
$$

so the last expression in [\(3.3\)](#page-6-1) is at most

$$
\left(\frac{e\ell}{d}\right)^d\sum_{j=t}^\ell\frac{q^j(1-p)^j}{(1-q)^{j+1}p^j}\ \leqslant\ \left(\frac{e\ell}{d}\right)^d\frac{1}{1-q}\sum_{j=t}^\infty\left(\frac{q(1-p)}{(1-q)p}\right)^j\ =\ \left(\frac{e\ell}{d}\right)^d\frac{p}{p-q}\left(\frac{q(1-p)}{(1-q)p}\right)^t.
$$

Finally, note that since $p \ge 2q$ by assumption, we have $p/(p-q) \le 2$ and $(1-p)/(1-q) \le 1$, so the last expression is bounded above by the desired quantity

$$
2\left(\frac{e\ell}{d}\right)^d\left(\frac{q}{p}\right)^t.
$$

3.3. Induction on *ℓ*

We now have all the ingredients necessary to prove Theorem [1.6.](#page-2-1) We first establish a slightly more technical statement designed to facilitate the inductive argument. For $d, \ell \in \mathbb{N}$, let

$$
\lambda_d(\ell) := \begin{cases}\n\log^* \ell + 2 & \text{if } \ell > 2^{3d}, \\
\log^* \ell + 1 & \text{if } 9d^2 < \ell \leq 2^{3d}, \\
\log^* \ell & \text{if } \ell \leq 9d^2.\n\end{cases}
$$

Recall that here we use the variant of the log^* function described in [§3.1.](#page-4-3)

Theorem 3.7. There is a universal constant $C > 0$ with the following property. Let H be an *l*-bounded set system on a ground set *X* with $\mathsf{VC}(\mathcal{H}) \leq d$ and let $q \in [0,1]$. Choose $\varepsilon \in (0, \frac{1}{2})$ $rac{1}{2}$ and let $\ell_0 \coloneqq 300 \, (d/\varepsilon)^3$. Then at least one of the following statements holds.

 $(Ind₁)$ There is a set system $\mathcal F$ with

$$
\mathcal{H} \subseteq \langle \mathcal{F} \rangle \text{ and } \sum_{F \in \mathcal{F}} q^{|F|} \leq \frac{1}{2} + 2 \sum_{i=\ell_0}^{\ell} \left(\frac{e}{di}\right)^d.
$$

 (Ind_2) For $p = Cq(log(d/\varepsilon) + \lambda_d(\ell))$ and $W \sim X_p$, we have

$$
\mathbb{P}[W \in \langle \mathcal{H} \rangle] \, > \, 1 - \varepsilon - \sum_{i=\ell_0}^\ell i^{-d}.
$$

PROOF. Let $C > 0$ be a constant that we will assume to be sufficiently large for all of the inequalities that appear in the sequel to hold. We fix *d* and prove the result by induction on let *l*. Note that we do not assume $d = \mathsf{VC}(\mathcal{H})$; in particular, it is possible that $d > l$.

Base case: $\ell \leq \ell_0$.

We apply Theorem [1.5,](#page-2-4) i.e., the Kahn–Kalai conjecture. If (KK_1) (KK_1) (KK_1) holds, then we are done as it implies ([Ind](#page-7-1)₁). On the other hand, (KK_2) (KK_2) (KK_2) yields (Ind₂) because

$$
48q \log(\ell/\varepsilon) \leqslant 48q \log(300 d^3/\varepsilon^4) < Cq \log(d/\varepsilon),
$$

where in the last step we use that *C* is large enough.

Inductive step: $\ell > \ell_0$ and the theorem holds for all smaller values of ℓ .

Now $\ell > d$, so Lemma [3.6](#page-6-2) can be applied. Pick $W_0 \sim X_{2q}$, set $t := 3d \log \ell$, and let

 $\mathcal{H}' \coloneqq \mathcal{H}_{W_0,t}^{\textsf{small}} \qquad \text{and} \qquad \mathcal{F}_0 \coloneqq \mathcal{H}_{W_0,t}^{\textsf{large}}.$

(This notation is defined in [§3.2.](#page-5-4)) By Lemma [3.6](#page-6-2) and Markov's inequality, $\tilde{}$

$$
\mathbb{P}\left[\sum_{F \in \mathcal{F}_0} q^{|F|} \ge 2\left(\frac{e}{d\ell}\right)^d\right] \le \ell^{2d} 2^{-t} = \ell^{-d}.\tag{3.4}
$$

By parts [\(2\)](#page-5-5) and [\(4\)](#page-5-6) of Lemma [3.5,](#page-5-2) \mathcal{H}' is *t*-bounded and $\mathsf{VC}(\mathcal{H}') \leq d$. Since $\ell > \ell_0$, we have $t < \ell$, so, by the inductive hypothesis applied to \mathcal{H}' , at least one of the following holds: (Ind'₁) There is a set system \mathcal{F}' with

$$
\mathcal{H}' \subseteq \langle \mathcal{F}' \rangle \quad \text{and} \quad \sum_{F \in \mathcal{F}'} q^{|F|} \leq \frac{1}{2} + 2 \sum_{i=\ell_0}^t \left(\frac{e}{di}\right)^d.
$$

 (Ind'_2) For $p' = Cq(\log(d/\varepsilon) + \lambda_d(t))$ and $W' \sim X_{p'}$, we have

$$
\mathbb{P}[W' \in \langle \mathcal{H}' \rangle] > 1 - \varepsilon - \sum_{i=\ell_0}^t i^{-d}.
$$

We emphasize that whether (Ind_1') (Ind_1') (Ind_1') or (Ind_2') holds depends on the random set W_0 .

Case 1: ([Ind](#page-8-0)₁) happens with probability $\alpha > \ell^{-d}$.

When (Ind_1') (Ind_1') (Ind_1') holds, we let \mathcal{F}' be a set system as in (Ind_1') and define $\mathcal{F} := \mathcal{F}_0 \cup \mathcal{F}'$. Then, by Lemma [3.5](#page-5-2)[\(1\),](#page-5-7) $\mathcal{H} \subseteq \langle \mathcal{F} \rangle$. Moreover, by [\(3.4\)](#page-8-2), with probability at least $\alpha - \ell^{-d} > 0$,

$$
\sum_{F \in \mathcal{F}} q^{|F|} \leq \frac{1}{2} + 2 \sum_{i=\ell_0}^t \left(\frac{e}{di}\right)^d + 2 \left(\frac{e}{d\ell}\right)^d \leq \frac{1}{2} + 2 \sum_{i=\ell_0}^\ell \left(\frac{e}{di}\right)^d,
$$

and hence $(Ind₁)$ $(Ind₁)$ $(Ind₁)$ is satisfied.

Case 2: ([Ind](#page-8-0)'₁) happens with probability at most ℓ^{-d} .

Set $p' := Cq(\log(d/\varepsilon) + \lambda_d(t))$, choose $W' \sim X_{p'}$ independently of W_0 , and let $W := W_0 \cup W'$. Note that $W \sim X_\tau$ for some

$$
\tau \leq 2q + p' = Cq \log(d/\varepsilon) + Cq \lambda_d(3d \log \ell) + 2q. \tag{3.5}
$$

We claim that, assuming *C* is sufficiently large,

$$
\lambda_d(3d\log\ell) + \frac{2}{C} \leq \lambda_d(\ell). \tag{3.6}
$$

Indeed, note that $\ell > \ell_0 > 9d^2$. If $\ell \leq 2^{3d}$, then $3d \log \ell \leq 9d^2$, which means that in this case

$$
\lambda_d(\ell) = \log^*(\ell) + 1 \ge \log^*(3d \log \ell) + 1 = \lambda_d(3d \log \ell) + 1,
$$

and we are done for $C \ge 2$. On the other hand, if $\ell > 2^{3d}$, then we use Claim [3.3](#page-4-4) to write

$$
\lambda_d(\ell) = \log^* \ell + 2 \geqslant \log^* (\log^2 \ell) + 1/2 + 2
$$

$$
\geqslant \log^* (3d \log \ell) + 1/2 + 2 \geqslant \lambda_d (3d \log \ell) + 1/2,
$$

and we are done assuming $C \geq 4$.

Putting [\(3.5\)](#page-8-3) and [\(3.6\)](#page-8-4) together, we see that

$$
\tau \leqslant Cq(\log(d/\varepsilon) + \lambda_d(\ell)) = p.
$$

Now, using Lemma [3.5](#page-5-2)[\(3\),](#page-5-8) we obtain

$$
\mathbb{P}[W \in \langle \mathcal{H} \rangle] \ge \mathbb{P}[(\text{Ind}_2')]\, \mathbb{P}[W' \in \langle \mathcal{H}' \rangle | (\text{Ind}_2')] \ge 1 - \ell^{-d} - \varepsilon - \sum_{i=\ell_0}^t i^{-d} \ge 1 - \varepsilon - \sum_{i=\ell_0}^\ell i^{-d},
$$
\nwhich yields (Ind_2) and finishes the proof.

Now it is easy to derive Theorem [1.6,](#page-2-1) which we restate here for convenience:

Theorem [1.6.](#page-2-1) There is a universal constant $A > 0$ with the following property. Let H be an *ℓ*-bounded set system on a ground set X with $VC(H) \le d$ and let $q \in [0, 1]$. Then at least one of the following statements holds.

(VC₁) There is a set system
$$
\mathcal{F}
$$
 with $\mathcal{H} \subseteq \langle \mathcal{F} \rangle$ and $\sum_{F \in \mathcal{F}} q^{|F|} \leq \frac{2}{3}$.

(VC₂) For all
$$
\varepsilon \in (0, \frac{1}{2}]
$$
, if $p = Aq(\log(d/\varepsilon) + \log^* \ell)$ and $W \sim X_p$, then $\mathbb{P}[W \in \langle \mathcal{H} \rangle] > 1 - \varepsilon$.

PROOF. Without loss of generality, we may assume that $d \geq 2$. Let C be the constant from Theorem [3.7.](#page-7-2) We will show that Theorem [1.6](#page-2-1) holds with $A = 4C$. Apply Theorem [3.7](#page-7-2) with *ε*/2 in place of *ε*. Then $\ell_0 = 2400(d/\varepsilon)^3$ and ([Ind](#page-7-1)₂) is stated for $W \sim X_{p'}$, where

$$
p' = Cq(\log(2d/\varepsilon) + \lambda_d(\ell)) \leq Cq(\log(d/\varepsilon) + \log^*(\ell) + 3) \leq p.
$$

Thus, to verify that (Ind_1) (Ind_1) (Ind_1) and (Ind_2) imply (VC_1) (VC_1) (VC_1) and (VC_2) , it is enough to check that

$$
2\sum_{i=\ell_0}^{\ell} \left(\frac{e}{di}\right)^d \leq 2\sum_{i=\ell_0}^{\ell} \left(\frac{e}{di}\right)^2 \leq \frac{3e^2}{d^2\ell_0} \leq \frac{e^2 \varepsilon^3}{800d^5} < \frac{1}{6},
$$
\n
$$
\sum_{i=\ell_0}^{\ell} i^{-d} \leq \sum_{i=\ell_0}^{\ell} i^{-2} < \frac{2}{\ell_0} < \frac{\varepsilon^3}{1200d^3} < \frac{\varepsilon}{2}.
$$

4. Sunflowers in low-dimensional families: Proof of Theorem [1.2](#page-1-1)

Let us state the theorem again:

Theorem [1.2.](#page-1-1) There exists a universal constant $C > 0$ such that the following holds. Let H be an *ℓ*-bounded set system with $VC(H) \le d$, where $d \ge 2$. If

$$
|\mathcal{H}|^{1/\ell} \geqslant Cr(\log d + \log^* \ell),
$$

then H contains an r -sunflower.

PROOF. We fix *d* and proceed by induction on ℓ . The base case $\ell \leq 1$ is trivial. Suppose $\ell > 1$ and the statement holds for all smaller values. Let $C \coloneqq 10A$, where *A* is the constant from Theorem [1.6,](#page-2-1) and set

$$
Q := Cr(\log d + \log^* \ell), \text{ so } |\mathcal{H}| \geq Q^{\ell}.
$$

The constant *C* is chosen so that $Q \geq 2Ar(\log(2d) + \log^* \ell)$. Therefore, applying Theorem [1.6](#page-2-1) with $p = 1/(2r)$ and $\varepsilon = 1/2$, we arrive at two cases.

Case 1: For $W \sim X_{1/(2r)}$ we have $\mathbb{P}[W \in \langle \mathcal{H} \rangle] > 1/2$.

By partitioning *X* into 2*r* subsets uniformly at random, we see that in expectation at least r of them include a set from H . This implies that H must contain r pairwise disjoint sets (i.e., an *r*-sunflower with an empty kernel).

Case 2: There is a set system $\mathcal F$ with

$$
\mathcal{H} \subseteq \langle \mathcal{F} \rangle \quad \text{and} \quad \sum_{F \in \mathcal{F}} q^{|F|} \leqslant \frac{2}{3},
$$

where $q := Q^{-1}$. Note that $\emptyset \notin \mathcal{F}$ since $1 > 2/3$. For each $i \geq 1$, we let

$$
\mathcal{F}_i := \{ F \in \mathcal{F} : |F| = i \}.
$$

For each $F \in \mathcal{F}$, let \mathcal{H}_F be the set of all $S \in \mathcal{H}$ such that $F \subseteq S$. If for some $F \in \mathcal{F}_i$, we have $|\mathcal{H}_F| \geqslant Q^{\ell-i}$, then we may apply the inductive hypothesis to the set system $\{S \setminus F : S \in \mathcal{H}_F\}$ to find an *r*-sunflower in \mathcal{H}_F (and hence in \mathcal{H}) with a kernel including *F*. Thus, we may assume that $|\mathcal{H}_F| < Q^{\ell-i}$ for all $F \in \mathcal{F}_i$. Since $\mathcal{H} = \bigcup_{F \in \mathcal{F}} \mathcal{H}_F$, this yields

$$
Q^{\ell} \leq |\mathcal{H}| < \sum_{i=1}^{\infty} Q^{\ell-i} |\mathcal{F}_i| = Q^{\ell} \sum_{i=1}^{\infty} q^i |\mathcal{F}_i| = Q^{\ell} \sum_{F \in \mathcal{F}} q^{|F|} \leq \frac{2}{3} Q^{\ell},
$$

a contradiction.

5. Kahn–Kalai for 1-dimensional families: Proof of Theorem [1.7](#page-2-3)

Let us state Theorem [1.7](#page-2-3) again:

Theorem [1.7.](#page-2-3) There is a universal constant $A > 0$ with the following property. Let H be a set system on a ground set X with $VC(H) \leq 1$ and let $q \in [0,1]$. Then at least one of the following statements holds.

(1d₁) There is a set system F with $\mathcal{H} \subseteq \langle \mathcal{F} \rangle$ and \sum $F \in \mathcal{F}$ $q^{|F|} \leqslant \frac{2}{2}$ 3 .

(1d₂) For all $\varepsilon \in (0, \frac{1}{2})$ $\frac{1}{2}$, if $p = Aq \log(1/\varepsilon)$ and $W \sim X_p$, then $\mathbb{P}[W \in \langle \mathcal{H} \rangle] > 1 - \varepsilon$.

Theorem [1.7](#page-2-3) is deduced from the following modification of Lemma [3.6](#page-6-2) (see [§3.2](#page-5-4) for the relevant definitions):

Lemma 5.1. Suppose $VC(H) \leq 1$ and for each pair of elements $x, y \in X$, there is some set $S \in \mathcal{H}$ with $S \cap \{x, y\} = \emptyset$. Let $p, q \in [0, 1]$ be such that $p \geq 2q$ and let $W \sim X_p$ be a random subset of *X*. Then, for all $t \geq 0$, \overline{a}

$$
\mathbb{E}\left[\sum_{F\,\in\,\mathcal{H}_{W,t}^{\text{large}}}q^{|F|}\right] \,\leqslant\, 2\,\left(\frac{q}{p}\right)^t.
$$

Crucially, compared to Lemma [3.6,](#page-6-2) there is no dependence on *ℓ* in Lemma [5.1.](#page-10-1)

The proof of Lemma [5.1](#page-10-1) is almost exactly the same as that of Lemma [3.6.](#page-6-2) The only difference is in the step where we bound the cardinality of the set

$$
\left|\left\{(W,F)\,:\,|W|=w,\,F\in\mathcal{H}_{W,t}^{\text{large}},\,|F|=k\right\}\right|.
$$

As in the proof of Lemma [3.6,](#page-6-2) we say that $|F\backslash W| = j$, where $t \leq j \leq k$, and then start by As in the proof of Lemma 3.6, we say that $|F \backslash W| = j$, where fixing the set $Z := W \cup F$, for which there are at most $\binom{n}{w+1}$ $\binom{n}{w+j}$ choices. We now claim that the set Z determines F uniquely. Otherwise, there would be two distinct sets F, F' of size k such that $F = S \cap \mathsf{core}_{\mathcal{H}}(Z)$ and $F' = S' \cap \mathsf{core}_{\mathcal{H}}(Z)$ for some $S, S' \in \mathcal{H}$. Also, let $S'' \in \mathcal{H}$ be any set such that $S'' \subseteq Z$, which exists since $Z \in \langle \mathcal{H} \rangle$. By the definition of the \mathcal{H} -core, $\mathsf{core}_{\mathcal{H}}(Z) \subseteq S''$. Since $|F| = |F'|$ and $F \neq F'$, we can pick elements $x \in F \backslash F'$ and $y \in F' \backslash F$. Now observe that $S \cap \{x, y\} = \{x\}, S' \cap \{x, y\} = y$, and $S'' \cap \{x, y\} = \{x, y\}.$ Furthermore, by the assumption of the lemma, there is some $S^* \in \mathcal{H}$ with $S^* \cap \{x, y\} = \emptyset$. This shows that $VC(\mathcal{H}) \geq 2$, a contradiction. Thus, once we know *Z*, we also know *F*. Given *F*, we have that $\mathsf{VC}(\mathcal{H})$
at most $\binom{k}{i}$ $\binom{k}{j}$ choices for the set $F\backslash W$, which then determines *W*. To summarize,

$$
\left| \left\{ (W, F) \, : \, |W| = w, \, F \in \mathcal{H}_{W,t}^{\text{large}}, \, |F| = k \right\} \right| \leqslant \sum_{j=t}^{k} {n \choose w+j} {k \choose j}.
$$

The remainder of the proof of Lemma [5.1](#page-10-1) proceeds in exactly the same way as the proof of Lemma [3.6,](#page-6-2) so we omit it.

Now we show how to derive Theorem [1.7](#page-2-3) from Lemma [5.1.](#page-10-1)

PROOF of Theorem [1.7.](#page-2-3) The argument is similar to the proof of Theorem [3.7](#page-7-2) (and even somewhat simpler as there is no induction). Let $A > 0$ be a constant that we will assume to be sufficiently large for all of the inequalities that appear in the sequel to hold.

Suppose that there are two elements $x, y \in X$ such that every set in $\mathcal H$ contains at least one of them, i.e., $\mathcal{H} \subseteq \langle \{\{x\}, \{y\}\}\rangle$. If $q \leq 1/4$, then we can take $\mathcal{F} = \{\{x\}, \{y\}\}\$ to make $(1d_1)$ $(1d_1)$ $(1d_1)$ hold. On the other hand, for $A > 4$, if $q > 1/4$, then $p > 1$, so in that case $(1d_2)$ holds. Therefore, we may assume that such elements *x*, *y* do not exist.

Now we pick $W_0 \sim X_{2q}$, set $t := 100/\varepsilon$, and let

$$
\mathcal{H}' \ := \ \mathcal{H}_{W_0,t}^{\textsf{small}} \qquad \text{and} \qquad \mathcal{F}_0 \ := \ \mathcal{H}_{W_0,t}^{\textsf{large}}.
$$

By Lemma [5.1](#page-10-1) and Markov's inequality,

$$
\mathbb{P}\left[\sum_{F \in \mathcal{F}_0} q^{|F|} \geq 2^{1-t/2}\right] \leq 2^{-t/2}.
$$
\n(5.1)

The family \mathcal{H}' is *t*-bounded, so, by Theorem [1.5,](#page-2-4) at least one of the following holds:

(KK¹) There is a set system \mathcal{F}' with $\mathcal{H} \subseteq \langle \mathcal{F} \rangle$ and \sum $F \in \mathcal{F}$ $q^{|F|} \leqslant \frac{1}{2}$ 2 .

 (KK_2') For $p' = 48q \log(2t/\varepsilon)$ and $W' \sim X_{p'}$, we have $\mathbb{P}[W' \in \langle \mathcal{H}' \rangle] > 1$ *ε* 2 .

As in the proof of Theorem [3.7,](#page-7-2) which of (KK_1') (KK_1') (KK_1') and (KK_2') holds depends on the set W_0 .

Case 1: ([KK](#page-11-0)[']₁) happens with probability $\alpha > 2^{-t/2}$.

When (KK_1') (KK_1') (KK_1') holds, we let \mathcal{F}' be a set system as in (KK_1') and define $\mathcal{F} := \mathcal{F}_0 \cup \mathcal{F}'$. Then $\mathcal{H} \subseteq \langle \mathcal{F} \rangle$ and, by [\(5.1\)](#page-11-2), with probability at least $\alpha - 2^{-t/2} > 0$,

$$
\sum_{F \in \mathcal{F}} q^{|F|} \leq \frac{1}{2} + 2^{1 - t/2} < \frac{2}{3},
$$

and hence $(1d_1)$ $(1d_1)$ $(1d_1)$ is satisfied.

Case 2: ([KK](#page-11-0)[']₁) happens with probability at most $2^{-t/2}$.

Set $p' := 48q \log(2t/\varepsilon)$, pick $W' \sim X_{p'}$ independently of W_0 , and let $W := W_0 \cup W'$. Note that $W \sim X_\tau$ for some

$$
\tau \leq 2q + p' = 48q \log(200/\varepsilon^2) + 2q \leq Aq \log(1/\varepsilon) = p,
$$

assuming *A* is large enough. Finally, using Lemma [3.5](#page-5-2)[\(3\),](#page-5-8) we obtain

$$
\mathbb{P}[W \in \langle \mathcal{H} \rangle] \geq \mathbb{P}[(\mathrm{KK}'_2)] \, \mathbb{P}[W' \in \langle \mathcal{H}' \rangle \, | \, (\mathrm{KK}'_2)] \geq 1 - 2^{-t/2} - \frac{\varepsilon}{2} \geq 1 - \varepsilon,
$$

which yields $(1d_2)$ $(1d_2)$ $(1d_2)$ and finishes the proof.
