

Ex. KernelDefiniton : using MATMULT = KernelDefinition<2, "elmatmult\_generic", kernel\_t::INT\_BIN, sort\_by<3>, float \*, float \* >;

## Using Application Space

```
__global__ void elmatmult_generic( float * a,
                                   float * b,
                                   float * c)
{
    int x = threadIdx.x;
    c[x] = a[x] * b[x];
    return;
}
```

## Using FLASH Sub-Space

```
__global__ void elmatmult_generic( float * a, float * b,
                                   float * c, size_t ** ind)
{
    //for CUDA kernels: first dimension must be less than 6 (0-5)
    //The second dimension is the index in subspace, relative to the
    //task group.
    //ind converts subspace indices to application space
    int x = ind[0][threadIdx.x];
    c[x] = a[x] * b[x];

    return;
}
```
