

# The road map of the pulmonary airway segmentation works

## EXACT'09

Propose the framework to establish the reference airway tree segmentation. It evaluated 15 different airway tree extraction algorithms on a diverse set of 20 chest CT scans without golden annotations. Most algorithms adopted region-growing and vessel filters in that **pre-deep-learning era**.

## Xu'15

Xu *et al.* proposed the **hybrid multi scale fuzzy connectedness** framework cooperating with morphological reconstruction and multi-scale vesselness enhancement for airway lumen segmentation. A spatially constrained Markov random walk used for airway wall estimation.

## Jean-Paul'17

Jean-Paul *et al.* designed a classifier via the ConvNet to **detect the leakage** phenomenon. The leakage removal can increase the tree length metric.

## Meng'17

Meng *et al.* introduced the concept of the **tracking** along the centerline (extracted by the gradient vector flow) to the airway segmentation problem. They designed the sampling strategy and 3 VOIs. 3D UNet was used for airway region extraction, leakage removal, and Furcation detection.

## Qin'19

Qin *et al.* converted the airway binary segmentation problem to the **26 neighborhood connectivity classification** problem. They concatenated the distance map and the coordinate map to final decoder stage.

## Wang'19

Wang *et al.* introduced a SCNN to capture **slice-wise propagation** message, adding strong spatial constraint. They also incorporate the distance map to establish a radial distance loss function.

## Nadeem'21

Nadeem *et al.* proposed the CT intensity based **freeze and growth propagation**. It starts with a conservative segmentation parameter and captures finer details through iterative parameter relaxation.

## Selvan'20

Selvan *et al.* posed the airway tree extraction as a **graph refinement** task. First, they used a mean-field network to approximate the posterior density. Second, a graph neural network refines the sub-graphs and derive edge probabilities.

## Zheng'21

Zheng *et al.* proposed the WingsNet combined with group supervision to deal with the **inter-class imbalance**. The general union loss was designed to tackle **intra-class imbalance** via distance map based weight and hard mining sample solution.

## ATM'22

ATM'22 challenge aimed to revolutionize the field of airway segmentation from three aspects: 1) **More Annotated Data**. 2) **More Comprehensive Metrics**. 3) **More Efficient Platform**.

The pulmonary airway segmentation is still an open-call challenging problem that needs to be explored further.
