A Nonparametric Test of Heterogeneous Treatment Effects under Interference

Julius Owusu *

October 2, 2024

Abstract

Statistical inference of heterogeneous treatment effects (HTEs) across predefined subgroups is challenging when units interact because treatment effects may vary by pre-treatment variables, post-treatment exposure variables (that measure the exposure to other units' treatment statuses), or both. Thus, the conventional HTEs testing procedures may be invalid under interference. In this paper, I develop statistical methods to infer HTEs and disentangle the drivers of treatment effects heterogeneity in populations where units interact. Specifically, I incorporate clustered interference into the potential outcomes model and propose kernel-based test statistics for the null hypotheses of (i) no HTEs by treatment assignment (or post-treatment variables for all treatment assignment vectors. I recommend a multiple-testing algorithm to disentangle the source of heterogeneity in treatment effects. I prove the asymptotic properties of the proposed test statistics. Finally, I illustrate the application of the test procedures in an empirical setting using an experimental data set from a Chinese weather insurance program.

Keywords: Heterogeneous treatment effects, conditional average treatment effects, interference. *JEL Classification:* C01, C12, C14.

1 Introduction

The literature on causal inference focuses primarily on identifying and estimating aggregate treatment effects. However, it is increasingly recognized that these aggregate effect metrics, while useful for measuring social welfare, often overlook the variations in treatment effects. These variations are crucial for designing welfare-maximizing treatment assignment rules. For instance, a job search assistance program may show positive aggregate effects on income and welfare. However, it could also lead to significant income and welfare disparities in society, as the impact of the program may vary across individuals. This observation has sparked a significant and growing research interest in estimating and inferring heterogeneous treatment effects (HTEs). This shift in focus from aggregate treatment effects to HTEs is a significant development in the field of causal inference. The classical approach to infer HTEs involves estimating and comparing conditional average treatment effects (CATEs) of predefined subgroups in a population. The formal comparison of CATEs requires some hypothesis testing procedure. Crump et al. (2006), Ding et al. (2016), Wager and Athey (2018), and Sant'Anna (2021) are among the few existing HTEs testing papers.

This paper introduces two nonparametric tests for inferring HTEs across subgroups while accounting for interference among economic units. According to Cox (1958), interference arises when the treatment response of one unit depends on the treatment of other units in the population. In other words, a unit's treatment response is a function of the treatment assignment — the vector of treatments of all units. Interference may result from physical, virtual, or social connections between members of a population. While the mechanisms behind interference may vary, its presence complicates the inference of HTEs across subgroups. In the presence of interference, treatment effects may depend on pre-treatment variables, post-treatment exposure variables (which capture exposure to other units' treatment statuses), or both. For example, suppose we find that the effectiveness of a Covid-19 vaccine varies across cities. The vaccine's efficacy for an individual may be influenced by the vaccination rate among their physical contacts. It is, therefore, essential to investigate whether the observed variation in vaccine effectiveness is driven by inherent population differences across cities (e.g., genetic factors) or by differences in vaccination rates, a post-treatment exposure variable. In this example, variations in vaccination rates may mask the heterogeneity due

to natural differences across cities in a standard test that does not control for the vaccination rates. This highlights that traditional tests for HTEs — which assume no interference between units are likely to produce inaccurate results when interference is present.

To address the challenges of testing HTEs in the presence of interactions between units, I consider a clustered interference setting, where interference is limited to within clusters. In this setting, I introduce kernel-based test statistics for the null hypotheses of (i) constant treatment effects (CTEs) by treatment assignment for all values of the pre-treatment variables and (ii) CTEs by the pre-treatment variables for all treatment assignment vectors. Then, I recommend the Holm (1979) multiple testing procedure to jointly test the null hypotheses and disentangle the source of heterogeneity in the treatment effects. The proposed test statistics are sums of the weighted L_1 norm of the differences in the consistent kernel estimators of CATE that characterize the null hypotheses.

The proposed testing procedure in this paper provides several practical advantages to policymakers. First, testing the null hypothesis of CTEs by treatment assignment for all covariates in isolation informs policymakers on whether to scale a program. Suppose we fail to reject the null hypothesis of CTEs across treatment assignments for all values of the pre-treatment variables. In that case, it implies that treatment spillover effects are absent, and a program can be scaled without any negative or positive externalities. Second, the null hypothesis of CTEs by the pre-treatment variables for all treatment assignment vectors in isolation helps to detect HTEs across subgroups defined by pre-treatment variables. Knowledge of a program's treatment effect variation across subgroups can guide its extension to other populations (external validation). Third, jointly testing both null hypotheses helps to disentangle the source of variation in treatment effects. Finding the drivers of the variations in treatment effects in an interconnected human society is crucial in designing welfare-maximizing treatment assignment rules.

The main theoretical results show that the proposed test statistics have an asymptotically standard normal null distribution. I prove these properties via a poissonization technique formulated by Rosenblatt (1975) and developed by Giné et al. (2003). The technique introduces additional randomness by assuming that the sample size is a Poisson random variable. It enables techniques that exploit Poisson processes' independent increments and infinite divisibility properties. Also, I show that the test statistics have asymptotically valid sizes and power against fixed alternatives and sequences of local alternatives. Moreover, I propose bootstrap procedures to benchmark the proposed asymptotic-based methods in finite samples. All the asymptotic results are based on a regime where the number of sampled clusters goes to infinity. As I discuss further in Section 3, an essential feature of this regime is that it permits the safe disregard of within-cluster dependencies for local estimators in large samples.

The main contribution of this paper is twofold. First, I highlight the issue of HTEs testing in the presence of interference. As a solution, I propose testing procedures for HTEs that (i) can accommodate several forms of clustered interference and (ii) can disentangle the sources of heterogeneity. Second, I extend the CATE identification and estimation in the literature to allow for clustered interference. From the technical perspective, I prove the asymptotic properties of the proposed testing procedures in this paper using the modern Poissonization technique of Giné et al. (2003).

The rest of the paper is organized as follows. I review the existing literature in the following subsection. Section 2 describes the setup, the testing problem, and the test statistics. In Section 3, I present the main asymptotic properties of the test statistics. Monte Carlo simulation design and results are in Section 4. To illustrate the usage of the proposed tests, in Section 5, I revisit the Chinese weather insurance policy data set in Cai et al. (2015) and test for HTEs by a post-treatment variable (treatment ratio) and a pre-treatment variable (the fraction of household income from rice production). My concluding remarks are in Section 6. All proofs, useful theorems, lemmas, and other simulation experiments are in the Appendix.

1.1 Related Literature

The nascent literature on the estimation and inference of HTEs continues to grow and spans multiple fields. The present paper falls under the arm of the literature that studies the inference of HTEs using tests based on average treatment effects (ATEs) of subgroups defined by pre-treatment variables. Bitler, Gelbach, and Hoynes (2006) provide an in-depth critique of this approach to testing for HTEs. They argue that heterogeneity of CATEs across subgroups often does not imply individual treatment effect variation unless one assumes constant subgroup treatment effect (CSTE). Nonetheless, regardless of the CSTE assumption, variations in ATEs of subgroups are

crucial in the design of treatment assignment rules where pre-treatment variables are used to set eligibility conditions. In econometrics, tests to detect variation in ATEs across subgroups have been studied by Crump et al. (2006) and Lee and Shaikh (2014). Both studies abstract from interference and propose nonparametric tests to infer HTEs across predefined subgroups. In contrast, I allow clustered interference and use kernel-based estimators to construct the test statistics. To the best of my knowledge, this is the first paper to test for HTEs under any form of interference.

The problem I consider, testing for HTEs in the presence of clustered interference, is distinct from and complementary to other CATE estimation problems in the literature. Abrevaya et al. (2015) and Fan et al. (2022) study the identification and kernel-based estimation of CATE for traditional and high dimensional data sets, respectively. By contrast, this paper focuses on testing for HTEs or varying CATEs. Also, the identification strategy and estimation in the current paper account for within-cluster interferences, whereas the above references impose a no-interference assumption. Similarly, Bargagli Stoffi et al. (2020) proposes a Network Causal Tree algorithm that seeks to find and estimate the treatment effect of subpopulations where treatment and spillover effects differ across individual, neighborhood, and network characteristics in clustered network populations. This is again distinct from my goal, which takes the subpopulations of interest as given and studies testing procedures to infer HTEs across these covariates-defined subpopulations. On the theoretical side, Lee et al. (2013) and Chang et al. (2015) establish asymptotic null distributions for the L_{v} -type functions of kernel-based CATE estimators using the modern poissonization technique of Giné et al. (2003). Allowing for clustered interference in the potential outcomes model requires a modification of the estimator of CATE to fit the current framework. In addition, the proposed test statistics in this paper are different, and the theoretical results are extensions of those in these Chang et al. (2015).

Finally, the nonparametric bootstrap algorithms proposed in this paper are similar to existing algorithms in the literature. For instance, Li et al. (2009) uses a bootstrap algorithm akin to that described in Section 3 .3.1 to test for the equality of two density or conditional density functions. Also, Racine (1997) employs a residual bootstrap algorithm similar to the wild bootstrap-t procedure proposed in Section 3 .3.2 to test for the significance of pre-treatment variables in regression models. Despite the similarities, the bootstrap procedures in this paper must account for the within cluster dependencies and, as such, are novelties that fit the current setting.

2 Framework

2.1 Setup

Consider a setting where units are partitioned into clusters, such as classrooms, villages, or states. Let N_c denote the number of *finite* units in cluster $c \in I$. Suppose that C clusters are randomly drawn from the population of clusters, and let N denote the number of units that make up the observed sample, i.e., $\sum_{i=1}^{C} N_c = N$. Furthermore, assume that units in the same cluster interact arbitrarily, leading to clustered or partial interference (Sobel, 2006). Let $T_{ci} \in \{0, 1\}$ be the binary treatment condition of unit $i \in \{1, ..., N\}$ in cluster $c \in \{1, ..., C\}$. Treatment is selected or assigned at the unit level. Thus, different clusters may have different treatment assignment vectors. The treatment vector of the units in cluster c is denoted as \mathbf{T}_c . Moreover, we observe the outcome variables $Y_{ci} \in \mathcal{Y} \subset \mathbb{R}$, and a vector $X_{ci} \in \mathcal{X} \subset \mathbb{R}^d$ of pre-treatment variables.

Adopting the potential outcomes model of Neyman (1923) and Rubin (1974), let $Y_{ci}(\mathbf{t}_c)$ represent the potential outcome of unit *i* in cluster *c* when the cluster treatment assignment vector \mathbf{T}_c equals \mathbf{t}_c . Therefore, the potential outcomes of a unit are indexed by her cluster treatment assignment vector. Effectively, the number of potential outcomes of a unit in cluster *c* is 2^{N_c} (i.e., the number of all possible cluster treatment assignment vectors). Note that in the classical case of no interference, only two potential outcomes exist for each unit. Hence, allowing for (clustered) interference exacerbates the missing data problem of causal inference. As such, a salient element of causal inference in the presence of (clustered) interference is a mapping $\pi(\cdot)$, which summarizes how the (cluster) treatment vectors affect the treatment response outcome. This is commonly referred to as the *exposure mapping* (see Manski (2013) and Aronow et al. (2017)). Formally, I define exposure mapping as

$$\pi_i: \{0,1\}^{N_c} \mapsto \mathbf{\Pi} \tag{1}$$

that maps the cluster treatment vector \mathbf{T}_c into an exposure variable $\Pi_{ci} := \pi_i(\mathbf{T}_c) \in \mathbf{\Pi} \subset \mathbb{R}$. The definition of π_i is application-specific, as it must account for the within-cluster interference structures of the given problem.

Next, for a given exposure mapping, I assume that $Y_{ci}(\mathbf{t}_c) = Y_{ci}(t, \pi)$ is the potential outcome for unit *i* if the cluster treatment vector \mathbf{t}_c is such that $T_{ci} = t$ and $\pi_i(\mathbf{t}_c) = \pi$. Thus, this assumption asserts that heterogeneity in treatment effects across treatment assignment vectors is analogous to heterogeneity in treatment effects across exposure variable's values (henceforth exposure values).

Remark 1. It is worth emphasizing that the exposure mapping in (1) depends only on the cluster treatment assignment vectors and requires no knowledge of the connections between units in the population. Thus, the exposure variable is typically defined at the cluster level — such as the number of treated units within a given cluster. However, the testing procedures in this paper also accommodate individual-specific exposure variables, including leave-one-out exposure variables — such as the number of treated units in a cluster excluding the i^{th} unit. As a result, the exposure variable of unit *i* is a reduced measure of the contagion or direct interference within *i*'s cluster. This is convenient because, in many applied settings, it is difficult to obtain information on links between economic units due to privacy concerns. For instance, Colpitts (2002) reveals that Canada abandoned a targeting program designed to use individual-level and network information to assign unemployed workers to different job activation programs due to data security concerns.

The following example provides a plausible specification of exposure mapping defined in (1).

Example 1 (Distributional clustered interaction). Manski (2013) explains that distributional clustered interaction occurs if the outcome of unit *i* does not depend on the sample size, and it is invariant to permutations of the treatments received by other units in the same cluster. In essence, distributional clustered interaction implies that $\pi_i(\mathbf{t}_c) \in \{0, 1/N_c, 2/N_c, \dots, 1\}$ represents the treatment ratio in cluster *c*. See Manski (2013) for other specifications.

I formalize the assumptions that describe the setting as follows.

Assumption 1 (Treatment-invariant clusters). Let *G* denote the cluster assignment variable, then for each unit *i*, $Pr(G_i|\mathbf{T}_c) = Pr(G_i)$, *i.e.*, *a unit's cluster and treatment assignment variables are independent*.

In other words, Assumption 1 suggests that the network is a fixed population characteristic, and units do not strategically select into clusters after treatment assignment.

Assumption 2 (Clustered Interference). Let $\pi_i(\cdot)$ be an exposure mapping function, i.e., $\pi_i : \{0, 1\}^{N_c} \mapsto \mathbf{\Pi}$, with $\mathbf{\Pi} = \{\pi_1, \dots, \pi_K : K < C\}$ being a discrete set of finite elements, $\forall c = 1, \dots, C, \forall i = 1, \dots, N_c$, and $\forall \mathbf{t}, \mathbf{t}' \in \{0, 1\}^N$ such that $t_i = t'_i$ and $\pi_i(\mathbf{t}_c) = \pi_i(\mathbf{t}'_c)$ then $Y_{ci}(\mathbf{t}) = Y_{ci}(\mathbf{t}')$

Assumption 2 is embedded with a couple of information and merits a lengthy discussion. First, it restricts the nature of interference, i.e., it imposes intra-cluster interference but no inter-cluster interference. Second, this assumption limits the range of the exposure variable to a discrete finite set of K < C elements; thus, the number of potential outcomes reduces significantly to $2 \cdot K$. This part of the assumption also implies that *units in different clusters can have the same exposure value*, as a result guaranteeing that there are "enough" units for each treatment and exposure value for precise estimation of the CATEs. Finally, Assumption 2 asserts that a unit's exposure to the treatment of other units in her cluster is in a "reduced form," and channels through which interference occurs in clusters are not distinguishable. Exploring general forms of interference with network information is a possible avenue for future research.

For each $\pi \in \mathbf{II}$ and $x \in X$, I define the CATE parameter as $\tau(x; \pi) \coloneqq \mathbb{E}[Y(1, \pi)|X = x] - \mathbb{E}[Y(0, \pi)|X = x]$. The following assumptions are crucial for the identification of the CATEs.

Assumption 3 (Consistency and Unconfoundedness).

(*i*) There is only a single version of each treatment.
(*ii*) For all π ∈ Π,

$$(T,\Pi) \perp (Y(0,\pi), Y(1,\pi))|X$$
 (2)

Assumption 4 (Overlap). *For all* $\pi \in \Pi$ *,* $x \in X$ *and for some* $\xi > \eta > 0$

$$\xi < P(T = 1|X = x) < 1 - \xi \text{ and } \eta < P(T = 1, \Pi = \pi | X = x) < P(T = 1|X = x) - \eta$$
(3)

Assumptions 3(ii) and 4 are the extensions of the usual ignorability assumptions imposed on the treatment assignment mechanism under no interference, see Imbens and Rubin (2015). Assumption 3(i) is the standard consistency condition that rules out multiple versions of the same treatment selected or assigned, and 3(ii) asserts that conditional on pre-treatment variables, self-selection of *effective treatment*, (T, Π) is ruled out. This Assumption holds when treatment is randomly assigned at the unit level. Assumption 4 is a modified version of the usual overlap or probabilistic assignment condition. It ensures a balance between treated and control units in each subgroup. It is particularly crucial because of the Hájek-type estimators of CATE I employ in this paper.

Proposition 1. Suppose Assumptions 1-4 hold, then $\forall \pi \in \Pi$ and $x \in X$

$$\tau(x,\pi) = \mathbb{E}[Y|T=1,\Pi=\pi, X=x] - \mathbb{E}[Y|T=0,\Pi=\pi, X=x].$$
(4)

2.2 The Testing Problem

In this section, I formally describe the testing problem. As mentioned above, in the presence of interference, treatment effects may vary by either pre-treatment variables, post-treatment exposure variables, or both. Figure 1 shows some plausible cases in a simple setting where $\mathbf{\Pi} = \{\pi_1, \pi_2\}$ and CATE is linear in a continuous *X*. Panels (a) shows CTEs by both classes of variables. In contrast, Panels (b) and (c) show scenarios where one class of variable has HTEs, and the other class has CTEs. Panel (d) depicts the case where both classes of variables have HTEs. These facts highlight that testing for HTEs in the presence of interference requires testing for heterogeneity across the two classes of variables and the need for methods to disentangle the source of the effect heterogeneity.

To test for heterogeneity across one class of variables requires controlling for the other class of variables. Formally, I consider the following null hypotheses. The first one is the null hypothesis of constant treatment effects (CTEs) by an exposure variable while controlling for pre-treatment variables:

$$H_0^{\Pi}: \ \forall x \in \mathcal{X}, \ \forall \pi, \pi' \in \Pi, \ \tau(x;\pi) = \tau(x;\pi'), \tag{5}$$

against the alternative hypothesis of HTEs by the exposure variable:

$$H_1^{\Pi}: \exists x \in \mathcal{X}, \exists \pi, \pi' \in \mathbf{\Pi}, \tau(x; \pi) \neq \tau(x; \pi').$$
(6)

The null hypothesis (5) is vital in answering several essential questions in program evaluation. For example, testing (5) when exposure is treatment ratios helps to determine whether a program should be scaled or not; rejecting the null hypothesis implies treatment spillover effects exist and program effects may vary by program scale. Although (5) resembles Hypothesis 2 in Athey et al. Figure 1: Treatment Effects Variation by a Continuous Pre-treatment Variable and a Binary Posttreatment Exposure Variable

(a) CTEs by a pre-treatment variable and an exposure (b) CTEs by a pre-treatment variable and HTEs by an variable.

(c) HTEs by a pre-treatment variable and CTEs by an (d) HTEs by a pre-treatment variable and an exposure exposure variable.

(2018), they are not the same. The null hypothesis (5) is a restriction on the treatment effect that there are no indirect or spillover treatment effects. In contrast, Hypothesis 2 in Athey et al. (2018) restricts the outcome of no spillovers or interference. Failure to reject Hypothesis 2 in Athey et al. (2018) implies that we fail to reject (5); however, the converse is not valid.

Remark 2. Generally, the null H_0^{Π} resembles the null of no or constant treatment effects for all covariates *X* in settings with multiple treatment effects. Given *K* possible treatments, to test for no treatment effects at all covariates points, one may have to test for no effects for all pairwise treatments across covariates. The main difference between the setting in this paper and the multiple treatment environment is the possibility of within-cluster dependencies. However, as I thoroughly discuss in Section 3 , such dependencies can be safely ignored in large samples because the CATE

function is estimated using the local constant estimators. Hence, with a slight modification of the estimands of interest, the testing procedure developed in this paper for H_0^{Π} , can be adapted to test for the null of no treatment effects for all covariates X in settings with multiple treatment effects.

The second hypothesis of interest concerns the null hypothesis of CTEs by pre-treatment variables while controlling for the post-treatment exposure variable:

$$H_0^X: \ \forall \pi \in \mathbf{\Pi}, \forall x, x' \in \mathcal{X}, \ \tau(x; \pi) = \tau(x'; \pi), \tag{7}$$

against the alternative hypothesis of HTEs by pre-treatment variables:

$$H_1^X: \exists \pi \in \Pi, \exists x, x' \in \mathcal{X}, \ \tau(x;\pi) \neq \tau(x';\pi).$$
(8)

Tests for the null hypothesis similar to (7) exist in the literature; see Crump et al. (2006). However, this paper is the first to allow some form of interference. Testing (7) is critical in extending existing programs to new populations; rejecting this hypothesis implies that treatment effects vary across subgroups defined by the pre-treatment variables. Therefore, a policymaker should expect different aggregate effects if the program is extended to a new population.

It is worth discussing the importance of distinguishing between the exposure variable (i.e., Π) and the pre-treatment variables in this framework. First, note that Π is a causal variable and, as such, is used to index the potential outcomes. In contrast, the pre-treatment variables are invariant to treatment assignment, i.e., they are a priori variables. Therefore, this distinction is necessary in the potential outcome framework for identification. Secondly, distinguishing between the pre-treatment and treatment exposure variables is imperative to determine the drivers of the heterogeneity in treatment effects. It has vital implications for policymakers. For instance, if the heterogeneity is solely due to the treatment effects in the population via the treatment assignment mechanism. See Han et al. (2022) for a statistical treatment assignment rule for homogeneous and heterogeneous populations in the presence of social interaction.

Remark 3. An important feature of H_0^{Π} and H_0^X is that testing each hypothesis in isolation may not clarify the source of heterogeneity in treatment effects. For example, failure to reject the null

hypothesis H_0^{Π} implies either *CTEs by exposure* and *HTEs by pre-treatment variables* or *CTEs by both exposure and pre-treatment variables*. Conversely, failure to reject H_0^X implies either *CTEs by the pre-treatment variables* and *HTEs by the exposure* or *CTEs by both the exposure and pre-treatment variables*. This highlights the necessity of testing both hypotheses simultaneously. In the following subsection, I propose a multiple testing procedure designed to conduct such simultaneous testing.

2.3 Test Statistics

The proposed test statistic for the null hypothesis H_0^{Π} in (5) is

$$\hat{T}_{1} := \int_{\mathcal{X}} \sum_{k=1}^{K} \sum_{j>k}^{K} \left\{ \sqrt{C} |\hat{\tau}(x; \pi_{k}) - \hat{\tau}(x; \pi_{j})| \right\} \hat{w}(x, \pi_{k}, \pi_{j}) dx,$$
(9)

where $\hat{\tau}(x;\pi)$ is a uniform consistent estimator of $\tau(x;\pi)$ and $\hat{w}(x,\pi,\pi')$ is the uniform consistent estimator of the inverse standard error of $\sqrt{Ch^d}(\hat{\tau}(x;\pi) - \hat{\tau}(x;\pi'))$ which is defined as $w(x,\pi,\pi') :=$ $1/\sqrt{\rho_2(x,\pi) + \rho_2(x,\pi') - 2Ch^d Cov(\hat{\tau}(x;\pi),\hat{\tau}(x;\pi'))}, 1$ with, $\rho_2(x,\pi)$ representing the variance of $\sqrt{Ch^d}\hat{\tau}(x;\pi)$. Also, note that *d* is the dimension of *X*, *h* is the bandwidth, and recall that *C* is the number of sampled clusters.

I propose a nonparametric kernel-based estimator of $\tau(x; \pi)$ defined as

$$\hat{\tau}(x;\pi) := \frac{1}{Ch^d} \sum_{c=1}^C \frac{1}{N_c} \sum_{i=1}^{N_c} Y_{ci} \cdot \mathbb{1}(\Pi_{ci} = \pi) \hat{\phi}(T_{ci}, x, \pi) K\left(\frac{x - X_{ci}}{h}\right),$$
(10)

where

$$\hat{\phi}(T_{ci}, x, \pi) := \frac{T_{ci}}{\hat{P}_1(x; \pi)} - \frac{(1 - T_{ci})}{\hat{P}_0(x; \pi)},$$

with

$$\hat{P}_t(x;\pi) := \frac{1}{Ch^d} \sum_{c=1}^C \frac{1}{N_c} \sum_{i=1}^{N_c} \mathbb{1}(\Pi_{ci} = \pi) \mathbb{1}(T_{ci} = t) K\left(\frac{x - X_{ci}}{h}\right), \ t = 0, 1,$$

and $K(\cdot)$ being a *d*-dimensional kernel function.

¹Since the network is clustered, $w(x, \pi, \pi') := 1/\sqrt{\rho_2(x, \pi) + \rho_2(x, \pi')}$ when the exposure variable is at the cluster level.

The test statistic for the null hypothesis H_0^X in (7) is defined as

$$\hat{T}_{2} := \int_{\{x:x\in\mathcal{X}\}} \int_{\{x':x'\in\mathcal{X}:x\neq x'\}} \sum_{k=1}^{K} \left\{ \sqrt{C} |\hat{\tau}(x;\pi_{k}) - \hat{\tau}(x';\pi_{k})| \right\} \frac{\hat{w}(x,x',\pi_{k})}{2} dx dx'$$
(11)

$$= \int_{\{(x,x')\in\mathcal{X}^2: x < x'\}} \sum_{k=1}^{K} \left\{ \sqrt{C} |\hat{\tau}(x;\pi_k) - \hat{\tau}(x';\pi_k)| \right\} \hat{w}(x,x',\pi_k) dx dx'$$
(12)

where, $\hat{w}(x, x', \pi)$ is a consistent kernel estimator of $w(x, x', \pi)$, the inverse standard error of $\sqrt{Ch^d} \cdot (\hat{\tau}(x; \pi) - \hat{\tau}(x'; \pi))$. Mathematically, $w(x, x', \pi) := 1/\sqrt{\rho_2(x, x', \pi)}$ with $\rho_2(x, x', \pi) := \rho_2(x, \pi) + \rho_2(x', \pi) - 2Ch^d Cov(\hat{\tau}(x; \pi), \hat{\tau}(x'; \pi))$. Throughout the paper, I use the first form of \hat{T}_2 in (11); however, to simplify notation, I let $\int_{\{x:x\in X\}} \int_{\{x':x'\in X:x\neq x'\}} be$ equal to $\int_X \int_X$. This should not be interpreted as integrating over the product of the covariate space as the set $\{x, x': x \neq x', x \in X, x' \in X\}$ may have non-zero measure.

If we test the null hypotheses H_0^{Π} and H_0^X simultaneously using a multiple testing procedure (MTP), we can disentangle the source of heterogeneity of treatment effects. If we fail to reject both null hypotheses, it implies CTEs by both variable classes. If we reject the null hypothesis H_0^{Π} but fail to reject H_0^X , it suggests HTEs by exposure variable and CTEs by pre-treatment variables. In contrast, if we fail to reject the null hypothesis H_0^{Π} but reject H_0^X , this implies CTEs by exposure variable and HTEs by pre-treatment variables. Finally, if we reject both null hypotheses, then it suggests HTEs for both variable classes. Thus, as mentioned in Remark 3, implementing both tests in a multiple-testing framework is imperative to disentangle the source of treatment effects heterogeneity.

To control the probability of rejecting at least one null hypothesis, given that they are both true — referred to as the family-wise error rate (FWER) — I recommend the step-wise multiple testing procedure of Holm (1979). Let the $p_{d_1} \le p_{d_2}$ be the ordered *p*-values, with corresponding null hypotheses H_{0,d_1} and H_{0,d_2} . Then the Holm step-down algorithm is as follows:

Algorithm 1 (Holm Procedure).

- 1. If $p_{d_1} > \alpha/2$ fail to reject both H_{0,d_1} and H_{0,d_2} and stop. If $p_{d_1} \le \alpha/2$ reject H_{0,d_1} and test H_{0,d_2} at level α .
- 2. If $p_{d_1} \leq \alpha/2$ but $p_{d_2} > \alpha$, fail to reject H_{0,d_2} and stop. If $p_{d_1} \leq \alpha/2$ and $p_{d_2} \leq \alpha$, reject H_{0,d_2} .

Several similar adjustments for multiple testing exist, but I opt for Holm's method due to its computational simplicity and robustness to dependencies between the two test statistics. See Lehmann and Romano (2022) for a comparison between Holm's method and other MTPs.

3 Asymptotic Results

In this section, I discuss the asymptotic properties of the proposed test statistics \hat{T}_1 and \hat{T}_2 when the null hypotheses are true and false. As mentioned in the introduction, I adopt an asymptotic regime where the number of sampled clusters *C* goes to infinity while the units with each cluster are fixed.

I show that appropriate studentized versions of the test statistics \hat{T}_1 and \hat{T}_2 converge to the standard normal distribution under the null hypotheses. Two forms of dependencies complicate the derivation of these asymptotic properties. The first is the within-cluster dependency among observations due to interference. Secondly, the terms in the combinatorial sum or integral may also be correlated for each test statistic.

Lin and Carroll (2000) show that when cluster sizes are finite, the most asymptotically efficient kernel estimator of the CATEs is obtained by completely ignoring the within-cluster correlation. This is commonly called the *working independence approach*. The intuition is that, for clusters of fixed sizes, the probability that two or more observations from the same cluster having significant kernel weights approaches zero as the bandwidth shrinks to zero (See Wang (2003) for more details).

Thus, the working independence approach provides a useful asymptotic method for handling the within-cluster correlations when the number of bounded clusters is large. In essence, it allows one to view observations — used to estimate the CATEs — as mutually independent in the asymptotics. Based on the foregoing argument and assuming, without loss of generality, that the clusters are of equal size N_0 , I rewrite the CATE kernel estimator as

$$\hat{\tau}(x;\pi) := \frac{1}{Nh^d} \sum_{i=1}^N Y_i \cdot \mathbb{1}(\Pi_i = \pi) \hat{\phi}(T_i, x, \pi) K\left(\frac{x - X_i}{h}\right),$$

where

$$\hat{\phi}(T_i, x, \pi) := \frac{T_i}{\hat{P}_1(x; \pi)} - \frac{(1 - T_i)}{\hat{P}_0(x; \pi)}, \quad N = CN_0,$$

with

$$\hat{P}_t(x;\pi) := \frac{1}{Nh^d} \sum_{i=1}^N \mathbb{1}(\Pi_i = \pi) \mathbb{1}(T_i = t) K\left(\frac{x - X_i}{h}\right), \ t = 0, 1.$$

Furthermore, the kernel estimator of $w(x, \pi, \pi')$ is defined as

$$\hat{w}(x,\pi,\pi') := \frac{1}{\sqrt{\hat{\rho}_2(x,\pi) + \hat{\rho}_2(x,\pi')}},$$

where $\hat{\rho}_2(x, \pi)$ is the kernel estimator of $\rho_2(x, \pi)$ (ignoring all covariance terms) defined as

$$\hat{\rho}_2(x,\pi) := (\hat{\mu}_1(x,\pi) - \hat{\mu}_2(x,\pi)) \cdot \int K(\xi)^2 d\xi,$$

and

$$\hat{\mu}_1(x,\pi) := \frac{1}{Nh^d} \sum_{t \in \{0,1\}} \sum_{i=1}^N \frac{Y_i^2 \mathbb{1}(T_i = t) \mathbb{1}(\Pi_i = \pi) K(\frac{x - X_i}{h})}{\hat{P}_t^2(x;\pi)},$$

and

$$\hat{\mu}_{2}(x,\pi) := \frac{1}{N^{2}h^{2d}} \sum_{t \in \{0,1\}} \sum_{j=1}^{N} \sum_{i=1}^{N} \frac{Y_{j}Y_{i}\mathbb{1}(T_{j}=t)\mathbb{1}(T_{i}=t)\mathbb{1}(\Pi_{i}=\pi)\mathbb{1}(\Pi_{j}=\pi)K(\frac{x-X_{j}}{h})K(\frac{x-X_{i}}{h})}{\hat{P}_{t}^{3}(x;\pi)}.$$

The asymptotic results for non-equal cluster sizes are a straightforward extension at the cost of additional notation. Before I state the asymptotic results, the following regularity conditions are required.

Assumption 5. (a) The joint distribution of $(Y, X) \in \mathcal{Y} \times X$ is absolutely continuous with respect to the Lebesgue measure; (b) the probability density function f of X is continuously differentiable almost everywhere; (c) $\rho_2(\cdot, \pi)$ is strictly positive and continuous almost everywhere on $\mathcal{W}_X, \forall \pi \in \mathbf{\Pi}$, where \mathcal{W}_X is a compact subset of X; (d) K is a product kernel function, i.e., $K(u) = \prod_{j=1}^d K_j(u_j), u = (u_1, \ldots, u_d)$, with each $K_j : \mathbb{R} \mapsto \mathbb{R}, j = 1, \ldots, d$, satisfying that K_j is an s-order kernel function with support $\{u \in \mathbb{R} : |u| \le 0.5\}$, symmetric around zero, bounded, and is of bounded variation, and integrates to 1, where s is an integer that satisfies s > 1.5d; (e) as functions of x, $\mathbb{E}[Y|X = x, T = t, \Pi = \pi], f(x), p_t(x, \pi)$ for t = 0, 1 are s-times continuously differentiable almost everywhere for each $\pi \in \mathbf{\Pi}$ with uniformly bounded derivatives; (f) $\sup_{x \in \mathcal{W}_X} \mathbb{E}[|Y|^3|X = x, T = t, \Pi = \pi] < \infty$ for t = 0, 1 and $\pi \in \mathbf{\Pi}$; (g) the bandwidth satisfies $Ch^{2s} \to 0$, $Ch^{3d} \to \infty$ and $(Ch^{2d})^{1/2}/\log C \to \infty$, where s > 1.5d; (h) For each $\pi, \pi' \in \mathbf{\Pi}$, $\sup_{x\in W_X} |\hat{w}(x,\pi,\pi') - w(x,\pi,\pi')| = o_p(h^{d/2}) \ and \ \sup_{(x,x')\in W_X^2} |\hat{w}(x,x'\pi) - w(x,x'\pi)| = o_p(h^{d/2}).$

These conditions are standard in the kernel estimation literature (see Lee et al. (2013), and Chang et al. (2015, p. 315)). Assumptions 5(a) and (b) are unnecessary for the asymptotic results. They are convenient assumptions imposing continuity on X and Y that help to present my main results. Assumption 5(c) ensures that the inverse standard error weight function is continuous and well-defined within a compact subset of X. Assumption 5(d) imposes conditions on the kernel function. Assumption 5(e) and (f) imposes restrictions on the underlying true data-generating process to ensure smooth and finite moments. Assumption 5(g) imposes standard restrictions on the choice of bandwidth. Finally, Assumption 5(h) ensures that the estimated weight functions are uniformly consistent.

It is worth emphasizing that for Assumption 5(g), the bandwidth depends on the number of clusters *C*. For instance, if d = 1 and a second order kernel is used (i.e., s = 2) then the bandwidth has to be of the form $h = \kappa_0 C^{-\lambda}$, where κ_0 is a positive constant and $1/4 < \lambda < 1/3$. However, since $N = CN_0$ and N_0 is fixed in asymptotics, the restrictions in Assumption 5(g) can be written in terms of *N*.

3.1 Asymptotic Null Distribution and Properties of the Test Statistics

Let's focus on the test statistic \hat{T}_1 . Rewriting it in the form $\hat{T}_1 = \sum_{k=1}^{K} \sum_{j=1}^{K} 2^{-1} \int_X \{\sqrt{N} | \hat{\tau}(x; \pi_k) - \hat{\tau}(x; \pi_j) | \} \cdot \hat{w}(x, \pi_k, \pi_j) dx$, it resembles the test statistic $\hat{D} := \int_X \sqrt{N} | \hat{\tau}(x) | \hat{w}(x) dx^2$ proposed by Chang et al. (2015) under no-interference. They show that a studentized version of \hat{D} converges to the standard normal distribution. Under the working independence approach, \hat{T}_1 is the sum of dependent random variables $\{2^{-1} \int_X (\sqrt{N} | \hat{\tau}(x; \pi_k) - \hat{\tau}(x; \pi_j) |) \hat{w}(x, \pi_k, \pi_j) : \pi_j, \pi_k \in \mathbf{II} \}$. Using the poissonization technique in Giné et al. (2003), I show that each of these random variables is asymptotically normal. See the details in Appendix B .3. Thus, as *C* tends to infinity, \hat{T}_1 is the sum of K(K-1)/2 dependent normal random variables. It suffices to find the pairwise asymptotic covariances between terms in the sum to obtain the asymptotic normality result of \hat{T}_1 .

To derive the formal asymptotic results, I studentized the test statistics \hat{T}_1 with its mean (bias)

 $[\]hat{x}(x)$ and $\hat{w}(x)$ are the CATE and inverse scaled standard error kernel estimators defined similar to $\hat{\tau}(x;\pi_k)$ and $\hat{w}(x,\pi_k,\pi_j)$ respectively.

under the null and standard error. The asymptotic bias³ of \hat{T}_1 is

$$a_1 := h^{\frac{-d}{2}} \cdot \mathbb{E}|\mathbb{Z}_1| \cdot \frac{K(K-1)}{2} \cdot \int_{\mathcal{X}} dx, \qquad (13)$$

where \mathbb{Z}_1 is a standard normal random variable. This diverging asymptotic bias, solely determined by the data-generating process (DGP) through the bounds of *X*, can be exactly computed.

Define $\hat{\Gamma}(x; \pi, \pi') := \hat{\tau}(x; \pi) - \hat{\tau}(x; \pi')$, the asymptotic variance⁴ of \hat{T}_1 is

$$\sigma_1^2 := \int_1 \operatorname{Cov}\left(\left| \sqrt{1 - \rho(x, t, \pi_i, \pi_j, \pi_k, \pi_l)^2} \mathbb{Z}_1 + \rho(x, t, \pi_i, \pi_j, \pi_k, \pi_l) \mathbb{Z}_2 \right|, |\mathbb{Z}_2| \right) dx dt,$$
(14)

where $\int_{1} = \int_{\mathbb{R}^{d}} \int_{T_{0}} \sum_{i=1}^{K} \sum_{j=1}^{K} \sum_{k=1}^{K} \sum_{l=1}^{K}, T_{0} = [-1, 1]^{d}$ and $\rho(x, t, \pi_{i}, \pi_{j}, \pi_{k}, \pi_{l})$ is the *unknown* correlation between $\hat{\Gamma}(x; \pi_{i}, \pi_{j}) / \sqrt{\hat{\rho}_{2}(x, \pi_{i}, \pi_{j})}$ and $\hat{\Gamma}(x; \pi_{k}, \pi_{l}) / \sqrt{\hat{\rho}_{2}(x, \pi_{k}, \pi_{l})}$, (i.e., $\rho(x, t, \pi_{i}, \pi_{j}, \pi_{k}, \pi_{l}) = Corr(\hat{\Gamma}(x; \pi_{i}, \pi_{j}) / \sqrt{\hat{\rho}_{2}(x, \pi_{i}, \pi_{j})}, \hat{\Gamma}(x; \pi_{k}, \pi_{l}) / \sqrt{\hat{\rho}_{2}(x, \pi_{k}, \pi_{l})})$). \mathbb{Z}_{1} and \mathbb{Z}_{2} are mutually independent standard normal random variables. A consistent kernel estimator of $\rho(x, t, \pi_{i}, \pi_{j}, \pi_{k}, \pi_{l})$ is defined as

$$\hat{\rho}(x,t,\pi_{i},\pi_{j},\pi_{k},\pi_{l}) = \begin{cases} \frac{\int K(\xi)K(\xi+t)d\xi}{\int K(\xi)^{2}d\xi} & \text{if } i = k \& j = l \\ \frac{-\int K(\xi)K(\xi+t)d\xi}{\int K(\xi)^{2}d\xi} & \text{if } i = l \& j = k \\ \frac{-\hat{\rho}_{2}(x,\pi_{j})}{\sqrt{\hat{\rho}_{2}(x;\pi_{i},\pi_{j})}\sqrt{\hat{\rho}_{2}(x;\pi_{k},\pi_{l})}} \cdot \frac{\int K(\xi)K(\xi+t)d\xi}{\int K(\xi)^{2}d\xi} & \text{if } j = k \& i \neq l \\ \frac{-\hat{\rho}_{2}(x,\pi_{i})}{\sqrt{\hat{\rho}_{2}(x;\pi_{i},\pi_{j})}\sqrt{\hat{\rho}_{2}(x;\pi_{k},\pi_{l})}} \cdot \frac{\int K(\xi)K(\xi+t)d\xi}{\int K(\xi)^{2}d\xi} & \text{if } j \neq k \& i = l \\ \frac{\hat{\rho}_{2}(x,\pi_{j})}{\sqrt{\hat{\rho}_{2}(x;\pi_{i},\pi_{j})}\sqrt{\hat{\rho}_{2}(x;\pi_{k},\pi_{l})}} \cdot \frac{\int K(\xi)K(\xi+t)d\xi}{\int K(\xi)^{2}d\xi} & \text{if } j = l \& i \neq k \\ \frac{\hat{\rho}_{2}(x,\pi_{i})}{\sqrt{\hat{\rho}_{2}(x;\pi_{i},\pi_{j})}\sqrt{\hat{\rho}_{2}(x;\pi_{k},\pi_{l})}} \cdot \frac{\int K(\xi)K(\xi+t)d\xi}{\int K(\xi)^{2}d\xi} & \text{if } j \neq l \& i = k \\ 0 & \text{otherwise,} \end{cases}$$

where $\hat{\rho}_2(x, \pi, \pi') \coloneqq \hat{\rho}_2(x, \pi) + \hat{\rho}_2(x, \pi')$. Plug $\hat{\rho}(x, t, \pi_i, \pi_j, \pi_k, \pi_l)$ into the right hand side of (14), and obtain the asymptotic variance estimator

$$\hat{\sigma}_{1}^{2} \coloneqq \int_{1} \operatorname{Cov}\left(\left| \sqrt{1 - \hat{\rho}(x, t, \pi_{i}, \pi_{j}, \pi_{k}, \pi_{l})^{2}} \mathbb{Z}_{1} + \hat{\rho}(x, t, \pi_{i}, \pi_{j}, \pi_{k}, \pi_{l}) \mathbb{Z}_{2} \right|, |\mathbb{Z}_{2}| \right) dx dt.$$
(16)

³See Appendix B .2 for the derivation.

⁴See Appendix B .2 for the derivation.

The studentized version of the test statistic \hat{T}_1 is defined as

$$\hat{S}_1 \coloneqq \frac{\hat{T}_1 - a_1}{\hat{\sigma}_1}.$$

Similarly, the studentized version of the test statistic \hat{T}_2 is defined as

$$\hat{S}_2 \coloneqq \frac{\hat{T}_2 - a_2}{\hat{\sigma}_2},$$

where

$$a_2 := h^{\frac{-d}{2}} \cdot \mathbb{E}|\mathbb{Z}_1| \cdot \frac{K}{2} \cdot \int_{\mathcal{X}} \int_{\mathcal{X}} dx dx',$$

and

$$\hat{\sigma}_{2}^{2} \coloneqq \int_{2'} \frac{\hat{\rho}_{2}(x,\pi_{k}) \cdot \operatorname{Cov}\left(\left|\sqrt{1-\rho(x,t,\pi_{k})^{2}}\mathbb{Z}_{1}+\rho(x,t,\pi_{k})\mathbb{Z}_{2}\right|,|\mathbb{Z}_{2}|\right)}{\sqrt{(\hat{\rho}_{2}(x,x',\pi_{k}))(\hat{\rho}_{2}(x,x'',\pi_{k}))}} dx dx' dx'' dt,$$
(17)

where $\rho(x, t, \pi_k) := (\int K(\xi)K(\xi + t)d\xi)/(\int K(\xi)^2 d\xi)$, $\hat{\rho}_2(x, x', \pi_k)$ is the plug-in estimator of $\rho_2(x, x', \pi_k)$ defined as $\hat{\rho}_2(x, x', \pi_k) := \hat{\rho}_2(x, \pi) + \hat{\rho}_2(x', \pi) - 2\hat{\rho}_2(x, \pi)\mathbb{1}(t \in [-1, 1]^d) \cdot \operatorname{Cov}((1 - \rho(x, t, \pi_k)^2)^{1/2}\mathbb{Z}_1 + \rho(x, t, \pi_k)\mathbb{Z}_2, \mathbb{Z}_2)$, and $\int_{2'} := \int_{[-1, 1]^d} \int_{\mathbb{R}^d} \int_{\mathbb{R}^d} \int_{\mathbb{R}^d} \sum_{k=1}^K \cdot 5$ It is worth to note that the asymptotic inverse scaled standard error to compute \hat{S}_2 also becomes

$$w(x, x', \pi) = \frac{1}{\sqrt{\rho_2(x, \pi) + \rho_2(x', \pi) - 2\rho_2(x, \pi)\mathbb{1}(t \in [-1, 1]^d) \cdot \operatorname{Cov}((1 - \rho(x, t, \pi_k)^2)^{1/2}\mathbb{Z}_1 + \rho(x, t, \pi_k)\mathbb{Z}_2, \mathbb{Z}_2)}},$$

where $t = (x - x')/h.^6$ As such, I obtain the sample analog of $w(x, x', \pi)$ by plugging in the estimators of $\rho_2(x, \pi)$ for all $x \in X$. See Appendix B .2 for the derivation of a_2 and $\hat{\sigma}_2^2$.

Proposition 2. Let Assumptions 1 - 5 hold, then under the

(*i*) null hypothesis (5) \hat{S}_1 converges to the standard normal distribution, i.e., $\hat{S}_1 \rightarrow N(0, 1)$ as $C \rightarrow \infty$;

(ii) null hypothesis (7) \hat{S}_2 converges to the standard normal distribution, i.e., $\hat{S}_2 \rightarrow N(0, 1)$ as $C \rightarrow \infty$.

⁵In the case where errors are homoskedastic, $\hat{\rho}_2(x, \pi_k) \cdot ((\hat{\rho}_2(x, \pi_k) + \hat{\rho}_2(x', \pi_k))(\hat{\rho}_2(x, \pi_k) + \hat{\rho}_2(x'', \pi_k)))^{-1/2}$ in (17) simplifies as $\hat{f}(x, \pi_k)^{-1} \cdot \{(\hat{f}(x, \pi_k)^{-1} + \hat{f}(x', \pi_k)^{-1})(\hat{f}(x, \pi_k)^{-1} + \hat{f}(x'', \pi_k)^{-1})\}^{1/2}$ with $\hat{f}(x, \pi_k)$ the estimated joint density.

 $^{{}^{6}}w(x, x', \pi)$ is well defined since $Ch^{d}Cov(\hat{\tau}(x; \pi), \hat{\tau}(x'; \pi)) \rightarrow \rho_{2}(x, \pi)\mathbb{1}(t \in [-1, 1]^{d}) \cdot Cov((1 - \rho(x, t, \pi_{k})^{2})^{1/2}\mathbb{Z}_{1} + \rho(x, t, \pi_{k})\mathbb{Z}_{2}, \mathbb{Z}_{2})$ after applying a change of variable. Thus, the argument of the square root in the denominator is positive.

Proposition 2 suggests that critical values of the tests can be obtained from the standard normal distribution. This proposition forms an integral part of the asymptotic properties that follow.

Theorem 1. Let Assumptions 1 - 5 hold, then under the

(*i*) null hypothesis (5)

$$\lim_{C\to\infty}\Pr(\hat{S}_1>z_{1-\alpha})=\alpha;$$

(*ii*) null hypothesis (7)

$$\lim_{C \to \infty} \Pr(\hat{S}_2 > z_{1-\alpha}) = \alpha$$

Theorem 1 shows that the test statistics \hat{S}_1 and \hat{S}_2 have correct sizes asymptotically under H_0^{Π} and H_0^X respectively. Hence, the following one-sided decision rule suffices: For j = 1, 2 reject the null hypothesis if $\hat{S}_j > z_{1-\alpha}$, where $z_{1-\alpha}, \alpha \in [0, 1]$ is the $(1 - \alpha)^{th}$ quantile (critical value) obtained from the standard normal distribution.

3.2 Power properties of the Test statistics

In this subsection, I investigate the power of the test statistics against a fixed and a sequence of local alternatives drifting to the null. First, I establish that \hat{S}_1 and \hat{S}_2 are consistent against the following fixed alternatives

$$H_1^{\Pi} : \int_{\mathcal{X}} \sum_{k=1}^K \sum_{j=1}^K \left\{ |\tau(x; \pi_k) - \tau(x; \pi_j)| \right\} w(x, \pi_k, \pi_j) dx > 0,$$
(18)

$$H_1^X : \int_{\mathcal{X}} \int_{\mathcal{X}} \sum_{k=1}^K \left\{ |\tau(x; \pi_k) - \tau(x'; \pi_k)| \right\} \frac{w(x, x', \pi_k)}{2} dx dx' > 0$$
(19)

respectively. These alternative hypotheses (18) and 19 are analogous to those in (6) and (8) respectively.

Theorem 2. Let Assumptions 1 - 5 hold, then

(i) under the fixed alternative hypothesis (18)

$$\lim_{C\to\infty}\Pr(\hat{S}_1>z_{1-\alpha})=1, \ and$$

(ii) under the fixed alternative hypothesis (19),

$$\lim_{C \to \infty} \Pr(\hat{S}_2 > z_{1-\alpha}) = 1.$$

Theorem 2 shows that the proposed test statistics have power against fixed alternatives. Next, I show that the proposed tests \hat{S}_1 and \hat{S}_2 can detect a sequence of local alternatives converging to the null hypotheses. Specifically, consider the following sequences of local alternatives

$$H_a^{\Pi}: \tau(x,\pi) - \tau(x,\pi') = C^{-1/2} h^{-d/4} \cdot N_0^{-1/2} \delta_1(x,\pi,\pi') \ \forall x \in \mathcal{X}, \pi, \pi' \in \Pi$$
(20)

$$H_a^X : \tau(x,\pi) - \tau(x',\pi) = C^{-1/2} h^{-d/4} \cdot N_0^{-1/2} \delta_2(x,x',\pi) \ \forall x,x' \in \mathcal{X}, \pi \in \Pi,$$
(21)

converging to the null hypotheses H_a^{Π} and H_a^X respectively where for $j = 1, 2, \delta_j(\cdot, \cdot, \cdot)$ is a real bounded function satisfying:

$$\int_{X} \sum_{\pi \in \Pi} \sum_{\pi' \in \Pi} |\delta_1(x, \pi, \pi')| w(x, \pi, \pi') dx > 0, \text{ and } \int_{X} \int_{X} \sum_{\pi \in \Pi} |\delta_2(x, x', \pi)| w(x, x', \pi) dx dx' > 0.$$

Theorem 3. Let Assumptions 1 - 5 hold, then

(i) under the sequences of alternative hypotheses (20),

$$\lim_{C\to\infty} \Pr(\hat{S}_1 > z_{1-\alpha}) = 1 - \Phi\left(z_{1-\alpha} - \frac{1}{\sqrt{2\pi\sigma_1}} \int_X \sum_{k=1}^K \sum_{j=1}^K \delta^2(x, \pi_k, \pi_j) dx\right),$$

and;

(ii) under the sequences of alternative hypotheses (21),

$$\lim_{C\to\infty} \Pr(\hat{S}_2 > z_{1-\alpha}) = 1 - \Phi\left(z_{1-\alpha} - \frac{1}{2\sqrt{2\pi\sigma_2}} \int_X \int_X \sum_{j=1}^K \delta^2(x, x', \pi_k) dx dx'\right),$$

where Φ denotes the cumulative distribution function (CDF) of the standard normal distribution.

Theorem 3 demonstrates that the test statistics have statistical power greater than zero against local alternatives approaching the null at a rate slower than $C^{-1/2}h^{-d/4}$. This rate agrees with that found in nonparametric kernel-based tests of parametric restrictions.

Remark 4. While the asymptotic results hold for $d \ge 1$, it is important to recognize that kernelbased estimators may be biased in higher dimensions due to the curse of dimensionality. However, this does not diminish the practical value of the testing procedures developed in this paper, as they remain highly effective for covariates of low dimension — as long as the data size is moderate which is a common setting in many empirical applications.

In general, testing HTEs in the presence of high-dimensional covariates remains an open area of research. Although Fan et al. (2022), Huang and Yang (2022), and some other papers have studied estimation and inference of CATE under the SUTVA assumption with high dimensional covariates *X*, no existing papers have studied HTEs testing with high dimensional covariates. A straightforward approach will involve an application of the two-stage method on split samples described in Fan et al. (2022). Specifically, a machine learning algorithm will reduce the dimension of *X* in the first stage. Then, the testing procedure proposed in this paper can be applied to the *X* selected from the first stage on an independent set of clusters.

3.3 Bootstrap-Based Inference

I introduce bootstrap resampling procedures in this subsection to obtain the null distributions of \hat{S}_1 and \hat{S}_2 . These bootstrap procedures provide a benchmark for the aforementioned asymptoticbased methods in finite samples. Specifically, I numerically compare the power and size of the asymptotic-based and bootstrap-based procedures for finite samples in Appendix A .

Following the recommendations of several authors, particularly Davidson and MacKinnon (1999), I propose the following bootstrap resampling procedures that impose the null hypotheses.

3.3.1 The Bootstrap resampling algorithm for \hat{S}_1

Let $\mathbf{W}_c = (\mathbf{X}_c, \mathbf{T}_c, \mathbf{Y}_c)$ denote the vector of variables for the c^{th} cluster. Therefore, the pooled sample across all clusters can be written as $\{\mathbf{W}_c\}_{c=1}^C$. I propose the following pairs cluster bootstrap-t procedure with the null H_0^{Π} imposed to generate the null distribution of \hat{S}_1 :

- For k = 1,..., K, randomly draw C_k clusters from the pooled clusters with replacement and denote the resulting bootstrapped pseudo-sample combined with a treatment exposure π_k as W^{*}(π_k) := {W_c^{*}, π_k}^{C_k}_{c=1}. That is, for each k, all the C_k clusters in that pseudo-sample have a treatment exposure of π_k which may differ from their true exposure.
- 2. Compute the test statistic $\hat{S}_1^* = \hat{T}_1^* a_1^*$ using the pooled bootstrapped data $\{W^*(\pi_k)\}_{k=1}^K$, where the definition of \hat{T}_1^* and a_1^* are the same as \hat{T}_1 and a_1 respectively. Comparing \hat{S}_1^* to its asymptotic counterpart, note that I omit the standard error term in the denominator to reduce computation time.
- 3. Repeat 1 and 2 a large number of times (say B_1 times) and use the empirical distribution of the B_1 bootstrapped test statistics $\{\hat{S}_{1,b}^*\}_{b=1}^{B_1}$ to approximate the null distribution of $\hat{T}_1 a_1$.
- 4. Compute the empirical *p*-value as $\hat{p}_* = B_1^{-1} \sum_{b=1}^{B_1} \mathbb{1}(\hat{S}_{1,b}^* > \hat{S}_1^o)$ where \hat{S}_1^o is the test statistic computed with the original data.

3.3.2 The Bootstrap resampling algorithm for \hat{S}_2

I propose the following wild cluster bootstrap-t procedure with the null H_0^X imposed to generate the null distribution of \hat{S}_2 :

- 1. Estimate a "restricted" nonparametric conditional mean function $\mathbb{E}(Y_{ci}|X = \bar{x}, \Pi_{ci}, T_{ci})$. Let the resulting fitted values be $\hat{M}(\bar{x}, \pi_c, t_{ci}), c = 1, ..., C, i = 1, ..., N$. The restricted conditional mean does not vary by the pre-treatment variables *X*, since they are held constant at their average value \bar{x} .
- 2. Let $\hat{\mathbf{M}}_c$ denote the vector of fitted values in cluster *c*. Then, obtain the cluster residuals $\hat{\mathbf{\epsilon}}_c = \mathbf{Y}_c \hat{\mathbf{M}}_c, c = 1, \dots, C$. Since we compute these residuals using the restricted conditional means, they are residuals obtained under the null hypothesis H_0^X .
- 3. For each cluster c = 1, ..., C, form cluster dependent vectors as

$$\mathbf{Y}_c^* = \hat{\mathbf{M}}_c + \hat{\boldsymbol{\varepsilon}}_c^*,$$

where $\hat{\boldsymbol{\varepsilon}}_c^* = \hat{\boldsymbol{\varepsilon}}_c \cdot V_c^*$ with V_c^* Rademacher distributed. These dependent vectors are used to create a bootstrap pseudo-sample $(\mathbf{X}_c, \mathbf{T}_c, \mathbf{\Pi}_c, \mathbf{Y}_c^*), c = 1 \dots C$, where $(\mathbf{X}_c, \mathbf{T}_c, \mathbf{\Pi}_c)$ are from the original sample.

- 4. Compute the test statistic $\hat{S}_2^* = \hat{T}_2^* a_2^*$ using the null bootstrap sample where I define \hat{T}_2^* and a_2^* the same way as \hat{T}_2 and a_2 respectively. Here also, I omit the scaling factor based on the same argument as in \hat{S}_1^*
- 5. Repeat 3–4 many times (say B_2 times) and use the empirical distribution of the B_2 bootstrapped test statistics $\{\hat{S}_{2,b}^*\}_{b=1}^{B_2}$ to approximate the null distribution of $\hat{T}_1 - a_2$.
- 6. Compute the empirical *p*-value as $\hat{p}^* = B_2^{-1} \sum_{b=1}^{B_2} \mathbb{1}(\hat{S}^*_{2,b} > \hat{S}^o_2)$, where \hat{S}^o_2 is the test statistic computed via the original data.

4 Monte Carlo Simulation

In this section, I investigate the finite sample performance of the proposed test statistics via Monte Carlo experiments. I first check the size and power of the test statistics. Then, I compare the performance with their parametric counterparts. I also report additional simulation results in Appendix A.

4.1 Empirical size and statistical power

All the rejection probabilities in the simulations are based on 1000 replications. In the experiments in this section, I focus on one pre-treatment variable X_{ci} ⁷ drawn from the uniform [0, 1] distribution allowing for within-cluster correlations. Each cluster is assigned one of four treatment vectors $\mathbf{T}(k)$, $k = 1 \dots 4$. The average of $\mathbf{T}(k)$ is π_k where $\{\pi_1, \pi_2, \pi_3, \pi_4\} = \{0.3, 0.4, 0.5, 0.6\} = \mathbf{II}$. The realized outcome Y_{ci} is constructed as follows:

$$Y_{ci} = (\tau(X_{ci}, \Pi_{ci}) + U_{1ci}) \times T_{ci} + U_{0ci} \times (1 - T_{ci}),$$

where U_{1ci} and U_{0ci} are independent normals with a mean of zero and variance of 0.1, and $T_{ci} \in \mathbf{T}(k)$. The general specification of the CATE is

$$\tau(x;\pi) = \beta_0 x + \beta_1 \pi.$$

⁷I extend the experiment to the case with two pre-treatment variables in Appendix A .4.

In the experiments, I compute CATEs on a uniform grid in the interval between the 10^{th} and 90^{th} percentiles of *X*. This way, I avoid the *boundary bias* issue associated with the kernel estimators. Integrals are computed with the composite trapezoid technique.

I adopt the following kernel function that satisfies Assumption 5(d):

$$K(u) = 1.5(1 - (2u)^2) \cdot \mathbb{1}\{|u| \le 0.5\},\tag{22}$$

and a bandwidth

$$h = \kappa_h \hat{s}_X C^{-2/7},\tag{23}$$

where \hat{s}_X is the sample standard deviation of *X* and κ_h is a constant. A similar kernel and bandwidth are employed in Chang et al. (2015). Moreover, I set *C* = 150 with 10 units ($N_c = 10$) in each cluster (i.e., N=1500 units).

To compute the empirical size of \hat{S}_1 , I fix $\beta_0 = 1$ and $\beta_1 = 0$. Thus, $\tau(x; \pi) = x$, and the null hypothesis H_0^{Π} of CTEs by Π is true. Note that as β_1 deviates further from 0 in both directions, the null hypothesis deviates further away from the truth. Again, I report the empirical rejection probabilities for values of β_1 in the range [-0.5, 0.5], with 0.05 increments.

In contrast, to obtain the empirical size of \hat{S}_2 , I set $\beta_0 = 0$, and $\beta_1 = 1$. Thus, $\tau(x; \pi) = \pi$, and the null hypothesis H_0^X of CTEs by X is true. I report the empirical rejection probabilities for each β_0 in the range [-0.5, 0.5], with 0.05 increments.

Focusing on the asymptotic-based procedure, a summary of the empirical rejection probabilities is in Figure 2 (and in Tables 6–8 in Appendix A). In each panel, the plots represent the rejection probabilities at the 1%, 5%, and 10% nominal levels. The left panel reports the empirical rejection probabilities of \hat{S}_1 , and the right panel reports those of \hat{S}_2 . When $\beta_0 = \beta_1 = 0$, the empirical rejection probabilities are close to the nominal probabilities, corroborating the theoretical results in Theorem 1. On the contrary, as β_0 and β_1 deviate towards ±0.5, the rejection probabilities approach 1, which aligns with Theorem 2.

Similarly, using the bootstrap procedures, I summarize the empirical rejection probabilities in Figure 3 (and in Tables 9–10 in Appendix A). The results are based on 399 bootstrap resamples. Compared to the asymptotic-based empirical rejection probabilities, the differences in the proba-

bilities are negligible. This suggests that the test statistics under the null hypotheses "converge in bootstrap distribution" to the standard normal distribution for large sample sizes.

Figure 2: Empirical rejection probabilities using asymptotic method.

Figure 3: Empirical rejection probabilities using the bootstrap method.

(a) Power curve for \hat{S}_1^* when β_1 lies between -0.5 and 0.5. (b) Power curve for \hat{S}_2^* when β_0 lies between -0.5 and 0.5.

4.2 Parametric Testing and Misspecification

The Monte Carlo experiment in this subsection seeks to show that parametric tests of H_0^{Π} and H_0^X may be misleading because parametric models are always misspecified to a certain degree. I only report the results of the asymptotic-based procedure to save space. I generate sample data $\{Y_i, X_i, T_i, \Pi_i\}$ of size N=600 (C = 60 and $N_c = 10$), and $\Pi_i \in \{0.3, 0.4, 0.5, 0.6\}$. The outcome is of

	Estimate	Std. Error	t value	<i>p</i> -value
Intercept	0.027	0.018	1.549	0.122
Т	4.473	3.018	1.483	0.139
Х	-0.012	0.016	-0.760	0.448
П	-0.022	0.042	-0.527	0.598
$T \cdot X$	-3.101	2.362	-1.313	0.190
$T \cdot \Pi$	-6.565	6.702	-0.980	0.328
Number of observations:	600			
\mathbb{R}^2	0.002			
Adjusted R ²	-0.007			
Residual Std. Error	3.517 (df = 594)			
F Statistic	0.200 (df = 5,594)			

 Table 1: Summary of Test Results for Simulated DGP based on Parametric Tests using clustered standard errors

the form:

$$Y_{ci} = (\tau(X_{ci}, \Pi_{ci}) + U_{1ci}) \times T_{ci} + U_{0ci} \times (1 - T_{ci}),$$

where

$$\tau(x;\pi) = 30 \cdot \cos(2 \cdot 3.142 \cdot x) \cdot (\pi^2 - \pi).$$

I keep the remaining design as in Section 4 .1 above. This new CATE specification is highly non-linear in X and Π .

I estimate the following linear regression model using ordinary least squares:

$$Y_{ci} = \beta_0 + \beta_1 T_{ci} + \beta_2 X_{ci} + \beta_3 \Pi_{ci} + \beta_4 T_{ci} \cdot X_{ci} + \beta_5 T_{ci} \cdot \Pi_{ci} + \varepsilon_{ci}.$$

The parameters β_4 and β_5 measures HTEs across *X* and Π respectively. The estimation results in Table 1 show that β_4 and β_5 are insignificant when we use clustered standard errors. It leads to the wrong conclusion that treatment effects do not vary by the exposure variable Π , and the pre-treatment variable *X*.

Next, I test the null hypotheses using this paper's proposed nonparametric test statistics. I use

the kernel function in (22) and the bandwidth formula in (23). Table 2 summarizes the results of the two tests at different bandwidth choices (different κ_h in the bandwidth formula in (23)). The results unequivocally reject the null hypotheses of CTEs by the exposure variable Π , and the pre-treatment variable X. This serves as a stark reminder of the potential for misspecification of the functional form of the conditional mean in parametric models to lead to an erroneous inference of HTEs, underscoring the need for the nonparametric testing procedures in this paper.

$\underline{H_0^{\Pi}: \text{CTEs across }\Pi}$		H_0^X : CTEs across X

Table 2: Summary of Test results for Simulated DGP based on proposed nonparametric test

5 **Empirical Application**

In this section, I use the experimental data from Cai et al. (2015) to demonstrate the usage of the proposed test statistics. This experiment was implemented to help determine whether farmers' understanding of a weather insurance policy affects purchasing decisions. The authors examine the impact of two types of information sessions on insurance adoption among 5335 households in 185 small rice-producing villages (47 administrative villages) in 3 regions in the Jiangxi province in China. They show that the type of information session directly affects participants' adoption and significantly affects the adoption decision of participants' friends.

The data includes each household's network information (each household has at most five friends) and additional pre-treatment information such as age, gender, rice production area, risk aversion score, the fraction of household income from rice production, and others. The outcome of interest is binary: whether or not a household buys the insurance policy. For each village in the experiment, there were *two rounds* of information sessions offered to introduce the insurance product. Households are randomly assigned to rounds.⁸ In each round, *two sessions* were held

⁸Each household can only participate in one of the two rounds.

simultaneously: a simple session (with less information) and an intensive session. Households are randomly assigned to sessions. Participants have to make a purchase decision on the spot in each session. Since the second round of information sessions were held three days after the first, Cai et al. (2015) argue that information may spill to households participating in the second round of information sessions from their friends who attended the first round. That is, the insurance adoption of those in the first round depends only on their treatment (participation) status, *but the insurance adoption of participants in the second round depends on their treatment and the treatment statuses of their friends in the first round.* Table 3 shows the result of a nonlinear probability (logit) model of insurance adoption on "Second-round" — a binary variable which is one if households participated in the second round session and zero otherwise — among households in the *simple sessions.* The coefficients of "Second-round" indicate that the probability of adoption among the second-round participants in the simple sessions is higher than their first-round counterparts. This is evidence of information spillover.

	Dependent variable: Insurance takeup			
	(Without village fixed effects)	(With village fixed effects)		
Constant	-0.609***	0.693		
	(0.064)	(0.875)		
Second-round	0.423***	0.474***		
	(0.084)	(0.089)		
Observations	2,453	2,453		
Log Likelihood	-1,646.452	-1,546.740		
Akaike Inf. Crit.	3,296.904	3,189.480		
Note:		*p<0.1; **p<0.05; ***p<0.01		

Table 3: Logit Regression Evidence of Information spillover

Furthermore, the analyses in Cai et al. (2015) rule out any form of between-administrative village diffusion of information, which makes the data fit into the clustered network setting of this paper. Figure 4 from Bargagli Stoffi et al. (2020) shows a network plot of the data for the 47 administrative villages.

Figure 4: Links between households in the 47 administrative villages. Different Villages have different colors.

In addition, Cai et al. (2015) show that while farmers are influenced by their friends who attended the first round of intensive sessions, they are unaffected by friends who attended the first round of simple sessions. They also show that people are less influenced by their friends when they have the same education about the insurance products (e.g., information from first-round households in the intensive session does not affect the purchasing decision of second-round households in the intensive session). These observations are crucial for defining the post-treatment exposure variable in this application.

To illustrate the use of the proposed test statistics, I focus on the second-round participants in each administrative village. I define the post-treatment exposure variable as the fraction of households who attended the first-round intensive session in an administrative village. I also focus on one pre-treatment variable: the fraction of household income from rice production.⁹ A household is considered "treated" if it attended an intensive session, while those that participated in the simple session are labeled "untreated." The outcome of interest is the second-round participants' adoption of the insurance policy.

There are 2653 households in my restricted sample (second-round participants with no missing values for the four variables). To ensure balance in the post-treatment exposure variable (treatment

⁹The fraction of household income from rice production should significantly influence a household's decision to purchase insurance. Households with a small fraction of income from rice production are unlikely to buy insurance, those with a moderate fraction are more likely to purchase it, and households with a large fraction are also unlikely to buy — because they may already have an insurance policy — *ceteris paribus*.

ratio), I binarize the treatment ratio: households from villages with the fraction of first-round intensive session participants less than 0.22 constitute the first group, and those from villages with the fraction of first-round intensive session participants greater than 0.22 make up the second group. There are 1488 and 1239 households in the two groups, respectively.¹⁰ Thus, technically, the exposure variable is a threshold function of the treatment ratio.

Using this sample, I test the two null hypotheses. Figure 5 shows the estimated average treatment effects against the fraction of income from rice production for the two exposure groups. Visually, the estimated ATEs seem to vary with the exposure variable and the fraction of household income from rice production. However, are these variations statistically significant? Using the kernel function defined in (22) and the bandwidth formula in (23), the results in Table 4 show that the proposed asymptotic-based tests fail to reject the null hypotheses of CTEs by the treatment ratio variable and the fraction of household income from rice production at different bandwidths and conventional significance levels. Moreover, based on Holm's MTP, I jointly fail to reject the two null hypotheses at the different bandwidths and conventional significance levels.

¹⁰Note that the threshold for the binarization is purely based on sample size considerations. I chose the threshold so the two groups will have sufficient units.

Bandwidth (h)	H_0^{Π} : CTEs across treatment ratios		H_0^X : CTEs across fraction of rice income		
	\hat{S}_1	<i>p</i> -value	\hat{S}_2	<i>p</i> -value	
0.096	1.076	0.141	0.143	0.443	
0.106	1.117	0.132	0.144	0.443	
0.116	1.192	0.117	0.363	0.358	

Table 4: Nonparametric test based on full sample

Based on Figure 5, there is a wider gap between the ATEs for the two categories of treatment ratio when the fraction of rice production lies between 0.5 and 0.8. Thus, to check the robustness of the proposed testing procedures, I restrict the sample to these households and re-implement the tests. Figure 6 shows a plot of the estimated ATEs against the fraction of income from rice production using the new sample. The test results in Table 5 show that ATE varies with the treatment ratio (at the conventional significance levels) but is constant across the fraction of income from rice production as expected.

Bandwidth (h)	H_0^{Π} : CTEs across treatment ratios		H_0^X : CTEs across fraction of rice income	
	\hat{S}_1	<i>p</i> -value	\hat{S}_2	<i>p</i> -value
0.099	3.288	< 0.01	-0.086	0.534
0.102	3.390	< 0.01	-0.081	0.532
0.106	3.425	< 0.01	-0.079	0.531

Table 5: nonparametric test of subsample

6 Conclusion

The nonparametric tests I develop in this paper not only allow for valid inference for heterogeneous treatment effects in the presence of clustered interference but also play a crucial role in disentangling the source of variation in the treatment effects. This unique feature sets the proposed tests apart from existing procedures. The test statistics are sums of weighted L_1 -norm pairwise differences in consistent nonparametric kernel estimators of conditional average treatment effects. Applying the poissonization technique in Giné et al. (2003), I show that the test statistics are asymptotically normally distributed and have correct sizes in large samples. Moreover, they are consistent under fixed alternatives and have nonzero power against local alternatives, drifting to the null. I provide Monte Carlo results that corroborate the theoretical findings. On the applied side, I illustrate the usage of the proposed tests with the data from Cai et al. (2015). I find no evidence of heterogeneous treatment effects across the values of both a post-treatment exposure variable and a pre-treatment variable: the fraction of household income from rice production.

There is room for several extensions. It will be interesting to provide theoretical guarantees for the proposed bootstrap methods in the paper. For instance, Table 11 in Appendix A provides simulation evidence that suggests that the bootstrap algorithm of \hat{S}_1 achieves asymptotic refinement. It will be insightful to theoretically investigate if the proposed bootstrap algorithms achieve asymptotic refinement over asymptotic-based tests. Since it is never trivial to show bootstrap refinements even in more standard tests, I defer such a study to future research. Secondly, it is valuable to provide HTEs testing procedures in networks that are not clustered (single un-clustered networks). Owusu (2023a) studies randomization tests for HTEs in single un-clustered networks. The procedures in this companion paper are, however, only applicable to experimental data.

7 Acknowledgments

This is a revised version of the first Chapter of my Ph.D. Dissertation at McMaster University, Owusu (2023b). It has benefited from feedback of Youngki Shin, Jeffrey S. Racine, Micheal Veall, Saraswata Chaudhuri, Sukjin Han, Emmanuel S. Tsyawo, Monika A. Márquez, Antoine A. Djogbenou, and participants at the 32nd Annual Meeting of Midwest Econometrics Group and the 56th Annual Conference of the Canadian Economics Association. This work was made possible by the advanced research computing platform provided by the Digital Research Alliance of Canada (formerly Compute Canada). All errors are my own.

Table 10: Empirical Rejection Probabilities with $n_c = 10$, C = 150, $h = \kappa_h \hat{s}_X C^{-2/7}$ and $\Pi = (0.3, 0.4, 0.5, 0.6)$.

A.3 Bootstrap versus Asymptotic in Small Samples

In Table 11, I compare the empirical sizes of the bootstrap-based test statistics with their asymptotic counterparts when the sample size is small, precisely when C = 50 and $N_c = 10$). The result shows that the empirical sizes computed using the bootstrapping algorithms and their asymptotic counterparts are close in general.

when sample size is sm	nall: $n_c = 10, C = 3$	$50, n = \kappa_h \cdot s_X C^{-2/4}$, and $\Pi = (0.3, 0.4)$, 0.5, 0.6).
Nominal probabilities	Test statistic for H_0^{Π}		Test statistic for H_0^X	
	Bootstrap-based	Asymptotic-based	Bootstrap-based	Asymptotic-based
0.01	0.012	0.029	0.017	0.013
0.05	0.052	0.094	0.055	0.050
0.10	0.106	0.158	0.106	0.128

Table 11: Comparison of empirical size for the bootstrap and asymptotic-based testing approach when sample size is small: $n_c = 10$, C = 50, $h = \kappa_h \cdot \hat{s}_X C^{-2/7}$, and $\Pi = (0.3, 0.4, 0.5, 0.6)$.

A.4 Extension of the Monte Carlo Simulation Experiment to Multivariate Covariates

I extend the experiment in Section 4 to multivariate pre-treatment variables. For both test statistics, each pre-treatment variable X_d , d > 1 is drawn independently from the standard uniform distribution that allows for within-cluster dependence. Each cluster is assigned one of two treatment vectors $\mathbf{T}(k)$. Here, the average of $\mathbf{T}(k)$ is either 0.3 or 0.4. I use the Monte Carlo integration technique to compute all integrals. The general functional form of the CATE is

$$\tau(\mathbf{x}, \pi) = \beta_0 \sum_{l=1}^d x_l + \beta_1 \pi.$$
 (A.1)

I restrict attention to the case where d = 2 and defer cases with d > 2 to a companion paper (in progress), which provides an R package of the testing procedures in this paper. This R package will be available for download and use. I keep the remaining design as in Section 4.1.

Focusing on \hat{S}_1 , fix $\beta_0 = 1$ and $\beta_1 = 0$ (i.e., the null hypothesis of CTEs by Π is true); and $\beta_1 = 0.5$, (which implies that the null hypothesis of CTEs by Π is false). Due to the curse of dimensionality associated with kernel estimation, one should expect a poor performance of the tests when the dimension of continuous variables increases. Table 12 reports the rejection probabilities of \hat{S}_1 under the two β_2 specifications, which give us the empirical size and power, respectively.

Table 12: Empirical size and power of \hat{S}_1 using multivariate *X*. *C* = 200, $N_c = 10$, bandwidth=5 $\cdot \hat{s}_X N^{-2/7}$ and $\Pi = (0.3, 0.4)$.

Nominal probabilities	<u>d =</u> Size	<u>= 2</u> Power
0.01	0.013	0.292
0.05	0.053	0.444
0.10	0.086	0.533

Next, I turn attention to \hat{S}_2 . Using the CATE in (A .1), fix $\beta_0 = 0$ and $\beta_1 = 1$ (i.e., the null hypothesis of CTEs by X is true); and $\beta_0 = 0.5$, (which implies that the null hypothesis of CTEs by X is false). In Table 13, I report the rejection probabilities of \hat{S}_2 under the two specifications.

Nominal probabilitios	d = 2		
Nominal probabilities	Size	Power	
0.01	0.040	1.000	
0.05	0.097	1.000	
0.10	0.018	1.000	

Table 13: Empirical size and power of \hat{S}_2 using multivariate *X*. *C* = 200, $N_c = 10$, bandwidth=5 · $\hat{s}_X N^{-2/7}$ and $\Pi = (0.3, 0.4)$.

The empirical size and power calculations in Tables 12 and 13 numerically show that the proposed test statistics have non-zero power and are valid for a multivariate $X \in X^2$. The empirical size and power calculations in Tables 12 and 13 numerically show that the proposed test statistics have non-zero power and are valid for a multivariate $X \in X^2$. However, as highlighted in the Remark 4, due to the curse of dimensionality, we observe some size distortion and loss in power.

B Proof of Main Results

B.1 Proof of Proposition 1

Proposition 1. Suppose Assumptions 1-4 hold, then

$$\tau(x;\pi_k) := \mathbb{E}[Y(1,\pi_k)|X=x] - \mathbb{E}[Y(0,\pi_k)|X=x]$$
$$= \mathbb{E}[Y|T=1,\Pi=\pi_k, X=x] - \mathbb{E}[Y|T=0,\Pi=\pi_k, X=x] \ \forall k = 1, \dots, K \ and \ x \in X.$$

Proof. Under Assumptions 1-2 and 3(i) realized outcomes can be written in terms of potential outcomes as:

$$Y = \sum_{k=1}^{K} \left(Y(0, \pi_k) + [Y(1, \pi_k) - Y(0, \pi_k)] \cdot T \right) \cdot \mathbb{1}(\Pi = \pi_k).$$
(B.1)

Hence, by Assumption 4, $\mathbb{E}[Y|T = t, \Pi = \pi_k, X = x]$ exists for all t = 0, 1 k = 1, ..., K and $x \in X$, with

$$\mathbb{E}[Y|T = 1, \Pi = \pi_k, X = x] = \mathbb{E}\left[\sum_{k=1}^K \left(Y(0, \pi_k) + [Y(1, \pi_k) - Y(0, \pi_k)] \cdot T\right) \cdot \mathbb{1}(\Pi = \pi_k) \middle| T = 1, \Pi = \pi_k, X = x\right]$$
$$= \mathbb{E}\left[Y(1, \pi_k) \middle| T = 1, \Pi = \pi_k, X = x\right]$$

$$=\mathbb{E}[Y(1,\pi_k)|X=x] \qquad [by Assumption 3(ii)] \qquad (B.2)$$

and

$$\mathbb{E}[Y|T = 0, \Pi = \pi_k, X = x] = \mathbb{E}\left[\sum_{k=1}^{K} \left(Y(0, \pi_k) + [Y(1, \pi_k) - Y(0, \pi_k)] \cdot T\right) \cdot \mathbb{1}(\Pi = \pi_k) \middle| T = 0, \Pi = \pi_k, X = x\right]$$
$$= \mathbb{E}\left[Y(0, \pi_k) | T = 0, \Pi = \pi_k, X = x\right]$$
$$= \mathbb{E}\left[Y(0, \pi_k) | X = x\right] \qquad \text{[by Assumption 3(ii)]} \qquad (B.3)$$

Hence, from (B.2) and (B.3), we have

$$\mathbb{E}[Y|T = 1, \Pi = \pi_k, X = x] - \mathbb{E}[Y|T = 0, \Pi = \pi_k, X = x] = \mathbb{E}[Y(1, \pi_k)|X = x] - \mathbb{E}[Y(0, \pi_k)|X = x]$$

as required.

B.2 Asymptotic Variance and Bias Derivations

Lemma 1. Suppose \mathcal{H} is a finite class of uniformly bounded real-valued functions H, equal to zero outside a known compact set. Further, let g(x)f(x) be continuously differentiable in x with $\sup_{x \in B} \left| \frac{d(g(x)f(x))}{dx} \right| < \infty$ where $B \subset \mathbb{R}^d$ is a compact set. Then uniformly in $H \in \mathcal{H}$

$$\sup_{x \in B} \left| \frac{1}{h^d} \int_{\mathbb{R}^d} g(z) f(z) H\left(\frac{x-z}{h}\right) dz - g(x) f(x) \int_{\mathbb{R}^d} H\left(\frac{x-z}{h}\right) dz \right| \to 0 \text{ as } h \to 0.$$
(B.4)

Proof. This lemma is similar to Lemma 6.1 in Giné et al. (2003) and Lemma B.9 in Chang et al.(2015). The proof given in Giné et al. (2003).

B.2.1 Test statistics \hat{T}_1

Define

$$\widehat{\Gamma}(x;\pi_k,\pi_j) \coloneqq \widehat{\tau}(x;\pi_k) - \widehat{\tau}(x;\pi_j)$$

$$=\frac{1}{Nh^d}\sum_{i=1}^N Y_i\left[\mathbbm{1}(\Pi_i=\pi_k)\hat{\phi}(T_i,x,\pi_k)-\mathbbm{1}(\Pi_i=\pi_j)\hat{\phi}(T_i,x,\pi_j)\right]K\left(\frac{x-X_i}{h}\right).$$

Under the null hypothesis, the bias of \hat{T}_1 is define as

$$\begin{aligned} \operatorname{Bias}(\hat{T}_{1}) &:= \mathbb{E}[\hat{T}_{1}] \\ &= \mathbb{E}\left[\int_{X}\sum_{k=1}^{K}\sum_{j>k}^{K}\left\{\sqrt{N}|\hat{\Gamma}(x;\pi_{k},\pi_{j})|\right\}\hat{w}(x,\pi_{k},\pi_{j})dx\right] \\ &= \int_{X}\sum_{k=1}^{K}\sum_{j>k}^{K}\mathbb{E}\left[\sqrt{N}|\hat{\Gamma}(x;\pi_{k},\pi_{j})|\right]\hat{w}(x,\pi_{k},\pi_{j})dx \\ &= \frac{1}{\sqrt{h^{d}}}\int_{X}\sum_{k=1}^{K}\sum_{j>k}^{K}\left\{\mathbb{E}\left|(\hat{\Gamma}(x;\pi_{k},\pi_{j}))\sqrt{Nh^{d}}\hat{w}(x,\pi_{k},\pi_{j})\right|\right\}dx \\ &\to \frac{1}{\sqrt{h^{d}}}\int_{X}\sum_{k=1}^{K}\sum_{j>k}^{K}\left\{\mathbb{E}\left|\frac{(\hat{\Gamma}(x;\pi_{k},\pi_{j}))}{\sqrt{\operatorname{Var}(\hat{\Gamma}(x;\pi_{k},\pi_{j}))}}\right|\right\}dx \quad \text{[by Assumption 5(h)]} \\ &= \frac{1}{\sqrt{h^{d}}}\int_{X}\sum_{k=1}^{K}\sum_{j>k}^{K}\mathbb{E}|\mathbb{Z}_{1}|dx \\ &= h^{\frac{-d}{2}}\cdot\mathbb{E}|\mathbb{Z}_{1}|\cdot\frac{K(K-1)}{2}\cdot\int_{X}dx \\ &= a_{1}. \end{aligned}$$

On the other hand, the variance of \hat{T}_1 under the null is

$$\begin{aligned} Var(\hat{T}_1) &\coloneqq \int_1 \operatorname{Cov}(|\sqrt{N}\hat{\Gamma}(x;\pi_i,\pi_j)\hat{w}(x,\pi_i,\pi_j)|, |\sqrt{N}\hat{\Gamma}(x';\pi_k,\pi_l))\hat{w}(x',\pi_k,\pi_l)|)dxdx' \\ &= \frac{1}{h^d} \int_1 \mathbb{1}\left(\frac{x-x'}{h} \in [-1,1]^d\right) \operatorname{Cov}(|\sqrt{Nh^d}\hat{\Gamma}(x;\pi_i,\pi_j)\hat{w}(x,\pi_i,\pi_j)|, |\sqrt{Nh^d}\hat{\Gamma}(x';\pi_k,\pi_l)|) \\ &\quad \cdot \hat{w}(x',\pi_k,\pi_l)|)dxdx', \end{aligned}$$

where $\int_1 \coloneqq \int_{\mathbb{R}^d} \int_{\mathbb{R}^d} \sum_{i=1}^K \sum_{j=1}^K \sum_{k=1}^K \sum_{l=1}^K$.

Now, let $(Z_{1n}(x, \pi_i, \pi_j), Z_{2n}(x', \pi_k, \pi_l)), x, x' \in \mathbb{R}^d$ be mean zero, bivariate Gaussian process such that for each $x \in \mathbb{R}^d$ and $x' \in \mathbb{R}^d, (Z_{1n}(x, \pi_i, \pi_j), Z_{2n}(x', \pi_k, \pi_l))$ and $(\sqrt{Nh^d}\hat{\Gamma}(x; \pi_i, \pi_j)\hat{w}(x, \pi_i, \pi_j), \sqrt{Nh^d}\hat{\Gamma}(x'; \pi_k, \pi_l))\hat{w}(x', \pi_k, \pi_l))$ have the same covariance structure. Thus, by the "bivariate normal distribution generation formula",

$$(Z_{1n}(x,\pi_i,\pi_j), Z_{2n}(x',\pi_k,\pi_l)) \stackrel{d}{=} \left(\sqrt{1 - \rho^*(x,x',\pi_i,\pi_j,\pi_k,\pi_l)^2} \mathbb{Z}_1 + \rho^*(x,x',\pi_i,\pi_j,\pi_k,\pi_l) \mathbb{Z}_2, \mathbb{Z}_2 \right)$$
(B.5)

where \mathbb{Z}_1 and \mathbb{Z}_2 are independent standard normal random variables and

$$\rho^*(x, x', \pi_i, \pi_j, \pi_k, \pi_l) := \operatorname{Corr}[\sqrt{Nh^d}(\hat{\Gamma}(x; \pi_i, \pi_j))\hat{w}(x, \pi_i, \pi_j), \sqrt{Nh^d}(\hat{\Gamma}(x'; \pi_k, \pi_l))\hat{w}(x', \pi_k, \pi_l)]$$

Let

$$\bar{s}_1^2 = \frac{1}{h^d} \int_1 \mathbb{1}\left(\frac{x - x'}{h} \in [-1, 1]^d\right) \operatorname{Cov}(|Z_{1n}(x, \pi_i, \pi_j)|, |Z_{2n}(x', \pi_k, \pi_l)|) dx dx'$$

Applying the change of variable x' = x + th, we have

$$\bar{s}_1^2 = \int_{\mathbb{R}^d} \int_{[-1,1]^d} \sum_{i=1}^K \sum_{j=1}^K \sum_{k=1}^K \sum_{l=1}^K \operatorname{Cov}(|Z_{1n}(x,\pi_i,\pi_j)|, |Z_{2n}(x+th,\pi_k,\pi_l)|) dx dt,$$

Furthermore, from Assumption 5(h) (i.e., $\sqrt{Nh^d}\hat{w}(x, \pi, \pi') \rightarrow (Var(\hat{\Gamma}(x; \pi, \pi')))^{-1/2}$), Lemma 1 (which holds under Assumption 5(e)) and the change of variable x' = x + th, we have that for almost every (x, t),

$$\rho^*(x, x', \pi_i, \pi_j, \pi_k, \pi_l) \to \rho(x, t, \pi_i, \pi_j, \pi_k, \pi_l)$$

with

$$\rho(x,t,\pi_i,\pi_j,\pi_k,\pi_l) = \frac{\operatorname{Cov}(\hat{\Gamma}(x,\pi_i,\pi_j),\hat{\Gamma}(x+th;\pi_k,\pi_l))}{\sqrt{Var(\hat{\Gamma}(x;\pi_i,\pi_j))}} \sqrt{Var(\hat{\Gamma}(x+th;\pi_k,\pi_l))}$$

$$\begin{cases} \frac{\int K(\xi)K(\xi+t)d\xi}{\int K(\xi)^2d\xi} & \text{if } i = k \ \& \ j = l \\ \frac{-\int K(\xi)K(\xi+t)d\xi}{\int K(\xi)^2d\xi} & \text{if } i = l \ \& \ j = k \\ \frac{-Var(\widehat{\tau}(x,\pi_{j}))}{\sqrt{Var(\widehat{\Gamma}(x;\pi_{i},\pi_{j}))}\sqrt{Var(\widehat{\Gamma}(x;\pi_{k},\pi_{l}))}} \cdot \frac{\int K(\xi)K(\xi+t)d\xi}{\int K(\xi)^2d\xi} & \text{if } j = k \ \& \ i \neq l \\ \frac{-Var(\widehat{\tau}(x,\pi_{i}))}{\sqrt{Var(\widehat{\Gamma}(x;\pi_{i},\pi_{j}))}\sqrt{Var(\widehat{\Gamma}(x;\pi_{k},\pi_{l}))}} \cdot \frac{\int K(\xi)K(\xi+t)d\xi}{\int K(\xi)^2d\xi} & \text{if } j \neq k \ \& \ i = l \\ \frac{Var(\widehat{\tau}(x,\pi_{i}))}{\sqrt{Var(\widehat{\Gamma}(x;\pi_{i},\pi_{j}))}\sqrt{Var(\widehat{\Gamma}(x;\pi_{k},\pi_{l}))}} \cdot \frac{\int K(\xi)K(\xi+t)d\xi}{\int K(\xi)^2d\xi} & \text{if } j = l \ \& \ i \neq k \\ \frac{Var(\widehat{\tau}(x,\pi_{i}))}{\sqrt{Var(\widehat{\Gamma}(x;\pi_{i},\pi_{j}))}\sqrt{Var(\widehat{\Gamma}(x;\pi_{k},\pi_{l}))}} \cdot \frac{\int K(\xi)K(\xi+t)d\xi}{\int K(\xi)^2d\xi} & \text{if } j \neq l \ \& \ i = k \\ 0 & \text{otherwise} \end{cases}$$

Hence, based on (B.5),

$$\operatorname{Cov}(|Z_{1n}(x)|, |Z_{2n}(x+th)|) \to \operatorname{Cov}\left(\left|\sqrt{1-\rho(x,t,\pi_i,\pi_j,\pi_k,\pi_l)^2}\mathbb{Z}_1+\rho(x,t,\pi_i,\pi_j,\pi_k,\pi_l)\mathbb{Z}_2\right|, |\mathbb{Z}_2|\right)$$

Finally, as in the proof of (6.35) in Giné et al. (2003), using the bounded convergence theorem with respect to the Lebesgue measure, we have $\bar{s}_1^2 - Var(\hat{T}_1) \rightarrow 0$, as such we have

$$\begin{split} &\lim_{N \to \infty} Var(\hat{T}_{1}) \\ &= \int_{\mathbb{R}^{d}} \int_{[-1,1]^{d}} \sum_{i=1}^{K} \sum_{j>i}^{K} \sum_{k=1}^{K} \sum_{l>k}^{K} \operatorname{Cov}\left(\left| \sqrt{1 - \rho(x,t,\pi_{i},\pi_{j},\pi_{k},\pi_{l})^{2}} \mathbb{Z}_{1} + \rho(x,t,\pi_{i},\pi_{j},\pi_{k},\pi_{l}) \mathbb{Z}_{2} \right|, |\mathbb{Z}_{2}| \right) dx dt \\ &=: \sigma_{1}^{2}. \end{split}$$

Recall that all the asymptotic results are based on equal cluster sizes. As a result, I safely interchange $C \to \infty$ and $N = N_0 C \to \infty$ unless there is a confusion. Plugging the kernel-based estimates of the variances into the formula for $\rho(x, t, \pi_i, \pi_j, \pi_k, \pi_l)$, gives us the plug-in estimator $\hat{\rho}(x, t, \pi_i, \pi_j, \pi_k, \pi_l)$. Hence, a consistent estimator of the asymptotic variance of \hat{T}_1 is

$$\hat{\sigma}_{1}^{2} = \int_{\mathbb{R}^{d}} \int_{\mathbb{R}^{d}} \sum_{i=1}^{K} \sum_{j>i}^{K} \sum_{k=1}^{K} \sum_{l>k}^{K} \operatorname{Cov}\left(\left| \sqrt{1 - \hat{\rho}(x, t, \pi_{i}, \pi_{j}, \pi_{k}, \pi_{l})^{2}} \mathbb{Z}_{1} + \hat{\rho}(x, t, \pi_{i}, \pi_{j}, \pi_{k}, \pi_{l}) \mathbb{Z}_{2} \right|, |\mathbb{Z}_{2}| \right) dxdt$$

B .2.2 Test statistics \hat{T}_2

Define

$$\hat{\Gamma}(x; x', \pi) := \hat{\tau}(x; \pi_k) - \hat{\tau}(x'; \pi_k)$$

Now under the null hypothesis, the bias of \hat{T}_2 as

$$\begin{split} \operatorname{Bias}(\hat{T}_{2}) &:= \mathbb{E}[\hat{T}_{2}] \\ &= \mathbb{E}\left[\int_{X} \int_{X} \sum_{k=1}^{K} \left\{\sqrt{N}|\hat{\Gamma}(x,x',\pi_{k})|\right\} \frac{\hat{w}(x,x',\pi_{k})}{2} dx dx'\right] \\ &= \frac{1}{\sqrt{h^{d}}} \int_{X} \int_{X} \sum_{k=1}^{K} \mathbb{E}\left[\sqrt{Nh^{d}}|\hat{\Gamma}(x,x',\pi_{k})|\right] \frac{\hat{w}(x,x',\pi_{k})}{2} dx dx' \\ &\to \frac{1}{2\sqrt{h^{d}}} \int_{X} \int_{X} \sum_{k=1}^{K} \left\{\mathbb{E}\left|\frac{(\hat{\Gamma}(x,x',\pi_{k}))}{\sqrt{\operatorname{Var}(\hat{\Gamma}(x,x',\pi_{k}))}}\right|\right\} dx dx' \quad \text{[by Assumption 5(h)]} \\ &= \frac{1}{2\sqrt{h^{d}}} \int_{X} \int_{X} \sum_{k=1}^{K} \mathbb{E}\left|\mathbb{Z}_{1}\right| dx dx' \\ &= h^{\frac{-d}{2}} \cdot \mathbb{E}|\mathbb{Z}_{1}| \cdot \frac{K}{2} \cdot \int_{X} \int_{X} dx dx' =: a_{2}. \end{split}$$

Also, the variance of \hat{T}_2 is

$$\begin{aligned} Var(\hat{T}_{2}) &:= \frac{1}{4} \int_{2} \operatorname{Cov}(\sqrt{N} |\hat{\Gamma}(x, x', \pi_{k})|, |\sqrt{N}\hat{\Gamma}(x'', x''', \pi_{k})|)| \hat{w}(x, x', \pi_{k}) \hat{w}(x'', x''', \pi_{k}) dx dx' dx'' dx''' \\ &= \frac{1}{4h^{d}} \int_{2} \operatorname{Cov}(\sqrt{Nh^{d}} |\hat{\Gamma}(x, x', \pi_{k})|, |\sqrt{Nh^{d}}\hat{\Gamma}(x'', x''', \pi_{k})|) |\hat{w}(x, x', \pi_{k}) \hat{w}(x'', x''', \pi_{k}) dx dx' dx'' dx''' dx''', \end{aligned}$$

where $\int_2 := \int_{\mathbb{R}^d} \int_{\mathbb{R}^d} \int_{\mathbb{R}^d} \int_{\mathbb{R}^d} \sum_{k=1}^K$. Now, note that the integral above is non-zero if at least one of the elements in the set

$$\mathbf{H} := \left\{ \mathbbm{1}((x-x^{\prime\prime})h^{-1} \in [-1,1]^d), \mathbbm{1}((x-x^{\prime\prime\prime})h^{-1} \notin [-1,1]^d), \mathbbm{1}((x^\prime-x^{\prime\prime})h \in [-1,1]^d), \mathbbm{1}((x^\prime-x^{\prime\prime\prime})h^{-1} \in [-1,1]^d) \right\}$$

equals 1. Thus, the variance becomes

$$\begin{split} & \operatorname{Var}(\hat{f}_{2}) = \frac{1}{4h^{d}} \int_{2} 1 \left(\frac{x - x''}{h} \in [-1, 1]^{d} \right) \\ & \cdot \operatorname{Cov}(|\sqrt{Nh^{d}} \hat{w}(x, x', \pi_{k}) \hat{\Gamma}(x, x', \pi_{k})|, |\sqrt{Nh^{d}} \hat{w}(x'', x''', \pi_{k}) \hat{\Gamma}(x'', x''', \pi_{k})|)| dx dx' dx'' dx''' \\ & + \frac{1}{4h^{d}} \int_{2} 1 \left(\frac{x - x'''}{h} \in [-1, 1]^{d} \right) \\ & \cdot \operatorname{Cov}(|\sqrt{Nh^{d}} \hat{w}(x, x', \pi_{k}) \hat{\Gamma}(x, x', \pi_{k})|, |\sqrt{Nh^{d}} \hat{w}(x'', x''', \pi_{k}) \hat{\Gamma}(x'', x''', \pi_{k})|)| dx dx' dx'' dx''' \\ & + \frac{1}{4h^{d}} \int_{2} 1 \left(\frac{x' - x'''}{h} \in [-1, 1]^{d} \right) \\ & \cdot \operatorname{Cov}(|\sqrt{Nh^{d}} \hat{w}(x, x', \pi_{k}) \hat{\Gamma}(x, x', \pi_{k})|, |\sqrt{Nh^{d}} \hat{w}(x'', x''', \pi_{k}) \hat{\Gamma}(x'', x''', \pi_{k})|)| dx dx' dx'' dx''' \\ & + \frac{1}{4h^{d}} \int_{2} 1 \left(\frac{x' - x'''}{h} \in [-1, 1]^{d} \right) \\ & \cdot \operatorname{Cov}(|\sqrt{Nh^{d}} \hat{w}(x, x', \pi_{k}) \hat{\Gamma}(x, x', \pi_{k})|, |\sqrt{Nh^{d}} \hat{w}(x'', x''', \pi_{k}) \hat{\Gamma}(x'', x''', \pi_{k})|)| dx dx' dx'' dx''' \\ & + \frac{1}{4h^{d}} \int_{2} 1 \left(\frac{x' - x'''}{h} \in [-1, 1]^{d} \right) 1 \left(\frac{x' - x'''}{h} \in [-1, 1]^{d} \right) \\ & \cdot \operatorname{Cov}(|\sqrt{Nh^{d}} \hat{w}(x, x', \pi_{k}) \hat{\Gamma}(x, x', \pi_{k})|, |\sqrt{Nh^{d}} \hat{w}(x'', x''', \pi_{k}) \hat{\Gamma}(x'', x''', \pi_{k})|)| dx dx' dx'' dx''' \\ & + \frac{1}{4h^{d}} \int_{2} 1 \left(\frac{x - x'''}{h} \in [-1, 1]^{d} \right) 1 \left(\frac{x' - x'''}{h} \in [-1, 1]^{d} \right) \\ & \cdot \operatorname{Cov}(|\sqrt{Nh^{d}} \hat{w}(x, x', \pi_{k}) \hat{\Gamma}(x, x', \pi_{k})|, |\sqrt{Nh^{d}} \hat{w}(x'', x''', \pi_{k}) \hat{\Gamma}(x'', x''', \pi_{k})|)| dx dx' dx'' dx''' \\ & + \frac{1}{4h^{d}} \int_{2} 1 \left(\frac{x - x'''}{h} \in [-1, 1]^{d} \right) 1 \left(\frac{x' - x'''}{h} \in [-1, 1]^{d} \right) \\ & \cdot \operatorname{Cov}(|\sqrt{Nh^{d}} \hat{w}(x, x', \pi_{k}) \hat{\Gamma}(x, x', \pi_{k})|, |\sqrt{Nh^{d}} \hat{w}(x'', x''', \pi_{k}) \hat{\Gamma}(x'', x''', \pi_{k})|)| dx dx' dx'' dx''' \\ & + \frac{1}{4h^{d}} \int_{2} 1 \left(\frac{x - x''}{h} \in [-1, 1]^{d} \right) 1 \left(\frac{x' - x'''}{h} \in [-1, 1]^{d} \right) \\ & \cdot \operatorname{Cov}(|\sqrt{Nh^{d}} \hat{w}(x, x', \pi_{k}) \hat{\Gamma}(x, x', \pi_{k})|, |\sqrt{Nh^{d}} \hat{w}(x'', x''', \pi_{k}) \hat{\Gamma}(x'', x''', \pi_{k})|)| dx dx' dx'' dx''' \\ & + \frac{1}{4h^{d}} \int_{2} 1 \left(\frac{x - x'''}{h} \in [-1, 1]^{d} \right) 1 \left(\frac{x' - x'''}{h} \in [-1, 1]^{d} \right) \\ & \cdot \operatorname{Cov}(|\sqrt{Nh^{d}} \hat{w}(x, x', \pi_{k}) \hat{\Gamma}(x, x', \pi_{k})|, |\sqrt{Nh^{d}} \hat{w}(x'', x''', \pi_{k}) \hat{\Gamma}(x'', x''', \pi_{k})|)| dx dx' dx'' dx'''$$

$$\begin{split} \cdot \operatorname{Cov}(|\sqrt{Nh^{d}}\hat{w}(x,x',\pi_{k})\hat{\Gamma}(x,x',\pi_{k})|, |\sqrt{Nh^{d}}\hat{w}(x'',x''',\pi_{k})\hat{\Gamma}(x'',x''',\pi_{k})|)|dxdx'dx''dx''' \\ &+ \frac{1}{4h^{d}}\int_{2}\mathbbm{1}\left(\frac{x-x''}{h}\in[-1,1]^{d}\right)\mathbbm{1}\left(\frac{x'-x''}{h}\in[-1,1]^{d}\right)\mathbbm{1}\left(\frac{x'-x'''}{h}\in[-1,1]^{d}\right)\mathbbm{1}\left(\frac{x'-x'''}{h}\in[-1,1]^{d}\right)\\ \cdot \operatorname{Cov}(|\sqrt{Nh^{d}}\hat{w}(x,x',\pi_{k})\hat{\Gamma}(x,x',\pi_{k})|, |\sqrt{Nh^{d}}\hat{w}(x'',x''',\pi_{k})\hat{\Gamma}(x'',x''',\pi_{k})|)|dxdx'dx''dx''' \\ &+ \frac{1}{4h^{d}}\int_{2}\mathbbm{1}\left(\frac{x-x''}{h}\in[-1,1]^{d}\right)\mathbbm{1}\left(\frac{x-x'''}{h}\in[-1,1]^{d}\right)\mathbbm{1}\left(\frac{x'-x'''}{h}\in[-1,1]^{d}\right)\\ \cdot \operatorname{Cov}(|\sqrt{Nh^{d}}\hat{w}(x,x',\pi_{k})\hat{\Gamma}(x,x',\pi_{k})|, |\sqrt{Nh^{d}}\hat{w}(x'',x''',\pi_{k})\hat{\Gamma}(x'',x''',\pi_{k})|)|dxdx'dx''dx''' \\ &+ \frac{1}{4h^{d}}\int_{2}\mathbbm{1}\left(\frac{x-x''}{h}\in[-1,1]^{d}\right)\mathbbm{1}\left(\frac{x-x'''}{h}\in[-1,1]^{d}\right)\mathbbm{1}\left(\frac{x'-x''}{h}\in[-1,1]^{d}\right)\\ \cdot \operatorname{Cov}(|\sqrt{Nh^{d}}\hat{w}(x,x',\pi_{k})\hat{\Gamma}(x,x',\pi_{k})|, |\sqrt{Nh^{d}}\hat{w}(x'',x''',\pi_{k})\hat{\Gamma}(x'',x''',\pi_{k})|)|dxdx'dx''dx''' \\ &+ \frac{1}{4h^{d}}\int_{2}\mathbbm{1}\left(\frac{x-x''}{h}\in[-1,1]^{d}\right)\mathbbm{1}\left(\frac{x-x'''}{h}\in[-1,1]^{d}\right)\mathbbm{1}\left(\frac{x'-x'''}{h}$$

In large samples, any integrals where it is possible for more than one of the elements in **H** to be equal to 1 will converge to zero as $C \to \infty$ ($h \to 0$). Theoretically, this is obvious after applying a change of variables. Intuitively, it is because the chance of having the scaled distance between two or more distinct points in the covariate space belonging to the hypercube goes to zero as $h \to 0$. Hence,

$$\begin{split} Var(\hat{T}_{2}) &\to \frac{1}{4h^{d}} \int_{2} \mathbb{1} \left(\frac{x - x''}{h} \in [-1, 1]^{d} \right) \\ &\cdot \operatorname{Cov}(|\sqrt{Nh^{d}} \hat{w}(x, x', \pi_{k}) \hat{\Gamma}(x, x', \pi_{k})|, |\sqrt{Nh^{d}} \hat{w}(x'', x''', \pi_{k}) \hat{\Gamma}(x'', x''', \pi_{k}))|) dx dx' dx'' dx''' \\ &+ \frac{1}{4h^{d}} \int_{2} \mathbb{1} \left(\frac{x - x'''}{h} \in [-1, 1]^{d} \right) \\ &\cdot \operatorname{Cov}(|\sqrt{Nh^{d}} \hat{w}(x, x', \pi_{k}) \hat{\Gamma}(x, x', \pi_{k})|, |\sqrt{Nh^{d}} \hat{w}(x'', x''', \pi_{k}) \hat{\Gamma}(x'', x''', \pi_{k}))|) dx dx' dx'' dx''' \\ &+ \frac{1}{4h^{d}} \int_{2} \mathbb{1} \left(\frac{x' - x''}{h} \in [-1, 1]^{d} \right) \\ &\cdot \operatorname{Cov}(|\sqrt{Nh^{d}} \hat{w}(x, x', \pi_{k}) \hat{\Gamma}(x, x', \pi_{k})|, |\sqrt{Nh^{d}} \hat{w}(x'', x''', \pi_{k}) \hat{\Gamma}(x'', x''', \pi_{k}))|) dx dx' dx'' dx''' \\ &+ \frac{1}{4h^{d}} \int_{2} \mathbb{1} \left(\frac{x' - x'''}{h} \in [-1, 1]^{d} \right) \\ &\cdot \operatorname{Cov}(|\sqrt{Nh^{d}} \hat{w}(x, x', \pi_{k}) \hat{\Gamma}(x, x', \pi_{k})|, |\sqrt{Nh^{d}} \hat{w}(x'', x''', \pi_{k}) \hat{\Gamma}(x'', x''', \pi_{k}))|) dx dx' dx'' dx''' \\ &=: \sigma_{2}^{2}. \end{split}$$

Thus,

$$\begin{split} \sigma_{2}^{2} &= \frac{1}{4h^{d}} \int_{2} \mathbb{1} \left(\frac{x - x''}{h} \in [-1, 1]^{d} \right) \cdot \operatorname{Cov} \left(\left| \frac{\hat{\tau}(x, \pi_{k})}{\sqrt{\operatorname{Var}(\hat{\Gamma}(x, x', \pi_{k}))}} \right|, \left| \frac{\hat{\tau}(x'', \pi_{k})}{\sqrt{\operatorname{Var}(\hat{\Gamma}(x', x''', \pi_{k}))}} \right| \right) dx dx' dx'' dx''' \\ &+ \frac{1}{4h^{d}} \int_{2} \mathbb{1} \left(\frac{x - x'''}{h} \in [-1, 1]^{d} \right) \cdot \operatorname{Cov} \left(\left| \frac{\hat{\tau}(x, \pi_{k})}{\sqrt{\operatorname{Var}(\hat{\Gamma}(x, x', \pi_{k}))}} \right|, \left| \frac{\hat{\tau}(x'', \pi_{k})}{\sqrt{\operatorname{Var}(\hat{\Gamma}(x'', x''', \pi_{k}))}} \right| \right) dx dx' dx'' dx''' \\ &+ \frac{1}{4h^{d}} \int_{2} \mathbb{1} \left(\frac{x' - x''}{h} \in [-1, 1]^{d} \right) \operatorname{Cov} \left(\left| \frac{\hat{\tau}(x', \pi_{k})}{\sqrt{\operatorname{Var}(\hat{\Gamma}(x, x', \pi_{k}))}} \right|, \left| \frac{\hat{\tau}(x''', \pi_{k})}{\sqrt{\operatorname{Var}(\hat{\Gamma}(x'', x''', \pi_{k}))}} \right| \right) dx dx' dx'' dx''' \\ &+ \frac{1}{4h^{d}} \int_{2} \mathbb{1} \left(\frac{x' - x'''}{h} \in [-1, 1]^{d} \right) \operatorname{Cov} \left(\left| \frac{\hat{\tau}(x', \pi_{k})}{\sqrt{\operatorname{Var}(\hat{\tau}(x, x', \pi_{k}))}} \right|, \left| \frac{\hat{\tau}(x''', \pi_{k})}{\sqrt{\operatorname{Var}(\hat{\tau}(x'', \pi_{k}))}} \right| \right) dx dx' dx'' dx''' \\ &= \frac{1}{4h^{d}} \int_{2} \mathbb{1} \left(\frac{x - x'''}{h} \in [-1, 1]^{d} \right) \frac{\sqrt{\operatorname{Var}(\hat{\tau}(x, \pi_{k}))\operatorname{Var}(\hat{\tau}(x'', \pi_{k}))}}{\sqrt{\operatorname{Var}(\hat{\tau}(x, \pi_{k}))\operatorname{Var}(\hat{\tau}(x'', \pi_{k}))}} \\ &\cdot \operatorname{Cov} \left(\left| \frac{\hat{\tau}(x, \pi_{k})}{\sqrt{\operatorname{Var}(\hat{\tau}(x, \pi_{k}))}} \right|, \left| \frac{\hat{\tau}(x''', \pi_{k})}{\sqrt{\operatorname{Var}(\hat{\tau}(x'', \pi_{k}))}} \right| \right) dx dx' dx'' dx''' \\ &+ \frac{1}{4h^{d}} \int_{2} \mathbb{1} \left(\frac{x - x'''}{h} \in [-1, 1]^{d} \right) \frac{\sqrt{\operatorname{Var}(\hat{\tau}(x, \pi_{k}))\operatorname{Var}(\hat{\tau}(x'', \pi_{k}))}}{\sqrt{\operatorname{Var}(\hat{\tau}(x, x', \pi_{k}))\operatorname{Var}(\hat{\tau}(x'', \pi_{k}))}} \\ &\cdot \operatorname{Cov} \left(\left| \frac{\hat{\tau}(x, \pi_{k})}{\sqrt{\operatorname{Var}(\hat{\tau}(x, \pi_{k}))}} \right|, \left| \frac{\hat{\tau}(x''', \pi_{k})}{\sqrt{\operatorname{Var}(\hat{\tau}(x'', \pi_{k}))}} \right| \right) dx dx' dx'' dx''' \\ &+ \frac{1}{4h^{d}} \int_{2} \mathbb{1} \left(\frac{x' - x''}{h} \in [-1, 1]^{d} \right) \frac{\sqrt{\operatorname{Var}(\hat{\tau}(x', \pi_{k}))}}{\sqrt{\operatorname{Var}(\hat{\tau}(x', \pi_{k}))\operatorname{Var}(\hat{\tau}(x'', \pi_{k}))}} \\ &\cdot \operatorname{Cov} \left(\left| \frac{\hat{\tau}(x'', \pi_{k})}{h} \in [-1, 1]^{d} \right) \frac{\sqrt{\operatorname{Var}(\hat{\tau}(x'', \pi_{k}))}}{\sqrt{\operatorname{Var}(\hat{\tau}(x'', \pi_{k}))\operatorname{Var}(\hat{\tau}(x'', \pi_{k}))}} \right) dx dx' dx'' dx''' \\ &+ \frac{1}{4h^{d}} \int_{2} \mathbb{1} \left(\frac{x' - x'''}{h} \in [-1, 1]^{d} \right) \frac{\sqrt{\operatorname{Var}(\hat{\tau}(x'', \pi_{k}))}}{\sqrt{\operatorname{Var}(\hat{\tau}(x'', \pi_{k}))}} \right) dx dx' dx'' dx''' \\ &+ \operatorname{Cov} \left(\left| \frac{\hat{\tau}(x'', \pi_{k})}{h} \in [-1, 1]^{d} \right) \frac{\sqrt{\operatorname{Var}(\hat{\tau}(x'', \pi_{k}))}}}{\sqrt{\operatorname{Var}(\hat{\tau$$

Now, let $(Z_{1n}(x, \pi_k), Z_{2n}(x'', \pi_k)), x, x'' \in \mathbb{R}^d$ be mean zero, bivariate Gaussian process such that for each $x \in \mathbb{R}^d$ and $x'' \in \mathbb{R}^d, (Z_{1n}(x, \pi_k), Z_{2n}(x'', \pi_k))$ and $(\sqrt{Nh^d}\hat{\tau}(x, \pi_k)w(x, \pi_k), \sqrt{Nh^d}\hat{\tau}(x'', \pi_k))\hat{w}(x'', \pi_k))$ have the same covariance structure. Thus, by the "bivariate normal distribution generation formula,"

$$(Z_{1n}(x,\pi_k), Z_{2n}(x'',\pi_k)) \stackrel{d}{=} \left(\sqrt{1 - \rho^*(x,x''\pi_k)^2} \mathbb{Z}_1 + \rho^*(x,x'',\pi_k) \mathbb{Z}_2, \mathbb{Z}_2 \right)$$
(B.6)

where \mathbb{Z}_1 and \mathbb{Z}_2 are independent standard normal random variables and

$$\begin{split} \rho^*(x, x'', \pi_k) &:= \operatorname{Corr} \left(\sqrt{Nh^d} (\hat{\tau}(x, \pi_k) - \mathbb{E}[\hat{\tau}(x, \pi_k)]) \hat{w}(x, \pi_k), \sqrt{Nh^d} (\hat{\tau}(x'', \pi_k) - \mathbb{E}[\hat{\tau}(x'', \pi_k)]) \hat{w}(x'', \pi_k) \right) \\ &= \frac{\mathbb{E}[(\hat{\tau}(x, \pi_k) - \mathbb{E}[\hat{\tau}(x, \pi_k)]) (\hat{\tau}(x'', \pi_k) - \mathbb{E}[\hat{\tau}(x'', \pi_k)])]}{\sqrt{Var(\hat{\tau}(x, \pi_k))} \sqrt{Var(\hat{\tau}(x'', \pi_k))}} \end{split}$$

Based on Lemma 1 (which holds under Assumption 5(e)) and the change of variable x'' = x + th, we have that for almost every (x, t),

$$\rho^*(x, x+th, \pi_k) \to \rho(x, t, \pi_k) := \frac{\int K(\xi) K(\xi+t) d\xi}{\int K(\xi)^2 d\xi}$$
(B.7)

Let

$$\bar{s}_{21}^{2} = \frac{1}{4h^{d}} \int_{2} \mathbb{1}\left(\frac{x - x''}{h} \in [-1, 1]^{d}\right) \frac{\sqrt{Var(\hat{\tau}(x, \pi_{k}))Var(\hat{\tau}(x'', \pi_{k}))}}{\sqrt{Var(\hat{\Gamma}(x, x', \pi_{k}))Var(\hat{\Gamma}(x'', x''', \pi_{k}))}} \cdot \operatorname{Cov}(|Z_{1n}(x, \pi_{k})|, |Z_{2n}(x'', \pi_{k})|)dxdx'dx''dx''',$$

Applying the change of variable x'' = x + th, we have,

$$\begin{split} \bar{s}_{21}^2 = & \frac{1}{4h^d} \int_{2'} h^d \frac{\sqrt{Var(\hat{\tau}(x,\pi_k))Var(\hat{\tau}(x+th,\pi_k))}}{\sqrt{Var(\hat{\Gamma}(x,x',\pi_k))Var(\hat{\Gamma}(x+th,x''',\pi_k))}} \\ & \cdot \operatorname{Cov}(|Z_{1n}(x,\pi_k)|, |Z_{2n}(x+th,\pi_k)|) dx dx' dx''' dt, \end{split}$$

where $\int_{2'} \coloneqq \int_{[-1,1]^d} \int_{\mathbb{R}^d} \int_{\mathbb{R}^d} \int_{\mathbb{R}^d} \sum_{k=1}^K dk_{k-1}$.

Now note that from (B.6) and (B.7),

$$\operatorname{Cov}(|Z_{1n}(x,\pi_k)|, |Z_{2n}(x+th,\pi_k)|) \to \operatorname{Cov}\left(\left|\sqrt{1-\rho(x,t,\pi_k)^2}\mathbb{Z}_1+\rho(x,t,\pi_k)\mathbb{Z}_2\right|, |\mathbb{Z}_2|\right)$$

Finally, as in the proof of (6.35) in Giné et al. (2003), using the bounded convergence theorem with

respect to the Lebesgue measure, the first term of the variance converges to

$$\begin{split} \bar{s}_{21}^{2} &= \frac{1}{4} \int_{2'} \frac{\sqrt{Var(\hat{\tau}(x,\pi_{k}))Var(\hat{\tau}(x+th,\pi_{k}))}}{\sqrt{Var(\hat{\Gamma}(x,x',\pi_{k}))Var(\hat{\Gamma}(x+th,x''',\pi_{k})}} \text{Cov} \left(\left| \sqrt{1 - \rho(x,t,\pi_{k})^{2}} \mathbb{Z}_{1} + \rho(x,t,\pi_{k}) \mathbb{Z}_{2} \right|, |\mathbb{Z}_{2}| \right) dx dx' dx''' dt \\ &= \frac{1}{4} \int_{2'} \frac{Var(\hat{\tau}(x,\pi_{k}))}{\sqrt{Var(\hat{\Gamma}(x,x',\pi_{k}))Var(\hat{\Gamma}(x,x''',\pi_{k}))}} \text{Cov} \left(\left| \sqrt{1 - \rho(x,t,\pi_{k})^{2}} \mathbb{Z}_{1} + \rho(x,t,\pi_{k}) \mathbb{Z}_{2} \right|, |\mathbb{Z}_{2}| \right) dx dx' dx''' dt, \end{split}$$

Analogously, the second term reduces to

$$\begin{split} \bar{s}_{22}^{2} &= \frac{1}{4} \int_{2'} \frac{\sqrt{Var(\hat{\tau}(x,\pi_{k}))Var(\hat{\tau}(x+th,\pi_{k}))}}{\sqrt{Var(\hat{\Gamma}(x,x',\pi_{k}))Var(\hat{\Gamma}(x'',x+th,\pi_{k}))}} \operatorname{Cov} \left(\left| \sqrt{1 - \rho(x,t,\pi_{k})^{2}} \mathbb{Z}_{1} + \rho(x,t,\pi_{k}) \mathbb{Z}_{2} \right|, |\mathbb{Z}_{2}| \right) dx dx' dx'' dt, \\ &= \frac{1}{4} \int_{2'} \frac{Var(\hat{\tau}(x,\pi_{k})))}{\sqrt{Var(\hat{\Gamma}(x,x',\pi_{k}))Var(\hat{\Gamma}(x'',x,\pi_{k}))}} \operatorname{Cov} \left(\left| \sqrt{1 - \rho(x,t,\pi_{k})^{2}} \mathbb{Z}_{1} + \rho(x,t,\pi_{k}) \mathbb{Z}_{2} \right|, |\mathbb{Z}_{2}| \right) dx dx' dx'' dt, \end{split}$$

the third term becomes

$$\begin{split} \bar{s}_{23}^{2} &= \frac{1}{4} \int_{2'} \frac{\sqrt{Var(\hat{\tau}(x',\pi_{k}))Var(\hat{\tau}(x'+th,\pi_{k}))}}{\sqrt{Var(\hat{\Gamma}(x,x',\pi_{k}))Var(\hat{\Gamma}(x'+th,x''',\pi_{k})}} \text{Cov}\left(\left|\sqrt{1-\rho(x',t,\pi_{k})^{2}}\mathbb{Z}_{1}+\rho(x',t,\pi_{k})\mathbb{Z}_{2}\right|, |\mathbb{Z}_{2}|\right) dx dx' dx''' dt \\ &= \frac{1}{4} \int_{2'} \frac{Var(\hat{\tau}(x',\pi_{k}))}{\sqrt{Var(\hat{\Gamma}(x,x',\pi_{k}))Var(\hat{\Gamma}(x',x''',\pi_{k})}} \text{Cov}\left(\left|\sqrt{1-\rho(x',t,\pi_{k})^{2}}\mathbb{Z}_{1}+\rho(x',t,\pi_{k})\mathbb{Z}_{2}\right|, |\mathbb{Z}_{2}|\right) dx dx' dx''' dt, \end{split}$$

and the fourth term reduces to

$$\begin{split} \bar{s}_{24}^{2} &= \frac{1}{4} \int_{2'} \frac{\sqrt{Var(\hat{\tau}(x',\pi_{k}))Var(\hat{\tau}(x'+th,\pi_{k}))}}{\sqrt{Var(\hat{\Gamma}(x,x',\pi_{k}))Var(\hat{\Gamma}(x'',x'+th,\pi_{k}))}} \operatorname{Cov} \left(\left| \sqrt{1 - \rho(x',t,\pi_{k})^{2}} \mathbb{Z}_{1} + \rho(x',t,\pi_{k}) \mathbb{Z}_{2} \right|, |\mathbb{Z}_{2}| \right) dx dx' dx'' dt \\ &= \frac{1}{4} \int_{2'} \frac{Var(\hat{\tau}(x',\pi_{k}))}{\sqrt{Var(\hat{\Gamma}(x,x',\pi_{k}))Var(\hat{\Gamma}(x'',x',\pi_{k}))}} \operatorname{Cov} \left(\left| \sqrt{1 - \rho(x',t,\pi_{k})^{2}} \mathbb{Z}_{1} + \rho(x',t,\pi_{k}) \mathbb{Z}_{2} \right|, |\mathbb{Z}_{2}| \right) dx dx' dx'' dt, \end{split}$$

Therefore,

$$\begin{split} \sigma_2^2 = &\bar{s}_{21}^2 + \bar{s}_{22}^2 + \bar{s}_{23}^2 + \bar{s}_{24}^2 \\ = & \int_{2'} \frac{Var(\hat{\tau}(x,\pi_k)))}{\sqrt{Var(\hat{\Gamma}(x,x',\pi_k))Var(\hat{\Gamma}(x'',x,\pi_k))}} \text{Cov}\left(\left|\sqrt{1 - \rho(x,t,\pi_k)^2}\mathbb{Z}_1 + \rho(x,t,\pi_k)\mathbb{Z}_2\right|, |\mathbb{Z}_2|\right) dx dx' dx'' dt, \end{split}$$

•

Plugging the kernel-based estimates of the variances into the formula gives us the plug-in estimator $\hat{\sigma}_2^2$. This variance formula can also be derived using the law of total variances.

B.3 Proofs of Lemmas and Theorems

In this section, I discuss the proof of the asymptotic normality of \hat{S}_1 and \hat{S}_2 given in Proposition 2.

Lemma 2 (Asymptotics of L_1 -norm of the CATE function, Chang et al. (2015)). Assume { $(Y_i, D_i, X_i), i = 1, ..., N$ } are *i.i.d* copies of (Y, D, X) Let $\hat{\tau}(x)$ be the standard local constant CATE estimator, and let $\hat{w}(x)$ be the inverse scaled standard error estimators. Set $\hat{D} := \int_X \sqrt{N} |\hat{\tau}(x)| \hat{w}(x) dx$. Then, under the regularity conditions in Assumption 5,

$$\frac{\hat{D} - \operatorname{Bias}(\hat{D})}{\sigma} \xrightarrow{d} N(0, 1),$$

where $\operatorname{Bias}(\hat{D})$ is the asymptotic bias of \hat{D} and $\sigma^2 := \lim_{N \to \infty} \operatorname{Var}(\hat{D})$, under the restriction that the true *CATE function* $\tau(x) = 0 \ \forall x$.

Proof. This lengthy proof involves

- 1. a uniform approximation $\hat{\tau}(x)$ to derive the asymptotic approximation of \hat{D} by D_N ,
- 2. Poissonization of D_N and limiting the integration interval to obtain $D_N^P(B)$, where $B \subseteq X$, and
- 3. de-Poissonizing $D_N^P(B)$ to derive its asymptotic normality and that of the studentized version of \hat{D} by allowing $B \to X$,

I omit the detail and refer readers to Appendix B of Chang et al. (2015). □

B.3.1 Proof of the asymptotic normality of \hat{S}_1

Recall that all within-cluster dependencies can be ignored under the working independence approach, and observations can be viewed as independent. Therefore, I can apply the results in Lemma 2.

Uniform asymptotic approximation

Write

$$\hat{\tau}(x,\pi) = \tau(x;\pi) + (\tau_{N0}(x,\pi) - \mathbb{E}(\tau_{N0}(x,\pi))) + (\mathbb{E}(\tau_{N0}(x,\pi)) - \tau(x;\pi)) + R_N(x,\pi),$$

where

$$\tau_{N0}(x,\pi) := \frac{1}{Nh^d} \sum_{i=1}^N Y_i \mathbb{1}(\Pi_i = \pi) \left[\frac{T_i}{P_1(x;\pi)} - \frac{(1-T_i)}{P_0(x;\pi)} \right] \cdot K\left(\frac{x-X_i}{h}\right),$$

$$\begin{aligned} R_N(x,\pi) &:= \frac{1}{Nh^d} \sum_{i=1}^N Y_i \mathbb{1}(\Pi_i = \pi) \left[\frac{T_i}{P_1(x;\pi)} - \frac{(1-T_i)}{P_0(x;\pi)} \right] \\ &\times \left(T_i \frac{P_1(x,\pi) - \hat{P}_1(x,\pi)}{\hat{P}_1(x,\pi)} + (1-T_i) \frac{P_0(x,\pi) - \hat{P}_0(x,\pi)}{\hat{P}_0(x,\pi)} \right) \cdot K\left(\frac{x - X_i}{h} \right). \end{aligned}$$

Therefore,

$$\begin{split} \hat{\Gamma}(x;\pi_k,\pi_j) = &\tau(x;\pi_k) - \tau(x;\pi_j) + (\tau_{N0}(x,\pi_k) - \tau_{N0}(x,\pi_j) - \mathbb{E}(\tau_{N0}(x,\pi_k) - \tau_{N0}(x,\pi_j))) \\ &+ (\mathbb{E}(\tau_{N0}(x,\pi_k) - \tau_{N0}(x,\pi_j)) - \tau(x;\pi_k) - \tau(x;\pi_j))) + R_N(x,\pi_k) - R_N(x,\pi_j). \end{split}$$

Now, define

$$\begin{split} \zeta_N(x,\pi) = & \mathbb{E}[Y|X=x,\Pi=\pi,T=1] - \mathbb{E}[Y|X=x,\Pi=\pi,T=0] \\ & - \mathbb{E}[Y|X=x,\Pi=\pi,T=1] \frac{1}{Nh^d P_1(x,\pi)} \sum_{i=1}^N T_i \mathbb{1}(\Pi=\pi) K\left(\frac{x-X_i}{h}\right) \\ & + \mathbb{E}[Y|X=x,\Pi=\pi,T=0] \frac{1}{Nh^d P_0(x,\pi)} \sum_{i=1}^N (1-T_i) \mathbb{1}(\Pi=\pi) K\left(\frac{x-X_i}{h}\right). \end{split}$$

The following lemma shows that $R_N(x, \pi)$ can be approximated by $\zeta_N(x, \pi)$ uniformly over x at a rate faster than $C^{-1/2}$.

Lemma 3. Under the regularity conditions, we find that for $\pi_k, \pi_j \in \mathbf{\Pi}$,

$$\sup_{x \in \mathcal{X}} |(R_N(x, \pi_k) - R_N(x, \pi_j)) - (\zeta_N(x, \pi_k) - \zeta_N(x, \pi_j))| = o_p(N^{-1/2}).$$

Proof. From, Lemma B.1 in Chang et al. (2015), for $\pi_k \in \Pi$, we have

$$\sup_{x \in X} |R_N(x, \pi_k) - \zeta_N(x, \pi_k))| = o_p(N^{-1/2}).$$

Now,

$$\begin{split} \sup_{x \in \mathcal{X}} |(R_N(x, \pi_k) - R_N(x, \pi_j)) - (\zeta_N(x, \pi_k) - \zeta_N(x, \pi_j))| &\leq \sup_{x \in \mathcal{X}} \{|R_N(x, \pi_k) - \zeta_N(x, \pi_k)| + |R_N(x, \pi_j) - \zeta_N(x, \pi_j)|\} \\ &= \sup_{x \in \mathcal{X}} \{|R_N(x, \pi_k) - \zeta_N(x, \pi_k)|\} + \sup_{x \in \mathcal{X}} \{|R_N(x, \pi_j) - \zeta_N(x, \pi_j)|\} \\ &= o_p(N^{-1/2}) + o_p(N^{-1/2}) = o_p(N^{-1/2}). \end{split}$$

Lemma 4. Under the regularity conditions, we have

$$\tilde{T}_1(\pi_k, \pi_j) - T^*_{1N}(\pi_k, \pi_j) = o_p(1),$$

where

$$\tilde{T}_1(\pi_k,\pi_j) \coloneqq \int_X \left\{ \sqrt{N} |\hat{\tau}(x;\pi_k) - \hat{\tau}(x;\pi_j)| \right\} \hat{w}(x,\pi_k,\pi_j) dx,$$

$$T_{1N}^{*}(\pi_{k},\pi_{j}) := \int_{\mathcal{X}} \left\{ \sqrt{N} \left| \Gamma(x,\pi_{k},\pi_{j}) + [\tau_{N}(x,\pi_{k}) - \tau_{N}(x,\pi_{j})] - \mathbb{E}[\tau_{N}(x,\pi_{k}) - \tau_{N}(x,\pi_{j})] \right| \right\} w(x,\pi_{j},\pi_{k}) dx$$
(B.8)

and

$$\tau_N(x,\pi) = \tau_{N0}(x,\pi) + \zeta_N(x,\pi).$$

Hence, under the null hypothesis such that $\tau(x; \pi_k) = \tau(x; \pi_j)$ *on* $X \times \Pi$ *, we have*

$$\tilde{T}_1(\pi_k, \pi_j) - T_{1N}(\pi_k, \pi_j) = o_p(1),$$

where

$$T_{1N}(\pi_k, \pi_j) := \int_{\mathcal{X}} \left\{ \sqrt{N} \left| [\tau_N(x, \pi_k) - \tau_N(x, \pi_j)] - \mathbb{E}[\tau_N(x, \pi_k) - \tau_N(x, \pi_j)] \right| \right\} w(x, \pi_j, \pi_k)^{11} dx$$

and

$$\begin{aligned} \tau_N(x,\pi) &:= \frac{1}{Nh^d} \sum_{i=1}^N (\{Y - \mathbb{E}[Y|X = x, \Pi = \pi, T = 1]\} \frac{T_i \cdot \mathbb{1}(\Pi = \pi)}{P_1(x,\pi_k)} \\ &- \{Y - \mathbb{E}[Y|X = x, \Pi = \pi, T = 0]\} \frac{(1 - T_i) \cdot \mathbb{1}(\Pi = \pi)}{P_0(x,\pi_k)}) \cdot K\left(\frac{x - X_i}{h}\right). \end{aligned}$$

Proof. Using the triangle inequality and the proof of Lemma B.2 in Chang et al. (2015), the proof of this Lemma is straight forward. □

Consistency of the estimators of asymptotic variance

Lemma 5. Under the regularity conditions, and using the working under independence approach the following hold:

- 1. $\sup_{x \in X} |\hat{\tau}(x, \pi) \tau(x, \pi)| = O_p((Nh^d)^{-1/2} \log N + h^s) \, \forall \pi \in \Pi,$
- 2. $\sup_{x \in X} |\hat{\rho}_2(x, \pi) \rho_2(x, \pi)| = O_p((Nh^d)^{-1/2} \log N + h^s) \, \forall \pi \in \Pi.$

Proof. This Lemma corresponds to Lemma B.2 in Chang et al. (2015). Hence I omit the proof.

Theorem 4. Under the regularity conditions, we have that

$$\frac{T_{1N}(\pi_k,\pi_j) - \operatorname{Bias}(T_{1N}(\pi_k,\pi_j))}{\sigma_{1N}(\pi_k,\pi_j)} \xrightarrow{d} N(0,1),$$

where $\operatorname{Bias}(T_{1N}(\pi_k, \pi_j))$ is the asymptotic bias of $T_{1N}(\pi_k, \pi_j)$, and $\sigma_{1N}^2(\pi_k, \pi_j) := \lim_{N \to \infty} Var(T_{1N}(\pi_k, \pi_j))$ under the null.

Proof. The proof of Theorem 4 is very lengthy so I defer it to Appendix C . \Box

¹¹Here, I use the true weight rather than the estimated weight but all results hold using the estimated weight since the estimator is uniformly consistent by assumption.

Now, from Lemma 4 and Theorem 4, we have

$$\frac{\tilde{T}_1(\pi_k, \pi_j) - \operatorname{Bias}(\tilde{T}_1(\pi_k, \pi_j))}{\tilde{\sigma}_1(\pi_k, \pi_j)} \xrightarrow{d} N(0, 1),$$
(B.9)

where $\operatorname{Bias}(\tilde{T}_1(\pi_k, \pi_j)) = \operatorname{Bias}(T_{1N}(\pi_k, \pi_j))$ is the asymptotic bias of $\tilde{T}_1(\pi_k, \pi_j)$ and $\tilde{\sigma}_1^2(\pi_k, \pi_j) := \lim_{N \to \infty} Var(\tilde{T}_1(\pi_k, \pi_j)) = \lim_{N \to \infty} Var(T_{1N}(\pi_k, \pi_j))$ under the null.

Next, observe that our test statistic \hat{T}_1 can be written as

$$\hat{T}_1 = \sum_{k=1}^K \sum_{j>k}^K \tilde{T}_1(\pi_k,\pi_j),$$

which asymptotically is the sum of dependent normal random variables with $\{\text{Bias}(\tilde{T}_1(\pi_k, \pi_j)), \pi_k, \pi_j \in \Pi\}$ as the asymptotic biases and, $\{\tilde{\sigma}_1^2(\pi_k, \pi_j), \pi_k, \pi_j \in \Pi\}$ as the asymptotic variances under the null hypothesis. Thus,

$$\frac{\hat{T}_1 - \sum_{k=1}^K \sum_{j>k}^K \operatorname{Bias}(\tilde{T}_1(\pi_k, \pi_j))}{\hat{\sigma}_1} \xrightarrow{d} N(0, 1)$$

where $\sum_{k=1}^{K} \sum_{j>k}^{K} \operatorname{Bias}(\tilde{T}_{1}(\pi_{k}, \pi_{j})) =: a_{1}, \hat{\sigma}_{1}^{2} := \lim_{N \to \infty} \widehat{Var}(\hat{T}_{1})$, with a_{1} and $\hat{\sigma}_{1}^{2}$ defined in Proposition 2. So, note that $\hat{\sigma}_{1}^{2}$ can also be viewed as the sum of the asymptotic variances of $\tilde{T}_{1}(\pi_{k}, \pi_{j})$ and their pairwise asymptotic covariances.

B.3.2 Proof of Asymptotic normality of \hat{S}_2

Uniform Asymptotic approximation

Recall that we can write

$$\hat{\tau}(x,\pi) = \tau(x;\pi) + (\tau_{N0}(x,\pi) - \mathbb{E}(\tau_{N0}(x,\pi))) + (\mathbb{E}(\tau_{N0}(x,\pi)) - \tau(x;\pi)) + R_N(x,\pi)$$

Therefore,

$$\hat{\Gamma}(x, x', \pi_k) = \tau(x; \pi_k) - \tau(x', \pi_k) + (\tau_{N0}(x, \pi_k) - \tau_{N0}(x', \pi_k) - \mathbb{E}(\tau_{N0}(x, \pi_k) - \tau_{N0}(x', \pi_k))) \\ + (\mathbb{E}(\tau_{N0}(x, \pi_k) - \tau_{N0}(x', \pi_k)) - \tau(x; \pi_k) - \tau(x', \pi_k))) + R_N(x, \pi_k) - R_N(x', \pi_k)$$

Now, define

$$\begin{split} \zeta_{N}(x,\pi) = & \mathbb{E}[Y|X=x,\Pi=\pi,T=1] - \mathbb{E}[Y|X=x,\Pi=\pi,T=0] \\ & - \mathbb{E}[Y|X=x,\Pi=\pi,T=1] \frac{1}{Nh^{d}P_{1}(x,\pi)} \sum_{i=1}^{N} T_{i}\mathbb{1}(\Pi=\pi)K\left(\frac{x-X_{i}}{h}\right) \\ & + \mathbb{E}[Y|X=x,\Pi=\pi,T=0] \frac{1}{Nh^{d}P_{0}(x,\pi)} \sum_{i=1}^{N} (1-T_{i})\mathbb{1}(\Pi=\pi)K\left(\frac{x-X_{i}}{h}\right). \end{split}$$

The following lemma shows that $R_N(x, \pi)$ can be approximated by $\zeta_N(x, \pi)$ uniformly over x at a rate faster than $N^{-1/2}$.

Under the regularity conditions, we find that for $\pi_k \in \mathbf{\Pi}$,

$$\sup_{x \in \mathcal{X}} |(R_N(x, \pi_k) - R_N(x', \pi_k)) - (\zeta_N(x, \pi_k) - \zeta_N(x', \pi_k))| = o_p(N^{-1/2}).$$

Proof. Similar to the proof of Lemma 3, for $\pi_k \in \Pi$, we have

$$\sup_{x \in X} |R_N(x, \pi_k) - \zeta_N(x, \pi_k))| = o_p(N^{-1/2}).$$

Now,

$$\begin{split} \sup_{(x,x')\in\mathcal{X}^2} &|(R_N(x,\pi_k)-R_N(x',\pi_k))-(\zeta_N(x,\pi_k)-\zeta_N(x',\pi_k))|\\ &\leq \sup_{(x,x')\in\mathcal{X}^2} \{|R_N(x,\pi_k)-\zeta_N(x,\pi_k)|+|R_N(x',\pi_k)-\zeta_N(x',\pi_k)|\}\\ &\leq \sup_{x\in\mathcal{X}} \{|R_N(x,\pi_k)-\zeta_N(x,\pi_k)|\} + \sup_{x'\in\mathcal{X}} \{|R_N(x',\pi_k)-\zeta_N(x',\pi_k)|\}\\ &= o_p(N^{-1/2}) + o_p(N^{-1/2}) = o_p(N^{-1/2}). \end{split}$$

Under the regularity conditions, we have

$$\tilde{T}_2(\pi_k) - T^*_{2N}(\pi_k) = o_p(1),$$

where

$$\hat{T}_2(\pi_k) \coloneqq \int_X \int_X \left\{ \sqrt{N} |\hat{\tau}(x;\pi_k) - \hat{\tau}(x';\pi_k)| \right\} \frac{\hat{w}(x,x',\pi_k)}{2} dx dx'$$

$$T_{2N}^{*}(\pi_{k}) := \int_{\mathcal{X}} \int_{\mathcal{X}} \left\{ \sqrt{N} \left| \Gamma(x, x', \pi_{k}) + [\tau_{N}(x, \pi_{k}) - \tau_{N}(x', \pi_{k})] - \mathbb{E}[\tau_{N}(x, \pi_{k}) - \tau_{N}(x', \pi_{k})] \right| \right\} \frac{w(x, x', \pi_{k})}{2} dx dx$$

and

$$\tau_N(x,\pi) = \tau_{N0}(x,\pi) + \zeta_N(x,\pi)$$

Hence, under the null hypothesis such that $\tau(x; \pi_k) = \tau(x', \pi_k)$ on $X \times \Pi$, we have

$$\tilde{T}_2(\pi_k) = T_{2N}(\pi_k) + o_p(1),$$

where

$$T_{2N}(\pi_k) := \int_{\mathcal{X}} \int_{\mathcal{X}} \left\{ \sqrt{N} \left| \left[\tau_N(x, \pi_k) - \tau_N(x', \pi_k) \right] - \mathbb{E}[\tau_N(x, \pi_k) - \tau_N(x', \pi_k)] \right| \right\} \frac{w(x, x', \pi_k)}{2} dx dx'$$

and

$$\begin{split} \tau_N(x,\pi) &:= \frac{1}{Nh^d} \sum_{i=1}^N \left\{ \{Y - \mathbb{E}[Y|X = x, \Pi = \pi, T = 1]\} \frac{T_i \cdot \mathbb{1}(\Pi = \pi)}{P_1(x, \pi_k)} \\ &- \{Y - \mathbb{E}[Y|X = x, \Pi = \pi, T = 0]\} \frac{(1 - T_i) \cdot \mathbb{1}(\Pi = \pi)}{P_0(x, \pi_k)} \right\} \cdot K\left(\frac{x - X_i}{h}\right). \end{split}$$

Theorem 5. Under the regularity conditions, we have that

$$\frac{T_{2N}(\pi_k) - \operatorname{Bias}(T_{2N}(\pi_k))}{\sigma_{2N}(\pi_k)} \xrightarrow{d} N(0, 1),$$

where $\operatorname{Bias}(T_{2N}(\pi_k))$ is the asymptotic bias of $T_{2N}(\pi_k)$, and $\sigma_{2N}^2(\pi_k) := \lim_{N \to \infty} Var(T_{2N}(\pi_k))$ under the null.

Proof. The proof of Theorem 5 is also very lengthy but similar to Theorem 4. I omit the proof to save space. □

Now based on the fact that $\hat{T}_2 = T_{2N} + o_p(1)$, and Theorem 5,

$$\frac{\tilde{T}_2(\pi_k) - \operatorname{Bias}(\tilde{T}_2(\pi_k))}{\tilde{\sigma}_2(\pi_k)} \xrightarrow{d} N(0, 1), \tag{B.10}$$

where $\operatorname{Bias}(\tilde{T}_2(\pi_k)) = \operatorname{Bias}(T_{2N}(\pi_k))$ is the asymptotic bias of $\tilde{T}_2(\pi_k)$ and $\tilde{\sigma}_2^2(\pi_k) := \lim_{N \to \infty} Var(\tilde{T}_2(\pi_k)) = \lim_{N \to \infty} Var(T_{2N}(\pi_k))$ under the null.

Finally, observe that our test statistic \hat{T}_2 can be written as

$$\hat{T}_2 = \sum_{k=1}^K \tilde{T}_2(\pi_k),$$

which asymptotically is the sum of independent normal variables with $\{\text{Bias}(\tilde{T}_2(\pi_k)), \pi_k, \in \Pi\}$ as the asymptotic biases and, $\{\tilde{\sigma}_1^2(\pi_k,), \pi_k, \in \Pi\}$ as the asymptotic variances under the null hypothesis. As a result,

$$\frac{\hat{T}_2 - \sum_{k=1}^{K} \operatorname{Bias}(\tilde{T}_2(\pi_k))}{\hat{\sigma}_2} \xrightarrow{d} N(0, 1)$$

where $\sum_{k=1}^{K} \text{Bias}(\hat{T}_2) =: a_2, \hat{\sigma}_2^2(\pi_k) := \lim_{N \to \infty} \widehat{Var}(\hat{T}_2)$, with a_2 and $\hat{\sigma}_2^2$ defined in Proposition 2 (b). So, one can view $\hat{\sigma}_1^2$ the sum of the asymptotic variances of $\tilde{T}_2(\pi_k)$.

B.4 Proof of Theorem 1

Proof. I prove the first part of Theorem 1. To save space, I omit the proof of the second part of Theorem 1 because it is similar to the first part.

$$Pr(\hat{S}_1 > z_{1-\alpha}) = Pr(\hat{T}_1 > a_1 + \hat{\sigma}_1 z_{1-\alpha})$$
$$= 1 - Pr(\hat{T}_1 \le a_1 + \hat{\sigma}_1 z_{1-\alpha})$$
$$\rightarrow 1 - (1 - \alpha)$$
$$= \alpha.$$

The convergence to $1 - (1 - \alpha)$ follows from Theorem 4.

B.5 Proof of Theorem 2

Proof. I prove the first part of Theorem 2. We can use similar arguments to prove the second part.

$$\begin{aligned} \Pr(\hat{S}_1 > z_{1-\alpha}) &= \Pr(\hat{T}_1 > a_1 + \hat{\sigma} z_{1-\alpha}) \\ &= \Pr\left(\frac{\hat{T}_1}{\sqrt{N}} > \frac{a_1 + \hat{\sigma} z_{1-\alpha}}{\sqrt{N}}\right) \\ &= \Pr\left(\frac{\hat{T}_1}{\sqrt{N}} > 0\right) - \Pr\left(0 < \frac{\hat{T}_1}{\sqrt{N}} < \frac{a_{1N} + \hat{\sigma} z_{1-\alpha}}{\sqrt{N}}\right) \\ &= \Pr\left(\frac{\hat{T}_1}{\sqrt{N}} > 0\right) - o(1) \\ &\longrightarrow 1. \end{aligned}$$

where the third equality holds because $(a_1 + \hat{\sigma} z_{1-\alpha})/\sqrt{N} = o(1)$ since $\sqrt{Nh^d} \to \infty$ as $C \to \infty$. The last convergence to one follows from the definition of the alternative hypothesis, i.e., H_1^{Π} : $\int_X \sum_{k=1}^K \sum_{j>k}^K \left\{ |\tau(x; \pi_k) - \tau(x; \pi_j)| \right\} w(x, \pi_k, \pi_j) dx > 0.$

B.6 Proof of Theorem 3

Proof. I prove the first part (i) of Theorem 3. We can use similar arguments to prove the second part (ii). Under H_a^{Π} : $\tau(x;\pi) - \tau(x;\pi') = C^{-1/2}h^{-d/4}N_0^{-1/2}\delta_1(x,\pi,\pi')$, with a slight modification of the arguments in the proof of Theorem 4, I can also show that under H_{1a} , $T_{1N}^*(\pi_k,\pi_j)$ in (B.8) is asymptotically normal, i.e.,

$$\frac{T_{1N}^*(\pi_k, \pi_j) - \mathbb{E}\left[T_{1N}^*(\pi_k, \pi_j)\right]}{\sigma_{1N}(\pi_k, \pi_j)} \xrightarrow{d} N(0, 1),$$
(B.11)

where $T_{1N}^{*}(\pi_{k}, \pi_{j}) :=$

$$\begin{split} \int_{X} \left\{ \left| h^{-d/4} \cdot \delta_{1}(x, \pi_{k}, \pi_{j}) + \sqrt{N} \Big([\tau_{N}(x, \pi_{k}) - \tau_{N}(x, \pi_{j})] - \mathbb{E}[\tau_{N}(x, \pi_{k}) - \tau_{N}(x, \pi_{j})] \Big) \right| \right\} w(x, \pi_{j}, \pi_{k}) dx, \\ \mathbb{E}\left[T_{1N}^{*}(\pi_{k}, \pi_{j}) \right] &= \int_{X} \mathbb{E}[|\mathbb{Z}_{1} \cdot h^{-d/2} \sqrt{\rho_{2}(x, \pi_{k}, \pi_{j})} + h^{-d/4} \delta(x, \pi_{k}, \pi_{j})|] \cdot w(x, \pi_{k}, \pi_{j}) dx, \end{split}$$

and, $\sigma_{1N}^2(\pi_k, \pi_j) := Var(T_{1N}^*(\pi_k, \pi_j))$ which is not affected by the restrictions of the alternative hypothesis. Thus, from Lemma 4 and (B.11), under H_a^{Π} , we have

$$\frac{\tilde{T}_1(\pi_k, \pi_j) - \mathbb{E}\left[\tilde{T}_1(\pi_k, \pi_j)\right]}{\tilde{\sigma}_1(\pi_k, \pi_j)} \xrightarrow{d} N(0, 1),$$
(B.12)

where $\mathbb{E}\left[\tilde{T}_1(\pi_k,\pi_j)\right] = \mathbb{E}\left[T_{1N}^*(\pi_k,\pi_j)\right]$ is the asymptotic bias of $\tilde{T}_1(\pi_k,\pi_j)$ and $\tilde{\sigma}_1^2(\pi_k,\pi_j) := \lim_{N\to\infty} Var(\tilde{T}_1(\pi_k,\pi_j)) = \lim_{N\to\infty} Var(T_{1N}^*(\pi_k,\pi_j))$ under H_a^{Π} .

As a result, under H_a^{Π} ,

$$\frac{\hat{T}_1 - \sum_{k=1}^K \sum_{j>k}^K \mathbb{E}\left[T_{1N}^*(\pi_k, \pi_j)\right]}{\hat{\sigma}_1} \xrightarrow{d} N(0, 1)$$

where, $\hat{\sigma}_1^2 := \lim_{N \to \infty} \widehat{Var}(\hat{T}_1)$, as defined in Proposition 2.

Moreover, analogous to arguments in the proof of Theorem 4.3 in Chang et al. (2015), we have

$$\lim_{N\to\infty} \{\mathbb{E}\left[T_{1N}^*(\pi_k,\pi_j)\right] - \operatorname{Bias}(T_{1N}(\pi_k,\pi_j))\} = \frac{1}{2\sqrt{\pi}}\int \delta^2(x,\pi_k,\pi_j)dx$$

which gives us

$$\lim_{N \to \infty} \left\{ \sum_{k=1}^{K} \sum_{j>k}^{K} \mathbb{E} \left[T_{1N}^{*}(\pi_{k}, \pi_{j}) \right] - \sum_{k=1}^{K} \sum_{j>k}^{K} \operatorname{Bias}(T_{1N}(\pi_{k}, \pi_{j})) \right\} = \frac{1}{2\sqrt{\pi}} \int \sum_{k=1}^{K} \sum_{j>k}^{K} \delta^{2}(x, \pi_{k}, \pi_{j}) dx$$

Thus, under H_a^{Π} ,

$$\begin{aligned} &\Pr(\hat{S}_{1} > z_{1-\alpha}) \\ &= \Pr(\hat{T}_{1} > a_{1} + \hat{\sigma}_{1}z_{1-\alpha}) \\ &= \Pr\left(\frac{\hat{T}_{1} - \sum_{k=1}^{K}\sum_{j>k}^{K}\mathbb{E}\left[T_{1N}^{*}(\pi_{k},\pi_{j})\right]}{\hat{\sigma}_{1}} > \frac{-\sum_{k=1}^{K}\sum_{j>k}^{K}\mathbb{E}\left[T_{1N}^{*}(\pi_{k},\pi_{j})\right] + a_{1}}{\hat{\sigma}_{1}} + z_{1-\alpha}\right) \\ &= \Pr\left(\frac{\hat{T}_{1} - \sum_{k=1}^{K}\sum_{j>k}^{K}\mathbb{E}\left[T_{1N}^{*}(\pi_{k},\pi_{j})\right]}{\hat{\sigma}_{1}} > \frac{-\sum_{k=1}^{K}\sum_{j>k}^{K}\mathbb{E}\left[T_{1N}^{*}(\pi_{k},\pi_{j})\right] + \sum_{k=1}^{K}\sum_{j>k}^{K}\operatorname{Bias}(T_{1N}(\pi_{k},\pi_{j}))}{\hat{\sigma}_{1}} + z_{1-\alpha}\right) \\ &\to \Pr\left(\frac{\hat{T}_{1} - \sum_{k=1}^{K}\sum_{j>k}^{K}\mathbb{E}\left[T_{1N}^{*}(\pi_{k},\pi_{j})\right]}{\sigma_{1}} > \frac{-\int\sum_{k=1}^{K}\sum_{j>k}^{K}\delta^{2}(x,\pi_{k},\pi_{j})}{2\sqrt{\pi}\sigma_{1}} + z_{1-\alpha}\right) \end{aligned}$$

$$=1-\Phi\left(z_{1-\alpha}-\frac{1}{\sqrt{2\pi}\sigma_1}\int\sum_{k=1}^K\sum_{j=1}^K\delta^2(x,\pi_k,\pi_j)dx\right)$$

C Proof of Theorem 4

Recall that Theorem 4 says that under the regularity conditions, we have that

$$\frac{T_{1N}(\pi_k,\pi_j) - \operatorname{Bias}(T_{1N}(\pi_k,\pi_j))}{\sigma_{1N}(\pi_k,\pi_j)} \xrightarrow{d} N(0,1),$$

where $T_{1N}(\pi_k, \pi_j) := \int_X \left\{ \sqrt{N} \left| [\tau_N(x, \pi_k) - \tau_N(x, \pi_j)] - \mathbb{E}[\tau_N(x, \pi_k) - \tau_N(x, \pi_j)] \right| \right\} w(x, \pi_j, \pi_k),$ Bias $(T_{1N}(\pi_k, \pi_j))$ is the asymptotic bias of $T_{1N}(\pi_k, \pi_j)$, and $\sigma_{1N}^2(\pi_k, \pi_j) := \lim_{N \to \infty} Var(T_{1N}(\pi_k, \pi_j))$ under the null.

The proof relies on the proofs in Giné et al. (2003) and Chang et al. (2015). I borrow most of the notation from the proof of Lemma B.10 in Chang et al. (2015). To begin, I restate the following fact which is Fact 6.1 in Giné et al. (2003)

Fact 1. Let $\{(W_i, V_i)' : i = 1, ..., N\}$ be a sequence of iid random vectors in \mathbb{R}^2 such that each component has mean zero and variance one and finite absolute moments of the third order. Also, let $(Z_1, Z_2)'$ be a bivariate normal with $\mathbb{E}[Z_1] = \mathbb{E}[Z_2] = 0$, $Var(Z_1) = Var(Z_2) = 1$ and $Cov(Z_1, Z_2) = Cov(W_i, V_i) = \rho$. Then there exist universal positive constants A_1, A_2 and A_3 such that

$$\left| \mathbb{E} \left| \frac{\sum_{i=1}^{N} W_i}{\sqrt{N}} \right| - \mathbb{E} |Z_1| \right| \le \frac{A_1}{\sqrt{N}} \mathbb{E} |W_i|^3$$
(C.1)

and, whenever $\rho^2 < 1$

$$\left| \mathbb{E} \left| \frac{\sum_{i=1}^{N} W_i}{\sqrt{N}} \cdot \frac{\sum_{i=1}^{N} V_i}{\sqrt{N}} \right| - \mathbb{E} |Z_1 Z_2| \right| \le \frac{A_2}{(1 - \rho^2)^{3/2} \sqrt{N}} (\mathbb{E} |W_i|^3 + \mathbb{E} |V_i|^3)$$
(C.2)

and

$$\left| \mathbb{E}\left[\frac{\sum_{i=1}^{N} W_i}{\sqrt{N}} \cdot \left| \frac{\sum_{i=1}^{N} V_i}{\sqrt{N}} \right| \right] - \mathbb{E}[Z_1 | Z_2 |] \right| \le \frac{A_3}{(1 - \rho^2)^{3/2} \sqrt{N}} (\mathbb{E} | W_i |^3 + \mathbb{E} | V_i |^3)$$
(C.3)

Now I use the "Poissonization" technique of Giné et al. (2003). Let N denote a Poisson random variable with mean N defined on the same probability space as the sequence $\{W_i : i \ge 1\} := \{(Y_i, X_i, T_i, \Pi_i) : i \ge 1\}$ and independent of this sequence. Define

$$\chi_{t,k} := \frac{\mathbb{E}[Y|X=x,\Pi=\pi_k,T=t]}{P_t(x,\pi_k)},$$

$$\chi(\pi_k, x, T) := [\chi_{1,k}(\pi_k, x) \cdot T - \chi_{0,k}(\pi_k, x) \cdot (1 - T)] \cdot \mathbb{1}(\Pi = \pi_k),$$

and

$$\psi(W_i, x, \pi_k) := [Y_i \cdot \mathbb{1}(\Pi_i = \pi_k)\phi(x, \pi_k, T_i) - \chi(\pi_k, x, T_i)] \frac{1}{h^d} K\left(\frac{x - X_i}{h}\right) + \tau(x; \pi_k).$$

Then

$$\tau_{N}(x,\pi_{k}) = \tau_{N0}(x,\pi_{k}) + \zeta_{N}(x,\pi_{k}) = \frac{1}{N} \sum_{i=1}^{N} \psi(W_{i},x,\pi_{k}).$$

Hence define,

$$\begin{split} \Gamma_N(x, \pi_k, \pi_j) &:= \tau_N(x, \pi_k) - \tau_N(x, \pi_j) \\ &= \frac{1}{N} \sum_{i=1}^N \psi(W_i, x, \pi_k) - \frac{1}{N} \sum_{i=1}^N \psi(W_i, x, \pi_j) \\ &= \frac{1}{N} \sum_{i=1}^N \Theta(W_i, x, \pi_k, \pi_j), \end{split}$$

where

$$\Theta(W_i, x, \pi_k, \pi_j) := \left\{ [Y_i \cdot [\mathbbm{1}(\Pi_i = \pi_k)\phi(x, T_i, \pi_k) - \mathbbm{1}(\Pi_i = \pi_j)\phi(x, T_i, \pi_j)] - [\chi(\pi_k, x, T_i) - \chi(\pi_j, x, T_i)] \right\} \cdot \frac{1}{h^d} K\left(\frac{x - X_i}{h}\right) + \Gamma(x, \pi_k, \pi_j)$$

Now we will Poissonize $\Gamma_N(x, \pi_k, \pi_j)$. To do so, again define

$$\Gamma_{\mathcal{N}}(x,\pi_k,\pi_j) = \frac{1}{N} \sum_{i=1}^{N} \Theta(W_i,x,\pi_k,\pi_j)$$

where the empty sum is defined to be zero. Note that by the law of iterated expectation and

variance,

$$\mathbb{E}\Gamma_{\mathcal{N}}(x,\pi_k,\pi_j) = \mathbb{E}\Gamma_{\mathcal{N}}(x,\pi_k,\pi_j) = \mathbb{E}[\psi(W,x,\pi_k)] - \mathbb{E}[\psi(W,x,\pi_j)], \quad (C.4)$$

$$\kappa_{\tau,N}(x,\pi_k,\pi_j) := NVar(\Gamma_{\mathcal{N}}(x,\pi_k,\pi_j)) = \mathbb{E}[\Theta^2(W,x,\pi_k,\pi_j)], \qquad (C.5)$$

$$\kappa_{\tau,N}(x,\pi) := NVar(\tau_N(x,\pi)) \tag{C.6}$$

and

$$NVar(\Gamma_N(x,\pi_k,\pi_j)) = \mathbb{E}[\Theta^2(W_i,x,\pi_k,\pi_j)] - \{\mathbb{E}[\Theta(W_i,x,\pi_k,\pi_j)]\}^2.$$
(C.7)

Let $\epsilon \in (0, \int_X f(x)dx)$ be an arbitrary constant. For constant $\{M_l > 0 : l = 1, ..., d\}$, let $\mathcal{B}(M) = \prod_{l=1}^d [-M_l, M_l] \subset X$ denote a Borel set in \mathbb{R}^d with nonempty interior with finite Lebesgue measure $\lambda(\mathcal{B}(M))$. For v > 0, define $\mathcal{B}(M, v)$ to be the *v*-contraction of $\mathcal{B}(M)$, i.e., $\mathcal{B}(M, v) = \{x \in \mathcal{B}(M) : \inf_{y \in \mathbb{R}^d \setminus B(M)} \{ ||x - y|| \} \ge v \}$, Choose M, v > 0 and a Borel set *B* such that

$$B \subset \mathcal{B}(M, v), \tag{C.8}$$

$$\int_{\mathbb{R}^d \setminus \mathcal{B}(M)} f(x) dx := \alpha > 0, \qquad (C.9)$$

$$\int_{\mathcal{X}} f(x)dx - \int_{B} f(x)dx > \epsilon.$$
 (C.10)

Such *M*, *v* and *B* exist by the absolute continuity of the density *f*. Lets define a Poissonized version

of $T_{1N}(\pi_k, \pi_i)$ (restricted to B) under the null hypothesis to be:

$$T_{1N}^{P}(B) := \int_{B} \left\{ \sqrt{N} \left| \left[\left(\Gamma_{\mathcal{N}}(x, \pi_{k}, \pi_{j}) \right] - \mathbb{E}\left[\left(\Gamma_{\mathcal{N}}(x, \pi_{k}, \pi_{j}) \right] \right] \right\} w(x, \pi_{j}, \pi_{k}) dx - \int_{B} \left\{ \sqrt{N} \mathbb{E} \left| \left[\left(\Gamma_{\mathcal{N}}(x, \pi_{k}, \pi_{j}) \right] - \mathbb{E}\left[\left(\Gamma_{\mathcal{N}}(x, \pi_{k}, \pi_{j}) \right] \right] \right\} w(x, \pi_{j}, \pi_{k}) dx$$

Let

$$\sigma_{1N}^2(B) = \operatorname{Var}(T_{1N}^P(B)).$$

The following lemma shows that the variance of the approximated and poissonized version of \hat{T}_1 in *B* converges to the variance of the "un-approximated" and "un-poissonized" version in *B* **Lemma 6.** If the regularity conditions holds and *B* satisfies (C .8)-(C .10), then

$$\lim_{C \to \infty} \sigma_{1N}^2(B) = \mathcal{P}(B) \cdot \operatorname{Var}(\hat{T}_1) = \sigma_{1,B}^2, \tag{C.11}$$

where

$$\sigma_{1,B}^{2} := \int_{-1}^{1} \int_{B_{0}} \operatorname{Cov}(|\sqrt{1 - \rho^{2}(x, \pi_{i}, \pi_{j}, \pi_{k}, \pi_{l}, r)}\mathbb{Z}_{1} + \rho(x, \pi_{i}, \pi_{j}, \pi_{k}, \pi_{l}, r)\mathbb{Z}_{2}|, |\mathbb{Z}_{2}|) \cdot \sqrt{\rho_{2}(x, \pi_{i}, \pi_{j})\rho_{2}(x, \pi_{k}, \pi_{l})} \cdot w(x, \pi_{i}, \pi_{j})w(x', \pi_{k}, \pi_{l})dxdr.$$
(C.12)

Proof. Note that for each $(x, \pi_i, \pi_j), (x', \pi_k, \pi_l) \in \mathbb{R}^d \times \Pi^2$ such that ||x - x'|| > h, the random variables $\Gamma_N(x, \pi_i, \pi_j) - \mathbb{E}[\Gamma_N(x, \pi_i, \pi_j)]$ and $\Gamma_N(x', \pi_k, \pi_l) - \mathbb{E}[\Gamma_N(x', \pi_k, \pi_l)]$ are independent because they are functions of independent increments of a Poisson process and the kernel *K* vanishes outside of the closed rectangle $[-1, 1]^d$. Therefore,

$$\begin{aligned} \operatorname{Var}(T_{1N}^{P}(B)) &= \int_{X} \int_{X} \operatorname{Cov}(\sqrt{N} | \Gamma_{N}(x, \pi_{i}, \pi_{j}) - \mathbb{E}[\Gamma_{N}(x, \pi_{i}, \pi_{j})]|, \sqrt{N} | \Gamma_{N}(x', \pi_{k}, \pi_{l}) - \mathbb{E}[\Gamma_{N}(x', \pi_{k}, \pi_{l})]|) \\ &\quad \cdot w(x, \pi_{i}, \pi_{j}) w(x', \pi_{k}, \pi_{l}) dx dx' \\ &= \int_{X} \int_{X} \operatorname{Cov}(\sqrt{N} | \Gamma_{N}(x, \pi_{i}, \pi_{j}) - \mathbb{E}[\Gamma_{N}(x, \pi_{i}, \pi_{j})]|, \sqrt{N} | \Gamma_{N}(x', \pi_{k}, \pi_{l}) - \mathbb{E}[\Gamma_{N}(x', \pi_{k}, \pi_{l})]|) \\ &\quad \cdot \mathbb{1}(h^{-1}(x - x') \in [-1, 1]^{d}) \cdot w(x, \pi_{i}, \pi_{j}) w(x', \pi_{k}, \pi_{l}) dx dx', \end{aligned}$$

Set

$$S_{\tau,N}(x,\pi,\pi') = \frac{\sqrt{N} \{\Gamma_N(x,\pi,\pi') - \mathbb{E}[\tau_N(x,\pi,\pi')]\}}{\sqrt{\kappa_{\Gamma,N}(x,\pi,\pi')}}$$
$$= \frac{\sqrt{N} \{\tau_N(x,\pi) - \mathbb{E}[\tau_N(x,\pi)]\}}{\sqrt{\kappa_{\Gamma,N}(x,\pi,\pi')}} + \frac{\sqrt{N} \{\tau_N(x,\pi') - \mathbb{E}[\tau_N(x,\pi')]\}}{\sqrt{\kappa_{\Gamma,N}(x,\pi,\pi')}}$$
$$\leq \frac{\sqrt{N} \{\tau_N(x,\pi) - \mathbb{E}[\tau_N(x,\pi)]\}}{\sqrt{\kappa_{\tau,N}(x,\pi)}} + \frac{\sqrt{N} \{\tau_N(x,\pi') - \mathbb{E}[\tau_N(x,\pi')]\}}{\sqrt{\kappa_{\tau,N}(x,\pi')}}$$
$$=:S_{\tau,N}(x,\pi) + S_{\tau,N}(x,\pi').$$
(C.13)

Now, with $\int_{B_0} dx < \infty$, by the Lemma 1, we can show that

$$\sup_{x \in B_0} \left| \sqrt{\kappa_{\Gamma,N}(x,\pi,\pi')} - h^{-d/2} \sqrt{\rho_2(x,\pi,\pi')} \right| = O(h^{d/2}), \tag{C.14}$$

where

$$\rho_2(x,\pi,\pi') = \left\{ \sum_{t \in \{0,1\}} \sum_{\pi_0 \in \{\pi,\pi'\}} \frac{\mathbb{E}[Y^2 | X = x, T = t, \Pi = \pi_0] - (\mathbb{E}[Y | X = x, T = t, \Pi = \pi_0])^2}{P_t(x,\pi_0)} \right\} \cdot \int K^2(\xi) d\xi$$

We also have that

$$\int_{B_0} \int_{B_0} \mathbb{1}(h^{-1}(x-x') \in [-1,1]^d) \cdot w(x,\pi_i,\pi_j)w(x',\pi_k,\pi_l)dxdx' = O(h^d).$$
(C.15)

And finally, by the Cauchy Schwartz Inequality, we have

$$\sup_{(x,x')\in B_0^2} \left| \operatorname{Cov}(|S_{\tau,\mathcal{N}}(x,\pi_i,\pi_j)|, |S_{\tau,\mathcal{N}}(x',\pi_k,\pi_l)|) \right| = O(1), \ \forall \ (\pi_i,\pi_j,\pi_k,\pi_l) \in \Pi^4.$$
(C.16)

Therefore, we have

$$Var(T_{1N}^{P}(B)) = \bar{\sigma}_{1N}^{2} + o(1),$$

where

$$\bar{\sigma}_{1N}^{2} := \int_{\mathcal{X}} \int_{\mathcal{X}} \text{Cov}(|S_{\tau,\mathcal{N}}(x,\pi_{i},\pi_{j})|, |S_{\tau,\mathcal{N}}(x',\pi_{k},\pi_{l})|) \cdot \sqrt{\rho_{2}(x,\pi_{i},\pi_{j})\rho_{2}(x',\pi_{k},\pi_{l})} \\ \times h^{-d} \cdot \mathbb{1}(h^{-1}(x-x') \in [-1,1]^{d}) \cdot w(x,\pi_{i},\pi_{j})w(x',\pi_{k},\pi_{l})dxdx'$$

Now, for $b \in \{1, 2\}$, let $Z_{bn}(x, \pi_i, \pi_j) = Z_{bn}(x, \pi_i) + Z_{bn}(x, \pi_j)$ where $(Z_{1n}(x, \pi_i), Z_{2n}(x, \pi_i), Z_{2n}(x, \pi_i), Z_{1n}(x, \pi_j), Z_{2n}(x, \pi_j))$ are mean zero pairwise independent Gaussian processes. Then $(Z_{1n}(x, \pi_i, \pi_j), Z_{2n}(x', \pi_k, \pi_l))$ for $(x, \pi_i, \pi_j), (x', \pi_k, \pi_l) \in \mathbb{R}^d \times \Pi^2$, is a mean zero bivariate Gaussian process. Now for each $(x, \pi_i, \pi_j) \in \mathbb{R}^d \times \Pi^2, (x', \pi_k, \pi_l) \in \mathbb{R}^d \times \Pi^2$, let $(Z_{1n}(x, \pi_i, \pi_j), Z_{2n}(x', \pi_k, \pi_l))$ and $(S_{\tau,N}(x, \pi_i, \pi_j), S_{\tau,N}(x', \pi_k, \pi_l))$ have the same covariance structure. That is,

$$(Z_{1n}(x,\pi_i,\pi_j),Z_{2n}(x,\pi_k,\pi_l)) \stackrel{d}{=} \left(\sqrt{1-\rho_N^*(x,\pi_i,\pi_j,\pi_k,\pi_l)^2} \mathbb{Z}_1 + \rho_N^*(x',\pi_i,\pi_j,\pi_k,\pi_l) \mathbb{Z}_2, \mathbb{Z}_2 \right),$$

where \mathbb{Z}_1 and \mathbb{Z}_2 are independent standard normal random variables and

$$\rho_N^*(x, x', \pi_i, \pi_j, \pi_k, \pi_l) := \mathbb{E}[S_{\tau, \mathcal{N}}(x, \pi_i, \pi_j)S_{\tau, \mathcal{N}}(x', \pi_k, \pi_l)].$$

Let

$$\begin{split} \bar{\tau}_{N,0}^2 &= \int_{B_0} \int_{B_0} \operatorname{Cov}(|Z_{1n}(x,\pi_i,\pi_j)|,|Z_{2n}(x',\pi_k,\pi_l)|) \cdot \sqrt{\rho_2(x,\pi_i,\pi_j)\rho_2(x',\pi_k,\pi_l)} \\ &\times h^{-d} \cdot \mathbb{1}(h^{-1}(x-x') \in [-1,1]^d) \cdot w(x,\pi_i,\pi_j)w(x',\pi_k,\pi_l)dxdx'. \end{split}$$

By a change of variables x' = x + th, we can write

$$\begin{split} \bar{\tau}_{N,0}^2 &= \int_{B_0} \int_{[-1,1]^d} \operatorname{Cov}(|Z_{1n}(x,\pi_i,\pi_j)|,|Z_{2n}(x+th,\pi_k,\pi_l)|) \\ &\quad \cdot \sqrt{\rho_2(x,\pi_i,\pi_j)\rho_2(x+th,\pi_k,\pi_l)} \times \mathbb{1}(x \in B_0)\mathbb{1}(x+th \in B_0) \\ &\quad \cdot w(x,\pi_i,\pi_j)w(x+th,\pi_k,\pi_l)dxdt. \end{split}$$

Note that

$$\begin{split} \rho_N^*(x,x',\pi_i,\pi_j,\pi_k,\pi_l) = & N \mathbb{E}\left[\frac{\{\Gamma_N(x,\pi_i,\pi_j) - \mathbb{E}[\Gamma_N(x,\pi_i,\pi_j)]\}}{\sqrt{\kappa_{\Gamma,N}(x,\pi_i,\pi_j)}}\frac{\{\Gamma_N(x',\pi_k,\pi_l) - \mathbb{E}[\Gamma_N(x',\pi_k,\pi_l)]\}}{\sqrt{\kappa_{\Gamma,N}(x',\pi_k,\pi_l)}}\right] \\ = & \frac{\mathbb{E}\left[Q(x,\pi_i,\pi_j)Q(x',\pi_i,\pi_j)Q(x,\pi_k,\pi_l)Q(x',\pi_k,\pi_l) \cdot \frac{1}{h^d}K\left(\frac{x-X}{h}\right)\frac{1}{h^d}K\left(\frac{x'-X}{h}\right)\right]}{\sqrt{\kappa_{\Gamma,N}(x,\pi_i,\pi_j)\kappa_{\Gamma,N}(x',\pi_k,\pi_l)}}, \end{split}$$

where

$$Q(x, \pi, \pi') := \left\{ [Y \cdot [\mathbb{1}(\Pi = \pi)\hat{\phi}(x, T, \pi) - \mathbb{1}(\Pi = \pi')\hat{\phi}(x, T, \pi')] - [\chi(\pi, x, T) - \chi(\pi', x, T)] \right\}$$

By Lemma 1 and a change of variable x' = x + th, we can show that

$$\rho_N^*(x, x', \pi_i, \pi_j, \pi_k, \pi_l) \to \frac{\int K(\xi) K(\xi + t) d\xi}{\int K(\xi) d\xi}.$$

Therefore, by the bounded convergence theorem, we have that

$$\lim_{n \to \infty} \bar{\tau}_{N,0}^2 = \sigma_{1,B}^2$$

Now, the desired result holds if

$$\bar{\tau}_{N,0}^2 \to \bar{\sigma}_{N,0}^2 \text{ as } C \to \infty.$$
(C.17)

To prove (C .17), let $\epsilon_0 \in (0, 1]$ and let $c(\epsilon_0) = (1 + \epsilon_0)^2 - 1$. Let Q_1 and Q_2 be two independent random variables that are independent of $(\{Y_i, X_i\}_{i=1}^{\infty}, N)$, each having a two-point distribution that gives two points, $\{\sqrt{c(\epsilon_0)}\}$ and $\{-\sqrt{c(\epsilon_0)}\}$, the equal mass of 1/2, so that $\mathbb{E}[Q_1] = \mathbb{E}[Q_2] = 0$ and $\operatorname{Var}(Q_1) = \operatorname{Var}(Q_2) = c(\epsilon_0)$. Let $S_{\tau,N,1}^Q(x, \pi, \pi') = \frac{S_{\tau,N}(x, \pi, \pi') + 2Q_1}{1+\epsilon_0} = \frac{S_{\tau,N}(x, \pi) + Q_1 + S_{\tau,N}(x, \pi') + Q_1}{1+\epsilon_0} =:$ $S_{\tau,N,1}^Q(x, \pi) + S_{\tau,N,1}^Q(x, \pi')$ and $S_{\tau,N,2}^Q(x, \pi, \pi') = \frac{S_{\tau,N}(x, \pi\pi') + 2Q_2}{1+\epsilon_0} = \frac{S_{\tau,N}(x, \pi) + Q_2 + S_{\tau,N}(x, \pi') + Q_2}{1+\epsilon_0} =: S_{\tau,N,2}^Q(x, \pi) + S_{\tau,N,2}^Q(x, \pi')$. Define

$$\bar{\sigma}_{1N,Q}^{2} := \int_{X} \int_{X} \operatorname{Cov}(|S_{\tau,N,1}^{Q}(x,\pi_{i},\pi_{j})|, |S_{\tau,N,2}^{Q}(x,\pi_{k},\pi_{l})|) \cdot \sqrt{\rho_{2}(x,\pi_{i},\pi_{j})\rho_{2}(x',\pi_{k},\pi_{l})} \times h^{-d} \cdot \mathbb{1}(h^{-1}(x-x') \in [-1,1]^{d}) \cdot w(x,\pi_{i},\pi_{j})w(x',\pi_{k},\pi_{l})dxdx',$$
(C.18)

and let $Z_{1,N}^{Q}(x, \pi, \pi') = \frac{Z_{1,N}(x,\pi) + Z_{1,N}(x,\pi') + 2Q_1}{1+\epsilon_0} =: Z_{1,N}^{Q}(x, \pi) + Z_{1,N}^{Q}(x, \pi')$ and $Z_{2,N}^{Q}(x, \pi, \pi') = \frac{Z_{2,N}(x,\pi) + Z_{2,N}(x,\pi') + 2Q_2}{1+\epsilon_0} =: Z_{2,N}^{Q}(x,\pi) + Z_{2,N}^{Q}(x,\pi')$. Then $(Z_{1,N}^{Q}(x,\pi_i,\pi_j), Z_{2,N}^{Q}(x',\pi_k,\pi_l))$ is a mean zero multivariate Gaussian process such that, for each $(x, \pi_i, \pi_j) \in \mathbb{R} \times \Pi^2$ and $(x, \pi_k, \pi_l) \in \mathbb{R} \times \Pi^2$, $(Z_{1,N}^{Q}(x, \pi_i, \pi_j), Z_{2,N}^{Q}(x', \pi_k, \pi_l))$ and $(S_{\tau,N,1}^{Q}(x, \pi_i, \pi_j), S_{\tau,N,2}^{Q}(x', \pi_k, \pi_l))$ have the same covariance structure.

Also, define

$$\begin{split} \bar{\tau}_{N,Q}^{2} &= \int_{B_{0}} \int_{B_{0}} \operatorname{Cov}(|Z_{1,N}^{Q}(x,\pi_{i},\pi_{j})|,|Z_{2,N}^{Q}(x',\pi_{k},\pi_{l})|) \\ &\quad \cdot \sqrt{\rho_{2}(x,\pi_{i},\pi_{j})\rho_{2}(x',\pi_{k},\pi_{l})} \times h^{-d} \cdot \mathbb{1}(h^{-1}(x-x') \in [-1,1]^{d}) \\ &\quad \cdot w(x,\pi_{i},\pi_{j})w(x',\pi_{k},\pi_{l})dxdx'. \end{split}$$

Using the triangle inequality, we have

$$\begin{split} |\tilde{\tau}_{N,Q}^{2} - \tilde{\sigma}_{N,Q}^{2}| &= \left| \int_{B_{0}} \int_{B_{0}} \left(\operatorname{Cov}(|Z_{1,N}^{Q}(x,\pi_{i},\pi_{j})|, |Z_{2,N}^{Q}(x',\pi_{k},\pi_{l})|) - \operatorname{Cov}(|S_{\tau,N,1}^{Q}(x,\pi_{i},\pi_{j})|, |S_{\tau,N,2}^{Q}(x,\pi_{k},\pi_{l})|) \right) \\ &\cdot \sqrt{\rho_{2}(x,\pi_{i},\pi_{j})\rho_{2}(x',\pi_{k},\pi_{l})} \times h^{-d} \cdot 1(h^{-1}(x-x') \in [-1,1]^{d}) \cdot w(x,\pi_{i},\pi_{j})w(x',\pi_{k},\pi_{l})dxdx' \right| \\ &\leq \int_{B_{0}} \int_{B_{0}} \left| \left(\mathbb{E}|Z_{1,N}^{Q}(x,\pi_{i},\pi_{l})| \mathbb{E}|Z_{2,N}^{Q}(x',\pi_{k},\pi_{l})| - \mathbb{E}|S_{\tau,N,1}^{Q}(x,\pi_{l},\pi_{l})| \mathbb{E}|S_{\tau,N,2}^{Q}(x,\pi_{k},\pi_{l})| \right) \\ &\cdot \sqrt{\rho_{2}(x,\pi_{i},\pi_{l})\rho_{2}(x',\pi_{k},\pi_{l})} \times h^{-d} \cdot 1(h^{-1}(x-x') \in [-1,1]^{d}) \cdot w(x,\pi_{i},\pi_{j})w(x',\pi_{k},\pi_{l})dxdx' \right| \\ &+ \int_{B_{0}} \int_{B_{0}} \left| \left(\mathbb{E}|Z_{1,N}^{Q}(x,\pi_{l},\pi_{l})| \mathbb{E}|Z_{2,N}^{Q}(x',\pi_{k},\pi_{l})| - \mathbb{E}|S_{\tau,N,1}^{Q}(x,\pi_{l},\pi_{l})| \mathbb{E}|S_{\tau,N,2}^{Q}(x',\pi_{k},\pi_{l})| \right) \\ &\cdot \sqrt{\rho_{2}(x,\pi_{i},\pi_{l})\rho_{2}(x',\pi_{k},\pi_{l})} \times h^{-d} \cdot 1(h^{-1}(x-x') \in [-1,1]^{d}) \cdot w(x,\pi_{i},\pi_{l})w(x',\pi_{k},\pi_{l})dxdx' \right| \\ &\leq \int_{B_{0}} \int_{B_{0}} \left| \left(\mathbb{E}|Z_{1,N}^{Q}(x,\pi_{l})| \mathbb{E}|Z_{2,N}^{Q}(x',\pi_{k})| - \mathbb{E}|S_{\tau,N,1}(x,\pi_{l})| \mathbb{E}|S_{\tau,N,2}(x',\pi_{k})| \right) \\ &+ \mathbb{E}|Z_{1,N}^{Q}(x,\pi_{l})| \mathbb{E}|Z_{2,N}^{Q}(x',\pi_{k})| - \mathbb{E}|S_{\tau,N,1}(x,\pi_{l})| \mathbb{E}|S_{\tau,N,2}(x',\pi_{k})| \right| \\ &+ \mathbb{E}|Z_{1,N}^{Q}(x,\pi_{l})| \mathbb{E}|Z_{2,N}^{Q}(x',\pi_{k})| - \mathbb{E}|S_{\tau,N,1}(x,\pi_{l})| \mathbb{E}|S_{\tau,N,2}(x',\pi_{k})| \\ &+ \mathbb{E}|Z_{1,N}^{Q}(x,\pi_{l})| \mathbb{E}|Z_{2,N}^{Q}(x',\pi_{k})| - \mathbb{E}|S_{\tau,N,1}(x,\pi_{l})| \mathbb{E}|S_{\tau,N,2}(x',\pi_{k})| \right) \\ &\cdot \sqrt{\rho_{2}(x,\pi_{l},\pi_{l})\rho_{2}(x',\pi_{k},\pi_{l})} \times h^{-d} \cdot 1(h^{-1}(x-x') \in [-1,1]^{d}) \cdot w(x,\pi_{l},\pi_{l})w(x',\pi_{k},\pi_{l})dxdx' \\ &+ \int_{B_{0}} \int_{B_{0}} \left| \left(\mathbb{E}|Z_{1,N}^{Q}(x,\pi_{l})| \mathbb{E}|Z_{2,N}^{Q}(x',\pi_{k})| - \mathbb{E}|S_{\tau,N,1}(x,\pi_{l})| \mathbb{E}|S_{\tau,N,2}(x',\pi_{k})| \right) \\ &+ \mathbb{E}|Z_{1,N}^{Q}(x,\pi_{l})| \mathbb{E}|Z_{2,N}^{Q}(x',\pi_{k})| - \mathbb{E}|S_{\tau,N,1}(x,\pi_{l})| \mathbb{E}|S_{\tau,N,2}(x',\pi_{k})| \right| \\ &+ \mathbb{E}|Z_{1,N}^{Q}(x,\pi_{l})| \mathbb{E}|Z_{2,N}^{Q}(x',\pi_{k})| - \mathbb{E}|S_{\tau,N,1}(x,\pi_{l})| \mathbb{E}|S_{\tau,N,2}(x',\pi_{k})| \\ &+ \mathbb{E}|Z_{1,N}^{Q}(x,\pi_{l})| \mathbb{E}|Z_{2,N}^{Q}(x',\pi_{k})| - \mathbb{E}|S_{\tau,N,1}(x,\pi_{l})| \mathbb{E}|S_{\tau,$$

 $=:\!\Delta_{1N,\mathcal{Q}}(\pi_i,\pi_k)+\Delta_{1N,\mathcal{Q}}(\pi_i,\pi_l)+\Delta_{1N,\mathcal{Q}}(\pi_j,\pi_k)+\Delta_{1N,\mathcal{Q}}(\pi_j,\pi_l)$

$$+ \Delta_{2N,\mathcal{Q}}(\pi_i,\pi_k) + \Delta_{2N,\mathcal{Q}}(\pi_i,\pi_l) + \Delta_{2N,\mathcal{Q}}(\pi_j,\pi_k) + \Delta_{2N,\mathcal{Q}}(\pi_j,\pi_l).$$

Following the proof of Lemma B.10 in Chang et al. (2015), note that for all $\{\pi, \pi'\} \in \Pi, \Delta_{1NQ}(\pi, \pi') = o(1)$, and $\Delta_{2NQ}(\pi, \pi') = o(1)$. It is straightforward to show that $|\bar{\sigma}_{N,Q}^2 - \bar{\sigma}_{N,0}^2| \to 0$ and $|\bar{\tau}_{N,Q}^2 - \bar{\tau}_{N,0}^2| \to 0$ as $\epsilon_0 \to 0$. Hence the triangle inequality establishes (C .17), and thus the lemma has been proved.

Let M be defined as in (C .8)-(C .10) and let

$$U_{N} := \frac{1}{\sqrt{N}} \left\{ \sum_{i=1}^{N} \mathbb{1}[X_{i} \in \mathcal{B}(M)] - N \operatorname{Pr}(X \in \mathcal{B}(M)) \right\}$$

and

$$V_N := \frac{1}{\sqrt{N}} \left\{ \sum_{i=1}^N \mathbb{1}[X_i \in \mathbb{R}^d \setminus \mathcal{B}(M)] - N \operatorname{Pr}(X \in \mathbb{R}^d \setminus \mathcal{B}(M)) \right\}$$

Also define

$$S_N := \frac{T^P_{1N}(B)}{\sigma_{1N}(B)}$$

Lemma 7. Under the regularity conditions, we have that

$$(S_N, U_N) \xrightarrow{d} (\mathbb{Z}_1, \sqrt{1-\alpha}\mathbb{Z}_2)$$

where \mathbb{Z}_1 and \mathbb{Z}_2 are independent N(0, 1) random variables and α is defined as in (C.9).

Proof. Let

$$\Delta_{N}(\pi_{k},\pi_{j},x) = \sqrt{N} \left\{ \left| \Gamma_{N}(x,\pi_{k},\pi_{j}) - \mathbb{E}[\Gamma_{N}(x,\pi_{k},\pi_{j})] \right| - \mathbb{E}\left| \Gamma_{N}(x,\pi_{k},\pi_{j}) - \mathbb{E}[\Gamma_{N}(x,\pi_{k},\pi_{j})] \right| \right\} \cdot w(x,\pi_{k},\pi_{j})$$

Construct a partition of $\mathcal{B}(M)$. Consider a regular grid $G_{\mathbf{i}} = (i_1h, (i_1+1)h] \times \cdots \times (i_dh, (i_d+1)h]$ where $\mathbf{i} = (i_1, \dots, i_d)$, i_1, \dots, i_d are integers. Define $R_{\mathbf{i}} = G_{\mathbf{i}} \cap \mathcal{B}(M)$, $I_i = \{\mathbf{i} \in \mathbb{Z}^d : (G_{\mathbf{i}} \cap \mathcal{B}(M)) \neq \emptyset\}$. Then, we see that $\{R_{\mathbf{i}} : \mathbf{i} \in I_i \subset \mathbb{Z}^d\}$ is a partition of $\mathcal{B}(M)$ with $\lambda(R_{\mathbf{i}}) \leq A_1h^d$, $m_N := \#(I_i) \leq A_2h^{-d}$ for some positive constants A_1 and A_2 .
In addition, set

$$\alpha_{\mathbf{i},N} = \frac{\int_{R_{\mathbf{i}}} \mathbb{1}(x \in B) \cdot \sum_{k=1}^{K} \sum_{j=1}^{K} \Delta_{N}(\pi_{k}, \pi_{j}, x) dx}{\sigma_{N}(B)}$$

and

$$u_{\mathbf{i},N} = \frac{1}{\sqrt{N}} \left\{ \sum_{j=1}^{N} \mathbbm{1}(X_j \in R_{\mathbf{i}}) - N \operatorname{Pr}(X \in R_{\mathbf{i}}) \right\}.$$

Then, we have $S_N = \sum_{i \in I_i} \alpha_{i,N}$ and $U_N = \sum_{i \in I_i} u_{i,N}$. We can verify that $Var(S_N) = 1$ and $Var(U_N) = 1 - \alpha$. For arbitrary λ_1 and $\lambda_2 \in \mathbb{R}$, let

$$y_{\mathbf{i},N} = \lambda_1 \alpha_{\mathbf{i},N} + \lambda_2 u_{\mathbf{i},N}.$$

Notice that $\{y_{i,N} : i \in I_i\}$ is an array of mean zero one-dependent random fields.

We need to show that

$$\operatorname{Var}\left(\sum_{\mathbf{i}\in\mathcal{I}_{i}}y_{\mathbf{i},N}\right) = \operatorname{Var}(\lambda_{1}S_{N} + \lambda_{2}U_{N}) \to \lambda_{1}^{2} + \lambda_{2}^{2}(1-\alpha)$$
(C.19)

and

$$\sum_{i \in I_i} \mathbb{E} |y_{i,N}|^r = o(1) \text{ for some } 2 < r < 3.$$
 (C.20)

The results of the Lemma follows from the central limit theorem of Shergin (1993) and the Cramér-Wold device. To show, (C .19), which holds if we have

$$\operatorname{Cov}(S_N, U_N) = O\left(\frac{1}{\sqrt{Nh^{2d}}}\right), \qquad (C.21)$$

which implies that

$$\operatorname{Cov}\left(\int_{B}\left\{\sqrt{N}\left|\left[\left(\Gamma_{\mathcal{N}}(x,\pi_{k},\pi_{j})\right)-\mathbb{E}\left[\left(\Gamma_{\mathcal{N}}(x,\pi_{k},\pi_{j})\right)\right]\right\}w(x,\pi_{j},\pi_{k})dx,U_{N}\right)=O\left(\frac{1}{\sqrt{Nh^{2d}}}\right).$$
 (C.22)

For any $(x, \pi_k, \pi_j) \in B \times \Pi^2$ we have

$$\left(S_{\tau,N}(x,\pi_k,\pi_j),\frac{U_N}{\sqrt{\Pr(X\in B(M))}}\right) \stackrel{d}{=} \left(\frac{1}{\sqrt{N}}\sum_{i=1}^N Q_{\tau,N}^{(i)}(x,\pi_k,\pi_j),\frac{1}{\sqrt{N}}\sum_{i=1}^N U^{(i)}\right)$$
(C.23)

where $(Q_{\tau,N}^{(i)}(x, \pi_k, \pi_j), U^{(i)})$ for i = 1, ..., N are i.i.d. copies of $(Q_{\tau,N}(x, \pi_k, \pi_j), U)$ with $Q_{\tau,N}(x, \pi_k, \pi_j)$ is defined as

$$Q_{\tau,N}(x,\pi_k,\pi_j) = \left[\sum_{i=1}^{\eta} \Theta(W_i,x,\pi_k,\pi_j) - \mathbb{E}[\Theta(W,x,\pi_k,\pi_j)]\right] / \sqrt{\mathbb{E}[\Theta^2(W_i,x,\pi_k,\pi_j)]}$$

and

$$U = \left[\sum_{i=1}^{\eta} \mathbb{1}[X_i \in \mathcal{B}(M)] - \Pr(X \in \mathcal{B}(M))\right] / \sqrt{\Pr(X \in \mathcal{B}(M))}.$$

where η denote an independent Poisson random variable with mean 1 that is independent of $\{W_i : n \ge 1\}$. Let $(Z_{1N}(x, \pi_k, \pi_j), Z_{2N})$ for $(x, \pi_k, \pi_j) \in \mathbb{R} \times \Pi^2$ be a mean zero Gaussian process such that, for each $(x, \pi_k, \pi_j) \in \mathbb{R} \times \Pi^2$, $(Z_{1N}(x, \pi_k, \pi_j), Z_{2N})$ and the left-hand side of (C .23) has the same covariance structure. That is,

$$(Z_{1N}(x,\pi_k,\pi_j),Z_{2N}) \stackrel{d}{=} (\sqrt{1-(\gamma_i^*(x,\pi_k,\pi_j))^2}\mathbb{Z}_1 + \gamma_i^*(x,\pi_k,\pi_j))\mathbb{Z}_2,\mathbb{Z}_2),$$

where \mathbb{Z}_1 and \mathbb{Z}_2 are independent standard normal random variables and

$$\gamma_i^*(x,\pi_k,\pi_j)) = \mathbb{E}\left[S_{\tau,\mathcal{N}}(x,\pi_k,\pi_j).\frac{U_N}{\Pr(X\in\mathcal{B}(M))}\right].$$

We can show that

$$\sup_{B} \left| \mathbb{E} \left[\frac{\tau_{\mathcal{N}}(x, \pi_{k}) - \mathbb{E}[\tau_{\mathcal{N}}(x, \pi_{k})]}{\sqrt{\kappa_{\Gamma, \mathcal{N}}(x, \pi_{k}, \pi_{j})}} \cdot \frac{U_{N}}{\Pr(X \in \mathcal{B}(M))} \right] \right| = O(h^{d/2}), \ \forall \pi \in \Pi.$$

Using the triangle inequality, notice that we have

$$\sup_{B} |\gamma_i^*(x, \pi_k, \pi_j))| = O(h^{d/2}), \ \forall \pi \in \Pi,$$
(C.24)

which in turn is less than or equal to ϵ for all sufficiently large *N* and any $0 < \epsilon < 1/2$. This result and (C .3) imply that

$$\sup_{B} \left| \operatorname{Cov}\left(\left| S_{\tau,\mathcal{N}}(x,\pi_{k},\pi_{j}) \right|, \frac{U_{N}}{\Pr(X \in \mathcal{B}(M))} \right) - \mathbb{E}[\left| Z_{1N}(x,\pi_{k},\pi_{j}) \right| Z_{2N}] \right| \le O\left(\frac{1}{\sqrt{Nh^{2d}}}\right) \quad (C.25)$$

Again, using the triangle inequality, this implies that

$$\sup_{B} \left| \operatorname{Cov} \left(\left| S_{\tau, \mathcal{N}}(x, \pi_{k}, \pi_{j}) \right|, \frac{U_{N}}{\Pr(X \in \mathcal{B}(M))} \right) - \mathbb{E} \left[\left| \sum_{k=1}^{K} \sum_{j=1}^{K} Z_{1N}(x, \pi_{k}, \pi_{j}) \right| Z_{2N} \right] \right|$$

$$\leq O\left(\frac{1}{\sqrt{N \cdot h^{2d}}} \right).$$
(C.26)

On the other hand, for all $\pi_k, \pi_j \in \Pi$,

$$\sup_{B} |\mathbb{E}[Z_{1N}(x,\pi_k,\pi_j)|Z_{2N}| = \sup_{B} |\gamma_i^*(x,\pi_k,\pi_j)\mathbb{E}[|Z_{1N}(x,\pi_k,\pi_j)|Z_{1N}(x,\pi_k,\pi_j)]$$
(C.27)

$$\leq \sup_{B} |\gamma_{i}^{*}(x, \pi_{k}, \pi_{j})| \mathbb{E}[Z_{1N}^{2}(x, \pi_{k}, \pi_{j})]$$
(C.28)

$$= \sup_{B} |\gamma_i^*(x, \pi_k, \pi_j)| = O(h^{d/2}).$$
(C.29)

Using the law of iterated expectations and (C .24).

Therefore, (C .26) and (C .27) imply that

$$\sup_{B} |\operatorname{Cov}(\sqrt{N}|[(\Gamma_{\mathcal{N}}(x,\pi_{k},\pi_{j})] - \mathbb{E}[(\Gamma_{\mathcal{N}}(x,\pi_{k},\pi_{j})]|, U_{N})| \le O\left(\frac{1}{Nh^{2d}} + h^{d/2}\right)$$

which when combined with $\lambda(B) < \infty$ yields (C .22) and hence (C .19) as desired. Next we establish (C .20). Chang et al. (2015) shows that for any $\pi_k \in \Pi$,

$$\sum_{i \in I_{i}} \mathbb{E} \left| \frac{\int_{R_{i}} \mathbb{1}(x \in B) \sqrt{N_{k}} \{ |\tau_{\mathcal{N}}(x, \pi_{k}) - \mathbb{E}\tau_{\mathcal{N}}(x, \pi_{k})| - \mathbb{E}[|\tau_{\mathcal{N}}(x, \pi_{k}) - \mathbb{E}\tau_{\mathcal{N}}(x, \pi_{k})|] \} w(x, \pi_{k})}{\sigma_{N_{k}}(B)} \right|^{r} \le O(N_{k} \cdot h^{rd/2}) = o(1)$$
(C.30)

Notice that,

$$\sum_{\mathbf{i}\in I_i} \mathbb{E}|\alpha_{\mathbf{i},N}| = \sum_{\mathbf{i}\in I_i} \mathbb{E}\left|\int_{R_\mathbf{i}} \mathbb{1}(x\in B) \cdot \Delta_i(\pi_k, \pi_j, x)dx\right|^r$$
$$= \sum_{\mathbf{i}\in I_i} \mathbb{E}\left|\int_{R_\mathbf{i}} \mathbb{1}(x\in B) \cdot \Delta_i(\pi_k, \pi_j, x)dx\right|^r$$
$$= o(1)$$
(C.31)

using (C .30).

Also, from existing results we can verify that

$$\sum_{\mathbf{i}\in I_i} \mathbb{E}|u_{\mathbf{i},N}|^r \to 0 \tag{C.32}$$

Therefore, combining (C .19) and (C .20), we have (C .20). This now completes the proof of the Lemma $\hfill \Box$

We are now ready to prove asymptotic normality

Lemma 8. Under the regularity conditions, the following holds

$$\lim_{N\to\infty}\int_{B_0}\left\{\sqrt{N}\mathbb{E}\left[\left|\left[(\Gamma_{\mathcal{N}}(x,\pi_k,\pi_j)]-\mathbb{E}[(\Gamma_{\mathcal{N}}(x,\pi_k,\pi_j)]\right]\right]-\mathbb{E}|\mathbb{Z}|\kappa_{\tau,N}^{1/2}(x,\pi_k,\pi_j)\right\}w(x,\pi_j,\pi_k)dx=0$$

and

$$\lim_{N\to\infty}\int_{B_0}\left\{\sqrt{N}\mathbb{E}\left[\left|\left[(\Gamma_{\mathcal{N}}(x,\pi_k,\pi_j)]-\mathbb{E}[(\Gamma_{\mathcal{N}}(x,\pi_k,\pi_j)]\right]\right]-\mathbb{E}|\mathbb{Z}_1|\cdot\kappa_{\tau,N}^{1/2}(x,\pi_k,\pi_j)\right\}w(x,\pi_j,\pi_k)dx=0,$$

where \mathbb{Z} is a standard normal random variable.

Proof. Using Lemma 1, and similar arguments in the proof of Lemma 6.3 of Giné, Mason, and Zaitsev (2003), the results are established. □

Define

$$L_N(B) = \frac{\sqrt{N}}{\sigma_N(B)} \int_{B_0} \left\{ \left| \left[(\Gamma_N(x, \pi_k, \pi_j)) - \mathbb{E}[(\Gamma_N(x, \pi_k, \pi_j))] \right| \right. \right.$$

$$-\mathbb{E}\left|\left[\left(\Gamma_N(x,\pi_k,\pi_j)\right)-\mathbb{E}\left[\left(\Gamma_N(x,\pi_k,\pi_j)\right)\right]\right|\right\}w(x,\pi_j,\pi_k)dx.$$

Lemma 9. Under the regularity conditions, we have

$$L_N(B) \xrightarrow{d} \mathbb{Z}$$

as $C \rightarrow \infty$ *, where* \mathbb{Z} *is a standard normal random variable.*

Proof. Notice that

$$S_{N} = \frac{\sqrt{N}}{\sigma_{N}(B)} \int_{B} \left\{ \sqrt{N} \left| \left[\left(\Gamma_{N}(x, \pi_{k}, \pi_{j}) \right] - \mathbb{E} \left[\left(\Gamma_{N}(x, \pi_{k}, \pi_{j}) \right] \right] \right\} w(x, \pi_{j}, \pi_{k}) - \frac{\sqrt{N}}{\sigma_{N}(B)} \int_{B} \left\{ \sqrt{N} \mathbb{E} \left| \left[\left(\Gamma_{N}(x, \pi_{k}, \pi_{j}) \right] - \mathbb{E} \left[\left(\Gamma_{N}(x, \pi_{k}, \pi_{j}) \right] \right] \right\} w(x, \pi_{j}, \pi_{k}) dx \right\}$$

Adopting the de-poissonization arguments of Giné et al. (2003), we have

$$(S_N|\mathcal{N} = N) \stackrel{d}{=} \frac{\sqrt{N}}{\sigma_N(B)} \int_B \left\{ \sqrt{N} \left| \left[(\Gamma_N(x, \pi_k, \pi_j)) - \mathbb{E}[(\Gamma_N(x, \pi_k, \pi_j))] \right] \right\} w(x, \pi_j, \pi_k) - \frac{\sqrt{N}}{\sigma_N(B)} \int_B \left\{ \sqrt{N} \mathbb{E} \left| \left[(\Gamma_N(x, \pi_k, \pi_j)) - \mathbb{E}[(\Gamma_N(x, \pi_k, \pi_j))] \right] \right\} w(x, \pi_j, \pi_k) dx \right\}$$
$$\rightarrow \mathbb{Z}$$

Now from Lemma 8, we know that

$$\lim_{C \to \infty} \int_{B} \left\{ \sqrt{N} \mathbb{E} \left| \left[(\Gamma_{\mathcal{N}}(x, \pi_{k}, \pi_{j})] - \mathbb{E} \left[(\Gamma_{\mathcal{N}}(x, \pi_{k}, \pi_{j})] \right] \right\} w(x, \pi_{j}, \pi_{k}) dx - \int_{B} \left\{ \sqrt{N} \mathbb{E} \left| \left[(\Gamma_{\mathcal{N}}(x, \pi_{k}, \pi_{j})] - \mathbb{E} \left[(\Gamma_{\mathcal{N}}(x, \pi_{k}, \pi_{j})] \right] \right\} w(x, \pi_{j}, \pi_{k}) dx = 0.$$

Hence, we have

$$L_N(B) \xrightarrow{d} \mathbb{Z}$$

as $C \rightarrow \infty$, as required

We are now ready to prove Theorem 4. We can show that for any $\pi_k \in \Pi$,

$$\lim_{C \to \infty} \sup \mathbb{E} \left(\sqrt{N_k} \int_{B_l^c} \{ |\tau_{N_k}(x, \pi_k) - \mathbb{E} \tau_{N_k}(x, \pi_k)| - \mathbb{E} [|\tau_{N_k}(x, \pi_k) - \mathbb{E} \tau_{N_k}(x, \pi_k)|] \} w(x, \pi_k) dx \right)^2 \\ \leq C_2 \lambda(X) \left(\sup_{x \in \mathcal{X}} \mathbb{E} [|Y^2 \hat{\phi}(\pi_k, x, T)^2| |X = x] + \mathbb{E} [|\chi(\pi_k, x, T)^2|] \right) \int_{B_l^c} f(x) dx,$$
(C.33)

where C_2 is a positive constant and $\{B_l : l > 1\}$ is a sequence of Borel sets in \mathbb{R}^d that has a finite Lebesgue measure $\lambda(B_l)$ and satisfies (C .8)-(C .10) with $B_l = B$ for each l and let

$$\lim_{l \to \infty} \int_{B_l^c} f(x) dx = 0.$$
 (C.34)

Also, for each $l \ge 1$, by Lemma 6, we have

$$\lim_{l \to \infty} \sigma_{1,B_l}^2 = \sigma_1^2. \tag{C.35}$$

Following the proof of Theorem B.2 in Chang et al. (2015), we can show that

$$\begin{split} &\lim_{C \to \infty} \sup \mathbb{E} \left(\sqrt{N} \int_{B_l^c} \left\{ \left| \left[(\Gamma_{\mathcal{N}}(x, \pi_k, \pi_j)] - \mathbb{E} [(\Gamma_{\mathcal{N}}(x, \pi_k, \pi_j)] \right| - \mathbb{E} \left| \left[(\Gamma_{\mathcal{N}}(x, \pi_k, \pi_j)] - \mathbb{E} [(\Gamma_{\mathcal{N}}(x, \pi_k, \pi_j)] \right] \right\} w(x, \pi_j, \pi_k) dx \right)^2 \\ &\leq C_2 \lambda(X) \cdot \left\{ \left(\sup_{x \in \mathcal{X}} \mathbb{E} [|Y^2 \hat{\phi}(\pi_k, x, T)^2| | X = x] + E[|\chi(\pi_k, x, T)^2|] \right) \right\} \cdot \int_{B_l^c} f(x) dx. \end{split}$$

Using this result, with the results in (C .34)–(C .35) and Theorem 4.2 in Billingsley (1968), we conclude that

$$\int_{X} \left\{ \sqrt{N} \left| \left[\tau_N(x, \pi_k) - \tau_N(x, \pi_j) \right] - \mathbb{E} \left[\tau_N(x, \pi_k) - \tau_N(x, \pi_j) \right] \right| \right\} w(x, \pi_j, \pi_k) dx \xrightarrow{d} \sigma_0 \mathbb{Z}.$$

The proof is complete because we can use Lemma (8) to show that

$$\lim_{C \to \infty} \int_{B_0} \left\{ \sqrt{N} \mathbb{E} \left[\left| \left[(\Gamma_{\mathcal{N}}(x, \pi_k, \pi_j)] w(x, \pi_j, \pi_k) - \mathbb{E} \left[(\Gamma_{\mathcal{N}}(x, \pi_k, \pi_j)] \right] - a_i \right\} dx = 0. \right] \right\}$$
