^{b)} Electronic mail: sylvain.bertaina@im2np.fr.

FIG. S2. Single crystal XRD pattern of DMAZnF:Mn²⁺ measured at 100K. The two domains of the twin are clearly identified

FIG. S3. EPR signal of DMAAMgF:Mn²⁺ when crossing the transition temperature T_c . The slope of the temperature is swiped from high to low. Note that due to the thermal hysteresis, T_c is higher when the temperature is swiped from low to high

| Configuration | Distance Mn-N _{DMA} (Å) | | | | D value (cm-1) | E/D |

TABLE S1. DFT-calculated EPR parameters for selected configurations of the minimal model. The number in the distances column correspond to the number of identical distance in the minimal model.

FIG. S4. Minimal configurations used for the DFT calculations. (top) configuration giving the highest zfs. (bottom) configuration giving the lowest zfs.

FIG. S5. Rabi frequency and resonance field distributions calculated in DMAMgF:Mn²⁺ using the crystal field parameters extracted from CW measurements for the "forbidden" transitions ($\Delta m_s = \pm 1$ and $\Delta m_s \pm 1$). The frequency distribution is presented vertically to help the comparison with the experimental data. The unit is set to be proportional to the Rabi frequency of the $S = 1/2$ isotropic caliber.

FIG. S6. Simulation of the distribution of Rabi frequencies using crystal field parameters of DMAMgF:Mn²⁺. The transitions are separated for clarity and regrouped by the same kind.

FIG. S7. Simulation of the distribution of Rabi frequencies using crystal field parameters of DMA⁺MgF:Mn²⁺. Only the allowed transitions $\Delta m_s = \pm 1$ and $\Delta m_s \pm 1$ are represented. The grid is represented as follow: from top ($m_s = -5/2 \leftrightarrow -3/2$) to bottom ($m_s = 3/2 \leftrightarrow 5/2$) for the different electronic transitions and from left ($m_I = -5/2$) to right ($m_I = +5/2$) for the nuclear projection.

FIG. S8. Simulation of the field sweep Rabi frequency distributions calculated using the crystal field parameters of DMAMgF: Mn^{2+} . Two orientations of the magnetic field was used which correspond to the two magnetic sites of Mn^{2+} separated by 58° . A distribution of the zfs of 40 MHz was used in order to simulate the field broadening.
