

Solution Suggestion:

1. Check the hardware status:

Check the physical status of network cards, cables and interfaces to ensure that there is no damage or looseness.

Check the server's hardware resource usage, such as memory and CPU, to ensure that there are no resource bottlenecks.

If possible, replace potentially problematic hardware components, such as network cards or cables, to troubleshoot hardware failures.

2. Check software status:

Check the operating system logs and application logs to analyze for any anomalies or error messages.

Update the operating system, network stack, and applications to the latest versions to fix possible bugs.

If possible, try to roll back to a previous software version to troubleshoot newly introduced issues.....
