

flash_runtime

/* private members */

```
get_runtime( std::string ) :  
    std::shared_ptr<flash_runtime>  
register_kernels( size_t, kernel_t [],  
    std::string[], std::optional<std::string>[]  
 ) : status  
execute(runtime_vars, uint,  
    std::vector<te_variable>,  
    std::vector<size_t>,  
    options ) : status  
create_transactions() : ulong  
process_transactions( ulong ) : status
```

sort_attr

group_attr

part_attr

runtime_vars

```
lookup : std::string  
kernel_name_override : std::string  
kernel_impl_override : std::string  
trans_subaction_id : std::pair<ulong,  
    ulong>  
get_lookup() : std::string  
get_ids() : std::pair<ulong, ulong>  
set_ids( std::pair<ulong,ulong> ) : void
```

The runtime variable structure is used to hold overrides from the kernel name and implementation, and transaction and subaction ids

te_variable

```
type_size : uint  
vec_size : size_t  
data : void *  
get_data() : void *  
get_bytes() : size_t
```

The te_variables stands for type erased variable. It is used to pass buffers args across runtime compiler boundaries (runtimes).

options

```
sort_option : std::optional<sort_attr>  
grp_option : std::optional<group_attr>  
part_option : std::optional<part_attr>  
set_sort_dims( std::vector<uint> ) :  
    void  
set_grp_dim_val( uint,  
    std::optional<size_t> ) : void  
set_part( std::optional<bool>,  
    std::optional<part_func> ) : void
```

The options structure encapsulate and converts compile-time constants to runtime variables to be passed across compiler boundaries.
