Figure 6: Performance measurement of frequency domain

4.2.3. Scenario-3: Classification using the Time-Frequency Domain Features Domain Features

The following Figure 7 shows the plots of the performance measures (mean ± SD) obtained from the classification of subjects addicted to smoking using the time domain features from four different classifiers, LR, KNN, SVM and RFC, respectively. The plots show that the gap between sensitivity and specificity is the highest in the case of SVM (7.5%) and lowest in the case of RFC (2.2%) and ANN (2.2%). Overall, RFC gives an accuracy of 91.3%, which performs the best.

Figure 7: Performance measurement of the time-frequency domain
Figure 8: Comparison of accuracy metrics for four different classifiers

4.3. Choosing the best Scenario

The overall accuracy was considered as the reference metrics while finding out the best scenario, as it is difficult to compare different classifiers using several measures. The plots of the accuracy for four different classifiers corresponding to different domain are shown in the Figure 8 below. From the given figure, it is evident that the accuracy for random forest classifier is better than any other domains for all the four classifiers.

The accuracy plots also reveal the relative comparison among the time domain features, frequency domain features and the effect of the fusion of both time and frequency domain. It is evident that the frequency domain features perform better than the time domain features for all of the classifiers. Again, the time-frequency fusion outperforms the previous scenarios when the time or frequency domain feature were used individually. So, in the rest of the paper, the combined-time frequency domain features will be considered for further analysis.

4.4. Choosing the best classifier

The plots for the area under the ROC curve for the classifiers built using the time-frequency domain of EEG features are shown in the Figure 9 below. The figure illustrates that the RFC classifiers show the best compromise between sensitivity and specificity, with covering the highest area under the ROC curve (AUC= 0.92%).
Figure 9: Comparison of AUC for four different classifiers for time-frequency domain
Figure 10: ROC Plots for time-frequency domain-based RFC model with 5-fold CV

Area under the AUC curve plots for 5 different experiments in 5-fold cross-validation with time frequency domain features using RFC classifier is shown in Figure 10. The AUC ranged from (0.78-0.92) for all the models with the time-frequency domain features, with a mean of 0.92 and 0.04 standard deviation. This signifies that the time-frequency domain shows an excellent performance than the other domains of EEG signal in tobacco smoking diagnosis.

5. Discussion

Four different classifiers were used in this study for assessing the performance of the EEG domains for the diagnosis of tobacco smoking. The results revealed that the time-frequency domain performs the best among the other domains. It also revealed that the maximum performance was obtained using the RFC Classifier, with a sensitivity, specificity and accuracy of 94.3%, 92.1% and 91.3%, respectively. Moreover, RFC based model time-frequency domain-based dataset shows promising AUC (0.92), which is a good compromise between sensitivity and specificity.

The finding of this study is consistent with some of the previous studies [1,7]. The study [7] achieved an accuracy ranged from 97.33-97.50%, while using the frequency domain features, such as, PSD and FFT features of EEG signal, which also supports the finding of the current study. Though the study of [7] used only RBF kernel based SVM, the current study validated the other classifiers which support the findings. In another study [1], where authors found the time-frequency domain as the best performing domain, though they have used only one classifier (ANN), and one performance metrics (Accuracy). Contrarily, the time domain performed the worst (RFC accuracy= 62.4%) in their study, while using a holdout approach for validation. The current study used a five-fold cross-validation and validated the outcome of the previous research with multiple classifiers.

Based on the results and analysis in the study, the following research implications and recommendations can be provided. First, using the frequency domain features is always recommended to diagnose tobacco smoking using the EEG signals. However, using time-frequency fusion is highly recommended as this combination provides a higher classification performance. Second, the given outcomes could be correlated with the drug-related impairment in the human brain, which could provide further insight into the correlation between the two addiction.

There are some feasibility issues with the study. First, using EEG sensors to detect the smoking habit could be a cumbersome procedure. However, the research could add value to observe the effect of different cigarettes depending upon their nicotine levels and their impact on the human brain. Second, the use of EEG as ground truth in tobacco-related experiments. If the setup is available in the lab, the EEG measurement could be used as ground truth when observing the effect of Tobaccos smoking on other factors. Third, the impact of drug addiction is more severe in the human brain than smoking. This experiment can add value to the relative comparison of the drug and tobacco addiction. However, the scope of the paper is not out of limitations. Inter-individual difference among participants is another factor, which is needed to be considered. As the paper represented a novel methodology of EEG based diagnosis of tobacco smoking, more research is required to find out the feasibility in real-world conditions as well.

6. Conclusion

To develop an EEG based diagnosis of tobacco addiction, an analysis was done in this study to find out the feasibility of the time and frequency domain features using this proposed model. Here, ultimate results were obtained after applying several steps- feature scaling, tuning of classifiers, and finally with five-fold cross-validation of the developed models. The research investigation found that the combination of the time-frequency domain features with RFC classifier showed the best accuracy while the time domain features showed the lowest accuracy. This analysis shows that time-frequency domain shows the best Accuracy with SVM (86.5 %), LR (87.2%), KNN (87.5%) and RFC (91.3%), Time-domain shows the lowest accuracy with all classifiers while the ffrequency domain shows higher accuracy than time domain, but still, this is less than the combined time-frequency domain performance. Among all the classifiers, RFC showed the best Accuracy and SVM showed the lowest accuracy. However, the experiment could be done on more number of participants to validate the model based on lave one participant out approach. Also, efficiency will increase with the addition of more EEG channels which could be considered for future implications.

Conflict of Interest

The authors declare no conflict of interest.

Multi-Layered Machine Learning Model For Mining Learners Academic Performance

Ossama Embarak[*]

Computer Information Science, Higher Colleges of Technology, Abu Dhabi, 51133, UAE

A B S T R A C T

Different colleges and universities have different approaches to dealing with low-performance learners. However, in most cases, analgesics do not deal with root problems. This research suggests a model of three layers of variables sequentially adaptable to a deep-root issue. The suggested model can identify early pupils who could be at risk because of inaccurate or lack of match sequences and suggest rehabilitation. The approach proposed was implemented at three levels. First, we examined the personality type for 180 learners from different majors: Security and Forensics, Networking, and Application Development, using the MBTI test. Second, we build a knowledge matrix for courses by dividing each learning outcome into its knowledge segments. Then, we build the skills matrix for courses by decomposing each learning outcome into its skills segments. We then use machine learning (SVM, DT and association rules) algorithms to mine student performance on a smaller scale of knowledge and skills, taking into account their personality types instead of measuring an entire course's holistic performance. Finally, we developed a system of recommendations to detect performance deviations in knowledge and skills and provide adaptive learning materials that fit the examined students' personality. The proposed approach demonstrates its validity and effectiveness. However, it needs regular updates on learners' performance, which could be automated and linked to evaluation tools. The framework also has a minor impact on learners' privacy since it exposes individual personalities to their advisors.

1. Introduction

This paper is an extension of work initially presented in 2018 Fifth HCT Information Technology Trends (ITT), IEEE [1]. On average, students have different talents, distinct attitudes, and different levels of enthusiasm in their educational programs. Although various students may share a major, it is, however, important to analyze students in many aspects, including the knowledge and skills they have learned. The students have a wide range of learning styles that reflect how they can analyze, plan, and respond to the learning environment [2]. Some students may be comfortable thinking of hypotheses and abstract ideas, while others feel better being a little more concrete with data. Some of the student body prefers active learning, interaction by taking notes and seeing the material presented [3]. It shows how different the students are to each other even within the same major. There are three learners of the course. One learner who has begun to learn by auditory means, another who has begun with tactile activities and finally another learner who is visually dominated [4]. The challenge of the day is to equip our students with the information and skills they will need to accomplish their goals into their future professional careers, regardless of their personal preference. There are many majors in computing that require different knowledge and essential skills than those

required for their future careers. To memorize everything here is not exactly effective; i.e., memorization is inefficient. An inability to memorize is a type of learning disorder. Students with such a condition do not expend much effort in studying or preparing for exams. There are two different behaviours that those students might do. Some students might adopt a more in-depth approach when understanding the meaning, whereas the others might make a more strategic approach to understand such type of knowledge, get the best knowledge of their peers and gain related skills [5,6]. As it should be, learners often have their own personal values that affect their own personal ability to absorb new knowledge and learn new functional skills [7].

Knowing students' personality patterns is extremely valuable in finding out their skills; the Myers-Briggs Type Indicator (MBTI) is very much in use. as a means to do just that. Neural dynamics testing techniques, as used in MBTI, helps with understanding the form of human personality. The four main personality traits are eye contact, emotional perception of facial expressions, sensitivity to language, and sensitivity to others' physical appearance [8].

The first pattern is the orientation of energy: Extroversion (E) is preferable to those who prefer to be energized for situations, people and things (that is, for the external world)

850

2

compared with their complement, preferring to direct their energy towards information, beliefs, ideas and explications (that is, the internal world) (I).

The second pattern is the information and things an individual wants to deal with; Those who prefer to deal with facts and describe clearly situations are sensitive (S). They prefer to deal with ideas, expectations and unknown factors that are not obvious, rather than their additions dependent on intuition. (N).

The third pattern is the sort of decision-making, People would rather make decisions based on objective logic and analysis- Thinking (T) than those who prefer to make decisions based on the values they believe important — feelings Feelings (F).

Fourth, how people make their planning, Those who prefer well-designed and planned lifestyles judge (J) against those who like flexibility, flow and react to things, i.e. perception (P) [9].

- ***Extraversion(E) vs Introversion (I)***
- ***Sensing (S) vs Intuition(N)***
- ***Thinking(T) vs Feeling(F)***
- ***Judging vs Perceiving(P)***

A person may be more inclined to be extroverted than an introvert. Likewise, a person could be more sensing than intuitive, more thoughtful than feeling and judging than perceived. The table below decipher examples of detected personalities.

Table 1:Sample types of personality

Personality Type	ISTJ	ISFJ	ESFP	INTP	ENTJ
Extraversion(E)	×	×	√	×	√
Introversion (I)	√	√	×	√	×
Sensing (S)	√	√	√	×	×
Intuition(N)	×	×	×	√	√
Thinking(T)	√	×	×	√	√
Feeling(F)	×	√	√	×	×
Judging(J)	√	√	×	×	√
Perceiving(P)	×	×	√	√	×

Each personality fits more than the others to a particular career; for example, the ISTJ personality type could fit more into the Systems administrator.

I: Propensity to think about things in the mind
S: Prefer ideas with practical applications
T: Take decisions on an impersonal basis, using a logical reasoning
J: Prefer detailed step-by-step instructions

Combining these four couples generates 16 alternative personality types that enable scientists to understand individuals and advance in a specific area through measurement (s). Students with a preference for introversion, probably doing a lot of thorough work or considering a problem, can find it difficult to live in a noisy or interactive environment [10]. Consequently, they can tend to pick less active and interrupted concentrations. The measurement of computer skills in vital terms and concepts, which are understandable and learning for students during their studies. We have to measure skills such as troubleshooting, network setup, audit protection framework, etc. In addition, it is possible to develop applications, systems, networks, etc.

Maintaining a system to ensure students' personality types is extremely important for understanding their emotions, thinking,

and behaviour. For example, understand if a student prefers to work alone or prefers to work with others. Prefers an extremely organized and fixed career, or someone who would like a flexible, open schedule, which allows him or her to be spontaneous. This information helps to determine which career(s) are appropriate for the preferences of students. There are no special advantages or disadvantages over these patterns as they complement each other. If a student has been detected as an Extroversion with a specific percentage, it is an Introversion of the supplement percentage; therefore, each pair is valid for each person but with different strength. The networking employee is expected to be self-driven to deal with network issues and not wait for outside directions. Extraverts tend to be more active when learning, while introverts tend to be more reflective when learning.
Figure 1:   Learner comprehension layers

3. Literature Review

We cannot think of a single method of teaching suitable for all pupils of the same major. Most academic institutions follow the same method, which relies on the delivery of lectures, where students have to absorb the material and then repeat it in the review. This approach does not solve the gaps in student skills, expertise and competencies. Different learning styles define students they prefer to interpret knowledge in different ways [11]. Several models were developed to classify the way people learn; Jung's psychological theory, also known as the Myers-Briggs Type Indicator, is the most famous model (MBTI) [12]. This test provides ample information about a person's personality and the consequences of his or her education. The engineering department of the University of Western Ontario has demonstrated that in the first year of engineering courses men introverts, intuition, thinkers and judges are more likely to excel than extraverts, felt, sensed, and interpreted people at the lower end of their range [13]. They used an MBTI test and performance test on 119 students to determine whether that particular group of seniors would perform very well later in a class like that. The type of personality that is more likely to drop out of the curriculum is recommended to be one that is not overly concerned with grades.

Sensors personality ratings were significantly lower than Intuitors in courses with few high abstractions, an especially important practical question posed by the tests. Introverts may be well-suited for team activities, but extraverts will enjoy working together. Persons who score highly in the Intuitive

cluster score higher on creativity and problem-solving skills than those with a Sensing personality [14]. For example, in understanding academic success, another model created in recent years is the Felder and Silverman [15]. Its purpose is to answer four questions, which are as follows.

On the student's preferred topic, what information do they preferentially perceive? For the student who has a sensory personality, they prefer to be focusing on interacting with what they see, hearing the sounds, and using their physical sensations as a way of experiencing. Those who think more specifically are more comfortable with their abstracts (theories, math, memories, thoughts, and are more likely to solve the problems faster and innovative. What kind of information are our senses perceived most effectively? That is visual personality (exhibited in the eyes) or verbal personality (expressed through speech). What process is the student used to incorporate this information into their outside learning?   Actively through participation in physical activity, or through meditation. How does the student characteristically   get   from   "not   understanding"   to "understanding?" The classroom needs to be set up with logical steps in place, with students thinking linearly and being able to only work with a partial understanding (logic step), or where students think globally and applying their knowledge until they fully understand the picture and have a holistic perspective (global system step) [16]. The Kolb Model assumes that every class possibly includes students of every category. This leads to the belief that these learners are often more likely to become better learners, leading them to perform better [17].

The key issue is how to find an appropriate method of learning for new students when the knowledge is lacking. There are numerous approaches that solutions tend to be used in solving a new state: a cold start problem, [18] Develop the algorithm that finds the closed likeminded learner, and so it generates its recommendations accordingly. [19] Researchers found that students with characteristics that esteem the parental world among students in technology majors were more likely to be of an ESFJ, ISFJ, ESFP, INTJ, and ISTP. On the other hand, students majoring in management information systems tend to be more ESTJ and ISTJ. In an article by [20]ISTJ, INTJ, and ISFJ are the most common personality types found in the computing industry. A study that was done by [21] shows that the relationship between the students' personality and their academic performance depends on the correspondence between the students' personality and the chosen major. Researchers have found, first of all, that system analysts are more extroverted than other thought-provoked people, that computer designers are more introverted and less extroverted than other thought-provoked people, and that programmers are more introverted and less extroverted than other thought-provoked people.

4.   The Proposed Approach

The details of the proposed approach are to be applied in four phases. In the first phase, we build the courses' knowledge and skills matrix by decomposing the course's learning outcomes into its knowledge and skills segments. This will help apply machine learning algorithms to mine learners' performance on a smaller scale of concept segments rather than on the entire course's performance or an entire block of concepts. In the second phase, we collected the personalities of students using the MBTI test. In the third level, we assess learners' success (Knowledge & Skills) considering their personality and

concentration. Finally, apply a recommendation framework to enhance the performance of learners using machine learning.

4.1. Construct a matrix of knowledge and skills

Analyze courses in terms of skill and knowledge. The starting point was to decompose the courses into their relevant knowledge and skills, representing all the concepts used in each CLO course and laid out in the PLO curriculum, as seen in the following analysis for CIS1403, fundamental to the programming course.

Table 2:Fundamental of programming knowledge & Skills

CLO Number	Description	knowledge	Skills
CLO1	Apply basic programming concepts to write simple programs that use data types, variables, constants, expressions, and statements, focusing on these constructs in Java.	Just remember data types. Recognize the appropriate parameters and values. Please, understand expressions.	Apply the data types. Read through the used data types Create a fully working application in which all variables are properly typed.
CLO2	Write programs that take control flow decisions by means of conditional statements and iterative decisions.	Understand how expressions work. Learn to understand Iteration statements.	Make use of iterations to accomplish control flow. Use conditionals to control the flow of a program.
CLO3	Write programs using unidimensional arrays for initialization, access, transversal, and searching for different data types.	Understand one-dimensional array	Write programs using single-dimensional arrays Write programs that access, update, and search one-dimensional arrays.
CLO4	Develop programs using built-in and user-defined functions with parameter lists.	Understand different user-defined functions {void and return}	Analyze user-defined functions Write functions with parameters
CLO5	Organize and document the program's source code in line with industry standards and best practices.	Recognize coding standers Recognize coding best practices	Apply coding best practices Analyze a programming problem Write a fully working program with function calls

The method retains four key components: intelligence, abilities, attitude and soft skills of the learner. The developed machine learning model used by these components to assess learners of the greatest importance, learners' key causes of At-risk, and we strive to calculate their employability ratio in the light of these core components.

4.2. Evaluation of student personalities

Understanding the personality type will help clarify the preferences, and how or why students may be different. Personality types are useful for understanding how a person can learn, manage, monitor, communicate, collaborate, compromise and cope with stress. Understanding the behaviours of learners helps prepare students to improve their knowledge and skills. This helps to apply a self-awareness tool to recognize strengths, consider and manage growth needs, and establish a career and personal development strategies.
Figure 2: Course knowledge and skills decomposition

We collected data about students' personality using https://www.16personalities.com/, where students' future profession can be categorized into MBTI Sixteen Personality Types shown below [22].

Figure 3: Personality types main features

4.3. Build a recommendation system

Build a recommendation framework that considers learners' personalities from on the one hand and the knowledge and skills they have from the other, as shown in the figure below.
Figure 4: Three-layered course personalization model.

5. Research Procedures

For this research, 180 students were asked twice to use different platforms to take the Myers-Briggs Style Test. Eliminating all irregularities, only correct and clean data for treatment has been processed. Data collection incorporates the Type of Personality and the Personality Code; Extraversion (E), Introversion (I), Sensing (S), and Intuition (N) (P).

Variables

Three factors influence the development of students and thus their academic status in this research. First, we will consider the

personality type created through a four-letter combination, each of which represents a set of independent characteristics. : extroverted versus introduced, sensing versus intuitive, thought versus feeling and judging versus prospecting. The second factor is the students' knowledge based on each class: the third factor is the students' skills that meet their concentration needs. We can determine if a student is in good academic standing by considering their first-year grades, time in school, etc.

5.1. Create Learners profiles

We have developed student profiles that incorporate their personality style and academic knowledge and skills. The figure below shows the types of students, which is used to analyze whether the student's personality affects their achievements in the three majors of computer networking.

Table 3: Learners measured personality

Catalog	Academic Standing	Cgpa	Major	Emsat English Overall Score	Emsat Math	High School Average	Personality Type	Extraverted	Introverted	Intuitive	Observant	Thinking	Feeling	Judging	Prospecting	Assertive	Turbulent

Figure 6: Recommendation Education system for At-risk learners

In order to find the best predictor for student performance, we have used different machine learning algorithms (Decision Tree, Random Forest, SVM and Association rules); then we evaluated and refined the used algorithm. The main aim is to develop a primitive platform that can be used to develop an education recommendation system to support At-risk learners 24/7 and teachers to coach students with poor knowledge, skills, and to provide them with the right advice.

Applying online coaching to at-risk students needs to build a recommendation framework that predicts at-risk students considering their knowledge and skills performance in segments of concepts rather than an entire course, considering their personality style. This helps to give coaching in the form of advice crumbs, as shown in the implementation figure 9 below, which may be tutorials, segment coding, exercises, peer discussions, etc.

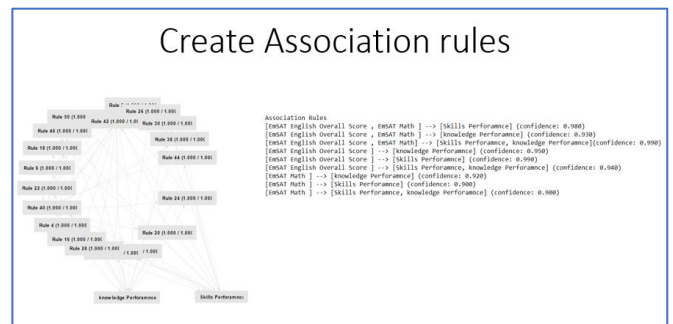
The association rules are used to created recommendations considering student knowledge and skills performance.


Figure 7: Applied Association rules for creating recommendations

5.2. Explore profiles of students

First, we purified information from all NA instances, measured the mean and variance and the range for each pattern.

As shown in the table below, we measured the mean and variance and the three majors' GPA quartile.

Table 6:   Descriptive statistical of the GPA - CIS three-concentrations

Major	count	mean	std	min	25%	50%	75%	max
Applications Development	32.00	3.10	0.40	2.15	3.00	3.20	3.25	3.90
Networking	56.00	2.69	0.61	1.40	2.27	2.56	3.20	3.74
Security and Forensics	126.00	2.69	0.54	1.30	2.40	2.68	3.00	3.68

In the application development department, the students typically have the highest average GPA, the Security and Forensics students have the second-highest average GPA, and the Networking students have the lowest average GPA. In the three conditions, we have been able to identify different personalities. Security and forensic students share the introverted sensing function type, which means they are more likely to feel, and judge - ISFJ.

It should be clear that, as demonstrated below, we have security students with various types of personalities, however, the GPA scores declined slightly accordingly.
Figure 8:   Personality type's weight-Security and Forensics Major.

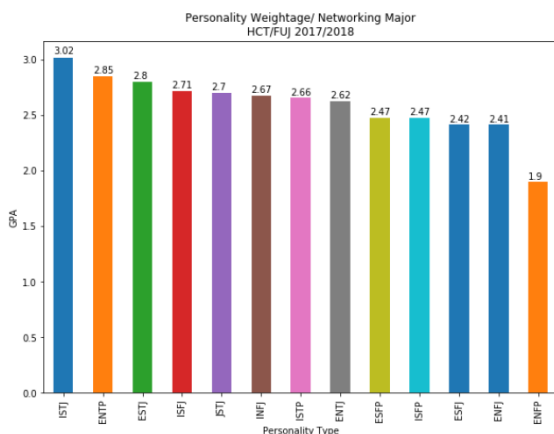
Students form Networking Major are more ISTJs, which means more Introduction (I), Sensing (S), Thinking (T), and Judging (J). As shown in the below figures, major students in the App development are more ISTJ.


Figure 9:   Personality type-Networking major.
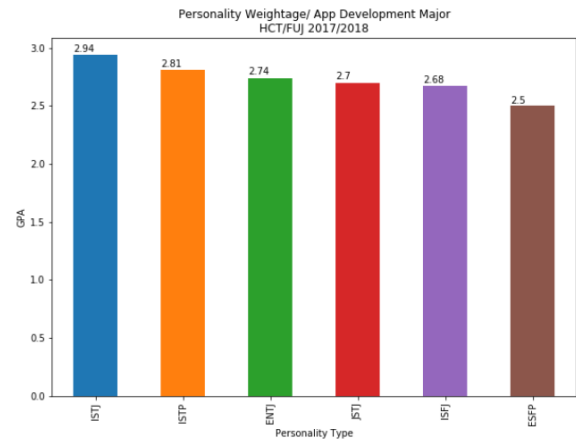

Figure 10: Personality type – App Development major.

6.   Experimental Results

In the following tables, we summarized the statistics on student success.

Table 7:   Four courses performance statistics for personality types - Security and Forensics major

The count feature shown in the above table should be clear, referring to each major's personality styles. In addition, the mean, minimum and standard deviation of GPA values from each course is calculated, and the four courses and personalities are also calculated. Apart from CSF 3103, the course for the security major, the App development students did not receive the results of NaN but took the networking course CIN-2003. We evaluated students' performance with their personalities in the four classes. In every course, according to the college grading system, we determined the GPA value of students.

Table 10: College GPA grades conversion values

Score	F	D	D+	C-	C	C+	B-	B	B+	A-	A
GPA	0	1	1.3	1.7	2	2.3	2.7	3	3.3	3.7	4

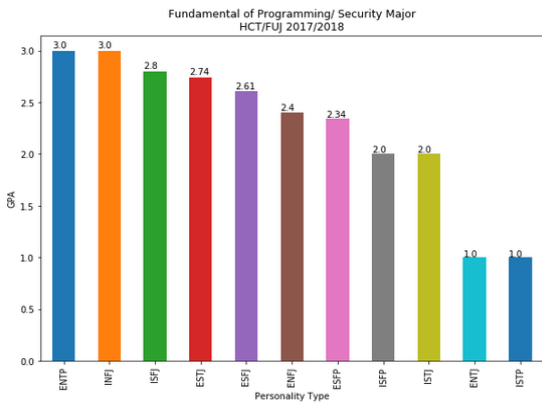
a) *The personalities patterns in the four courses for Security and Forensics major.*


Figure 11: The impact of personality as a measure for four courses on security and forensics major.

b) *The personalities patterns in the four courses for Networking major.*

858
Figure 12: Impact of personality for Networking major as a measure on the four courses

c) *The personalities patterns in the four courses for App Development major*
Figure 13: The personality impact on App Development as measured on the four courses.

In each major and different course, the following table summarizes the results of the best personalities.

Table 11: Personality performances in the four courses.

	GPA	Fundamentals of Programming	Object-Oriented Programming	Enterprise Network Services	Computer Forensics and Investigation
Security and Forensics	>=3.0	ENTP, INFJ	ISTP	ISFJ	ENFJ, ISFJ, ISFP
	>=2.5	ISFJ, ESTJ, ESFJ		ENFJ, ESTJ, INFJ, ESFJ, ENTP, ISFP, ISTJ, ESFP	ESFP, ESTJ
	>=2.0	ENFJ, ENFP, ISTJ, ISFP	ISFJ, ESTJ, ENTP	ENTJ	ESFJ, INFJ
Networking	>=3.0	ENTP, INFJ, ENFP		ISFP, ENFP	ENFJ, ISFP, ISFJ
	>=2.5	ISTJ, ESTJ, ENFJ, ISTJ		ISTJ, ENFJ, INFJ, ENTP, ESTJ	ESFP, ESTJ
	>=2.0	ESFJ, ISTP, ISFJ	ISTJ, ISTP, ENTP	ESFJ, ISFJ, ISTJ, ISTP, ESFP	ESFJ, INFJ
App Development	>=3.0				
	>=2.5	ISTJ, ISTP, ISTJ	ISTJ	ISTJ, ISTP	
	>=2.0			ISTJ	

Based on their personality, we may describe the conditions for a major choice to be made, or we have the ability to predict a student's GPA (grade point average). Take an example such as this study by the hospital and try to analyze it with the below algorithm.

If *"ISFJ" or "ESTJ"*
➔ *The best major is Security & Forensics*

ELSE IF *"ISTJ" or "ENTP"*
➔ *The best major is Networking*

ELSE IF *"ISTJ" or "ISTP"*
➔ *The best major is App Development.*

In the case of teaching computers to "understand" the best major, we can also rely on specific patterns, the systematic way, in the algorithm below.

If *"S" and "J"*
➔ *choose Security & Forensics*

ELSE IF *("S" or 'N') AND "T"*
➔ *The best major is Networking*

ELSE IF *"S" AND "T"*
➔ *The best major is App Development.*

It is important to have measured students' knowledge and skills to recognize getting into trouble students' academic status and their needs. Students are given an assessment in four courses that cover OOP, Enterprise Networks and Services. A breakdown of students' knowledge from various academic majors was compiled, and the numbers are listed below.

The factors that we looked at were the students' different academic performance, as well as the skills they demonstrated in the OOP course.

Table 12: The knowledge of OOP course over the three majors.

Knowledge		Object-Oriented Programming					
	GPA	Concepts of object-oriented programming	Terminology of methods	Terminology of functions	Terminology of inheritance	Terminology of encapsulation
Security and Forensics	>=3.0	82%	77%	76%	81%	83%
	>=2.5	0%	0%	0%	0%	0%
	>=2.0	74%	71%	71%	76%	75%
Networking	>=3.0	0%	0%	0%	0%	0%
	>=2.5	0%	0%	0%	0%	0%
	>=2.0	77%	68%	74%	69%	67%
App Development	>=3.0	0%	0%	0%	0%	0%
	>=2.5	77%	72%	76%	68%	81%
	>=2.0	0%	0%	0%	0%	0%

Table 13: OOP skills performance in the three major categories.

Skills		Object-Oriented Programming				
	GPA	Implement OOP tools	Use advanced features	Develop programs	Use Collections Framework	Test and evaluate a program
Security and Forensics	>=3.0	87%	79%	77%	76%	79%
	>=2.5	0%	0%	0%	0%	0%
	>=2.0	77%	65%	68%	72%	81%
Networking	>=3.0	0%	0%	0%	0%	0%
	>=2.5	0%	0%	0%	0%	0%
	>=2.0	80%	66%	71%	73%	72%
App Development	>=3.0	0%	0%	0%	0%	0%
	>=2.5	79%	69%	77%	80%	83%
	>=2.0	0%	0%	0%	0%	0%

7. Discussion and Conclusions

This study proposes a model for evaluating university students' academic status and GPA performance ambitions. Faculty and staff call upon these three factors in decisions: personality preferences, perceived knowledge and skills as well as what they expect from each student. In their attitudes, knowledge and skills, computing students are not identical. We see the disparities between students' grades because the universities lack an understanding of these disparities between learners' abilities and a special opportunity for creating a truly unique learning method that matches their individuality. This makes it difficult to apply the same philosophy and expects all students to be highly qualified.

This system allows for specific algorithms to be included, in the students' guidance, academic major choice or even the selection process. In a class on security, when we use sections for personality types, we can use an algorithm to predict the student's ranking automatically.

IF "Security & Forensics major."
  IF "ENFJ" or 'ISFP' or ISFJ'
    ➔ *Expected high grade*
  ELSE IF 'ENTJ' or 'ENPT'
    ➔ *Expected fail case*

ELSE
    ➔ *Expected low grade*

We did not look at all scenarios, only example algorithms.

IF "OBJECT-ORIENTED COURSE"
  IF "ISTP" or "ISTJ"
    ➔ *Expected high grade*
  ELSE
    ➔ *Expected low grade*

In general, consider how OOP awareness is summarized in Table 9. Security students have the ability to implement higher object-oriented concepts than those with a non-security background. Again, we want to emphasize the personality that makes these differences, not the selected major. This clarifies that major security students could perform well than other major students because of the difference in a student's personality that corresponds to the offered programming course. See the algorithm below that demonstrates it.

For a Major
  If Personality 'ISTJ' & 'FUNDAMENTAL OF PROGRAMMING'

    ➔ *Expect GPA >=2.0*

In view of the basics, the students in App developers major with the 'ISTJ' personality achieve round 2.91 GPA, while networking students are expected to achieve 2.8 GPA and security and forensics students 2.0 GPA. The differences are seen in the second and third levels as a result of other factors: knowledge and skills.

In the following sections, the benefits of implementing the three-layer model are listed.

1. Maintain high-quality graduates with an appropriate level in their technical knowledge and skills.
2. Minimize cases at risk.
3. Keep an eye on signs of inattentiveness and poor academic performance.
4. A decrease in the number of delayed graduate students.
5. Avoid the disproportionate dropout from prospective students in response to dismissal or academic warnings.
6. Make sure to have a high level of student retention.
7. Provide tools to assist individuals to become more effective in selecting courses and getting the right major.
8. Keep clear knowledge of each student's academic progress in case of a student falling behind.

8. The Conclusion & Future Work

Educational institutions have a tremendous burden of handling students with low academic performance (At-risk students). Many approaches support this group of pupils, such as psychological therapy, a proper timetable for vulnerable pupils, recall, personal training, mock-tests, direct private education, or success centres. However, these methods are not enough to solve the issue, since other factors could also influence the learner's success, which could be their family difficulties, cognitive style, prior academic performance, and the foundation of the college level. Learners personalities are the most important factor that needs a great deal of attention to understand students' individuality and natural abilities. This greatly helps to adapt the

materials supplied to their perceptions and offers solid support during the study programme. This paper proposes a recommendation system based on three key angles: personalities of the learner, skills of the learner and academic knowledge of the learner. The proposed layered model helps predict at-risk students, provide better advising, enhance learners' performance and skills, discover their employability competencies, and support learners with a recommendation in terms of tutorials, exercises, etc. during their study period. Based on the association rule, the proposed recommendation framework is structured to predict student success in different college programs and predict their academic status based on their personality analysis and academic performance. It is highly recommended that the admission and consultancy framework be maintained at the university level to fill the fragmentation of students' knowledge and skills. This improves student success and clearly identifies the study program's weaknesses and encourages students to address any observed fragmentations.

This pilot study offers further insight as to the strengths and weaknesses of the three specific majors who receive the most job postings, "Application Development, Networking and Security and Forensics." In addition to measuring a student's actual academic performance, the system also distributes personalized advice based on the student's digital profile. Collecting data from multiple learners from different programs allows us to understand what the program is trying to accomplish and what students need to know. The data completed throughout the learning process helps guide and get the learners to further levels of understanding. Future research will continue to create more trust in this advice through the study's continuation to include students from various other programs, like Business Solutions, Applied Media and Engineering. The proposed and implemented solution is very successful and leads to quick results, but it does not offer as much information because it does not account for the students' learning progress. Advisors constantly have access to learners' information about their personalities which affect their privacy.

Conflict of Interest

The authors declare no conflict of interest.

The purpose of the research is an investigation of different accounting software products, their functions, and specific features to make easier choice among variety of similar products and analysis of their pros and cons that can influence on companies' performance. Authors classified accounting software according to its capabilities to serve the different managerial purposes. Because accounting software contains hundreds, some of them even thousands of features, the grouping method gave a possibility to assort similar models that might suit the company's specific requirements – size, cost, customizing, formats, appointments, models, and providers. Observation and comparing of data showed that the cost of accounting programs is critical to making the right choice. As the global accounting software market has a tendency to abrupt change to e-accounting, so that makes it impossible to predict the future behavior of accounting software users. To determine the objectives of this research statistical procedures are conducted. Received results can help potential users of accounting software products to choose the appropriate one based on listed advantages and disadvantages among the best sellers – customization tools, foreign currencies handling, financial and managerial reporting system and analytical capabilities. Lack of prior research studies on the topic and lack of available data have caused significant limitation of the analysis scope. The obtained results gave possibility to identified the main elements in formation the list of features necessary for making right choice of accounting software products. Facts showed managers, who don't consider specific needs and features of accounting software, encounter with problem of discrepancy to company's requirements.
The research is based on theoretical and empirical data. To collect the necessary data for research there was used a quantitative approach. Analytical method helped to analyze and evaluate the ponderable factors which must be considered in selecting process the most appropriate accounting software for companies. The research is dedicated to problems connected with an uncertainty that appears in the accounting software market. This research adds new knowledge to the accounting field as there was disproving theoretical and practical knowledge about accounting software.

1. Introduction

Accounting software has become an integral part of all types of business. Nowadays accounting and financial management became the scientific tools in running the business where software programs help to manage finance more effectively. Companies also spread their activities on international markets to get their

shares and as a result, there is an increased demand for new and more sophisticated accounting software packages capable for handling international accounting issues [1]. There are more than 150 well-identified software products around the world and most of them are targeted on large business. But the main stress must be made especially on small business as companies this size are most unprotected and cannot finance much in accounting programs. There are a number of vendors which serve this share

of market [2], but there is a very short list of scientific researchers conducted on this theme which would help business owners make the right and cost suitable choice.

As accounting systems are connected with other management platforms such as inventory management, warehouse management, order management, customer relationship management, enterprise resource planning, sales and production planning, enterprise quality management, supply chain and distribution systems, accounting software must be more than the simple programs for record and storage accounting information. Except this point, when it comes to select the right accounting product, the choices can be contradictory how to choose necessary speed, accuracy and reliability. The relationship between accounting software and company performance might be distinguished only in case when the accounting software program is suitable for some special company features. It also should be stressed that many specialists are involved in the accounting process. Many conducted researches showed that accounting information system adoption really influenced effectively on companies' performance, profitability and operations efficiency in some countries: Malaysia, Finland, Spain, Iran and Pakistan [3]-[6]. But there is also limitation in similar researches in the EU countries.

So, an accounting software program together with specialists and methods used to gather financial information about business events create the accounting information system. Accounting software without other components of AIS is the only device for recording and storage of information. Owners often buy simple accounting software with limited functional specification and do not get all possible results when it connects with other managerial systems. Choosing among cloud accounting and traditional accounting software is the main dilemma and problematic challenge for a lot of small and medium sized businesses and the important issue of current research.

Problems related to the right choice of accounting software programs could be solved only in complex: with selection of appropriate interconnected technical components – input and output devices, information storage and processors; and after deep examination of all accounting software pros and cons.

Current research has shown that it is important for companies to make special investigation to find what type of accounting software is necessary and suitable for satisfaction of accounting and managerial needs. There was made authors' contribution to develop knowledge in the theoretical and practical acquisition of accounting sphere. There have no researches been conducted which would show statistical analyses of companies produce accounting software according to different types, comparison of price policies and only few researches were conducted to evaluate the impacts of using accounting software on the companies' performance (only in separate countries).

2. Literature Review

Professional technologies have changed the way professionals conduct accounting. For past several decades accounting software has been used only to conduct monetary transactions between companies and with individuals but with time it became more complex. Nowadays accounting software is an effective tool in managing business processes. There are thousands of firms producing different kinds of accounting software. Managers collide with problems in choosing the most suitable accounting software to fit all companies' requirements.

Many scientists tried to investigate the influence of accounting information system (AIS) on the performance of all types of business. But most of them are connected to separate countries. Research [7] showed the influence of accounting information systems (AIS) on the performance of small and medium enterprises (SMEs) in Iraq and proved that AIS is one of the most important indicators for SMEs sustainability. Another author [8] investigated the impact of accounting software on the business performance of Malaysian firms. The research was based on participants' attitudes towards the importance of AIS. Results were positive and the author affirmed that accounting software has the significant importance and a great value to businesses, organizations and the economy. Some scientists [9] indicated that accounting software plays a critical role in the creation of quality accounting information and in storage necessary information to the decision-makers. In scientific paper was [10] investigated the impact of accounting information systems on organizational performance in the context of Saudi's SMEs and there was defined that it is a tool that helps to improve control of company's managers about business performance. It also can reduce the cost of accounting spending. Accounting software has a direct influence on the quality of financial statements submitted to the different state departments. Conducted investigation [11] showed the sufficient impact of accounting IS on the quality of financial statements, time of their preparation in Jordan and showed the positive result in case of its usage. Several scientists conducted research connected with defining the impact of AIS on performance measures in a case of Spanish SMEs, [12] and they found that it has a positive influence on outcome indicators and productivity. Other scientists went ahead and proved that with rapid technological development the transactions of a business are becoming more complex than it was ever that course more demand for control. Good accounting software can put a business in efficient control.

But in the literature, there are almost no scientific approaches to the classification of features and specifications of accounting software which can meet separate requirements of companies according to their sizes. Only a few accounting software types were analyzed according to their advantages and disadvantages.

3. Results: Theoretical Background

Accounting tasks are spreading each year; it is much than a booking, so many specialists have been thought about simplification of accountants' work and making storage of information more reliable. A computerized accounting system could be defined as an effective means of keeping accounting records in the electronic version. Accounting software is a special class of computer programs that helps to manage a business. The most suitable definition of 'accounting software' was given by Barron's Accounting Dictionary: 'Accounting software are programs used to maintain books of account on computers. The software can be used to record transactions, maintain account balances, and prepare financial statements and reports'[13]. Many accounting software programs are designed to create simple

money transactions (bookkeeping) between companies and others to record entire financial comings and goings for simplifying analysis procedures and decisions making processes. It depends on their scopes and functions.

History of accounting software. Most accountants affirm that accounting software is an invaluable tool for modern business but at first it was only appointed to simple operations storage. And the essential meaning of accounting software was recording financial data and later its function was extended to turning it into useful financial information [14]Error! Reference source not found.. With time professionals titled the accounting software as a 'magic wand', since before the computerizing of accounting transactions many tasks were conducted by hands and companies kept large transaction journals. The change happened only in the 20th century when computers transformed accounting significantly. The first computer for accounting purposes was sold in 1955 [15]. Later, **Peachtree Software** introduced the first accounting software in 1978 – a package for the early personal compute [16]. The Internet era has caused a significant increase in demand for accounting software. A list of companies and competitiveness among them has been increasing each year. Such innovation gives a real picture of the company's performance or as it is modishly to talk 'fair view' and 'health status of company'.

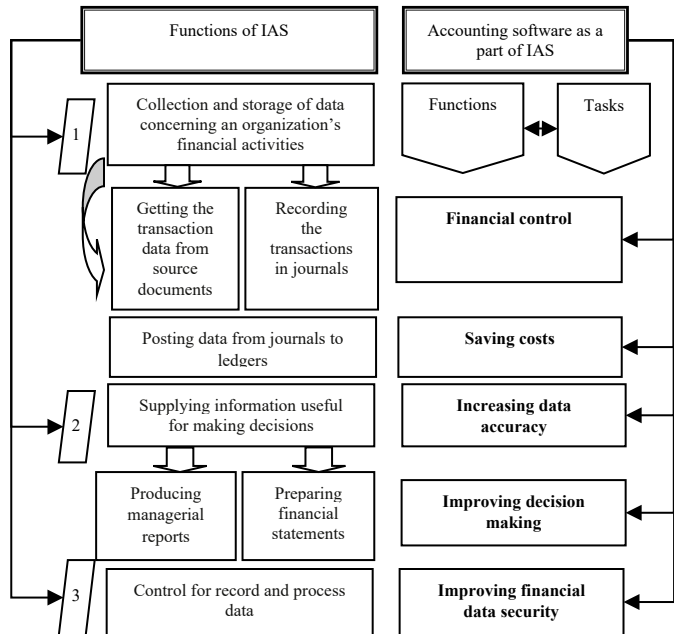
Functions, features and requirements to users. But even though the automated program **makes mach manual accounting and bookkeeping easier processes,** all software should meet the necessary requirements for legal and ethical characteristics of each country. The general functions of accounting software in IAS are analyzed in Figure 1.


Figure 1: Managerial functions and tasks of accounting software in complex with IAS [17]; [14]

Accounting software has standard functions in the accounting field reflected in Figure 2.

The speed and accuracy of operations are the main characters of accounting software. Scientists also emphasize two other features of such computer programs; one of them is the managing

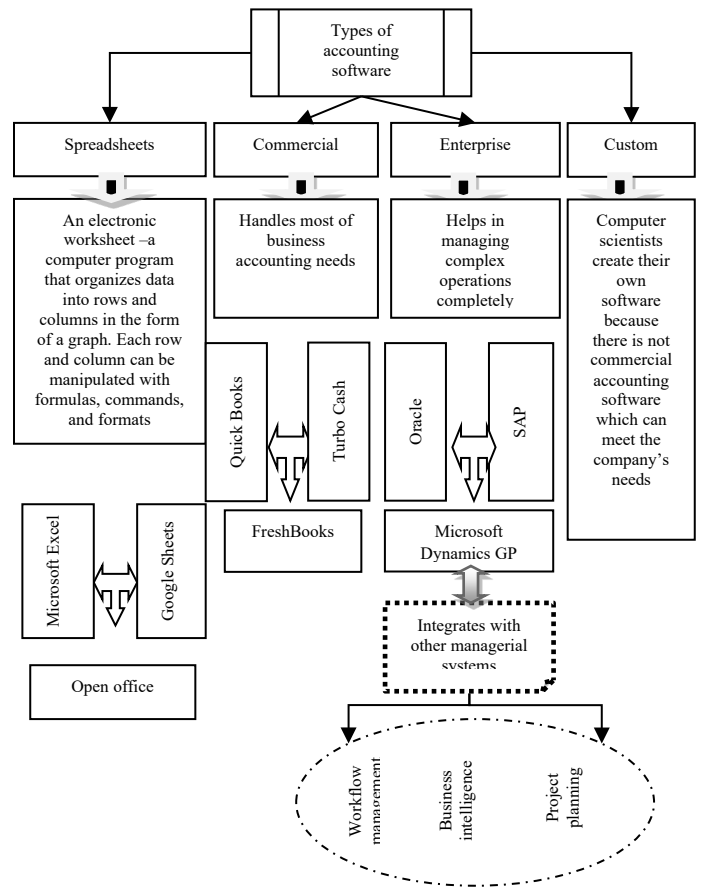
of resources more efficiently in accounting departments and other reducing of costly bookkeeping mistakes [18]. Calculation of math figures and sums in the accounting process became far easier with new computer technology.
Figure 2: Productive (basic) functions of accounting software


Figure 3: Types of accounting software [20]

But there was not proved how much time was reduced in an accounting cycle after computer programs appeared. Overall work from all departments is faster because a computer can keep and calculate thousands of indicators simultaneously. Most of managers and business owners separate another controversial dilemma – the requirement of qualified accountants on each stage of the accounting process. In past years accountants had to obtain necessary education, knowledge and experience in the accounting sphere and then they could work with accounting procedures for a long period, only changes in Government Standards on the state level required of Certification training or additional educational programs (courses). Accounting computer programs work faster

but only after clearly defined tasks. Computerized accounting procedures require accountants who can use specific software and therefore special computer skill. Only few accountants have possibilities to obtain the necessary qualification and experience themselves. Others need special education or training. But it is additional expense for many business owners. This problem is also connected with the high cost of training courses. But, the future benefit is higher than temporary expenses. Moreover, AIS can easily integrate with other management systems of enterprises.

Accounting software has a row of advantages and disadvantages. But most practitioners do not take into account them; this is evidenced by fact that almost all organizations and companies have used computer programs for accounting purposes in everyday business [19]. Scientists predict that computerization of accounting work will continue in the future as managers have value benefit from it – a stable source of information expressed in three forms – a document query, report and results of calculation (mostly expenses and income).

The effectiveness level of accounting software units depends on many factors such as types, appointments and their functions (Figure 3).

It is also necessary to stress on other classification of accounting software [22], where the author excreted three types of accounting software – database, installed and cloud. Large companies and corporations need to secure own data so owners install database software that has a higher level of security, fulfills more complex tasks, integrates with large network and complicated accounting functions (ex. Oracle). Installed accounting software is useful for businesses where internet connection is limited or absent. Meanwhile, cloud accounting is becoming more popular among startups and small-sized companies (ex. Freshbooks, Quickbooks, Xero and Sage 50 Premium Accounting in different versions). Currently, 6% of SMEs use a 'cloud-based' accounting system worldwide [23]. There is also another classification of software which fits accounting purposes [24], and it is reflected in Figure 4.

Figure 4: Types of accounting software serving the different purposes [24]

Table 1: Advantages and disadvantages of accounting software

Advantages and disadvantage of separate accounting software					
Cloud accounting software		Commercial accounting software (Peachtree)		Enterprise accounting software	
Pros	Cons	Pros	Cons	Pros	Cons
Lower operational costs (investment, maintenance is absent), this type of accounting software is cheaper then purchasing software	Stable demand in access to the internet connection	Offer a set of the most widespread features to perform accounting tasks	Comparable high cost	Easy to install on a system and deploy to end-users quickly	Comparable high cost
Higher reliability	There is the risk of data confidentiality (hacking – there is no guarantee that data is 100% safe)	Affordability for companies' owners – the average cost	There is a small but real possibility to lose information if the system is attacked by computer viruses in case it is not enough protected	Easy to customize	There is a small but real possibility to lose information if the system is attacked by computer viruses in case it is not enough protected
Higher accuracy (fewer mistakes). Much easier tools then other types propose	Technical problems	There is no demand in well-experienced skills	Increasing of productivity	Meet almost all user requirements	The necessity of high qualified personals
Pay only for subscription	Vendor lack-in/ lack-of control	High level of security	Flexibility and timeliness	Increasing productivity	On-going support
24/7 access and possibilities to recover data (restore)	In some cases limits to the data that can be freely store	Low risk	The necessity of high qualified personals	Management information	Mistakes in data entry can throw off a whole set of data
Collaboration	A lack of specialized tools	Flexibility and timeliness	Mistakes in data entry can throw off a whole set of data	Flexibility and timeliness	Can be inflexible

Table 2: Cost comparison of 12 top accounting software programs and description of their capabilities [27]**Error! Reference source not found.**; [28]; [29]; [30]; [31]; [32]; [33]

№	Accounting software	Form	Manufacturer	Cost, $ per month/y	Appointment
			For start-ups, small and medium-sized businesses		
1	QuickBooks	Online	Intuit United States	20-150	Easy for working accounting software with features that can satisfy complex accounting needs: reconciliation, taxes, reporting and inventory management. 4,5 million customers globally use QuickBooks
		Desktop		299, 95	
2	FreshBooks		Designed by Mike Mc Derment in Toronto, Ontario	6-20	FreshBooks is a cloud-based accounting designed software. It is ideal for freelancers (accountants) and small businesses that look to fast track their sales cycle and keep their processes in line with standards and regulations. Over 12 million users in 120 countries
3	Accounting by Wave	Online	Wave (Wave Apps)	Free (only several payroll services)	It is a very suitable and free accounting software for many owners of small companies. It is a powerful bookkeeping. Easily integrates with other management systems of companies
		Mobile version			
4	FreeAgent	Cloud-based	FreeAgent Central	Free	It is the accounting software for small business in the UK. There are over 80 000 small business users.
5	Manager	Online	NGSoftware	Free	For a small business, all industries, 70 languages
		Desktop			
			For mid-sized and large businesses		
6	QuickBooks Enterprise	–	Intuit United States	1419-3442	The end-to-end accounting software designed for growing business. Usage of the program helps to manage inventory, run payrolls, track sales and report. This type of software manages accounting transactions from start to finish. 135 000 companies chose QuickBooks Enterprise. There is another version QuickBooks Desktop Enterprise 20.0. Users: manufacturers, wholesalers, retailers and nonprofit (for different industries)
7	Xero	Online	Xero (New Zealand)	20-40	It is the smart online accounting for small business. Experts consider this type of accounting software one of the best for growing companies. It is also suited for mid and large businesses.
8	Finsync	Cloud-based	Finsync	From 40	It is a powerful accounting software (all-in-one) with different options. All types of business can use it.
9	NetSuite	Cloud-based	Oracle	–	It is suitable accounting software for companies that have grown out of their accounting software and are ready for full ERP[1] software
10	Zoho Books	Online	Zoho	9-29	The main features of accounting software are: end-to-end accounting, easy collaboration and integrated platform
11	FinancialForce accounting	Cloud-based	FinancialForce	From 175	This accounting software is designed for the companies with employees 100 +. It allows managing company's accounting and it works with a large amount of data. It also boasts powerful features. Experts prove that accounting software can satisfy complex enterprise requirements. The main characters of the product are multicurrency and global tax
12	*MYBOS Accounting & Billing*	Desktop	SBSCC Sri Lanka	249	Full integrated multi-user accounting software. In general, this accounting software is for medium-sized business. It is also accounting management that helps companies' owners to control sales and purchases, inventory, and journal entries. For companies, it is possible to obtain a hybrid cloud system
	MYBOS Accounting on Cloud	Online		199	

Some special industries order to design separate accounting software which belongs to Commercial off-the-shelf software. These are positive determinates of selecting accounting software. But other features might influence the appropriate choice of accounting software. Owners must choose among free, paid, or online accounting software. Most of the producers give a trial period for testing their products. In [25], the author stressed that selecting the most appropriate accounting software package has become one of the most critical decisions for most organizations in the fast-changing business world. A choice depends on the advantages and disadvantages of accounting software packages.

Vendors of accounting software try to advertise the main positive aspects of their products and it is very hard to exaggerate meaning of benefit from the accounting software. But many owners have a predisposition to make choice among types of software which give not only gain inside of companies but competitive advantages in the marketplace. In the question of

---

[1]ERS – enterprise resource planning.

choice among accounting software advantages must overweight completely disadvantages (Table 1).

The list of some of the best accounting software for three groups of business according to size is reflected in Figure 5.
Figure 5: Different accounting software for three types of business
Figure 6: Brief characteristic of cloud accounting system [26]

There are other suitable accounting software programs for different types of business. More and more consumers need special software that contains features of effective management. Nowadays, true and fast information for external and internal users is only one of the main reasons for the purchase of accounting software. Cloud accounting software: This term appeared in far 2011. It gives the possibility to perform all accounting functions through internet-based devices. The main features of cloud accounting are shown in Figure 6.

Cloud accounting is a more flexible system with one strong requirement – connection to the internet. It is appointed to work with traditional accounting functions, updates financial information automatically and provides complex financial reports.

4. Practical aspects of accounting software choice

Cost of accounting software: The world market is full of different accounting programs with a variety of capabilities. Prices for accounting programs vary from several dollars to thousand. It depends on many factors and the number of users supported it. The cost of accounting software includes installation, implementation, training programs for users, customizing the software, and operational costs. Nowadays, many producers offer accounting programs on a cloud base and the number of venders who sell licenses has been decreasing each year. It is better for producers to get charge a monthly subscription fee from users. For small businesses and start-ups, the most appropriate accounting software is QuichBooks, Wave, Manager and FreshBooks, but some of their manufactures offer packages for growing business and thriving firms with competitive items. For large companies, there are several worldwide famous accounting software producers such as Intuit (USA), Xero (New Zealand) and Oracle (USA), (Table. 2).

The price is the second indicator which influences on the right choice. For small companies the price is affordable, it varies from $5 to $500 (Figure 7). But companies with multinational transactions and a large amount of staff need accounting software with additional opportunities and integration capabilities. The scientist [34] advised to choose optional enterprise-class accounting software that can meet the company's specific needs but the price is higher accordingly.
Figure 7: Compression of the prices for different accounting software products [35]

Many manufactures of accounting software offer additional payment options for some special requirements. Byers also desire to combine accounting software with human resources management (HRM) and POS[2] (software) systems; integration with the last one is limited in many accounting products. The right

---

[2]POS – point of sale.

accounting system must be adopted not only for information gathering but for synchronizing transactions, serving with oversight into the company's position, and proposing accounting solutions. The other point which must be accounted by users is a pricing policy for accounting software. Venders offer two popular pricing models: subscription-based on a cloud platform or 'pay-as-you-go' model[3] and perpetual licensing. Subscription price must be made monthly/year and it guarantees necessary support and maintenance. Some venders give buyers a choice to use all components, special modular components or features they need and pay for them. Many designers of accounting software include additional services and support in the base price of core products but others offer additional features, or modules for an extra payment. Before making the eventual choice for any type of accounting software it is very important to learn whether venders have professionals who are specializing in installation, supporting, and integrated with other company's systems processes or they involve the third party. Third-party consultants sometimes have divergences. It is worldwide accepted to provide the basic training services for free but there are some exceptions.
Figure 8: Global accounting software market in 2017-2019, Bn, USD dollars [36]-[38]
Figure 9: Perception of cloud technologies by accountants, 2017 [39]

The global market of accounting software: The market size of accounting software has been increasing each year and scientists predict the continuation of this tendency for the next few years (Figure 8)**.** Most of the rising is observing in the cloud-based sector. Now, cloud accounting replaced the old desktop versions. Many business owners invest in the cloud accounting system that gives the future long-term benefit in a case when they plan to expand their activity. It is always useful to exploit such type of software when a lot of employees work on the same data. Large companies which are represented by foreign branches perceive

cloud-based accounting software more flexible. Most of the users are worried by one main question – is it enough safe? It's protected by the individual password. Accounting software providers also create backup servers in different locations for reinsurance if one server would go down, users can access to necessary data. Excess to cloud accounting software is more protected than the traditional one. The team of 'Finances Online' investigated that more than 50 % of owners and accountants are satisfied by the cloud accounting platform (Figure 9).

Other useful statistical data shows that companies have increased their profits after adopted online accounting (Figure 10).
Figure 10: Cloud accounting statistics in 2018 [40]

Any type of accounting software is a great solution for each business as its advantage's overweight disadvantages. There is a huge variety of accounting software, producers, and venders. Many specialists try to model the best one or make the most suitable for all businesses. But the best accounting product for one company might not be the best for another even with similar features. The main character which must fit all customers is trust in it.

5. Accounting Software Influence on Companies Performance

Accounting software provides companies' owners and managers with quick and easy reports for decision making [41]. Accounting system can effect on all spheres of activity [42] and has positive influence on companies' performance. Appropriate accounting software gives some benefits, the most important among them are affordability, time savings, higher accuracy and one place for all financial tasks; they are all available to each form of business.

6. Generalization of Results

Accounting software in modern business plays very important role and it is a great progress made in the accounting sphere. The main goal of accounting software is tracking financial transactions and generating various financial reports. It is a p a r t of w h o l e accounting systems which might include different types of software from simple transaction-entry programs to advanced accounting systems integrated with other management

---

[3] Pay-as-you-go system is one in which you pay for a service before you use it and you cannot use more than you have paid for. Cambridge Dictionary.

programs of the company. Accounting software makes accountants work easier and gives information about the 'true health' of business, companies' owners agree to pay a substantial sum for complicated and advanced accounting technologies. Companies with foreign branches have always troublesome issues with coordination among them (mainly a time of reports' delivery that could cause a delay in decision making process) but after cloud technologies appeared, most problems have solved. Cloud accounting or e-accounting is rather a new type of service than IT. The main advantage of cloud accounting software is no time and place limitation as well as putting the whole accounting system to the cloud-based platform.

Analyzed scientific researches proved the positive interrelationship between accounting software and business performance. But in this relationship, many factors have an indirect influence. There are several benefits for companies' owners who use such software: the establishment of financial control, saving costs, increasing data accuracy, and improving data security. With a good accounting system, accountants and business owners can make financial forecasting and improve the decision-making process.

Nowadays, the global accounting market is represented by a lot of producers who offer from traditional old desktop accounting software to the modern cloud-based platforms on license subscription conditions. The tendency of the global market has a positive and stable increasing character. Research showed that more than 60% of accounting specialists are satisfied with their current accounting programs and most of them are ready to invest in accounting technologies for getting future benefits. Most specialists affirm that cloud-based accounting software together with other intelligent online programs is the future of accounting.

7. Conclusion

Research showed a significant increasing of accounting software popularity and that fact has caused sufficient diversification in computer accounting programs. And it's becoming difficult to decide which one to choose. There was grouping of accounting software programs of the most famous world producers using affordable and easy-to-use approaches, listed their advantages and disadvantages, analyzed price policy parameters. There were indicated items to keep in mind when selecting accounting software for companies: special features (accounts receivable and accounts payable tools, track inventory, time tracking, project management, payroll or advanced reporting capabilities), usability (desktop software, cloud software or mobile version and number of users) and costs (inexpensive, average price or expensive with extra features). Also research reports about some risks which connect with storage accounting date and information. As recommendation there are some offers for each type of accounting software program – to give detail explanation on its security level, use multi-business support, find providers with additional services and possible training programs.

ARTICLE INFO

ABSTRACT

Despite the significant progress made in data mining technologies in recent years, breast cancer risk prediction and diagnosis at an early stage using DNA microarray technology still a real challenging task. This challenge comes especially from the high-dimensionality in gene expression data, i.e., an enormous number of genes versus a few tens of subjects (samples). To overcome this problem of data imbalance, a gene selection phase becomes a crucial step for gene expression data analysis. This study proposes a new Decision Tree model-based attributes (genes) selection strategy, which incorporates two stages: fisher-score-based filter technique and the gene selection ability of the C5.0 algorithm. Our proposed strategy is assessed using an ensemble of machine learning algorithms to classify each subject (patients). Comparing our approach with recent previous works, the experiment results demonstrate that our new gene selection strategy achieved the highest prediction performance of breast cancer by involving only five genes as predictors among 24481 genes.

1 Introduction

Ranked second among 36 kinds of cancers, breast cancer has the greatest number of incidences and moralities among females worldwide. As per a recent publication of the WHO (World Health Organization), in 2018, 627,000 females were estimated to lose their lives from this disease, representing approximately 15% of all cancer deaths among females worldwide. According to the same source, early detection is becoming a critical tool to reduce breast cancer morbidity and mortality [1]. At present, breast mammogram and ultrasound images are the most traditionally used breast cancer detection techniques. However, besides their high computational cost, these techniques may lead to an overdiagnosis (false positives), which can cause serious clinical consequences, including death from the side effects of a potential Overtreatment [2]. An alternative to this technique is to take the advantages of both data mining and gene expression technology to predict breast cancer. However, this alternative is not without challenges since the significant number of non-informative features in gene expression data may increase the search space size, which makes gene analysis an impossible task [3]. In the context of this new alternative, a gene selection phase is mandatory to deal with the problem of high-dimensionality in gene

expression data. The gene selection process aims at getting rid of any irrelevant and redundant genes in gene expression data, which can simplify the learning model by using a strict minimum number of predictors, and thus improving breast cancer risk prediction performance [4]. In terms of contribution to this research field, this study proposes a new Decision Tree model-based gene selection approach, which incorporates two stages: fisher-score-based ranked technique and the gene selection capability of the C5.0 algorithm. The ranked method consists in reducing the computational cost by removing non-informative genes from the original gene expression data, while the C5.0 algorithm consists in identifying the optimal subset of genes, which are quite informative to classify patients. Finally, the genes contained in the obtained gene subset are used as predictors to construct an ensemble of predictive models using 6 learning algorithms: Random Forests (RF), Support Vector Machine (SVM), Logistic Regression (LR), K-Nearest Neighbors (KNN), Artificial Neural Network (ANN) , and C5.0 Decision Tree algorithm. In the next section, we briefly outline existing approaches. Methodology and Materials are described in section 3. Section 4 is devoted to discussing all experiment results. The final section concludes the proposed work.

2 Existing literature

From different approaches, a variety of studies have been proposed on breast cancer risk prediction.

Through the implementation of Random Forest(RF) and Extreme Gradient Boosting (XGBoost) , S. Kabiraj et al. predicted breast cancer with an accuracy of 74.73% and 73.63%, respectively[5].

Using the breast cancer Coimbra dataset provided by the University of California Irvine (UCI), Naveen et al., proposed 6 machine learning-based prediction models. The learning process was initialized by a Z-Normalization and cross-validation technique. Experimental results show that the Decision tree and KNN algorithms achieved the highest prediction performance [6]. Agarap proposed a deep learning-based approach on normalized features implementing rectified linear units (ReLU) as the activation function, while the Softmax function as the classifier function. The average cross-validation performance using 10-fold does not exceed 87.96% in terms of accuracy on WBCD (Wisconsin Breast Cancer Data) dataset[7]. S. S. Prakash and K. Visakha also proposed a deep neural network-based approach to predict breast cancer. The authors optimized the neural network model using the early stopping mechanism and dropout layers to avoid overfitting problems. The selected predictors were obtained from the WBCD provided by UCI [8].

Using gene expression signature, Turgut et al., in their work, first proposed 8 machine learning-based predictive models without using any gene selection algorithms. Then they combined the proposed machine learning algorithms with two feature selection methods: RLR (Randomized Logistic Regression) and RFE (Recursive Feature Elimination). The most striking results concern the SVM algorithm since it achieved the best accuracy of 88.8% after using the selection process [9]. In the same context of gene expression data, Al-Quraishi et al. presented a breast cancer prediction model based on an ensemble classifier using FCBF (Correlation-based filter) algorithm. Compared to the existing works, their framework achieved an accuracy of 96.11% by involving 112 genes [10]. Aldryan et al. developed a prediction framework using MBP (Modified Backpropagation) with Conjugate Gradient Polak-Ribiere and the standard ACO (Ant Colony Optimization). The MBP was used as a classifier, while the ACO as a gene selection technique. For breast cancer classification using MBP without gene selection, they get the average F-Measure score of 0.2328. After combined with the feature selection using the ACO algorithm, it obtains an average of 0.6412 in terms of performance by involving 2448 genes [11]. Jain et al. presented a two phases-based hybrid feature selection strategy. Their approach combines the Correlation-based Feature Selection (CFS) with the improved-Binary Particle Swarm Optimization (iBPSO) algorithm. The proposed strategy was assessed using Naïve–Bayes (NB) algorithm, and the experiments results showed an accuracy of 92.75% for breast cancer classification using an average of 32 genes [12]. To overcome class imbalance issue and time consumption of their old gene selection approach, Li et al. introduced a more efficient implementation of linear support vector machines based recursive feature elimination system (SVM-RFE). Their proposed approach was assessed on 6 public gene expression datasets, and results demonstrated a slight enhancement in terms of

time consumption and prediction performance [13].

3 Research methodology

3.1 Description

Using gene expression data, the present paper proposes a new framework that improves breast cancer prediction performance. Figure 1 summarizes the main steps of the proposed framework, where fisher score combined with C5.0 are used to select a small number of informative features, and ANN, SVM, KNN, LR, RF , and C5.0 algorithms are applied to the new gene subset to assess the effectiveness of the proposed gene selection approach. The overall pseudo-code of the whole prediction system is illustrated in Algorithm 1 . -discussed in the following sections.

Algorithm 1: Our proposed prediction system

Function *Classification(Training_set, Test_set)*:

7    $Sub_{train}, Sub_{test} \leftarrow C5.0(F_{train}, F_{test})$;

    /* Classification using the optimal gene subset   */

8    $Models \leftarrow Classification(Sub_{train}, Sub_{test})$;

9 **Return** all generated prediction models "*Models*"

3.2 Genes selection strategy

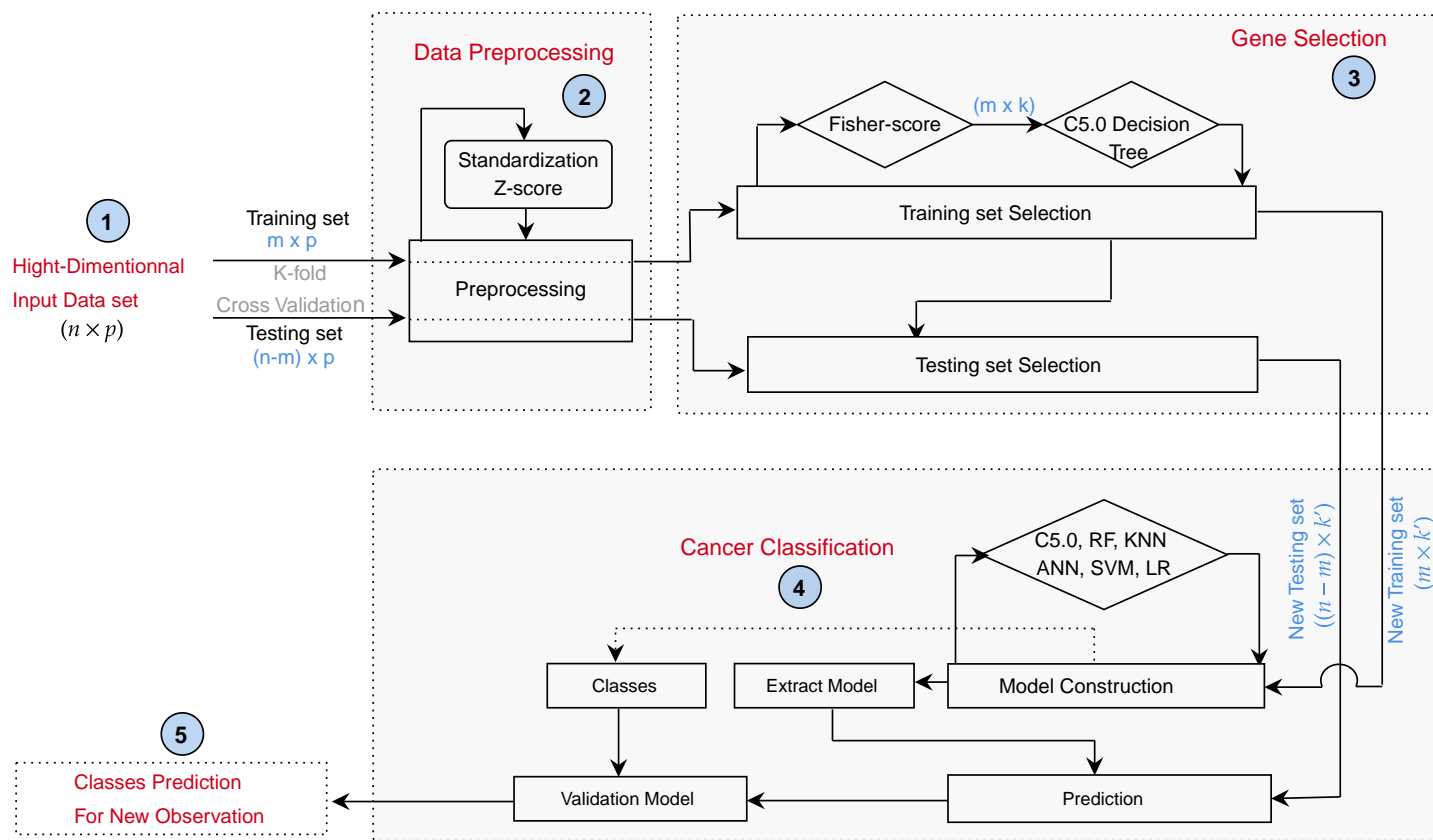
Feature selection is an important stage in intelligent systems modeling, especially in prediction systems [14, 15]. The feature selection or gene selection in the context of microarray data analysis


Figure 1: The proposed Framework

is a useful technique that can reduce dimensionality by removing any redundant, irrelevant, or noisy genes, which can lead to improve the classification performance and reduce the cost of computation [4], [16]–[18]. As shown in Figure 2, gene selection process can be reformulated as follows: given an original set of p genes, $X = (X_1, X_2, .., X_p)$, find a subset of genes $X_{sub} = (X_{i1}, X_{i2}, .., X_{ik<<p})$ such that the most informative genes are selected.
Figure 2: Feature Selection process

Here we present a novel gene selection strategy composed of two steps -Fisher score combined with the C5.0 algorithm- presented into the sequel.

3.2.1 Filter method using Fisher score

Because it acts independently of any classification process, Fisher score-based filter technique is considered as a fast supervised fea-

ture selection technique, the reason why it is frequently used when it comes to working with a large number of features (genes) [19]. It can be reformulated as follows: given an input data matrix G of genes, then the Fisher score of each gene (denoted by F) j can be represented by (1) :

$$F\left(G^j\right) = \frac{\sum_{k=1}^c \eta_k \left(\mu_k^j - \mu^j\right)^2}{\sum_{k=1}^c \eta_k \left(\sigma_k^j\right)^2} \qquad (1)$$

With μ_k^j, σ_k^j are the mean and standard deviation of k-th class, corresponding to the j-th feature. μ^j denotes the mean of the whole j-th gene in the G matrix.

As the F of each gene is calculated independently from original genes, only 10% of the highest-ranked genes were selected to achieve the second round of our proposed gene selection strategy.

3.2.2 C5.0 Decision Tree

C5.0 is a new decision tree algorithm developed from C4.5, which has proved its high detection accuracy in many research fields. Compared to C4.5, C5.0 can handle different types of data, deal with missing values, and support boosting to improve classification accuracy [20]. Besides its ability in classification tasks, C5.0 was was used as an efficient feature selection technique in many research Fields [21]–[24]. In the present work, we take both advantages of C5.0, its ability as a powerful feature selection method combined

with the Fisher score-based filter technique, and as a classifier to achieve the classification task in our whole prediction framework.

In the context of gene selection using C5.0 Decision Tree, all genes were initially compared by using the following process: first of all, we set the pruning degree (Pruning is an inherent technique that consists in reducing the size of decision trees by getting rid of branches of the tree that provide little information which can reduce the complexity of the classifier, thus improving classification performance) to 75% as a default value to prevent overfitting. Then, the information gain ratio of each gene is calculated using the formula (2).

$$GainRatio(G) = \frac{Info(S) - Info(S/G)}{Split(G)} \quad (2)$$

Where :

-$Info(S)$ is the Information Entropy which calculated as in (3) :

$$Info(S) = -\sum_{i=1}^{m} p_i log_2(p_i) \quad (3)$$

With m the number of classes in the training set (in our case m=2), S a given set of n samples ($|S| = n$) , and $p_i = \frac{n_i}{|S|}$ the probability that an object in S belongs to the class C_i (with n_i the number of samples that belong to the class C_i)

-$Info(S/G)$ denotes the Conditional Information Entropy which is defined as in (4):

$$Info(S/G) = -\sum_{j=1}^{v} \frac{|S_j|}{|S|} \sum_{i=1}^{m} \frac{n_{ij}}{|S_j|} log_2(\frac{n_{ij}}{|S_j|}) \quad (4)$$

Assuming that G divide the set S into v subsets ($S_1, S_2, ..., S_v$), then n_{ij} denotes the number of classes C_i samples in the subset S_j with $|S_j| = \sum_{i=1}^{m} n_{ij}$ and $|S| = n$.

-$Split(G)$ is defined as in (5) :

$$Split(G) = -\sum_{j=1}^{v} \frac{|S_j|}{|S|} log_2(\frac{|S_j|}{|S|}) \quad (5)$$

The most informative gene (best predictor) with the maximum information gain is selected to be the root node of the whole tree. Then, the root node in each level of the tree is selected from remained genes using the same principle. The gene selection process continues until a maximum depth is meet. As the tree was pruned, the optimal gene subset is determined [20, 25].

4 Classification Algorithms

4.1 Artificial Neural Network

The ANN is a form of distributed computation inspired by networks of human biological neurons. Typically, an ANN consists of a set of interconnected artificial neurons that are organized in several layers called, input, output, and one or several hidden layers. In a typical 3-layer network as shown in Figure fig :ANN, each neuron in a layer is connected to the all next layer neurons with no interconnectivity among the neurons of the same layer and no connection back. All the connections are defined by weight values denoted by w. In the input layer, all nodes get information from the outside and pass it to

the nodes of the next layer. Each node computes the weighting sum of all the N neurons of the previous layer and passes it through an activation function (usually logistic) [26]
Figure 3: Artificial Neural Network diagram

4.2 Random Forest

As a powerful supervised pattern classification algorithm, RF is used in many intelligent systems. Random Forest is viewed as a combination of several independent decision tree classifiers. Each decision tree is constructed using a randomly selected subset of features. In RF, a majority voting process is used to affect samples to one of the classes by taking the most popular class among all predicted classes by all the tree predictors in the RF [27]. Many processes are used to construct a decision tree classifier; the most commonly used are the Information Gain (IG) and the Gini Index (GI) [28]. In the present paper, we used the GI for the random feature selection measure.

4.3 K-Nearest Neighbors

K-Nearest Neighbors is an easy and simple machine learning algorithm that is widely used in many domains of pattern classification. As the KNN is a non-parametric classifier, new samples are affected to the class represented by a majority of its K-nearest neighbors using a feature similarity rule; since there is no mathematical model to predict labels for new samples. The similarity process is defined using different distance metrics such as Hamming Distance, Euclidean Distance, and Minkowski distance [29] . In the present work, the similarity is measured between K-nearest neighbors using the Euclidean distance metric as in(6), and the number of neighbors K is set to k=4.

$$d(S_1, S_2) = \sqrt{\sum_{i=1}^{p} (s_{1i} - s_{2i})^2} \quad (6)$$

Where S_1 and S_2 are two given samples and p is the number of features .

4.4 Logistic Regression

As an extension of the linear regression algorithm for classification problems, Logistic Regression aims to find the best fitting model, which squeezes the output of a linear equation between 0 and 1 using the logistic function. In linear regression, the relationship between output and features is modeled by using a linear equation. However, in a classification problem, it is strongly recommended to have probabilities between 0 and 1, which can force the outcome to be only between 0 and 1 using (7).

$$L(x) = \frac{1}{1 + e^{-(a_0 + a_1 x_1 + a_2 x_2 + ... + a_n x_n)}} \qquad (7)$$

4.5 Support Vector Machine

The SVM is a binary classifier algorithm that has been successfully applied in many pattern recognition areas. In linear classification, SVM constructs a classification hyper-plane that separates the data into two sets by maximizing the margins and minimizing the classification error. The hyper-plane is constructed in the middle of the maximum margin. Thus, samples above the hyper-plane are classified positives. Otherwise, they are classified as negatives (Figure 4). SVM is a linear classifier algorithm, meaning that it uses a linear separation to classifier samples. However, in real intelligent systems, datasets are often linearly non-separable. To overcome this problem of non-linearity, a nonlinear transformation of the input vectors into a new feature space is performed, and then a linear separation is performed using the new feature space. In this work, the Gaussian kernel using (8), was used to overcome the non-linearity issue.

$$k(x_i, x_j) = \exp(-\frac{\| x_i - x_j \|^2}{2\sigma^2}) \qquad (8)$$

Where: $\| x_i - x_j \|^2$ denotes the Euclidean distance and σ a positive parameter which denotes the smoothness of the kernel.
Figure 4: SVM diagram

4.6 Evaluation Metrics

The data mining process has several ways to check the performance of any classification model. The quality of any classification model is built from the confusion matrix (see Figure fig :CM), which summarizes the comparison between predicted and observed classes for all samples. Different types of evaluation measure are calculated from the confusion matrix, and the most commonly used in practice are the classification accuracy as in (9), and F1-score as in (10).

$$Accuracy = \frac{TP + TN}{TP + TN + FP + FN} \times 100 \qquad (9)$$

$$F1 - score = \frac{2TP}{2TP + FP + FN} \qquad (10)$$

		Predicted classes	
		Positives	**Negatives**
Observed classes	**Positives**	**TP** (True Positive)	**TN** (True Negative)
	Negatives	**FP** (False Positive)	**FN** (False Negative)

Figure 5: Confusion Matrix for binary classification

Another common evaluation metric used in Machine Learning is the receiver operating characteristic (ROC) curve, which is created by plotting the True Positive Rate (TPR=TP/(TP+FN)) against the False Positive Rate (FPR=FP/(FP+TN)). The Area Under the ROC Curve (AUC) provides a good idea about model performance. The model that gives 100% of corrects predictions has an AUC of 1, while the model that gives 100% of wrong predictions has an AUC of 0.

In the present paper, the average of each evaluation metric (described above) in training and test sets is calculated to evaluate the quality of each prediction model using (11).

$$metric = \frac{metric_{train} + metric_{test}}{2} \qquad (11)$$

5 Experimental results and discussion

Before presenting our experimental results in the next section, we describe the gene expression data set used in this paper, K-Fold cross-validation, data preprocessing, and the system configuration.

5.1 Breast cancer dataset details

The proposed prediction framework was conducted on the public available microarray breast cancer dataset [30], which includes 24,481 features with 97 samples, 51 (52.58%) of which are healthy and 46 (47.42%) are diagnosed with breast cancer. Details of our used microarray dataset are given in Table 1.

Table 1: Microarray datasets details

Dataset	Genes	Samples	Classes	Ref
Breast cancer	24481	97	Relapse/Non-relapse	[30]

5.2 Stratified 10-fold Cross-validation

In order to avoid overestimating prediction, a stratified 10-fold cross-validation technique was employed. By using this technique, samples are split into five equal folds (subset) of samples. One of the 10- fold is used for the testing step, and the remaining four folds are put together to form the training data. This process is repeated ten times. The stratification process was used to ensure that all folds are made by preserving the same percentage of samples for each class.

5.3 Preprocessing

Before supplying the datasets to our analysis system (Figure 1), it was necessary to perform a data preprocessing as it is an important step to overcome data imbalance issue. In the present paper, Gene expression levels for each gene were standardized using (12). The result is that expression levels for each feature have a mean 0 and variance 1.

$$X = \frac{X - \overline{X}}{\sigma} \tag{12}$$

Where: $\overline{X}$ the overall mean of the feature X and σ its standard deviation.

5.4 System configuration

By using parallel processing, our proposed framework was implemented in Python 3.7 language under Ubuntu 18.04.3 with v5.0 based Linux kernel 64bits operating system. All of the experiments were carried out using an Intel Xeon E5-2637 v2 3.5 GHz PC with 64 GB of RAM.
Figure 6: Classification performance with and without our proposed gene selection approach

5.5 Results and discussion

In order to see how good our new approach behaves in situations where there is a large number of genes versus few observations, this section aims at analyzing the results of our proposed framework in terms of classification accuracy, degree of dimensionality reduction, and the running time.

To prove the power of our gene selection approach in terms of prediction performance, we first applied our six proposed machine

learning algorithms on the whole breast cancer gene expression data set (without using any feature selection process). Table 2 presents the experimental results and shows the classification performance in terms of accuracy, F1-score, and AUC of each constructed classifier. As we can notice, the most striking performance was achieved by the ANN classifier, which does not exceed 86.99%, while the KNN algorithm shows the lowest performance rate of 64.62%. Almost the classification performances of all constructed classifiers do not exceed the eighties in terms of all evaluation metrics.

Table 2: Performance measurement without gene selection

Classification Model	Time (s)	Accuracy (%)	F1-score	AUC
ANN	42	86.99	0.84	0.85
KNN	1	64.62	0.65	0.65
LR	13	83.91	0.83	0.84
RF	1	83.71	0.86	0.84
SVM	1	80.05	0.79	0.8
C5.0	25	79.01	0.79	0.8
Figure 7: ROC curve of our shrinkage models using the proposed gene selection approach

Table 3 shows the experimental results of our gene selection method when used along with our proposed machine learning algorithms. The results are presented in terms of classification performance matched with the number of selected genes. As we can notice, using our approach, the dimensionality of our research space (the number of genes) was reduced in two phases. First, the number of genes passed from p=24481 (the original number of the gene as shown in Table 1) to k=2448 using the Fisher ratio-based filter method, the new k represents 10% of the original number of genes that have the highest score. In the second phase, the number of previously selected genes k was reduced for a second time using the inner feature selection ability of C5.0 Decision Tree algorithm; thus, the k passed from 2448 genes to five genes (k'=5). Thereafter, the new subspace of k'=5 predictors (genes) was used to construct the ensemble of classifiers (SVM, KNN, LR, ANN, C5.0, and RF). As

Table 3: Performance measurement using our framework

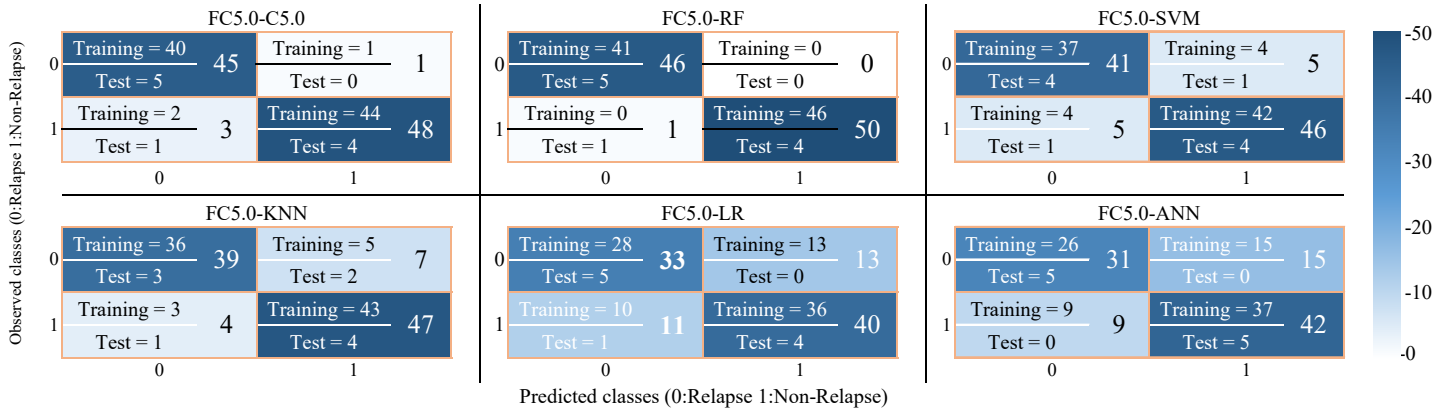
Input Data	Original Genes Number	Gene Selection approach		Selected Genes	Classification Model	Time (s)	Accuracy (%)	F1-score	AUC
		Fisher score (F)	C5.0						
Breast Cancer gene expression data	p=24481	k=2448	k'=5	NM_013438, AL137615, NM_003477, Contig26768_RC, Contig55662_RC	**FC5.0-RF**	**31**	**95.00**	**0.94**	**0.95**
					FC5.0-C5.0	31	93.28	0.94	0.97
					FC5.0-ANN	31	86.21	0.89	0.86
					FC5.0-SVM	31	85.4	0.86	0.85
					FC5.0-LR	31	81.78	0.82	0.81
					FC5.0-KNN	31	80.4	0.82	0.8


Figure 8: Confusion Matrix of our shrinkage models

we can see from experiment results (Table 3 and Figure 6), almost all constructed shrinkage models produced a classification performance that could exceed the eighties; and the most striking result concerns the FC5.0-RF and FC5.0-C5.0 models since they achieved the best prediction performance that could reach respectively to 95% and 93.28% in terms of all evaluation metrics, which is much better than what was reported in the first experiment (without applying gene selection Table 2). In contrast, the prediction performance has slightly deteriorated when it comes to LR and ANN classifiers when using our gene selection approach.

In Figure 7, the ROC curves are plotted to estimate the AUC of each constructed classifier model when using our gene selection method, which can help to compare their prediction performances. As we can see from this figure, ROC curves of FC5.0-RF and FC5.0-C5.0 models are the closest to the perfect performance curve, which can explain the quality of these models reported in Table 3. In the same context of the second experiment using our gene selection approach, Figure 8 gives a better overview of the relations between our generated prediction models outputs and the true labels. As we can notice, for our favorite model (FC5.0-RF) all samples in the training set are correctly classified, while in the test set, only one sample out of 10 is miss-classified, which confirms the achieved average classification accuracy of 95%.

According to all results reported above, it can be summed up that the power of our whole system (illustrated in Figure1)) comes from its ability to predict breast cancer risk with high performance by involving a bar minimum of genes predictors (only five genes).

Table 4 compares the performance (in terms of accuracy and the number of selected genes) of our gene selection-based breast cancer classification technique with existing gene selection methods. The comparison is made to demonstrate the capability of our

approach over other techniques in predicting breast cancer. As it can be noticed, the proposed approach led to a higher prediction performance by involving only five genes, which is much better than was reported for the other techniques.

Table 4: Comparison of the proposed FC5.0 approach with other feature selection-based approaches

Paper	Approach	# Selected genes	Best accuracy (%)
[9]	RFE+SVM	50	88,82
	RLR+SVM		87,87
[10]	FCBF+DNN+SVM	112	96.11
[11]	ACO+MBP	2448 (10%)	64.12
[12]	CFS+iBPSO+NB	32	94.00
[13]	SVM-VSSRFE	-	90.03
Ours	FC5.0-RF	5	95.00

6 Conclusion

By using gene expression data to improve breast cancer risk prediction, this study proposed a new Decision Tree model-based gene selection strategy, which incorporates two stages: fisher score-based filter method and the feature selection capability of the C5.0 algorithm. The prefiltering phase using the Fisher score aims at reducing the dimensionality of breast cancer gene expression data by getting rid of any irrelevant or redundant genes in the predictive genes. Then in the second stage, we make use of the obtained low-dimensional research space to find the best gene subset that maximizes the prediction performance by using the feature selection capability of the C5.0 decision tree algorithm. The optimal genes subset was used as the input for cancer classification using six machine learning algorithms. To prove the impact of our approach on breast cancer

risk prediction, we compared the classification performance of our generates models between them and with the performance of classifiers without using any gene selection process. Experimental results show that our gene selection approach led to a higher prediction performance that reached 95% using FC5.0-RF model by taking fewer genes, which is better than what was reported in Table 2 and Table 4 .

This work can be enhanced in two different aspects: the classification models and the search engine. For the classification model, we intend to propose the use of other supervised machine learning algorithms in order to achieve more accurate results in terms of prediction. For the search engine, other gene selection approaches can be proposed or combined with our proposed one. We expect these improvements to predict breast cancer risk with high accuracy, which may guide further breast cancer researches.

Cyclic Evaluation of Capacity of Recovered Traction Battery after Short-Circuit Damage

Matus Danko[*], Marek Simcak

University of Zilina, Faculty of electrical engineering and information technologies, Department of mechatronics and autotronics, Zilina, 010 26, Slovakia

A R T I C L E I N F O	A B S T R A C T
	Presented paper discusses possibilities related to the recovery of the damaged lithium batteries after the short-circuit. The recovery procedure was applied on the selected traction LiFePO4 40Ah cell which was initially short-circuited. After the short-circuit, the damaged cell has visible damage of the electro-mechanical properties. For the recovery of damaged traction cell as much as possible, the experimental recovery procedure has been proposed. For the realization of this recovery procedure, the automated workplace for the cell discharging and charging with the proposed algorithm was created. For verification of the proposed recovery algorithm, the traction cell was tested with a delivered ampere-hour test at the various discharging currents. Results of the delivered ampere-hour test of the recovered cell were compared to results of delivered ampere-hour tests of the new cell. From the final evaluation is seen that the proposed recovery algorithm can recover up to 90% of capacity within a wide range of discharge and charge current.

1. Introduction

Batteries (in general form) are increasingly applied in fully electric vehicles or hybrid electric vehicles, energy storage systems, and other consumer product. The increasing of usage lithium batteries requires their bigger production and minimization of their ecological impact like footprints of carbon dioxide. Moreover, the raw materials access must be ensured, and the cost of materials must be kept low, then production rates will dramatically rise in the next several years. To secure enough battery materials, the spent lithium for batteries, especially those for hybrid electric vehicles or electric vehicles, must be recycled or recovered and used in other energy storage systems [1-5].

In present, complete recycling of lithium batteries is very costly so recycling is unprofitable. Production of batteries from recycled materials is unattractive for manufacturers because is up to 5 times more expensive than the new battery production from newly extracted materials. One of the ways to increase number of reused batteries is to regenerate them. The batteries used in cars are unusable in a vehicle when its usable capacity falls below 60%, but can still be used, for example, like energy storage in the photovoltaic system. In this simpler application, battery can safely

serve until the real end of life comes. It is assumed that up to 60% of li-ion batteries from vehicles can be used in this way [6-10].

Currently, the R&D institutions are not only involved into the research on recovery of raw materials, but also on reuse or second life of batteries which cannot fulfil the requirements of their original application area but are highly usable in less demanding application. Best example of battery second life is application of batteries from hybrid electric vehicles (HEV) or fully electric vehicles (EV) in small or medium battery storage systems (BSS) for example photovoltaic systems [11–13].

On the other side, there is also an issue that is common if operation of battery cells is considered. We can talk about improper storage or operation of cells which can resulting into the damage caused for example by deep discharge, over current discharging or short-circuit. Therefore, recovery or regeneration of such cells or harmed batteries is an important topic, due to the environment and the price of new batteries [14–18]. Nowadays, the recovery processes mainly used for NiMH and batteries lead-acid which was used in hybrid electric vehicles or large electricity storage systems. In present, lithium-based cells are largely used for e-mobility, so the topic of lithium battery recovery is more and more important, because of high lithium price [19–22].

Therefore, within the presented paper, the recovery procedure of damaged battery caused by application of long-term short-

[*]Corresponding Author: Matus Danko, University of Zilina, Faculty of electrical engineering and information technologies, Department of mechatronics and autotronics, Zilina, 010 26, Slovakia, +421 41 513 1610, matus.danko@feit.uniza.sk

circuit is being presented. The focus is given on the traction battery cell Sinopoly LiFePO4 - 40Ah/128Wh because LiFePO4 battery type are often used as traction batteries for electric or hybrid electric vehicles. Initially is being described the procedure of the application of long-term short-circuit, followed by the detection and evaluation of the damages caused by this improper operation. Consequently, the proposal procedure of regeneration is being described, while it is based on the pulsed charging with defined amplitude of charging current and durations of pluses, followed by adequate regeneration breaks. As an evaluation of suitability of proposed regeneration approach, the experimental test of the recovered battery capacity was realized, while received results have been compared to the similar tests of undamaged new cell.

2. Short-circuit damage of traction battery

During the operation of traction batteries, several hazardous conditions which are related to the behavior of the batteries can occur. These conditions can cause damage to the battery itself. Results of operation in inappropriate conditions primarily reflect into the open-circuit voltage (OCV) drop and significant loss of the capacity. If battery operation in hazardous condition is lasting, it can cause damage to the internal structure which can lead to damage of the package of the battery. In this paper is focus on operation at long-term short-circuit. Because unwanted hazardous operational conditions result in damage of battery structure, it is important to find the most suitable recovery procedure which can be applied for battery regeneration as near as possible to its nominal state.

In this paper, the attention is focused on the investigation of regeneration 40 Ah-128 Wh Sinopoly LiFePO4 3.2 V cell after short-circuit. In Table 1 are listed main parameters of tested cell.

Table 1: Parameters of selected cell

Electrical Parameter	Sinopoly LiFePO$_4$ 3.2 V 40 Ah	
Nominal voltage	3.2	(V)
Maximum charging voltage	3.65	(V)
Minimum voltage	2.5	(V)
Discharge current - maximum (continuous)	3	(C)
Discharging current - optimal	13	(A)
Charging current - maximum	60	(A)
Charging current - optimal	20	(A)
Operating temperature	−45 to +85	(°C)
Capacity	40	(Ah)
Package material	plastic	(-)

2.1. Experimental application of the short-circuit

For obtain a reference cell which can be used for recovery with proposal algorithm, selected LiFePO$_4$ 3.2 V, 40 Ah, 128 Wh battery cell was selected. Therefore, selected cell was short-circuited for obtaining reference short-circuited cell. Short-circuit, which is worst scenario of operation from safety point of view. On Figure 4 shown test set-up used for experiment of the short-circuit. This configuration uses mechanical switch rated for very high current for star of short-circuiting test. Thermo-vision camera

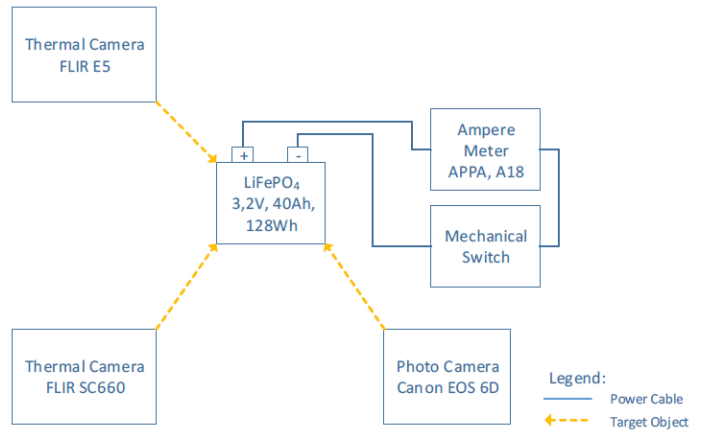
FLIR E5 and thermo-vision camera FLIR SC 660 used for thermal analysis during short-circuit.


Figure 1: Block diagram of set-up for short-circuit test

The measurement of current during short circuit test was provided by current meter APPA A18, while measured values were stored on NI PXI with measurement cards NI PXI 1031 using LabVIEW. For the evaluation of battery dimensions and shape changes from pictures, camera Canon EOS 6D was used.
Figure 2: Current profile during the short-circuit experiment

On new battery cell which was formatted during manufacturing process was used for short-circuiting test. Secondary formatting was realized before short-circuiting test within laboratory conditions. Before short-circuiting test, battery open circuit voltage was 3,24 Vdc.

Figure 2 shows the current waveform during the short-circuit experiment. From this figure we can see that after short-circuiting, discharging current of the battery reached up to 430 A. Following more than 300 s, discharging current of the battery was over 350 A, than in next 100s is visible rapid fall of discharging current. After more than 600 s of test, current was reduced to the value of 11.5 A and finally to 2.7 A. The duration of this test was 25 min.

During short-circuited test, the battery discharging current reached more than 10C what is 3-times higher than maximal continuous discharging current determined from manufacturer. Even due to this critical operational condition, the maximum surface temperature recorded during experiment reached 49.2 °C (Figure 3), while during short-circuit test the ambient temperature was 18 °C. This maximum temperature was measured at the end

of the short-circuit test and the safety pressure valve was inactive during whole duration of short-circuit.
Figure 3: Maximal temperature during short-circuit test

The result of the short-circuit was visible mechanical change of the battery internal structure which cause change dimension of package. Figure 4 indicates structural damage after the end of the experiment, whereby depth of the package raised from 46 mm up to 54 mm, height of the package has risen from 186 mm up to 186.5 mm, and width had changed by 0.5 mm, i.e. from 116 mm down to 115.5 mm.
Figure 4: Changes of dimensions of the tested cell after experiment of long-term short-circuit

3. Regeneration procedure application after long-term short-circuit

After the short-circuit test, the tested cell was left resting for 22 days. After this rest period, geometrical dimension of cell was checked again while no dimensional or shape change was observed

compared to measured dimensions immediately after the short-circuit test. Consequently, the regeneration procedure which is explained by table 2. Was applied. The proposal procedure is based on the sequential charging with pulse charging current. This charging sequence is split into six subsequences. After finish of each subsequence, approximately 16 h resting period is applied. Each pulse subsequence duration is 100 min is divided into four cycles which duration is 25 min. The main difference between the cycles is the charging current amplitude (Table 2).

Table 2: Parameters of the regeneration procedure after long-term short-circuit.

Subsequence	Duration	Charging current amplitude	Maximal charging voltage
1	25 min × 4 cycle = 100 min	Increasing after each cycle = 0,5 – 2A	3.65 V
2	25 min × 4 cycle = 100 min	Increasing after each cycle = 2,5 – 4A	3.65 V
3	25 min × 4 cycle = 100 min	Increasing after each cycle = 4,5 – 6A	3.65 V
4	25 min × 4 cycle = 100 min	Increasing after each cycle = 6,5 – 8A	3.65 V
5	25 min × 4 cycle = 100 min	Increasing after each cycle = 8,5 – 10A	3.65 V
6	25 min × 4 cycle = 100 min	Increasing after each cycle = 10,5 – 12A	3.65 V

Capacity of cell was tested with delivered ampere-hour test after regeneration and after formatting procedure, while the results have been presented within [23].

During initial capacity testing the cell showed similar performance to reference, unused new cell up to 80 A of discharge current. However, for maximal 3C discharging current, the recovered cell showed just less than half of the capacity (Figure 5).
Figure 5: Voltage waveform during discharge with 3C discharging current for regenerated (yellow) and referenced cell (green)

After 28 days of storage, recovered battery was tested ten times in a row with delivered ampere-hour test. Differences in capacity values between repeated delivered ampere-hour tests were under

2%. The main issue, which was not satisfactory for the recovered cell, was the fact that for higher currents (above 2C) the battery lost its performance by more than 50 %. Therefore, second regeneration was applied once more, consequently resting period of 22 days was applied followed by formatting procedure. After this second regeneration procedure, once the cyclic testing of the capacity of regenerated battery was realized.

4. Cyclic testing of the capacity of recovered LiFePO$_4$ traction cell

Before this cycling testing, it is necessary to charge recovered batteries as well as reference one (non-damaged, unused and formatted cell). CC&CV charging (Constant Current and Constant Voltage) is recommended for selected types of batteries. Capacity of both batteries was verified by test of delivered ampere-hours.

For the battery capacity test, five discharging and charging strategies were chosen. Each strategy is specific by a different value of discharging and charging current, while the values of discharging currents was chosen based on manufacturer recommendations of selected cell 13A-120A (0.3-3C). Cyclic experiments have been made, i.e. recovered battery had continuously undertaken verification for each of charging and discharging test for 5 times to prove robustness of proposed regeneration procedure [24-25].
Figure 5: Block diagram of set-up for capacity testing with delivered ampere-hour test

4.1. Test of the discharged capacity

In figures 6 to Figure 10 can be seen voltage waveforms of battery cell during constant current discharge for 5 different current values (0.3C-3C). Each situation compares the situation for recovered cell and for reference (new) cell. From individual results is visible, that recovered battery exhibits the same performance as undamaged new cell.
Figure 6: Cyclic discharging (I = 13A)
Figure 7: Cyclic discharging (I = 20A)
Figure 8: Cyclic discharging (I = 40A)
Figure 9: Cyclic discharging (I = 80A)

Each discharging test of recovered cell, i.e. for each value of discharge current, the measurement was validated for 4 times in order to prove stable value of recovered capacity. Simultaneously, there is a small difference between new and recovered cell. When comparing capacity for individual discharging currents, the highest difference of app. 2 Ah is visible for low discharging currents (Figure 6 – Figure 8). For higher values difference is reduced /Figure 9 – Figure 10).
Figure 10: Cyclic discharging (I = 120A)

Within the datasheet of tested battery type it states that it is necessary to monitor the value of the temperature when discharging the cell with a current of 120 A. Temperature profile during whole discharging process by current of 120 A of recovered cell can be seen in Figure 11. From this figure is can be seen that temperature is reaching approximately 37.3 °C at the end of the discharging process. The value is much lower than critical discharging temperature listed in datasheet, which value is 85°C. This temperature profile was recorded for each discharging sequence.
Figure 11: Temperature profile of recovered cell during discharge with 120A

The other two figures (Figure 12 and Figure 13) are representing reference results for individual situations, while independently the results for recovered and undamaged, new formatted cells are interpreted. Here the voltage waveforms are being showed during discharge with different discharging current values. At the beginning of discharging process there is a voltage drop. Voltage drop magnitude depends on the magnitude of the discharge current. The higher value of the discharge current cause the greater the voltage drop. This is caused by the effect of internal resistance of the cell. The difference between Figure 12 and Figure 13 is not markedly great, i.e. recovered cell exhibits similar behavior to undamaged. Therefore, it can be said that application of proposed capacity recovery algorithm has positively influenced the internal resistance of the cell as well.
Figure 12: Voltage profile waveforms of recovered cell for various discharging currents
Figure 13: Voltage profile waveforms of new cell for various discharging currents

4.2. Test of charged capacity

Similary to the test of the discharging process, the test of the charging process was realized for recovered and new cell.
Figure 14: Charging waveforms of voltage and current (I_{CC} = 20A)

The recovered cell was tested several times to prove stability of the recovered capacity once again. Figure 14 shows the cell voltage and current waveforms during charging profile. Here we

can see the value of the constant current (in this case 20A) and the value of the charging voltage (3.65V). The charging profile is reflecting constant current, constant voltage procedure (CC/CV), what is an optimal charging method of tested type of bateries.
Figure 15: Cyclic charging (I = 20A)
Figure 16: Cyclic charging (I = 40A)
Figure 17: Cyclic charging (I = 60A)

In Figure 15 to Figure 17 are the voltage waveforms during charging proces. Individual figures are specific by the value of charging current. Each graph shows 3 measurements for recovered cell and one measurement for new cell. The graphs show that

charging process of new cell exhibits higher capacity if low value of charging current is applied (Figure 15). This process was also visible during discharge process by low values of current. The higher the charging current, the smaller the capacity differences between the recovered and new cell.

Figure 18 and Figure 19 are representing reference voltage profiles during charging process. Figure 18 is shown that maximum capacity of recovered cell is achieved at 33 Ah, while voltage is at the level of 3,65 V. From figure 19 can be seen that the capacity of new cell achieves approximately 37 Ah at maximum voltage level 3,65 V. Based on this results we can state, that recovered cell lost about 10% of its nominal capacity. This result is also confirmed by the voltage waveform from Figure 12 and Figure 13 where is seen, that recovered cell provides less capacity than new. However, even due to reduction of available capacity, the recovery algorithm enables to recover more than 90% of damaged cell capacity.
Figure 18: Reference waveforms of shorted cell based on the current
Figure 19: Reference waveforms of new cell based on the current

5. Conclusion

This paper present charging algorithm for recovery of lithium phosphate traction batteries after long-term short circuit. This recovery algorithm was applied to short-circuited Sinopoly LiFePO4 3.2V 40Ah cell. Proposal algorithm was verified with

delivered ampere-hour tests. Result of these tests was compared to delivered ampere-hour test of same type battery which was, new and formatted. From comparison of tests of new and recovered battery was found that proposed algorithm can recover up to 90% within wide range of discharge and charge currents.

Conflict of Interest

The authors declare no conflict of interest.

	The current concept of open innovation corresponds to the R&D products transfer model – "role changes". One of the fundamental provisions of the model is that R&D products are considered for commercialization not only at the final stage of technological readiness, but at any of them. In today's changing market environment, special attention is paid to the transfer and commercialization of R&D products at the early stages of readiness, but this process is characterized by significant problems from the point of view of technological forecasting. To solve the problems, the article substantiates the method of technological forecasting of market behaviour of R&D products at the early stages of technological readiness, which is based on taking into account the strengths and weaknesses, development factors and limiting factors of R&D product. The method allows you to predict indicators of product behaviour relative to the market where its commercialization is planned. *As a component of the above method and in order to increase the level of reliability of calculations and validity of results, a method for determining the correction factor of indicators of market behaviour of R&D product has been developed. The method was developed on the basis of fuzzy set theory algorithms using the fuzzy logic toolbox (MATLAB), which made it possible to integrate a set of different types of forecast data on the market behaviour of an R&D product, taking into account the relationships and interdependencies between them, into one correction factor. This coefficient contains the characteristics of signs of the impact of R&D product on the market (in particular, market effects, types of market changes) and the impact of market effects on R&D product (effects generated by R&D products, organizational and technological changes in R&D products). To justify the correction factor, a knowledge base of responses from subject area experts has been formed. In order to further select a commercialization strategy for R&D product, a system with normative indicators has been developed that interpret the following types of strategies: zero-level commercialization of R&D product; first-level commercialization of R&D product; commercialization of the second level of R&D product.* *The author's method of technological forecasting of market behaviour of R&D products and choosing a commercialization strategy for a product is universal, can be applied to R&D product of any type of economic activity, transfer method, etc. Testing of the method on the example of a number of R&D products presented by the developers of the Lviv Polytechnic National University (Lviv, Ukraine) showed the validity of the author's method and its relevance in modern conditions of market singularity.*

1. Introduction

1.1. Framework of theme relevance

   This work is a continuation of a number of our scientific papers in the framework of research on the transfer of R&D products, in particular, presented at the 14th International Scientific and Technical Conference on Computer Sciences and Information Technologies (2019) [1].

   In recent years, there has been a change in a number of models

of R&D products transfer, due to changes in the models of the innovation process, globalization and digitalization. The current concept of open innovation corresponds to the R&D products transfer model – "role changes". One of the fundamental provisions of the model is that R&D products are considered for commercialization not only at the final stage of technological readiness, but at any of them. This position is important from several positions. First, depending on the stage of R&D product readiness for commercialization, both its original purpose and the level of consumer value may change (for example, when R&D products converge at the stage of idea justification).

Secondly, in the context of the spread of digitalization, the commercialization of R&D product is much faster, compared to the similar situation that was inherent in the global economy several decades ago.

In general, the level of technological readiness of an R&D product indicates its presence at a certain stage (research, development, etc.), which is compared with the planned (or final) stage, and, taking into account the features of R&D product development, predict the duration, cost and nature of market behaviour of the product. In other words, the market behaviour of a commercialized R&D product, which is evaluated at different stages of its technological readiness, will be different.

The above actualizes the need to pay attention to the study of approaches, methods and models of technological forecasting of market behaviour of R&D products. The success of implementing the R&D products commercialization strategy will depend on the reasonable choice of methodological tools for technological forecasting. The development of such methodological tools is relevant both from the point of view of the needs of the modern economy, and from the point of view of predicting the market behaviour of R&D products in the conditions of a market singularity.

1.2. Statistical Background

The relevance of the above problem is confirmed by numerous statistical data. In particular, among the problems that will befall R&D products in the form of startups, there is insufficient funding in the early stages of product development – 29 %, which is the second significant reason in the list of their failures (the first reason is the lack of market demand – 42 %) [2]. At the same time, startups are characterized by a growth trend. For example, for two dozen top universities in the United States, the number of startups has more than tripled in 20 years-from 306 units in 1998, up to 1098 units in 2018 [3], which explain the focus of universities to generate R&D products in the early stages with the help of startups. At the same time, 20 % of startups fail in the first year, 50% of startups fail in the first five years [4].

Traditionally, among small business owners, about 77 % of early-stage product financing is done by raising their own funds [4], which requires careful technological forecasting of the development and payback of R&D products. However, only 2 – 3 % of development funding belongs to alternative sources (Venture Investors, Business Angels, crowd funding, etc. [4]).

The importance of paying attention to technological forecasting of market behaviour of R&D products in the early stages of technological readiness is confirmed by the results of the NanoCom Consortium study [5], in which 214 people were interviewed about barriers to commercialization of R&D products

in the field of nanotechnology. Among them, 63 people noted significant barriers at 3 – 5 levels of TRL (technology readiness level), where R&D is conducted. Other significant barriers included commercially available at TRL levels 8 – 9 (93 responses). The participants of this organization also argue that the most significant impact of barriers occurs in the early stages of TRL – domain technological, and in subsequent stages TRL gives way to marketing and strategic domain.

R&D is one of the defining components of the structure of a number of global country competitiveness indices (Bloomberg Innovation Index, Global Competitiveness Index, Creativity Index, etc.), so technological forecasting of market behaviour of R&D products can be a strong argument for explaining other components of such indices (market perception, productivity, added value, etc.).

1.3. Formulation of the problem

Without a sound approach to technological forecasting of market behaviour of R&D products, there is a high probability that they will not forget or partially acquire the utility function that turns the product into a market innovation.

To develop a method of technological forecasting of market behaviour of R&D product in modern economic conditions, and, based on this, to justify the commercialization strategy for it, it is necessary to conduct a comprehensive study of both the product and the market. We should learn trends and patterns of the market, the readiness of R&D product for commercialization, and so on.

In this paper, we consider R&D product from the point of view of customer-oriented marketing, that is, the focus is on the consumer value of the product. Product R&D marketing is directly related to the consumer's consciousness. Therefore, in order to assess the level of technological readiness of an R&D product, it is necessary to keep in mind the readiness of the consumer (or market) to accept this technology. Starting from the first stage of evaluating the technological readiness of an R&D product it is necessary to formulate evaluation tasks in such a way that in the end we reach such technological, economic and other indicators that will best satisfy the business structures to which this technology will be transferred.

2. Theoretical Background

2.1. Approaches to substantiating R&D product development strategies

The development and commercialization of an R&D product requires considerable effort and resources from all participants in innovation activities. At the same time, one of the most important tasks is technological forecasting of changes that can occur with an R&D product and affect its commercialization and market distribution.

In modern scientific works on the problems of technological forecasting of R&D product development, various approaches, methods and models of research of R&D product and their market development are presented. In particular, to truly manifest innovation and reap its benefits, one must recognize that innovation is three different things: innovation is an outcome, innovation is a process, and innovation is a mindset [6].

A number of models of market development of R&D product

have been developed. The new technological innovations are changing the ways businesses are being operated. The sharing economy – based new business models (SEBMs) using technology have many benefits, it is paramount to understand these SEBMs models and the behaviour of the market, particularly on how to influence the market's attitude [7] this approach actualizes the importance of tasks to justify and choose a strategy for market development of R&D products.

The formation of a market development strategy should include forecasting factors and the dynamics of their impact on the market success of R&D products, sources of change and inertia that issue from the introduction of innovations in the market [8], business logic as consequence of far-reaching technological developments [9] using technological forecasting methods. Such factors should be systemic and complex, because focusing solely on the effectiveness of the technological innovation is detrimental to long-term operational benefits [10].

The above-mentioned problem is quite complex, since, as scientists note, chain reactions from one innovation can have effects so significant that the entire world alters its way of life to incorporate the new technology. Often times, the effects of a new type of technology build upon existing technology with future innovations building on the inventions of today. This constant evolution and growth forces businesses to adapt or expire [11].

In addition, scientists distinguish the interdependence between the introduction of different types of innovations, which determine the market prospects for each other's development, as in the case of the introduction of technological and organizational innovations [12]. Sustainability, adoption of various types of innovation [13], accounting for the environment in the agenda of companies [14]. The success of innovations depends in part on the business models used to distribute them [15]. Also important is the impact of specific types of information on commercialization rates of technologies [16].

Scientific papers note that the innovation adoption is a process, rather than a dichotomic choice [17]. Therefore, for a rational and effective process of adapting R&D products to the market, it is necessary to develop and implement strategic solutions.

For the formation of innovation development strategies, many approaches justify strategic management decisions from different positions. Marketing strategies and particularly brand associations with brand awareness, perceived quality, and brand loyalty [18], co-branding strategies become important [19].

In addition, market opportunities for innovation are associated with the implementation of competitive strategies and market-based assets (customer orientation, competitor orientation, and marketing creativity) were assessed for their ability to help an innovating firm deal with dysfunctional competition and improve the returns from innovation [20].

In connection with the development of the open innovation model, the following factors are becoming important: intellectual property strategy, the shaping of complementary and substitute appropriability regimes is central when strategizing in dynamic and systemic innovation contexts [21].

2.2. Tools for justifying R&D product development strategies

The study of tools for the formation of strategies for the development of technological innovations has led to a revision of methods of technological forecasting, that can be useful for bringing a new perspective to explain and generalize properties of the evolution of technology and predict which innovations are likely to evolve rapidly in society [22]. The tasks of modern technological forecasting are strategic foresight, sustainability, technology transfer, entrepreneurship, and absorptive capacity can be explored further [23].

When justifying the R&D products development strategy, scientists highlight two generative cognitive processes- analogical reasoning and conceptual computation [24].

More and more scientists are using matrix approach to technological innovations based on design science research, entrepreneurship, and innovation theories, especially in digital innovation [25].

Combined methods of forming strategic decisions based on MULTIMOORA (Multi-Objective Optimization on the basis of Ratio Analysis plus full multiplicative form) is a somewhat new multi criteria decision-making (MCDM) method which provides high efficiency and effectiveness in problem solving [26].

In order to avoid the subjectivism of expert assessments, the authors suggest novel approach for forecasting method selection and a recommendation-based ensemble forecasting approach [27].

Determination of the weighting coefficients of factors influencing the development of technological innovations can be carried out based on exponential smoothing; autoregressive integrated moving average and neural network are chosen to form the combined approach [28].

2.3. Theoretical generalization

The considered approaches to development strategies allow us to approach the justification of strategic decisions on the market development of R&D products from the standpoint of priority of a specific factor. However, according to successful practices, the market perception of R&D products is interdisciplinary in nature. In addition, the scientific and practical developments discussed above are based on the consideration of mostly completed innovations as objects, that is, the results of the completed innovation process. However, the object of this research is the intermediate result of the innovation process, namely, R&D product at the early stages of technological readiness.

These objects have different parameters of technological readiness [29] and features of market application. Therefore, it is necessary to take a differentiated approach to the development of methods for technological forecasting of market development of R&D products, choosing a strategy for their commercialization, and so on.

The author's method must be defined:

— the ability to differentiate in the projected period of market development of R&D products their functional advantages and weaknesses, factors that will restrain or stimulate the development of the product;

— the ability to take into account the features and characteristics of R&D product of various types of economic activity and business areas;

— with the ability to objectively predict market drivers and anti-drivers of R&D product development;

— it is an opportunity to take into account the dynamic nature

of the market development of R&D product in relation to the satisfaction of consumer needs;

— flexibility in changing input data, managerial maneuverability, and so on.

3. Research design

3.1. Methodology approach

The aim of the work is to develop a method for technological forecasting of market behaviour of R&D products at the early stages of their technological readiness.

The basis for conducting such a study is a number of hypotheses.

Hypothesis 1. The method of technological forecasting of market behaviour of R&D products is universal and can be applied to products of any type of economic activity, business sector, etc.

Hypothesis 2. Fuzzy set theory algorithms allow us to take into account changes in the market behaviour of R&D products in the short, medium and long term.

Hypothesis 3. Justification of the R&D product market behaviour indicator based on the author's method should correlate with the early stages of technological readiness of the product.

To prove / refute hypotheses and develop this method, it is advisable to conduct a study of the problems of technological forecasting of R&D products development at the empirical, theoretical and applied levels.

3.2. Methodology

3.2.1. Fundamentals of technological forecasting of market behaviour R&D product

When evaluating an R&D product for the purpose of market launch and developing strategies for its commercialization, analysts mainly use methods and models of technological forecasting of product *market development*.

Most of the known methodological tools for technological forecasting of market development of R&D products are based on the justification of its strengths and weaknesses, risks and chances, etc. [30–32]. However, the category "market development" is a general concept that implies a process that results in a change in the quality of a product, its transition from one qualitative state to another (higher). In the situation with technological forecasting of R&D product development, the category "market behaviour" will give a more accurate description of the above change. Within the framework of neobehaviourism, behaviour is considered visible manifestations that can be observed, internal states associated with external manifestations. Moreover, market behaviour is a set of states (characteristics) of an R&D product that a product reveals under the influence of certain environmental factors (market). However, the market behaviour of R&D products is not often taken into account by analysts in the context of technological forecasting. Therefore, traditional approaches to technological forecasting for R&D products do not always allow us to justify effective strategies for their commercialization.

If an R&D product is in the early stages of technological readiness, it is not always correct to assess the chances and risks

of a product. Odds are the probability of such market behaviour of an R&D product that will contribute to its success in the market. Risks are a combination of the probability and consequences of adverse events based on the market behaviour of an R&D product. To determine the chances and risks, first of all, it is necessary to assess the future consumer value of an R&D product. However, when an R&D product is only in the process of development, significant errors may occur when determining the level of its consumer value. The assessment of chances and risks can be more reliable when evaluating R&D products at the stages of appropriability high technological readiness – then it is possible to predict the market behaviour of R&D product and its perception by the market environment with a significant degree of reliability. Therefore, in the case of evaluating an R&D product at the early stages of readiness, it is advisable to clarify the categories "*chances*" and "*risks*" in a meaningful way. It is proposed to replace them with "*development factors*" and "*limiting factors*". These factors determine the probability of events occurring in the R&D product market (events that will determine the chances or risks of R&D product spreading in the market).

When making technological forecasting of the market behaviour of R&D product, it is advisable to pay attention, on the one hand, to the stage of technological readiness of R&D product on the other – to the perception of R&D product by the market environment.

To determine the early stages of technological readiness of R&D products, we will use the NASA approach [33]:

— basic principles observed and reported;
— technology concept and / or application formulated;
— analytical and experimental critical function and / or characteristic proof-of-concept;
— component and / or breadboard validation in laboratory environment;
— component and / or breadboard validation in relevant environment.

In the early stages of R&D product readiness, it is advisable to conceptually determine the level of compatibility of the current market data set with the corresponding set of knowledge about the technological readiness of R&D product.

The set of data (characteristics) obtained based on studying the technological readiness and market perception of R&D product can be systematized into stimulants and destimulants of R&D product, highlighting from them – strengths and weaknesses, development factors or limitations of R&D product. To organize the characteristics of an R&D product, you can use the following list.

Strengths / weaknesses of R&D product
— stage of technological readiness;
— functional indicators of the main and additional purpose of R&D product;
— indicators of the value of technical / analytical / marketing support from the developer;
— the level of environmental safety of the product;
— the level of economic efficiency of investment in R&D product (commercialization);
— the level of costs for the use and disposal of R&D product;
— R&D product patent protection level;
— the level of uniqueness / standardization of the R&D product;

— the level of complexity of implementing an R&D product;
— the time level of expected use of the R&D product before replacement or improvement;
— the level of novelty / improvement of the main functional characteristics of the R&D product;
— scale of implementation and use of R&D products, etc.

Development factors / limitations for R&D product
— the nature and number of direct / indirect competitors of the R&D product;
— nature and number of substitutes R&D product;
— market capacity;
— stage of the R&D product lifecycle;
— dependence on R&D product participants / developers;
— the level of access to resources for using the R&D product;
— the level of availability of R&D product information, etc.

These characteristics can be adjusted according to the scope of R&D product, market specifics, comparison with market analogues, and so on.

In order to substantiate the method of technological forecasting of market behaviour of R&D product, we have proposed the following sequence of actions:
1) systematize the evaluation basis (reference matrix) of technological forecasting of market behaviour of R&D product;
2) develop a methodological approach to correcting indicators of market behaviour of R&D product;
3) substantiate the method of evaluating the results of technological forecasting of market behaviour of R&D product;
4) develop a system for selecting strategies for commercializing an R&D product based on technological forecasting of its market behaviour.

Systematization of existing methodological approaches to technological forecasting and the application of development factors and limitations of R&D product allowed us to develop a reference matrix for technological forecasting of market behaviour of R&D product – table 1.

Table 1: Reference matrix for technological forecasting of market behaviour of R&D product

Characteristics		Significance of the parties (Z)	Evaluation of parties (A)	Rank (F)
Strengths (S)	S_1	Z_{S_1}	A_{S_1}	$F_{S_1} = \dfrac{Z_{S_1} \times A_{S_1}}{\sum_{i=1}^{n} Z_S \times A_S}$
	S_2	Z_{S_2}	A_{S_2}	$F_{S_2} = \dfrac{Z_{S_2} \times A_{S_2}}{\sum_{i=1}^{n} Z_S \times A_S}$
	...	...	...	...
	S_n	Z_{S_n}	A_{S_n}	$F_{S_n} = \dfrac{Z_{S_n} \times A_{S_n}}{\sum_{i=1}^{n} Z_S \times A_S}$
	Σ	$\sum_{i=1}^{n} Z_S \times A_S$		1
Weaknesses (W)	W_1	Z_{W_1}	A_{W_1}	$F_{W_1} = \dfrac{Z_{W_1} \times A_{W_1}}{\sum_{i=1}^{n} Z_W \times A_W}$
	W_2	Z_{W_2}	A_{W_2}	$F_{W_2} = \dfrac{Z_{W_2} \times A_{W_2}}{\sum_{i=1}^{n} Z_W \times A_W}$
	...	...	...	...
	W_n	Z_{W_n}	A_{W_n}	$F_{W_n} = \dfrac{Z_{W_n} \times A_{W_n}}{\sum_{i=1}^{n} Z_W \times A_W}$
	Σ	$\sum_{i=1}^{n} Z_W \times A_W$		1
Development factors (D)	D_1	Z_{D_1}	A_{D_1}	$F_{D_1} = \dfrac{Z_{D_1} \times A_{D_1}}{\sum_{i=1}^{n} Z_D \times A_D}$
	D_2	Z_{D_2}	A_{D_2}	$F_{D_2} = \dfrac{Z_{D_2} \times A_{D_2}}{\sum_{i=1}^{n} Z_D \times A_D}$
	...	...	...	...
	D_n	Z_{D_n}	A_{D_n}	$F_{D_n} = \dfrac{Z_{D_n} \times A_{D_n}}{\sum_{i=1}^{n} Z_D \times A_D}$
	Σ	$\sum_{i=1}^{n} Z_D \times A_D$		1
Limiting factors (L)	F_{L_1}	Z_{L_1}	A_{L_1}	$F_{L_1} = \dfrac{Z_{L_1} \times A_{L_1}}{\sum_{i=1}^{n} Z_L \times A_L}$
	F_{L_2}	Z_{L_2}	A_{L_2}	$F_{L_2} = \dfrac{Z_{L_2} \times A_{L_2}}{\sum_{i=1}^{n} Z_L \times A_L}$
	...	...	...	...
	F_{L_n}	Z_{L_n}	A_{L_n}	$F_{L_n} = \dfrac{Z_{L_n} \times A_{L_n}}{\sum_{i=1}^{n} Z_L \times A_L}$
	Σ	$\sum_{i=1}^{n} Z_L \times A_L$		1

Table 2: Correlation matrix of strengths, weaknesses, development / limiting factors and indicators of R&D product market behaviour

Characteristics of R&D production			Development factors (D)				Limiting factors (L)				Market behaviour indicators (P)
			D_1	D_2	...	D_n	L_1	L_2	...	L_n	
		Ранг	F_{D_1}	F_{D_2}	...	F_{D_n}	F_{L_1}	F_{L_2}	...	F_{L_n}	
Strengths (S)	S_1	F_{S_1}	$K^{SD}_{1,1}$	$K^{SD}_{1,2}$	...	$K^{SD}_{1,m}$	$K^{SL}_{1,1}$	$K^{SL}_{1,2}$	...	$K^{SL}_{1,m}$	P^{SDL}_1
	S_2	F_{S_2}	$K^{SD}_{2,1}$	$K^{SD}_{2,2}$	...	$K^{SD}_{2,m}$	$K^{SL}_{2,1}$	$K^{SL}_{2,2}$	...	$K^{SL}_{2,m}$	P^{SDL}_2
	...	...	...	...	...	...	...	...	...	...	...
	S_n	F_{S_n}	$K^{SD}_{n,1}$	$K^{SD}_{n,2}$	...	$K^{SD}_{n,m}$	$K^{WL}_{n,1}$	$K^{WL}_{n,2}$	...	$K^{WL}_{n,m}$	P^{SDL}_n
Weaknesses (W)	W_1	F_{W_1}	$K^{WD}_{1,1}$	$K^{WD}_{1,2}$	...	$K^{WD}_{1,m}$	$K^{WL}_{1,1}$	$K^{WL}_{1,2}$	...	$K^{WL}_{1,m}$	P^{WDL}_1
	W_2	F_{W_2}	$K^{WD}_{2,1}$	$K^{WD}_{2,2}$	...	$K^{WD}_{2,m}$	$K^{WL}_{2,1}$	$K^{WL}_{2,2}$	...	$K^{WL}_{2,m}$	P^{WDL}_2
	...	...	...	...	...	...	...	...	...	...	...
	W_n	F_{W_n}	$K^{WD}_{n,1}$	$K^{WD}_{n,2}$	...	$K^{WD}_{n,m}$	$K^{WL}_{n,1}$	$K^{WL}_{n,2}$	...	$K^{WL}_{n,m}$	P^{WDL}_n

In order to assess the strengths and weaknesses, development factors and limitations of an R&D product, it is necessary to involve experts in the relevant subject area and skill level. Experts determine the significance of the parties to the R&D product (Z) and evaluate them (A) according to the expressions in table. 1.

Significance is a non – repeating indicator for each of the characteristics (according to the principle: highest value-highest significance). A rating can be assigned, for example, from the interval 1…10, where 1 is the weakest manifestation of the characteristic, and 10 is the strongest. After that, the rank of ratings is determining. It is the specific weight of the impact of each characteristic on their entire group.

When making calculations, the priority should be the value of the R&D product for the consumer, its market competitiveness, as well as the expected efficiency of commercialization.

After establishing the ranks, we determine the pairwise correlation coefficients (C) of factors influencing the R&D product and calculate the indicator of its market behaviour (P). The matrix of relationships between indicators is shown in table 2.

Therefore, K [x; y], where x and y are in the range 0…1, is the correlation coefficient of strengths and weaknesses, development factors, and limitations of the R&D product. The sum of "x + y" placed in the corresponding cells will reflect the strength of the influence of a particular pair of factors: *SD, SL, WD* and *WL,* respectively, on the indicator of market behaviour.

The market behaviour indicator shows the strength of the manifestation of R&D product characteristics, due to the corresponding development factors or restrictions on it. This indicator is relative and is measured in fractions of units. Calculating the market behaviours indicator helps determine the level of R&D ability of a product in relation to market development.

To determine the indicator of market behaviours of an R&D product, it is advisable to follow the following systematic procedure:
1) summarize the correlation coefficients (K) separately for the strengths, weaknesses, development factors, and limitations of the R&D product. Use expressions to determine the indicator of market behaviour of an R&D product to set its value. For this purpose, expressions (1) – (2):

$$P^{SDL}_{n,m} = \sum_{i=1}^{n} K^{SD}_{n,m} - \sum_{i=1}^{n} K^{SL}_{n,m} , \qquad (1)$$
$$P^{WDL}_{n,m} = \sum_{i=1}^{n} K^{WD}_{n,m} - \sum_{i=1}^{n} K^{WL}_{n,m} ; \qquad (2)$$

2) interpret the obtained values of market behaviour indicators. In particular, $P^{SDL}_{n,m}$ shows how much the strengths of an R&D product supported by development factors can withstand limiting factors, $P^{WDL}_{n,m}$ reflects how much the weaknesses of an R&D product supported by developmental factors can overcome limiting factors. The "−" and "+" signs of the indicators indicate the dominance of the influence of factors of restriction or development, respectively. In general, the level of the indicator indicates the strength of influence of the characteristics used in the assessment.

In practice, when evaluating an R&D product, such important indicators of technological forecasting as trends and features of market development that will affect the market behaviour of an R&D product often fall out of sight. In particular: technology diffusion, convergence of products and markets, synergy of R&D products, multiplier and spillover effect of R&D product, etc. Such indicators are practically not taken into account by modern appraisers, which is due to the complexity of their determination. It is even more difficult to identify interdisciplinary factors influencing R&D products and their relationships. However, you cannot ignore them either. Market effects can determine the market behaviour of an R&D product and the choice of its commercialization strategy.

To take into account these aspects, it is advisable to introduce a correction factor for indicators of market behaviour of R&D product. In our opinion, the correction factor should consist of two interrelated components: I (the impact of R&D product on the market) and II (the impact of market effects on R&D product). In order to justify such a correction factor, it is advisable to apply an economic and mathematical apparatus that would be based on not only quantitative estimates, but also take into account qualitative assessments of the market behaviour of R&D product. To do this, you can apply the algorithms of fuzzy set theory.

The criterion for the effectiveness of correcting indicators of market behaviour of an R&D product based on fuzzy set theory algorithms can be expressed by maximizing the degree of suitability of the result in each specific case of technological forecasting.

The correction factor (M) of R&D product market behaviour indicators can be described by the function (3):

M = f (I – Impact of R&D product on the market;
II – impact of market effects on R&D product), (3)

which is a next-level system of functions (see table 3).

Table 3: Signs of adjustment of indicators of market behaviour of R&D products and their linguistic terms

Signs of adjustment of R&D products market behaviour indicators	Characteristics of signs of adjustment of indicators of market behaviour of R&D product	Meaning of linguistic terms of signs of adjustment of market behaviour indicators R&D product
I – Market impact of R&D product	a) *market effects:* market convergence, spillover effect, Diffusion, synergy, crowd effect, etc.	*Low* [− 100; − 80; − 60], *L; Admissible* [− 59; − 29.5; 0], *A; Middle* [0; 29.5; 59], *M; High* [60; 80; 100], *H*
	b) *types of market changes:* the level of market renewal; the number and types of market participants affected by R&D product; the level and depth of market changes that accompany the introduction of R&D product; barriers to market entry, etc.	*Low* [− 100; − 80; − 60], *L; Admissible* [− 59; − 29.5; 0], *A; Middle* [0; 29.5; 59], *M; High* [60; 80; 100], *H*
II – Impact of market effects on R&D product	a) *effects generated by R&D products:* convergence of R&D products; multiplier effect, etc.	*Low* [− 100; − 80; − 60], *L; Admissible* [− 59; − 29.5; 0], *A; Middle* [0; 29.5; 59], *M; High* [60; 80; 100], *H*
	b) *organizational and technological changes of R&D products:* flexibility (adaptation) of individual parameters of R&D product; the level of novelty of R&D product; the number and access to marginal resources that need to be attracted for the market development of R&D product and the level of costs for them; environmental friendliness of R&D product; scale of R&D product monetization; level of intellectual property protection, etc.	*Low* [− 100; − 80; − 60], *L; Admissible* [− 59; − 29.5; 0], *A; Middle* [0; 29.5; 59], *M; High* [60; 80; 100], *H*

To output the desired correction factor, use the Fuzzy Logic Toolbox (MATLAB). Within the framework of fuzzy set theory algorithms (based on the Mamdani model), the characteristics of signs of correction of market behaviour of R&D product are systematized by types (a, b, c, d), which are assigned the value of linguistic terms – table 3.

The correction factor of market behaviour is within the same limits as the characteristics of its features.

We have formed a knowledge base – a set of ratios of linguistic terms of adjustment features, taking into account their impact on the indicator of market behaviour of R&D product. In figure 1 shows a fragment of this knowledge base using the fuzzy logic toolbox (MATLAB).

1. If (a is Low) or (b is Admissible) or (c is Admissible) or (d is Low) then (Correction_factor is Admissible) (1)
2. If (a is Low) and (b is not Middle) and (c is Middle) and (d is Admissible) then (Correction_factor is Admissible) (1)
3. If (a is Low) and (b is Low) and (c is Low) and (d is Low) then (Correction_factor is Low) (1)
4. If (a is Low) or (c is High) or (d is Low) then (Correction_factor is Middle) (1)
5. If (a is Low) and (b is Low) and (c is Low) and (d is Low) then (Correction_factor is Low) (1)
6. If (a is Admissible) or (b is Admissible) or (c is Admissible) or (d is Admissible) then (Correction_factor is Admissible) (1)
7. If (a is Admissible) or (b is Admissible) or (c is Middle) or (d is Middle) then (Correction_factor is Middle) (0.7)
8. If (a is Admissible) and (b is Middle) and (c is Admissible) and (d is High) then (Correction_factor is Middle) (0.3)
9. If (a is Admissible) and (b is Low) and (c is High) and (d is Admissible) then (Correction_factor is Middle) (0.3)
10. If (a is Admissible) and (b is High) and (c is High) and (d is Middle) then (Correction_factor is Admissible) (0.7)
11. If (a is Middle) or (b is Admissible) or (d is Low) then (Correction_factor is Admissible) (0.7)
12. If (a is Middle) and (b is Admissible) and (c is Middle) and (d is High) then (Correction_factor is Middle) (0.7)
13. If (a is High) or (b is not High) or (c is High) or (d is High) then (Correction_factor is High) (0.5)
14. If (a is Low) and (c is Middle) and (d is Admissible) then (Correction_factor is Middle) (0.8)
15. If (a is High) and (b is Middle) and (c is High) and (d is High) then (Correction_factor is Middle) (0.8)
16. If (a is High) and (b is Low) and (c is Admissible) and (d is High) then (Correction_factor is Middle) (0.5)
17. If (a is High) and (b is not High) and (c is Admissible) and (d is Admissible) then (Correction_factor is Middle) (1)
18. If (a is Low) and (b is not Middle) or (c is Admissible) then (Correction_factor is Admissible) (1)
19. If (a is Low) or (b is Low) or (c is Low) or (d is Low) then (Correction_factor is Low) (1)

Figure 1: Knowledge base of relations of linguistic terms of adjustment features, considering their impact on the indicator of market behaviour of R&D product (fragment)

Visualization of the ratio of signs of adjustment of indicators of market behaviour of R&D product is shown in figure 2 – 3.

Implementing the described sequence, we obtain a relative correction factor, by the value of which we specify the indicators of market behaviour R&D product $P_{n,m}^{SDL}$ and $P_{n,m}^{WDL}$.
Figure 2: Visualization of the ratio of *a* and *b* signs of adjustment of R&D product market behaviour indicators
Figure 3: Visualization of the ratio of *c* and *d* signs of adjustment of indicators of market behaviour of R&D product

3.2.2. Evaluating results

There are many approaches to choosing an R&D product commercialization strategy, but none of the current ones takes into account technological forecasting of R&D product market behaviour. Taking into account the best practices of scientists [34 – 39], we have formed a system for choosing the strategy of

commercialization of R&D product, based on three methods of commercialization:

1) zero-level commercialization of R&D product;
2) commercialization of the first level of R&D product;
3) commercialization of the second level of R&D product.

If an R&D product is at the first or second stages of technological readiness (*basic principles observed and reported; technology concept and / or application formulated*), it is obvious that a zero-level commercialization strategy will be suitable for it. This strategy is the most efficient way to make a profit, since its object is the idea of an R&D product.

The object of the first – level commercialization strategy is an R&D product that is at the third or fourth stages of technological readiness: *analytical and experimental critical function and / or characteristic proof-of-concept; component and / or breadboard validation in the laboratory environment.*

The second – level commercialization strategy is possible for an R&D product at the fifth stage of technological readiness-*component and / or breadboard validation in a relevant environment.*

Calculated and adjusted values of market behaviour indicators (clause 3.2.1) should be noted in the system developed for this purpose (figure 4).
Figure 4: A system for selecting an R&D product commercialization strategy based on technological forecasting of market behaviour indicators*

* Symbols: I-zero-level commercialization strategy, II-first-level commercialization strategy; III-second-level commercialization strategy

The system is based on a Cartesian coordinate system (on the abscissa – *SDL* axis, on the ordinate – *WDL* axis), described by three circles – the boundaries of the choice of a particular strategy for commercialization of an R&D product, according to technological forecasting of its market behaviour.

The explanation of the choice of this form of representation of the system is justified by us in [38]. All circles have a centre at the zero point. The radius of the smallest circle is 5 units, average – 10 units. For the largest circle of Radius, it is established that its radius must be more than 10 units.

According to Figure 4, the division of scenarios within certain commercialization strategies is as follows: *DS* sector – measures that are necessary to use the strengths of R&D product for its development; *WD* sector – measures that need to be carried out, overcoming the shortcomings of R&D product and using development factors in relation to it; *LW* sector – measures that minimize the shortcomings and take into account the limiting factors of R&D product; *SL* sector – measures that use the strengths of R&D product and take into account the limiting factors in relation to it.

3.3. Data analysis

The author's method has been tested on a number of developments of Ukrainian business entities. Here is an example of technological forecasting of market behaviour of R&D product – OSL dosimetry of ionizing radiation (IR) based on Yap:Mn crystals. The main purpose of R&D product is individual passive (cumulative) IR dosimetry of people working with IR sources or may be exposed to radiation from such sources. The technology was developed by scientists of the Department of semiconductor electronics of the Lviv Polytechnic National University (Ukraine) [40, 41]. The R&D product includes a dosimeter with several detectors in a cassette; detectors (based on single crystals of yttrium-aluminum oxide activated with manganese); a device for determining the radiation dose absorbed by the cassette with detectors (reader); a method for performing measurements that provides determination of dosimetric values with a given degree of accuracy and reliability.

Research of the global market of OSL dosimetry of IR in the field of security and defense and the study of this R&D product allowed us to form strengths and weaknesses, development factors and limitations in relation to it (table 4).

Table 4: Evaluation of the characteristics of OSL dosimetry of IR technology for technological forecasting of their market behaviour

	Characteristics	Z	A	$Z_n \times A_n$	F
S	Increased level of product functionality for rescuers	8	10	80	0.229
	Tissue equivalence of the dosimetric detector material and localization of dose measurements	6	9	54	0.154
	Ability to record the dose of different types of IR in a wide range of values	7	9	63	0.180
	Ability to identify the IR source type	3	8	24	0.068
	Dosimetric material with extremely high sensitivity	4	7	28	0.080
	The material of the dosimetric detector allows you to measure the absorbed dose of IR in a wide range (from units of micrograms to several tens of kg), is a more stable and stable material, compared to analogues	5	7	35	0.100
	Ability to perform a rapid assessment of radiation energy and determine the type of unknown source	2	6	12	0.034
	The ability to quickly determine the radiation dose (important for portable readers, allows you to save the dosimeter with the accumulated dose after its partial reading, makes it possible to re-read multiple times)	9	5	45	0.128

	Synthesizer of OSL dosimetry of IR technology. Package patenting	1	8	8	0.022
	Σ			**349**	**1**
	Inflation, currency instability in the global IR dosimetry market	1	9	9	0.073
	Capital and knowledge intensity of product production	3	6	18	0.146
W	Difficulty in finding a qualified workforce to start product production	5	10	50	0.406
	Significant need for investment to start production	4	8	32	0.260
	Undeveloped sales channels in the country of origin (Ukraine) [42]	2	7	14	0.113
	Σ			**123**	**1**
	The North American region is promising from the point of view of the market launch (it is characterized by the largest global market share of manufacturers of IR dosimetry equipment and technology of 93.32 %, but the region's market is not saturated with these products) [38]	9	9	81	0.231
	Significant opportunities for product differentiation by Application Area	6	10	60	0.171
	In the country of producer (Ukraine), competitive products are presented in fragments; they are significantly more expensive than the analyzed product. The market of individual IR dosimetry in Ukraine is unsaturated today: up to 23,000 units. / year, or about $1.1 million (15.33 %) [43]	1	5	5	0.014
	Zoom effect	3	4	12	0.034
	The global dosimeters market will grow at a CAGR of 6.8% with a base value of $2.92 billion in 2020 to $4.36 billion in 2026 during the forecast period of 2020 – 2026 [44]	4	7	28	0.080
D	There is a tendency to increase demand for IR dosimetry products and technology in the medical field (the radiotherapy market is projected to grow from an estimated $5.6 billion in 2018 to $6.8 billion by 2023, at a CAGR of 4.1% during the forecast period) [45]	8	8	64	0.182
	The market of manufacturers and consumers of IP dosimetry equipment is characterized by an increase in demand for OSL dosimetry of IR and a tendency to replace TLD dosimetry with OSL dosimetry, due to the expanded list of opportunities that OSL dosimetry provides	5	5	25	0.071
	The OSL dosimetry of IR market is 25% of the world market	2	6	12	0.034
	The OSL dosimetry of IR market is characterized by the expansion of the personal dosimetry segment, due to the improvement of the "performance / cost" ratio and wider application opportunities	7	9	63	0.180
	Σ			**350**	**1**
	Low demand elasticity	1	4	4	0.024
	Insufficient communication between consumers and the manufacturer	3	5	15	0.093
	High level of specialization of competitive analogues presented in the markets	2	7	14	0.086
	Dependence on strategic relationships	4	7	28	0.173
L	Product complexity, production	5	8	40	0.248
	The OSL dosimetry of IR market is monopolistic (the main market operator is LANDAUER, Inc. (USA)), which is due to the scale of production of this enterprise and legal barriers to other market participants (patent protection of technology, etc.)	6	10	60	0.372
	Σ			**161**	**1**

The results obtained are used to determine pairwise correlation coefficients of factors influencing the R&D product, based on which indicators of its market behaviour (table 5) are calculated.

Using the author's method for determining the corrective coefficient of market behaviour of an R&D product, with the involvement of a group of expert appraisers from the subject area and based on the fuzzy logic toolbox (MATLAB), the desired coefficient is determined for the OSL dosimetry of IR technology (figure 5).
Figure 5: Results of determining the correction factor of indicators of market behaviour of OSL dosimetry of IR technology

The correction factor M for OSL dosimetry of IR technology will be − 2.97 %. The coordinates of the market behaviour indicator of this product, taking into account the correction factor, will be:

WDL: 3.258 * (− 2.97 %) = − 3.161;

SDL: 3.022 * (− 2.97 %) = − 2.93.

So, an indicator of the market behaviour of OSL dosimetry of IR technology in the R&D product commercialization strategy selection system (see figure 4) will have the coordinates – K [− 3.161; − 2.93], that is, it falls into the second matrix circle. In this case, a zero-level commercialization strategy is proposed for the product.

Since the product is located in the *LW* sector, as part of the chosen commercialization strategy for it, it is advisable to consider in detail for which positions of the correction factor the

market development of the product may slow down. Based on this, appropriate corrective measures can be developed.

The result obtained correlates with the stage of technological readiness of OSL dosimetry of IR technology – *technology concept and / or application formulated* (second stage).

Testing of a reasonable method of technological forecasting of market behaviour of R&D product and the choice of commercialization strategy based on this, carried out on the example of a number of R&D products presented by the development teams of the Lviv Polytechnic National University (Lviv, Ukraine), showed the following results (table. 6).

So, in the case of technological forecasting of market behaviour for the 1st and 4th R&D products, a zero-level commercialization strategy is defined, for the 2nd, 6th and 7th – a first-level commercialization strategy, for the 3rd, 5th – a second-level commercialization strategy.

Table 6: Results of technological forecasting of market behaviour of OSL dosimetry of IR technology using the author's method

№	R&D products	Technological readiness stage of R&D product [1…5]*	Value of the correction factor, %	Coordinates (K) in the strategy system	Type of commercialization strategy
1	Technology of optically-stimulated luminescent dosimetry	2	− 2.97	[− 3.161; − 2.93]	Zero-level commercialization strategy
2	Continuation of the life of machine parts by the method of surfacing under a layer of flux	3	4,48	[5.45; 6.89]	First-level commercialization strategy
3	Autonomous smoke and leak detection system carbon monoscope	5	7.14	[10.38; 14.91]	Second-level commercialization strategy
4	Forecasting and providing a given value of the initial resistance of dissimilar and homogeneous materials of small thicknesses and cross sections during point capacitor contact micro welding	2	− 1.6	[− 2.85; − 4.03]	Zero-level commercialization strategy
5	Contact point capacitor micro welding equipment	5	6.31	[10.03; 11.82]	Second-level commercialization strategy
6	Technology of surface friction strengthening of working surfaces of machine parts	4	3.56	[7.21; 8.025]	First-level commercialization strategy
7	Technology of surface friction displacement of working surfaces of machine parts	4	− 1.56	[− 5.01; − 5.87]	First-level commercialization strategy

* Stages are defined according to the NASA approach [33].

Based on the R&D products that were taken to test the method, it can be applied to products of any type of economic activity, transfer method, etc. However, the use of the author's method is characterized by reservations:

1) in a situation where the chosen strategy has a marginal value (it is on the edge of the circles that determine the choice of strategies for commercialization of R&D product), decisions should be made based on the current market situation, the overall strategy of the business entity and the objective vision of the analyst;

2) to obtain reliable results when applying the correction factor of market behaviour based on the fuzzy logic toolbox (MATLAB), it is advisable to review and, if necessary, correct the set of data involved in the assessment in each evaluation situation.

4. Conclusions

The method of technological forecasting of market behaviour of R&D products at the early stages of their technological readiness is substantiated. The method is based on taking into account the strengths and weaknesses, development factors and limiting factors of the product R&D, which allows you to predict indicators of market behaviour of the product relative to the market where its commercialization is planned.

The market is characterized by an array of different types of factors that in one way or another influence the market behaviour of R&D products. Therefore, within the framework of the method of technological forecasting of market behaviour of R&D products and in order to increase the level of reliability of calculations and validity of results, a method for determining the correction factor of indicators of market behaviour of R&D product has been developed. The method is developed on the basis of fuzzy set theory algorithms using the fuzzy logic toolbox (MATLAB). This made it possible to integrate a set of data on the market behaviour of an R&D product, taking into account their relationships and interdependencies, into one correction factor. This coefficient contains the characteristics of signs of the impact of R&D product on the market (in particular, market effects, types of market changes) and the impact of market effects on R&D product (effects generated by R&D products, organizational and technological changes in R&D products). To justify the correction factor, a knowledge base was formed based on the answers of experts who have knowledge of trends, patterns and features of market development in the subject area.

To select the R&D product commercialization strategy, a system with normative indicators that interpret the types of strategies has been developed. In particular, this allowed us to offer the following types of strategies: commercialization of the zero level of R&D product; commercialization of the first level of R&D product; commercialization of the second level of R&D product.

Due to the clarification of content categories (development factors and limitations) and the introduction of a correction factor for market behaviour indicators, the results of choosing an R&D product commercialization strategy are more accurate and reliable.

The **hypothesis 1** put forward in this paper is justified. The method of justifying the indicator of market behaviour of R&D products for the purpose of technological forecasting is universal, can be applied to products of any type of economic activity,

transfer method, etc.

The method of justifying the indicator of market behaviour of R&D products for the purpose of technological forecasting can only give errors if S, W, D, and L are poorly defined, compared, and weighed. Therefore, experts are recommended to pay thorough attention to studying the features of the product and market in each evaluation situation.

Hypothesis 2 is not fully justified. The proposed correction factor for indicators of market behaviour of R&D products based on fuzzy set theory algorithms makes it possible to take into account changes in the market behaviour of products only in the short term. The characteristics of the features that this coefficient is based on can only be relevant at the time of technological forecasting. To apply such methods in the medium and long term, it is necessary to take into account the volatility and singularity of the market.

Hypothesis 3 is true. Justification of the indicator of market behaviour of R&D product based on the principles of the author's method correlates with the early stages of technological readiness of the product, since: 1) the economic content of the stages of technological readiness of R&D products was laid in the author's method of technological forecasting of market behaviour of R&D products; 2) the characteristics of the signs of the correction factor of market behaviour indicators are based on phenomena, market effects, etc., which are characteristic of R&D product at a specific stage of technological readiness.

The economic interpretation of the obtained indicators of market behaviour of R&D products and the commercialization strategies selected based on this showed the validity of the author's method and its relevance in the changing conditions of the modern market. The study of the characteristics of the features of the correction factor of market behaviour indicators is the subject of the following scientific work.

	This paper proposes an active disturbance rejection control (ADRC) design for a haptic display platform structure. The motivation for the following scheme originates from the shortcomings faced by classical proportional integral derivative (PID) controllers in control theory. The ADRC is an unconventional model-independent approach, acknowledged as an effective controller in the existence of total plant uncertainties, and these uncertainties are inclusive of the total disturbances and unknown dynamics of the plant. The design and simulation for ADRC are established in MATLAB/ Simulink. The concerned electro-mechanical platform consists of dual ball screw driving system and DC motors. This overall physical system constitutes the haptic interface. Modelling of the two-dimensional physical platform is also explained in this article. Designing of ADRC controller and the human-machine interface (HMI) is followed by their integration, in order to obtain simulation results, thus proving the practicality and validity of the overall system. The results of the proposed controller are compared with the Proportional Integral (PI) controller, which suggests that the ADRC controller performs better as compared to the conventional PI controller.

1. Introduction

This paper is an extension of work originally presented in *2020 International SAUPEC/RobMech/PRASA Conference* [1]. Haptic feedback control systems containing human- in- the- loop (HITL) is relatively a young field of research, that display the interaction between human-machine systems. A typical bilateral teleoperation system consisting of the master device (human operator), communication channel and slave teleoperator, provide human operator's necessary interface and the experience of 'telepresence' [2, 3]. In simple text, the human perceives direct control and manipulation of the environment with their own hands, which is achieved by having their actions mediated physically by means of a robot, communication channel and control systems (i.e., controller), by providing the haptic sensing feedback signals (mostly interaction forces and position constraints) to the operators. Thus, the human operator can execute tasks remotely without physically being present there. Potential applications of teleoperation systems include highly specialized professions like telesurgery, mining, micro, and nanoparticles handling and artificial intelligence to name just a few [4]. These operations are performed globally, mainly to aid and assist the population with special needs.

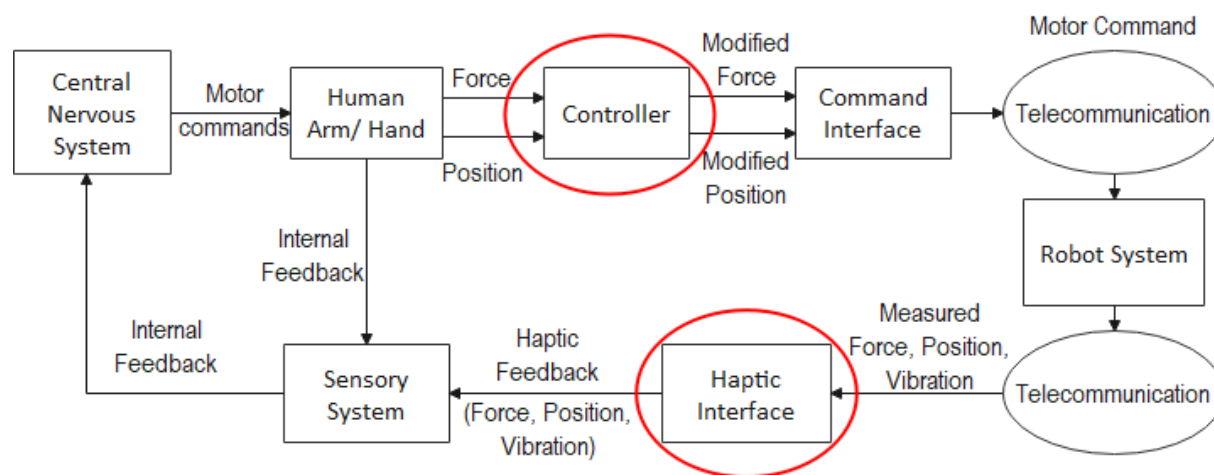
The block diagram shown in Figure 1 gives a control system viewpoint of haptic teleoperation system. The main purpose of this system is the operator's ability to interact with the remote environment via haptic feedback. In this haptic teleoperation system, a human operator gets the feel of telepresence in the form of force operation and vibrations (sensations) from the haptic interface system, for instance, a simulator. Thus, the movement of the human arm is based on the haptic feedback signals received from the haptic interface device. Accordingly, the human arm will send force and position signals to the controller (highlighted in the top red circle) which will forward the modified force and position signals to the robot system. The robot will then exert the received control signal to the concerned object present in the remote environment. The measured signals (force, position, and vibration) are then fed back to the haptic interface (highlighted in the bottom red circle) resulting in haptic feedback and HITL system. Thus, the human operator feels they are directly executing control operation of the remote side themselves.


Figure 1: Control system viewpoint of haptic teleoperation system

In teleoperation systems, stability and transparency are both critical properties and conflicting to each other [5]. One of the main concerns relating to control systems design, is to achieve a decent tradeoff between these two contrasting goals. Stability can be achieved using Proportional integral derivative (PID) controls [6], wave-variables based passivity control [7] and time-domain passivity approach [8]. Whereas transparency is related to the human operator's potential to sense the slave side interaction with the environment. To enable this, force sensors are installed at the end effector providing force feedback control. Conversely, these force sensors impose measurement limitations due to their high cost, restricted area of contact and noise/ disturbances in the environment. Hence, disturbance observers were introduced [9]. On the contrary, these observers do not consider specific knowledge of the system like unmodelled dynamics and parameter uncertainties, resulting in narrowing the effectiveness of model-based controllers. Thus, these shortcomings have motivated the application of a model independent approach in the domain of bilateral teleoperation systems. Hence, an Active disturbance rejection control (ADRC) has been proven effective to tackle the limitations of both PID and model-based approaches [10,11]. ADRC's dynamic structure components, such as, the ESO (Extended state observer) and TD (Tracking differentiator), are used to compensate for internal and external disturbance(s) respectively. Therefore, the total system from the outside looks linear. The ADRC takes into account the time-varying nature of the system, unlike the PID controller, that considers particular time instants only. References [12–14] are survey papers that review the development of ADRC from its early beginning, along with, the controller's analysis being conducted from its methodology and theoretical perspective.

This paper aims to addresses and release the above mentioned constraints related to model- based approaches in control theory. This can be attained by introducing a model free approach (ADRC controller) for the physical interface platform (HMI) developed for this research. The objective of this paper includes the study of the disturbance rejection performances and control variable responses of the ADRC and PI controllers. The former provides a

better understanding on the system response curves obtained, whereas the latter depicts more information on controller behaviour. Contributions of this paper include the algorithmic innovation of the ADRC controller and development of a controlled object that serves as a movable two- dimensional (2D) interface platform. Based on this platform, we propose an ADRC for the system shown in Figure 1. Furthermore, this paper focusses on the integration of the designed controller with the human machine interface platform, followed by their experimental analysis and comparison with the previously obtained PI controller results in [1]. This integration and analysis serves as the main focal point of the paper. Thus, by this comparison, the effectiveness of the total proposed system is measured. All the simulations will be conducted via MATLAB and Simulink in this study. Apart from MATLAB/ Simulink, experimental analysis for ADRC based applications have been conducted using other softwares, like LabView, Scilab/ Xcos and OpenPCS, to name a few.

The rest of the paper is structured in this way: Initially, the related work is briefly explained in Section 2, subsequently the proposed hardware platform is addressed in Section 3. Furthermore, Section 4 discusses the design and simulation of an ADRC controller, followed by results and discussions in Section 5. Lastly, Section 6 closes the paper.

2. Related Works

2.1. ADRC Controller

For almost a century, the PID controller has dominated the control technology to meet the ever-increasing demands of the automation industry. However, the PID controller design being system-dependent falls under the category of error-based empirical design paradigm (EDP) [11]. Tuning of such controllers is challenging due to model mismatch between the actual system and approximate model. Other challenges include computational error, noise deterioration caused by derivative control, performance degradation in the control law (linear weighted sum) and complications by integral control due to accumulation of

errors [10]. These conditions necessitated the introduction of a special type of nonlinear controller being system model-independent, called the ADRC. This controller possesses features of strong robustness, fast response speed, high accuracy control, minimum overshoot (smooth curve) and capability to estimate and compensate the overall effects of uncertainties and is thus minimized. These uncertainties include unknown plant dynamics, external disturbances and internal disturbances, in real-time. The capability to control uncertainties in a given system is one of the principal concerns in the field of modern control theory. The ADRC design was first proposed in [15], followed in 1998 [16], for plants with a large number of uncertainties. The same was introduced in [17], followed by an extension in [11]. An adequate transient response is attained using an ADRC design, which possesses a relatively simple framework.

2.1.1. Disturbance Rejection Mechanism

The existing paradigms in the field of control engineering, are the Modern Control Paradigm (MCP) (model-based approach) and error-based Empirical Design Paradigm (EDP) (classical trial and error approach) [11]. But there is a significant gap between theory and practice in the field of feedback control engineering. This calls for a paradigm shift introducing a new paradigm, namely, Disturbance Rejection Paradigm (DRC) [18].

The basic idea of ADRC can be put straight in the following train of thoughts. Firstly, cascade integral design of the canonical (ideal) configuration of the plant. Secondly, portion of the plant that is distinct from the ideal form can be called the 'total disturbance', and is rejected. This includes internal disturbance (i.e. variations in plant dynamics) and external disturbance (i.e. arises from the environment). Lastly, estimate and compensate the total disturbance using an extended state observer (ESO), so as to reduce the nonlinear time-varying system to the canonical form. In short, two main characteristics of modern control theory on which the fundamentals of ADRC are set: Firstly, the concept of canonical form; Secondly, the objective of a state observer [12]. Thus, with such a unique design concept, ADRC provides exceptional outstanding solutions to various pressing problems in the engineering field. Thus, practical applications of ADRC include robot motion control and aerial robotic systems [19], control tool for practitioners [20], control of humanoid robot [21], quadrotor helicopter [22], in several chemical processes, MEMS systems and power converters [23,24], to name a few.

2.2. Haptic Feedback Control

Over the last four decades, several bilateral teleoperation architectures were developed serving as the key technology for human interaction with the remote environment, by supplying the operator with haptic feedback. This haptic feedback control improves the quality of human-robot interaction, on the other hand, stability and transparency parameters are greatly affected due to time delay and packet loss in the communication channel, between the master side (operator) and slave side (remote robot interaction with the environment), as shown in Figure 2.
Figure 2: A basic haptic teleoperation system

Some of the important teleoperation architectures, along with their methods, studied and analysed in the past include Wave-variable (WV) approach [25,26], Time-domain passivity approach (TDPA) [27,28], and Model- mediated teleoperation (MMT) approach [29]. A detailed survey on the bilateral teleoperation algorithms and model-based control architectures for haptic interfaces is given in [3]. Such model-based methods represent input-output relationships using mathematical expressions, like the state-space model, Lagrange model, and transfer function model. They are also represented using various control laws, for example, the proportional integral (PI), proportional derivative (PD), PID, model predictive, sliding mode, and energy-based controllers [8,30].

The haptic teleoperation system control and design experience certain shortcomings, such as, uncertainties related to the communication channel and human operational dynamics, along with unsteady human operator decisions [31]. These uncertainties are time-varying and distinctive among individuals. Such inaccuracies make the model-based controller operation challenging and stimulate the use of model-free controllers, like the ADRC for smooth operations [10]. Thus, ADRC can contribute to the development of applications in connection with feedback control systems in man- machine interface systems. Recent studies on ADRC controller for teleoperation systems based on distinct parameters, and for nonlinear systems, have been explained in [32] and [33,34] respectively.

3. Hardware design and modelling

3.1. Proposed Hardware Platform

The basic idea behind the platform shown in Figure 3, is to manoeuvre the operating handle in a rectangular coordinate system.
Figure 3: Experimental setup of the assembled hardware platform- 2 degree of freedom (2 DOF)

3.1.1. Mechanical components of the HMI design

Mechanical and electrical components constitute the experimental platform. The mechanical components used are stated in this subsection. The operating handle is a three-dimensional (3D) printed object, obtained using a designing software called Onshape. Both X-axis and Y-axis have a ball screw feed drive system (SFU1605) aligned parallel to each of the axis, with the operating handle assembled over the lead screw system. The ball-lead screws and nut dimensions are 600mm (length) x 16mm (diameter) x 5mm (pitch). Ball screw nuts provide the required linkage between the lead screws and the operating handle. Hence, ball lead-screw's rotational motion is transformed to operating handle's linear translation motion. As seen in Figure 3, two pairs of linear guide rails of dimensions 600mm (length) x 4mm (width) hold up the handle and screws. The guide rails used are called the Igus W series (WS-10-40-600), which possess benefits like low wear and tear, low friction, low noise system, and requires no maintenance being resistant to dust and dirt. The 3D printed carriages that firmly hold both ends of the lead screws, together with the sliding rails, are all mounted on a levelled surface. The end supports used for the ball screw (SFU16XX - BK 12 + BF 10) contains two parts, one for the front and the other for the rear of the lead screw. The fixed part is 10mm in diameter, whereas the floating part is 12mm in diameter. Also includes circlips and deep groove ball bearings. A DC motor mounted on one end-support component, and the motor shaft mechanically connected to the lead screw, help to drive the lead screw system.

3.1.2. Electrical components of the HMI design

The electrical components used in the experimental setup are explained in this subsection. As seen in Figure 3, a DC motor shaft equipped with an encoder is incorporated at one end of both the lead screws. The motors chosen are called the Metal Gearmotor 75:1 (gear ratio), with a 48 CPR quadrature encoder integrated on each motor, which provides 3592 counts per revolution of the gearbox's output shaft. Size of the motor is 25mm (diameter) x 66mm (length), with a shaft diameter of 4mm. These motors are intended for comfortable operation in the 3- 9V range. The encoders are connected to the Arduino MEGA 2560 board. Both motors are provided with a specific motor driver called the BTS7960 High Power H- Bridge motor driver. The motor driver has the following specifications, 43A of maximum current and input voltage range of 6V to 27V. According to the inout voltage received from the Arduino board, the motor drivers will adapt to these incoming signals, and then apply the appropriate voltage to the motor. The system contains two ACS714 current sensors, one for each motor driver, to aid in measuring the strength applied on the operating handle.

On accomplishing the hardware installation, signal transmission between MATLAB and the proposed interface system (HMI) was performed using Arduino 2560. This Arduino board was powered by an external power supply. Currently, only a single axis movement of the lead screw drive system is considered in this paper.

3.2. Mathematical Modelling of the Assembled Hardware Platform

Two of the single-axis electro-mechanical platform shown in Figure 3 are coupled together to implement the 2D movement. Torque (T_M) generated by the DC motor is transmitted to the ball screw shaft via coupling, which in turn causes the operating handle to move. Transmission ratio 'i' of ball screw system is defined as the distance travelled 'h' during one revolution of the shaft [35], also denotes, the transformation of rotational movement of screw shaft into linear motion of the operating handle. 'i' is given by the following equation,

$$i = {}^h\!/_{2\pi} \tag{1}$$

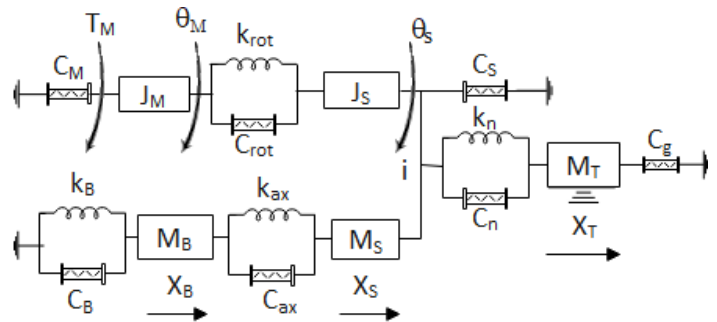
The lumped mass model (LMM) developed in [35,36] is adopted to derive the mathematical model for this structure. Such a model indicates several functions related to the system, by simplifying the simulation model to a reduced number of DOF system. As seen in Figure 4, all the rigidity parameters (k), inertial components (M), and damping parameters (c) are denoted in terms of axial and rotational components of the same parameter, i.e., total rotational and axial rigidity components, represented as (k_{rot}) and (k_{ax}) respectively.


Figure 4: The LMM of the recommended HMI platform

The LMM parameters in Figure 4 consists of screw shaft rotary inertia J_S, base mass M_B, motor inertia J_M, screw shaft side equivalent mass M_S, handle mass M_T, equivalent torsional rigidity k_{rot}, ball screw nut rigidity k_n, axial base rigidity k_B, equivalent axial rigidity k_{ax}, DC motor torsional damping C_M, equivalent rotational damping C_{rot}, sides screw shaft damping C_S, ball screw nut damping C_n, axial guide damping C_g, axial base damping C_B, and equivalent axial damping C_{ax}.

Parameters (DOF) of the model shown in Figure 4 include,

θ_M- Angular rotation of the DC motor

θ_S- Angular rotation of screw shaft at handle position

X_B- Axial base displacement

X_S- Axial displacement of the screw shaft at handle position

X_T- Operating handle position

Equation 2 represents the mathematical model of a DC motor,

$$\dot{T}_M = \frac{-K_{bm}K_t}{L_a}\dot{\theta}_M - \frac{R_a}{K_t}T_M + \frac{K_t}{L_a}E_a \tag{2}$$

where, K_t and K_{bm} denote motor torque and back emf constants, L_a is winding leakage inductance, $\dot{\theta}_M$ is the angular velocity of the

rotor inside motor, E_a is the voltage source, and R_a is the armature resistance. References [1,36] provide a detailed step by step Lagrange and state-space mathematical modelling for the physical structure in Figure 4.

3.2.1. Lagrange Model

Second order Lagrange's equations are employed to develop the ball screw feed drive system's dynamic model. Lagrange function is defined by the variation between kinetic and potential energies of a physical system. Equation (3) gives the mathematical relations for total kinetic energy (T), potential energy (U) and dissipation function (D), associated with the total system.

$$\begin{cases} T = \frac{1}{2}J_M\dot{\theta}_M^2 + \frac{1}{2}J_S\dot{\theta}_S^2 + \frac{1}{2}M_B\dot{X}_B^2 + \frac{1}{2}M_S\dot{X}_S^2 + \frac{1}{2}M_T\dot{X}_T^2 \\ U = \frac{1}{2}k_{rot}(\theta_M - \theta_S)^2 + \frac{1}{2}k_B X_B{}^2 + \frac{1}{2}k_{ax}(X_S - X_B)^2 + \frac{1}{2}k_n(X_T - X_S - i\theta_s)^2 \\ D = \frac{1}{2}C_M\dot{\theta}_M^2 + \frac{1}{2}C_{rot}(\dot{\theta}_M - \dot{\theta}_S)^2 + \frac{1}{2}C_S\dot{\theta}_S^2 + \frac{1}{2}C_B\dot{X}_B^2 + \frac{1}{2}C_{ax}(\dot{X}_S - \dot{X}_B)^2 + \frac{1}{2}C_n(\dot{X}_T - \dot{X}_S - i\dot{\theta}_s)^2 + \frac{1}{2}C_g\dot{X}_T^2 \end{cases} \quad (3)$$

Lagrange equation, $L = T - U = \frac{1}{2}J_M\dot{\theta}_M^2 + \frac{1}{2}J_S\dot{\theta}_S^2 + \frac{1}{2}M_B\dot{X}_B^2 + \frac{1}{2}M_S\dot{X}_S^2 + \frac{1}{2}M_T\dot{X}_T^2 - \frac{1}{2}k_{rot}(\theta_M - \theta_S)^2 - \frac{1}{2}k_B X_B{}^2 -$
$$\frac{1}{2}k_{ax}(X_S - X_B)^2 - \frac{1}{2}k_n(X_T - X_S - i\theta_s)^2 \quad (4)$$

Equation (5) represents the Lagrangian function of a system. This function is calculated about force 'Q' and the generalized coordinate 'q'.

$$\frac{d}{dt}\left(\frac{\partial L}{\partial \dot{q}}\right) - \frac{\partial L}{\partial q} - \frac{\partial D}{\partial \dot{q}} = Q \quad (5)$$

Coordinates 'q' and 'Q' indicate independent coordinates and force inputs to the physical system respectively, given by the following relations in (6),

$$\begin{cases} q = (\theta_M \ \theta_S \ X_B \ X_s \ X_T)^T \\ Q = (T_M \ 0 \ 0 \ 0 \ 0)^T \end{cases} \quad (6)$$

On solving (4) using (5) and (6), the following set of equations were obtained,

$$\begin{cases} J_M\ddot{\theta}_M + k_{rot}(\theta_M - \theta_S) + C_M\dot{\theta}_M + C_{rot}(\dot{\theta}_M + \dot{\theta}_S) = T_M \\ J_S\ddot{\theta}_S - k_{rot}(\theta_M - \theta_S) - ik_n(X_T - X_S - i\theta_S) + C_S\dot{\theta}_S + C_{rot}(\dot{\theta}_M + \dot{\theta}_S) + iC_n(\dot{X}_T + \dot{X}_S + i\dot{\theta}_S) = 0 \\ M_B\ddot{X}_B + k_B X_B - k_{ax}(X_S - X_B) + C_B\dot{X}_B + C_{ax}(\dot{X}_S + \dot{X}_B) = 0 \\ M_S\ddot{X}_S + k_{ax}(X_S - X_B) - k_n(X_T - X_S - i\theta_S) + C_{ax}(\dot{X}_S + \dot{X}_B) + C_n(\dot{X}_T + \dot{X}_S + i\dot{\theta}_S) = 0 \\ M_T\ddot{X}_T + k_n(X_T - X_S - i\theta_S) + C_n(\dot{X}_T + \dot{X}_S + i\dot{\theta}_S) + C_g\dot{X}_T = 0 \end{cases} \quad (7)$$

After rearranging the terms in (7), a set of five equations are obtained, that is given in (8). Based on these equations, the Simulink model is built on the MATLAB software, this software-based mathematical model is displayed in Figure 5.

$$\begin{cases} \ddot{\theta}_M = \frac{1}{J_M}[T_M - k_{rot}(\theta_M - \theta_S) - \dot{\theta}_M(C_M + C_{rot}) - C_{rot}\dot{\theta}_S] \\ \ddot{\theta}_S = \frac{1}{J_S}[-\dot{\theta}_S(C_{rot} + C_S + i^2 C_n) - \theta_S(k_{rot} + i^2 k_n) - C_{rot}\dot{\theta}_M + k_{rot}\theta_M + ik_n X_T - ik_n X_S - iC_n\dot{X}_T - iC_n\dot{X}_S] \\ \ddot{X}_B = \frac{1}{M_B}[-X_B(k_{ax} + k_B) + k_{ax}X_S - C_{ax}\dot{X}_S - \dot{X}_B(C_B + C_{ax})] \\ \ddot{X}_S = \frac{1}{M_S}[k_{ax}X_B - X_S(k_{ax} + k_n) + k_n X_T - ik_n\theta_S - C_{ax}\dot{X}_B - \dot{X}_S(C_{ax} + C_n) - C_n\dot{X}_T - iC_n\dot{\theta}_S] \\ \ddot{X}_T = \frac{1}{M_T}[-k_n X_T - \dot{X}_T(C_n + C_g) + k_n X_S + ik_n\theta_S - C_n\dot{X}_S - iC_n\dot{\theta}_S] \end{cases} \quad (8)$$

LMM of the proposed design, is given in matrix form by the following relation in (9),

$$m\ddot{q} + c\dot{q} + kq = Q \quad (9)$$

Equations (10), (11) and (12) indicate the values for matrices m, k and c respectively. These matrix values are acquired from (7).

$$m = \begin{bmatrix} J_M & 0 & 0 & 0 & 0 \\ 0 & J_S & 0 & 0 & 0 \\ 0 & 0 & M_B & 0 & 0 \\ 0 & 0 & 0 & M_S & 0 \\ 0 & 0 & 0 & 0 & M_T \end{bmatrix} \quad (10)$$

$$k = \begin{bmatrix} k_{rot} & -k_{rot} & 0 & 0 & 0 \\ -k_{rot} & (k_{rot}+i^2 k_n) & 0 & i k_n & -i k_n \\ 0 & 0 & (k_B+k_{ax}) & -k_{ax} & 0 \\ 0 & i k_n & -k_{ax} & (k_{ax}+k_n) & -k_n \\ 0 & -i k_n & 0 & -k_n & k_n \end{bmatrix} \tag{11}$$

$$c = \begin{bmatrix} (C_M+C_{rot}) & C_{rot} & 0 & 0 & 0 \\ C_{rot} & (C_{rot}+C_S+i^2 C_n) & 0 & i C_n & i C_n \\ 0 & 0 & (C_B+C_{ax}) & C_{ax} & 0 \\ 0 & i C_n & C_{ax} & (C_{ax}+C_n) & C_n \\ 0 & iC_n & 0 & C_n & (C_n+C_g) \end{bmatrix} \tag{12}$$

3.2.2. State-Space Model and Transfer Function

Matric values given in (10-12), are substituted in (13), to provide the state-space representation of system model.

$$\ddot{q} = \frac{1}{m}(Q - c*\dot{q} - k*q) \tag{13}$$

For the state-space model, we first determine the number of states. In this experiment, each of the five equations in (7) are second-order differential equations, i.e, each equation will include at least two states.

State-state model is represented as, $\dot{x} = Ax + Bu$ and $y = Cx + Du$. In this system A is (11x11) matrix, B is (11x1) matrix, C is (1x11) matrix and D matrix is 0.

Equations (14) and (15) represent the State- space model and Transfer function of the system.

$$\dot{X} = \begin{bmatrix} \frac{-(C_M+C_{rot})}{J_M} & \frac{-k_{rot}}{J_M} & \frac{-C_{rot}}{J_M} & \frac{k_{rot}}{J_M} & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ \frac{-C_{rot}}{J_S} & \frac{k_{rot}}{J_S} & \frac{-(C_{rot}+C_S+i^2 C_n)}{J_S} & \frac{-(k_{rot}+i^2 k_n)}{J_S} & 0 & 0 & \frac{-i C_n}{J_S} & \frac{-i k_n}{J_S} & \frac{-i C_n}{J_S} & \frac{i k_n}{J_S} & 0 \\ 0 & 0 & 1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & \frac{-(C_B+C_{ax})}{M_B} & \frac{-(k_B+k_{ax})}{M_B} & \frac{-C_{ax}}{M_B} & \frac{k_{ax}}{M_B} & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 1 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & \frac{-i C_n}{M_S} & \frac{-i k_n}{M_S} & \frac{-C_{ax}}{M_S} & \frac{k_{ax}}{M_S} & \frac{-(C_{ax}+C_n)}{M_S} & \frac{-(k_{ax}+k_n)}{M_S} & \frac{-C_n}{M_S} & \frac{k_n}{M_S} & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 1 & 0 & 0 & 0 & 0 \\ 0 & 0 & \frac{-i C_n}{M_T} & \frac{i k_n}{M_T} & 0 & 0 & \frac{-C_n}{M_T} & \frac{k_n}{M_T} & \frac{-(C_n+C_g)}{M_T} & \frac{-k_n}{M_T} & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 1 & 0 & 0 \\ \frac{-K_{bm}K_t}{L_a} & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & \frac{-R_a}{L_a} \end{bmatrix} X + \begin{bmatrix} 0 \\ 0 \\ 0 \\ 0 \\ 0 \\ 0 \\ 0 \\ 0 \\ 0 \\ 0 \\ \frac{K_t}{L_a} \end{bmatrix} E_a \tag{14}$$

$$Y = [\,0\,0\,0\,0\,0\,0\,0\,0\,0\,1\,0\,]X \tag{15}$$

where $X = [\,x_1\,x_2\,...\,x_{11}\,]$. The output is the operating handle position (X_T), which is assigned to the state variable x_{10}.

The transfer function (G) stated in (16) is obtained from the state-space model by using the following MATLAB codes,

```
Sys = ss(A,B,C,D);G= tf(Sys)
```

$$G = \frac{0.001122\,s^6 - 1.1*10^8 s^5 + 3.453*10^{12}s^4 - 7.294*10^{14}s^3 + 2.29*10^{19}s^2 - 1.896*10^{19}s + 5.954*10^{23}}{\substack{s^{11} + 407.7s^{10} + 1.817*10^7 s^9 + 7.334*10^9 s^8 + 4.094*10^{13}s^7 + 1.552*10^{16}s^6 + 9.493*10^{18}s^5 + 3.353*10^{21}s^4 + \\ 3.329*10^{23}s^3 + 7.323*10^{25}s^2 + 3.045*10^{27}s + 1.138*10^{16}}} \tag{16}$$

The Controllability and Observability of the system can be obtained from its state- space model in (14). The Controllability matrix (C_M) and Observability matrix (O_M) were calculated using the following MATLAB commands, '$ctrb(A,B)$' and '$obsv(A,C)$' respectively. Both the matrices were found to be invertible with their determinant values not equal to zero. Thus, this shows that the system is controllable and observable.
Figure 5: Simulink Block of the concerned Haptic Machine Interface (hardware platform)

4. Algorithm and Simulink Modelling of ADRC

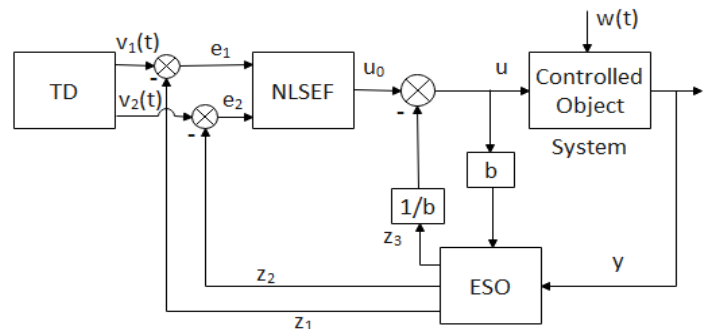
ADRC originates from the classical PID controller, retaining the central idea of error feedback control. The drawbacks of the PID controller are overcome by the significant dynamic structure of ADRC. As seen in Figure 6, an ADRC architecture is composed of three parts, namely, the Tracking Differentiator (TD), Extended State Observer (ESO) and Nonlinear State Error Feedback (NLSEF). Each of the subsystems is explained here, followed by their Simulink model created on MATLAB.


Figure 6: Basic ADRC structure of a two- order system
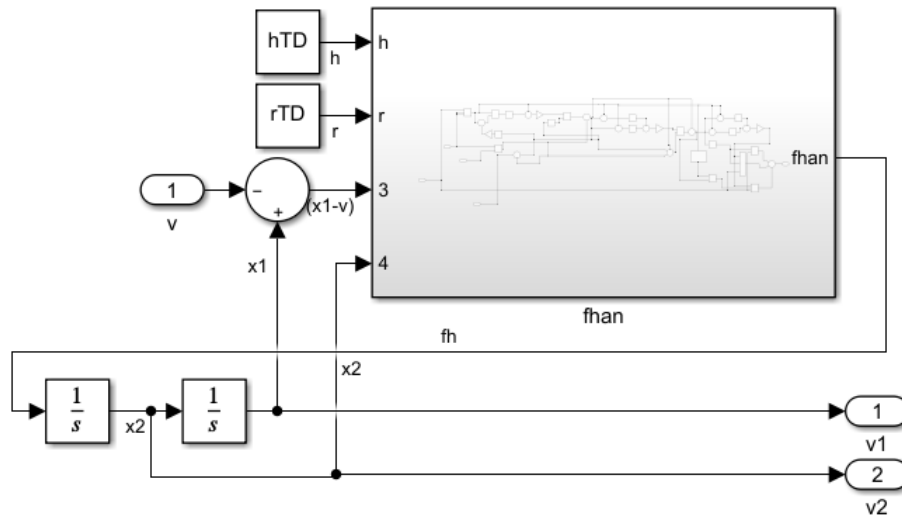

Figure 7: Simulink Model of TD subsystem

Definitions of parameters used for ADRC design: $v_1(t)$ or v_1 is the tracking signal, and $v_2(t)$ or v_2 is the differential signal of the given input signal. The output signal of the system and input signal of ESO is given by 'y'. u is called the control volume, it is the input signal of the controlled object and the ESO. z_1 and z_2 are variables of the estimated state. z_3 is the estimated signal of the total disturbance, i.e., both internal disturbance and the external interference present. $w(t)$ is the external disturbance acting on the concerned system. e_1 and e_2 are the error signals fed to the NLSEF.

$$\begin{cases} e_1 = v_1 - z_1 \\ e_2 = v_2 - z_2 \end{cases} \tag{17}$$

4.1. Tracking Differentiator (TD)

TD determines the transition process for the system input, in order to obtain a smooth input signal $v_1(t)$ which is the desired trajectory and its differential signal $v_2(t)$. Consider the input signal $v(t)$ is to be differentiated, thus, TD provides the fastest tracking $v(t)$ given by (18). By solving the following differential equation, the required transient profile is obtained.

$$\begin{cases} \dot{x}_1 = x_2 \\ \dot{x}_2 = -r\, sign(x_1 - v(t) + \frac{x_2\,|x_2|}{2r}) \end{cases} \tag{18}$$

The parameter r is chosen according to the speed of the transient profile, i.e., to expedite or moderately slow down the transient profile. v is the desired value for x_1. The Simulink model of TD is shown in Figure 7, wherein $fhan$ is a nonlinear function denoted as $fhan(x_1 - v, x_2, r, h)$. h is the simulation step, also called the sampling period.

$$fh = fhan(v_1 - v, v_2, r_0, h_0) \tag{19}$$

The function $fhan$ is presented later in this paper. Equation (19) is a time-optimal solution provides no overshoot and fastest

convergence from v_1 to v. Parameters r_0 and h_0 are equated to r and h respectively [10].

4.2. Nonlinear State Error Feedback (NLSEF)

The control law of PID controller implements a linear combination of the present, past and future predictive kinds of the tracking error. For an infinite time, the tracking error attains zero value for linear feedback systems. Whereas, for a nonlinear feedback function given in (20), the error can reach zero value much earlier in a finite time ($\alpha < 1$). Such a mechanism significantly alleviates the steady-state error in comparison to an integral control [10]. Thus, in an ADRC control framework, the nonlinear feedback functions fal and $fhan$ play a significant role during operation.

$$fal(x, \alpha, d) = \begin{cases} \frac{x}{d^{1-\alpha}}, |x| \le d \\ |x|^\alpha sign(x), |x| > d \end{cases} \tag{20}$$

The Simulink model of NLSEF seen in Figure 8, has been developed using the mathematical relations from (20-23).

$$u = k_0 e_0 + fhan(e_1, c * e_2, r, h_0) \tag{21}$$

Parameter c denotes the damping coefficient. And function $fhan(x_1, x_2, r, h)$ is represented using the following set of equations [37],

$$fhan = -r\left(\frac{a}{d} - sign(a)\right) s_a - r sign(a) \tag{22}$$

where,

$$s_a = \frac{[sign(a + d) - sign(a - d)]}{2} \tag{23}$$

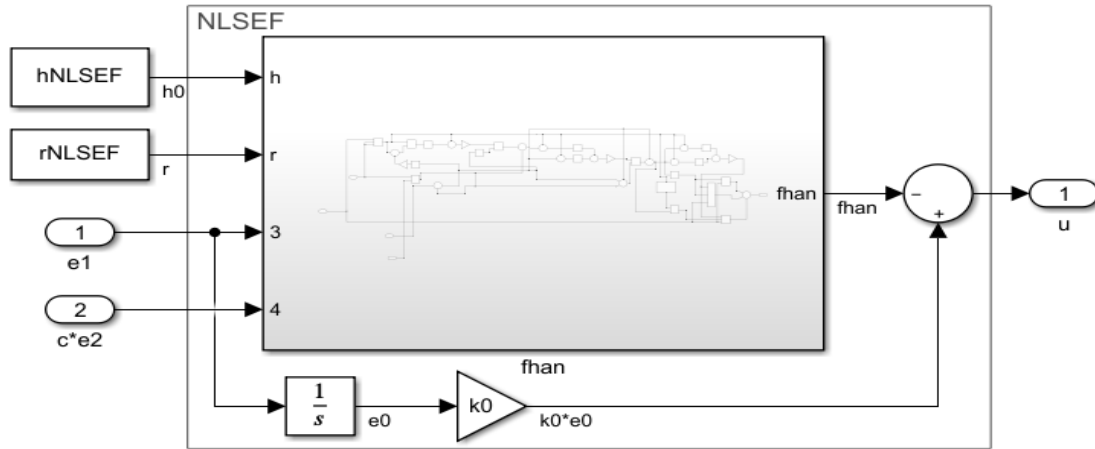
$$\begin{cases} a = (a_0 + y - a_2)s_y + a_2 \\ d = rh^2 \\ a_0 = hx_2 \\ y = x_1 + a_0 \\ a_2 = a_0 + [sign(y)(a_1 - d)/2] \\ s_y = [sign(y + d) - sign(y - d)]/2 \\ a_1 = \sqrt{d(d + 8|y|)} \end{cases} \tag{24}$$


Figure 8: Simulink Model of NLSEF subsystem

4.3. Extended State Observer (ESO)

ESO estimates full system states and the total effect of disturbances (or extended states) in real-time. These disturbances may arise from unknown or nonlinear system dynamics of the manipulator, external disturbances, and mismatch of control parameters. Thus, in robot control, ESO present in the feedback loop is used to estimate and cancel the effects of these uncertainties. Figure 9 gives a detailed Simulink model of the ESO block. This subsystem constitutes of the nonlinear feedback function fal defined in (20). The algorithm for ESO is characterized as follows [37,38]:

$$\begin{cases} fe_1 = fal(e, 0.25, h) \\ fe = fal(e, 0.5, h) \end{cases} \tag{25}$$

$$\begin{cases} e = z_1 - y \\ \dot{z}_1 = z_1 + h(z_2 - \beta_{01}e) \\ \dot{z}_2 = z_2 + h(z_3 - \beta_{02}fe + b_0u) \\ \dot{z}_3 = z_3 + h(-\beta_{03}fe_1) \end{cases} \tag{26}$$

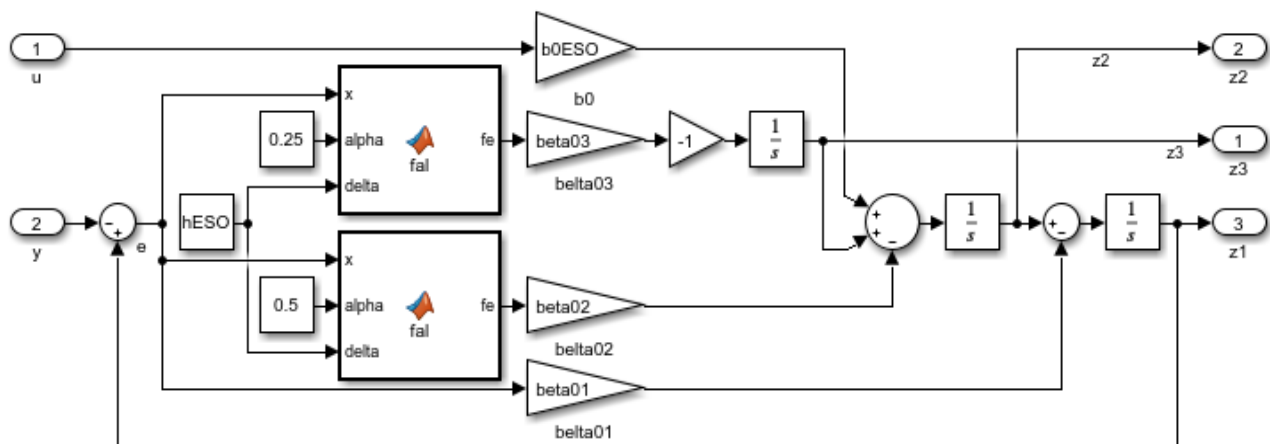
where, $\beta_{01}, \beta_{02}, \beta_{03}$ are parameters of ADRC that can be obtained from the system's sampling step. Thus, four main parameters to be controlled are, simulation step (h), control gain (r), damping coefficient (c) and compensation factor (b_0).


Figure 9: Simulation Model of ESO subsystem
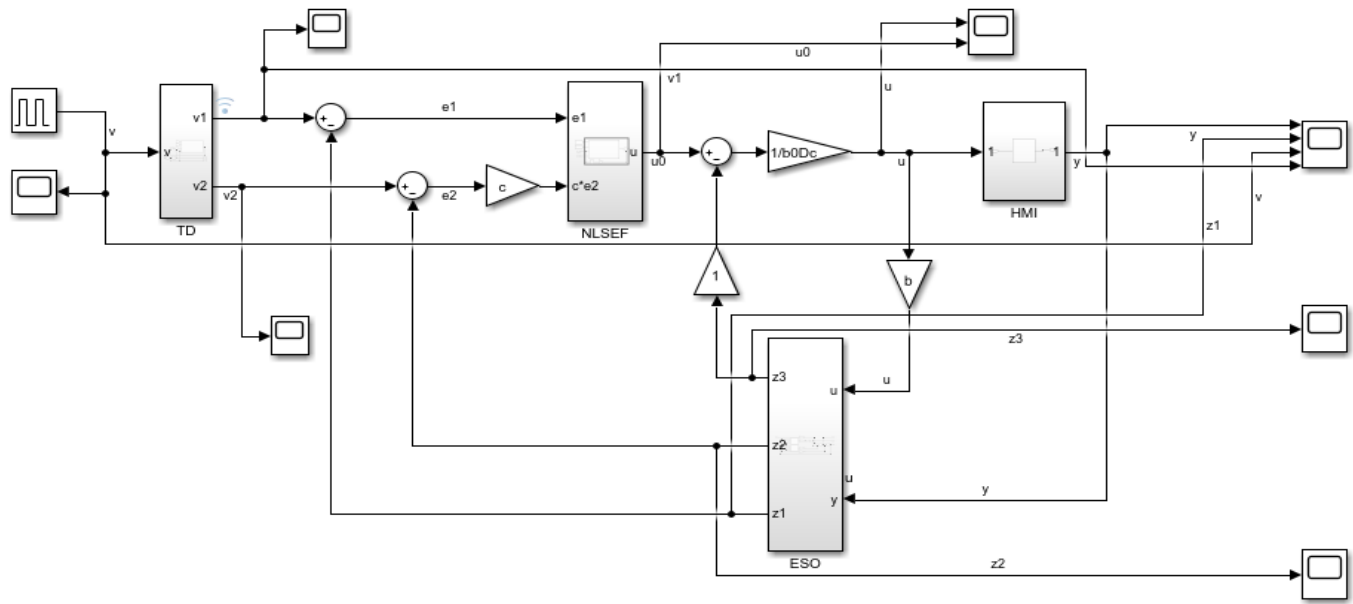

Figure 10: Simulink model of ADRC system including the HMI as the Controlled object

4.4. Controlled Object

The integration of TD structure, with the NLSEF structure, followed by the nonlinear ESO structure (which provides total disturbances estimation and rejection), altogether constitute the ADRC system. This controller is integrated with the HMI system. The Simulink model of HMI shown in Figure 5, is called the Controlled object in the ADRC system as seen in Figure 10.

5. Results and Discussions

5.1. Validation of the consistence between the physical interface system and the Simulink model

Figure 11 depicts the output response of the proposed physical system with PI controller, and Figure 12 depicts the LMM's response executed via MATLAB and Simulink.
Figure 11: Output response of handle position from the physical system

As seen in Figures 11 and 12, except for the magnitude, output response curves obtained from the physical interface platform and from the Simulink model respectively, are found to be similar. Dissimilarity in magnitude is mainly because, firstly, the units of the Y-coordinates are distinct. Secondly, it is difficult to measure

the lumped parameter values of the physical platform. Thus, the proposed platform's parameter values are slightly different from the simulation model values (i.e. designed via Simulink). Yet the simulation model substantiated the fundamental characteristic of the recommended HMI platform. The parameter values that were used in the Simulink model are listed in Table 1.
Figure 12: Output response of the Handle position (X_T) from Simulink model

Table 1: Parameter values of HMI used in Simulink Model

Parameters	Value
J_M	$6.75 * 10^{-3} (kg \cdot m^2)$
J_S	$1.7 * 10^{-3} (kg \cdot m^2)$
M_B	$3820 (kg)$
M_S	$11.28 \ (kg)$
M_T	$206 (kg)$
k_{rot}	$3.14 * 10^3 (N \cdot m \cdot rad^{-1})$
k_n	$9.8 * 10^7 (N \cdot m^{-1})$
k_B	$1 * 10^8 (N \cdot m^{-1})$
k_{ax}	$0.743 * 10^8 (N \cdot m^{-1})$
C_M	$0.001 (N \cdot s \cdot m^{-1})$
C_{rot}	$0.1 (N \cdot s \cdot m^{-1})$

C_n	$0.001\ (N \cdot s \cdot m^{-1})$
C_S	$0.001\ (N \cdot s \cdot m^{-1})$
C_B	$0.1\ (N \cdot s \cdot m^{-1})$
C_{ax}	$0.001\ (N \cdot s \cdot m^{-1})$
C_g	$0.001\ (N \cdot s \cdot m^{-1})$
L_a	$1.5 * 10^{-3}(H)$
R_a	$0.5\ (\Omega)$

K_{bm}	$0.05\ (V \cdot rad^{-1} \cdot s^{-1})$
T	$0.01\ (s)$
i	$7.96 * 10^{-4}(m \cdot rad^{-1})$

5.2. Disturbance rejection performance of the designed ADRC controller and comparison with PI controller

Experimental analysis of the comparison between ADRC and PI controllers is based on the following performance indices, that is, the system response obtained in the vicinity of disturbance present in the motor voltage, and controller variable values of both the controllers. The volatage unstability in the motor is one of the primary disturbance to the control system. In this experiment, the disturbance on the voltage supply to the motor is added to validate the disturbance rejection performance of the designed ADRC and PI controllers. The disturbance is added at the 5th second with an amplitude of 5000mV and lasting 0.2s, as shown in Figure 13.

Figure 14 shows the system response of the system controlled by ADRC and PI controllers. For the sake of fair comparison, the ADRC and PI controllers are tuned to have similar overshoot values. From Figure 14, one can find the system response with ADRC (Figure 14(a)) goes back to the reference value quickly after the overshot, however, the PI controller takes longer time to

do so. Both system responses are affected by the disburance (starting from 5s in Figure 14), but the ADRC controlled system gets much smaller shift from the reference value than the PI controller.

Figure 15 demonstrates the control variable values of the two controllers, which depicts more details on controller behaviour. From Figure 15(a), one finds the ADRC controller starts with a mild control at the beginning due to the soften effect obtained in the tracking differentiator, which makes a smaller peak value on the control (Figure 15(a)). When the disturbance happens, the designed ADRC depresses the shift from reference value greatly, which leads to only a small change on the system response (refer to Figure 15(a)) from 5s. The PI controller is much more rigid when compared with the designed ADRC, which makes the controller start with an aggressive control (Figure 15(b)) at the beginning, and bigger shift from the reference value after the disturbance (refer to Figure 15(b)) from 5s.

These advantages of the system response controlled by ADRC can be explained in Figure 16, i.e. the total disturbances estimated by the ADRC. From Figure 16, one finds at the beginning of the control, the intial stage of the input step signal is considered as a disturbance (around 0s in Figure 16) which is compensated to obtain a soft rise of the system. This is obtained by the TD. When the disturbance occurs (around 5s in Figure 16), it is considered as disturbance (z_3 in (26)) as well and is compensated accordingly. Now the ESO observes the disturbance, and is compensated to the control variable generated by the NLSEF. This mechanism is shown in Figure 10. Thus, this disturbance rejection property of ADRC controller makes it unique in operation as compared to the PI controller.

6. Conclusions and Future work

The shift of feedback control paradigm design has been extensively studied over the past few decades. With a huge potential of disturbance rejection control method, this paradigm shift will play a critical role in the migration from the primitive PID controller to an ADRC. A PID controller passively responds to disturbances, causing zone oscillations. But on the other hand, ADRC actively rejects disturbances, delivering a smooth control system. In an ADRC, the unmeasurable states and total disturbances are actively compensated by the ESO present in the feedback loop. Whereas TD effectively acquire the continuous and differential form of signals from a measurement signal containing random noise, or from a discontinuous signal. It is easy to tune the parameters of TD due to its model independence property. The nonlinear feedback combination (NLSEF) of the two nonlinear functions play a significant role in this recently proposed control framework. Thus, considering the system parameters and model uncertainties, ADRC shows higher tolerance with merits of simple and intuitive model-free control design methods. Along with, it needs less energy in control in comparison to other control strategies.

This paper gives a detailed step by step design and mathematical modelling of the proposed HMI system developed for the research. After installation of the mechanical and electrical hardware components, Lagrange equations were derived based on the LMM of the system. An ADRC controller was designed and integrated with the haptic display platform Simulink model. Simulation studies were conducted to illustrate the efficiency and robustness of the ADRC controller.

However, up to date, debates and inconsistencies on the new paradigm concept still exist, and reports and validation on the successful integration of ADRC into the field of control theory are quite limited. This work pushes the realms of ADRC integration with actual physical plants for practical applications, and potentially opens up new realms constituting of new control laws formulated through experimentation.

Future research of this project will include the analysis of ADRC controller for a two-axis ball screw driving system dealing with time delay, and coupling between the two axes of the experiment. This analysis will be conducted with the modelling environment created on MATLAB/ Simulink.

	Classic surgical skill evaluation is performed by an expert surgeon examining an apprentice in a hospital operating room. This method suffers from being subjective and expensive. As surgery becomes more complex and specialized, there is an increase need for an automated surgical skill evaluation system that is more objective and determines more exactly the skills (or lack thereof) the apprentice has. The main purpose of our proposed approach is to use an existing skill database with known proficiency levels to evaluate the skills of a given apprentice. The skill of the apprentice will be assessed to be similar to the closest skill example found in the database (case-based reasoning). A key element of the system is the skill distance measure employed, as each skill example is a multidimensional time series (sequence) with widely varying values. In this paper, we discuss a new surgery skill distance measure denoted as Procrustes dynamic time warping (PDTW). PDTW integrates the search for exact alignment between two skill sequences using DTW and Procrustes distance as a measure for the similarity. The Procrustes approach is a shape distance analysis that involves rotation, scaling, and translation. We evaluated our proposed distance on three surgical motion data, a widely used JIGSAWS robot surgery dataset, a wearable sensor dataset, and a Vicon motion system dataset. The results showed that the proposed framework produced a better performance for surgeon skill assessment when PDTW was used compared to other time series distances on all three datasets. Also, some experimental results for the JIGSAWS dataset outperformed existing deep learning-based methods.

1. Introduction

This paper is an extension of work initially presented in the E-Health and Bioengineering Conference (EHB) [1] . Recently, the need for objective surgical skills assessment has captured the interest of practitioners and medical institutions due to the ever-increasing complexity and degree of specialization of the surgical procedure [2]. Traditionally, a senior expert surgeon performs direct observation, scores, assess, and gives feedback to the trainee surgeon (apprentice) with less practice in the hospital operating room. This traditional surgical proficiency evaluation approach is problematic due to its subjectivity, time consumption and cost. Furthermore, it is prone to errors and sometimes insufficient as

lacking details related to deficiencies. To address these difficulties, an automated skill assessment procedure is needed for an objective and detailed measure of proficiency levels [3, 4].

As any healthcare domain, surgery is continuously changed by technological advances and medical innovations that alter everyday surgical procedures. The challenge is to assist surgical procedure via the quantifiable data analysis to a better understanding of the surgical operating and to obtain more knowledge about human activities during surgery for advance and further study [5]. A reasonable solution to these challenges is to use technological advances like Robotic Minimally Invasive Surgery (RMIS) that improve overall operating room efficiency [5]. For instance, da Vinci surgical technology provides data-driven that potentially helps optimize and develop training skills

* Corresponding Author: Safaa Albasri, University of Missouri, USA.
saaxfc@mail.missouri.edu

for surgeons [6]. This information includes kinematic and video data that conduct a useful resource of quantifiable human motion during surgical operating [7, 8]. Wearable sensing devices that provide detailed motion information for surgical activities are a further example [9]. These recorded data give spacious resources to assess surgical proficiencies by modeling and analyzing descriptive mathematical approaches. The emergence of using machine learning methods with recent robotic surgery systems such as da Vinci and wearable sensing devices via data-driven enable and encourage developers to build and analyze automatic models for evaluating surgeon expertise and may help better coaching potential apprentices [10–12] .

Different earlier works focused on the automated surgical assessment seen good progress. The current techniques for objective surgical evaluation can be divided into three main research areas [10, 13]: 1) surgeon skill assessment, 2) surgical task analysis, and 3) surgemes recognition. These methods considered the surgeon movement using either: 1) kinematic information recorded by a robotic surgical system, 2) video records and 3) wearable sensors data. In this paper, we focused on the surgical skill evaluation based on kinematic and wearable sensors information. One of the initial works used Hidden Markov models (HMM) [14] to evaluate the surgical skills. This approach is structured-based and depends on the number of training samples, tuning parameters and it takes massive pre-processing. This type of model needs complicated preprocessing [3] and leads to low performance with a low number of samples [14]. Another method was proposed by [3] to predict the surgeon skill level (expert and novice) based on movement features of the surgical arms using logistic regression (LR) and support vector machines (SVM) classifiers for suturing surgical task. They extended their work to include eight global movement features (GMF) in [15], they applied LR, SVM, and kNN classifier to distinguish between the previous expertise levels for suturing and knot tying surgical tasks. In [16], a framework based on trajectory shape using DTW and k-nearest neighbor classifier proposed for surgical skill evaluation. This model can also provide online performance feedback through training. More recently, [13] proposed an approach based on symbolic aggregate approximation (SAX) and vector space model (VSM) to identify distinctive patterns of surgical procedure. They used the SAX to obtain the sequence of letters by discretizing the time series first. Then they utilize the VSM to find the discriminative patterns that represent a surgical motion which finally used them to be classified. A variety of holistic analysis features and a weighted features integrated approach proposed by [9] for automated surgical skill evaluation and GRS score prediction. These holistic features include approximate entropy, sequential motion texture, discrete Fourier and discrete cosine transform. They used the nearest neighbor as a classifier and linear support vector regression (SVR) for prediction. The works of literature mentioned above used the kinematic data information obtained from RMIS for surgical skill assessment. However, none of these methods were applied to the wearable sensors data like accelerometer which might give more information about the surgeon's motion during a surgical practice.

Recently, several advanced techniques applied the convolution neural network and deep learning methods for automated surgical skill evaluation. A parallel deep learning framework was proposed by [17] to identify the surgeon skill and task recognition. In their approach, they used a fusion technique between convolution neural networks and gated recurrent networks. Alternative deep convolution neural architecture based on ten layers proposed by [12] for surgical expertise evaluation. Another parallel deep learning approach was proposed in [18] by combining the LSTM recurrent network and CNN to indicate the skill levels. Additionally, recent studies have suggested approaches that use motion from videos [19,20] and wearable sensors to evaluate surgical skills [21,22]. These methods platform various features to perform Objective Structured Assessment of Technical Skills (OSATS) assessments. An approach proposed for surgical skill assessment is based on the acceleration data of both hands performing a basic surgical procedure in dentistry [2]. Also, an entropy-based features technique that utilizes both video and accelerometer data proposed for surgical skill assessment [4]. Despite these techniques which are building the basis and inspire performance results in the surgical skill area, however, some limits and drawbacks occur for the existing methods. some methods need predefined boundaries of the surgemes which done usually by a chief surgeon, i.e., consuming a large time. In other methods, decomposing the motion sequence requires a massive and complicated preprocessing in addition to a deficiency of robustness. Alternatively, the need to developing a new distance measure might have an advantage to a more robust and accurate assessment framework.

In this paper, our contribution to this work can be abridged as follows: 1) we defined a new surgical skill distance combined the best alignments between two multidimensional signals using DTW and measuring the distance between the two aligned sequences using Procrustes analysis 2) we proposed an automated skill classification framework based on using PDTW and kNN technique in the proposed framework to distinguish between the expertise levels focusing on overall performance 3) we investigated the proposed framework on a wearable sensor data for a surgical task. The purpose of this work is to present a technique that handles different kinds of sensor data in addition to the existing public JIGSWAS dataset. Some surgery motion results obtained by a Vicon camera with a 3D marker-based system and wearable device data are examples of the data we use.

2. Methodology

In this section, we illustrate the main components of our proposed framework, which are: motion alignment, Procrustes distance, and skills classifier, as shown in Figure 1. First, DTW is used to align two multidimensional time series performed by surgeons, while the Procrustes distance calculates similarity measure. Lastly, the skill levels of the surgeon are classified by kNN.

2.1. Similarity Measure

To obtain a useful classification, defining a reasonable distance is a crucial element to measure between two surgery tasks. Each

surgery task is represented by a set of features obtained from the traces (time series) of the motion capture sensors. One possible method is the Euclidean distance.
Figure 1: kNN based PDTW evaluation Framework

Euclidian distance is simple and widely used, whereas, it has some limitations and disadvantages. The Euclidean method is very sensitive to outlier and it is suffering from noise, shifting, and requires both signals to have the same length. Thus, we need a measure that can handle sequences with different lengths because the same surgery task might have different lengths even when operated by the same surgeon. A warping distance measure such as the Dynamic Time Warping (DTW), is one solution to do the job. The DTW can process time series with different lengths, it expands or contracts both signals (aligns them) such that their length becomes equal [23].

Let $X_{n \times v} = [X_1, X_2, \dots, X_n]$ and $Y_{m \times v} = [Y_1, Y_2, \dots, Y_m]$ be two sequences having v features and of length n and m respectively. To align X and Y, we form a two-dimensional ($n \times m$) grid distance. Each point d_{ij} of the grid corresponds to the distance measure (usually Euclidean) between every possible combination of two instances x_i from X and y_j from Y of the same features length (v) as follow [24]:

$$d_{ij}(x_i, y_j) = \sqrt{\sum_{k=1}^{v} (x_{ik} - y_{jk})^2} \tag{1}$$

The next step is to find the warping path through the grid, the path that attempts to minimize the total distance (warping cost) and give the best match between two signals and satisfy boundary conditions, continuity, and monotonicity constraints. It is usually achieved by using a dynamic program to calculate the cumulative distance $\gamma(i, j)$, which is the distance of the current cell (d_{ij}) and the minimum of the cumulative distance of the adjacent cells [24]:

$$\gamma(i, j) = d_{ij} + \min\{\gamma(i-1, j-1), \gamma(i-1, j), \gamma(i, j-1)\} \tag{2}$$

Despite the wide use of DTW in many applications and is a more robust distance measure than Euclidean distance, it fails for complex multidimensional signals. Also, when the unevenness occurred in the Y-axis, DTW can produce singularities by warping the X-axis. Inflection points, valleys, and peaks features can cause DTW to fail to align two signals properly [24].

The Procrustes analysis is a standard method in statistical analysis to compare the similarity of shape objects [25, 26]. The Procrustes distance is a shape metric that involves matching two shapes using similarity transformations (rotation, reflection, scaling, translation) to be as close as possible in the least-squares sense [27]. The Procrustes analysis also can estimate the mean shape to examine the shape variability in a dataset [28].

Assume X_1 and X_2 be two configuration matrices of the same $k \times m$ dimension (k points in m dimensions) that can be centered (normalized) using the following equation [28]:

$$(X_i)_c = CX_i \quad, \quad i = 1,2 \tag{3}$$

$C = H^T H$ is the centering matrix and H is the Helmert submatrix, let Z_1 and Z_2 be the pre-shapes unit size of X_1 and X_2 respectively, where the original configuration is invariant under the scaling and translation with the pre-shape [28]:

$$Z_i = \frac{(X_i)_H}{\|(X_i)_H\|} = \frac{H(X_i)}{\|H(X_i)\|} \quad, \quad i = 1,2 \tag{4}$$

$$(X_i)_H = HX_i \quad, \quad i = 1,2 \tag{5}$$

The full Procrustes distance between X_1 and X_2 is achieved by fitting the pre-shape Z_1 and Z_2 as closely as possible as the following [25]:

$$D_P(X_1, X_2) = \inf_{s,a,b,\theta,} \|Z_1 - Z_2\, s\, e^{j\theta} - (Z_2 + jb)1_k\| \tag{6}$$

where $\|.\|$ is the Euclidean norm, s is the scale, θ is the rotation, and $(a + jb)$ is the translation, 1_k is a k-dimensional vector of ones.

This work presents a distance measure PDTW based on a pairwise synchronization between two time series by utilizing a combination of Procrustes distance and DTW to overcome the drawbacks of using DTW alone. First, we use DTW as an alignment approach and then use Procrustes as a distance measure. DTW is used to locate the best matching between two signals, whereas Procrustes is used to minimize the distance.

2.2. Classification

The simplicity of the k-Nearest Neighbors (kNN) method and its reasonable results made it a handy feature classifier. It predicts the new unlabeled query point by using the labels of training data based on their similarity measure. kNN classifier assigns a label for the test point to the majority label of the k-closet neighborhoods [29]. We found k = 3 is a reasonable value and the one we utilize in this paper.

3. Experimental Evaluation

We used three datasets to evaluate the proposed PDTW-kNN model on the public surgical data JIGSAWS [7], and our two data MU-EECS [30], and EM-Cric. The JIGSAWS is a minimally invasive surgical skill assessment working set consist of various fundamental surgical tasks. Each task performed by a surgical surgeon with a different proficiency degree; an expert surgeon who performs the da Vinci Surgical System (dVSS) more than 100 hours of training, a novice surgeon who practice less than 10 hours on dVSS, and an intermediate surgeon (practice on dVSS between 10 and 100 hours). A motion capture based on markers, a Vicon system is used to collect the data from a resident surgeon in the MU-EECS data. The surgeon presented a tracheostomy surgery performed the same procedure six times. The EM-Cric data includes data from four surgeons with different expertise levels who performed the Emergency Cricothyrotomy task. Each surgeon performs the task four times, where the wrist wearable sensors are used to capture both hand motions. More details about the three datasets in the following parts:

3.1. JIGSAWS Data

We evaluate the proposed PDTW-kNN method for surgical proficiency assessment on a public widely used JIGSAWS dataset [7]. Moreover, we use this dataset for direct comparisons with other state-of-the-art approaches for surgical skill evaluation. MIS surgeons performed many types of elementary procedures on Da Vinci robotic systems because it gives confidence, precision, and real-time feedback to improve overall surgical treatment for the patient in the operation room [31].

JIGSAWS dataset consists of kinematic and video data collected from surgical surgeons with various surgical robotic skills performing basic surgical training curricula. All surgeons were right-handed: two expert surgeons (E) with > 100 robotic surgical practice hours, four novice trainee surgeons (N) having < 10 practice hours, and four intermediate surgeons (I) reported between 10 and 100 surgical robotic experience practice hours. The dataset provides two types of data: video and kinematic records for each trail get done by a subject in each task. All the subjects were required to do three fundamental surgical tasks five times repetitively. In this work, we use only kinematic data captured as 76-dimensional time series at 30 Hz from the da Vinci Surgical System (dVSS) using its Application Programming Interface (API). The three elementary surgical tasks are identified as suturing (SU), knot-tying (KT), and needle-passing (NP). Figure 2 presented sample frames of the three surgical tasks achieved by a surgical surgeon and defined them as follows [7]:

- Suturing: the surgeon picks the needle up, first and advances it to the bench-top model toward the incision. Then, the subject stitches up the needle through a dot-marked tissue on one aspect of the incision and extracts it out from the corresponding dot-marked on the other part of the incision. Lastly, the surgeon passes it to the right-hand and repeats the same process till the surgeon gets four times in total.

- Knot Tying: the surgeon makes one tie after selecting one side of a stitch that is tied to an elastic tube connected by its rims to the surface of the bench-top model.

- Needle Passing: the surgeon selects the needle. Then, passes the needle from the right side to the left through 4 tiny metal hoops that are placed over the surface of the bench-top model.
Figure 2: RMIS basic surgery tasks [7].

This dataset consists of a surgical manual annotation for the surgical skill of each trial. An annotating surgeon, with extensive robotic surgical experience, watched the entire trial and appointed a score based on a modified global rating score (GRS). GRS is the measure of the surgical technical skill of the surgeon who

performed the trial. GRS presents the total score of six elements illustrated in Table I. Where each component rating scale is between 1 and 5 and the best with a higher total score [7].

Table 1: Elements of Global Rating Score (GRS) [7]

Element	Rating scale		
Respect for tissue	Force on tissue	Careful tissue handling	Consistent handling
Suture/needle handling	Poor knot tying	Majority appropriate	Excellent suture
Time and motion	Unnecessary moves	Efficient time/ unnecessary moves	Economy moves/ Max efficiency
Flow of operation	Frequent interrupted	Reasonable progress	Planned operation/ efficient transitions
Overall performance	Very poor	Competent	Superior
Quality of the final product	Very poor	Competent	Superior
Rating score	**1**	**3**	**5**
Min. score =	∑ = 6	Max. score =	∑ = 30

3.2. MU-EECS Vicon Data

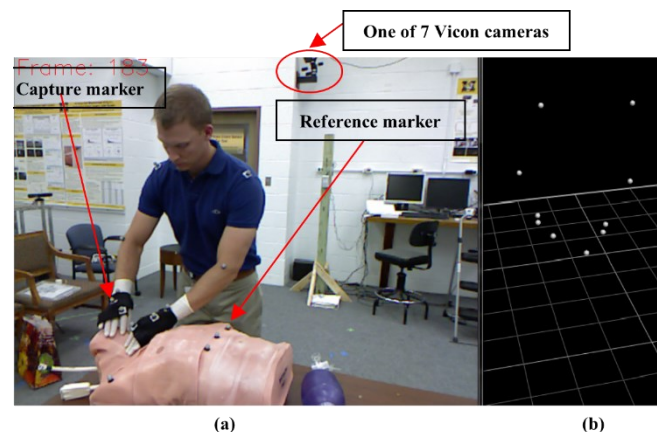
In this dataset, a Vicon system and IR reflective markers were used synchronously to trace and visualize the arms movement of the surgeon while carrying out a surgical procedure. Ten IR reflective markers were placed in different positions on both surgeon's arms as displayed in Figure 3 (a). Also, we can see seven Vicon cameras were located inside the lab to capture the resident surgeon's motions. The MU-EECS includes data presented by a resident surgeon who performed the same tracheostomy surgical procedure six times repeatedly. The earliest three procedures repeat in a consistently appropriate manner, whereas the remaining practices were performed with inaccurately way. This working set was collected through a project at the Center for Eldercare and Rehabilitation Lab in the Dept. of EECS at the University of Missouri Columbia [30].


Figure 3: Tracheostomy surgery with Vicon Camera

3.3. EM-Cric Dataset

Emergency Cricothyrotomy (Cric) is a procedure for potentially lifesaving a human being under a high-stress situation, it happens when a person fails to restore enough oxygenation. Cric

is an incision through the skin and cricothyroid, which results in a better patient airway [32]. There are three main steps of the surgical Cric procedure skin incision, incision cricothyroid, and endotracheal tube placement membrane [33].

The EM-Cric dataset includes data from four surgical surgeons (subjects) who performed the Cric procedure with varying expertise levels to study skilled surgical human motion. Two residents reported as Novice (N) surgeon, one intermediate (I) surgeon, and one expert (E) surgeon, respectively. All surgeons are reportedly right-handed except one lefty hand. All surgeons perform the Cric procedure five times on a Trauma Man Surgical Simulator at the Medical Intelligent System Laboratory (MISL) in the Medicine School at the University of Missouri-Columbia. We placed the wristband sensors on both wrists of the surgeon's hands to capture the data, as shown in Figure 4. We use low cost synchronized data transmission MetaMotionR (MMR) sensors introduced by MbientLab. MMR is a 9-axis IMU wearable device that provides continuous monitoring of movement and real-time sensor data [34].

Figure 4: Cric surgical operation on TraumaMan Simulator by a medical surgeon.

The data was conducted for a total of three male right-handed, and one female left-handed participants with different expertise levels were recruited for this study. Two MMR sensors were used for the Cric procedure task, one attached to each wrist of the surgeon's hand. The captured data consists of three-dimensional acceleration with respect to time for each accelerometer, and result in 6-dimensional time series for both sensors. For this study, we use only raw accelerometer data which range was set to ±16 g. The sampling rate of data collection was set to 100Hz.

3.4. Performance Evaluation

We used different cross-validating schemes to evaluate our skill assessment framework on both kinematic and accelerometer data to compare our results with other approaches.

- Leave-One-Trial-Out (LOTO): For each surgical task, training all the trials except one i-th trial reserved for testing ($i = 1, .., N$). N is the total number of trials in a task.

- Leave-One-Supertrial-Out (LOSO): Different from LOTO setup, where we created five folds ($j = 1, 2..5$). The j-th fold combines all the j-th trials from all the surgeons for a given surgical task. Then, we repetitively training on four sets and keeping a single set for testing and reporting the average

classifying results. The fold j-th is known as supertrial j-th. In this scheme, the robustness of a technique can be assessed by keeping a supertrial out each time [7]. Also, repeating the task in a row can possibly impact the performance of the surgical apprentice in terms of boredom or tiredness, hence keeping the supertrial out perhaps catch that effect on the surgeons.

To evaluate the performance of our proposed technique and to quantitatively compare with other methods, we used the mean accuracy of surgical classification for each output class on the data-driven to validate the performance. The average accuracy, defined in (10), is the percentage of the sum of accurately predicted (TP+TN) over the total number of predictions (TP+TN+FP+FN) [35]:

$$ACC = \frac{T_P + T_N}{TP + TN + FP + FN} \tag{10}$$

where T_P, T_N, F_P, and F_N represent the number of true positive (predicted correctly belong to the target class), true negative (correctly classified not belong to the target class), false positive (incorrectly predicts to the target class), and false negative (incorrectly predict not belong to the class level) respectively [35].

4. Results and Discussions

In this part, the proposed approach and evaluation metrics described in the preceding sections were evaluated on kinematic and accelerometer data. Also, the results for all the datasets that were explained previously were reported in the following sections, respectively.

4.1. JIGSAWS Dataset

For JIGSAWS data, we perform two sets of experiments for the LOSO validation set up to identify the three expertise levels (E, I, and N) on our proposed approach. For the first assortment, we made use of all the 76-dimensional movement features of the time series. Whilst, in the second set we utilized just the coordinates features (x, y, z) of the two hands.

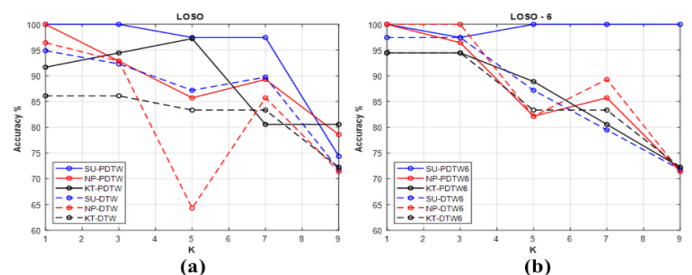
Figure 5 (a) illustrates the comparison of classification accuracy for surgical expertise levels versus k (the number of neighborhoods) in each task using all kinematic information. For the LOSO scheme, the improvement in accuracy for almost all cases of k of our kNN classifier based PDTW for all surgical tasks. e.g., the mean accuracy for all tasks at k = 3 is 95.7%. Also, kNN-PDTW provide an advantage over the traditional method (DTW) with a reduction in sensitivity to changing the number of neighbors (k) in k-NN.


Figure 5: Accuracy of the proposed approach using PDTW and DTW as a function of k.
Figure 6: kNN-PDTW Confusion matrix of the three tasks SU, NP, KT for LOSO at k=3.

We also perform another experiment by using only 3D location information of the two hands for the LOSO scheme. Some interesting intuitions results can be seen in Figure 5(b). The accuracy results of the proposed kNN-PDTW6 using the Cartesian coordinates almost achieved the same results as using all the 76-dimensional motion data. This can be explained by the fact that Procrustes analysis works on the similarity of shapes and the motion data are traces in three dimensions space, which encourages us to use the wearable sensors later.

For a further comprehensive comparison, the confusion matrices result for each task is shown in Figure 6 at k=3. For the suturing task, surgeon expertise levels are 100% correctly classified. However, for the other tasks, the misclassifying happened when distinguishing between intermediate level and

other levels which in turn reduced the average accuracy to about 94% and 93% for knot tying and needle passing tasks, respectively. We must put into our perspective that each surgeon performs the task in a different style from other surgeons, even within the same expertise level regardless of the hours spent on practice. Because individual surgeons like to improve their proficiencies following their mentor. Thus, small differences between an intermediate surgeon and an expert make the classifier to introduce an error to recognize their skill levels and vice versa. The same case between intermediate and novice surgeons happened.

Another interest intended of our analysis, that we calculate the pairwise PDTW distance inside a group of expert-expert, expert-intermediate, and expert-novice surgeons, separately for each task. Figure 7 illustrates the boxplot of each group distance in each task. From the results, it is clear that the smallest distance is among expert surgeons, and then between expert-intermediate surgeons followed by the expert-novice group for each task. Also, we can see that the differentiating among expert-intermediate surgeons is more complicated in needle-passing than other tasks. one explanation is the needle-passing might be more challenging to learn or more complicated than suturing or knot tying. This might be related to the complication level of the task as can be seen in Figure 6 for the needle-passing task where an expert surgeon classified as intermediate surgeon mistakenly.
Figure 7: PDTW-distance within E/E, E/I, and E/N surgeons in each task.

Table 1 shows the classification accuracy results of our proposed skill assessment for the JIGSAWS dataset using the kinematic data only. Also, we report the state-of-the-art results for comparative intent under the LOSO validation scheme for each task separately. The results show that the proposed kNN-PDTW properly recognizes the surgeon skill levels and matched the work from CNN [36] for suturing. From Figure 7 we can see that it is straightforward to differentiate between the expertise levels with the help of using PDTW measure. Additionally, the NN classifier learned the dynamic information which already comes from various motion patterns of the surgeons that might benefit this result. In knot-tying, our proposed kNN-PDTW approach outperforms both CNN [36] and Deep Learning [12] approaches in terms of accuracy. Also, our results were near the CNN+LSTM+SENET method [18]. Our results were improved more for suturing and knot-tying tasks than the needle-passing

task, and we did slightly better than [12] in this task. The small distinctions between intermediate surgeons with other surgeons in this task illustrated in Figure 7 might explain the less performance on the needle-passing task. Furthermore, we can notice from Table I that no technique is suitable for the three tasks. In other words, an integration methodology of various approaches is needed for surgical proficiency assessment purposes for these tasks.

Table 2: Skill Assessment Classification Comparative of kNN-PDTW Performance using LOSO for JIGSAWS Data.

Approach		Accuracy		
		SU	NP	KT
Farad [15]	kNN	89.7%	-	82.1%
	LR	89.9%	-	82.3%
	SVM	75.4%	-	75.4%
Wang [12]		93.4%	89.8%	84.9%
Forestier [13]		89.7%	96.3%	61.1%
Fawaz [36]		**100%**	**100%**	92.1%
Anh [18]		98.4%	98.4%	**94.8%**
kNN-PDTW (proposed)		**100%**	92.8%	94.4%

As mentioned previously in section 3.1, the modified global rating score measures the surgical technical skill done by the annotation surgeon for the entire trial provided in the JIGSAWS dataset. Figure 8 presents the boxplot of the surgeons' GRS scores for each task. We can see from this figure, the consistency of the expert surgeons compared to the novice and intermediate surgeons in all tasks. Where the lowest variance the expert surgeons have ultimately implied their steadiness. Another interesting viewpoint from Figure 8, that we can see the scores challenge to differentiate among the surgeon's proficiency in the needle-passing task, which produces the misclassifications. One more thing to be observed in Figure 8, some intermediate subjects score better than expert subjects. This means that these surgeons might be eligible to be in a higher skill level or position.
Figure 8: Boxplot of GRS scores for each task.

4.2. MU-EECS dataset

We experiment on the tracheostomy dataset to classify the trial level as either *Good* or *Bad*. In this experiment, we calculate the pairwise PDTW distance among the six trials that operated by a

resident surgeon [30]. Figure 9 presents the resulting distance of this experience for the MU-EECS dataset, where the yellow color is the farthest and the closer trials to each other are in darker blue.
Figure 9: PDTW distance matrix for MU-EECS data.

Overall, the *Good* trials, which are the first three trials in Figure 9, has a similarity less than or equal to 0.5. e.g., about 0.3 is the difference between trials 2 and 3. On the other hand, the pairwise distance between *Bad* procedures, the last three trials, is greater than 0.7 in distance to each other. Also, we can see those *Good* procedures are nearly 0.7 far away from *Bad* trials except among trial-Good 1 and trial-Bad 5 about 0.55 difference.

Another insight from Figure 9, it is straightforward to cluster the trials into *Good* (the upper left corner) and *Bad* (in the lower right corner). That means the PDTW distance helps accurately to identify between the trials in this task where each group looks to cluster together. Finally, the boxplot of the PDTW measure among the Good and Bad trials separately is presented in Figure 10. In this figure and from a statistical viewpoint comparison, the mean and variance of the *Good* procedures ($\mu_{G-G} = 0.12$, $\sigma_{G-G} = 0.08$) is less than the *Bad* procedures ($\mu_{B-B} = 0.21$, $\sigma_{B-B} = 0.16$) which is consistent along with prior results.
Figure 10: Boxplot of PDTW distance for MU-EECS dataset.

4.3. EM-Cric dataset

For the EM-Cric dataset, we performed two sets of cross-validation schemes, the LOTO for the trial level and the LOSO to identify the surgical proficiency levels (Expert, Intermediate, or Novice) of the subjects. As we mentioned previously in section 3.3, this dataset includes accelerometer data collected from four surgeons (expert, intermediate, and two novices) who performed the same task five times repetitively.

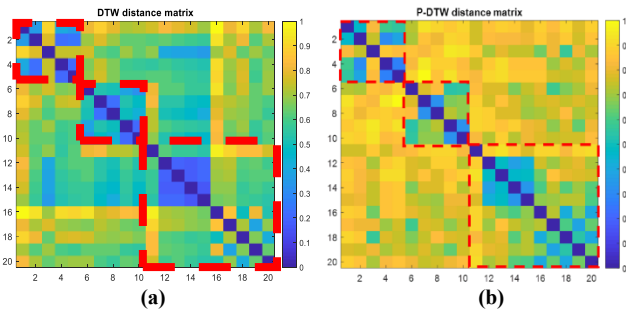
Before evaluating the classification accuracies, we calculate the pairwise distance among all the collected trials. Figure 11 (a) and (b) illustrate pairwise distance matrices comparison between DTW and PDTW measures, respectively. The first five trials represent the expert surgeon procedures, the second five stand for the intermediate surgeon trials, and the remaining ten trials are for the two novice surgeons, all performing the same task. Where the similar performances made by participants are indicated in strong blue squares in this figure. Also, the three separate square blocks in Figure 11 (b) give a visual insight for the possibilities of clustering expertise levels where the task is performed by different surgeons for this data using only the accelerometer data. Also, we can notice from this figure that PDTW distance separates well between expertise levels better than using DTW distance alone. The results in Figure 11 (b) shows that the expert surgeon has a dissimilar pattern to both intermediate and novice surgeons. Moreover, novice surgeons themselves are quite like each other.


Figure 11: The pairwise distance for each trial on EM-Cric using (a) DTW and (b) P-DTW
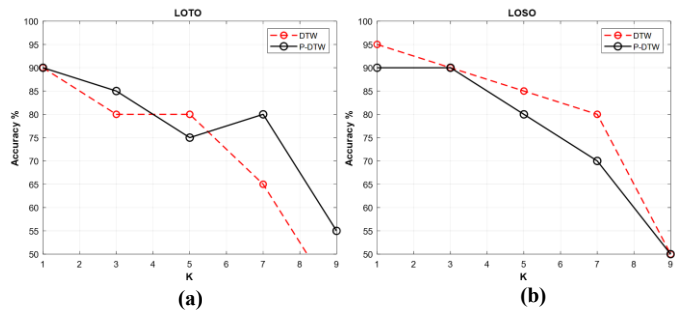

Figure 12: Classification accuracy as a function for k (a) LOTO and (b) LOSO cross-validation for Cric data

First, we performed experiments to compare how DTW and PDTW perform for classifying surgeon levels on Cric data using both LOTO and LOSO configurations. Figure 12 presents comparisons of the classification accuracy results of the proposed model for different values of K (number of neighbors) using LOTO and LOSO cross-validations, respectively. Figure 12 (a) shows that the results of our method based on PDTW performs better compared to using only DTW distance. These results indicate that our approach can identify the surgical skill levels well at trial levels because it utilizes the Procrustes analysis. Secondly, Figure 12 (b) presents the kNN-PDTW performance for the LOSO setup for the Cric dataset. The kNN based DTW approach performs slightly better for the accelerometer data. Whereas our approach results were improved, and the performance was

reasonably well and still having a higher classification accuracy of 90% at k = 3.

Figure 13 shows the confusion matrix of our kNN based PDTW for surgeon expertise at k = 3 for Cric data using LOSO configuration. We can see that the intermediate surgeon was classified correctly, whereas both expert and novice surgeons were misclassified in one trial. From Figure 11 (b), we can notice that there is one trial (#3) from the expert surgeon that seems far from other trials with Expert trials and the same for novice surgeons with the trial (#11) in the same figure. The average classification accuracy was 90%.
Figure 13: kNN-PDTW Confusion matrix for LOSO at k=3 for Cric data
Figure 14: Balanced data classification results for the Cric data

Lastly, for a more thorough comparison, we perform another experiment for Cric data by using balanced data and evaluating using LOSO with a k-fold cross-validating scheme. The balanced data was obtained by having equal trials from each surgeon level. The reason we chose the balanced data experiment because we had two novice surgeons, one expert, and one intermediate surgeon. In this conduct experiment, we pick five trials randomly from a total of ten novice surgeon's trials and put them together with other trials from the expert surgeon and the intermediate surgeon trials. Then repeat the process ten times and report the average classification accuracy. Figure 14 shows the comparison classification accuracy as a function of k between PDTW and DTW based kNN classifier. Furthermore, Figure 15 presents the confusion matrix of kNN-PDTW predictions of the surgical skill classes. We can see from both above figures that the average accuracies of using PDTW much better than using DTW for all

values of k. Also, our approach using balanced data achieved average classification accuracy about 3% higher than using unbalanced data. the balancing data helps classified the novice surgeon's skill correctly with 100%.

Figure 15: Balanced data confusion matrix for the Cric data

5. Conclusions

In this paper, we define a new surgery skill distance measure PDTW. It incorporates the exploration for best alignment using DTW and the similarity measure using Procrustes distance among two multidimensional time series. We show that the proposed framework based PDTW can enhance the overall performance for surgical proficiency evaluation. We attain an average accuracy of 97% for the JIGSAWS dataset and the results outperform most state-of-the-art methods using kinematic data and are comparable to techniques based on deep schemes.

Also, here we have examined the use of wearable motion sensor devices in proficiency assessment to achieve an entirely objective evaluation. Although our results are encouraging, there are quite a few limitations. The number of subjects is relatively small, not as desired. Furthermore, only one surgical task the subjects were asked to work on and there is no break between the trials which might impact the performing of the trials. Despite the limitations, our results indicate that PDTW distance can be used by classifying techniques to categorize the expertise levels accurately. In the future, we plan to increase the number of participants with a variety of expertise which might have the potential to give more information and robustness to our method. Also, more tasks to be utilized instead of only a given surgical task. Furthermore, consider using another or a combination of classifiers to improve the overall classification accuracy for skill assessment.

A B S T R A C T

Disruptive innovation has created fast changes in the business environment and competition among companies, especially on information technology companies. Knowledge creation and entrepreneurial orientation are two variables that can improve firm performance. There is still limited study on how knowledge creation and entrepreneurial orientation both affects firm performance. This study aims to discuss how to effectively apply knowledge creation and entrepreneurial orientation to develop firm performance. A questionnaire has been conducted to 55 medium-large IT companies in Jakarta, Indonesia, and analyzed using structural equation modeling (SEM). The result showed that knowledge creation did not directly affect firm performance but indirectly affected entrepreneurial orientation. Knowledge creation also had a positive and significant effect on entrepreneurial orientation, and so does entrepreneurial orientation towards firm performance. Therefore, IT companies should consider both variables to improve their performance. Future studies may consider using qualitative or mixed-method approaches, conducting research for small IT companies and in other countries.

1. Introduction

The world is changing fast with the innovation that happens in the world. Disruptive innovation, where a new market disrupts and replaces the old market, shows how quickly the world is changing [1]. This situation raises the competition among companies as well [2].

Disruptive innovation heavily impacts the information technology (IT) sector. As the largest economy in South East Asia, Indonesia has many growing industries, especially in the digital sector [3]. Nevertheless, IT companies need to prepare themselves for disruption and the competitive environment to survive.

According to dynamic capabilities theory, companies need to explore their knowledge assets to face rapid technological change [4]. Knowledge is an essential part of IT companies that focus

more on intangible assets to compete. Knowledge creation is a way to create value for IT companies.

Technology advancement that changes rapidly can help companies find new opportunities to improve their performance [5]. One of the sectors that are affected by these changes is the IT sector. So, IT companies need to find a way to seek opportunities within this condition. Entrepreneurial orientation can be one way where they will be able to survive the competition and to increase their performance [6].

Although there are a lot of previous studies talking about how knowledge creation is related with entrepreneurial orientation [7, 8] and how each of those variables are related with firm performance [9], [10], but there is still limited study on how knowledge creation and entrepreneurial orientation both affects firm performance. It is also interesting to see how the variables will be related in IT sector that relies on intangible assets, such as knowledge. These explanations show the novelty of this study.

* Corresponding Author: Desman Hidayat, Email: d4906@binus.ac.id

This study aims to enrich the literature by investigating the interaction between knowledge creation, entrepreneurial orientation, and firm performance. Overall, this study makes two contributions: (1) It expands the understanding of the knowledge creation-firm performance relationship in IT companies, and (2) It explores how entrepreneurial orientation can be related to knowledge creation and firm performance.

2. Literature Review

2.1. Firm Performance

Firm performance is a variable that is often used to measure how good companies run. Researches often use firm performance as a dependent variable [11]. This study used firm performance to measure how good IT companies manage their businesses.

Firm performance is derived from the organizational effectiveness theory [12]. The performance of a company can show the effectiveness of that organization [13]. It takes more than just the financial factor to measure performance [12].

In this study, the firm performance was measured using financial and non-financial performance. It used five indicators: revenue, ROI, employees, products, and development [14, 15]. Financial performance was measured by using revenue and ROI, while non-financial performance was measured using employees, products, and development.

2.2. Knowledge Creation

Knowledge creation is an activity or process of developing new knowledge by sharing and combining tacit and explicit knowledge [16]. It enables firms to improve efficiency and create value [17]. Knowledge creation needs participation from individual members of an organization to be effective [18].

Knowledge-based view of the firm is the most common foundation used to define knowledge creation theory [19]. This view argued that firms' significant resources are mainly intangible and dynamic, such as knowledge [20]. This view is derived from dynamic capabilities.

Socialization, Externalization, Combination, and Internalization (SECI) are indicators to measure knowledge creation [18]. These indicators are representing the interaction between tacit and explicit knowledge [19]. This study used SECI as indicators to measure knowledge creation.

2.3. Entrepreneurial Orientation

Entrepreneurial orientation is one of the most researched topics in entrepreneurship literature [21]. It is the processes, practices, philosophy, and decision-making activities that help companies innovate [22]. Companies with the right entrepreneurial orientation continuously try to find new opportunities and strengthen their competitive positions [8].

The foundation of entrepreneurial orientation was based on entrepreneurship theory itself, where the main point of entrepreneurship is to understand how companies can seek and exploit opportunities [23]. Opportunities do not have to be related to something new, but they can focus on optimizing the existing framework. To discover the opportunities, companies must possess prior information related to the opportunities and cognitive properties to value them.

Five indicators are commonly used to measure entrepreneurial orientation. Those indicators are autonomy, innovativeness, risk-taking, proactiveness, and competitive aggressiveness [6]. The earlier concept of entrepreneurial orientation used three aspects: innovativeness, proactiveness, and risk-taking [24], but now it has been improved by adding the other two indicators. This study used the five indicators mention above to measure entrepreneurial orientation.

2.4. Hypothesis Development

Knowledge is one of the critical intangible resources that can help companies develop their performance [9, 25]. A lot of previous studies discuss how vital knowledge creation in relationship with performance [19]. High-tech companies need to have adequate knowledge resources in order to remain competitive [26]. Hence the hypothesis:

H1: There is a positive effect of knowledge creation towards firm performance.

Entrepreneurial orientation has been known to have a positive association with firm performance [8,9]. It has been tested in different contexts and countries [27]. This statement is also argued to be true for technological companies [28]. Therefore, hypothesis two is predicted as below.

H2: There is a positive effect of entrepreneurial orientation towards firm performance.

Knowledge creation and entrepreneurial orientation are often researched together. Previous studies showed that both variables are related [7, 8]. IT companies need to pay attention to both variables to maximize their performance. Therefore, hypothesis three states:

H3: There is a positive effect of knowledge creation towards entrepreneurial orientation.

Even though most of the previous research discussed how knowledge creation and entrepreneurial orientation separately affect firm performance, some studies talked about how they can simultaneously affect firm performance by having entrepreneurial orientation as the mediating variable [29]. This study argued that innovativeness and competitive aggressiveness as part of entrepreneurial orientation play the mediator between knowledge and performance. Hence the hypothesis:

H4: There is a positive indirect effect of knowledge creation towards firm performance mediated by entrepreneurial orientation.
Figure 1: Research Model

3. Research Methodology

This study was conducted using an online survey with quantitative analysis. The unit analysis of this study is medium-

large IT companies in Jakarta. Indonesian Micro, Small, and Medium Enterprise Regulation No.20 (2008) defined medium enterprises as companies with 2.5-50 billion IDR revenues per year or 178-3.5 million USD and large enterprises as companies that have >50 billion IDR revenues per year or >3.5 million USD. According to 2016 Economic Census by Statistics Indonesia, the population of medium-large IT companies in Jakarta, the capital of Indonesia, is 303 companies [30].

This study used probability sampling design with simple random sampling. The samples for this study were 55 companies. The minimum sample size was 33 data, calculated using two arrows pointing at a construct, 5% significance level, and minimum R Square 0.25 [31]. Therefore, the samples are sufficient for this study. The survey was conducted for three months, from August to November 2020. The unit of observation in this study was a managerial level employee. Only one employee per company participated in this study.

Based on the companies' established period, most of the respondents (42%) were companies that have already been established for at least twenty years, and the smallest frequency came from new companies that have only been established for less than five years (7%). This data shows that many medium and large IT firms in Jakarta took a long time to develop their business into a medium-large company. Table 1 shows the details of the company establishment period.

Table 1: Companies' Established Period

Established Period	Frequency	Percentage
<5 years	4	7%
5-9 years	11	20%
10-14 years	9	16%
15-19 years	8	15%
>=20 years	23	42%
TOTAL	55	100%

Most of the company respondents have 11-50 employees (40%). Only one respondent has less than ten employees, while seven companies have more than five hundred employees. This data shows that medium or large companies do not mean that they must have many employees. Table 2 below shows more details on the numbers of employees.

Table 2: Companies' Number of Employees

Number of Employees	Frequency	Percentage
<=10 employees	1	2%
11-50 employees	22	40%
51-200 employees	20	36%
201-500 employees	5	9%
>500 employees	7	13%
TOTAL	55	100%

This study was done by using exploratory empirical research. The data analysis was done by partial least squares structural equation modeling (PLS-SEM). PLS-SEM is mainly used for the development of theories and exploratory research [31]. The analysis for this study was done using the smartPLS program. This study used a five-point Likert scale on the questionnaires. A five-point scale increases the response rate and quality of the responses while reduces the stress of the respondent [32].

4. Results and Discussion

4.1. Results

Validity was measured by removing items with less than 0.7 outer loadings. From the result, the risk-taking indicator measuring entrepreneurial orientation is not valid. Other indicators are all proven to be valid. Cronbach's Alpha, Composite Reliability (CR), and Average Variance Extracted (AVE) measure reliability. Variables should have Cronbach's Alpha >0.5, CR >0.6, and AVE >0.5 to be considered reliable [31]. The result showed that all the variables are reliable. More details on validity and reliability test result on entrepreneurial orientation (EO), firm performance (FP), and knowledge creation (KC) can be seen in table 3.

Table 3: Validity & Reliability Test Result

Variables	Indicators	Items	Instrument	Outer Loading	Cronbach's Alpha	CR	AVE
EO	Autonomy	EO11	Our company gives freedom to employees or team to express their business concept and vision, and oversees them until finish	0.783	0.892	0.913	0.569
		EO12	Our company has the self-directed ability and willingness to seek for opportunities	0.809			
	Innovativeness	EO21	Our company supports employees' creativity	0.771			
		EO22	Our company has a lot of new marketable products/services within the last five years	0.723			
	Proactiveness	EO41	Generally, our company's top managers have the tendency to lead the competition with new idea or product	0.721			
		EO44	Our company reacts quickly on the market demand	0.743			
	Competitive Aggressiveness	EO51	Our company is very aggressive	0.756			
		EO52	Our company is very competitive	0.723			
FP	Employee	FP12	Our company has good planning towards the future of employees	0.706	0.865	0.899	0.597

KC	Product	FP22	Our company's automation is higher than our competitors in the same industry	0.830			
	Development	FP31	Our company is very keen on investing in new market development	0.733			
		FP32	Our company is very keen on investing in new technology development	0.778			
	Revenue	FP41	Our company's income is higher than our competitors in the same industry	0.779			
	ROI	FP51	Our company's Return on Investment is higher than our competitors in the same industry	0.803			
KC	Socialization	KC11	Our company emphasizes on the creation of working environment that helps employees learn skills	0.700	0.930	0.939	0.586
		KC12	Our company arranges employee meetings to share and trade knowledge and experiences	0.742			
	Externalization	KC21	Our company uses collaborative learning tools	0.741			
		KC22	Our company usually develops working group discussion by using several techniques through internet	0.775			
		KC23	Our company usually share information, experiences, best practice, and learning to solve problems	0.732			
	Combination	KC31	Our company emphasizes on manual and document creation on products and services	0.835			
		KC32	Our company emphasizes content creation from management data gathering	0.791			
		KC33	Our company emphasizes content creation from technical information gathering	0.872			
	Internalization	KC41	Our company emphasizes on value seeking and sharing	0.764			
		KC42	Our company emphasizes on new thoughts seeking and sharing	0.709			
		KC43	Our company usually use on the job training to enrich knowledge	0.744			

Based on the result of Fornell-Lacker criterion, discriminant validity, all three variables are valid. Correlation between items and the square root of AVE shown no problem with the top numbers being the biggest one. Table 4 shows the details of discriminant validity.

Table 4: Fornell-Lacker Criterion

	EO	FP	KC
EO	**0.754**		
FP	0.752	**0.773**	
KC	0.689	0.570	**0.766**

The last part of discriminant validity measure beside loading factor and Fornell-Lacker criterion is Heterotrait-Monotrait Ratio (HTMT). The score for HTMT ratio should be <1.00 [31]. Based on the result, all variables are valid. Table 5 shows the HTMT result.

Table 5: HTMT Ratio

	EO	FP	KC
EO			
FP	0.848		
KC	0.703	0.616	

R Square shows the proportion of variation of dependent variables towards independent variables. Results showed that 57,1% of firm performance could be described through entrepreneurial orientation and knowledge creation, while 47.5% of entrepreneurial orientation can be described through knowledge creation. R square result can be seen in table 6.

Table 6: R Square

	R Square	R Square Adjusted
EO	0.475	0.465
FP	0.571	0.554

Goodness of fit can be seen from the value of Standardized Root Mean Square Residual (SRMR) and Normal Fit Index (NFI). On this study, the result of SRMR estimated model is 0.108 while the NFI score is 0.555. Although there are several PLS-SEM based model fit measures, but those measures are still in development [31].

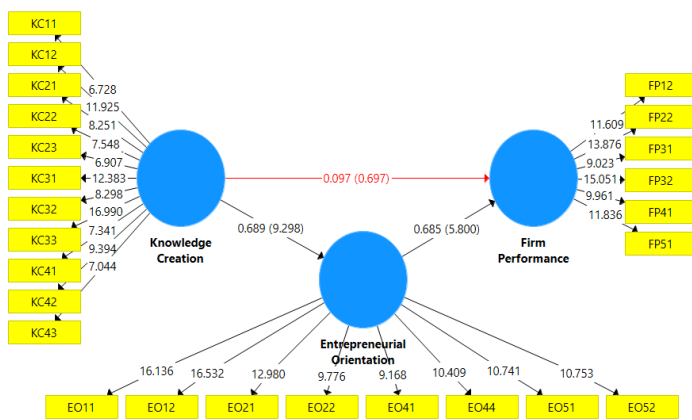
After testing the validity and reliability, the next step was to test the path between variables. The test was done using SmartPLS. How the research model looked with the path coefficient and t-value can be seen in Figure 2.


Figure 2: Research Model with Path Coefficient and T-Value

T-value should be >2.021 and p-value <0.050 for a significant path on a 5% error rate [33]. From the result, the direct effect of entrepreneurial orientation is positive and significant towards firm performance, and the direct effect of knowledge creation is positive and significant towards entrepreneurial orientation. However, knowledge creation has an insignificant direct effect on firm performance. By measuring the indirect effect, knowledge creation has a positive and significant effect on firm performance mediated by entrepreneurial orientation. Details on the structural equation model (SEM) test result can be seen in table 7.

Table 7: SEM Test Result

	Path Coef.	T-Stat	P-Value	Sig.
KC-> FP	0.097	0.697*	0.486*	Insignificant
EO -> FP	0.685	5.800	0.000	Positive & Significant
KC->EO	0.689	9.298	0.000	Positive & Significant
KC->EO->FP	0.472	4.873	0.000	Positive & Significant

4.2. Discussion

Based on this study, knowledge creation does not have a significant effect on firm performance. This argument supported previous research [34]. IT companies should not only be focusing on knowledge creation if they want to raise their performance. They should also think about other factors to make the knowledge creation effective. Therefore, hypothesis 1 is rejected.

Entrepreneurial orientation in this study is proved to have a positive and significant effect on firm performance. This statement strengthened the arguments done by previous researches [21,35,36]. By focusing on entrepreneurship, IT companies can find and exploit opportunities to improve their performance. Therefore, hypothesis 2 is accepted.

Knowledge creation has a positive and significant effect on entrepreneurial orientation, according to this study. This result strengthened previous research that argued the correlation between knowledge creation and entrepreneurial orientation [37] and supported the argument that showed knowledge creation affected entrepreneurial orientation [7]. IT companies must pay attention to

knowledge creation to increase their entrepreneurial orientation. Therefore, hypothesis 3 is accepted.

This study showed that knowledge creation has a positive and significant effect on firm performance when it is mediated by entrepreneurial orientation. This result supported the previous research on the same topic [29]. Both knowledge creation and entrepreneurial orientation are essential factors to improve IT company performance. Therefore, hypothesis 4 is accepted.

4.3. Implication

IT companies generally rely on intangible resources such as knowledge as their important asset. Nevertheless, the result of this study showed that knowledge alone is not enough to make the company perform better. Therefore, medium-large IT companies in Jakarta should think about other factors while focusing on their knowledge creation.

Technology changes rapidly. IT companies should think about a way to face this challenge. Entrepreneurial orientation can help the companies to seek opportunities and adapt to changes. The result of this study showed that it is important to develop entrepreneurial orientation in the companies to increase their firm performance.

Another important result from this study is the relation between knowledge creation and entrepreneurial orientation. This study showed that knowledge creation is important to develop entrepreneurial orientation, which in the end raise the firm performance. Therefore, IT companies should develop both their knowledge creation and entrepreneurial orientation.

5. Conclusion

5.1. Conclusion

The results of this study indicate the factors that can increase IT firm performance. This study's main conclusion is that knowledge creation and entrepreneurial orientation are essential antecedents of firm performance, especially for companies in the IT sector. However, knowledge creation alone is not enough to raise firm performance. It must also be mediated by entrepreneurial orientation.

The interesting finding in this study is that entrepreneurial orientation mediates the relationship between knowledge creation and firm performance. It indicates that IT companies should create an environment that supports knowledge creation for the employees. Companies should also have entrepreneurial orientation to adapt with the fast-changing environment.

5.2. Limitation and Future Work

This study has several limitations. The analysis in this study was done by quantitative approach. Adding qualitative approaches by having interview or focus group discussion on future research will enrich this study. Mixed-method research is also a good approach to understand more about the industry.

The companies observed is also limited to medium-large IT companies. Future research can be done to small IT companies. The knowledge creation might be different in small companies and their way to face the changes can also be different. Therefore,

doing study in small IT companies or conducting comparative study between small, medium, and large IT companies will enrich this study.

Other limitation is the scope of this research. This study used IT companies in Jakarta, Indonesia. Therefore, it will be hard to generalize this result to other countries. Future research ought to be held on other countries as well.

A R T I C L E   I N F O

A B S T R A C T

This paper aims to understand the impact of eLearning capabilities on organizational performance. It also addresses the obstacles of organizational learning using eLearning methods and highlighting some emerging trends and technologies that will impact the eLearning experience in organizations. It examines a brief history of knowledge management and how it is related to learning, organizational learning, and performance. It also explores different eLearning technologies and trends. A systematic literature review was used to examine previous papers between 2016–2020. Results show eLearning can impact organizational performance in many ways, and human factors can be one of the most challenging obstacles in deploying eLearning solutions in organizations, and many emerging eLearning trends were explored including open educational resources, gamification, flipped classrooms, and many others.

1. Introduction

The fast-paced growth of information communication and technology is changing the world we live in into a knowledge-based society [1–3]. Within the context of the fourth industrial revolution and the knowledge-based economy, knowledge and learning systems play an important role in countries' competitiveness and organizational performance (OP).

Knowledge capturing has become a strategic priority for many countries as an essential asset [4–8], especially if they want to remain competitive, driven by rapid development in knowledge creation and high demand for skilled human capital [9–12]. In the past, countries and organizations could achieve that by traditional educational and vocational training systems; however, the new era requires faster and shorter innovation cycles to remain innovative, which increases the need for continuous skilled and trained human capital with constant knowledge updates and skillsets.

The current workforce is transforming the traditional "single-skilled personnel to multi-skilled employees" who can manage multi-tasks under one job title. Such a goal will be possible only through new disruptive learning models and life-long learning

(LLL) [13]. One of the knowledge-capturing and sharing tools is eLearning, where organizations and educational institutes can conduct training via electronic media via the internet. The COVID-19 pandemic has forced many institutes and organizations to carry out their training and education activities via eLearning tools [14,15]. These activities revealed some limitations in current eLearning practices such as quality of interaction, lack of natural discussions, and limited nonverbal communication [16]. The reason can be anything, ranging from the use of old-fashioned eLearning practices to poor content and connection quality.

Alternatively, the use of technology-enhanced learning (TEL) via mobile is changing the learning process for many. Language learning apps, for example, are impacting how learning is taking place. A recent study concluded that Duolingo is fostering vocabulary and grammar development [17]. Other fun and engaging examples include fitness training apps from Adidas and Nike and musical instrument training apps like Yousician. TEL is becoming one of the trending topics in computer science as it utilizes the use of computers, mobile, software and apps to assist learning [6].

The advantage of TEL is that it guarantees learning continuity in different circumstances such as during pandemics, natural

disasters, extreme weather conditions or for learners with disabilities. It frees the instructor from creating redundant lessons and devotes more time to developing quality learning materials. It also allows learners to engage in active and independent play-based learning and life-long learning [18].

Organizations need to encourage LLL via on-the-job training and eLearning methods. These learning methods will ensure that the current workforce is well equipped with the latest skills. Before knowledge is transformed into learning materials (eLearning), it is necessary to manage such knowledge first. Learning is an essential part of the Knowledge Management's (KM) life cycle, which complements the process of establishing, distributing, implementing, and managing the knowledge and information of an organization. It refers to a multidisciplinary approach to achieve organizational objectives by making the best use of knowledge. The most recent studies uncover the massive significance of presenting KM insights into eLearning frameworks. KM is believed to encourage an eLearning framework, where the joint effort between eLearning and KM will provide the single objective of hierarchical learning [19].

In this paper, we have included papers that are relevant to the role of KM, eLearning, and OP. We have reported a systematic review of the advances in eLearning in KM in response to OP. The objective is to provide overviews of the research studies within this field, how these concepts interact with each other, the main obstacles, and the recent emerging trends. More specifically, we have asked the following questions:

Table 1: Research question.

#	Research question
RQ1	How is eLearning capabilities in KM impacting OP?
RQ2	What are the challenges in implementing eLearning in organizations?
RQ3	What are some of the emerging trends and technologies in eLearning?

2. Literature Review

This section will highlight the recent contribution that focuses on the subject of this study, including the discussion of the latest practices related to KM, eLearning, training technologies, organizational learning, and performance.

2.1. Origin of KM

KM started within the management consulting community. They had realized how the internal networks in their organization is a vital tool to share and access information with their units, especially when these units were scattered in different geographical locations. While these consulting groups were working on facilitating their network to their use, they have gained some knowledge and recognized some good practices, such as developing and building these tools, expertise locators, lesson-learned databases, and designing dashboards.

They have realized the newly acquired expertise can be packaged, marketed, and sold to other similar entities, who might have multiple locations and experienced the same challenges. However, the new product needed a name. It seemed the term

"Knowledge Management" had appeared in this context for the first time in 1987. The KM term was spotted in an internal study in McKinsey on how to handle and utilize their information.

In 1993, the knowledge management went public at a conference organized by Ernst and Young. A young man at Ernst and Young came up with one of the first classic one-line definitions of KM. Tom Davenport defined KM as the process of capturing, distributing, and effectively using knowledge [20].

In 1998, the authors of [21] worked on a revised definition. They described KM as the activities related to utilizing and developing organization knowledge assets in line with organizational objectives. Early work by [22] in 2005 was among the first to link KM with innovation, as he defined KM as the purposeful and systemic coordination of an organization's individuals, technology, process, and structure to create values via reuse and innovation [23].

There were many models aroused around coordination between people, process, technology, and organization structure, including Wigg Model (1993), Zack Model (1996), Bukowitz and William Model (2000), and McElroy Model (2003). The following table explains the KM lifecycle steps, according to the four proposed models [24].

Table 2: KM lifecycle steps according to the four proposed models.

WIGG 1993	Zack 1996	Bukowitz & Williams 2000	McElroy 2003
Creation	Acquisition	Get	Learning
Sourcing	Refinement	Use	Validation
Compilation	Store	Learn	Acquisition
Transformation	Distribution	Contribute	Integration

In [24], the author summarizes the steps in seven steps: Identity, Create, Store, Share, Use and Learn. For this review, the focus has been on the learning aspect and knowledge sharing with more details.

2.2. KM & learning

A study by [25] explained how KM and learning work together. The knowledge assets used and shared in the past could be the foundation for creating new and improving current ones. In situations where experts provide a certain understanding in a context, the employees gain and learn a new experience and apply that knowledge to their workplace. If the knowledge resources have been found insufficient or incomplete, the researcher goes back to the identity/creation phase where additional resources are created based on the gaps found. This repeatable process creates double-loop learning. Some of the activities that assist the learning stage are benchmarking, best practices, lessons learned, and knowledge gap analysis. Technological applications and examples can be found in learning management and help desk systems [24].

2.3. KM in organizations

In addition to organizations' ability to learn and unlearn, collective knowledge is an essential asset in improving OP. It would also increase profitability, which will eventually create and maintain a competitive advantage. A study by [26] defines

organizational learning (OL) as using a purposeful learning process on individual, group, and system levels while changing the organization to satisfy its stakeholders. Scholars of [27] describe organizational learning as a social process where individuals engage in practices and speeches that reproduce the OL and expand it simultaneously.
Figure 1: The KM Cycle (KMC) Model [24]

Four major vital areas were identified in [12]. These areas are the business drivers for the increased importance of KM in the organization today.

1. *Globalization of business:* The organization today is more global, multisite, multilingual, and multicultural.
2. *Leaner organizations:* Productivity is increasing faster, but it also needs to be done smarter as workers in KM are adapting to an increasing work pace and load.
3. *Organization amnesia:* Workforces are becoming mobile, which creates a challenge in sustaining knowledge in the organization and requires continuous learning. Employees are no longer expected to spend their entire lives in the same organization.
4. *Technology advancement:* People are connected seamlessly. The connections are not only ubiquitous but have radically changed expectations. Workers are expected to be "on" all the time, and response turnarounds are now measured by minutes, not weeks or even days [24].

One of the key challenges organizations face is the uncertainty of how exactly learning and KM impact OP. A dilemma that might create an ambiguity among leaders is how to optimize resources from KM. KM has no choice but to demonstrate how exactly they add value to the stakeholder [28]. A study by [29] examined the impact of KM on organizational learning, using OL in a mediating role. Results taken from 150 random samples show a close relationship between KM and OP. A critical insight is that OL is playing a mediating role between OP and KM. The study also revealed a positive relationship between emotional intelligence and OP.

In contrast, [30] investigated the effects of KM strategy and the effects of OL on OP. This study was conducted using a 5-point Likert-scale questionnaire on all levels of management in oil cooperation. The data collected from 161 managers confirmed that KM strategy is one of the preconditions and impactful factors

regarding OP and innovation. In contrast, OL does not seem to have correlated with organizational innovation.
Figure 2: Relation between KM and OP [29].

2.4. eLearning

If we want to take a closer look at learning and training in the organization today, technology will be found as the driving force in workplace training. ATD's state of the industry report (2018) indicated that eLearning accounted for 40 percent of the formal learning hours used in 2017 [31]. The commonly known eLearning definition usually describes the activities of conducting learning using information and communication technologies. The authors of [32] identified that the most important remarkable milestones in learning are the evolution from distance learning to electronic learning to mobile learning. These three stages are in line with the impact of the Industrial Revolution in the eighteenth and nineteenth centuries and the Electronic Revolution in the last decade of the twentieth century [32].

Recent studies suggest that Massive Online Open Courses (MOOCs) will play a prominent role in organizational learning, provided these courses are relevant to the workplace and integrated effectively into the current training systems [33]. For many leaders and human resources trainers, eLearning is an easy way to provide workplace gamification content. The challenge remains that most training courses are theoretical and based on college courses, and they might not meet the corporate training version yet (except Udemy). However, a few work particularly with corporations to tailor-make their business knowledge into user-friendly courses, similar to ones we can identify with MOOCs platforms.

2.5. Computer-Assisted Learning

Computer-Assisted Learning (CAL) is one of the top 5 emerging trends in computer science in recent years [18]. This term can also be referring to Computer-Based Instruction (CBI), Computer-Aided Learning (CAL), or Computer-Aided Instruction (CAI) [34]. CAL can be defined as "learning that supplements regular classroom activities with computer activities during or surrounding classroom time" [35]. Apps are one well-known form of CAL applications. The authors of [36] found that educational apps can have added values to the learning process not available in the conventional eLearning tool, including repetitions, swift feedback, fun, creative tools, variety of methods, and pronunciation.

For this review, we can simply define CAL as "the learning procedures and environments facilitated through computers" [34]. The application of CAL is unlimited. One example of CAL applications can be seen in the medical field, which has recently become "a truth universally acknowledged" as a proven way to enhance the student learning process. In contrast, some instructors and trainers may lack the basic computer science skills needed to

fully utilize technology in learning. Lacking key ICT skills might be one of the obstacles that limit the use of TEL tools [36].

2.6. Technology-Enhanced Learning

The emerging term Technology-Enhanced Learning (TEL) is a broad category that does not have a particular definition. It can refer to any type of technology that enhances the learning experience [37]. "Mentimeter" is an example of an interactive presentation platform that utilizes the capabilities of TEL. The trainer can build an interactive presentation; collect polls, data, and opinions from learners; and export the insights, data, and trends from participants' input. Media Technology and Interaction Design have identified many research areas around TEL, including learning analytics, the interplay of learning design and technology, design-based research, computer-supported collaborative learning, blended learning, sustainable design, and visualization for TEL-related issues [38]. A study by [39] provided an interesting application in eLearning. The Georgia Institute of Technology in the United States provided some of their online courses using virtual teaching assistants (TAs). The chatbot was developed using IBM *Watson*; the TAs can reply to student questions without informing the learner that they are artificial intelligence agents.

2.7. eLearning in Information Technology (IT) Companies

When it comes to technology companies and IT organizations, one can assume they are already ahead of others when it comes to their eLearning capabilities. There is little known about how they transform knowledge internally. One of the interesting findings that high-tech companies like Microsoft, Google, IBM, Cisco, Canon and Microsystems are using gamification capabilities to motivate and train their people. Canon technicians are learning how to fix and repair by literally dragging and dropping parts virtually, while Cisco has a platform called MyPlanNet, where employees play the role of a company's manager. Additionally, IBM developed a game simulation that allows employees to run an entire city [40].

Another common practice among technology companies is to share their online training materials externally. In other words, they focus on training individuals before they hire them, particularly because high-tech companies require highly skilled human resources already trained in their preferred way of working. For example, IBM- and Google-certified specializations can be found on eLearning platforms like Coursera, Microsoft courses, Edx and Udacity. This practice not only cuts training costs for IT organizations but may also become an additional profit centre as they license these certificates. In addition, companies can access a pool of talented full-stack programmers when needed.

2.8. Life-long Learning and eLearning

Life-long learning (LLL) sometimes gets confused with adult learning. LLL is a process where individuals seek learning opportunities to develop their knowledge, skills and life (Richardson, 1978 in Mouzakitis & Tuncay, 2011). Individuals who have an interest in LLL have a continuous ambition to learn and are responsible for their self-learning. According to the European Commission (briefing paper 20, 2001), LLL has become a targeted objective for learning policies at the national and international levels in recent years. In [41], the author conducted

empirical research on 138 employees and found that seven out of ten employees prefer eLearning course delivery over classroom attendance. These data support how eLearning should play a vital role in executing lifelong training, especially for employees between 55 and 64 years old in all sectors.

3. Methodology

In an attempt to follow a preferred reporting items for systematic reviews and meta-analyses (PRISMA), research should provide an explicit statement and form questions including participants, interventions, comparisons, outcomes, and study design (PICOS) [42]. Therefore, the research questions (Table 1) have been formed based on PICOS principles. The following detailed systematic review is based on results from research papers obtained in different online journals and databases that focus on eLearning, KM, and OP, in addition to CAL.

3.1. Data sources and Search Strategies

Different articles were found to match the searching criteria. In particular, 211 materials were found in credible online journals. All the results were found using WorldCat.org, Google Scholar and Crossref databases, as shown in Figure 3. The searching algorithms used included the presence of the required elements in the research objective; additionally, the exclusion aided to sort out the sources which were undesirable, and no organizational context was side-lined, leaving only the required data. The following keywords have been used to locate information from the journal kw: ("computer-assisted education" OR "computer-assisted learning" OR "computer-assisted training" AND "knowledge management" AND "computer science") AND kw: ("e-learning" OR "eLearning" OR "online learning") AND (yr: 2016–2020). Additional keywords used to refine the search are "eLearning" AND "organizational performance" OR "organizational performance". Table 3 gives more insights on the inclusion and exclusion criteria.

Table 3: Inclusion and exclusion criteria

Inclusion	Exclusion
Articles published in 2016 or later	Articles published before 2016
Should be related to KM methodologies, processes, or lifecycles	Related to KM or OP but not linked to eLearning
Should be related to computer-assisted learning or techniques	Related to eLearning but not linked to KM or OP
Should have five or more citations	Has fewer than five citations
Papers are in English	Papers are not in English
Articles	Books or book chapters

3.2. Challenges faced

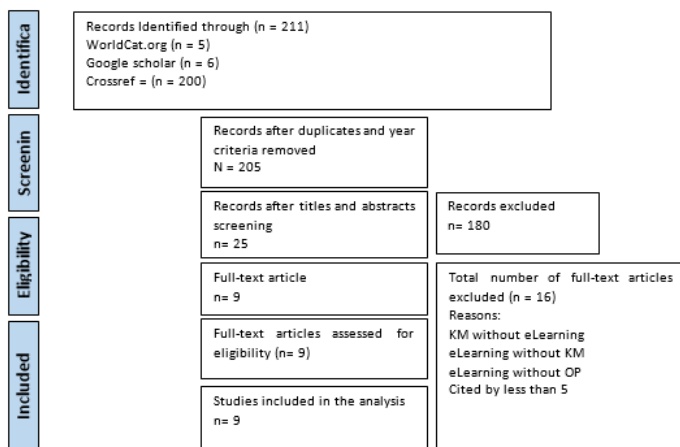
There is no one clear definition of the field of computer-assisted learning, making it challenging to locate all the research about it and its relation to the eLearning and KM cycle. Some related terms are computer-assisted education, computer-assisted instruction and TEL. The category of TEL may be too broad or have no direct relation with eLearning and OP yet.


Figure 3: Research PRISMA model [43]

4. Results

The following is the result of reviewing the shortlisted nine research articles published between 2016 and 2020 on the impact of KM strategy and learning capabilities on OP.

4.1. RQ1. How are eLearning capabilities in KM impacting OP?

Previous studies mentioned that organizational eLearning capabilities in their KM context could enhance OP in many ways. Table 4 summarizes the main findings of the analysed KM researches in the context of eLearning and OL.

The finding revealed the many ways eLearning capabilities can impact OP. eLearning is a scalable tool that can increase individuals' competency levels on large scales. Every single individual can contribute to their organizational competitiveness, accelerate innovation rate and ultimately achieve a knowledge-based economy for their societies [19]. eLearning can also cut training and travel costs and ensure consistent training for all, increasing the quality and ensuring everyone is getting the same high-quality training [44]. Using the right eLearning capabilities can make a difference in the impact of the performance and quality result. eLearning Management Systems such as Moodle have proven to be the most effective tool in knowledge transferring compared to other distance learning tools such as email and teleconferences. Picking the right eLearning tool is essential because it increases the knowledge sharing among individuals and eventually increases performance and productivity [45]. Developing and sharing eLearning content on open platforms can also lead to gaining customer trust, attracting talent and enhancing organizational reputation. eLearning can also work as a new revenue stream for organization setting on knowledge assets [33].

Table 4: Analysis of KM research with regards to eLearning and OL.

Ref.	Purpose	methods	Finding	Country
[19]	KM and eLearning in Organisations.	Literature review	eLearning will not run alone without the KM.	Malaysia
[33]	The role of open educational resources (OER) in the eLearning movement	Literature review	Opportunities and advantages and limitation of OERs	Iran
[44]	E-Training & employees' performance.	Survey	Significant relationship between e-training (including e-training infrastructure & methods) and job performance,	Bahrain
[45]	The effectiveness of eLearning on change management and KM strategy in the organization using "Moodle".	Case Study	eLearning is the most effective method of knowledge transfer.	Canada
[46]	Study deep learning applications for developing resource for eLearning platform.	Qualitative	Deep learning enables the reusing repurposing current eLearning resources to create more personalized experience.	Saudi Arabia
[47]	How mobile learning experiences can support the co-creation of new knowledge.	Qualitative	That mobile technology is an excellent way to stimulate the social co-creation of new knowledge.	Thailand
[48]	A review of the current literature on digitally based serious games & gamification using digital tools in corporate training.	Literature review	Design principles for a game-based training methodology.	United States
[49]	The role of OL in employee engagement. The role of eLearning resources quality in bank sector.	Survey	OL positively impacts employee engagement, and eLearning resources quality partially impact employee engagement.	India
[50]	To integrate inquiry learning and KM into a flipped classroom to programming students in a higher education setting.	Quantitative	Integrating KM and inquiry-based approach into a flipped classroom can improve students' performance.	Thailand

4.2. RQ2. What are some obstacles to organisation learning using eLearning?

There are many factors that could undermine eLearning's effectiveness in any organisation. The first factor is the human factor. Some employees will resist sharing or allowing knowledge to transform because it might threaten their existence and will make them replaceable. Another factor related to human nature is the willingness to learn. Employees being in their comfort zones too long will not benefit from eLearning materials, and they might need some explanation on how eLearning can be useful for their career advancement [19]. Another human-related factor is the widespread belief that free and accessible content is worthless. The language [33] and the user interface can also be an obstacle to accessing the eLearning platform. The platform needs to be easy and straightforward to use, or the employee should be trained on it if necessary [44]. The quality source of the eLearning is also vital to ensure that useful and accurate messages are being delivered. This factor is particularly critical in some industries, such as the financial sector [49].

Content high initial development cost can also be a challenging factor in some small and medium organisations. However, the long-term impact can be scalable and widely accessible [46]. Intellectual properties of the content itself can also be restricted in some cases and limit the opportunity of sharing it, and this can go both ways [33]. Finally, the top management endorsement is vital to ensure that a knowledge-sharing and learning culture is in place [19,44].

4.3. RQ3. What are some of the emerging trends and technologies in eLearning?

Many significant trends emerged in eLearning in the last decade (Table 5). Some of them impact learners' outcomes and enhance their learning experience. These trends include Mobile Computer-Supported Collaborative Learning (mCSCL) [47], game-based learning - Gamification [48], flipped classroom [50], using Deep learning and artificial Inelegance in the eLearning field [46] and Open Educational Resources (OER) [36]. What the majority of these trends have in common can be summarized in their ability to provide social interaction, fun, and interactive and unlimited access. The instructor becomes a facilitator; learners are in control, and they co-create the new knowledge [47].

Table 5: The main trends and technologies eLearning found in the reviewed papers

5. Discussion

5.1. eLearning capabilities & OP

In [19], the study discussed the impact from an economic development perspective. As the economic evolution is witnessing a shift from an industrial-based economy to a knowledge-based economy, the whole country's performance, and not just the organization's, depends on the human capital being equipped with the necessary academic skills. Learning capabilities remained the

key challenge in a country like Malaysia to fully transform its economy into a knowledge-based one. This study valued learning capability as a vital role for remaining competitive. Successful organizations are those that can capture intalactual assets by managing their knowledge. The paper also acknowledged the critical role of top management, as they need to understand the best way to combine and share the knowledge sources to improve the company's performance. Once learning capabilities are rooted and embraced as part of the organizational culture; it will lead to increasing the competency level of every single individual, driven by the role of its KM system. Only then can the organization reach its full potential and increase its competitiveness performance [19]. However, the author did not specify what methodology was used to reach his findings, and he did not support his findings with examples or case studies.

The study by [33] pointed out how eLearning capabilities could reduce training costs and have a long-term impact on reducing operational expenses, which would lead eventually to better financial performance. Some researchers think organizations that create and share open-learning resources should be exempt from taxes.

The results of [44] also confirmed the [33] finding in cost savings. The study highlighted the importance of eLearning and its impact on individual performance. One direct impact of endorsing eLearning capability can be a huge amount of saving in training. This saving includes travel expense and training time. Other advantages include flexibility in self-based training and the variety and availability of training content. The eLearning model can also guarantee unified training for all, which will keep the resource inside the organization. The business will not be interrupted by those who take leave for training. This will increase the workers' productivity and the number of skilled and trained human capital, which ultimately will allow the business to remain competitive [44]. In addition, long-term organizational success is linked to embracing a learning culture among employees. One significant finding is the role of the eLearning infrastructure on employee performance.

The results of [45] are in line with the above findings, as the authors also found that eLearning is the most effective method of knowledge transfer. The authors examined how different learning capabilities can impact executing a successful KM strategy and improve the chance of knowledge sharing among individuals, which ultimately will lead to improving an individual's productivity and OP.

Three knowledge transfer types were used (email, teleconference, and eLearning), and eLearning proved to have the most significant impact. It created a sharing culture and a common place to retrieve information, but the authors also pointed out that further investigation was needed to ensure that the reuse of this module would lead to performance improvement [45]. Although the study used Moodle, an open-source eLearning platform, it did not discuss the security issues associated with open systems and platforms.

The study also highlighted the importance of matching learning modules with the right organizational needs; this will result in improving OP. In addition, the learning capabilities involving the use of eLearning modules can constitute a useful tool for sharing knowledge. This system will allow "just in time" training that will enable employees to cope with the necessary changes to their overall performance.

Another way in which an organization can use eLearning to stimulate their performance involves sharing their knowledge in an open platform or on the company's website, where they can attempt to gain customers' trust and attract talent's confidence. It is also a way to enhance the organizational image and reputation. In addition, the distribution of free learning materials can lead to an individual doing something for free in return. A study [33] has also highlighted the increased willingness of individuals to engage in an activity associated with a company after benefitting from free services such as knowledge sharing.

The results of [46] support the proposal of [33]. Deep learning applications in eLearning can automate this process and boost the repurposing of current organizational learning resources to create more customized experiences and content using the power of the natural language process (NLP) and machine learning.

5.2. Challenges in eLearning

In [19], the authors pointed out that, as everyone could imagine, eLearning practices were not a comfortable ride. The biggest obstacle in this paper was not the technology or the KM itself. Surprisingly, it lay in the human factor of the process. It has been found that employees can resist sharing the necessary knowledge. Individuals in organizations may argue that sharing the knowledge they have will threaten their existence in the organization, leading to their replacement with younger, cheaper staff. In addition, the embracing of comfort zone culture in organizations can be a barrier to making use of the full potential of eLearning tools. However, this finding could have been enhanced if it is supported by more concrete evidence. Further studies are needed to support this claim.

In [33], the study referred to an unfortunate widespread belief that if something like eLearning is free and accessible by all, such as OER, it might mean it is worthless. However, these concerns are not in line with those of [52], who found OER improves students' grades and addresses attainment gap concerns. They also offer opportunities for part-time students and populations historically underserved by higher education.

Intellectual properties were also raised in this study, where content producers restricting the reuse, editing, combining, or distributing of training materials. Language can also be a barrier for those who do not speak English as a second language. The same also applies to cultural diversity; the contextual gap can be another challenge that will result in a barrier for understanding not only the words but the context of the concept expressed through them.

The results of [44] are consistent with that, as the findings pointed out the importance of the simplicity and the accessibility of the eLearning platform as it might be an obstacle of the user interface was not interactive or attractive enough [44].

In [53] the authors have discussed the role of the eLearning resource quality and how the message of the content can be lost in the process. The issue related to updating multiple organizations, scattered in different locations from one credible source. Banks industries, for example, are impacted by several changes based on the economic situation. This industry is regulated by government economic policies that keep constantly changing to respond to the economic situation. Delivering these new updates effectively and swiftly is essential to bank employees. Banks are usually developing eLearning capabilities to inform their employees with these continuous updates; however, lacking a suitable mechanism to understand the quality of the learning resources can affect the understanding of these updates, resulting in outdated products and services, and eventually effects the bank's performance [53]. Unfortunately, high-quality content is usually associated with high cost. The results of [46] reinforce that by flagging out the cost involved in developing learning content. Although eLearning facilitates learning anytime and anywhere, the initial cost of developing eLearning resources can be a barrier to further deployment on an organizational level [46]. However, [46] also suggests tackling the cost linked with content development by using deep learning applications in reusing and purposing existing content, and save cost for the long-run.

5.3. eLearning emerging trends

In [47], the paper has discussed the mobile devices as one of the learning tools enhancing corporative learning. They describe the mobile learning operationally by a cooperative social process, supported by handsets, where the participant uses their handsets to interact internally and externally, to share and generate new knowledge. They used the terminology "mobile computer-supported collaborative learning" (mCSCL) to describe these activities. The paper also found six emerging perspectives on what learners are experiencing in mobile learning nowadays. They summarised their finding in the following points: 1) Social interaction is necessary, 2) Unlimited learning experience, 3) Learning becomes fun and interactive, 4) Instructor is becoming facilitator, 5) Learners control their learning between each other, 6) Learners value the co-creation of new knowledge [47].

A study by [48] highlighted another emerging field in adapting eLearning in an organization using game-based learning. These learning tools utilize the psychological readiness of individuals to engage in games. Game-based learning uses the same motivational and addiction mechanism used in video games and applies it to real-world activities to make them more enjoyable and attractive. The efforts focused on employing gamification techniques in the workplace to motivate, training and recruiting. Game-based training increases engagement, motivation, performance, and retention.

The study uses some empirical evidence as a successful application of game-based learning in the workplace environment.

Including L'Oreal, IBM, Cisco, Deloitte, and McDonald's. Whereby these companies have developed and implemented gamification and serious games as part of their overall training strategy. The impact has been measured by reducing lost time, an increase in engagement, and an increase in revenue up to USD 30 million [48].

In [50], the results suggested a flipped-classroom approach to improve learning outcomes. Flipped classroom or flipped workshop is considered an effective learning way by many researchers. The flipped classroom concept focuses on post-course activity, forcing learning to prepare and preview the material outside the class hours. For example, online learning tools are usually utilized, and learners have to attend online learning materials provided by the trainer before joining the actual class. The early finding indicates an improvement in learner's performance.

Authors of [46] have highlighted deep learning using artificial intelligence as one of the emerging trends in many eLearning fields. The value of deep learning comes in its ability to offer learners intuitive algorithms, automated delivery of content, the ability to swiftly reuse the current resource, and decrease the cost of content development. Some deep learning applications in eLearning includes Personalized learning path, Chatbots Performance indicator and Virtual teaching assistant.

The study of [33] discussed the role of OER in eLearning applications. The advantages of OER have gained increased attention worldwide; this could be for OER's potential in overcoming educational, demographic, economic, and geographic limitations. OER can come with various models, for example, the 4A model characterizes OER in the following As Accessible, appropriate, accredited, and affordable. In contrast, the 4R model characterized it in a 4R model, these Rs are: Reuse (open license of applying all or part for an individual goal), Revise (Editing, translating and modifying the content, Remix (Combining two materials to create a new resource and Redistribute (sharing with others).

The MOOC is one of the well-known concepts that has emerged from OERs. MIT's open courseware, for example, is the largest provider of such courseware. Up to 2015, MIT has successfully archived 2,250 training courses, and 450 training courses are being added annually. Many educational institutes have followed MIT's practices policy in publishing free open courses on MOOC platforms, such as Coursera, Edx, and Udacity platforms. Some corporations have even started to follow that practice, including IBM, Microsoft, and Google [33].

6. Conclusions

This paper has explained the importance of eLearning as a knowledge transfer tool on OP. It has also discussed the challenges and obstacles of applying eLearning tools and has highlighted the recent eLearning trends from 2016 to 2020. This study has further shown how individual LLL is critical in creating a knowledge-based economy and how eLearning capabilities provide an ideal solution for that mission. The research has shown that eLearning can impact OP in many ways. Also shown was the importance of matching learning modules with the right organizational needs in order to achieve the desired performance. One of the more significant findings is that sharing knowledge externally on an open eLearning platform can lead to gaining customers, attracting talent, and increasing a company's reputation and value. However, many of the findings discussed need further investigation. There is little known on how eLearning capabilities have impacted organizations during and after COVID-19 in different regions. Further study suggested studying the impact of eLearning as an LLL practice. Moreover, researchers must look at how students, young people, and senior employees engage in the eLearning platform, determine what motivates them, and decide how to validate their learning outcomes.

ARTICLE INFO

ABSTRACT

In the modern marketing system in a mass consumer society, the central place is given to the formation and promotion of brands. Professional conceptual approaches to brand management are able to preserve and increase the value and stability of the brand and allow the brand to survive in the most difficult competitive and crisis market conditions. In view of the fact that there is a fairly large number of theoretical developments, the purpose of the study was to develop practical recommendations regarding the strategic management of brand positioning in the market. The authors have developed an Algorithm for the strategic management of brand positioning in the market, which consists of 5 stages and 11 tasks. The tools proposed by the authors, which were discussed in detail and clearly demonstrated in the article, are of practical value. The product positioning process is not an easy process, and therefore even experienced professionals are not immune from mistakes. This research will help better to understand the brand positioning strategy in the market.

1. Introduction

Transformation processes in the economy in recent years have led to significant economic changes. With the transition to a market system, business entities' conditions have changed significantly, so the existing management and marketing technologies are no longer sufficient for successful management in market management conditions.

Given the saturation of the market with goods and services to stand out from the competition and take a worthy place in the minds of not only consumers but also all market participants, companies focus their efforts on differentiating offers, based on which they position their products. Branding in modern society is more than just creating a name, company logo or product. Thanks to the successful development and implementation of strategic

management of brand positioning in the market today, brands can become not only consumer market products, but also corporations, law firms, cities, countries, universities, hospitals, museums, restaurants and even individuals [1]. It is not surprising that consumers are willing to buy, first of all, well-known and high-quality so-called branded items or use the services of branded companies. They can increase the company's rating, on the one hand, and consumer status in society – on the other. Understanding the need and effectiveness of creating and positioning a product or corporate brand, the number of domestic brands consulting agencies – specialized companies for the strategic management of brand positioning in the market. Despite the growing interest in the problem of positioning by marketing theorists and practitioners, the main approaches to the selection and implementation of positioning strategies are still not systematized; there is no single approach to their classification and complementarity and mutual

avoidance, which complicates the positioning of products, brands and enterprises in practice.

Thus, branding is a relevant and demanded marketing tool for the formation of consumer demand, sales promotion and sales. The brand regulates the buyer's behaviour, creates a stable favourable image of the company and the product, and guarantees long-term stable relations with a loyal consumer. It is the relevance that explains the purpose of the study - the development of practical recommendations for the strategic management of brand positioning in the market.

2. Theoretical aspects of brand positioning management in the market

Jack Trout coin the term product positioning. Trout detailed the product positioning theory in his Industrial Marketing article, which was published in June 1969 [2]. The article aroused great interest in the marketing community, and later, in 1981, in their book Positioning, Battle for Minds, Jack Trout and Al Rice elaborated on the concept of "product positioning", supplementing it with many examples and illustrative business cases [3].

The reason for the emergence of the positioning theory is the desire to find a way to distinguish a product among products with similar properties and characteristics through marketing communications. Positioning theory says that the consumer cannot remember all goods' characteristics on the market due to their large number; therefore he remembers by the method of associations, endowing each product with certain attributes that are important to him when buying a product [4].

Branding is activity on development and brand management. Brand (from the English brand – stigma) – is the "brand name", the name of the enterprise, product, product group, service, etc., the official trademark. The brand provides wide popularity of the object, the ability to recognize it, uniqueness, deep penetration into the consciousness/subconscious of many members of the target audience, and significant value in consumers' eyes. This is a correctly and effectively constructed image, embodied, first of all, in the name. A brand is an information about the company, product or service; popular, easily recognizable and legally protected symbols of the manufacturer or product. Creativity is the most critical moment in the life of a brand. It is necessary to be noticed and to achieve the maximum positive perception of the market offer [5].

Branding requires high financial costs that are justified only for specific products. Also, relevant issues are related costs – inventory management [6, 7], human resources [8], innovations [9], etc. Thus, among branded goods without branding, victory is impossible in competition. Such goods, in turn, due to the high cost, contribute to the growth of profits and the formation of a producer's successful image [10]. There are various methods of brand evaluation, which are used to determine the ratings of the latter. Annual brand ratings illustrate certain phenomena and their patterns that occur in the economy and allow you to predict certain future events [11]. Marketing strategy, which also includes product positioning, is an area where practice prevails over theory. Due to the limited volume of the article, the authors decided to focus on the practical aspects of strategic management of brand positioning

in the market, namely, to develop an algorithm and tools for its effective use.

3. Results: an algorithm for the strategic management of brand positioning in the market

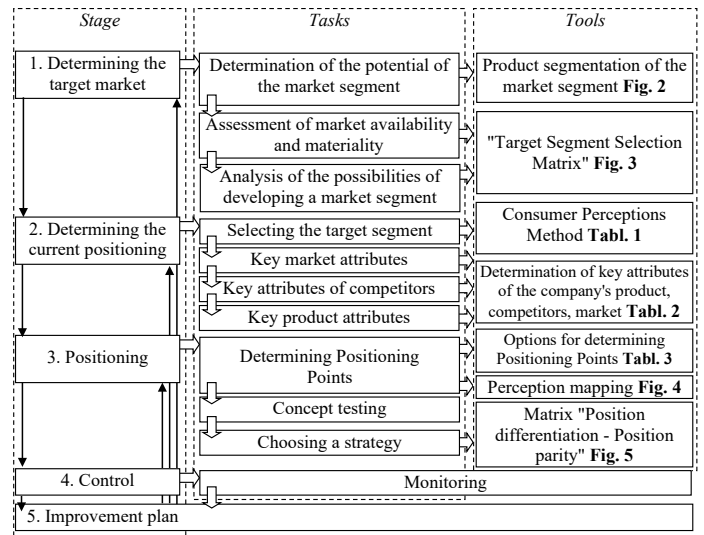
Based on the literature and existing practices analysis, the authors present an algorithm for developing brand positioning in the market (Fig. 3).


Figure 1: Algorithm for the strategic management of brand positioning in the market

The process of developing brand positioning consists of the following stages: determining the target market, assessing the current perception of the brand and competitors, developing and testing possible product positioning concepts, as well as monitoring the competitiveness of the approved strategy in the future and ways for further improvement if necessary. Let's consider the stages in more detail.

Stage 1. Selecting the target market. Setting a target market is the process of deciding which market segments a company should actively work to increase sales. Companies choose between an undifferentiated or differentiated approach or prefer a so-called concentrated approach.

The target market is the most suitable and profitable group of market segments (or one and the only segment) for the company, to which its marketing activities are directed.

Step 1.	List all the products available on the market: in the listing it is not necessary to be a maximalist and try to cover the market by 100%. It is enough to list all the products of large and medium players.
Step 2.	Determine all the characteristics by which the listed products differ. These characteristics can be: properties, volume, packaging, price, special taste, smell, etc.
Step 3.	Survey of consumers of the target market: what characteristics do they actually divide the goods on in the market. Target audience polling is a very important point in any market segmentation.
Step 4.	Compilation of a complete list of segmentation criteria based on Steps 2 and 3.
Step 5.	Description of each product from the list according to the listed characteristics.

Figure 2: Algorithm for product segmentation of the market segment (developed by the authors)

Suppose the company is faced with the task of conducting product segmentation of the industry. In that case, we propose to use the following algorithm (Fig. 2), with which it is possible not only to assess in detail the structure of the market but also to find free market niches for expanding the scope of the company.

The choice of the target market is closely related to the issues of product positioning, identifying its distinctive features and characteristics and determining its place in the market among other similar products from the perspective of the consumer himself. Positioning makes the product recognizable in the market. "Target Segment Selection Matrix" (Fig. 3) will allow a better understanding of the availability for the company of the materiality of the market and analyze the possibilities of developing a market segment.
Figure 3: Target Segment Selection Matrix

In practice, these strategies can be implemented in the following ways:

1. Narrow specialization, concentration on one market segment, for example, on the production of one type of gadgets for adolescent girls.

2. Focus on consumer needs, for example, the production of one type of gadgets for all age groups of consumers.

3. Targeting a consumer group, such as producing a wide range of gadgets for teenage girls.

4. Selective specialization, such as the production of certain types of gadgets for certain age groups.

5. Full coverage of the market, namely: production of all types of gadgets for all age groups of consumers.

When selecting the optimal market segments, it is recommended to give preference to the largest segments, segments with clearly defined boundaries and not intersecting with other market segments, segments with new, potential demand, etc. It is considered to be the most optimal segment, where there are about 20% of buyers of this market, purchasing about 80% of the goods offered by the company.

Stage 2. Determination of the current position The stage involves assessing how the target audience (= target market) perceives the company's product and competitors' product. It is necessary to determine from 5-10 definitions that best characterize the goods in the opinion of consumers (Table 1).

Table 1: An example of determining the current positioning of a product of a company and main competitors based on consumer perception

Current perception of the company's product	Current perception of competitor's product 1	Current perception of competitor's product 2	Current perception of competitor's product 3
modern	traditional	known	expert
fashionable	known	widely advertised	high quality
young	widely advertised	recommended by experts	expensive
plain	recommended by experts	quality	recommended by experts
cheap	quality	safe	innovative
dynamic	safe	innovative	foreign
safe	family	dynamic	
A modern product without unnecessary additions for the younger generation at an affordable price	*Renowned Recommended Brand for the Whole Family*	*A well-known innovative brand recommended by experts*	*Innovative import brand expert*

To determine the key attributes of a product is necessary to decide on the properties of the product, which are essential in the industry and can become the basis for positioning the company's product (Table 2) ensuring the security of the region.

Market properties – mandatory properties for each product;

Distinctive properties of the company and competitors - characteristics of the product that are unique and not found elsewhere on the market;

Consumer properties is a description of the ideal product in the words of the consumer. The last column indicates the basic needs that the consumer seeks to solve using the desired product property (based on his motivation).

Stage 3. Positioning Now that all the preparatory stages have been passed, you can proceed directly to the very process of developing product positioning, which consists of four sequential phases: determining points of differentiation (= positioning points), building perception maps and testing the developed positioning concepts and choosing a strategy.

Points of differentiation. All good profitable markets have been occupied for a long time; they are highly competitive. In such markets, some companies are "first and best"; in such industries, all market niches are usually occupied, and it takes a lot of effort to find a competitive positioning for a new product. Points of differentiation (= positioning points) will help a company find vacant niches and look at the market from different angles (Table 3).

Table 2: Determination of the key attributes of the company's product, competitors, market

Properties of goods on the market	Market properties of goods	Company product properties	Competitor properties	Consumer properties	Problems and needs that the consumer seeks to solve with this property
Property 1	+	+		+	need 1
Property 2		+	+	+	need 2
Property 3			+		
Property 4	+	+		+	need 3
Property 5		+	+		
Property 6		+	+	+	need 4
Property 7	+			+	need 5
Property 8		+	+	+	need 6
Property 9		+			
Property 10	+	+	+	+	need 7

Table 3: Examples of positioning points

Options			Could it be a positioning point?
Option for creating a new subcategory on the market			
Product category improvement options	How can this sound? O1	How can this sound? O2	PP
improvement 1	not just (product category), but (improved product category)	The first in ...	yes/no
improvement 2	not just (product category), but (improved product category)	The first in ...	yes/no
EXAMPLE: new brand	Not just a brand, but a changing perception	Not just a brand, but a changing perception	yes
Option for Solving Consumer Needs			
Needs and problems of the target audience	Are the current market players solving this problem?	Is leadership possible in solving the problem?	PP
problem 1	yes/no	yes/no	yes/no
problem 2	yes/no	yes/no	yes/no
problem 3	yes/no	yes/no	yes/no
permanent breakdowns	no	yes	yes
inaccurate measurement	yes	yes	yes
impractical design	yes	no	no
The Option to Create the Opposite Image			
Perceptions and properties of competitors	Opposite	Attractive to the target audience?	PP
perception 1	…	yes/no	yes/no
property 1	…	yes/no	yes/no
traditional	innovative	yes	yes
known	little known	no	no
widely advertised	unadvertised (not overpriced)	yes	yes
Market Leadership Option			
Market properties of goods	Will it be valuable to the consumer if the product performs this property best?	Is there a product that best implements this property?	PP
property …	yes/no	yes/no	yes/no
ease of use	yes	yes	yes
memory	yes	no	yes
the ability to change the design	no	no	no

It is also possible to search for positioning points by opposition to the main competitor, by the method of product use, etc.

Choosing of strategy is one of the most important decisions in brand positioning. We propose using the matrix "Position differentiation – Position parity" (Fig. 5).

	Strong	Neutral	Weak
Strong	Raising the parity of the position	Maintaining a differentiated position	Maintaining a leading position
Neutral	Increasing the parity of the position and creating additional points of differentiation	Adjustment of position in the direction of strengthening parity and (or) differentiation of position	Maintaining a parity position
Weak	Repositioning	Creation of additional points of parity and strengthening of position differentiation	Enhancing position differentiation

Position differentiation (Y-axis label) — *Position parity* (X-axis label: Strong, Neutral, Weak)

Figure 5: Matrix "Position differentiation - Position parity"

The construction of the matrix is based on the following indicators.

1. Differentiation of the organization's position for consumers (Y-axis):

$$D = \sum_{i=1}^{n} W_i O_i \qquad (1)$$

where D is an indicator of differentiation of position for consumers;

W_i is the rank of the i-th differentiation point for the consumer (ranking in descending order, where the highest rank is the most significant differentiation point);

O_i is the assessment of the i-th point of differentiation by consumers (in points, from 1 to 5);

n is the number of points of differentiation;

2. Parity of the organization's position for consumers (plotted along the X-axis):

$$P = \sum_{i=1}^{m} W_i Q_i \qquad (2)$$

where P is the position parity indicator;

W_i is the rank of the i-th categorical point for the consumer (ranking in descending order, where the highest rank is the most significant point of differentiation);

O_i is the assessment of the i-th categorical point by consumers (in points, from 1 to 5);

m is the number of categorical points.

According to the matrix, the following types of strategies can be used [5].

Leadership strategies:

The strategy of maintaining a leading position assumes that the position of an educational organization is unique and contains the main characteristics associated by consumers with its activities – an optimal set of points of parity and differentiation. With distinct differences from the competition, the educational organization offers consumers exactly what they expect. It is the strongest and most attractive position in the minds of consumers.

The strategy of maintaining a differentiated position provides that the position is strong enough and has unique points of differentiation, but requires the educational organization to clearly understand why it has fewer parity points than the leading organization. The parity points taken as a basis are not very significant for consumers, or not all consumer expectations regarding these points are fully satisfied.

The strategy of maintaining a parity position assumes that the existing position is beneficial to the educational organization, since, despite the absence of unique characteristics (points of differentiation), consumers rate it highly and consider it attractive in terms of the proposed set of parity points.

Market Follower Strategies:

The strategy of increasing the parity of the position is a strategy in which the position of an educational organization is unique and has certain points of differentiation. Still, it is not significant enough for consumers. In this situation, the educational organization, as a rule, concentrates its marketing communication efforts on demonstrating to consumers those points of differentiation that do not matter to them. As a result, it is necessary to adjust the position, supplementing it with points of parity that are important for consumers.

The strategy of adjusting the position in the direction of increasing parity and (or) differentiation of the position assumes that the position of the educational organization is represented by characteristics that are different from competitors. Still, they are not of particular importance to consumers. The author has proved that in this case the position can be considered as promising, provided that the educational organization directs marketing efforts to increase its attractiveness - increasing the level of implementation of existing points of parity and points of differentiation through a significant set of marketing communications.

The strategy to enhance position differentiation is a strategy whereby a position is attractive in the short term because it is highly regarded by consumers. Nevertheless, in the context of continuously increasing competition in the market, it can "get lost", which dictates the need to direct marketing efforts to find points of differentiation to form a position in the long term.

Market Challenger Strategies:

The strategy of increasing the parity of the position and creating additional points of differentiation is used if the current status of the educational organization is not entirely attractive to consumers, since it does not contain a set of mandatory points of parity with which they associate its activities. As a result, the position does not have significant points of differentiation to attract the attention of consumers, which requires adjustments to complement the points of parity and differentiation that are meaningful to them.

The strategy of creating additional points of parity and strengthening the differentiation of the position is applied if the position of the educational organization does not stand out among others and is of little interest to consumers since it is not represented by points of differentiation and does not include all characteristics and points of parity that are important for consumers. In this situation, it is necessary to optimize the position by a set of parity points.

The repositioning strategy is used if the position does not have parity and is not differentiated, which requires an educational organization to make immediate marketing efforts to change it significantly.

The choice of an adequate strategy makes it possible to match the position transmitted using marketing communications and the position that has developed in the perception of consumers, thereby increasing the efficiency of brand management. This is possible using a set of communications for brand promotion on the market, developed by the chosen positioning strategy and implemented in marketing practice.

Stage 4. Control The product positioning process is not an easy process, and therefore even experienced professionals are not immune from mistakes. Therefore, after choosing a positioning control strategy, it is necessary to check it for compliance with the following criteria:

- positioning is based on 2-3 essential product characteristics;

- the target group of the product is clearly defined, it is evident from the positioning that the product is designed "not for all consumers";

- if the positioning is based on price, then it is not the only parameter;

- if a product is positioned against the prominent market leader, then it has absolute superiority in a particular area;

- for one target market, only one type (strategy) of product positioning is used;

- positioning is based on promises and product properties that the company is able to fulfil;

- positioning does not provide for cardinal repositioning of the product, or intermediate product positioning has been developed;

- if the existing positioning of the product was successful, then the new positioning only improves it, and does not change it;

- when developing positioning, a sufficient number of alternatives were considered, and the first successful option was not chosen.

Monitoring also includes tracking possible changes in market conditions, the emergence of new consumers, the strengthening of competitors, etc. The company can choose the different frequency of monitoring various components depending on the rate of their change.

Stage 5. Improvement plan Almost any company strives to maximize profits, sometimes this is not a primary goal, but it is also essential; therefore it is periodically necessary, after monitoring the current situation, to make forecasts for the future and improve the positioning strategy. Over time, the strategy can transform into a company's diversification strategy. When drawing up an improvement plan, it is necessary to go through stages 1-3 especially carefully, because sometimes top management makes the main mistake in this, considering these stages "passed" and does not go through them in detail again.

Thus, the proposed algorithm for the strategic management of brand positioning in the market and tools for its effective use will allow business entities to understand better and implement marketing tools to strengthen their competitive positions.

4. Conclusion

The basis of the success of any business is the presence of sustainable competitive advantages of goods and services, which consists of the consumer's understanding of their distinctive properties. The application of strategic positioning management significantly contributes to the solution of this problem. Brands and trademarks bring significant benefits to producers and consumers, which guarantees producers additional profits, ensuring consumer loyalty, and thus reducing the impact of competition on fluctuations in sales. The presence of a brand and consumer loyalty shows that one or another business entity is more competitive, especially in crisis conditions, and has greater advantages compared to other entities. This significantly mitigates the reaction of consumers to possible price fluctuations, opens up new opportunities for expanding markets for enterprises of the national economy.

Strategic management of brand positioning in the market is one of the most important marketing processes, which determines the adequate market position of the product and/or the company as a whole. The positioning strategy is multifaceted and requires separate consideration; tactics indicate the relationship with the marketing mix, and in the latter, the main role is given to promotion.

In the study, the authors focused on the development of practical recommendations for brand management: The proposed algorithm for the strategic management of brand positioning in the market and tools for its effective application will allow business entities to better understand and implement marketing tools, reduce costs, expand market share to strengthen their competitive positions.

Areas of further research may be the approbation of the proposed tools at domestic enterprises and the development of theoretical and methodological recommendations for rebranding.

Conflict of Interest

The authors declare no conflict of interest.

	In this paper, we are concerned to investigate the efficiency of the second-order Redlich-Kister Finite Difference (RKFD) discretization scheme together with the Four Point Explicit Group Kaudd Successive Over Relaxation (4EGKSOR) iterative method for solving two-point boundary value problems (TPBVPs). In order to apply this block iteration to solve any linear system, firstly we discretize all derivative terms via the second-order RKFD discretization scheme over the proposed problem in order to get the second-order RKFD approximation equation. Due to the main characteristics of the coefficient matrix for the generated linear system which are large-scale and sparse, the best choice for solving this linear system is using one of the iterative methods. Therefore, the formulation of the Kaudd Successive Over Relaxation method together with the Explicit Group iteration method mainly on the Four-Point Explicit Group Kaudd Successive Over Relaxation (4EGKSOR) iterative method has been presented to solve this linear system iteratively. In order to show the efficiency of the 4EGKSOR, another two iterative methods have also been considered which are the Gauss-Seidel (GS) and the Kaudd Successive Over Relaxation (KSOR) to solve three examples of the proposed problems in which all numerical results obtained were recorded based on the number of iterations, execution time and maximum norm. Based on the performance analysis, clearly, the 4EGKSOR iterative method shows substantiated improvement in terms of the number of iterations and execution time.

1. Introduction

The successful of the development of numerical techniques for boundary value problems has been growing rapidly in the past few decades. Many researchers give more attention to this problem numerically and show the capability of their numerical techniques in solving this problem especially TPBVPs; due to its application, this problem can be found in science, engineering and physics fields including optimal control, beam deflection and heat flow [1-4]. In initial works on obtaining the numerical solutions of TPBVPs, many authors attempted to achieve higher accuracy by using the various numerical methods. It was done either by suggesting the families of spline methods for solving second-order two-point boundary value problem, see in [5-9]. The basic approach of these methods is dividing the interval into subinterval and at the same time, the construction of spline, B-spline and extended B-spline in each subinterval considered. For achieving better accuracy, these methods are required to solve a system of equations. Another numerical method is to solve TPBVPs by

developing the innovative method based on the Galerkin method see in [10-12]. Numerous numerical methods are used to solve the boundary value problems related TPBVPs for obtaining the approximation equation can be seen in [13-17].

Besides of using the above numerical methods to solve the proposed problem (1) as stated in the first paragraph, many studies were also introduced via the use of the concept of finite difference method (FDM). As a result, several numerical discretization schemes mainly in a family of the finite difference schemes have been proposed to form a new finite difference discretization scheme. For example, the standard finite difference [18], Chebyshev finite difference [19] and Rational Finite Difference [20] are imposed for solving TPBVPs. Clearly, the development of Chebyshev finite difference and Rational Finite Difference schemes has been encouraged by the combination of the standard finite difference concept together with the Chebyshev and rational approximation functions respectively. In conjunction with these combinations, the author in [20] also introduced a new finite difference scheme via the combination of exponential

954

approximations and finite difference discretization schemes which is known as exponential finite difference discretization schemes to show its capability for solving TPBVPs [21].

Apart from the use of Chebyshev, rational and exponential approximation functions as mentioned in the previous second paragraph, this paper attempts to investigate the feasibility of the Redlich-Kister polynomial as a numerical method for solving TPBVPs. Based on the previous studies on the application of the Redlich-Kister polynomial, the findings have pointed out that various types of Redlich-Kister polynomial functions have successfully been used to develop the appropriate mathematical models in physics and chemistry fields [22-24]. In addition to these functions, only one study has been explored to investigate the application of the Redlich-Kister approximation function in the numerical analysis particularly on constructing the mathematical model. For instance, in [25], the authors investigated the construction of two mathematical models based on the piecewise third-order Redlich-Kister polynomial model and the piecewise first-order polynomial model respectively to show the relationship of the number of iterations for Gauss-Seidel towards its corresponding grid size. The findings of their work concluded that the results of the piecewise third-order Redlich-Kister polynomial model gave highly accurate solutions as compared with the first-order polynomial solution. Inspired by the high accuracy of the Redlich-Kister (RK) function based on high-order approximation function, we present a feasibility study of two newly established Redlich-Kister Finite Difference (RKFD) discretization schemes for solving TPBVPs.

In order to solve the proposed problem, firstly, the RKFD discretization scheme will be used to discretize TPBVPs to form the RKFD approximation equation. After that, the approximate equation was obtained will lead us to construct a linear system. Since the generated linear system has a large and sparse matrix, the use of iterative methods is the best linear solver [26-28]. For instance, the implementation of the point iteration family namely SOR [29], AOR [30] and KSOR [31] can be used to solve this linear system. In addition to this point iteration family, Evans [32] introduced the Explicit Group (EG) iterative method which is faster than the Gauss-Seidel (GS) iterative method to get the numerical solution of this linear system. Despite the speed up the convergence rate for Explicit Group (EG) iteration, many researchers also developed new variants of the EG iteration family such as 9-Point EG [33], EGSOR [34], EDGSOR [35] and MEGSOR [36] in which all these block iterations have significantly reduced their convergence rate. Therefore, further discussion of this paper focuses on investigating the efficiency of the 4EGKSOR iterative method which is inspired by the paper research [37] and apply together with the newly established RKFD discretization scheme for solving the system of Redlich-Kister approximation equations. The formulation of the 4EGKSOR iterative method can be established via the combination of the EG and KSOR iterative methods.

Before applying and investigating the performance of this 4EGKSOR method, we need to do the process of discretization and let us consider the general equation for TPBVPs, which are given as follows

$$\frac{d^2U}{dx^2} + Z(x)\frac{dU}{dx} + G(x)U(x) = r(x), \quad x \in [0, \phi] \tag{1}$$

with the Dirichlet conditions,
$$U(0) = \varphi_0, \qquad U(\phi) = \varphi_1.$$

2. Redlich Kister Finite Difference Approximation Equation

The previous section has mentioned that the use of the RK function to introduce two newly established RKFD discretization schemes for approximating the proposed problem (1). To start the discretization process, firstly let us consider the RK approximation function of order n as follows

$$U_n(x) = \sum_{k=0}^{n} a_k \cdot T_k(x) \tag{2}$$

where $a_k, k = 0,1,2,...,n$ are the unknown parameters to be determined.

Figure 1: Distribution of grid network considered.

To facilitate us in discussing the use of this approximation function, let us construct the distribution of uniformly node points as indicated in Figure 1. Based on Figure 1, let us consider the first three RK functions that need to consider the number of node points as shown in Figure 2.

Figure 2: The path for T_1, T_2 and $_3$.

Then to derive the new second-order RKFD approximation equation, let us consider $n = 2$ in equation (2) and applying the concept in Figure 2, the second-order RK approximation function can be written as

$$U(x) = a_0 T_0(x) + a_1 T_1(x) + a_2 T_2(x) \tag{3}$$

where the first three RK functions are defined as

$$T_0(x) = 1,$$
$$T_1(x) = x,$$
$$T_2(x) = x(1-x).$$

Referring to Figure 1, let us define the node points, $x_c = x_0 + ch, c = 0,1,2,...,n$ where $h = \frac{\phi - 0}{n}, n = 2^p, p \geq 1$ donates the uniform step size. Then $U(x_k) = U_k, k = c-1, c, c+1$ and $T(x_k) = T_k, k = c-1, c, c+1$ represent the approximation value of functions, $U(x)$ and $T(x)$. By considering any group of three node points, x_{c-1}, x_c and x_{c+1} for equation (3), we have the following equations

$$U_{c-1} = a_0 T_{0,c-1} + a_1 T_{1,c-1} + a_2 T_{2,c-1}, \tag{4}$$

$$U_c = a_0 T_{0,c} + a_1 T_{1,c} + a_2 T_{2,c}, \tag{5}$$

$$U_{c+1} = a_0 T_{0,c+1} + a_1 T_{1,c+1} + a_2 T_{2,c+1}. \tag{6}$$

After that, the expression of three parameters $a_k, k = 0,1,2$ in equation (3) can be determined by solving the equations (4), (5) and (6) via a matrix approach. With these three parameters, we rewrite the second-order RK approximation function, $U(x)$ in equation (3) in which it can be shown as follows

$$U(x) = N_0(x)U_{c-1} + N_1(x)U_c + N_2(x)U_{c+1} \tag{7}$$

where the second-order RKFD shape functions, $N_k(x), k = 0,1,2$ are defined respectively as

$$\begin{cases} N_0(x) = \dfrac{1}{2h^2}\left(x^2 - 2xhc - xh + h^2c^2 + h^2c\right), \\ N_1(x) = \dfrac{1}{h^2}\left(2xhc - x^2 - h^2c^2 + h^2\right), \\ N_2(x) = \dfrac{1}{2h^2}\left(x^2 - 2xhc + xh + h^2c^2 - h^2c\right), \end{cases} \tag{8}$$

Then the first and second derivative of these RK shape functions can be shown as

$$\begin{cases} N_0'(x) = \dfrac{1}{2h^2}(2x - h - 2hc), \\ N_1'(x) = \dfrac{1}{h^2}(2hc - 2x), \\ N_2'(x) = \dfrac{1}{2h^2}(2x + h - 2hc), \end{cases} \tag{9}$$

and

$$\begin{cases} N_0''(x) = \dfrac{1}{h^2}, \\ N_1''(x) = -\dfrac{2}{h^2}, \\ N_2''(x) = \dfrac{1}{h^2}. \end{cases} \tag{10}$$

Then, by applying the first derivative concept into the function (7) with respect to x_c, it can be shown that the second-order RKFD discretization scheme of the first derivative of the function, $U(x)$ is given as

$$\left.\frac{\partial U}{\partial x}\right|_c = N_0'(x_c)U_{c-1} + N_1'(x_c)U_c + N_2'(x_c)U_{c+1} \tag{11}$$

and for the second derivative of the function $U(x)$ with respect to x_c can be approximated by

$$\left.\frac{\partial^2 U}{\partial x^2}\right|_c = N_0''(x_c)U_{c-1} + N_1''(x_c)U_c + N_2''(x_c)U_{c+1} \tag{12}$$

where $U(x_c) = U_{c,c=0,1,2,...,n}$ represent the approximation solution of function $U(x)$. Clearly, equations (11) and (12) are known as two newly established Redlich-Kister finite difference discretization schemes.

From the proposed problem (1), it needs to be rewritten in the discrete form at a node point, x_c and then we get

$$\left.\frac{d^2 U}{dx^2}\right|_c + Z(x_c)\left.\frac{dU}{dx}\right|_c + G(x_c)U(x_c) = r(x_c), \tag{13}$$

Then by considering both equations (11) and (12) and substitute them into equation (13), it can be pointed out that the newly established RKFD approximation equation of TPBVPs can be formulated as follows

$$\alpha_c U_{c-1} + \beta_c U_c + \gamma_c U_{c+1} = r_c, \tag{14}$$

where

$$\begin{aligned} \alpha_c &= N_0''(x_c) + Z_c N_0'(x_c), \\ \beta_c &= N_1''(x_c) + Z_c N_1'(x_c) + G_c, \\ \gamma_c &= N_2''(x_c) + Z_c N_2'(x_c). \end{aligned}$$

and

$$Z_c = Z(x_c), G_c = G(x_c), r_c = r(x_c), \quad c = 1,2,3,...,n-1.$$

Referring to the RKFD approximation equation (14) and considering $c = 1,2,...,n-1$, it is obvious that we can construct a generated linear system with its large-scale and sparse coefficient matrix as follows

$$W \cdot U = r \tag{15}$$

where

$$W = \begin{bmatrix} \beta_1 & \gamma_1 & 0 & 0 & 0 & 0 \\ \alpha_2 & \beta_2 & \gamma_2 & 0 & 0 & 0 \\ 0 & \alpha_3 & \beta_3 & \gamma_3 & 0 & 0 \\ 0 & 0 & \ddots & \ddots & \ddots & 0 \\ 0 & 0 & 0 & \alpha_{n-2} & \beta_{n-2} & \gamma_{n-2} \\ 0 & 0 & 0 & 0 & \alpha_{n-1} & \beta_{n-1} \end{bmatrix},$$

$$U = \begin{bmatrix} U_1 & U_2 & U_3 & \cdots & U_{n-2} & U_{n-1} \end{bmatrix}^T,$$

$$r = \begin{bmatrix} r_1 - \alpha_1 \cdot \varphi_0 & r_2 & r_3 & \cdots & r_{n-2} & r_{n-1} - \gamma_{n-1} \cdot \varphi_1 \end{bmatrix}^T.$$

3. Derivation of 4EGKSOR Iterative Method

Since the characteristics of the coefficient matrix of the linear system (15) are large-scale and sparse, the family of iterative methods can be chosen to be the best linear solver as stated in the first section. To solve this linear system, the Kaudd Successive Over Relaxation (KSOR) iterative method was developed by [38] as one of more efficient point iterative methods by using one weighted parameter which is used to speed up its convergence rate and show to be more economical computationally than the Gauss-Seidel (GS) iterative method. Due to the advantage of lower

computational complexity, we establish the formulation of the Four-Point Explicit Group Kaudd Successive Over Relaxation (4EGKSOR) iterative method, which is a combination between a standard Kaudd Successive Over Relaxation (KSOR) iterative method and Explicit Group approach by using the newly established RKFD approximation equation (14). To derive the formulation of 4EGKSOR, let us consider the grid network in Figure 1 and a group of block node points concept in Figure 3. Figure 3 illustrates the finite grid network of the RKFD approximation equation where block approach has been done until iteration convergence is achieved.
Figure 3: Distribution of grid network for 4EGKSOR method.

Before discussing more details on the formulation of the 4EGKSOR method, let us consider the coefficient matrix W (15) being defined as

$$W = F + J + L \tag{16}$$

where J is diagonal matrix, F and L are strictly lower and upper matrices of the generated linear system (15). Then, the large-scale and sparse linear system (15) becomes

$$(F + J + L) \cdot U = r \tag{17}$$

In drive to achieve the linear system (17) based on the point iteration approach, the implementation of the KSOR method over the linear system can be stated in matrix form as follows [31,39]

$$U^{(q+1)} = [(1-\omega)J - \omega F]^{-1}(J+L)U^{(q)} + [(1-\omega)J - \omega F]^{-1}r \tag{18}$$

where $U^{(q+1)}$ indicates the current value of U at the $(q+1)^{th}$ iteration.

Again, imposing the KSOR method (18) can also be rewritten in the point iteration approach as follows

$$U_c^{(q+1)} = \frac{1}{(1+\omega)} U_c^{(q)} + \frac{\omega}{(1+\omega)} \left(r_c - \alpha_c U_{c-1}^{(q+1)} - \gamma_c U_{c+1}^{(q)} \right) \tag{19}$$

for $c = 1,2,3,...,n-1$, whereas the optimum value of ω the different value subject to the size value of n. The range value of ω is given [31] by $\omega \in R - [-2,0]$.

By using the same steps to obtain equation (19), let us begin to introduce the KSOR block iteration approach. To start this discussion, let us consider again a sequence of a group of four and three node points in Figure 3. As we can see that two types of blocks were used to form during the implementation of the 4EGKSOR iteration. Firstly, the four-point block iteration is applied for the completed group of four and three point block is imposed into the ungrouped case. Referring to equation (15), the 4EGKSOR iterative method is defined as [37]

$$\begin{bmatrix} U_c \\ U_{c+1} \\ U_{c+2} \\ U_{c+3} \end{bmatrix}^{(q+1)} = \frac{1}{(1-\omega)} \begin{bmatrix} U_c \\ U_{c+1} \\ U_{c+2} \\ U_{c+3} \end{bmatrix}^{(q)} + \frac{\omega}{(1-\omega)} \begin{bmatrix} \beta_c & \gamma_c & 0 & 0 \\ \alpha_{c+1} & \beta_{c+1} & \gamma_{c+1} & 0 \\ 0 & \alpha_{c+2} & \beta_{c+2} & \gamma_{c+2} \\ 0 & 0 & \alpha_{c+3} & \beta_{c+3} \end{bmatrix}^{-1} \begin{bmatrix} S_1 \\ S_2 \\ S_3 \\ S_4 \end{bmatrix} \tag{20}$$

where

$$\begin{cases} S_1 = r_c - \alpha_c U_{c-1}, \\ S_2 = r_{c+1}, \\ S_3 = r_{c+2}, \\ S_4 = r_{c+3} - \gamma_c U_{c+1}, \end{cases}$$

Meanwhile, for the ungrouped case has been applied for only one group of three points block is shown as follows

$$\begin{bmatrix} U_{n-3} \\ U_{n-2} \\ U_{n-1} \end{bmatrix}^{(q+1)} = \frac{1}{(1-\omega)} \begin{bmatrix} U_{n-3} \\ U_{n-2} \\ U_{n-1} \end{bmatrix}^{(q)} + \frac{\omega}{(1-\omega)} \begin{bmatrix} \beta_{n-3} & \gamma_{n-3} & 0 \\ \alpha_{n-2} & \beta_{n-2} & \gamma_{n-2} \\ 0 & \alpha_{n-1} & \beta_{n-1} \end{bmatrix}^{-1} \begin{bmatrix} S_{n-3} \\ S_{n-2} \\ S_{n-1} \end{bmatrix} \tag{21}$$

where

$$\begin{cases} S_{n-3} = r_{n-3} - \alpha_i U_{n-4}, \\ S_{n-2} = r_{n-2}, \\ S_{n-1} = r_{n-1} - \gamma_n U_n, \end{cases}$$

Thus, Algorithm 1 describes a summary of the 4EGKSOR iterative method, which has been implemented for solving the proposed problem (1).

Algorithm 1:4EGKSOR iteration
i.   Set the initial value $U = 0$.
ii.   Calculate the coefficient matrix, W.
iii.   Calculate the vector, r.
iv.   For $c = 1,5,9,...,n-7$, calculate the equation (20).
v.   For $c = n-3$, calculate the equation (21).
vi.   Check the convergence test, $\left\| U_c^{(q+1)} - U_c^{(q)} \right\| < \varepsilon = 10^{-10}$. If yes, go to step (vii). Otherwise, go back to step (iv).
vii.   Display approximate solution.

4. Numerical Problem and Discussion

In this section, we investigate the feasibility of the 4EGKSOR iterative method for solving three examples of one-dimensional TPBVPs and then compared with GS and KSOR methods which are set up as a benchmarking for this study. All the results that have been obtained by imposing these three methods considered into these three examples are analyzed based on three comparison parameters such as the number of iterations (Iter), execution time (Time) in seconds and maximum norm (MaxNorm) at five different sizes, $n = 256, 512, 1024, 2048, 4096$. In this study, we also set up the value of tolerance error, $\varepsilon = 10^{-10}$ for all grid sizes are considered.

Example 1 [40]

Consider one-dimensional TPBVPs as

$$\frac{\partial^2 U}{\partial x^2} - \frac{\partial U}{\partial x} = -e^{(x-1)^{-1}}, \tag{22}$$

The analytical solution of problem (22) is $U(x) = x\left(1 - e^{(x-1)}\right)$.

Example 2 [41]

Consider one-dimensional TPBVPs

$$\frac{\partial^2 U}{\partial x^2} + xU(x) = \left(3 - x - x^2 + x^3\right)\sin(x) + 4x\cos(x), \qquad (23)$$

The analytical solution of problem (23) is $U(x) = \left(x^2 - 1\right)\sin(x)$.

Example 3 [42]

Consider one-dimensional TPBVPs

$$\frac{\partial^2 U}{\partial x^2} + U(x) = -1, \qquad (24)$$

The analytical solution of problem (24) is

$$U(x) = \cos(x) + \frac{1 - \cos(1)}{\sin(1)}\sin(x) - 1.$$

All results of GS, KSOR and 4EGKSOR iterative methods in solving these three examples are stated in Tables 1, 2 and 3 and illustrated in Figure 4, 5, and 6 respectively. Table 4 shows that the reduction percentage of KSOR and 4EGKSOR iterative methods which compared with GS method for three examples considered.

Table 1: Numerical results based on comparison criteria considered for Problem 1.

Table 4: Reduction percentage for the KSOR and 4EGKSOR in term of the iteration and time.

n	Method	Iter	MaxNorm
Problem 1	Iter	99.06-99.84	99.56-99.95
	Time	89.71-99.56	97.29-99.87
Problem 2	Iter	99.14-99.92	99.55-99.96
	Time	95.91-99.62	98.48-99.89
Problem 3	Iter	99.13-99.92	99.57-99.96
	Time	98.13-99.92	99.14-99.96
Figure 4: Comparison of three iterative methods based on error over the solution domain of Problem 1 at n = 4096.

All results are presented in Tables 1 to 4, the KSOR method gives reduced iteration and speeds up its execution time as compared with GS iterative method. Then, in terms of a reduction percentage, the KSOR iteration in Example 1 has significantly reduced number of iterations approximately by 99.06-99.84% and

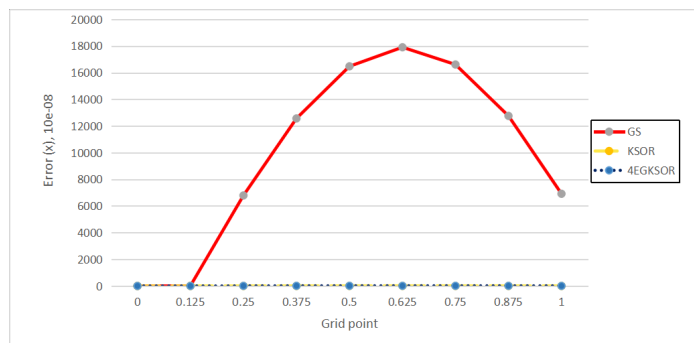
speed up by 89.71-99.56%. For Examples 2 and 3 also give the pattern as same as Example 1 in which KSOR iteration is better than GS iteration. However, the 4EGKSOR iteration gives tremendously improved either in the number of iterations or execution time which are 99.56-99.95% and 97.29-99.87% for Example 1, 99.55-99.96% and 98.48-99.89% for Example 2 and 99.57-99.96% and 99.14-99.96% for Example 3 respectively. In conclusion, it shows that the KSOR iteration has greatly reduced its number of iterations and execution time as compared to the GS iteration. It means that the 4EGKSOR iteration has the least amount compared to GS and KSOR iterations in terms of the number of iterations and execution time. In addition to these findings, for the maximum norm, KSOR and 4EGKSOR iterative methods show a good agreement and become close to their analytical solution compared to GS iterative method, see in Figures 4, 5 and 6.


Figure 5: Comparison of three iterative methods based on error over the solution domain of Problem 2 at n = 4096.
Figure 6: Comparison of three iterative methods based on error over the solution domain of Problem 3 at n = 4096.

5. Conclusions

The formulation of GS, KSOR and 4EGKSOR iterative methods have been successfully derived by using two newly established RKFD discretization schemes for solving TPBVPs. Then, the generated large-scale and sparse linear system based on two newly established RKFD approximation equations have been solved by using three iterative methods in which all results were recorded. Based on the implementation of these three iterative methods, the 4EGKSOR iterative method has tremendously reduced the iteration and Time as compared with GS and KSOR methods. Therefore, the combination of the KSOR block technique with the standard EG iterative method can reduce iteration and Time compared to the KSOR point approach. For

further study, this paper can be extended to perform the use of the newly established RKFD discretization scheme for solving the multi-dimensional boundary value problems by using the two-step iteration family [43,44], and the half-sweep [45,46] and quarter-sweep [47,48] iteration families.

[2]Faculty of Economics, Department of Applied Statistics and Informatics, University of Tirana, Tirana, 1000, Albania

A R T I C L E I N F O	A B S T R A C T
	The article investigated the banking determinants of loans' growth using the quarterly data of Albanian banking sector during 2003-2018. We estimated the linear model of control variables to examine the bank's sound effects on loan's capacity. Empirical results demonstrated the initial positive outcome of the growth of non – performing loans on the loans' growth, but negative effect incorporating with the structural changes. This divergence emphasized the optimum loans' supply through the existence of U relationship amongst them and confirming the banking shrinking behavior related to the lending policy. Also, we confirmed the negative impact of capital regulation and long run correlation to capital regulation growth and growth ratio of loans.

1. Introduction

The economic progress of emerging economies affected by bank lending to attain the essential growth. Otherwise, the lending activity demonstrated the convinced hazard due to the bad credits and it would be one more reason to examine and to assurance the quality of lending in banking sector. The lending activity in banking sector associated with more theoretic and practical investigations particularly to the evolving economies past to the 2008's crisis. These investigations focused to the examination of theoretic and practical assessments according to the bad credits due to the borrower's defaulting. The bank lending has no option to avoid completely the phenomena of adverse selection and moral hazard. In [1], the authors analyzed the determinants of banking credit related to the emergent economies before and after the periods of 2008's crisis. They emphasized that the national and foreign funding affected positively the credit growth. Also, authors concluded that the economic growth, inflation growth and loose monetary policy induced the credit's increase. Meanwhile in [2], the authors examined the determinants of lending activity of banking sector pre – global crisis and post – global crisis in Central Eastern and Southeastern European countries. They emphasized that the economic growth, credit quality, financial intermediation level and foreign and domestic financing sources affected the credit's expansion.

The author in [3] analyzed the linkage among the cost's efficacy and non – performing credits related to banking sector in Zimbabwe during $2009 – 2014$. Author concluded the inefficiency of credit managers related to the non – performing growth. He recommended to applying the international best practical approach by credit managers in order to avoid the fragile policy and detrimental impact in long run on the banking loan's quality. His results approved the bad management hypothesis. Also, [4] highlighted that the significance of banking supervision joining to the large activities restrictions and expanding the market power decreased thoughtfully the threat of banking failure. These outcomes proved that banking procedures marked synchronously the banking effective environment and the banking performance.

The banking sector in Albania has been operated into a dynamic growth and induced the more exertions by banks to take the more appropriate position in the market. This goal of banks induced the enlarge lending strategy contributing to the increasing of non- performing loans ratio. These surroundings marked by the precise banking determining factors, mostly the decision – making procedures and the macroeconomic changes. Otherwise, these outcomes relied to the performance of principal economic segments.

The article followed by this structure: First section included the outline. Section 2 provided the literature review according to the determinants of bank lending and the linkage with non-performing loans. Section 3 demonstrated the empirical view

*Corresponding Author: Valentina Sinaj, sinajv@yahoo.com

related to banking loan's growth and non – performing loans in Albanian banking sector. Section 4 analyzed the description of econometric methodology and empirical results using in this article. The last section summarized the last remarks of this article.

2. Literature Review

The bank lending has always correlated with several kinds of banking risks which they investigated according to the theoretic and practical background of banking sector. This examination will focus to hypothetical and applied evaluations related to the determinants of bank loan's growth and the effect of non-performing loans to banking behavior related to lending. The bank lending has always associated with the phenomena of adverse selection and moral hazard.

In [5], the author examined the non-performing loans' effect towards the loan growth. He highlighted the banking lending behavior could restrain the economic activity particularly during the stress periods linked to the large ratios of non – performing loans. His outcomes using regression analysis concluded the robust effect of non – performing credits ratios on the loaning decisions referring to the upper and under threshold.

In [6], the author investigated the factors of banking loan related to 146 states during 1990 – 2013. His empirical results suggested the crucial effects of economic growth and healthy domestic banking sector related to bank lending. He highlighted that the dependence of foreign capital inflows exposed the domestic banking sector to external shock and faced to credit boom – bust cycles.

In [7], the author estimated the determining factors of lend evolution in Montenegro related to the demand stimulus and supply stimulus simultaneously. She confirmed that the positive economic developments and increasing banks' deposits potential induced the credit growth. Also, she emphasized that the bad credits and low soundness ratio affected negatively the lend supply and banking sector soundness was more influential according to the promoting of banks' lending. She found that the significance of supply factors related to credit growth during the post –crisis, meanwhile she provided the significance of both supply and demand factors to explain the credit growth during pre- crisis.

In [8], the author investigated the Italian bank lending behavior during financial crisis if the increase of credit risk would reduce the bank lending. Also, she analyzed the cooperative and commercial banks behaviors related to lending activity during 2007 - 2103. She found the negative impact linked to the bad loans and ratio of credit loss provision like the measurement of credit risk on bank lending behavior.

In [9], the authors investigated the endogenic and exogenic determinants related to the loan growing in selected Western Balkan economies and Turkey through a multiple regression analysis during 2007 – 2017. Their results emphasized the reverse relationship between non – performing credits ratio and credit rising's ratio according to each economy. Also, they concluded the positive effects of economic growth and deposits growth ratio on banking credit growth for all sample, except Croatia which it demonstrated the positive effect of return on equity on it.

In [10], the authors analyzed the impact of nonperforming loans (NPLs) related to the banking loan supply towards the nonfinancial businesses in Italy during 2008 - 2015. They found that the banks' lending behavior did not affect by NPL ratios using time-varying firm fixed effects to control meant for demand shifts and changes related to the borrower characteristics. Their results demonstrated the negative correlation among NPL ratios and loan growth. Although the exogenous appearance of new NPLs and the linked enhance within provisions could reflect the negative adjustment in loan supply.

In [11], the authors investigated the credit growing and banking behavior according to risk-taking during the expansive lending of 2006 – 2014 in Pakistan. They confirmed the loan's growth associated with increasing bad credits and decreasing the bank's creditworthiness due to the frail provident guideline amongst participants and unequal information of debtors, particularly the underestimated risk of lending through credit booms.

In [12], the authors investigated the determining factors of banking loan to business sector and they found the positive relationship among bank lending and economic growth according to Albanian banking sector. Also, they found that banking and financial intermediation and financial liberalization induced the increasing of lending demand. Authors emphasized the positive effect of exchange rate on banking loan and negative impact of crowding – out effect on it in the long run. Also, they concluded that the decreasing of bad loans and loaning's efficiency increased the loan's supply.

In [13], the author investigated the results of tight lending into banking sector related to innovation relying on German firms' data. Author confirmed the restriction of firms' capacity to enhance their external financial sources through banking sector during the financial crisis. He emphasized the increasing of firm's probability related to suspending innovation projects due to tight policy of banking sector and its negative outcome in long run.

Theoretic outcomes and functional results proved the convergence of non – performing loans towards the loans' ratios in banking sector despite of diverse backgrounds.

3. Loans growth and non-performing loans in Albanian banking sector

The banking solidity in Albania has sustained despite of sporadic tremors linked to effects of 2008's crisis. Figure 1 confirmed the subtleties of the growing ratio of non-performing loans and total gross loans during 2008 – 2018 relied on trimestral figures. According to the figure 1 the non – performing loans linked to the explosive propensity leading by the descendent propensity, especially after last quarter of 2008. The last quarter of 2008 demonstrated the outlier highlighting the contagious effects of 2008's crisis in Albanian banking sector and political cycles. Meanwhile the downward trend of non-performing loans' growing ratio related to the restrictive banks' loaning policy and the loans' rearrangement by the involvement through Bank of Albania. However, the flat propensity of loans' growth ratio affected by the restricted loaning policy of banks due to the increasing ratio of bad credits to total gross loans after 2008. The growth ratio of whole loans associated with the convergent trend

toward zero percentage, but the growth ratio of non-performing loans ratio linked to divergent trend compare to loan's growth ratio. Meanwhile the figure 2 demonstrated the comparative analysis amongst Western Balkan countries related to non – performing loans into banking sector during to 2009 - 2017. Figure 2 highlighted the upward trend of non – performing loans for each Western Balkan until 2013. It confirmed the largest ratio for Albania and Serbia until 2016 compare to others countries, especially Albania along entire period despite of trend and volatility.
Figure 1: Growth rates of non-performing loans and total loan in banking sector, Source: Authors' calculations on dataset of Bank of Albania
Figure 2: Non-performing loans ratios in banking sector of Western Balkan countries, Source: Central banks of individual countries

However, the banking sector in our country runs into a progressive growth and persuades the extra controls by banks concluding to their conduct. The banking concentration has contributed to the common advancement of banking sector.

Figure 3 demonstrated the banking concentration using Herfindahl–Hirschman Index (HHI) related to the total loans and non – performing loans in the banking sector through individual banks and banks' size (G1, G2 and G3) during 2005 - 2017. It exposed the stability of the loans' concentration and non – performing loans' concentration relied on individual banks along this period. Despite of convergence related to moderated concentration, non – performing loans demonstrated the higher concentration compare to loans according to individual banks. Meanwhile the concentration of total loans and non – performing loans through banks' size demonstrated the large values and approximately identical values during the specified period. Also, the concentration related to banks' size revealed the similar propensity according to total loans and non – performing loans despite of slight volatility, but higher concentration and large gap compare to the concentration of individual banks.
Figure 3: Concentration of loans and non-performing loans ratios in Albanian banking sector Source: Authors' calculations on dataset of Bank of Albania

4. Methodology and empirical results

4.1. Data description and econometric methodology

The loans' growth estimated to the linear model by least squares method referring on the quarterly data of Albanian banking sector during 2003-2018. The general linear model is following:

$$G\_loans_t = \beta_0 + \beta_1 G\_NPL_t + \beta_2 G\_deposits_t + \beta_3 G\_Cap.\,Re\,g_t + \beta_4 ROE_t + u_t$$

for t=1,…,64, and the residual completed the Ordinary Least Squares assumption and $u_t \sim N(0, \sigma^2)$ [14].

The linear model includes the variables controlling for bank sound effects on loan's capacity. The model used the growth ratio of banking control variables including the non-performing loans' growth (G_NPL), deposit's growth (G_Deposit), regulator capital's growth (G_Cap.Reg.) and return on equity (ROE). We expected the negative relationship among growth of non-performing loans and loans' growth supporting by theoretical and empirical view. Meanwhile we should investigate the U-shaped relationship between loans' growth and non – performing loans' growth supporting by the empirical model [5]. Ambiguous results of this correlation clarified the inverted conduct through the optimum of loans' growth affecting by non performing loans' growth. Furthermore, we expected the positive impact of return

on equity related to the loans' growth due to profitability in order to maximize banking profitability. Also, we expected the positive effect of deposits' growth on the loans' growth due to the deposits meant the probable loans' capacity and loans' source for banking sector. Moreover, the indicator of regulatory capital anticipated the negative outcome due to the banking capability to cover with capital the losses' risk exposure by the bad loans. This expectation supported that the capital rigidity merely confirmed the frail negative results on loan's growth, but the components of capital rigidity demonstrated the strongest negative effect related to loan's growth [15]. Also, the regulatory capital required the comprehensive fulfilment the Basel's criterions in order to be the well – capitalized banks and consequently inducing the banks' lending shrinkage. We proved our expectations related to the variables' impact on the loans' growth using R software.

4.2. Results of examination

We used the "Student test" related to the significance of coefficients' model. The null hypothesis demonstrated the non – significance of variable, and if the p-value of "T test" was less than the significance level meaning the rejection of null hypothesis. Meanwhile the model's significance was testing by Fisher statistics meaning the null hypothesis related to non – significance of model. Table 1 demonstrated the statistical significance of model and variables. Referring to the p-values we confirmed that the model was significant and all of variables were significant according to 5% level despite of ROE. The only non-significant variable was ROE, which it resulted to p-value of 6.8%. We selected the good – fit model using stepwise method based on the model selection criteria. We choose the model with the highest value of adjusted R^2 and related to Information Criteria, Akaik criterion (AIC, [16]), and Baeysian criterion [17], we decided the model with the smallest value of each criterion. Referring to the selection of regression Mallow's criterion [18], if the model is correct then Cp will tend to be close to or smaller than p. We used R software according to the whole evaluations and selections.

Also, we used variables and their lags and investigated the structural break[1] according to first quarter of 2008. Due to this reason, we used the dummy variable for year 2008 (value 1 before this moment and otherwise zero after this moment) related to the growth of non-performing loans and ROE. We applied several tests to examine the significance and consistence of model (see more details for results of tests in the appendix (table 2-5)). The estimated results referring to table 1 demonstrated the initial positive effect of non – performing loans' growth on the loans' growth. Otherwise, when we incorporated both the structural changes using dummy variable with non – performing loans' growth, we observed the negative effect of non – performing loans' growth. This result emphasized the change of banks' behavior related to loans' supply meaning the demonstration of U-form relationship among loans' growth and non – performing loans' growth.

The outcome supported the several empirical results due to contagious effect of 2008's crisis linked to the structural deviations. Meanwhile our estimated outcomes verified the

positive correlation amongst the growth of credits and deposits due to the deposits remain the main banking loans' source. Banks inclined to increase the loans' supply in order to add to their interest incomes and to maximize their profitability. This result supported our expectations and theoretical and empirical views. Also, ROE demonstrated the positive effect on the loans' growth and has continued the similar effect when we incorporated both the structural changes using dummy variable with ROE. This effect explained by banks' propensity to enhance the loans' supply due to higher profitability. Empirical results have testified the sustainable ROE's effect on loans' growth despite of structural changes due to 2008's crisis. Otherwise, our estimations proved the adverse effect of regulatory capital on the loans' growth. This result supported other empirical outcomes and converged to banks' lending shrinkage towards the intended well – capitalized banks due to rigid Basel's standards and contagious effects of 2008's crisis.

Table 1: Estimated results

Coefficients:

Source: R, authors' estimations

In [19], the author emphasized if two time series have stochastic trends (i.e., they are nonstationary), a regression of one other may cancel out the stochastic trends, which it may advice the coexistence in the long-run, or equilibrium, among them even though individually the two series are nonstationary. We verified the stationarity of series using Augmented Dickey-Fuller test[2] (ADF) to determine the presence of unit roots. According to the ADF test, the null hypothesis is the series has a unit root. We used T-test to test the hypothesis and if the p-value was less than 5% significance level than null hypothesis rejected. Table 8 demonstrated the results of ADF test and it confirmed three series which they were the first order integration or I(1), particularly series of ROE, G_L and G_Cap.Reg. According to [20], the economic interpretation of cointegration states that if two (or more) series are linked to form an equilibrium relationship spanning the long run, then even though the series themselves may contain stochastic trends and thus be non-stationary, they will nevertheless move closely together over time and the difference between them will be stable or stationarity.

---

[1] See results in Table 7 in Appendix.

[2] See results in Table 8 in Appendix.

We examined the long run relationship amongst variables' series through the co-integration procedure using Granger causality test[3] to investigate empirically the direction of relation between variables. The null hypothesis emphasize that the first variable demonstrates no Granger causality to the second variable. The null hypothesis rejects, if p-value of Fisher test is less than the significance level. Table 9 demonstrated the empirical results of Granger causality test and it confirmed the short run relationship amongst variables, ROE, G_L and G_Cap.Reg at 10% level of significance.

Meanwhile the Johansen Procedure is used for co-integration of three non-stationary series, ROE, G_L and G_Cap.Reg. According to the results of Trace statistic in table 10 and their critical value, we confirmed only one couple of series which are co-integrated. Table 11 related to Engel – Granger procedure with one-equation, we derived one coupled variable which they were co-integrated, precisely the loans' growth and the growth of capital regulation demonstrated the long run correlation. This result emphasized the significance of capital regulation to take into more considerations by banking managers and policy makers due to its impact in long run. Also, we investigated the U shape relationship amongst loans' growth and non – performing loans' growth [4]. We calculate the minimum (turning point) of the parabola defined as in which corresponds to the averaged level loans' growth and non – performing loans' growth. The second order polynomial demonstrated its general form through the following equation:

$f(x)=ax^2+bx+c$ where $x\epsilon$ (0; $+\infty$) and at least $a\neq0$. Thus, the minimum (turning point) is defined as: $\left(-\frac{b}{2a}, f\left(-\frac{b}{2a}\right)\right)$.

Otherwise, it can be calculated by using the first derivative of function f(x): $f'(x)=2ax+b$ and by solving the equation: $f'(x)=2ax+b=0$. The solution of second equation estimated the level of non – performing loans' growth. Related to the threshold at which the relationship among the loans' growth and non – performing loans' growth turns from positive to negative. The empirical results of table 12 demonstrated the optimum value of loans' growth by 321 basis points when we included the structural changes of 2008's global financial crisis. This result explained the negative impact pending the non – performing loans' growth ratio and the loans' growth curvature was curved to 321 basis points due to the structural break point of 2008. The propensity of banks' behavior adjusted subsequent to optimum point in order to compensate the loss due to non – performing loans. Also, this result confirmed the banking shrinking behavior correlated to the lending policy consequently of non – performing loans subsequent to optimum loans.

5. Concluding remarks

The propensity of the growing ratio linked to the non-performing loans and total gross loans in Albanian banking sector during 2008 – 2018 has sustained its stability excluding the effects of contagious effects of global financial crisis, particularly subsequent to last quarter of 2008. The growth rate of total loans

and non-performing loans ratio diverge amongst them during this period. This divergence described by the restraining loaning strategy of banks and the credits' restructuring through Bank of Albania contribution. Meanwhile Albania demonstrated one of the largest ratios of non – performing loans into banking sector during to 2009 – 2017 despite of volatility referring to the comparative analysis amongst Western Balkan countries. Also, the non – performing loans and loans converged to the moderated concentration related to individual banks even though the high concentration of non – performing loans compare to the loans. However, the total loans and non – performing loans correlated to banks' size demonstrated the high concentration compare to the individual banks' concentration. This discrepancy justified the tight lending policy due to the increasing propensity of non – performing loans' concentration by banks' size.

We examined the initial positive outcome of growth ratio linked to non – performing loans towards the loans' growth. Meanwhile we tested the negative effect of non – performing loans' growth related to the dual incorporation by dummy variable of the structural changes. Ambiguous results confirmed by the contagious effect of 2008's crisis linked to the structural changes. This reversal of behavior confirmed the optimum of loans' growth affecting by non-performing loans' growth.

The optimum break demonstrated the U shape relationship amongst loans' growth and non – performing loans' growth through empirical result and explained the dual effect. The negative relationship was curved to the optimum of loans' growth by 321 basis points incorporating the structural break of 2008's global financial crisis. The propensity of banks' behavior adjusted subsequent to optimum loans to compensate the loss due to non – performing loans and converged to the banking shrinking behavior correlated to the lending policy. Policymakers should be monitoring continuously the non-performing loans' growth in the forthcoming to control the optimal loans' growth ratio.

The regulatory capital illustrated the negative effect on the loans' growth and proved the convergence to banks' lending shrinkage to retain the well – capitalized banks due to rigid Basel's standards and contagious effects of 2008's crisis. Empirical result tested the long run correlation amongst growth of loans and growth of capital regulation and highlighted to take into more considerations related to the capital regulation by banking managers and policy makers.

Meanwhile the deposits growth demonstrated the positive effect on the loans' growth confirming the core source of banking loans' supply. Furthermore, ROE confirmed the dual positive effect on the loans' growth with and without incorporation of the structural changes. This effect explained the banks' propensity to enhance the loans' supply due to higher profitability and testified the sustainable ROE's effect despite of 2008's crisis.

A B S T R A C T

Modern power systems are topologically and structurally complicated due to their complex interconnections. Consequently, the complexity of the dynamic stability assessment be-comes more tedious, most especially, when considering a power electronics-based power system operating under faulty conditions. This paper, therefore suggests an alternative approach of Network Structural-Based Technique (NSBT) for the analysis and enhancement of transient stability of a power system considering Flexible Alternating Current Transmission Systems (FACTS) devices integration. The mathematical formulations based on the NSBT as well as the dynamic swing equations, required for carrying out the stability analysis, are presented. The structural characteristics of the network are captured by considering the interconnections of the network elements and the impedances between them. The eigenvalue analysis is then explored to identify suitable and possibly weak load node locations where the influence of FACTS device placement within the network, could be most beneficial. The transient stability analysis before and after critical outage conditions is investigated. The transient stability of the network operating under critical outage condition is then enhanced considering the integration of a multi- UPFC controller, which is suitably located as identified by NSBT. The effectiveness of the suggested approach is tested using the modified standard IEEE 5-bus, 30-bus networks as well as the practical Nigerian 28-bus grid incorporating a multi-FACTs controller. The results obtained show that the FACTS device contributes significantly to improving the transient stability of a multi-FACTS-based power network. The information provided by this study is highly beneficial to the system operators, utilities investors and power engineers, most especially, for predicting system collapse during critical outage conditions.

1. Introduction

The dynamic stability assessment of most practical power systems, which are topologically weak, has been a major concern to most power system engineers and researchers in recent times [1]. This becomes inevitable as a result of the ever-increasing demand for electric energy, which is causing the system to operate close to its capacity limits. In order to avoid system collapse without sacrificing the integrity of the network, it is expected that economic efficiency and the reliability of the network are maintained [2]. With the aim of achieving these, the power networks are faced with challenges such as overloading, voltage instability, and excessive transfer of power along transmission lines, to mention a few [3, 4]. Moreover, the frequent voltage collapse recorded in most modern power system networks is due to the fact that the networks are structurally weak [5]. This effect could be as a result of the reactive power deficit in the network. It

could also be traced to networks with very high resistance to reactance ratio, which is a characteristic of a distribution network or a radial transmission network. According to authors in reference [5], the least eigenvalue is approximately zero, and the magnitude of the elements of eigenvector associated to the least eigenvalue are approximately equal [5]. This constant magnitude shows that the network is a topologically weak power system, and it is due mainly to a wide relative electrical distance gap between the network load buses. A topologically weak network cannot be loaded up to its full capability limit without yielding a lower power transfer capability, and most power systems exhibit these structural characteristics, which make them be operated close to or beyond their permissible operating limits [6]. Therefore, there is a need for adequate compensation in order to enhance the transient stability of topologically weak power systems operating under critical contingencies and thereby enhancing the transfer capability of the network. This paper, therefore, attempts to provide an alternative approach to the enhancement of the transient stability of structurally weak power networks, which are operating under fault conditions considering the integration of FACTS devices.

Several contributions have been proposed by different authors for improving the transient stability of power systems undergoing disturbances through the integration of these FACTS devices [3]. FACTS devices are unique for their ability to preserve synchronism of generators whenever a major fault occurs within the network [7]. However, in order to obtain optimum performance of these FACTS devices, it is important to ensure that they are optimally placed within the power network under consideration. Traditionally, the problem is usually formulated as an optimisation problem, which is iterative in nature. For instance, the Modified Salp Swarm Optimization Algorithm (MSSOA) is used in [8] for the location of the UPFC (Unified Power Flow Controller. Another method proposed is the Particle Swarm Optimization algorithm in [7] for the optimal location of the STATCOM. Authors in reference [1] proposed a scheme using the zero dynamic approach to control the Thyristor Controlled Series Capacitors (TCSC) for its optimal location. The scheme controls the TCSC to investigate the transient stability of a multi-machine power system. The authors of [9] also present a hybrid BBO-DE algorithm to examine the performance of the system using the Static Var Compensator (SVC) and Power System Stabilizer (PSS). However, these iterative-based solution methods are not without challenges. The problem is formulated as a non-linear problem, which is a bit difficult to solve. Other problems include the existence of local minimal, non-convergence, time and space complexities etc. This influences to a greater extent, the results obtained, most especially, when dealing with a large practical network with multiple of contingency situation.

In this paper, a non-iterative method which solely depends on the structural interconnections of the network elements and their impedance values is suggested. This is because the study has shown that obtaining an effective solution to the problem actually lie in the structural interconnections of the network elements [10]. The main merit of this approach lies in the fact that the problem formulation as a linear and simple based on the fundamental circuit theory laws. Consequently, the solution is obtained in just one computation time. Hence, time and space complexities issues are totally eliminated. Also, the problem associated with the slack bus identification in the iterative-based methods is totally avoided.

Among the available FACTS controllers, UPFC has some inherent characteristics that are highly beneficial to solving some power system operational problems. For example, it can be used to control the flow of both active and reactive powers independently. Another benefit that could be derived from using UPFC is that it is a good controller for regulating the network load node voltages. These benefits are explored in this paper.

It has been shown, in the existing study that obtaining an effective solution to most power system problems does not depend on the loading conditions of the system but actually lie in the structural interconnections of the network elements [10]. Consequently, in this paper, a non-iterative method which solely depends on the structural interconnections of the network elements and their impedance values is proposed. The contributions of this paper to the active stream of research are as follows: The existing methods formulates the problem considered in this paper as an optimization problem which are without drawbacks such as local minimal issues, divergence problem etc. This present study, however, reformulates the problem of identifying UPFC placement as a linear problem based on the fundamental circuit theory laws. Consequently, the solution is obtained in just one computation time. Hence, time and space complexities issues are totally eliminated. Also, the problem associated with the slack bus identification in the iterative-based methods is totally avoided.

The remaining parts of the paper are structure as follows: section 2 presents the theoretical framework as well as the mathematical formulations to the problem, in section 3, the descriptions of the networks used are presented. The programming tools used are also presented in section 3. Section 4 presents the numerical results obtained and the discussion of the results. The paper is concluded in section 5.

2. Theoretical Background and Mathematical Formulations

This section provides the mathematical formulations and methodology used in building the numerical approach for the study. In this paper, the Newton-Raphson method used in carrying out the load-flow analysis is briefly revisited, the derivation of swing equation is presented, the mathematical formulation of the non-iterative dependent approach for identifying suitable load nodes where FACTS Devices could be placed for enhancement of the transient stability is presented, and the formulation for enhancing a structurally weak network is presented.

2.1. Static and Dynamic Modelling for Transient Stability Assessment

The steady-state analysis of power system is usually studied by solving the static power flow equations. Various approaches to solving these equations abound in the literature. However, the prominent solution techniques include Gauss-Seidel method [11], Fast Decoupled method and Newton – Raphson method [11, 12]. For the purpose of this study, the Newton – Raphson method is used because of its fastest rate of convergence as well as its self-correcting mechanism [13]. The complex power equations at any node i of an n-bus power system can easily be expressed as [14].

$$P_i + jQ_i = \dot{V}_i \sum_{j \in i} \hat{Y}_{ij} \hat{V}_j \qquad (1)$$

$$\forall j \in i (i = 1, 2, \ldots, n)$$

$$\dot{V}_i = V_i e^{j\theta_i} \tag{2}$$

where V_i and θ_i are the magnitude and phase angle of voltage at bus i.

The elements of admittance matrix can be expressed as

$$Y_{ij} = G_{ij} + jB_{ij} \tag{3}$$

From (1), the real and reactive power at any bus i respectively can be formulated as

$$P_i = V_i \sum_{j \in i} \widehat{V}_j \left(G_{ij} \cos \cos \theta_{ij} + jB_{ij} \right. $$
$$\left. \sin \sin \theta_{ij} \right) \tag{4}$$

$$Q_i = V_i \sum_{j \in i} \widehat{V}_j \left(G_{ij} \sin \sin \theta_{ij} - jB_{ij} \right.$$
$$\left. \cos \cos \theta_{ij} \right) \tag{5}$$

such that $(i = 1, 2, \ldots, n)$

where $\theta_{ij} = \theta_i - \theta_j$, which is the voltage phase angle difference between bus i and j.

The result is a linear system of equations that can be expressed as follow:

$$[\Delta\theta \, \Delta|V\,|\,] = J1[\Delta P \, \Delta Q\,] \tag{6}$$

where ΔP and ΔQ are mismatch equations given by (7) and (8) respectively as

$$\Delta P_i = -P_i + V_i \sum_{j \in i} \widehat{V}_j \left(G_{ij} \cos \cos \theta_{ij} + jB_{ij} \right.$$
$$\left. \sin \sin \theta_{ij} \right) \tag{7}$$

$$\Delta Q_i = -Q_i + V_i \left(G_{ij} \sin \sin \theta_{ij} - jB_{ij} \right.$$
$$\left. \cos \cos \theta_{ij} \right) \tag{8}$$

and J is a matrix of partial derivatives known as a Jacobian given as

$$\left[\frac{\partial \Delta P}{\partial \theta} \; \frac{\partial \Delta P}{\partial |V\,|} \; \frac{\partial \Delta Q}{\partial \theta} \; \frac{\partial \Delta Q}{\partial |V\,|} \right] \tag{9}$$

The linearised system of equations is solved to determine the next guess $(m + 1)$ of voltage magnitude and angles as follows:

$$\theta^{m+1} = \theta^m + \Delta\theta \tag{10}$$

$$|V\,|^{m+1} = |V\,|^m + \Delta|V\,| \tag{11}$$

where m is the iteration count. The process is iterated with a common stopping condition where the mismatch result is less than a given tolerance, ε.

For effective evaluation of power system transient stability assessment, the rotor angle dynamics provides a helpful insight into the behaviour of the system, most especially, when a sudden disturbance occurs. The sudden occurrence of a disturbance in a power system usually causes an increase in the mechanical torque (T_m) of the prime mover, and an acceleration torque (T_a) is developed if the mechanical torque is greater than the electromagnetic torque (T_e). Mathematically,

$$T_a = T_m - T_e \tag{12}$$

The machine is accelerated with an inertia J which consists of the inertia of the generator and prime mover. Therefore,

$$J\frac{d\omega_m}{dt} = T_a = T_m - T_e \tag{13}$$

where t is time in seconds and ω_m is the angular velocity of the rotor in mechanical rad/s. Expressing J in terms of inertia constant H results to

$$J = \frac{2H}{\omega_{0m}^2} VA \tag{14}$$

Therefore,

$$\frac{2H}{\omega_{0m}^2} VA \frac{d\omega_m}{dt} = T_m - T_e \tag{15}$$

Introduction of a new angular velocity of the rotor, ω_r (rad/s) results to

$$2H \frac{d\omega_r}{dt} = T_m - T_e \tag{16}$$

Alternatively,

$$\frac{d\omega_r}{dt} = \frac{d^2\delta}{\omega_0 dt^2} \tag{17}$$

where δ is the angular position of the rotor (elect. rad/s) with respect to a synchronously rotating reference frame.

By combining (16) and (17), the dynamics model of the rotor angle known as the swing equation can, therefore, be easily obtained expressed as

$$\frac{2H}{\omega_0} \frac{d^2\delta}{dt^2} = T_m - T_e \tag{18}$$

2.2. Identification of Suitable Load Nodes for Facts Device Placement: A Network Structural Perspective

The mathematical formulation for the problem considered in this paper is viewed from the fundamental circuit theory laws perspective. This is employed to develop the inherent structural

properties of power network considering the interconnectivity of the network elements and the impedance between them [15]. Though this theory has been extensively applied to solve various power system problems in the literature [16–19], there are more to the theory than we have had in the past. For instance, the application of this topological-based concept in resolving transient stability issues has not been holistically investigated. This is the main focus of this paper.

First, let us consider a simple power system network, to depict the structural interconnections of various power network elements, as shown in Figure 1.
Figure 1: Interconnections of power network elements [4]

The matrix equation that relates the node voltages and line currents in terms of the line parameters can be written in its compact form as [5]

$$[A_c][V'] = \begin{bmatrix} z_{ij} \ 0 \ 0 \ z_{kl} \end{bmatrix} \begin{bmatrix} I_{ij} \\ I_{kl} \end{bmatrix} \tag{19}$$

where

$$[V'] = \begin{bmatrix} V'_1, V'_2, \dots, V'_i, V_j, \dots, V'_l, \dots, V'_n \end{bmatrix} \tag{20}$$

where

A_c is termed as the coupling matrix, $[V']$ represents the vector of the nodal voltage within the network after the enhancement through the identification of suitable nodes for placement of reactive power supports, I_{ij} and I_{kl} are the currents through the network branches $i-j$ and $k-l$ respectively.

For instance, the coupling matrix, based on Figure 1 can be formulated as

$$[A_c] = [\ 0 \ 0 \ 0 \ . \ . \ . \ 0 \ . \ . \ .1 \ 0$$
$$-1 \ . \ . \ . \ 0 \ . \ . \ . \ 0 \ \ 1 \ \ 0 \ . \ . \ .$$
$$-1 \ . \ . \ .0 \ 0 \ ] \tag{21}$$

Since a change in current causes a change in bus voltages, we can therefore write

$$[V'] = [Z_l][l_o + \Delta l] \tag{22}$$

Alternatively,

$$[V'] = [V] + [\Delta V] \tag{23}$$

where $[V]$ represents the voltage profile of the original power network.

$[\Delta V]$ denotes the change in the vector of the voltage profile for the network before the enhancement, which can easily be expressed as

$$[\Delta V] = -[Z_l][A_c^T]\begin{bmatrix} I_{ij} \ I_{kl} \end{bmatrix} \tag{24}$$

From equation (24),

$$\begin{bmatrix} I_{ij} \ I_{kl} \end{bmatrix} = [Y_{bus}]\begin{bmatrix} V_i -V_j \ V_k -V_l \end{bmatrix} \tag{25}$$

$$[Y_{bus}] = \{z^{new} + [A_c][Z_l][A_c^T]^{-1}\} \tag{26}$$

$$z^{new} = \begin{bmatrix} z_{ij} \ 0 \ 0 \ z_{kl} \end{bmatrix} \tag{27}$$

Obviously, the structural interconnections that exist between the network nodes of the enhanced network is fully captured in (26)

In order to investigate the influence of the network structural properties on the location of the FACTs devices for effective enhancement of the network, the eigenvalue decomposition approach is applied to (26) as [15]

$$[Y_{bus}] = W \sum W^T = \sum_{i=1}^{n} \omega_i \rho_i \omega_i^T \tag{28}$$

where W and $W^T = n$–by–n orthogonal eigenvectors of $[Y_{bus}]$.

ρ_i = The eigenvalue at any bus i, ω_i and ω_i^T respectively.

The inverse relationship between the bus voltage and their respective eigenvalues can be expressed as

$$[V] = \sum_{i=1}^{n} \frac{\omega_i^T \omega_i}{\rho_i} [I] \tag{29}$$

Various methods have been identified to determine the eigenvalue of the power network. They are broadly classified under iterative and no-iterative based methods. More recently, network structural characteristics based approach presents a model which provides a clear distinction between generation and load buses, as presented in reference [19]. This is shown by formulating the generator voltage and the load current as functions of their respective generator currents and load voltages as

$$[V_G \ I_L \ ] = [Z_{GG} \ H_{GL} \ W_{LG} \ C_{LL} \ ][I_G \ V_L \ ] \tag{30}$$

where

$$Z_{GG} = Y_{GG}^{-1} \tag{31}$$

$$H_{GL} = -Y_{GG}^{-1}Y_{GL} \tag{32}$$

$$W_{LG} = Y_{LG}Y_{GG}^{-1} \tag{33}$$

$$C_{LL} = Y_{LL} - Y_{LG}Y_{GG}^{-1}Y_{GL} \tag{34}$$

Obviously, from (30), it can be seen that the relationship between the vector of generator node voltages and the load node currents is governed by the matrix CLL, which captures the influence of all the interconnections of load buses after the influence of generator buses has been eliminated. Application of the eigenvalue presented in (29) can, therefore, be used to decompose CLL, which gives an inverse relationship between the load bus voltage and the associated eigenvalue. This relationship is used in this paper to identify the weak load nodes within the network [19].

3. Numerical illustrations

Case 1: The Standard IEEE 5-Bus Network

The standard IEEE 5- bus system network consists of two-generation nodes and three load nodes, which are interconnected by seven transmission lines. The one-line diagram is presented in Figure 2 using the PSAT interface. The line data are adapted from reference [20] and are sampled for determining the eigenvalues of the nodes and their corresponding eigenvectors.
Figure 2: Single-line diagram of the standard IEEE 5-bus network

Case 2: The Standard IEEE 30 – Bus Network

Figure 3 shows the single line diagram, drawn in the PSAT environment, for the standard IEEE 30-bus network. This is used, as the second case study considered, in order to verify the effectiveness of the methodology suggested in this study. It comprises of six generator buses, twenty-four load buses, which are interconnected by forty-one transmission lines. In this study, the PSAT environment is used in conjunction with the MATLAB 2016a as the programming tools.

Case 3: The Nigerian 28-Bus Network

In order to investigate the effectiveness of the proposed approach in this study to practical power systems, the Nigerian 28-bus is considered whose one-line diagram is shown in Figure 4. The network comprises ten generator buses, eighteen load buses, which are connected by thirty-one transmission lines. It worth noting that the sizing of the UPFCs used in this study is adapted from the work of Melodi [21].

4. Results and Discussion

This section presents and discusses the simulation results in this study obtained based on the approach suggested. Three power system networks are considered to verify the efficiency of the method. The standard IEEE 5-bus network is first considered, then the standard IEEE 30-bus system using PSAT simulation and then the Nigerian 28-bus system using MATLAB programming tools. The data used is on 100MVA base. The graphical representation as well as the tabular presentation of the results are displayed and explained. The transient stability of the networks before reinforcement and before the integration of UPFC are presented, which serve as the base case. These results are then compared with the transient stability, of the system, after the reinforcement and integration of UPFC.

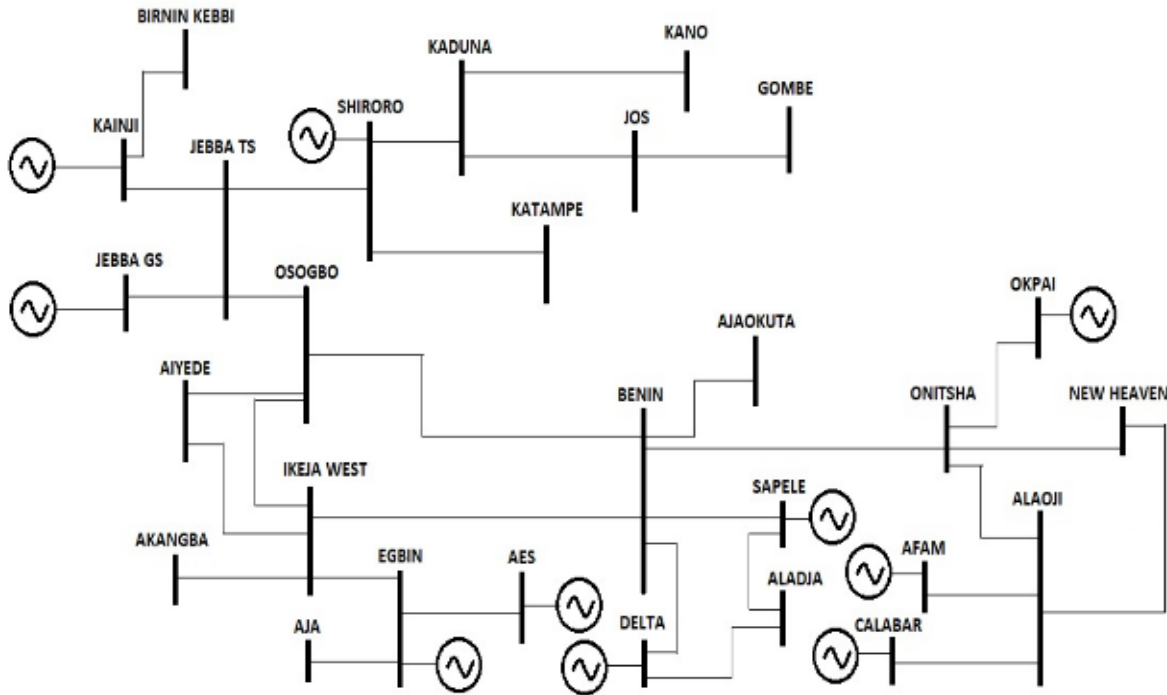
Figure 3: Single-line diagram of the standard IEEE 30-bus network


Figure 4: Single-line diagram of the Nigerian 28-bus network

4.1. Investigation of The Network Strength and Identification of The Suitable Load Nodes for Network Reinforcement

The eigenvalue analysis, on the reduced bus admittance of the network, based on the CLL matrix, is first performed. In this matrix, the interaction of the generators has been eliminated. So, the output of this matrix contains only the load-to-load interaction.

The IEEE 5-bus and the IEEE 30-bus networks are subjected to tests of determining the eigenvalues and the corresponding eigenvector, measured to confirm or ascertain the strength of the network. The network data are from reference [20]. The same procedures are extended to the Nigerian 28-bus network whose line data are adapted from reference [22]. The MATLAB 2016a is used as the programming tool to determine the eigenvalues and their corresponding eigenvectors in each case. It should be iterated that the sizing of the UPFCs employed in this study is carried out based on the existing work presented by the authors of reference [21]. The results obtained, for each case, are presented and discussed in the subsections that follow:

Case 1: The Standard IEEE 5-Bus Network

The modified network of the IEEE 5-Bus power network is shown in Figure 5. The transmission line where the multi-UPFC is located is first identified using eigenvalue analysis and then integrated into the network at the identified location, as shown in Figure 5. This UPFC is controlled such that appropriate compensation is delivered to the network, in steps, in order to maintain the network voltage profile such that the integrity of the network is maintained. This is carried out using the Newton-Rapson power-flow-based technique. The load-flow analysis is performed in this study to determine the base case voltage profile of the two networks considered. Figure 6 shows the graphical representation of the voltage profile obtained for the power-flow analysis using the standard IEEE 5-bus system.
Figure 5: Single-line diagram of the modified IEEE 5-bus network
Figure 6: Base case voltage profile for the standard IEEE 5-bus network

The study then investigates the influence of FACTS device (UPFC) integration into the network during a disturbance. This is carried out by considering the transient stability of the network with and without FACTS. The simulation results for the two scenarios (with and without UPFC) are then compared. The results obtained from the eigenvalue analysis is ranked in ascending order, as shown in Table 1. The load node associated with the least eigenvalue is the suitable bus where the placement of the FACTS device would be of the highest benefit to the network. From Table 1, it can be seen that the least eigenvalue is ranked 1st, and this corresponds to load node 4 within the

network. In other words, as evident from Table 1, Bus 4 has the least eigenvalue of 0.1120, and this makes it the weakest bus in the system. This implies that the FACTS device will provide better compensation to the network if placed on the transmission line connecting buses 4 and 5. The eigenvector elements associated with the least eigenvalue of 0.1120 at bus 4 are found to be approximately equal to 0.571, as shown in Figure 7. This confirms the structural weakness of the network.

Table 1: Identification of a suitable location of FACTS device in the IEEE 5-Bus

Load node	Eigenvalue	Ranking
4	0.1120	1st
5	15.6029	2nd
3	71.4702	3rd
Figure 7: Eigenvectors associated with the least eigenvalue of the IEEE 5-bus network

Case 2: Standard IEEE 30-Bus Network

When the analysis of the eigenvalues is performed using the standard IEEE 30-bus power network, the transmission line, which is most suitable for placement of the multi-UPFC controller is determined. The modified network for the standard IEEE 30-bus network, when the UPFC is integrated, using the PSAT interface is shown in Figure 8. The same procedures, as explained in the preceding section, are repeated for the standard IEEE 30-bus network. The base case voltage profile using the standard IEEE 30-bus system is presented in Figure 9.

The same procedural steps followed in the case of the IEEE 5-bus network are also followed using the standard IEEE 30-bus network for identifying the suitable load nodes where the reactive power supports should be located within the network. Similar simulations are also carried out using the standard IEEE-30 bus system. The ten buses with the least eigenvalues within the network are selected, ranked and presented in Table 2.

Bus 23 is the load bus associated with the least eigenvalue of 0.00216, as shown in Table 2. The corresponding eigenvectors for this least eigenvalue are found to be equal in magnitude with a value of 0.235, as shown in Figure 10. This constant eigenvector magnitude shows that a very wide electrical distance exists between the load nodes, which accounts for the topological weakness within the network under consideration. This has a greater influence on the power-flow through the transmission lines within the network.

Table 2: Identification of a suitable location of FACTS device in the IEEE 30-Bus

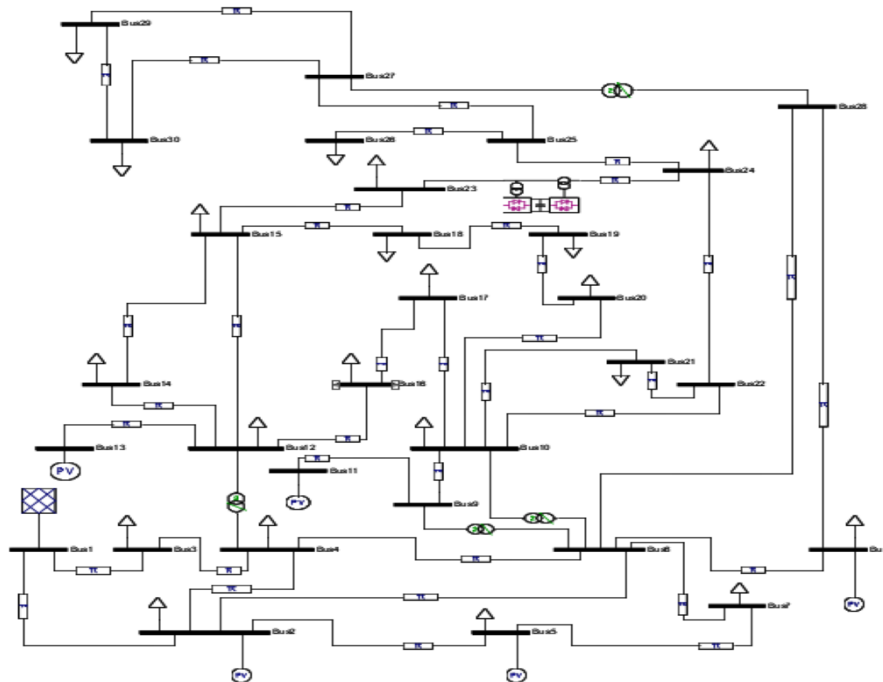
Load node	Eigenvalue	Ranking of eigenvalue
21	7.3285	10th
22	6.7473	9th
23	0.0216	1st
24	0.7491	2nd
25	5.5871	8th
26	1.5335	3rd
27	2.1872	4th
28	4.5805	7th
29	3.2186	6th
30	3.0953	5th


Figure 8: Single-line diagram of the modified IEEE 30-bus Network
Figure 9: Base case voltage profile of the standard IEEE 30-bus network
Figure 10: Eigenvectors of the least eigenvalue of the standard IEEE 30-bus network
Figure 11: Base case voltage profile of the Nigeria 28-bus network

Table 3: Identification of a suitable location of FACTS device in the Nigerian 28-Bus

Load node	Name	Eigenvalue	Ranking of eigenvalue
19	Akangba	143.3201	10th
20	Ikeja West	103.4449	9th
21	Onitsha	98.5211	8th
22	New Haven	2.8253	1st
23	Alaoji	3.8524	2nd
24	Aladja	54.0964	7th
25	Aja	19.7755	3rd
26	Birnin Kebbi	32.3796	5th
27	Kaduna	29.6417	4th
28	Kano	51.5486	6th

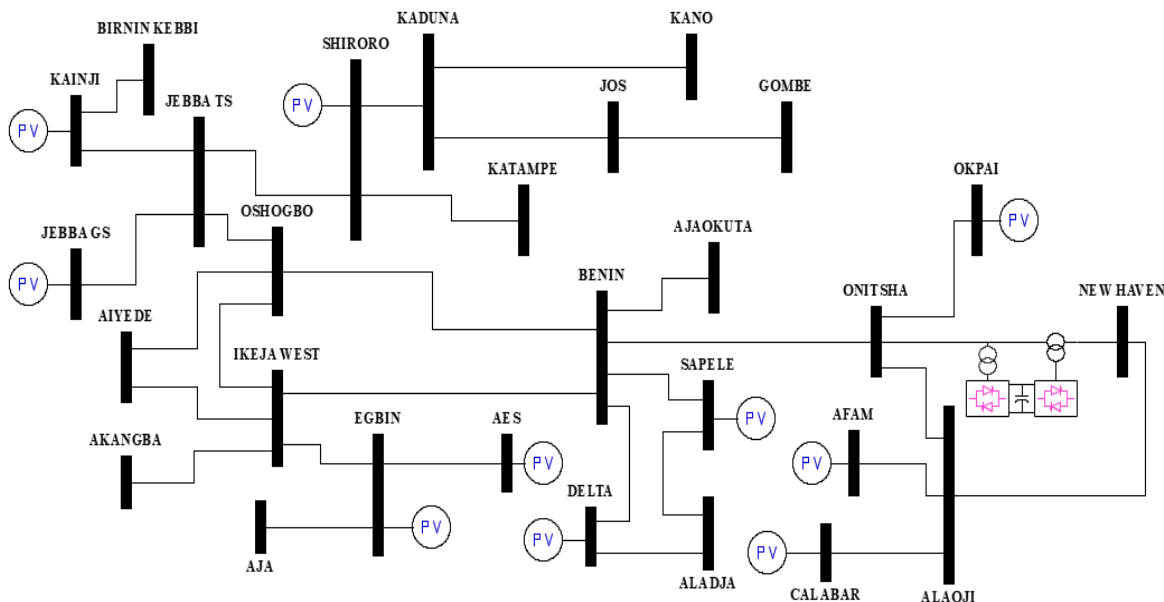
The results of the eigenvalues, which are associated with the network load buses, as presented in Table 3, are then ranked in increasing order from the least value to the largest value. It is revealed based on the results that the weakest node within the network is bus 22 (New Haven) whose eigenvalue is 2.8253 and the next to it is bus 23 (Alaoji), with the eigenvalue of 3.8524. The implication of this is that a large electrical distance exists between the load buses 22 (New Haven) and 23 (Alaoji). This, therefore, suggests that the load bus 22 (New Heaven) is the weakest bus within the network. With this, the critical line is determined and the transmission line (New Haven - Alaoji), through which the UPFC is connected, is as therefore identified. The UPFC placement is, therefore, located between the buses 22 (New Haven) and 23 (Alaoji) as shown in the modified network shown in Figure 12. The eigenvectors that correspond to the least eigenvalue of 2.8253 is found to be approximately constant with a value of 0.2371, and the results are shown graphically in Figure 13 in which all the load buses are seen to maintain equal values of eigenvector.


Figure 12: Single-line diagram of the modified Nigerian 28-bus Network
Figure 13: Eigenvectors corresponding to the least eigenvalue of New Heaven in the Nigerian 28-bus network

4.2. Transient Stability Assessment

In this section, the assessment of the system transient stability, when subjected to disturbances, is investigated. The responsiveness of the power systems to the sudden occurrence of faults are assessed. This serves as the base case solution, and the results obtained are presented. Based on the phase difference and the angle of convergence, the time taken by the power systems to regain stability and return to a normal mode of operation is considered. The transient stability assessment, considering the reinforcement of the network through the integration of multi-UPFC, is then carried out. The comparison of results is then made in order to investigate the impact of the FACTS device on the reinforcement of the topologically weak power networks. The results obtained from the simulations are presented in the sections that follow.

Case 1: Transient Stability Assessment of The IEEE 5-Bus System

This power network is subjected to a fault on bus 4 being the most critical load bus as identified based on the eigenvalue analysis. The contingency analysis is then performed by the removal of the transmission lines connected to it based on the N-1 criterion to determine the impact of the transmission line outages on the stability of the system. The results obtained from the simulations before the integration of the UPFC are shown in Figure 14.

Figure 14 (a) – (c) show the dynamic response for the transient stability assessment before the integration of UPFC for possible upgrading of the network. In Figure 14 (a), it can be seen that the effect of the disturbance during which line 2-4 is removed causes the rotor angle to fluctuate between the values of -2.5o and -22.5o. The phase angle after returning to synchronism, is found to become stable at -12.5o. However, the result of the transient assessment for the outages of line 3-4 and line 4-5 shows similarities in the phase angle difference, as shown in Figure 14 (b) and (c) respectively. The rotor angles fluctuate between -4o and -22.5o in both cases and the stable phase angle difference after returning to synchronism is -13.25o.

In order to investigate the impact of the multi-UPFC on the transient stability of the network, the transient stability assessment of the network is carried out considering the integration of the multi-UPFC into the network. From the eigenvalue results presented earlier in Table 1, suitable locations for the placement of multi-UPFC are identified based on the magnitude of the eigenvalues of the network load buses. It is seen that the bus with the least eigenvalue is identified as the most critical bus (bus 4) within the network. The transmission line connecting the most critical bus and the next ranked eigenvalue bus (bus 5) is identified as the most critical transmission line in the system. In other words, the most critical line in the IEEE 5-bus system, based on the approach suggested in this work, the critical line is the line connecting buses 4 and 5. In this paper, we assumed the worst scenario and therefore suggested that when a fault occurs at the most critical bus, the line connecting buses 4 and 5 should be removed to clear the fault. Furthermore, as presented in Table 1, the next ranked eigenvalue bus after bus 5 is bus 3. This implies that the network under consideration can easily be enhanced or upgraded by placing the multi-UPFC controller in series with the

line which connects the most critical bus (bus 4) and bus 3. It is noteworthy that the third line (line 2-5) is connected to bus 2, which is a generator bus. This is not considered for the muti-UPFC as the generator is capable of reinforcing the line with the needed compensation.

After the integration of FACTS devices into the network, the same procedure carried out without the incorporation of UPFC is repeated. The reactive power is then improved in steps, and the transient stability of the system is analysed. The most significant variation is observed when the reactive load demand is compensated to 30.5MVAR. The results obtained, considering the N-1 criterion within the network is shown in Figure 15.

It is observed that an improvement in the phase angle difference occurs after integrating the UPFC between the lines. Also, the angle of convergence is seen to have been improved. Figure 15 shows that the phase angle difference is found between -4 and -20 and the angle of convergence after the system regains synchronism is -12o, which is a significant improvement from the base case examined.

Figure 15: IEEE 5-bus transient stability assessment considering UPFC integration

Case 2: Transient Stability of The IEEE 30-Bus System

In this subsection, the transient stability assessment of the standard IEEE 30-bus power network is carried out. The simulation results obtained when the critical load bus (bus 23) with the least eigenvalue is subjected to a fault are presented and discussed in this section. The N-1 criterion is also taken into consideration as explained for the IEEE 5-bus network. To determine the Critical Clearing Time (CCT) for the network, the transient stability assessment of the network is first performed using a small clearing time and increase in steps to determine the actual clearing time the network becomes unstable. This maximum clearing time at which the network becomes stable is taken as the CCT.

The dynamic responses obtained from the simulation before integrating the multi-UPFC are shown in Figures 16 (a) and (b). Based on the simulation results obtained, the Critical Clearing Time (CCT) of 0.01s is obtained for the network. Figure 16 (a) shows the transient analysis when line 15-23 is removed. The network regains transient stability after 30 seconds. Similarly, when line 23-24 is removed, the time taken to regain transient stability is 50 seconds, as presented in Figure 16 (b).

The most critical line based on the results presented in Table 2 is line 23-24. Based on the eigenvalue analysis results obtained, the line on which the series UPFC is placed is identified to be the one connecting buses 23 and 15. Considering the N-1 contingency conditions, when a fault occurs at the most critical bus (bus 23), the most critical transmission line (the line connecting buses 23 and 24), as identified by the approach suggested in this study, is disconnected. For faults on bus 23, the reactive power is increased in steps, and the critical line attached to it, based on N-1 criterion is removed, and the transient stability analysed. The dynamic response obtained from the simulation is shown in Figure 17

It is evident from results obtained in Figure 17 that the inclusion of the multi-UPFC controller causes the network to regain transient stability faster than the time taken without the UPFC controller. Figure 17 confirms the improvement in time to 20 seconds from the base case of 50 seconds which it takes the system to regain transient stability when the critical line (line 23-24) is disconnected. The result shows that by the integration of the FACTS device, the transient stability of the power system improves significantly. The improvement is evident in the time-reduction of the distortion period, and this goes a long way at avoiding total system collapse during any major disturbance, usually faults.

Figure 17: IEEE 30-bus transient stability assessment considering UPFC integration

Case 3: The Nigerian 28-Bus System

The same simulation procedures, as earlier discussed, are followed in this case. The total simulation time of 50 seconds and the clearing time of 0.08 second are considered for the simulation. The results obtained are presented in Figures 18 (a) and (b). By considering the N-1 criterion, the transmission line connecting New Heaven to Onitsha (line 22-21) is first disconnected with reference to a fault occurring on the bus 22 and the simulation result obtained is shown in Figure 18 (a). The simulation result obtained when the transmission line connecting New Haven to Alaoji (22-23) is disconnected is shown in Figure 18 (b).

The base cases show that three generators are significantly out of synchronism with the others, with reference to the generator at Egin. The worst scenario is seen at a phase angle of -10.75o. The procedure is once again repeated after the integration of the UPFC to examine the impact of ingesting reactive power into the system through the UPFC.
(a): Phase angle difference with line 21-22 removed
(b): Phase angle difference with line 22-23 removed

Figure 18: Nigerian 28-Bus Transient Stability Before Integrating FACTS Device

From the results of the eigenvalue presented in Table 3, the placement of the UPFC is identified based on the magnitude of the eigenvalues of the network load buses. The bus with the least eigenvalue, within the network, is identified to be bus 22 (New Haven). The transmission line connecting this bus and the next ranked eigenvalue bus 23 (Alaoji) based on the approach suggested in this work is identified as the most critical transmission line in the system. In other words, the most critical line in the Nigerian 28-bus system is the transmission line connecting New Haven and Alaoji buses (bus 22- bus 23). This, therefore, suggests that from the worst scenario when a fault occurs, the line connecting buses 22 and 23 should be removed to clear the fault. Furthermore, as presented in Table 3, the next ranked eigenvalue bus, connected to the critical bus, after Alaoji bus (bus 23) is Onitsha bus (bus 21). This implies that the network can easily be reinforced by placing the UPFC controller in series with the line which connects the most critical bus 22 and bus 2 (New Haven and Onitsha).

The impact of the multi-UPFC when the transmission line connecting New Haven and Alaoji (bus 22- bus 23) is removed is shown in Fig. 19. The results show that two more generators are caused to get into synchronism to make it a total of eight generators with reference to the generator at Egbin. Only one generator was thrown out of synchronism, and this shows a notable improvement in the system by reinforcing with multi-UPFC.
Figure 19: Transient stability for the phase angle difference with line 22-23 removed

When the generator bus at Sapele, which is out of synchronism with the critical line (line 22-23) is removed, a phase difference of -5.2o (as against -10.75o of the base cases) is obtained. This is evidence of the improved stability of the Nigerian 28-bus power network by reinforcing with the multi-UPFC controller.

5. Conclusion

In this paper, the influence of FACTS device integration on the assessment and enhancement of power system transient stability, in topologically weak power networks, have been presented. An extensive review of the existing studies on various approaches for solving the problem has been presented. The theoretical framework, as well as the mathematical formulations required for the analysis, are presented. Based on the mathematical formulations presented, a non-iterative based technique, which identifies the critical parts of the network where FACTS devices could be suitably located, for reinforcement of weak network, is

suggested. The multi-UPFC is employed for this purpose in this study. The standard IEEE 5-bus and 30-bus, as well as the Nigerian 28-bus networks, are used as case studies in order to test the effectiveness of the method suggested in this study. The results obtained before and after the integration of UPFC are compared. From the comparison of results obtained, it is clearly revealed that the UPFC also has a great influence on the simulation times. More conclusively, this study has shown that the integration of FACTS devices into a power system is effective for improving transient stability when the system faults occur in any part of the system. It is shown, in this study, that the integration of FACTS Devices reduces, to the barest minimum, the total time taken for the system to regain balance and return to its normal operating conditions without experiencing system collapse.

Conflict of Interest

The authors declare no conflict of interest.

A R T I C L E I N F O	A B S T R A C T
	This manuscript exhibits a perfect design for a flexible number of modified DC nanogrids within an open energy distribution network (OEDN) that interconnected via a DC bus. Each modified nano-grid implies a single-input multi-output switched boost inverter (SIMO-SBI). The DC-output for each inverter is robustly controlled to keep the DC-bus interconnected voltage constant. The proposed control uses model reference technique to defeat the non-linearity of the system. In addition, a control algorithm is proposed to manage the optimum power flow and increase the system reliability. The MATLAB/Simulink program is used in modelling and simulation of the suggested arrangement to achieve the robustness of the proposed OEDN with multiple 5-Kw interconnected nanogrids fed from photovoltaic (PV) arrays. Several simulation results are introduced for both open and closed loop control to verify the robustness and validity of the system against the main parameters' changes. In accession, the smoothing power flow between nanogrids indicates that the proposed algorithm for the controller is sophisticated and able to supervise the power among all nanogrids of an OEDN.

1. Introduction

AC generation, distribution and transmission for long distances had been in existence for even more than a century with the high spread for the AC loads in the markets [1].

Conventional AC grid depends mainly on traditional energy sources - such as oil, coal and natural gas - that are permeable and polluting the environment. Also, this classical grid uses a centralized control system that is sensitive to any fault occurrence and cause an outage for the whole network such as New York blackout in Aug. 2003. So, decentralized control techniques are good solutions for this traditional network [2].

Renewable energies such as solar, wind, geothermal, biomass are environmental friendly distributed generation (DG) resources. Most of these renewable resources such as photovoltaic systems and fuel cells produce a DC output power that can directly feed to the DC loads without AC conversion. Unfortunately, the generated power from those renewable resources is limited and intermittent. These small-rated resources can be classified according to its rating capacity as: mini grid rate from 50 kW to 1.5 MW, micro grid rate from 5 kW to 50 kW, nano grid rate from 1.5 kW to 5.0 kW, and the smallest one is a pico grid rate less than 1.5 kW [3].

These compact DC grids can be interconnected with each other via a simple-configuration DC bus instead of AC interconnections. DC-interconnection don't need to synchronization, quickly integrated with distributed generation (DG), and no skin effect for transmission lines [4].

Classical DC nano-grid has large numbers of two-stage converter-inverter set. The interconnection of this combined set causing some problems such as communication interference with noise. In addition, the main disadvantage of the two-stage converter-inverter set is that it needs to be protected against overlapping of the two inverter-switches on the same arm [5].

The authors in [6-8] described a new modified model for the DC nanogrid with the help of single-input multi-output switched boost inverter (SIMO-SBI). It improves the system efficiency and increase its reliability. In addition, it produces simultaneously DC and AC voltages in a single stage.

In [9], the authors presented a complete analysis for SBI, control circuits, and open-loop control strategy fed from photovoltaic (PV) generator was proposed. Also, in [10], The authors proposed a closed-loop control technique to ensure the robustness of the system against main parameter variations. In addition, the authors introduced a buck-boost converter as a host controller for a battery management system utilized within an autonomous nanogrid.

So, this study is an extension of the previous work of references [9, 10] as a part of an internal research project at Electronics Research Institute, Egypt. It utilizes the features of DC-interconnection to join between several autonomous nanogrids within an OEDN. Before interconnection, a model reference robust control scheme is tested to keep the interconnection dc-link voltage constant. Also, a sophisticated control algorithm is proposed for power management between two-interconnected nanogrids as a case study. This guarantees an optimal and smooth bi-directional power flow between nanogrids even though one of them has been disrupted. This algorithm depends mainly on load demands for each nanogrid. The performance and robustness of the proposed system is tested after modelling and simulation of mathematical models with the help of Matlab/ Simulink software program. Test results ensure the robustness of the proposed system against parameter variations and the validity of the proposed system to be applied for several off- or on-grid DC interconnection.

This manuscript is organized as follows: section 2 compares between the classical AC grid and the OEDN. But, section 3 involves the proposed interconnection of multiple modified DC nanogrids within an OEDN. Section 4 discusses the single input - multi output switched boost inverter (SBI) topology with its open and closed loop algorithms. Section 5 introduces the design of the proposed OEDS as a case study. It also includes the test results of the proposed OEDN control technique to evaluate its performance and check the robustness against load variations. Finally, section 6 is the conclusion.

2. The Classical AC Network via OEDN

There are three stages in the AC-grid cycle: generation, transmission, and utilization. If a fault occurs in any part of this network, it will cause a trip for the whole system. Moreover, the classical power grid can't accommodate the rapid rise in electricity demand. It is also unyielding to promote the introduction of clean energy or other types of technology that will make it more competitive. To solve these mentioned problems, figure 1 proposes some guides. It also shows that the valuable solution for delivering effective, sustainable, safe and reliable power to the customer is the decentralized renewable grids. So, this paper introduces one of these solutions by interconnecting nanogrids with each other's via a DC link to form an open energy distribution network (OEDN) [4] as described in Figure 2.

The OEDN is a modern type of the decentralized network that described by building up several numbers of interconnected modified DC nanogrids via a local DC power bus and managed in a distributed way to form a reliable OEDN [4]. The authors in

In [11, 12], the author studied the main advantages of interconnecting grids. They also proposed a multi-level grid system in the form of interconnecting renewable energy microsystems.

So, this framework proposed an alternate control mechanism for interconnecting scattered modified islanded nanogrids to form a complete OEDN. Table 1 shows a comparison between a single designed nanogrid system and a complete OEDN.

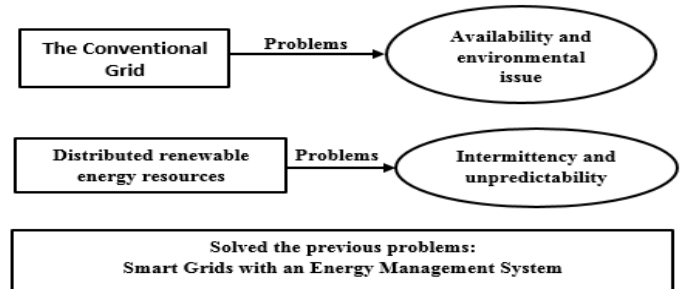
The OEDN gives many benefits rather than the separated single DC nanogrid as it improves the grid performance and guarantees stability of the system. It ensures the continuity of the load feeding even though one of the nanogrid had been disrupted. Since, this allows a power management through nanogrids to all loads without interruption from other available nanogrids [11]. The OEDN structure relies on the two main DC layers [4]. The first layer implies a group of interconnected modified DC nanogrids based-on the single input-multi output switched boost inverter (SBI). And the second layer is a DC power bus that interconnects nanogrids to each other. The DC links are chosen for both levels due to their advantages such as: the DC link is more simpler to integrate than the AC link. The DC link makes mathematical model analysis simpler since there is no need for synchronization (no frequency, no phase shift and no AC-complex control). In addition, the DC link increases the reliability of the transmission lines and enhances the safety of the grid due to lack of reactive power [11].


Figure 1: several problems with solutions for the classical grid
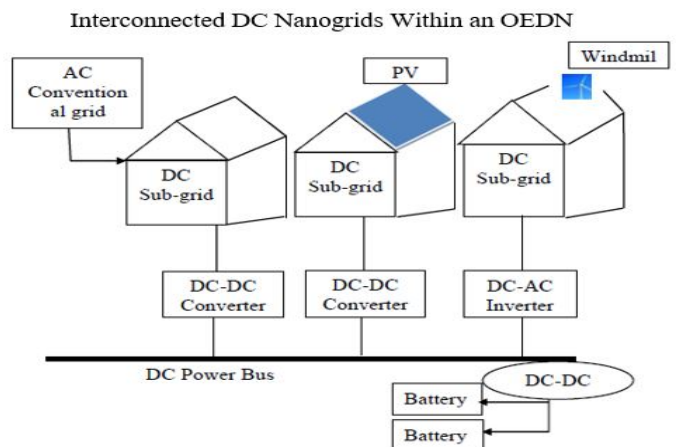

Figure 2: The structure of interconnected DC Nano grids within an OEDS

3. A Modified DC-Nanogrid against Traditional One

The standard DC nano-grid requires a 2-stage AC-DC power conversion system to support both DC and AC loads. So, its

design has several challenges as it involves a great number of converters and inverters, as seen in Figure 3. Moreover, different separated security and control algorithms are needed for each stage. This series of conversions rises the system total cost and losses.

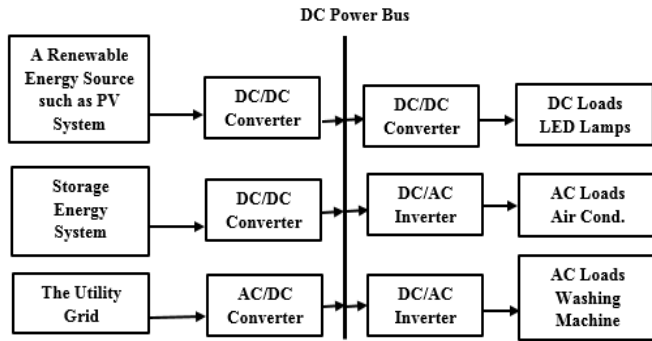
But on the other hand, a single-stage conversion system was proposed to overcome some drawbacks mentioned in the standard one. Those updated nanogrids are modified with few numbers of conversion stages [12-14].


Figure 3: The standard nanogrid structure

Table 1: Show a comparison between OEDN and single nanogrid system

An OEDS	Single nanogrid
Power generated is uncentralized	Power generated at the end user
50 – few hundred households	Less than 50 households
Coverage ranges from a few hundred meters to 1-2 kilometres	Coverage ranges less than 100 metres
Need a few large numbers of DC / AC conversion sets	A few numbers of DC/AC inverters are required

4. A Single Input Multi Output - Converter

The suggested modified DC nanogrid system is based on a single entry switched boost inverter (SBI) as shown in figure 4. SBI is a single-stage power converter capable of providing DC and AC loads simultaneously from the same DC input voltage. It can also provide an output AC voltage whether higher (boosting) or lower (bucking) than its DC input voltage. It prevents noise due to electromagnetic interference (EMI) compared with the classical two stage power converters [14]. Moreover, SBI doesn't need to a dead time circuit as its operation technique depends on the shoot-through state. The SBI operation is originated its basic concept from the Inverse Watkins topology and the Z-source inverter (ZSI) operating idea. But, the SBI has many benefits compared with the ZSI - as explored in table 2 [15-19].

4.1. Topology of a Single Stage Switched Boost Inverter

The circuit diagram of the SIMO-SBI contains five IGBT switches, two passive elements (an inductor (L) with capacitor (C)), two diodes (D_a, D_b), and a low pass LC passive filter is connected across the AC output of the inverter to mitigate un-desirable harmonic components as shown in figure 5. SBI has

two operating modes non-shoot through state mode and shoot through state mode. The AC Output voltage of the SBI can be controlled by the following equations:

$$V_{AC} = M.V_{DC} \qquad (1)$$

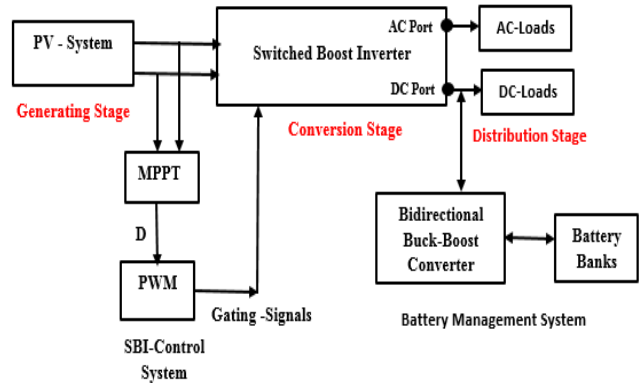
$$V_{AC} = M. (1-D/1-2.D).V_G \qquad (2)$$


Figure 4: Block diagram for the suggested modified DC nanogrid

Table 2: Comparison between ZSI and SBI

SIMO Inverters	Active Switches	Reactive switches	Noise Interference	Accuracy
SBI	More	Less	Less	More
ZSI	Less	More	More	Less
Figure 5: The Circuit diagram of the SIMO-SBI

So, M and D are chosen in such a way to control its peak output AC voltage V_{AC}. Also, the sum of shoot-through duty ratio (D) and the modulation index (M) should be less than or equal to unity, i.e.

$$M + D \leq 1 \qquad (3)$$

4.2. Open Loop Control Algorithm for a SIMO-SBI

The SBI open loop control technique derives its basic idea from the traditional sinusoidal pulse width modulation (PWM) technique. But, the standard PWM scheme should be changed in order to allow use of its shooting-through mode territory. So, this new approach has been used during the positive and negative half periods of the sinusoidal modulation signal Vm (t). The SBI open loop control algorithm was discussed in details in [9, 20]. SBI doesn't need to a dead time circuit in its operation technique. On the other hand, its main drawback was summarized in its limiting duty ratio (D) (0-0.5) which cause high harmonics in its output voltages when the duty ratio gets closer to the end of the range (0.4 - 0.5).

Figures 6 and 7 are included as samples in the process of main-parameter changes manually for SBI to adjust its performance before interconnection. Figure 6 demonstrates the performance of the switched boost inverter as a buck converter to obtain an AC output voltage less than its DC input at duty ratio equal 0.22.
Figure 6: The SBI operation in a bucking mode (with D=0.22)
Figure 7: The SBI operation in a boosting mode with (D=0.4515)

While, figure 7 illustrates the performance of the inverter as a boost converter and to raise AC output voltage higher than its DC input with a duty ratio equal 0.4515. So, the robust closed loop control should be used to maintain the SBI output voltages constant, especially through the critical range of the duty ratio (0.4 – 0.5).

4.3. Closed Loop Control Algorithm for a SIMO-SBI

The purpose of the closed loop control is to keep the system stable even after it has been subjected to a certain variety. The output of the inverter is highly sensitive to any slight change in its duty ratio [19].

As, the output of the inverter will go to infinity if the system duty ratio (D) is 0.5. And the system output is observed to be erratic with a very high percentage of harmonics when its duty ratio becomes closer to 0.45. So, the system DC output voltage of

the SBI should be controlled by using a robust closed-loop control algorithm to keep it constant.

This control algorithm is mainly depending on comparing the DC output voltage and the DC reference voltage and the resulting error is managed by a PID control strategy. The PID controller was chosen due to its simplicity, easy in continuous tuning, provides good stability, and rapid response. The parameters of the PID controller were designed based on the Ziegler-Nichols formulas. The proportional, integral, and derivative gains are selected as [20]:

$$K_P = 5 \times 10^{-7}, K_I = 5 \times 10^{-7}, K_D = 1 \times 10^{-6}$$

The output of this controller is used to readjust the PWM pattern applied to the inverter switches. This controller strategy is applied to overcome the disadvantages of the inverter and to monitor its DC output value. As a consequence, its AC output voltage will regulate according to Equation 2, at a constant modulation index (M=0.5), as discussed in details in [10].
Figure 8: The input voltage, control signal, the duty ratio, the DC/AC output voltages respectively by decreasing the reference voltage from 622 to 311v.
Figure 9: the input voltage, control signal, the duty ratio, the DC/AC output voltages respectively by increasing the reference voltage from 311 to 622v.

For insurance of the robustness of the controller in maintaining the DC-link voltage constant before interconnection the following sample figures test the time response of the closed loop control under disturbances. Figures 8 ,9 demonstrates the system response to the sudden increase/ decrease in the DC reference output voltage of the SBI (V_{ref}) from (622 to 311 V) and vice versa (with step time 0.3). This robustness of the controller keeps the inverter DC output voltage constant. This can be achieved for each interconnected modified DC nanogrid to form a complete stable OEDN.

Hence, each proposed modified DC nanogrid in the OEDN contains solar photovoltaic (PV) arrays supply as a renewable energy distributed generation (DG). Although PV is a clean, pure, natural replenished resource, and environmental friendly, but also is an intermittent resource that is very sensitive to the sun's heat, temperature, humidity and climatic conditions. So, this standalone system will require a power storage scheme such as batteries to retain the excess energy produced from the renewable PV systems. Also, storage system supplies energy in the load peak hours, or through nights and cloudy days.

However, the battery storage system is connected to the system via a bi-directional buck-boost converter that control the battery loading / unloading algorithm. This converter interconnects between both sides of the SBI DC-bus and the lead acid battery banks. This will happen during the charging process of the battery bucking the voltage of DC-link from 622 V to 240V of the battery-bank voltage. On the other hand, through discharging process, it operates as a booster to raise battery voltage form 240V to the DC-link voltage (i.e., 622V). This process can be achieved through a sophisticated algorithm discussed in [10, 20]. This technique guarantees consistency of operation of the scheme without a lack of load requirements. The block diagram for the battery management system is shown in figure 10.

5. The Open Energy Distribution Network (OEDN) Control Algorithm

The SBI robust closed loop control technique allows to maintain the DC-nanogrid output voltages constant under different system operating conditions. It allows for smooth power transfer from one nanogrid to another by applying a simple additional control algorithm to manage the load demands [21,22]. The OEDN control algorithm is depending on a bi-directional controlled-switch that is used to allow power flow between the adjacent nanogrids as seen in Figure 11.

In the proposed system, the control signal turns the switch Sng1 on when any of either the DC or AC load requirements of nanogrid 1 is lower than that obtained from its PV source. So, The Sng1 is turned on to allow the excess power to transfer easily and smoothly from grid 1 to grid 2. While, the control signal turns the switch Sng2 on when any of either the DC or AC loads requirements of nanogrid 2 is lower power than that obtained from its PV source.

In other words, nanogrids with different values of generated power will able to transfer excess power between them according to load demands. As a consequence, this control algorithm allows the smooth flow of excess power from one grid to another. The

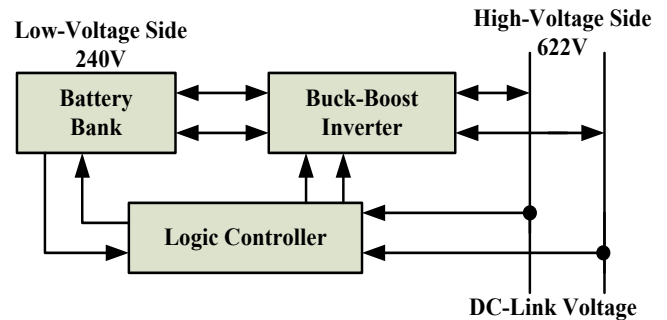
regulation of the working switches is relying mainly on the signal from the output of the comparator control algorithm is facilitating the energy swap between several interconnected nanogrids in an OEDN. Figure 12 introduced the control schematic diagram and Figure 13 provides in details the flow chart for this proposed algorithm.


Figure 10: Battery management system
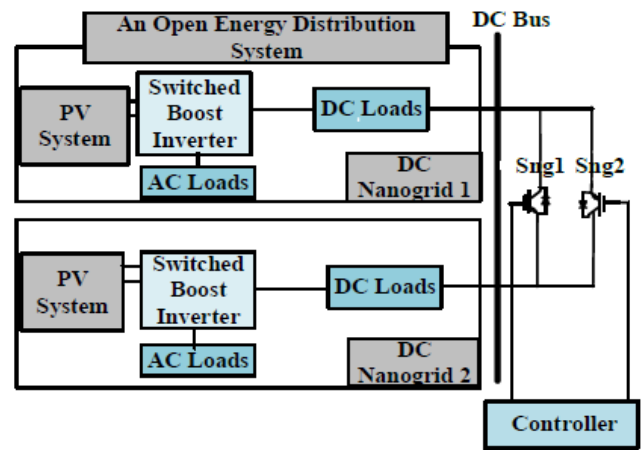

Figure 11: The block diagram for an OEDS control system
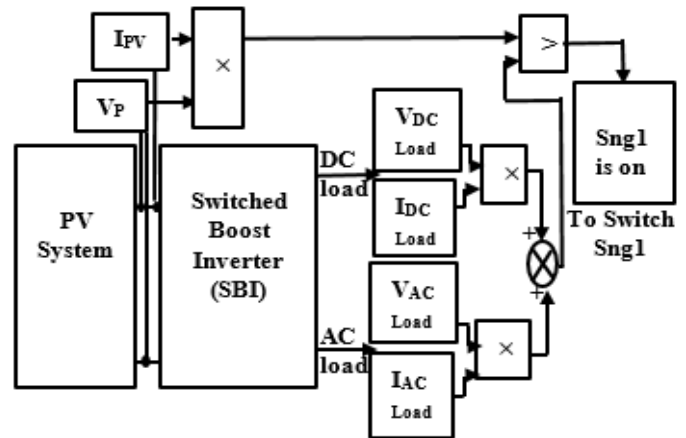

Figure 12: The two interconnected nanogrids control algorithm

5.1. Case study: an OEDN-based two DC-nanogrids

The following results introduce the efficiency of the proposed OEDN control algorithm to operate stably under various conditions. They also demonstrate the performance of the SBI output voltages with its rigorous robust closed loop control

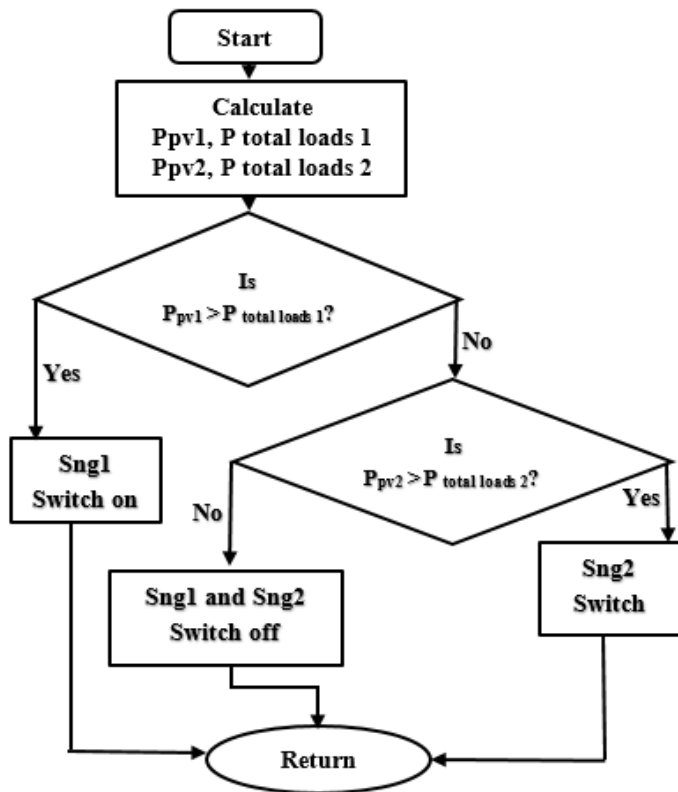
technique. Matlab / Simulink software package was used in modelling and simulation of the proposed system [23].


Figure 13: The OEDS controller flow chart

The Following test results demonstrate the system robustness under different conditions. Figures 14 and 15 show the flow of power in a full OEDN with two interconnected grids from separate solar generators. All nanogrids are energized from independent solar generators with checking stability of the overall control system under any fault conditions within the same OEDN. Each figure shows the AC, DC output and the total load powers for the two DC-interconnected nanogrids within an OEDN .

Figure 14 shows that the generating power of one grid PV source is 6 kW and 4.5 kW for other. If the load of the first one will consume the full power in the first 0.4 sec. Then, if the power of that load are distributed abruptly and minimizing its consumption to just 4.5 kW. At the same time, the demands of the other load in (NG2) increased and need to this excess power to its load.

So, the extra power of the first nanogrid will transfer in the same time to the load of other grid to compensate the power shortage. At this instant (i.e., t=0.4 Sec.), the demand power for other grid will be increased to 1.5 kW. As a sequence, figures 14 ((a) and (b)) represents the AC and DC output powers of both interconnected nanogrids followed by the total load power with their different requirements at 0.4 sec (as shown in figure 14c).

While, figure 15 shows two other nanogrids with different generating powers. As, the first nanogrid with a PV source of rating 6.5 kW. The utilities of this nanogrid consume all power through 0.4 sec. Then, Its consumption is reduced to just 5.5 kW. So, the extra power of the first nanogrid will transfer in the same

time to satisfy the shortage of power in the other nanogrid loads. The previous two cases ensured the system ability of the exchange power stably between the interconnected modified DC nanogrids in an OEDN.

Note: if there is a surplus power from Ng1 and Ng2, then this excess power will be transferred to the battery banks for storage and emergency use.

(b) The power consumed by DC- loads for both nanogrids
(c)The total interconnected power transferred for both nanogrids

Figure 14: AC,DC and total power of the two PV-based nano-grids with rated generated power of values 6 and 4.5 kW respectively

6. Conclusion

This paper explored the importance of the DC interconnection and DC distribution systems. It identified a perfect design for the OEDN with interconnected DC grids. A bi-directional robust control technology was introduced to assure an efficient energy transmission between the linked DC nanogrids. It guarantees the system optimum operation even if any of the grid generating sources are cut off. Thusly, it converted the centralized scheme to a decentralized one with high reliability of mental process.

Moreover, The modified, adapted SIMO power electronic SBI with its adaptive monitoring control system was carried out in each nano-grid. It tends to ameliorate the performance of the inverter by adjusting its outputs to high levels. In this mode, it allows the AC output voltages to be grown to a value (220 V rms) which is suitable for the loads in EGYPT.

Also, DC-interconnection among nanogrids is suitable and efficient more than AC in the two cases (autonomous off – and on-grid) systems.

A B S T R A C T

Online fashion market is constantly growing, and an algorithm capable of identifying garments can help companies in the clothing sales sector to understand the profile of potential buyers and focus on sales targeting specific niches, as well as developing campaigns based on the taste of customers and improve user experience. Artificial Intelligence approaches able to understand and label humans' clothes are necessary, and can be used to improve sales, or better understanding users. Convolutional Neural Network models have been shown efficiency in image classification. This paper presents four different Convolutional Neural Networks models that used Fashion-MNIST dataset. Fashion-MNIST is a dataset made to help researchers finding models to classify this kind of product such as clothes, and the paper that describes it presents a comparison between the main classification methods to find the one that better label this kind of data. The main goal of this project is to provide future research with better comparisons between classification methods. This paper presents a Convolutional Neural Network approach for this problem and compare the classification results with the original ones. This method could enhance accuracy from 89.7% (the best result in the original paper, using SVM) to 99.1% (with a new cnn model called cnn-dropout-3).

1. Introduction

This paper is an extension of work originally presented in the Iberian Conference on Information Systems and Technologies [1].

The fashion market has changed dramatically over the last 30 years, resulting in an evolution in that industry [2]. Understanding customer tastes and better-directing sales are the way to increase profit [3].

The rise of internet business lets people buy their clothes through websites, faster and easier. The introduction of methods to improve user's experience when searching for items in these platforms is decisive [4].

Classifying clothes is part of the broad task of classifying scenes [5–9]. The automatic generation of image labels that describe those products can alleviate human annotators' workload [10]. This kind of information may also help labeling scenes and better understanding users' tastes, culture, and financial status [5].

In [11], the authors present Fashion – MNIST data set based on images from Zalando, which is the Europe's largest online fashion platform. Fashion MNIST has 70,000 products with 28x28 pixel grey scale images divided into 10 categories: t-shirt, trouser, pullover, dress, coat, sandals, shirt, sneaker, bags and ankle boots.

[*]Corresponding Author: Alisson Steffens Henrique, ash@edu.univali.br

Those images were formerly thumbnails on their web store. This dataset is widely used in Artificial Intelligence (AI) benchmarks, and it is preloaded in Keras [12].

The original work used different AI models on this dataset to discover which one is better suited for the data labeling [11]. The evaluated implementations (from scikit-learn) were: Decision Tree, Extra Tree, Gaussian Naive Bayes, Gradient Boosting, k Neighbors, Linear Support Vector Classification, Logistic Regression, Multilayer Perceptron, Passive Aggressive Classifier, Perceptron, Random Forest, Stochastic Gradient Descent and Support Vector Classification. Their best result was using SVM, and they could achieve 89.7% of accuracy.

CNNs can have better results when compared to SVM [13]. Knowing that, this paper proposes the use of Convolutional Neural Networks (CNN) to label FashionMNIST dataset. The main goal is to compare those results with the original one, providing future research to be able to easily choose the most suitable classification method. In this paper, we present the development of four different CNN models and compared the results with the original ones. Our original work [1], used these four models with TensorFlow 1 (TF1) to get the results. Now, we present this extension using TensorFlow 2 (TF2) and GPU computing (with tensorflow-gpu and keras).

2. Background

2.1. Feature Learning

Machine Learning refers to computer systems capable of learning and modifying their behavior, in response to external stimuli or through experiences accumulated during their operation [14].

The main objective of Machine Learning is to generalize beyond the existing examples in training set, because regardless the amount of existing data, it is very unlikely that during the tests, the same examples will appear [15].

Conventional Machine Learning techniques are limited to processing natural data in its raw form. To build a model capable of doing pattern recognition, it is necessary to develop a feature extractor, which transform raw data into a representation that the classifier can detect [16, 17].

The group of methods that allow systems (based on Machine Learning) to discover the necessary representations for detecting and classifying raw data is known as Feature Learning [18].

These methods can not only learn how to map the feature to a result, but also to build the representation itself, often resulting in better performance than the representations developed by a specialist [19].

The growing scientific interest in this topic has been followed by a notable success, both in academia and industry. Mainly in areas of speech recognition, signal processing, object recognition and natural language processing [20].

Some of the Feature Learning techniques that have been producing promising results refer to Deep Learning. As more data becomes available, the more successful this technique will be [19].

2.2. Deep Learning

There are several techniques capable of Feature Learning, some are known as Deep Learning. They are models made by multiple nonlinear transformations, to produce abstract and more useful representations.

These models transform a representation into another, more abstract than the previous. In classification models, for example, more representation layers tend to amplify aspects of the data that are important for classification and hide irrelevant variations. By adding more layers, these models can represent more complexes functions [21].

The key aspect of Deep Learning is that layers of representations are not specified by a human specialist. They are learned through data, using common Machine Learning procedures. In the Deep Learning context, we can use Convolutional Neural Networks for this.

2.3. Convolutional Neural Network

Convolutional Neural Networks [22], refer to a variation of MLP (Multilayer Perceptron) and are based on the visual cortex behavior, where the neurons of the initial regions are responsible for detecting simple geometric shapes in the image, such as corners and edges, and the final neurons detect more complex graphic shapes. The process is repeated throughout the cortex until neurons in the final region detect characteristics of higher abstraction level, such as specific faces [23].

CNNs are used in problems where it is necessary to find relevant information implicit in data set, through operations that occur in convolution and pooling layers. In relation to the image classification task, variants of Convolutional Neural Networks that have been prevalent in the literature [24], and they demonstrate excellent results in the MNIST, CIFAR and ImageNet datasets [11, 25].

A convolutional layer is composed by several neurons, each one is responsible for applying a filter to a piece of the input matrix [23]. The convolution operation consists of applying a series of filters, sliding over the entire input matrix, and the result of applying the filters is called a feature map [22].

A pooling layer implements a nonlinear sub sampling function to dimensional reduction and small invariances capture. Pooling reduces the dimensionality of the input feature map and produces a new feature, creating something like a summary of the input.

For each filter, the highest value (max pooling) is selected, or the average (average pooling) is calculated. The pooling application speeds up training and reinforces CNN's strength in relation to position and size of most important characteristics of the training data.

2.4. Dropout

One of the most common challenges in training a Convolutional Neural Network is overfitting. There are several ways to mitigate this problem in a Deep Learning model: increasing the number or size of layers, or use a technique known as dropout.

The term dropout refers to "dropping" units (neurons) from a neural network, which means, temporarily removing them from model. The choice of which neuron to remove is random, and the amount can be fixed using a constant, for example, the constant 0.5 defines that half of the neurons will be removed.

This technique has considerably improved the accuracy and performance of neural network in several applications, such as object classification, speech recognition and document classification, among others [6]. This shows that this technique can be generalized for any problem.

3. Related Work

In [6], the authors presented a context sensitive grammar in an And-Or graph representation, that can produce a large set of composite graphical templates of cloth configurations.

In [5], the authors introduce a pipeline for recognizing and classifying clothes in natural scenes. To do so, they used a multi-class learner based on a Random Forest. Data was extracted features maps which were converted to histograms and used as inputs for a Random Forest (for clothing types) and an SVM (for clothing attributes) classifier. As result, their pipeline can describe the clothes on a scene, as show in Figure 1. They also created their own dataset with 80000 images labeled in 15 classes.
Figure 1: Model presented in [5].

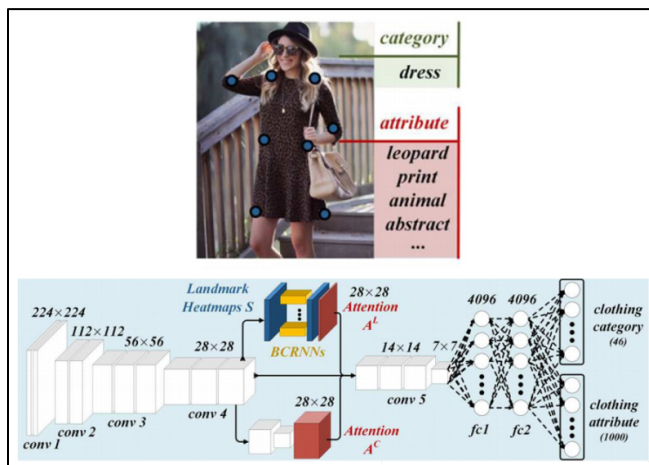
In [26], the authors propose a knowledge-guided fashion analysis network for clothing landmark localization, and classification. To do so, they used a Bidirectional Convolutional Neural Network. As results, the model can not only predict landmarks, but also category and attributes, as shows Figure 2.


Figure 2: Model proposed [25].

4. Data Set

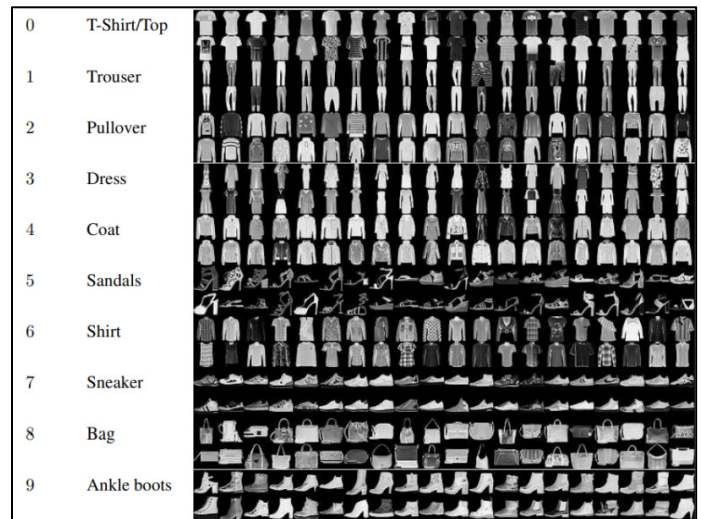
Fashion-MNIST is a direct drop-in alternative to the original MNIST dataset, for benchmarking machine learning algorithms [11]. MNIST [27] is a collection of handwritten digits, and contains 70000 greyscale 28x28 images, associated with 10 labels, where 60000 are part of the training set and 10000 of the testing. Fashion-MNIST has the exact same structure, but images are fashion products, not digits. A sample of this set can be seen in Figure 3.


Figure 3: Fashion-MNIST sample

The dataset can be obtained as two 785 columns CSV, one with training images, and the other with testing ones. Each CSV row is an image that has a column with the label (enumerated from 0 to 9) and 784 remaining columns that describe the 28x28 pixel image with values from 0 to 255 representing pixel luminosity.

To make data access easier, we generated images divided in directories by usage, and labels. This way, we are able, to easily obtain image information by using only its path e.g., resources/test/dress/10.png.

5. CNN Models

To label this dataset, four CNN models were done in Python with Keras and TensorFlow. Training was executed in a Jupyter notebook, using GPU. We also used Weights and Biases [14] to grab information about training and hardware usage.

Proposed models were named: cnn-dropout-1, cnn-dropout-2, cnn-dropout-3 and cnn-simple. The goal of those models was to be able to label the dataset without the need of too much training or processing on activation, so developers can use it on real time applications such as online stores and searching websites.

5.1. cnn-dropout-1 and cnn-dropout-3

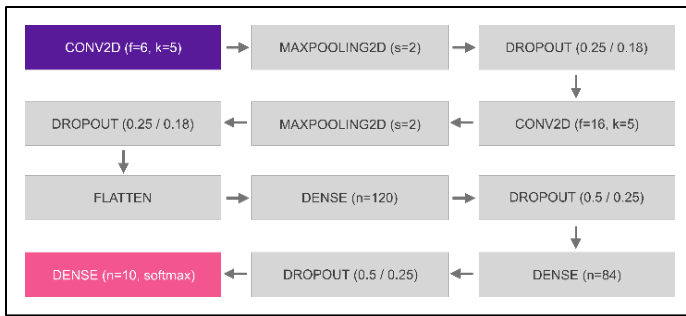
Both models use two consecutive blocks containing: a convolution, a max pooling, and finally a drop out. These blocks are connected to two more fully connected layers, who are connected to an output layer of ten neurons, each one representing a category. The only difference between these two models is that cnn-dropout-3 has considerably lower dropout values, as show in Figure 4.


Figure 4: Topology of cnn-dropout-1 and cnn-dropout-3.

where the first drop out values is for model 1, and the second one for model 3. This topology has 44426 trainable parameters.

5.2. cnn-dropout-2

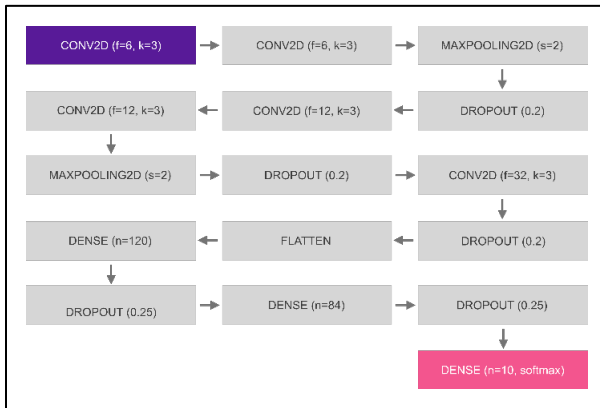
This proposed model is very similar to the cnn-dropout-1 model. However, it has two layers of convolutions before each max pooling. This model has about 32340 trainable parameters as shows Figure 5.


Figure 5: Topology of cnn-dropout-2.

5.3. cnn-simple

Cnn-simple is a model with less layers. It has only two convolutions, followed by a fully connected layer, in addition to the respective dropout and max pooling like other models. This model has 110968 trainable parameters and is shown in Figure 6.
Figure 6: Topology of cnn-simple.

Since this model has only one max pooling, the image gets to the dense layer with 14x14 pixels in size (four times the size of other models which is 7x7). So, de dense layer training is expected to be slower.

All those models were modeled based on Keras Sequential model. Convolutional and dense layers used Rectified Linear Unit (ReLU) activation functions, except by the last dense layer on each

model (output layer), were Softmax was used. The optimizer used was Adadelta [28] Batch size was 128 and we trained the models for 12 epochs. To improve results, image pixel luminosity values were normalized to float numbers between 0 and 1.

6. Results

On the training dataset, the most accurate model was cnn-simple, with 98.95% of accuracy. Figure 7 shows that other models were also acceptable, based on the results obtained: 98,06% (cnn-dropout-3), 97.51% (cnn-dropout-2), and even the worst model (cnn-dropout-1), got an accuracy of 96,46%.
Figure 7: Accuracy

Validation accuracy had different results (as shows Figure 8), with cnn-dropout-3 having the best results 99.1%, followed nearly by cnn-dropout-2 (99.08%) and cnn-simple (99.05%). Cnn-dropout-1 still the one with the worst results (98.69%).
Figure 8: Validation Accuracy

Loss had good results, with cnn-simple having the best results both in training and validation loss, followed by cnn-dropout-3, cnn-dropout-2, and cnn-dropout-1. Results are shown in Figure 9.

When evaluating time, the two more accurate models, were also de faster in training. Figure 10 presents the relation between time and the training epoch. The lines tilt angle shows how fast the training was.
Figure 9: Training and Validation Loss
Figure 10: Training Time

Since we are using the same dataset, it is possible to compare these models with traditional non-convolutive machine learning algorithms presented in [11]. Table 1 presents the comparison among our model with theirs.

Table 1: Models Comparison

Model	Accuracy
cnn-dropout-3	99.10%
cnn-dropout-2	99.08%
cnn-simple-1	99.05%
cnn-dropout-1	98.69%
support vector classification	89.70%
gradient boosting	88.00%
random forest	87.30%
multilayer perceptron	87.00%
k neighbors	85.40%
logistic regression	84.20%
linear support vector classification	83.60%
stochastic gradient descent	81.90%
decision tree	79.80%
Perceptron	78.20%
passive aggressive classifier	77.60%
extra tree	77.50%
gaussian naive bayes	51.10%

Results shows that even our worst results (cnn-dropout-1) got better results than the best result in [11] (SVC, 89.70%).

7. Conclusions

Obtained results evidence that classifying fashion products with CNN can be more accurate than by using other conventional machine learning models. In addition, it was observed that the dropout technique together with more convolutive layers are effective when it comes to reducing the bias of a model.

Using TensorFlow 2 and GPU for training, we could reach not only a better training time, but also, better accuracies. Table 2 shows the differences between our original work and the present.

Table 2: Version Comparison

Model	TF1				TF2			
	Loss		Accuracy		Loss		Accuracy	
	Train	Test	Train	Test	Train	Test	Train	Test
cnn-dropout-1	0.21	0.26	91.87	90.35	0.13	0.04	96.47	98.69
cnn-dropout-2	0.19	0.25	92.59	90.81	0.08	0.03	97.51	99.08
cnn-dropout-3	0.14	0.25	94.53	90.86	0.06	0.02	98.06	99.10
cnn-simple-1	0.04	0.26	98.91	91.72	0.03	0.02	98.95	99.05

We also could decrease loss and bias, which were our main problems. We could not evaluate improvements in runtime since we used different hardware than in the original run.

Our original work found that the best model was cnn-simple, but now, with these new results, we discovered that cnn-dropout-3 is better (using TF2). This is good news because this model is faster to train, since it has an extra max-pooling layer that decreases dense layer inputs by a quarter.

About our goals, we could compare obtained results with the ones from the original FashionMNIST paper, and they show that CNNs can be great classifiers for garments. Table 1 contains our main results about it and can be used in future works to help researchers and developers finding the best classification technique.

Conflict of Interest

The authors declare no conflict of interest.

A B S T R A C T

Resilience is the way in which the person develops their self-determination to solve conflicts that compromise their physical and mental well-being in the face of a crisis such as the COVID-19 pandemic, therefore the objective of this study is to determine resilience during the COVID-19 pandemic in female heads of household residing in a marginal population in Lima. It is a quantitative, non-experimental, descriptive, and cross-sectional study, with a total population of 650 and a sample of 590 in the study, who answered a questionnaire with sociodemographic data and the Connor and Davidson Resilience Scale in its short version of 10 items. The results show the total resilience of female heads of households, 271 (45.9%) of women heads of households have moderate resilience, 186 (31.5%) have high resilience and 133 (2.5%) have low resilience. In conclusion, it is recommended to seek strategies that allow women to improve resilience since this will benefit them to be able to overcome and face what is experienced by the COVID-19 pandemic.

1. Introduction

In the world, the coronavirus pandemic (COVID-19) has taken the entire population by surprise [1], where they are mainly reflected in the capacities that individuals have to face this stressful situation, where personality and psychological functioning are seen affected in the well-being of each individual [2].

In the same way, the population in the world has had to take measures to have the capacity to face these situations due to the COVID-19 pandemic that compromise their mental and emotional health as a result of social isolation and by not doing their daily routines [3], in such a way so that the resilience that each individual possesses decreases [4]. Resilience is the capacity of each individual to face traumatic circumstances caused by COVID-19, but this decreases due to the fact that anxiety, depression and post-traumatic stress are evident in the population as a result [5], [6].

As a result, the resilience that each individual possesses to face this global crisis is not adequate, because contagion in one of its

family negatively compromises facing it, leading to factors of depression, anguish, sadness [7].

Resilience is of vital importance to cope with stress and to maintain balance in mental health [8], where it acts against the effects generated by stress and also on sleep quality [9]. For this reason, the resilience that is sought to be acquired during the COVID-19 pandemic will improve each individual and allow them to face this situation in a healthy way that helps mentally both in their person and family [10], [11].

In a study in Spain [12], it was observed in 459 participants that resilience in 139 (30.6%) of the participants had a low resilience, while 115 (25.4%) had a high level of resilience, but that the scores falls were more related to obsessive thoughts and fear due to the pandemic that compromised sleep.

In a study from the United Kingdom [13], the author mention in their results of 250 female participants, they stated that 18.9% of the participants presented a lower level of resilience, but 65% obtained a moderate and high resilience, where it means that the Participants have resilience characteristics that they do not

necessarily need to strengthen in order to improve their ability to cope with any situation that compromises their health.

In a study from Peru [14], the authors presented in the results of 315 female heads of household surveyed on resilience, it was observed that 49% of women presented a moderate level of resilience, 27.9% presented a high level of resilience and 22.9% a low level of resilience, this is due to the fact that the pandemic generates a situation of conflict, where the lives of women become more compromised because they live in an area where the economic crisis is present long before the pandemic.

In a study from Israel [15], in their results of 300 participants they verified a relationship between resilience and individual well-being where they significantly and negatively interpreted the feeling of danger and symptoms of distress, where the greater the individual resilience and well-being, the lower the feeling of danger and symptoms of distress in the population.

Therefore, this study seeks strategies that improve resilience in women heads of households where it allows them to face this COVID-19 pandemic in a way that does not harm their physical and mental health.

The objective of the research work is to determine the resilience during the COVID-19 pandemic in women heads of households who reside in a marginal population in Lima. In which it will give us important data that allow us to observe how resilience is in women heads of household.

2. Methodology

In this part, the type and design of the research was developed, also he population which the research work was carried out, the inclusion and exclusion criteria will also be given in detail and finally the technique and instrument of data collection.

2.1. Research type and Design

In the study, due to its characteristics, way of collecting data and measuring the variables involved, has a quantitative approach. Regarding the methodological design, it is a non-experimental, descriptive, cross-sectional study [16].

2.2. Population and sample

The total population was 650 female heads of household who were identified, of which 590 agreed to participate voluntarily and signing the informed consent.

Inclusion Criteria

- Women heads of households who have leadership and decision-making in the family within the household.
- Female heads of household who reside at least 6 months in the area.
- Women who participate voluntarily and who gave their informed consent.

2.3. Technique and Instrument

The technique used is the virtual survey of the Google form, in which, through the data collection instrument, the Connor and Davidson Resilience Scale in its short version of 10 items (CD-RISC 10) that aim to measure the Resilience during the COVID - 19 pandemic in female heads of household residing in a marginal population of Lima.

For data collection, it has been structured in 2 blocks: 1. Sociodemographic data such as age, marital status, level of education and current occupation; 2. CD-RISC 10 that comprises 10 items in which it presents a one-dimensional dimension with the 10 respective items, in which it is assessed with a Likert-type scale with 5 response options: "0 = never", "1 = almost never" , "2 = sometimes", "3 = almost always" and "4 = always", obtaining a total score by adding all its items, so that its score would be from 0 to 40 points, where "0 to 9" is a low resilience, "10 to 30" moderate resilience and "31 to 40" high resilience, the higher the score corresponds to a higher resilience in female heads of household [17].

The validity of the instrument was determined based on the exploratory factor analysis technique with Varimax rotation. The Kaiser-Mayer-Olkin sample adequacy measure obtained a coefficient of 0.894 (KMO> 0.5), while the Bartlett sphericity test obtained significant results (X^2 approx. = 10708.291; gl = 45; p = 0.000). The measures of sampling adequacy of the anti-image diagonal obtained significant coefficients for the 10 items (MSA> 0.8). The principal components analysis determined that there is a single factor that explains the variance by 85.125%. Since there is only one factor, the matrix of rotated components could not be extracted. For all the above, the instrument is considered valid.

The reliability of the instrument was determined based on Cronbach's Alpha statistical test, the same one that obtained a coefficient of 0.980 (α> 0.8) for all the items (i = 10).

In this research, the data to be entered was given in a data matrix that was designed in the statistical program IBM SPSS Statistics Base 25.0, its corresponding analysis was carried out, in which it will allow us a better processing of data to make tables and statistical graphics so that they are later described and interpreted in results and discussions, respectively.

2.4. Place and Application of the Instrument

The virtual survey was carried out to measure resilience during the COVID-19 pandemic in women heads of households who reside in a marginal population of Lima, in which it was carried out in the district of Comas in the Carmen Alto area, which is a vulnerable area where they do not have basic services (water, electricity, sewage), where most of the families live in poverty and extreme poverty, since most of the family members do not have stable jobs, everything is done eventually.

3. Results

The results of the surveys carried out following the guidelines corresponding to the study will be shown in figure 1:

Figure 1 shows the results of the total resilience of women heads of households where 271 (45.9%) of women heads of

households have moderate resilience, 186 (31.5%) have high resilience and 133 (2.5%) have low resilience. Regarding high resilience, it is the person who faces extreme situations such as COVID-19 and that leads to maintaining their emotions, maintains their self-confidence and self-motivates to get ahead, moderate resilience, is the person who keeps their impetus to go out forward in the face of the COVID - 19 crisis and low resilience is the person who does not face the situation due to the COVID - 19 pandemic, leading to depressive symptoms and anxiety due to this fact.

In relation to the total resilience and the marital status of women heads of household, it was verified using Pearson's Chi-square test (X^2) to determine the relationship between both variables, where the level of significance of the test obtained a value of 1.35 (p> 0.05) $(X^2 = 3.632; df = 6)$. Therefore, emphasis is placed on a hypothesis of association between both variables. Therefore, we interpret that women heads of household in relation to their single marital status have a moderate resilience 61 (43.9%), as does the marital status married 51 (49%), cohabiting 156 (45.7%) and widowed marital status 3 (50%) have moderate resilience and 3 (50%) have high resilience.

Figure 1: Resilience during the COVID - 19 pandemic in female heads of household residing in a marginal population of Lima

Table 1: Resilience during the COVID - 19 pandemic in female heads of household in relation to marital status residing in a marginal population of Lima

| | | | MARITAL STATUS | | | | |
			Single	Married	Cohabiting	Widow	Total
RESILIENCE	LOW	Count	30	21	82	0	133
		% within marital status	21,6%	20,2%	24,0%	0,0%	22,5%
	MODERATE	Count	61	51	156	3	271
		% within marital status	43,9%	49,0%	45,7%	50,0%	45,9%
	HIGH	Count	48	32	103	3	186
		% within marital status	34,5%	30,8%	30,2%	50,0%	31,5%
Total		Count	139	104	341	6	590
		% within marital status	100,0%	100,0%	100,0%	100,0%	100,0%

Chi-square tests

	Value	df	Asymptotic significance (bilateral)

Chi-square tests

	Value	df	Asymptotic significance (bilateral)
Pearson's Chi-square	4,456[a]	8	,814
Likelihood ratio	4,388	8	,821
Linear by linear association	,184	1	,668
N° of valid cases	590		

a. 3 cells (20.0%) have expected a count less than 5. The minimum expected count is 1.35.

Table 3: Resilience during the COVID-19 pandemic in female heads of household in relation to the occupation that reside in a marginal population in Lima

				Current Occupation		
			Stable worker	Temporary worker	No occupation	Total
RESILIENCE	LOW	Count	1	65	67	133
		% within current occupation	10,0%	24,5%	21,3%	22,5%
	MODERATE	Count	5	111	155	271
		% within current occupation	50,0%	41,9%	49,2%	45,9%
	HIGH	Count	4	89	93	186
		% within current occupation	40,0%	33,6%	29,5%	31,5%
Total		Count	10	265	315	590
		% within current occupation	100,0%	100,0%	100,0%	100,0%

Chi-square tests

	Value	df	Asymptotic significance (bilateral)
Pearson's Chi-square	4,088[a]	4	,394
Likelihood ratio	4,258	4	,372
Linear by linear association	,217	1	,642
N° of valid cases	590		

a. 3 cells (33.3%) have expected a count less than 5. The minimum expected count is 2.25.

In relation to the total resilience and the level of education of women heads of household, it was verified using Pearson's Chi-square test (X^2) to determine the relationship between both variables, where the level of significance of the test obtained a value of 1.35 (p> 0.05) ($X^2 = 4.456$; df = 8). Therefore, emphasis is placed on a hypothesis of association between both variables. Therefore, we interpret that women heads of households without education show moderate resilience 31 (46.3%), at the primary education level 38 (42.2%) have moderate resilience, at the secondary education level 145 (48.3%) have moderate resilience, in university 2 (33.3%) have low resilience, 2 (33.3%) have moderate resilience and 2 (33.3%) have high resilience and in technical 55 (43.3%) have resilience moderate.

In relation to the total resilience and the level of education of women heads of household, it was verified using Pearson's Chi-square test (X^2) to determine the relationship between both variables, where the level of significance of the test obtained a value of 2.25 (p> 0.05) ($X^2 = 4.088$; df = 4). Therefore, emphasis is placed on a hypothesis of association between both variables.

Therefore, we interpret that female heads of household with stable work have moderate resilience 5 (50%), with temporary work 111 (41.9%) have moderate resilience and no occupation 155 (49.2%) have moderate resilience.

4. Discussion

In this research work, the approach to mental health of women heads of household was revealed, emphasizing the ability to resolve conflicts or face situations that compromise their health due to the COVID-19 pandemic.

In the results of resilience during the COVID-19 pandemic in women heads of households present a moderate level of resilience, in our findings it has been observed that due to the coping with the danger caused by COVID-19 in the society and in the families, women who are heads of households have anticipated this great change and have sought a way to resolve this conflict in order to maintain the well-being of their children, also, it has been foreseen that the resilience in families has been maintained without the financial support of the state, but that the state does need social or

family support to support it at home. In [12], the authors maintain that mainly in women who do not have family support, they tend to manifest depressive symptoms and anxiety because they cannot support their family and this leads to poor health in them. Similarly in [13], the authors identify that depression and anxiety manifest themselves because the individual cannot cope with the problems caused by the COVID-19 pandemic, where one of their relatives is infected or has died, all this has repercussions on the head of the household and can compromise their physical and mental well-being.

In the results of resilience with marital status, it is interpreted that in family's resilience is important since this will allow them to reorganize and recover their optimal levels of functioning and well-being in the family that is subjected to stress because of the pandemic of the COVID - 19. In [15], the authors argue that resilience within the family is very important because supporting each family member will allow them to maintain a balance in their mental health during the COVID - 19 pandemic, since this has generated symptoms such as depression, anxiety and stress due to social isolation and quarantine.

In the results of resilience with the level of education, we can interpret that it is important to be resilient since it favors the person for their self-determination process in the face of any coping situation, especially during the health crisis due to COVID - 19. In [4], the authors argue that being resilient during the COVID-19 pandemic will allow them to improve their coping skills and self-determination in any dangerous situation and allow them to overcome any circumstance within the family.

5. Conclusions

It is concluded that resilience is important since it is a protective factor to an adaptation response to stressful situations such as the COVID-19 pandemic.

It is concluded that psychological support should be given to the population according to their needs and vulnerability due to the COVID-19 pandemic.

It is concluded that the present study emphasizes the understanding of female heads of households who have an inappropriate state of mind during the COVID-19 pandemic.

It is recommended to look for strategies that allow to improve the resilience of women since this will benefit them to be able to overcome and face what is experienced by the COVID - 19 pandemic.

The limitation of this research work is that there are few studies in our country and that access to the mothers' homes was not adequate since some were not present or did not want to be present in the study.

Conflicts of Interest

The authors declare no conflict of interest.

Underwater Computing Systems and Astronomy–Multi-Disciplinary Research Potential and Benefits

Ayodele Periola[*], Akintunde Alonge, Kingsley Ogudo

University of Johannesburg, Electrical and Electronic Engineering Technology, Johannesburg, 2092, South Africa

ARTICLE INFO	ABSTRACT
	The Ocean plays an important role in hosting investigations in underwater astronomy and enabling the realization of new research prospects. This paper discusses synergistic prospects of the blue economy from the perspective of underwater astronomy and scientific inquiry, technological and economic development. The presented research investigates how the synergy enhances computing applications. The paper presents the overloaded application paradigm that explores the ability of underwater telescope networks to accommodate additional applications. The investigated metrics for computing applications are the accessible computational resources, and power usage effectiveness (PUE) that is investigated in a scenario where onshore computing stations used in underwater astronomy observations are integrated with existing terrestrial data centers. This is necessary as onshore computing stations benefit from free cooling being located near natural maritime resources. The performance evaluation investigates how the proposed synergy and the emerging crowd–sourcing can enhance the observation resolution for underwater astronomy observations. Investigation shows that the synergy enhances accessible computational resources, PUE and observation resolution by an average of 48.8%, 1.6% and 41.3%, respectively.

1. Introduction

Knowledge discovery and the conduct of research is an important goal that can be realized via the emergence of new paradigms that aim to answer existing and new research questions. An important research aspect in this regard is that of astronomy observations. The role of the ocean in expanding research frontiers is relatively under–explored in comparison to earth's terrestrial environment with respect to astronomy. There are different forms of astronomy such as optical astronomy, X–ray astronomy, gamma astronomy, and radio astronomy.

A new frontier for the conduct of astronomy is the ocean that enables the realization of underwater astronomy. Underwater astronomy focuses on the study of neutrinos and uses underwater telescopes (i.e., scientific underwater vehicles). The conduct of underwater astronomy requires the launch of underwater telescopes (scientific underwater vehicles) into the ocean at varying locations and altitudes. In underwater astronomy, the concerned telescopes are organized into a network that observes different aspects of the underwater environment with the aim of detecting neutrinos.

In similarity to other aspects of astronomy, underwater astronomy is a scientific endeavour that aims to advance human knowledge. This can create a false notion that underwater astronomy does not enhance the conduct of other technologies and applications. The result of this is a reduced participation in the conduct of underwater astronomy observation. This leads to lack of or reduced collaboration between scientists in astronomy and other disciplines. A significant effect of this reduced or lack of collaboration is an increased paucity of funds required to develop and deploy underwater astronomy systems. The paucity of funds reduces the chances of underwater astronomy systems in realizing its full potential in contributing to knowledge and also enhancing other application areas. It is important to address this challenge as a conduct of astronomy has enabled technological breakthroughs resulting in useful applications in other domains [1–6]. Nevertheless, it is important to note that the breakthroughs in [1–6] do not consider the new domain of underwater astronomy [7–9].

The discussion in [7–9] presents an outline of the development of the science of underwater astronomy. In addition, the discussion in [9] identifies other sources that were previously thought to be neutrino sources in the universe. Some of these sources are X-ray binaries and gamma ray bursts. In addition, Spiering recognized that the use of underwater neutrino detectors has been considered

[*]Corresponding Author: Ayodele Periola, periola@hotmail.com

suitable since 1960. However, the consideration of an approach in which underwater astronomy concerns forms a synergy with other applications requires further research consideration.

The focus of the research presented in this paper is to demonstrate the usefulness and value potential of underwater astronomy. The non–consideration of underwater astronomy in [1–6] alongside the need to demonstrate the usefulness of underwater astronomy to other application is addressed in this paper.

Contribution: The discussion in the presented research focuses on the conduct of underwater astronomy. The research recognizes that it is challenging to provide a societal basis to justify the conduct of scientific investigations via underwater astronomy observations. The provision of a societal basis is important to convince other applications and disciplines to donate resources in designing and deploying systems for conducting underwater astronomy observations. The realization of this goal requires the identification of other applications that benefit from the conduct of underwater astronomy observations. This goal is realized by identifying applications that can potentially benefit from the launch of systems intended for use in underwater astronomy observations. Two applications i.e., underwater surveillance, and computing systems have been identified. The consideration of the applications of underwater surveillance and computing alongside the concerns in underwater astronomy shares the system realization costs amongst these applications. This reduces the cost associated with the realization of underwater astronomy systems. In addition, the conduct of underwater astronomy while accommodating the concerns of underwater surveillance and computing enhances these applications by improving their performance. This paper also explores how the conduct of underwater astronomy observations provides a platform enabling the conduct of scientific enquiry in reducing pseudo–science towards verifying the existence of aquatic humanoids. In addition, the paper presents a case from the public health perspective to justify the need to continue the conduct of investigation in this direction. Furthermore, the consideration of the applications in underwater surveillance, and computing increases the potential of underwater astronomy in other areas leading to an overloaded application context.

The contribution of this paper is the presentation of the overloaded application paradigm. In the proposed overloaded application paradigm, the ability of underwater astronomy observations to provide support to new research motives and computing applications is examined. The contributions of this paper are:

1) Firstly, the paper proposes the probe of the ocean with the aim of enhancing knowledge discovery and reducing the propagation of pseudo – science. This is important in investigating the existence of aquatic humanoids. The proposed investigation aims to answer questions from two perspectives. The first perspective is that of providing scientific and technical answers to a long-standing concern. The second perspective aims to provide a platform to further investigate how aquatic humanoids have developed immune response to marine viral outbreaks. This paper provides and discusses the rationale and presents a design of the system for conducting the proposed scientific investigation.

2) Secondly, the paper recognizes that the deployment of underwater telescopes increases the coverage of the ocean thereby enabling the realization of underwater surveillance applications. The conduct of underwater astronomy also necessitates the design of novel computing networks for data processing. The discussion in this paper proposes a novel underwater surveillance network that re–uses the infrastructure and network deployed to realize underwater astronomy applications. In addition, the paper proposes a novel computing network architecture enabling the integration of onshore computing platforms with existing terrestrial cloud computing platforms. The paper also recognizes the potential of underwater astronomy to spur technological development in other areas.

In addition, the paper formulates and investigates benefits arising from the synergy in the proposed paradigm. The performance benefits are analysed from the perspectives of computing applications and astronomy investigations. The formulated and investigated metrics from the computing perspective are the accessible computing resources and the PUE. The observation resolution metric has received consideration from the astronomy investigation perspective.

2. Background

The value potential of conducting astronomy observations with a focus on Africa receives consideration in [10]. In their discussion, astronomy is considered from a broad perspective i.e. it comprises the use of terrestrial and space-based telescopes. Technological advances in astronomy are recognized to enhance education (for students and teachers), healthcare (eye care), and fostering skills development and; ensure equal gender participation in science, technology, engineering and mathematics.

The discussion in [10] recognizes that additional work is needed to increase astronomy's relevance in Africa. This can be achieved by directing the effort of researchers in astronomy system design to other potential impact areas. The conduct of collaborative research is required to maximize the developmental profits obtainable from astronomy. However, the potential of driving multi–disciplinary research via an examination of multi–domain problems are not done in [10]. This can be addressed in additional research.

The development motive underlying the participation of African nations in Astronomy is discussed in [11]. The Ethiopian initiative uses space science and technology to address challenges being faced in accessing water and enhancing agricultural productivity. The drive by Kenya and Zambia to engage in radio astronomy has motivated the need to develop capacity in converting satellite earth stations to terrestrial radio telescopes. The Sudanese institute of Space Research and Aerospace also aims to establish an astronomy exploration centre and terrestrial telescope. The drive to conduct astronomy research in this case motivates aerial surveillance systems development and; advances small satellite application in education. The drive to conduct astronomy also drives development in remote sensing, satellite meteorology, information and communication technology; and security and defence.

Astronomy has prospects to enable technological development and advance research in information and communication technology, and security and defence. The discussion in [11] is themed towards developing terrestrial and space-based astronomy assets. It also recognizes the potential of astronomy research to enhance the future of life in Africa. However, this does not consider new areas of astronomy such as aerial astronomy [12] and underwater astronomy observations. The knowledge values and development potential of these aspects should also be examined.

The African Union in [13] discusses the developmental role of space science and astronomy in technological development. The conduct of astronomy has enabled the development of technologies such as the geographical positioning systems, space geodesy, and key roles in analyzing ocean and ice level measurements and continental drifts analysis. The conduct of astronomy observations enables development of conceptual and practical skills that can be transferred to other areas like meteorology, and; information and communication technology. These conceptual skills are useful in other domains such as technology research thereby enabling astronomy to have a significant knowledge value. However, exploring this aspect requires further research.

It is recognized in [14] that most astronomy observatories are located in terrestrial and space-based locations. This view is shared with [11] and [13]. The perspective does not consider underwater astronomy. The conduct of terrestrial astronomy and space astronomy is recognized to drive the development of supercomputing technology and big data analysis methods. Though [12], recognizes the importance and role that terrestrial and space-based astronomy plays in driving technological development; its role in role in designing future computing platforms architecture for distributed terrestrial and space-based astronomy requires further consideration.

The development potential of the square kilometer array is considered in [15] where it is recognized that the square kilometer array enables advances in big data processing algorithms and supercomputing. These developments enhance human capital development and positions South Africa as an emerging knowledge economy. It also enables the emergence of private sector spin–offs that participate in the high-tech global value chain. A similar perspective can be found in [16].

The growing interest in underwater astronomy as seen in [17] positions it to address puzzles in physics such as the origin of the cosmic rays. Developmental efforts are required to realize the design of KM3NeT array [16]. However, lessons that can be learnt from the development of digital optical modules and associated software are not deemed to be useful in addressing underwater research and development concerns.

The study in [18] describes procedures required to determine the suitability of an underwater site for hosting an underwater telescope. A desired site should have suitable optical properties, low background noise and bioluminescence. The optical property of water is influenced by its chemical properties. However, the potential of using the optical properties in other applications has not been examined.

This section shows that the desire to conduct astronomy observations drives technological development. This technology advancing role has been motivated mainly by space-based and terrestrial-based astronomy observations. This has not considered underwater astronomy as recognized and addressed in this paper.

3. Underwater Astronomy – Support for Scientific Inquiry

This section explores how ocean exploration and underwater astronomy influences the conduct of investigations in seeking answers to scientific inquiry. It has two aspects. The first and second discuss the motivation for scientific inquiry and the associated system design respectively.

3.1. Rationale for Scientific Investigation

The ocean is a vast resource whose exploration is a key goal of scientific investigation. Being explored to a lesser extent in comparison to earth's terrestrial plane, the ocean serves as a platform enabling the conduct of investigations for the purpose of verifying different claims. An important scientific inquiry being considered is verifying the existence of aquatic humanoids biological species. This is deemed necessary to reduce the propagation of pseudo–science [19–21] in the public domain. In addition, the successful detection (thereby proving their existence) or non–existence is deemed important to enhance knowledge discovery in the information age. The discussion in this section also discusses the implications on future global health.

The launch of underwater telescopes enables increased ocean exploration. This provides access to new ocean regions and opportunities to probe for answers to scientific questions such as verifying the actual existence of aquatic humanoids. The research in [20–21] shows that there is the need to conduct additional research to verify this claim. This can potentially provide answers to questions on public health as the ocean is recognized to host a significant number of marine viruses [22–24]. A potential research step is to investigate how aquatic humanoids (if detected) have developed resilience to marine viruses and marine viral outbreaks.

A successful detection of aquatic humanoids is an advantageous step in studying their adapted and developed immune response to viruses. This is helpful in understanding how to develop new systems and solutions to manage viral outbreaks, epidemics and pandemics. A study in this regard is potentially useful in developing solutions to enhance human viral immunity in the future. This is important for future global public health and human welfare.

3.2. Scientific Investigation–System for Executing Scientific Search

The execution of a search to scientifically provide an answer on the existence of aquatic humanoids requires a probe of the ocean. This probe can be realized via the launch of scientific payload integrated in a system designed for this purpose. However, this approach incurs a high expense making it prohibitive for developing nations and other capital constrained contexts where underwater telescopes have already been deployed. The approach being proposed in this paper is to re–use the existing framework provided by already deployed underwater telescopes to find answers to the scientific inquiry under investigation. This is being considered as it enables the re–use of hardware and computing

infrastructure initially deployed for the purposes of underwater astronomy.

Underwater telescopes comprise photomultipliers that are embedded in digital optical modules [25]. These modules are deployed in a string configuration with a pre-defined separating distance. The strings have 15 m separating distance at depths lying between 745 m to 1270 m. Additional payload to support other scientific investigations in the underwater environment can be placed in the gap i.e. separating distance lying between digital optical modules. For example, the ANTARES neutrino telescope is at a depth of 2475 m [26]. The neutrino telescope in [27] is located in the ocean's bathypelagic zone extending between the depths of 1 km to 4 km. The siting of ANTARES in the bathypelagic zone makes it feasible to conduct ocean related research in this zone. The distance between strings on average in the KM3Net underwater telescope is about 90 m. In addition, the KM3Net underwater telescope has an information and communication network, and supporting infrastructure. The infrastructure is used to transmit acquired results on the scientific search from the ocean.

The payload that executes the search under consideration is hosted in the string gap (separating distance between digital optical modules). It is located in the string gap to prevent disturbance to digital optical module observation. The payload comprises underwater camera (capturing image and video); and underwater acoustic camera. The realization and use of underwater video camera systems is now technologically feasible [28–30]. The underwater video cameras are accompanied with underwater acoustic cameras. The use of underwater acoustic cameras is also feasible because of technology maturation. The underwater acoustic camera detects bio-acoustic signatures from previously undetected biological sources. The underwater video camera [28–30] and acoustic underwater camera [30–32] are deployed to scan the underwater environment. The use of the acoustic underwater camera is deemed suitable because biological sources have acoustic bio-signatures [33]. The deployed cameras are immobile and utilize the computing resources aboard the onshore computing station.

A combination of the acoustic bio–signature, picture (alongside video) at a given epoch is sent to the onshore computing facility. Relations between the digital optical modules, underwater (video), underwater acoustic cameras and the onshore computing facility (hosting several servers) is shown in Figure 1. The servers host computing resources used for algorithm execution and data processing. The digital optical modules and cameras are connected to a central module that is linked to the onshore computing facility.

In Figure 1, the cameras are deployed in a network and have varying coverage in various directions within the underwater environment. The deployed cameras and sensors incorporate the benefit of viewing diversity. The limited viewing capabilities of
Figure 1: Network Scenario showing the role of the Network Module and Onshore Computing Entity

some cameras and sensors are compensated by cameras and sensors with improved capabilities. Viewing diversity implies the ability of either an acoustic or video camera being able to detect objects that cannot be detected by another acoustic or video camera. This is feasible considering the heterogeneous capabilities of sensors and cameras in a large spatial underwater network.

The consideration of viewing diversity reduces the need to explicitly consider the detecting ranges of sensors and the cameras being presented in Figure 1. This reduces underwater surveillance network design complexity because additional details on the individual technical capabilities of each underwater acoustic sensor and underwater video camera need not be individually considered. In Figure 1, the underwater camera sensors and underwater acoustic camera are stationary. The underwater camera sensors and underwater acoustic cameras differ from the underwater telescope. The underwater telescope is stationary, executes the functionality of the scientific underwater vehicle and is realized by the digital optical module.

As seen in Figure 1, the deployment of the underwater telescopes is considered at different ocean depths. Each depth is also associated with a distance from a reference shore. The underwater cameras and sensors are integrated in the string gaps existing between underwater telescopes. Hence, they constitute the sensors that are placed in the string gaps. String gaps are the spaces un-utilised between conductors that link the digital optical modules intended to capture neutrino radiation in underwater astronomy observation.

Therefore, the sensors placed in the string gaps are also deployed at different ocean depths. The data on the ocean depths are acquired and accessed while planning for the deployment of the underwater telescopes. The underwater cameras and sensors acquire information from a three dimensional perspective. The considered dimensions are the: (1) concerned ocean depth, (2) distance from the reference shore and (3) Epoch of observation. The information on the concerned ocean depth, distance from the reference shore and epoch of observation are associated with each observation by the concerned sensor or camera.

Figure 2: An acoustic camera capable of underwater operation [34]

Figure 3: An underwater video camera suitable for proposed use [35]

The illustration in Figure 4 shows the execution of observation by the underwater acoustic camera and underwater video camera in the string gap. Figure 4 shows the three dimensional

representation as seen in the varying distances of the considered regions from a reference shore and the differing depths. Each region of the underwater environment is being observed by the digital optical module. The combination of each region alongside the underwater acoustic camera and underwater video camera is known as the logical observation group. In Figure 4, there are four logical observation groups i.e. logical observation group 1, logical observation group 2, logical observation group 3 and logical observation group 4. In each observation group, underwater acoustic cameras and underwater video cameras that are integrated into the string gap observe the concerned area. The observation is accompanied with data recording alongside the information on the depth (distance along the vertical i.e., y–axis), distance from the reference shore (along the x–axis) at different epochs (being the time dimension). An observation in this manner results in a three–dimensional observation.
Figure 4: Scenario describing the role of underwater acoustic camera and underwater video camera in observing selected area of the underwater environment. These sensors are integrated into the string gap.

4. Underwater Astronomy – Knowledge Advances and Benefits to Computing Systems Design

The discussion in this section describes how the conduct of underwater astronomy enhances knowledge advances in near ocean and underwater computing systems design. The underwater environment hosts a significant number of applications besides underwater astronomy such as networking and computing. This section has two parts. The first describes the rationale for considering the impact of underwater astronomy in computing networks. The second presents the supporting system model.

4.1. Underwater Astronomy and Computing Systems – A Rationale

The emergence of underwater astronomy necessitates the design of onshore computing station networks. The processing of data arising from underwater astronomy requires designing onshore computing station networks. This is capital intensive. Therefore, it is important to design solutions that reduce the associated costs. The ability of underwater astronomy's computing station to potentially address this challenge is considered in this aspect.

4.2. Underwater Astronomy and Computing – Architecture and System Design Concerns

The advent of underwater astronomy increases the amount of ocean data requiring processing. This increases the volume of data

requiring access to computing resources for processing. The need to enable data processing has necessitated the deployment of onshore computing stations to receive and process data from underwater neutrino telescopes [36–37]. In [36], the trigger and data acquisition system is not integrated with cloud computing systems. Therefore, organizations seeking to deploy underwater telescopes require ownership of onshore computing platforms. The drawback to this perspective is that it increases the cost of conducting underwater astronomy. This is because all organizations desiring to conduct underwater astronomy have to deploy own computing platforms and do not subscribe to existing terrestrial cloud computing platforms. Therefore, it is desirable to design novel network architecture linking onshore computing entities to existing cloud computing platforms. This is because cloud computing has been recognized to be beneficial to astronomy [37]. In the case of underwater astronomy, underwater data centres such as those in [38] are useful. This contributes to knowledge in the area of wireless network architecture.

The use of underwater computing platforms also enhances the PUE in comparison to terrestrial computing platforms [39–40]. The use of underwater computing platforms in data processing is suitable for processing scientific data as seen in [41]. However, designing architecture and network enabling the underwater astronomy telescopes to utilize underwater data centres requires research attention. The need to integrate underwater telescope data processing with underwater computing platforms is beneficial in two aspects. The first is that it enables the design of integrated systems that connect underwater telescope arrays with underwater computing platforms. This is advantageous in terms of contributing to knowledge in systems architecture. The second is that the use of underwater computing platforms opens a new vista for sub–marine application data processing. Therefore, underwater astronomy has prospects in advancing research in network architecture and integrated systems.

5. Underwater Astronomy – Enabling Underwater Surveillance

Deploying underwater telescopes over a vast sub–ocean area provides vast ocean coverage thereby enabling the development of an underwater surveillance strategy. The resulting large area coverage provides a potential underwater surveillance application. This enables the realization of an underwater surveillance network. The discussion here has two aspects. The first discusses the rationale for considering how underwater astronomy can enable underwater surveillance. The second presents a potential system model.

5.1. Underwater Astronomy and Surveillance Applications – Rationale

The deployment and maintenance of underwater telescopes necessitates and increases human–ocean interaction. The maintenance of underwater telescopes can be done at the ocean shore or aboard an ocean vessel at the expense of high logistics costs; and reduced underwater telescope observation time. The maintenance can also be conducted in the underwater environment with reduced degradation in the observation ability of other underwater telescopes. However, this is at the expense of hiring ocean divers for the execution of maintenance procedures. This is challenging because telescope engineers and technicians are not

trained ocean divers. Alternatively, submarines can also be used at the expense of high costs. Nevertheless, these approaches facilitate human–ocean interaction which is useful for underwater surveillance. Underwater surveillance approaches are considered from two perspectives. The first and second considers that maintenance of underwater telescopes is done on the surface (shore or aboard an ocean vessel) and in the underwater environment, respectively.

5.2. Underwater Astronomy–Architecture and System Design Concerns

Underwater surveillance and maritime security are closely related [42–43]. Underwater security can be realized via the use of submarines or autonomous underwater vehicles which is capital intensive. The high cost makes it challenging to ensure adequate underwater maritime security. A conservative estimate shows that a sum of about \$20B is required to design and realize an operational submarine [44]. This is beyond the reach of capital constrained organizations.

Therefore, developing nations have challenges in using submarines for underwater surveillance and security. Autonomous underwater vehicles are a feasible low-cost alternative to submarines. However, deploying multiple autonomous underwater vehicles also has high costs. The scenario shown in Figure 1 describes how cameras can be integrated in the string gap of underwater telescopes. These cameras can be integrated during the execution of a scheduled telescope maintenance manoeuvre.

The deployment of underwater telescopes alongside underwater cameras is suitable for realizing underwater surveillance. In this case, the underwater cameras give a video output that is processed by the organization(s) deploying the underwater cameras and owns the copyright to the video content. The resulting video is processed to extract security related information from the received underwater data. The network of video cameras is also suited for underwater surveillance and is cheaper than using multiple autonomous underwater vehicles. The realization of an underwater surveillance network enables advances in: (i) Video acquisition via underwater camera networks, (ii) Video processing with focus on preference of underwater surveillance, and (iii) integration of video processing results with cloud computing platforms.

Underwater surveillance can also be addressed when the maintenance is conducted in the underwater environment. The design of an underwater vehicle with lower acquisition and operational costs in comparison to submarines is proposed. The required capability can be realized via variable duration short mission manned underwater vehicles. The proposed variable duration short mission underwater vehicle serves as an underwater habitat that hosts telescope technicians and engineers. It hosts the payload used to execute the maintenance procedures. The variable duration short mission underwater vehicle operates for a maximum of 3 hours in the underwater environment before returning to the surface/shore. The telescope technicians and engineers execute the maintenance via robotic arms and do not exit the variable duration short mission underwater vehicle's interior.

The proposed variable duration short mission underwater vehicle is suitable for use by naval authorities for underwater

surveillance applications. In this case, the robotic arms host camera payload and enables the operator to record image and video of the underwater environment. Therefore, regional and national organizations such as the Navy can benefit from technological advancements arising from the need to conduct underwater astronomy.

6. Value Addition – Aspects of the Blue Economy

The development of the blue economy enhances future economic growth [45, 46] and can be realized via marine spatial planning [47, 48]. Marine spatial planning determines the suitability of marine resources for use in different ocean applications. The integration of sensors in the 'string gap' makes it easy to monitor the ocean. The acquired data can be used to determine the best way for allocating ocean resources.

The locating of multiple underwater telescopes in the ocean requires the conduct of ocean survey [47, 48]. This enables the determination of best ocean zones to site underwater telescopes. For example, it is noted in [49] that water composition influences the variation of water's optical parameters. This implies that ocean site selection for placing underwater telescopes involves the acquisition of knowledge on sea water's instantaneous optical and chemical properties. The chemical properties of water influence other factors such as the time varying underwater specific heat capacity. This is useful in the determination of the suitable location for siting underwater data centres.

The discussion in [50] notes that the exploration of maritime resources such as Lake Baikal (Domogatsky, Bezrukov), Atlantic Ocean, Black Sea, Indian Ocean, Pacific Ocean and Mediterranean Ocean (with sites in Zheleznyk and Petrukhin). The exploration of maritime resources in these locations enables the acquisition of data on the maritime resources at the mentioned locations. The acquired underwater maritime underwater data provides a significant amount of underwater and oceanographic big data. The data is suitable for use in determining the physical properties of different aspects of the underwater environment at different epochs. The role of such data in marine spatial planning (for different ocean zones) is recognized in [51, 52].

The blue economy encompasses a significant number of opportunities such as seabed mining [53], large scale fishing, maritime transportation, underwater tourism and seaweed farming. The conduct of underwater astronomy observations provides an opportunity to explore the sub-surface ocean environment. This makes it feasible to determine underwater ocean zones suitable for deploying the applications identified in [54, 55].

The prospects and challenges of underwater technological development has motivated by the conduct of underwater astronomy is shown in Table I. Table I focuses on the prospects and benefits associated with underwater surveillance and the blue economy. The information presented in Table I focuses on how the desire to conduct underwater astronomy can make contributions to underwater surveillance and the blue economy.

7. Performance Formulation

This section examines the benefit of the proposed solution and has two parts. The first and second aspects discuss the performance benefits and formulate the performance model, respectively.

Table 1: Potential Benefits to Ocean Surveillance, Underwater Security and Blue Economy

S/N	Sector	Potential Contributions
1	Underwater Security (infrastructure Acquisition)	Variable duration short mission manned underwater vehicles can be used as low cost entities with capabilities similar to a submarine and suitable for short length missions by a Naval force.
2	Naval Security Services	The use of cameras integrated in the string gap for underwater surveillance improves the naval surveillance services because of the use of a distributed underwater camera network.
3	Technological Development–Robotics	The need to design robotic arms for underwater maintenance and camera positioning contributes to research and technological development.
4	Astronomy Organizations	Sharing of onshore computing facility costs with Naval organizations reduces the cost burden on astronomy organizations.
5	Entertainment: Underwater Media	Acquired underwater video can be sold to channels where it can be viewed as entertaining video content.
6	Marine Spatial Planning	The obtained images and video of the underwater environment can be used to characterize the ocean environment. This is useful for marine spatial planning purposes
7	Blue Economy–Application Identification	A successful marine spatial planning process helps in determining suitable revenue earning applications that can be hosted in a given ocean zones.
8	Knowledge Contribution – Chemical and Optical Properties	The study of the optical properties of ocean water for determining the viability of an underwater location for hosting telescopes provides opportunity to understand the relations between chemical composition of water and its optical properties at an epoch.
9	Computing–Future Computing Platforms	The acquisition of information on chemical properties is suitable for determining the viability of a given maritime resources for hosting underwater data centres; determining number of suitable hosting locations.
10	Knowledge Contribution–Ocean Maps	The information obtained via cameras and used to develop a profile of different underwater ocean zones can be used to develop an ocean profile or underwater map. This is a novel contribution to knowledge.
11	Human Capital Development–Naval Infrastructure	The development of variable length duration manned underwater vehicles (with submarine capability) enables the development of human capital in the aspect of underwater vehicle hardware design and manufacture; as well as software design and realization.
12	Human Capital Development–Software	Processing of Video from underwater environment for security preferences enables skill acquisition with regard to video editing software design and development.

7.1. Performance Benefits

The discussion has proposed the adoption of a multi-domain approach to ocean exploration with a focus on underwater astronomy. In the proposed consideration, external technological and scientific interests are recognized to benefit from the conduct of underwater astronomy. The resulting crowd–sourcing effort reduces the costs of conducting underwater astronomy. In addition, the launch of multiple underwater telescope units' results in an array that enhances the resolution of underwater astronomy observations. This is because multiple entities that were previously unconsidered now launch additional logical underwater telescope units. The benefit of this is an increase in the baseline of the resulting underwater interferometer system. From a perspective of general observation, a longer baseline is beneficial to obtain improved resolution in astronomy observations [56–57]. The launch of additional logical underwater telescope unit at low costs due to the incorporation of a crowd–sourced approach increases the interferometer size and baseline. This improves the observation resolution of underwater astronomy systems.

The integration of onshore computing platforms into the existing cloud computing platform framework increases the computational resources accessible to computing applications. Two computing applications are recognized in this regard. These are underwater astronomy and wireless computing applications. In addition, onshore computing platforms are located at vantage locations where they can easily benefit from free cold air cooling. This is because onshore computing platforms are able to take advantage of the cold air and cold water available in nearby maritime resources such as rivers and the ocean shore. This reduces the reliance on the use of conventional cooling methods that uses components such as air conditioners, pumps and chillers. Therefore, the integration of onshore computing platforms into existing data centers can enhance the PUE.

Therefore, the proposed multi–domain perspective has three benefits. These are: (i) increasing the computational resources accessible to underwater astronomy, wireless networks and computing applications, (ii) Enhancing the PUE of existing cloud computing platforms and (iii) improving the resolution of underwater astronomy.

7.2 Performance Formulation

Let α and β denote the set of vessels and cameras (integrated in the string gap), respectively.

$$\alpha = \{\alpha_1, \alpha_2, \dots, \alpha_A\} \tag{1}$$
$$\beta = \{\beta_1, \beta_2, \dots, \beta_B\} \tag{2}$$

In addition, let γ and Υ be the set of onshore computing platforms and data centers (cloud computing platforms), respectively.

$$\gamma = \{\gamma_1, \gamma_2, \dots, \gamma_C\} \tag{3}$$
$$\Upsilon = \{\Upsilon_1, \Upsilon_2, \dots, \Upsilon_D\} \tag{4}$$

The set of servers associated with the onshore computing platform $\gamma_c, \gamma_c \in \gamma$ and data centers (cloud computing platforms) $\Upsilon_d, \Upsilon_d \in \Upsilon$ are given as:

$$\gamma_c = \{\gamma_c^1, \gamma_c^2, \dots, \gamma_c^I\} \tag{5}$$
$$\Upsilon\Upsilon_d = \{\Upsilon\Upsilon_d^1, \Upsilon\Upsilon_d^2, \dots, \Upsilon\Upsilon_d^J\} \tag{6}$$

Let $C_2(\gamma_c^i, t_y)$, $\gamma_c^i \in \gamma_c$, $t_y \in t$ denote the computational resources accessible on i^{th} server aboard the cth onshore computing platform γ_c at the yth epoch t_y. The computational resources accessible on the jth server aboard the dth computing platform $\Upsilon_d^j, \Upsilon_d^j \in \Upsilon_d$, $t_y \in t$ at the yth epoch t_y is denoted $C_2(\Upsilon_d^j, t_y)$. In the case, where cloud computing platforms are not accessed by underwater astronomy applications, the accessible computing resources, θ_1 is

$$\theta_1 = \sum_{c=1}^{C} \sum_{i=1}^{I} \sum_{y=1}^{Y} C_2(\gamma_c^i, t_y) \tag{7}$$

In the case where cloud computing platforms are accessible by underwater astronomy applications, the accessible computing resources, θ_2 is:

$$\theta_2 = \sum_{c=1}^{C} \sum_{i=1}^{I} \sum_{y=1}^{Y} C_2(\gamma_c^i, t_y) + \sum_{d=1}^{D} \sum_{j=1}^{J} \sum_{y=1}^{Y} C_2(\Upsilon_d^j, t_y) \tag{8}$$

The power required to operate the servers γ_c^i and Υ_d^j at the epoch t_y are denoted as $P_1(\gamma_c^i, t_y)$ and $P_1(\Upsilon_d^j, t_y)$, respectively. In addition, the power required to cool the servers γ_c^i and Υ_d^j at the epoch t_y are denoted as $P_2(\gamma_c^i, t_y)$ and $P_2(\Upsilon_d^j, t_y)$, respectively. The PUE of a cloud computing platform comprising only servers in existing data centers ν_1 is:

$$\nu_1 = \sum_{c=1}^{C} \sum_{i=1}^{I} \sum_{y=1}^{Y} \left(\frac{P_1(\gamma_c^i, t_y) + P_2(\gamma_c^i, t_y)}{P_1(\gamma_c^i, t_y)} \right) \tag{9}$$

When the cloud platform comprises both non–onshore based servers and onshore based servers, the PUE of the resulting cloud computing platform, ν_2 is:

$$\nu_2 = \sum_{c=1}^{C} \sum_{d=1}^{D} \sum_{i=1}^{I} \sum_{j=1}^{J} \left(\sum_{y=1}^{Y} \frac{A + B}{P_1(\gamma_c^i, t_y) + P_1(\gamma\Upsilon_d^j, t_y)} \right) \tag{10}$$

$$A = P_1(\gamma_c^i, t_y) + P_1(\gamma\Upsilon_d^j, t_y) \tag{11}$$

$$B = P_2(\gamma_c^i, t_y) + \left(1 - \acute{\Gamma}(j, d, t_y)\right) P_2(\gamma\Upsilon_d^j, t_y) \tag{12}$$

$\acute{\Gamma}(j, d, t_y)$ is the reduction in the cooling energy on the server Υ_d^j due to the maritime resource at the yth epoch t_y.

Furthermore, let ς denote the set of organizations that benefit from the proposed integration approach such that:

$$\varsigma = \{\varsigma_{ao}, \varsigma_{nao}\} \tag{13}$$

$$\varsigma_{ao} = \{\varsigma_{ao}^1, \varsigma_{ao}^2, \dots, \varsigma_{ao}^F\} \tag{14}$$

$$\varsigma_{nao} = \{\varsigma_{nao}^1, \varsigma_{nao}^2, \dots, \varsigma_{nao}^M\} \tag{15}$$

ς_{ao} and ς_{nao} are the set of underwater astronomy organizations and non–underwater astronomy organizations respectively.

$\varsigma_{ao}^f, \varsigma_{ao}^f \in \varsigma_{ao}$ and $\varsigma_{nao}^m, \varsigma_{nao}^m \in \varsigma_{nao}$ are the fth underwater astronomy organization and m^{th} non–underwater astronomy organization, respectively.

The underwater telescopes associated with the fth underwater astronomy and m^{th} non–underwater astronomy organizations are given as:

$$\varsigma_{ao}^{f} = \{\varsigma_{ao}^{f,1}, \varsigma_{ao}^{f,2}, \dots, \varsigma_{ao}^{f,Q}\} \qquad (16)$$

$$\varsigma_{nao}^{m} = \{\varsigma_{nao}^{m,1}, \varsigma_{nao}^{m,2}, \dots, \varsigma_{nao}^{m,L}\} \qquad (17)$$

The baseline for underwater telescopes $\varsigma_{ao}^{f,q-1}, \varsigma_{ao}^{f,q-1} \in \varsigma_{ao}^{f}$, $(q-1) \geq 1$ (the $(q-1)^{th}$ underwater telescope belonging to the underwater astronomy organization) and $\varsigma_{ao}^{f,q}, \varsigma_{ao}^{f,q} \in \varsigma_{ao}^{f}$ (the $(q)^{th}$ underwater telescope belonging to the underwater astronomy organization) at the epoch t_y is denoted $\ddot{Y}(\varsigma_{ao}^{f,q-1}, \varsigma_{ao}^{f,q}, t_y)$.

The underwater interferometer baseline without and with the synergy are B_1 and B_2 , respectively and given as:

$$B_1 = \sum_{y=1}^{Y} \left(\sum_{f=1}^{F} \sum_{q=2}^{Q} \ddot{Y}(\varsigma_{ao}^{f,q-1}, \varsigma_{ao}^{f,q}, t_y) \right) \qquad (18)$$

$$B_2 = \sum_{y=1}^{Y}(C + D) \qquad (19)$$

$$C = \sum_{f=1}^{F} \sum_{q=2}^{Q} \ddot{Y}(\varsigma_{ao}^{f,q-1}, \varsigma_{ao}^{f,q}, t_y) \qquad (20)$$

$$D = \sum_{m=1}^{M} \sum_{l=2}^{L} \ddot{Y}(\varsigma_{nao}^{m,l-1}, \varsigma_{nao}^{m,l}, t_y) \qquad (21)$$

The resolution of the underwater astronomy radiation if λ is the Cherenkov radiation wavelength, without and with the proposed synergy is denoted $\hslash_1$ and $\hslash_2$, respectively:

$$\hslash_e = \frac{\lambda}{B_e} , e \in \{1,2\} \qquad (22)$$

8. Performance Evaluation and Analysis

The performance evaluation of the proposed mechanism is done using the parameters in Table 2. The computational resource aboard the servers used in the simulation has been chosen considering the parameters used in [58]. The proportion of energy used in cooling servers aboard terrestrial data centers is considered to have a value of 40% as seen in [59]. The value of the power consumption used in servers is motivated by information obtained from [60]. In Table 2, the coverage of underwater telescopes from participating organizations differs from the coverage of telescopes deployed by underwater astronomy organizations. In addition, the baseline in both cases has been selected to have a similar range of values. This is done to prevent a scenario where a greedy approach is used when adding underwater telescopes from participating organizations. The performance simulation and analysis has been performed with the MATLAB software package.

The results for the simulated accessible computational resources and PUE performance is shown in Figure 5 and Figure 6, respectively. The results obtained and presented in Figure 5

shows that the joint usage of onshore computing platforms alongside existing terrestrial computing platforms increases the accessible computational resources. In the existing case, a server unit is a server in an existing terrestrial computing platform. A server unit in the proposed case is a logical combination of individual servers in the onshore and existing terrestrial computing platforms.

Figure 6 shows that the use of the onshore computing platforms with the existing terrestrial computing platforms improves the PUE (a lower PUE is better) because of the reduced cooling energy in onshore computing platforms as they are closer to maritime resources. Onshore computing platforms are sited in near long term low temperature environments such as rural maritime resources. This increases the available cold water that can be freely accessed for server cooling. Such a performance benefit can be seen in the Google Hamina onshore computing platform [60].

Analysis of the results shows that leveraging on a synergy between underwater astronomy organizations and identified technology interests enhance the accessible computational resources, and the PUE. The accessible computational resources and PUE are enhanced by an average of 48.8% and 1.6%, respectively.

The influence of the proposed synergy on the observation resolution is also investigated and the obtained result is in Figure 7. Figure 7 shows that observation resolution improves with an increase in the number of logical telescope units. A lower observation resolution implies that more details can be obtained from the observation procedure and is better than a higher observation resolution. In the proposed case, a telescope deployed by a participating organization and the one telescope deployed by the underwater astronomy organization comprises a logical telescope. However, the logical telescope unit has a longer baseline (i.e. telescope separation) thereby resulting in a lower observation resolution. The simulation uses an observation wavelength of 450 nm for the Cherenkov radiation as obtained from [61]. Analysis shows that the synergy enhances the observation resolution by 41.3% on average.

Table 2: Parameters used for Performance Evaluation

S/N	Parameter	Value
1	Quantity of Servers in the Onshore Computing Platform	70
2	Quantity of Servers in the Existing Terrestrial Computing Platform	120
3	Minimum Computational Resources in the Onshore and Existing Terrestrial Computing Platform Server	[2.02, 0.99] Gbytes
4	Maximum Computational Resources in the Onshore and Existing Terrestrial Computing Platform Server	[78.75,95.95] Gbytes
5	Average Computational Resources in the Onshore and Existing Terrestrial Computing Platform Server	[35.47,44.52] Gbytes
6	Minimum Power Consumed by Server in the Onshore and Existing Terrestrial Computing Platform Server	[0.38, 1.48] W
7	Maximum Power Consumed by Server in the Onshore and Existing Terrestrial Computing Platform Server	[46.29, 71.78] W

8	Average Power Consumed by Server in the Onshore and Existing Terrestrial Computing Platform Server	[19.53, 36.84] W
9	Proportion of power used in cooling servers in existing terrestrial data centers	40%
10	Minimum proportion of cooling power reduction due to onshore location	0.1%
11	Maximum proportion of cooling power reduction due to onshore location	4.92%
12	Average proportion of cooling power reduction due to onshore location	2.54%
13	Number of Underwater Astronomy Organizations	1
14	Number of Participating Organizations	1
15	Minimum Baseline of Underwater Telescopes from Underwater Astronomy Organizations	9.50 m
16	Maximum Baseline of Underwater Telescopes from Underwater Astronomy Organizations	1.99 km
17	Average Baseline of Underwater Telescopes from Underwater Astronomy Organizations	1.01 km
18	Minimum Baseline of Underwater Telescopes from Participating Organizations	114.98 m
19	Maximum Baseline of Underwater Telescopes from Participating Organizations	1.43 km
20	Average Baseline of Underwater Telescopes from Participating Organizations	0.79 km
21	Wavelength of the Cherenkov Radiation under observation ([61])	450 nm.

Figure 5: Simulation results obtained for accessible computational resources

Figure 6: Simulation results obtained for the PUE.

9. Conclusion

This paper recognizes that the future conduct of underwater neutrino astronomy has significant research and knowledge value prospects. The knowledge prospect advances scientific research and knowledge. The identified aspects constitute areas where additional research is required. The paper describes the synergy between underwater astronomy and other applications in computing and scientific investigations. In addition, the performance evaluation examines performance improvements that can be obtained by using the proposed synergistic approach. This is done using computing and observation related metrics. The computing related metrics are the PUE and accessible computational resources. The observation related metric is the observation resolution. Investigation shows that the use of the collaborative approach improves accessible computational resources, PUE and resolution by 48.8%, 1.6% and 41.3% on average, respectively.

Conflict of Interest

The authors declare no conflict of interest.

Text Mining Techniques for Sentiment Analysis of Arabic Dialects: Literature Review

Arwa A. Al Shamsi[*], Sherief Abdallah

The British University in Dubai, Faculty of engineering and IT, Dubai, 345015, UAE

A R T I C L E I N F O	A B S T R A C T
	Social media attracts a lot of users around the world. Many reasons drive people to use social media sites such as expressing opinions and ideas, displaying their diaries and sharing them with others, social communication with family and friends and building new social relationships, learning and sharing knowledge. Written text is one of the most common forms used for communication while using social media sites. People use written texts in different languages, and due to the increased usage of social networking sites around the world, the amount of texts and data resulting from this use is large. These generated data considered as a valuable source of information that attracted business owners, companies, government institutions, and of course, it attracts researchers and data scientists as well. Researchers and data scientists increasingly presented great efforts in investigating and analyzing Arabic Language texts. Most of these efforts targeted the Modern Standard form of Arabic Language. While exploring the social media sites, most of the Arab users tend to use their dialects while utilizing Social Media sites, which results in generating a massive amount of Arabic Dialects texts. The number of researches and analysis of Dialects' form of the Arabic language are limited, however, it is increasing recently. This literature review aims to explore approaches and methods used for Sentiment Analysis of Arabic Dialects text.

1. Introduction

Social Media sites have become very popular in society, the popularity of social media is increasing day by day. Recently, many people prefer to spend their time using various applications in smart devices and using the Internet as well. Perhaps social media may take the majority of this usage. People use social media for various reasons such as online shopping, learning, communication, expressing opinions and ideas, sharing their diaries, and many different reasons. People tend to express their opinions, thoughts, feelings, and comment on the various topics that are posted on social media using their dialects. Dialects are the informal form of the language. Each country of the Arab world has its Dialect, and each dialect has many sub-dialects. In [1], the author stated that the population of the Arab world prefer to utilize their dialects in their daily communication, Arabic dialects increasingly utilized online for communications and in social media, moreover, Arabic dialects utilized in TV shows as well as radio programs. As social media usage increased sharply, the amount of data generated as a result of this usage is increasing as well. In [2], the author stated that due to the great amount of data in the form of Natural Language generated in a daily manner online, there is a great need to process this kind of data. This huge amount of generated data attracted companies' owners, marketers

and business owners, government institutes and, scientists and researchers as well.

Recently, the world witnesses the revolution of Artificial Intelligence, Data Science, and Machine Learning. Researchers and data scientists are increasingly interested in studying and analyzing natural language texts. Great efforts and researches increasingly targeted the Modern Standard form of Arabic Language, however, researches that targeted the dialects form of Arabic language are limited. In [1], the author stated that due to the limited tools and software that can be utilized for Dialects, researches that targeted dialects are very limit. Many factors affected this limitation, such as the dialect's complexity. Authors in [3] stated that the Dialectal form of the Arabic language has no standard written format which is considered a challenge for analyzing and processing Arabic Dialects. Authors in [4] added to the Arabic Dialects challenges the Diacritical issue and explained how it may change the meaning of the same word, moreover, authors explained how negation may be considered as a challenge while dealing with Arabic Dialects.

This literature review aims to explore researches that involve constructing resources for Arabic Dialects and investigate approaches and methods used for Sentiment Analysis of Arabic Dialects text, focusing on machine learning approaches and Lexicon-based approaches.

2. Literature Review

2.1. Arabic Language Background

Arabic is one of the most popular languages that are spoken by millions of people all around the world. In [5], the author stated that the Arabic language is considered the fifth most common language that is spoken by more than 420 million people all around the world. The Arabic language has its unique features. It consists of 28 letters and it is written from the right side to the left side. In [6], the author mentioned that based upon statistics presented by Wikipedia in 2018; the Arabic language is the official language of 25 nations and 380 million is the approximate number of Arabic speakers. In [7], the author mentioned that the Arabic language is one of the Semitic languages meaning that it is written from the right side to left, moreover, Arabic language letters shape changed according to the position of the letter in the word itself. In [1], the author stated that Arabic language letters are used as well in Malay, Urdu, and Persian languages. The Arabic Language is written from right to left. The Arabic language has three types i.e. Classical Arabic which is the language of the Holy Qur'an, Modern Standard Arabic, and Dialectal Arabic form. The Arabic language attracted researchers due to the increased usage of this language over the internet. In [7], the author stated that Arabic users over social media are increasing year after year according to official statistics, this increase resulted in a massive amount of data generated daily online that are in Arabic language. Hence, there is an increasing need for powerful tools and effective approaches for processing Arabic language texts that are in either the Modern Standard Arabic form or in the Arabic Dialects form.

2.1.1. Modern Standard Arabic

Modern Standard Arabic (MSA) is the standard form of the Arabic language that is used in formal papers, schoolbooks, education, TV news, newspapers, street signs, etc. Modern Standard Arabic has a written standard format while the dialects are not. As mentioned earlier, the Arabic language attracted researchers due to the increased use of this language over the internet. Most of the researches that targeted the Arabic language focused on the Modern Standard Arabic form of the Arabic language. In [8], the author stated that NLP tools and applications are mostly based upon the Modern Standard Arabic form of the Arabic language. Modern Standard Arabic is closer to Classical Arabic compared to Arabic Dialect that is less related to classical Arabic. In [9], the author attracted by NLP for Arabic Language and most of the researches done concentrated on MSA as reported in a systematic review.

2.1.2. Arabic Dialect

Arab World consists of 22 countries. Each of these Arab countries has a special Arabic dialect that their population used for daily conversations and talk. In [1], the author mentioned some of the most common Arabic Dialects such as Levantine Arabic, Egyptian Arabic, Gulf Arabic, North African Arabic, and many other Arabic Dialects are spoken by the Arab population. It stated that the Arab population prefers to use their dialects in their daily communication, Arabic dialects increasingly used online in social media sites, moreover, Arabic dialects appeared and utilized in TV shows as well as radio programs. The main dialect for each country can be divided into more sub-dialects. It stated that Arabic Dialects consists of Arabic and non-Arabic words that exist as a result of many reasons; an example of the reasons: Gulf people traveling to India and Iran, moreover, European traders came to Gulf countries after oil discovery, these reasons resulted in non-Arabic words existence in Gulf dialects. In [10], the author interested in their research in studying Arabic dialects. The authors described how Gulf Arabic dialect is the language of the population of Gulf Cooperation, however, this Gulf Arabic dialect is differing slightly between the population of each of the Gulf Cooperation Countries. In [1], the author mentioned that the limited number of Dialects software and NLP tools resulted in limited works and researches that studied and analyzed Dialects. However, [9] in a systematic review presented some research papers that have studied Arabic Dialects. Authors presented valuable researches done in the field of basic language analysis such as ADAM which is an Analyzer for Dialectal Arabic Morphology of Egyptian and Levantine dialectal language, and CALIMA which is an analyzer for Egyptian dialects morphological. Authors as well presented researches and works that have been concentrated on building resources such as Curras which is a dataset of Palestinian dialects and it consists of 56,000 morphologically annotated tokens, DART which is a dataset of around 25000 Arabic tweets, ArabicWeb16 which is a dataset of 10.8 TB of Arabic dialects, CALYOU which is a dataset of Algerian dialect, NileULex which is an Arabic sentiment lexicon of Egyptian and Levantine dialects in addition to Modern Standard Arabic, and TSAC dataset which is sentiment analysis dataset for Tunisian dialects.

2.2. Machine. Learning

Machine Learning involves constructing systems and models that can be improved over experience. It stated that Machine Learning involves machines and systems that can program themselves to learn and get the knowledge needed for better performance. The most common machine learning methods are Classification, Clustering, Regression, Deep Learning and Neural Networks, Transfer Learning, Word Embeddings, Natural Language Processing, Dimensionality Reduction, Reinforcement Learning, and Ensemble Methods. Deep Learning and Neural Networks, Word Embeddings, Transfer Learning, and Natural Language Processing methods of Machine Learning will be further explained below.

2.2.1. Deep Learning and Neural Networks

Deep Learning and Neural Networks are considered a revolutionary approach in the Machine Learning domain. In [6], the author explained that Artificial Neural Network utilized for complex problem solving as it functions in a way similar to Neural Network in brains of humans. Deep Neural Networks are known for their accuracy as well as outstanding performance. Deep Learning approaches are used increasingly for NLP tasks. Researchers utilized Deep Learning approaches for Arabic NLP. As an example of researches used Deep Learning for Arabic NLP: [6] used nine Deep Learning models for text categorization. Moreover, they utilized Word Embeddings approaches and evaluated performance and accuracy. Results showed that all of the nine Deep Learning models presented very good performance and high accuracy, moreover, the use of Word embeddings increased the accuracy and improved the performance. Additionally, in [11] the author investigated different Deep Learning models for Arabic Dialects text classification. Authors concentrated on Egyptian, Levantine, and Gulf dialects and reported that for Egyptian-Gulf pair; Bi-Directions LSTM offered better performance than other Deep Learning models, while for other dialects pairs; LSTM presented better performance.

2.2.2. Transfer Learning

Transfer learning involves using tasks or models that have been learned and transfer the learned knowledge along with applying improvements for a new task or model. In [12], the author defined transfer learning as the process of using data from a source domain to solve problems in another domain. The problem aimed to be solved is related to the data from the source domain, but it is different. In [13], the author successfully presented a model in which Transfer Learning can be used effectively in the case of multiple source domains used for solving problems in multiple target domains. In [14], authors used the Transfer Learning method for ANLP. Transfer learning was used as an extension for the word embeddings model. Authors investigated the effectiveness of the extension applied to skipgram model, the extension involved incorporation of lemmas and efficient use of word2vec word embedding model. The authors reported that the extended model presented better performance than word2vec and fastText on the Arabic word similarity task.

2.2.3. Word Embeddings

Word embeddings is an emerging field that involves distributed word representations which mean representing words as vectors in space. Word Embeddings models are either monolingual or bilingual. The most common is the monolingual models. In [15], the author stated that monolingual word embedding models can be utilized for word order and morphology, while bilingual word embedding models can be utilized for machine translation and parallel sentence extraction. The authors explained that bilingual word embedding models are vector representations of two languages, these languages are mapped into the same space. Word Embeddings have been implemented and utilized for NLP purposes. In [16], the author stated that word embeddings involve using semantic features for representing words as vectors, word embeddings utilized in NLP most commonly for classification and sentiment analysis. In [17], the author stated that the most common Word Embeddings methods are Word2Vec and GloVe. In [18], the author mentioned that there are 4 Arabic word Embeddings which are CBOW, GloVe, Skip-gram model, and Arabic part of the Polyglot word embeddings. The authors evaluated 4 Arabic word embeddings models utilizing benchmark and reported that the best performance achieved from the CBOW model, while the least performance was achieved from the Polyglot model of word embeddings. In [5], the author defined Word Embeddings as vectors used to represent words in continuous space to find any relation between them. The authors presented AraVec which is an open-source Word Embeddings project utilized in the ANLP field. In [19], authors enlarged the informative content of the training sentences by efficient adaptations to word embeddings tools which result in improving the accuracy and performance. Authors as well were able to successfully utilize one embedding space to represent disparate dialects.

2.2.4. Natural Language Processing NLP

Language is the way of communication between people. Language helps us to understand the world around us. The languages that are spoken by people all around the world are known as natural languages. Natural Language Processing (NLP) involves the use of computers to understand and deal with natural languages. In [70], the author define NPL as a section of Artificial Intelligence and Computer Science that involves studying the interactions between human natural languages and computers, moreover, NLP involves Natural Language understanding and generation. The authors mentioned that the increased information in natural language form increased the need for understanding and processing this kind of information. In [2], the author agreed that the massive amount of Natural Language form of data generated daily online increased the need for processing this kind of data. The authors identified NLP as the process of automatic analysis, understanding, and presentation of human Natural Languages.

2.2.4.1. Arabic Natural Language Processing ANLP

ANLP is short for Arabic Natural Language Processing and it involves automatic analysis and processing of Arabic Natural Language. As mentioned earlier, the Arabic Language has three main forms; Classical Arabic, Modern Standard Arabic (MSA), and Arabic Dialects (AD). ANLP tools are supposed to have the ability to deal with the three forms of the Arabic language. However, Classical Arabic is rarely targeted by researchers as it represents the Arabic form of the Holy Qur'an. Tools and techniques are mostly utilized for MSA compared to AD. In [10], the author stated that the use of ANLP tools for AD may be hard due to the nature of AD and the differences between MSA and AD i.e. phonological differences and morphological differences.

2.3. Researches and works on Arabic Dialects

Recently, Arabic Dialects AD attracted researchers. The need to analyze, classify and process the Arabic dialects is increasing due to the fact of increasing the content of Dialect texts, especially in Social Media as stated in [10] . The authors stated that efforts done on MSA are big compared to the works on AD which are limited and mostly targeted Egyptian and Saudi Dialects. However, researchers increasingly do researches and studies that targeted AD. Researches conducted on AD involve basic language analysis, building resources, language identification, and Semantic level analysis. One of the most common examples of semantic level analysis is Sentiment Analysis.

2.3.1. Basic Language Analysis

Basic language analysis for Arabic Dialects involves Orthographic Analysis, Morphological Analysis, and Syntactical Analysis. Sections below present a brief description of each of the basic language analysis type.

2.3.1.1. Arabic Dialects Orthographic Analysis

Arabic dialects have no standard orthographic format meaning that the same word can be written in two or more different ways which may release challenges for NLP tools. In [8], the author stated that MSA and AD are phonologically different, AD have no standard orthographic, i.e. there is no standard format for written AD, Arabic Dialects usually written based upon its phonetics which makes it difficult for analyzing and processing AD. Researchers presented efforts in orthographic analysis for the Arabic language. In [20], the author introduced CODA which is a Conventional Orthography for Dialectal Arabic. CODA offered a computational model that can be utilized for AD. In [21], the author presented valuable efforts in providing conventional orthography that can be utilized for Tunisian Arabic. The presented conventional orthography is based upon CODA that was mentioned earlier. In [10], the author introduced Gumar Corpus which is a Gulf dialects corpus that consists of 110 million words. The corpus was annotated, and the authors presented guidelines for standard orthography analysis.

2.3.1.2. Arabic Dialects Morphological Analysis

The Arabic language is recognized as a rich language of Morphology. In [22], the author defined morphology as the science that involves extracting the word's branches from the word's source. In [8], the author explained how the morphology of MSA is different from the morphology of AD even the grammar, as well as stems of words, may differ. The exploration of Arabic dialects morphology attracted researchers early. In [23], the author introduced MAGEAD which is an Arabic Language Morphological analyzer. MAGEAD is considered as an online morphological generator as well as an analyzer. In [24], the author presented an accurate Egyptian dialect morphological analyzer which is an extension for the Egyptian Colloquial Arabic Lexicon. In [25], the author constructed a lexicon for Tunisian dialects and proposed an approach for Tunisian dialects morphological analysis. Researchers presented efforts as well in constructing a corpus that is morphologically annotated. In [26], the author successfully constructed a morphologically annotated Emirati dialects corpus that consists of about 200,000 words.

2.3.1.3. Arabic Dialects Syntactical Analysis

Dialects are different syntactically, the syntax in dialects affected by many factors, the most common factor that affect the syntax of Arabic dialects is the foreign languages. Syntactical analysis for Arabic dialects has been addressed in several research papers. In [27], the author explored the difficulties in Arabic dialects syntactic analysis, the authors proposed an approach for constructing treebank for Tunisian dialects. In [28], the author proposed a method that involves integration between syntactic analysis and morphological tagging for automatic diacritization of the Arabic language. The method is applied through the case and features prediction improvements. In [29], the author presented guidelines used for syntactic annotation for the treebank of Quranic Arabic dependency which is part of Quranic Arabic Corpus. In [30], the author proposed CamelParser which is a syntactic dependency analysis system for the Arabic language. The proposed system can be used for Morphological Disambiguation.

2.3.2. Building Resources

Researchers worldwide have done great efforts on collecting corpus for Modern Standard Arabic MSA, researchers increasingly attracted by Dialectal Arabic, Great efforts as well have been done to collect corpus for Arabic Dialects.

2.3.2.1. Modern Standard Arabic Corpus Resources

Researchers are increasingly attracted by the Arabic language analysis. One of the most important efforts conducted in the field of ANLP is building resources for the Arabic language. Most of the resources that have been built for the Arabic language are in the form of MSA. In [8], the author stated that almost all available Arabic datasets are for MSA form. Below are some of the researches in which great efforts have been conducted to create corpora of MSA. In [6] the author created two corpora of Modern Standard Arabic text i.e. SANAD and NADiA from Arabic news articles and offered the created corpora as open-source for the public to be utilized for further researches. Moreover, in [31] the author constructed a corpus of MSA that is manually annotated on the sentence level. The corpus was collected from newswire documents. In [32], the author presented AWATIF which is a corpus of MSA that is labeled for Sentiment Analysis purposes at the sentence level. In [33], the author presented noticeable efforts for creating a corpus of MSA from online newspapers.

2.3.2.2. Arabic Dialect Corpus Resources

Dialectal Arabic involves all the dialects that the population of the Arab World use. Arabic Dialects can be categorized according to the region and similarity into: (1) Gulf Dialects which include the Arabic Dialects Spoken by Arab Gulf people, (2) Egyptian Dialect, (3) Levantine Dialect which involves dialects spoken by the population of Palestine, Jordan, Syria, and Lebanon, (4) North African Dialect which include dialects spoken by Morocco, Algeria, Libya and Tunis people. In [8], the author stated that social media websites are considered as one of the most precious sources of AD as people tend to express their thoughts and opinions in written forms using their dialects. In [34], the author stated that although the Arabic Language has been used in a wide range online, the available Arabic datasets are still limited. Internet World Stats statistics represented that the Arabic Language is the fourth most common language used across the internet. Recently, researchers tend to present efforts in ANLP and especially in creating an Arabic corpus that can benefit researches in the ANLP domain. In [10], the author constructed corpus for Gulf Dialects that made up of 100 million words collected from 1200 forum novels, and this Gulf Dialects corpus called Gumar Corpus. In [26], utilized Gumar Corpus to collect a corpus of Emirati dialects. The Collected Emirati dialects consist of around 200,000 words of Emirati Dialects. In [8], the author created a Dialectal Arabic Dataset that include Gulf Dialects, Egyptian Dialect, Levantine Dialects, and North African Dialects. In [34], the author presented BRAD 2.0 which is an extension to BRAD 1.0 corpus. BRAD 1.0 is a dataset of Arabic book reviews that can be utilized for Sentiment Analysis as well as Machine Learning. While BRAD 2.0 is a dataset that is much bigger than BRAD 1.0 and it consists of more than 600,000 Arabic book reviews written in both Modern Standard Arabic and Dialectal Arabic. The Arabic dialects in BRAD 2.0 dataset are Gulf, Egyptian, and Levantine. In [35], the author successfully constructed a corpus of MSA and Saudi Dialect from Twitter and manually annotate the constructed corpus, and offered the constructed corpus for the research community. The authors named the generated corpus AraSenTi-tweet corpus, number of tweets collected were 2.2 million tweets while after annotation the remaining tweets are 17,573 tweets. In [36], the author constructed a corpus of Arabic Dialects. The sources for the corpus text are from Twitter, Facebook, and Newspapers comments. The corpus consisted of Gulf, Egyptian, North African, Levantine, and Iraqi dialects. Twitter texts are classified based upon either seed words, or coordinate points. While Comments from Facebook and Newspapers are classified depending on the nationality of the page owner and country of Newspapers respectively. The authors as well presented an online game that is utilized for text annotation. In [37], the author constructed two corpora i.e. News Corpus (NC) and Arts Corpus (AC) both corpora consist of Arabic Dialects texts from Facebook that can be utilized for Sentiment Analysis. From the above, it is clear how researchers are increasingly interested in building resources for Arabic Dialects. In this literature review, the author targeted research papers that are published in the period from 2014 onward. The databases the author utilized are IEEE, Springer, ScienceDirect, ACM, and WorldCat. The keywords mentioned below have been used for collecting the research papers:

- "Arabic Dialects" and "lexicon"
- "Arabic Dialects" and "dataset"
- "Arabic Dialects" and "corpus"

The inclusion criteria for research papers:

- Must involve constructing resources (dataset / corpus / lexicon) for Arabic Dialects.

- Must be for Arabic Dialect texts only.
- Must be published in the period from 2014 onward.
- Research paper published in journal or conference

Table 1: research and studies that involve constructing a dataset for Arabic Dialects texts

Ref	Data size	Platform or Source	Dialect type	Annotated	Features Extracted
[10]	Gumar Corpus: 110 million words	from 1,200 forum novels	Gulf Arabic	Yes, for sub-dialects at document level for the dialect, novel name and writer name for each	
[26]	about 200,000 words	from eight Gumar corpus novels in the Emirati Arabic variety	Emirati Dialect	Yes, manually annotated	
[8]	13,876,504 word	Twitter, comments from online newspapers, and Facebook	Gulf, Iraqi, Egyptian, Levantine, and North African.	Yes, manually using annotation tool	
[34]	BRAD 2.0 : 692586 annotated reviews	Arabic Book Reviews from www.goodreads.com	MSA and DA (Egyptian, Levantine, and Gulf)	Yes	Yes, unigrams and bigrams
[38]	8000 tweets	Twitter	Arabic and mostly Egyptian	Yes, tweets were labelled into positive, negative, neutral and both	
[71]	Arabic Online Commentary Data set AOC : 52.1M words	Three online newspapers Al-Ghad from Jordan, Al-Riyadh from Saudi Arabia, and Al-Youm Al-Sabe' from Egypt	MSA and Arabic Dialects	Yes, at sentence level	
[35]	AraSenTi-Tweet Corpus: 17,573 tweets	Twitter	Saudi Dialect	Yes, manually and lablled into: positive, negative, neutral and mixed	
[36]	200K tweets, 10K online newspaper comments, and 2M comments from Facebook → total words= 13.8M words	Twitter, Facebook, and Online newspaper	Gulf Dialect, Iraqi Dialect, Egyptian Dialect, Levantine Dialect, and North African Dialect.	Yes, using online game	
[37]	2000 posts, (1000 posts News Corpora NC), and (100 post Arts Corpora AC)	(NC) Al Arabiyya News Facebook page posts, and (AC) collected from The Voice Facebook page	Arabic Dialects	Yes, manual annotation	
[39]	Egyptian Dialect Gender Annotated Dataset (EDGAD) : 70000 tweets	Twitter	Eygptian Dialects	Yes, manually	N-Gram Feature Vector (NFV)
[40]	438,931 tweets	Twitter	Arabic Dialects	Yes, automatically	Ngrams feature
[41]	7698 comments	Facebook	Algerian Vernacular Arabic	Yes, manually	
[42]	1800 tweets	Twitter	MSA and Jordanian Dialect	Yes, manually	N-grams TF-IDF TF
[43]	ArSentD-LEV: 4000 tweets	Twitter	Levantine Dialect	Yes, via crowdsourcing	
[44]	Curras: more than 56 K tokens	Facebook, Twitter, Blogs, and Forums	Palestinian Dialect	Yes, manually	
[45]	194 negative comments & 194 positive comments	Three Algerian newspapers	Algerian Dialect	Yes, by two Arabic native speakers	
[46]	8000 messages	Facebook	Algerian dialect (Arabic and Arabizi)	Yes, automatically	
[47]	151,548 tweets	Twitter	MSA and Egyptian Dialect	Yes, manually	
[48]	Around 6 million tweets	Twitter	MSA and Arabic Dialects	Yes, automatically	

Table 1 illustrates some of the research and studies that involve constructing a dataset for Arabic Dialects texts. Table 2 below illustrates some of the research and studies that involve constructing a Lexicon for Arabic Dialects texts.

Table 2: research and studies that involve constructing a Lexicon for Arabic Dialects texts

	Data size	Platform or Source	Dialect type	Method
[38]	8000 tweets	Twitter	Arabic and Egyptian	lexicon was created by the human annotators from tweets
[7]	1527 idioms and 7358 Words	From NileULex [51]	MSA and Egyptian Dialect	Extend NileULex which is an Arabic sentiment lexicon
[51]	NileULex: 5953 unique terms	Perivoulsy available lexicons	MSA and Egyptian Dialect	Automatically and manually update to lexicons that are developed earlier
[37]	2817 lexemes	(NC) Al Arabiyya News Facebook page posts, and (AC) collected from The Voice Facebook page	Arabic Dialects	Lexemes were extracted from the posts
[50]	words lexicon, idioms lexicon, emoticon lexicon and special intensified word lexicon	Constructed from different datasets based on manual annotation	Arabic Dialects	Lexicons were built by tool dynamically and expanded incrementally over time.
[41]	Keywords lexicon (L1): 2380 negative polarity and 713 positive polarity	Arabic and Egyptian Lexicon	Algerian Vernacular Arabic	Lexicons built by translating words from Arabic and Egyptian Lexicons
	Negation words lexicon (L2)	MSA dictionary		
	Intensification words Lexicon (L3)	MSA dictionary		
[52]	2000 topics (1000 tweets and 1000 comments)	Twitter and Arabic microblogs	MSA and Egyptian Dialect	Basic lexicon is manually collected and annotated, then synonym set and antonym set are used for automatic expansion of the lexicon
[53]	25086 words	Dialect Lexicon	Algerian dialect	Construct a dialect lexicon then merge two lexicons (a dialect and a sentiment lexicon)
[54]	AIPSeLEX: 3632 idioms/ proverbs	Websites and books	MSA and Egyptian Dialect	Collected and annotated manually at sentence level

2.3.2.1. Arabic Dialect lexicon

Great researches and studies have been conducted in the field of creating lexicon for the English Language texts that can be used for the NLP domain while a limited number of research papers considered creating lexicon for Arabic Language either in its Modern Standard Arabic form or Arabic Dialects form. In [37], the author defined lexicon as a set of lexemes utilized for text classification. In [49], the author created a lexicon of MSA form of Arabic Language. The created lexicon used for text classification and the accuracy was high and reached around 97% of classification accuracy. In [37], the author successfully developed a lexicon that can be utilized for Sentiment Analysis. In [50], the author utilized 5 datasets for lexicon construction. All the utilized datasets are constructed from Twitter i.e. consisted of tweets that are annotated. the generated lexicon is dynamic as it is updated automatically to include new words. Table 2 below illustrates some of the research and studies that involve constructing a Lexicon for Arabic Dialects texts.

2.3.3. Language Identification: Arabic Dialect Identification

Language Identification involves the automatic identification of the language from speech or text. Researchers are increasingly interested in exploring approaches for dialects identification. Arabic Dialect Identification involves dialect automatic identification either dialectal text identification or dialectal speech identification. Some of the researches and studies in the domain of dialect identification are mentioned below. In [55] authors identified and classified Arabic Dialects text of 25 cities of the Arab world. Results were promising as the accuracy of the developed system was 67.9% for sentences of about 7 words length and 90% accuracy in the case of utilizing 16 words. Additionally, in [71] the author utilized an annotated dataset of online newspaper contents to train classifiers for the identification of Arabic dialects. The proposed system determines whether the given sentence is in Modern Standard Arabic form or Gulf, Levantine, Egyptian, Iraqi, Maghrebi dialects forms.

2.3.4.   Semantic-level Analysis

The semantic-level analysis involves Machine Translation and Sentiment Analysis. In this literature survey, the author concentrated on Sentiment Analysis for Arabic dialects.

2.3.4.1. Sentiment Analysis Literature

One of the most common implementations that involve the use of NLP is Sentiment Analysis (SA). SA involves classifying text to describe whether its expressions are positive or negative. In some cases, the text is classified into positive, negative, or neutral. In [38], the author mentioned that Sentiment Analysis involves the text classification based upon its polarity or emotion. In [17], the author stated that people recently tend to express their thoughts, ideas, and opinions about products, services, etc. on websites, blogs, social media, and many other channels through the web. This massive content generated by users all over the world attracted NLP researchers. In [34], the author mentioned how Sentiment Analysis is important for investigating public attitudes

toward product or services, Sentiment Analysis as well can be used for exploring wider public opinions. In [56], the author agreed that online websites and applications recently considered as a valuable source of opinions that can benefit business owners, services providers as well as customers who aim to explore public reviews about different products or facilities, etc. In Arab world, Arab people usually tend to use dialect language in their daily life rather than MSA form. Moreover, Arab people express their ideas and opinions as well thoughts through the web most commonly using their dialectal form of language which results in generating a massive amount of dialectal Arabic texts that are considered a challenge for ANLP researchers.

2.3.4.1.1. Sentiment Analysis Approaches

There are different approaches used for Sentiment Analysis; Lexicon-based approach for Sentiment Analysis in which lexicon is utilized, Machine learning approach for Sentiment Analysis, or in some cases, researchers utilized an approach that is a combination of both Lexicon-based approach and Machine Learning approach. In [7], the author mentioned that the Sentiment Analysis approaches are the Lexicon-based approach, machine

learning approach, and hybrid approach which is a mix of both approaches. In this literature review, the author targeted research papers that are published in the period from 2014 onward. The databases the author utilized are IEEE, Springer, ScienceDirect, ACM, and WorldCat. The keywords mentioned below have been used for collecting the research papers:

- "Arabic Dialects" and "Sentiment Analysis"
- "Arabic Dialects" and "Sentiment Analysis" and "approach"

The inclusion criteria for research papers:

- Must involve Sentiment Analysis experiment study
- Must be for Arabic Dialect texts only.
- Must be published in the period from 2014 onward.
- Research paper that is published in journal or conference.

Table 3 below presents a comparative summary between the different approaches that are used so far in recent researches and studies for Sentiment Analysis of Arabic Dialects.

Table 3: Approaches that are used so far in recent researches and studies for Sentiment Analysis of Arabic Dialects

Ref	Data size	Platform	Dialect type	Features	Approach		Performance			
							Accuracy	Precision	Recall	F-Measure
[38]	8000 tweets	Twitter	Arabic and mostly Egyptian	unigrams, bigrams and trigrams	Lexicon-based approach		0.665	0.485	0.845	N/A
					machine learning approach: Naive Bayes		0.7	0.47	0.35	N/A
[34]	BRAD 2.0 : 692586 annotated reviews	Arabic Book Reviews from www.goodreads.com	MSA and DA (Egyptian, Levantine, and Gulf)	unigrams and bigrams	Naive Bayes (NB)		87.14	N/A	N/A	N/A

* only best classification results in term of accuracy, recall, Precision, and F-measure are included in this table

2.3.4.1.2. Applications of Sentiment Analysis

Companies, Government authorities, institutions as well show great interest in Sentiment Analysis. In [64], the author explained in detail some of the most common applications of Sentiment Analysis. In the field of business, Sentiment Analysis can be utilized for consumer reviews analysis. Such implementations of Sentiment Analysis witnessed in Google Product search and Amazon websites. Moreover, Business owners and companies value the information retrieved from Sentiment Analysis as it would positively affect their production and help them apply required improvements. On the other hand, in the business field, Sentiment Analysis can be utilized for advertising and commerce online as well as for brand reputation. While in the political field, Sentiment Analysis can be used for monitoring public opinions about government practices and services provided. Sentiment Analysis can be utilized as well in the finance field to monitor financial situations and avoid financial risks. These are some of the applications in which Sentiment Analysis can be effectively used.

2.3.4.1.3. Sentiment Analysis of Arabic Dialect

Huge works for Sentiment Analysis have been conducted and targeted the English language, moreover, researches in the field of Sentiment Analysis for the Arabic Language are increasing as well. In [56], the author stated that limited works and researches have been conducted for Arabic Sentiment Analysis due to many reasons such as the morphological complexity nature of the Arabic Language, the requirement for pre-processing, feature representation, spam opinion elimination and handling the negation in Arabic language. The authors explained how the Arabic language has complex morphological nature such as words with different meanings that may have the same root. Sentiment Analysis for Arabic dialects has been addressed by several research papers. Below are some of the researches and studies that investigated Sentiment Analysis for Arabic Dialects. In [7], the author perform automatic extraction of opinions over social media that are written in MSA and Egyptian Dialects, Authors analyzed

Sentiment automatically into either positive or negative. In [50], the author successfully generated hybrid system that can be utilized for Sentiment Analysis for Arabic language. The developed system offered high accuracy and great performance as lexicon was generated from five datasets and it intelligently allows for an automatic update to include new words. In [65], the author utilized OCA freely available corpus and generated ARMD corpus, both are for movie reviews analysis. The authors utilized both supervised and unsupervised approaches for Sentiment Analysis, after that, the authors combined both approaches. The authors reported that the hybrid approach in which supervised and unsupervised methods are used offered the best results in terms of precision, recall, and F-measure. In [22], the author stated that the most common classifiers for Sentiment Analysis of Arabic language are Support Vector Machine and Naïve Bayes. Authors found that the hybrid approach for Sentiment Analysis presented the best results in terms of preciseness both at the document level and sentence level. In [1], the author proposed a rule-based stemmer that can be utilized for gulf dialects. The performance of the offered stemmer is better than other algorithms. The offered stemmer as well showed acceptable accuracy. In [38], the author presented valuable efforts in creating a web-based tool that can be utilized for Sentiment Analysis of Arabic text. The presented web-based tool was developed using the R language and it showed good performance in term of Accuracy. To perform Sentiment analysis for Arabic dialects, some important steps should be taken into consideration such as Pre-Processing and Feature Extraction.

2.3.4.1.3.1. Pre-Processing

Pre-processing is a critical step; sometimes it is referred to as normalization and it involves transforming the word into its standard form. In [38], the author define the pre-processing step as the process of cleaning data to reduce errors and improve Sentiment Analysis performance. In [34], the author mentioned that the pre-processing step for the dataset would allow classifiers to efficiently learned the dataset. In [16], the author stated that pre-processing is essential for Arabic Natural Language Processing

implementations such as sentiment analysis and summarization tasks. Authors explained that pre-processing for Dialectal Arabic involves the following steps: Tokenization, Remove Diacritics, remove non-Arabic words and letters, Remove Punctuations, replace Arabic Letters (أ,إ,آ), (ة), (ئ,ي) and (ؤ) with (ا), (ه), (ي) and (و) respectively. [56] as well described the pre-processing steps and mentioned that it involves Tokenization, non-Arabic words removal, Normalization, stop words removal, and light stemming. In [7], the author stated that the steps of pre-processing involve Tokenization which means text splitting into separated words, Normalization which involve return letters into the same form, all stop words are removed, and finally words stemming.

2.3.4.1.3.2. Feature Extraction

Sentiment Analysis involves text classification. The classification of texts requires the selection and extraction of text features. Features are the classifier's input. In [39], the author stated that feature selection is the process of extracting features that would affect the classification process. In [38], the author explained how features can be utilized for analyzing raw data. In [66], the author stated that features include part of Speech, frequency, opinion words, and negation. In [38], the author stated that the most common features utilized are N-grams which is frequency (terms presence) features, and the most commonly utilized type of N-grams is unigram followed by bigram and trigram. In [34], the author stated that bigram features consider two words, and these words most commonly come together. Authors mentioned as well that bigram tokens can be effectively utilized for negation detection for either MSA or AD as well. In [55], the author effectively extracted words n-grams and characters n-grams and utilized them as features for AD identification.

2.3.4.1.4. Machine Learning Approaches for Sentiment Analysis of Arabic Dialects

Machine Learning techniques have been widely used for Sentiment Analysis purposes for Many Languages. Machine Learning techniques as well have been used for Sentiment Analysis for the Arabic Language. In [22], the author stated that machine learning techniques can be used in sentiment analysis for Arabic text and SVM presented good performance when used for the sentiment analysis of Arabic texts. In [40], the author utilized Machine learning approaches for Sentiment Analysis for Arabic Dialects. The authors utilized different classifiers for Sentiment Classification of a labeled dataset and reported that PA and RR classifiers presented the best results in terms of accuracy, recall, F-measures, and precision. However, in [6] the author stated that the utilization of Deep Learning approaches recently for NLP tasks presented better performance and results. Table 3 above presents a comparative summary between the different approaches that are used so far in recent researches and studies for Sentiment Analysis of Arabic Dialects.

2.3.4.1.5. Sentiment Analysis for Arabic Dialects Challenges

In [22], the authors mentioned several challenges encountered while working with ANLP such as its complexity. Moreover, fewer works and researches have been done in the field of the Arabic Language compared to English language. In [10], the author presented how Dialectal Arabic does not have a standard orthographic written form. In [3], the author described how dialectal Arabic has no standard written form which results in a lack of NLP tools for Arabic Dialects. In [1]. the author mentioned challenges while working with Arabic dialects; Arabic dialects

have no standard written format, moreover Arabic Dialects have complicated morphological forms. In [7], the author agreed that the Arabic language has complex nature; for MSA each word has a root and the task of finding the root for words is not easy and may reduce the accuracy, moreover, the Dialectal Arabic represents the language of different regions, meaning that each Dialect has its collection of words and this would add further challenges to Dialectal Arabic processing and analyzing tasks. In [4], the author mentioned several challenges while dealing with the Arabic language, first, Diacritical may change the meaning of the same word, second, the negation in Arabic may be challenging compared to English language in which negation is presented mostly using the prefix, moreover, the use of dialectal Arabic may present spelling errors since there is no standard written form for Arabic dialects.

3. Conclusion

Social media attracts people all around the world. Due to the increased utilization of Social Media, a massive amount of written text is generated daily and considered as a valuable source of information that attracted business owners, companies, government institutions, and of course, it attracts researchers and data scientists as well. Natural Language Processing NLP is an important field of science that involves studying and analyzing Natural language texts. Increasing efforts were presented in investigating and analyzing the Modern Standard form of Arabic Language as well as the Arabic Dialects. This literature review aims to explore researches that involve constructing resources for Arabic Dialects and investigate approaches and methods used for Sentiment Analysis of Arabic Dialects text, focusing on machine learning approaches and Lexicon-based approaches.

A R T I C L E   I N F O

A B S T R A C T

The objective of this article is to determine if the self-perception of professional competences has been affected, in systems engineering students, during the health emergency declared in Peru by Covid-19; The results will allow the public university of Peru to make corrective decisions and formulate proposals to improve the functioning of the variable under study. Initially, the comparative analysis was carried out, where it is observed that in the academic semester 2020-I (during the health emergency), there is a greater number of students who present a better self-perception of the 10 indicators of the professional skills dimension, compared to the semester 2019-II (before the health emergency). Likewise, the indicators "To solve problems and cases of the specialty" and "To master practical professional skills" present a higher rate of improvement in self-perception, of 8.14% and 10.37%, respectively. Finally, when carrying out the statistically validation of the association of the two mentioned indicators, using the contingency table, it is observed, by the Chi-square statistic, a significance (bilateral) lower than α = 0.05, with this, it is verified , the significant association of the indicators; This is supported by the percentage obtained in the contingency table, where it is shown that 90.6% of the systems engineering students in the 2019-II semester and 95.5% of the students in the 2020-I semester , who are satisfied with the indicator "To master practical professional skills", have experienced a positive impact with the indicator "To solve problems and cases of the specialty".

1. Introduction

A commonly perceived scenario in many universities in Latin American countries is one in which students who graduate from their professional careers do not seem to be sufficiently prepared for the challenges that arise in real life; In this regard in [1], the author highlights that many students lack skills that allow them to take risks, organize and go beyond what they have learned in class.

That is why it is almost necessary for the model in which the teacher is the center of attention in a class, to be totally displaced. In this regard, in [2], the author states that emphasis should be placed on the figure of the teacher as a tutor or facilitator, and the center of attention in a class session should be on the student, on their ability to learn and learn by doing; hence, many universities have redefined the teaching objectives in terms of competencies.

In [3], the author points out that in the context of education in which we find ourselves, the great paradigm that students face is to move from traditional models in learning processes, towards more open models in which the student is part of their own learning process.

In this regard, in [4], the author points out that university higher education currently poses multiple challenges, among them: raising quality, relevance, equity, greater links with the community

*Corresponding Author: Teodoro Díaz-Leyva, Edif. R Dpto. 202 Sec.I A.M.C, Ventanilla, Lima, 982716223, isdiazl@hotmail.com

and emphasis on research; all this obtained from the competences that students are acquiring in their professional training period.

From a general perspective in relation to professional competences, in [5], the author affirms that when the professional competencies that a student must acquire to carry out a task are investigated, not only those inherent to knowledge are recreated, knowledge or particular practice, but those that are linked to thoughts; therefore, controlling the former will make the latter more efficient.

In relation to the aforementioned, in [6], the author establishes that a professional competence is the set of skills, attitudes and responsibilities that describe the learning outcomes of a subject or educational program, which enable the student to develop a professional activity.

In [7], the author points out that changes in the world of work, information management processes and knowledge production, ways of knowing and researching, characteristics of today's society, traversed by ICT (Technology of Information and Communication), permanently generate new training needs that the classroom and the university do not always seem to be able to satisfy.

In [8], the author points out that higher education institutions that are in charge of training systems engineering professionals must remain attentive to the reality of their environment and continually verify the profile of their graduates to be trained; since the contents based on technological tools are quite changeable over time.

Another outstanding contribution in relation to the competences in the training of students in systems engineering is indicated in [9], so that systems engineers are prepared to take on the challenges of the new knowledge society that they express in their mission, they must possess skills to transmit information, select the ideal medium, possess skills in the use of ICT, ability to select and classify information, among others.

In this regard in [10], the author specifies that in order for university students to have a positive perception in relation to the professional skills acquired during their university days, these must represent tools that allow them to effectively face the challenges that await them, giving significant contribution to society.

In [11], the author defines the university student's self-perception as the way in which he perceives himself within the educational process. Also in [12], the author points out that the university student's self-perception indicates how the student or students feel about themselves, how they see themselves in the field they are developing.

Perhaps all of the above is seen from a non-pandemic context, with classroom development in person, making use of laboratories or equipment installed at the University; However, today we are in the midst of a Covid-19 pandemic; In this regard in [13], the author points out that the unexpected expansion of Covid-19 has forced university classes to take place virtually or not in person in many countries, which at a certain point results in knowing whether through These platforms the student manages to develop the

professional competences, typical of the professional career of systems engineering.

In this sense, the objective of this article is to carry out a comparative analysis of the variation of the self-perception of students of the systems engineering professional career of the academic semesters before (2019-II) and after (2020-I) the declared health emergency in Peru due to Covid-19. In addition, to identify which were the indicators that make up the self-perception variable that have experienced a greater impact on their satisfaction; whose association validation will be carried out through contingency tables.

2. Investigation methodology

2.1. Research design

The design is non-experimental, of a cross-sectional type, because the variable is studied simultaneously in a single year, in a single time, in which the survey of students from the 7th to the 10th cycle the Public University of Peru. The diagram that presents the cross-sectional design under study is as follows. It should be noted that the data collection period is carried out at different times, and at different samples, because the number of students surveyed is not the same in the 2019-II semester, as in the 2020-I semester.

Figure 1: Research design

where:

M1 and M2, represent the systems engineering students of the academic semester 2019-II and academic semester 2020-I, respectively

T1 and T2, represent the data collection period, both in the academic semester 2019-II, and in the academic semester 2020-I

O1 and O2, represents the observation made of the self-perception of the professional competencies of systems engineering students, both in the 2019-II semester and in the 2020-I semester.

2.2. Research level

The research level is descriptive, because the variables are not altered, and what is intended to be highlighted are the aspects related to the variation of the self-perception of those of the professional competences established in Public University located in Peru satisfaction survey, which was validated in [14].

2.3. Population and sample

The population is made up of students from the 7th to the 10th cycle Public University, in both the 2019-II and 2020-I semesters; Likewise, the sample is made up of all students, these being 149 and 140, students respectively; because there is no equality in the number of students per semester, the sample is not the same; It

should be noted that, as it is the mandatory survey at Public University of Peru, it has been carried out on all students.

2.4. Data Collection Technique and Instrument

The data collection, as indicated in [15], it is carried out by applying the instrument, using various techniques or tools, for this case the survey technique is used and the instrument is the questionnaire, 6 dimensions are established (professional competencies, teaching staff, library services, administrative services of the faculty and professional school, university support service and personal and social attitudes), which will identify student satisfaction in the education Public University of Peru. In this research, the dimension "professional competences" has been chosen.

Data collection, as indicated in [16], is a selective process since it cannot be all-encompassing; Given the aforementioned, it is established that the sample is composed of students from the 7th to the 10th cycle Public University of Peru both in the 2019-II and 2020-I semester; Regarding this, in [17] it is pointed out that the results are more valid when the survey is applied to students in the last cycles, because they are more aware of the understanding of the competences they must acquire.

Likewise, the data collected were processed and transformed, initially using the scale of attitudes and opinions, known as the Likert scale; Since the questionnaire has two self-perception options to choose from, these being unsatisfied and satisfied, each one was valued with the numeral 1 and 2, respectively.

To carry out the data analysis, initially the validation test of the data collection instrument will be carried out by means of the SPSS software, then the comparative analysis of the results will be carried out using the Microsoft Excel software, finally, to carry out the validation of the data. association of the indicators, the contingency table that indicates the Chi-Square value will be used, this test is performed with the SPSS software.

3. Results of the Investigation

3.1. Validation of the data collection instrument

There are various models of reliability, for this research we will use Cronbach's Alpha, as indicated in [18], this model is based on the correlation between the study variables, through this test, it will be demonstrated statistically by means of the software IBM SPSS V25, that the data collection instrument, which is applied is reliable. This test has established the following criteria:

- 0.9 - 1 = The measuring instrument is excellent
- Between 0.89 - 0.8 = The measuring instrument is very good
- Between 0.79 - 0.7 = The measuring instrument is acceptable
- Between 0.69 - 0.6 = The measuring instrument is weak
- Between 0.59 - 0.5 = The measuring instrument is poor
- <0.5 = The measuring instrument is not acceptable

Table 1: Reliability Analysis

Reliability statistics	
Cronbach's alpha	N of elements
.894	20

As can be seen in table 1, the Cronbach's Alpha coefficient is equal to 0.894, this means that the data collection instrument is very good, therefore, its use and the data collected are reliable. It should be noted that the number of elements equal to 20 corresponds to the 10 indicators of the "professional competences" dimension, both for the 2019-II and 2020-I semesters.

3.2. Comparing indicators that are part of professional skills

At this point, the results that respond to the objective of this article are shown, which is to perform a comparative analysis of the variation of the self-perception of students of the systems engineering professional career of the academic semesters before (2019-II) and after (2020-I) of the health emergency declared in Peru by Covid-19.

Initially, in figure 2, the results of the self-perception of the professional competences dimension and its 10 indicators are presented; These results belong to the 149 systems engineering students from the 2019-II academic semester, before the health emergency declared in Peru by Covid-19, and when the classes were held in person.
Figure 2: Self-perception of students in the academic semester 2019-II

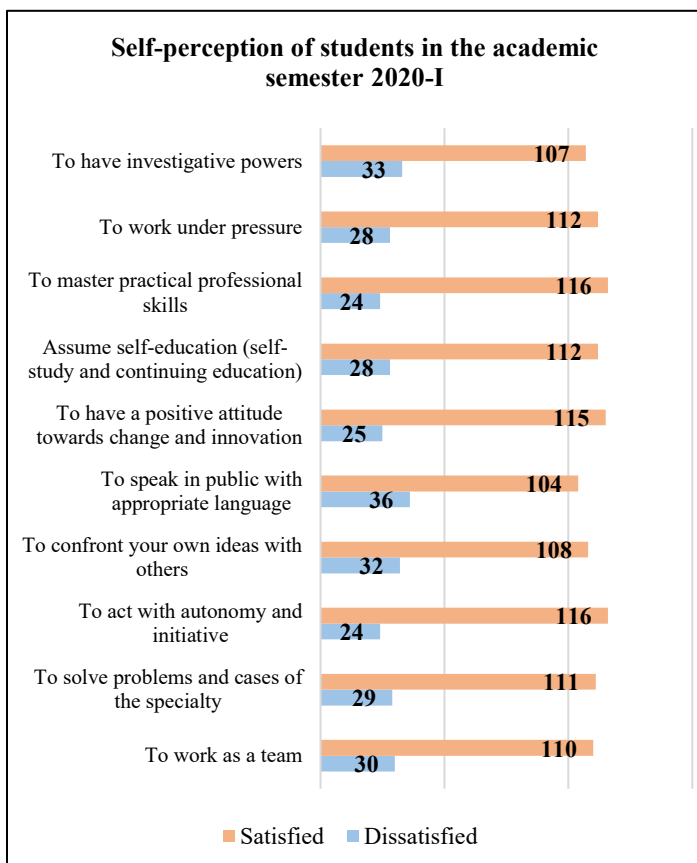
Next, in the following figure 3, the results of the self-perception of the professional competences dimension and its 10 indicators are presented; These results belong to the 140 systems engineering students of the 2020-I academic semester, during the health emergency declared in Peru by the Covid-19, and when the classes were held virtually or not in person.


Figure 3: Self-perception of students in the academic semester 2019-II

Table 2: Percentage of variation of the variable self-perception of professional competences

		To solve problems and cases of the specialty	To master practical professional skills
2019 - II	Satisfied	102	107
	% Satisfied	71.14%	72.48%
2020-I	Satisfied	111	116
	% Satisfied	79.29%	82.86%
% OF VARIATION		8.14%	10.37%

Figure 4 shows the increase in these two indicators.
Figure 4: Indicators with the greatest increase in satisfaction (2019-II - 2020-I)

As shown in the results obtained (figure 2 and 3) in the systems engineering career, in the 2020-I semester, there is a greater number of students who present a better self-perception of the 10 indicators of the professional competences dimension, compared to the academic semester 2019-II, where there was no health emergency declared in Peru by Covid-19, and classes were held in person.

3.3. Identifying the two indicators with the highest increase post Covid-19 pandemic

Continuing with the research, and once the number of students with a better self-perception of the professional competences dimension has been determined in the comparative analysis, both in the academic semester 2019-II and in the semester 2020-I; Through the results obtained, we proceed to identify the indicators that make up the professional competences variable, which have experienced a greater increase in satisfaction, post-Covid-19 pandemic. These results are shown in Table 2.

Table 2 shows that, in the systems engineering career, in the 2020-I semester, during the Covid-19 pandemic, students have experienced a greater impact of the satisfaction of the indicators "To solve problems and cases of the specialty" and "To master practical professional skills"; As can be seen, the satisfaction index for these two indicators has improved by 8.14% and 10.37%, respectively. It should be noted that this test counts the number of students who coincide with the perception of satisfaction of the indicators, therefore, the total sample is not reached.

3.4. Analysis of indicators through contingency table

Once the results are obtained, at this point the statistical validation of the association between the two indicators with the greatest increase in satisfaction in the systems engineering career is carried out, during the Covid-19 pandemic; These indicators are "To solve problems and cases of the specialty" and "To master practical professional skills".

This validation is carried out using the IBM SPSS V25 statistical software, in which the contingency table tool will be used.

It should be noted that the contingency table is used to validate an association between two variables, and thus, to test the hypothesis. In this sense, once the indicators with the greatest increase in satisfaction after the Covid-19 pandemic have been identified, the null (Ho) and alternative (Ha) hypotheses of the research are established.

Ho: Mastering practical professional skills does not allow problem solving and specialty cases in systems engineering students.

Ha: Mastering practical professional skills allows students to solve problems and specialty cases in systems engineering.

Table 3 shows the validation results of the association of the indicators in the 2019-II semester.

Table 3: Contingency table of the association of the indicators with the greatest increase in satisfaction in the 2019-II semester

	Value	gl	Significance (bilateral)
Pearson's Chi-square	60.217	1	.000
Likelihood ratio	57.117	1	.000
N of valid cases	149		

Likewise, table 4 shows the validation results of the association of the indicators in the 2020-I semester.

Table 4: Contingency table of the association of the indicators with the greatest increase in satisfaction in the 2020-I semester

	Value	gl	Significance (bilateral)
Pearson's Chi-square	60.259	1	.000
Likelihood ratio	50.145	1	.000
N of valid cases	140		

As can be seen in Table 3 and 4, the value of the Chi-square statistic is 60.217 and 60.259, respectively, and the likelihood ratio 57.117 and 50.145, as established by different authors, if these values differ significantly from 5 for levels of significance greater than 0.05, it is stated that there is an association. Likewise, the significance (bilateral) of Chi-square is less than $\alpha = 0.05$, due to this, the null hypothesis is rejected, thereby accepting the alternative hypothesis.

As the value of p is less than 0.05, it is shown that there is a significant association between the two indicators; Therefore, table 5 shows the percentage of satisfaction between the association of the analyzed indicators, for the 2019-II semester.

Table 5: Contingency table of the percentage of satisfaction among the indicators with the greatest increase in satisfaction in the 2019-II semester

Contingency table			
% within to solve problems and cases of the specialty			
		To master practical professional skills		Total
		Dissatisfied	Satisfied	
To solve problems and cases of the specialty	Dissatisfied	72.1%	27.9%	100.0%
	Satisfied	9.4%	90.6%	100.0%
Total		27.5%	72.5%	100.0%

In the same way, supporting the result, Table 6 shows the percentage of satisfaction between the association of the analyzed indicators, for the 2020-I semester.

Table 6: Contingency table of the percentage of satisfaction among the indicators with the greatest increase in satisfaction in the 2020-I semester

Contingency table			
% within to solve problems and cases of the specialty			
		To master practical professional skills		Total
		Dissatisfied	Satisfied	
To solve problems and cases of the specialty	Dissatisfied	65.5%	34.5%	100.0%
	Satisfied	4.5%	95.5%	100.0%
Total		17.1%	82.9%	100.0%

As shown in table 5 and 6, 90.6% and 95.5% of systems engineering students who are satisfied with the indicator "To master practical professional skills", have experienced a positive impact with the indicator " To solve problems and cases of the specialty".

Through these results, it can be stated that there is a significant association between the indicators; establishing that students of systems engineering by mastering practical professional skills, can solve problems and cases of the specialty.

4. Discussion of results

It is important to indicate that the systems engineering career was chosen, for the present investigation why in the context of the pandemic it was sought to determine the impact, on student satisfaction, with respect to the dimension of self-perception of acquired competences, taking into account that the development of it, lies in its vast majority in the use of a PC.

Given the development of the research, it was obtained that, in the systems engineering career, in the 2020-I semester, during the Covid-19 pandemic, there is a greater number of students who present, a better satisfaction of the 10 indicators of the professional competences dimension, compared to the academic semester 2019-II; This is supported by the fact that, in the face-to-face classes, it was evident that the laboratories were deficient in terms of the number of computers per student, therefore, the practical learning of the subjects was not the most efficient, while in the context After the pandemic, each student uses their own PC at home, thus achieving greater use of the software used.

What is described in the previous paragraph reaffirms the following result, which reveals that, in the systems engineering career, in the 2020-I semester, during the Covid-19 pandemic, students have experienced a greater impact of the satisfaction of the indicators "To solve problems and cases of the specialty" and "To master practical professional skills"; As can be seen in table 2, the satisfaction index for these two indicators has improved by 8.14% and by 10.37%.

In relation to the indicators obtained, in [19], it is pointed out that to obtain an ideal professional performance, the specialty problems that are most often presented to the student must be taken into account, as well as the contents and tools that are counted for the development of the subjects; the correct handling of it must be visualized in the integration of knowledge that allows the student

to solve professional problems according to their rigor and complexity; Likewise, the academic organization provided by the educational institution in relation to the environment with which the professional counts for its development, allows the teacher to efficiently carry out his evaluation of said professional competencies.

Due to the (bilateral) significance of Chi-square is less than α = 0.05, it can be verified statistically that there is a significant association between the analyzed indicators, with this it can be affirmed that systems engineering students have mastered practical professional skills, can solve specialty problems and cases. Regarding this, in [20] it is indicated that universities must integrate in their academic decisions, plans that allow keeping the contents taught in classrooms up to date, as well as tools for their development, in order to keep up with what the labor market dictates; For example, the student by learning properly, the programming languages most used for the design of solution software or tools mostly used in communication networks of companies, will be able to solve problems and cases of the specialty, thus managing to face the problem. working market.

Reaffirming everything described, the results expressed in the contingency table indicate that 90.6% of the systems engineering students in the academic semester 2019-II and 95.5% of the students in the 2020-I semester, who are satisfied with the indicator "To master practical professional skills", have experienced a positive impact with the indicator "To solve problems and cases of the specialty".

5. Conclusions

When carrying out the comparative analysis of the variation in the self-perception of students of the systems engineering career of the academic semesters before (2019-II) and after (2020-I) of the health emergency declared in Peru by Covid-19 , it is concluded that in the systems engineering career, in the 2020-I semester, there is a greater number of students who present a better satisfaction of the 10 indicators of the professional competencies dimension, compared to the 2019-II academic semester.

When carrying out the identification of the indicators that make up the self-perception variable, which have experienced a greater impact on their satisfaction, it is concluded that the indicators "To solve problems and cases of the specialty" and "To master practical professional skills" present a higher index improvement in satisfaction, of 8.14% and 10.37%, respectively.

When carrying out the validation of the association of the indicators that have experienced a greater impact on their satisfaction, through contingency tables, it is concluded that 95.5% of the students who are satisfied with the indicator "To master professional skills practices", have experienced a positive impact with the indicator "To solve problems and cases of the specialty". Likewise, the Chi-square statistic gives us a (bilateral) significance lower than α = 0.05, due to this, the significant association of the indicators is statistically verified, stating that systems engineering students by mastering practical professional skills they can solve specialty problems and cases.

Conflict of Interest

The authors declare no conflict of interest.

ARTICLE INFO	ABSTRACT
	In vital energy applications especially the agricultural environments, the service of adaptive power utilization plays an essential role in facilitating the usage of Internet of Things systems. Such environments are distinguished by the large range of lands where most of the region lacks the commercial power lines. Reaching some high or deep sensing points is also difficult in such environments. The adaptive power system will pave the way to make a smart service for users to create a platform for real time interaction. It can enhance the reliability, stability and sustainability of power supply, and provide more humanized and various intelligent services for the users. The usage of adaptive power can be improved effectively using IoT technology with its strong data processing and reliable communication. In this paper, an algorithm is proposed to offer a sustainable power service for smart agriculture system to guarantee continuous system operation. It mainly rely on controlling the load demands and managing the renewable energy. A model is built on Matlab that governs the proposed algorithm and the results of the simulation are discussed.

1. Introduction

This paper is an extension of work originally presented in 15th International Computer Engineering Conference (ICENCO) [1]. The food demand increased due to the huge growth in population so it is essential to increase the food production and try to avoid any production losses. Agriculture has a major impact on food production so monitoring the plants' performance is very important. In order to avoid any crop losses, agro systems were designed. Remote sensors were used in these systems to measure light, humidity, soil moisture and temperature. The measured data will indicate whether the plants' performance is good or not and the data will be collected and sent to the user for further action[2, 3]. IoT is a new technology that is used recently in most of the smart systems. Using IoT technology in agro systems allow the plants to express its needs only when it is needed which will allow the efficient usage of resources. There are some challenges that appears in IoT systems, energy optimization is one of the main challenges that faces IoT. It is a major challenge due to the high number of devices that exist in the network which need high

energy to keep it active for long time. It is essential to study this challenge as wireless sensors are commonly used in precision agriculture in remote areas and the agro systems depend mainly on sensors' power so battery drainage will cause the system to stop which isn't desired [4, 5].

The life time of sensor nodes needs to be long in order for the network to be active and to avoid battery drainage. In this paper, an energy management technique based on intelligent load scheduling is introduced for agro-applications. The battery state of charging and the solar power are the main parameters used in the proposed algorithm to activate or deactivate the loads. Based on the loads' priority and the availability of power provided by the battery or solar, loads are activated for specific time. The loads' priority is standard defined as the applications that need to be operating due to criticality are defined based on the standards of agro.

2. Literature Review

Researchers have implemented and introduced some systems using various methods and sensors to monitor the status of plants' health. It improved the agricultural production and helped in

preventing crop losses. In [6], the author illustrated the demonstration of a smart plant monitoring system. The system was enabled to discover any changes occurred in the measurements of light, moisture level and temperature. The plant received its required irrigation and illumination using a machine based curation. An Android device was used by the user in order to enable the user to override an operation which is a machine curated and in this case it is shifted to user based curation instead of machine based curation. In [7], the author explained a system that uses IoT technology in order to control and monitor an agricultural production. The sensors' data was gathered in the monitoring system from IoT devices and then stored at the database of the cloud in order to be accessible by the users. The users could control the actuators in the controlling system over the internet with the usage of IoT devices.

The main source of power for the systems presented previously is the sensors' batteries so systems that uses energy efficiently are studied. Energy plays a significant role in monitoring the environment of agriculture. Researchers presented various algorithms which assure the efficient usage of energy using energy harvesting, load scheduling and power reduction techniques. In [8], the author presented a method used in wireless sensor network for managing power efficiently. The system model consisted of three parts: sensing unit, transmitter unit , and power unit. Energy harvesting was used in the power unit as the power source used for charging the battery is the solar energy. Sending and collecting the data was the responsibility of the other two units. The microcontroller is utilized to monitor the sensed signal and if any disorder detected, it would be transmitted to the receiver.

In [9], the author concentrated on elongating the sensor nodes' life time by minimizing the consumption of energy. A solar cell was utilized to power the system to assure energy sustainability. The minimization of power consumption was achieved by proposing two methods of power reduction. Sleep/wake based on duty cycling was utilized and the second method was integrating the redundant data of the soil moisture with sleep/wake scheme. This research introduced the Sleep/wake on redundant data (SWORD).

In [10], the author presented an algorithm based on devices scheduling in order to optimize and reduce the electricity cost. Two methods were tested for load scheduling optimization either without the usage of renewable energy or with the usage of it. The results of the implementation showed that the cost is reduced up to 53% when combining the proposed algorithm with renewable energy and in case no renewable energy is combined with the algorithm, the cost is reduced up to 40%.

In [11], the author illustrated an algorithm that depends on electricity cost changes and renewable sources real time output in order to schedule the loads. The scheduling and management of energy was established according to the exchange of sensor data and control demands. It would update the real time output of the renewable sources and determine the devices' priority. After the sensed data was received, the energy management unit in the system updated the devices' priority status and the output of renewable sources. The energy management unit would transfer the devices to on or off status if required depending on the energy management and devices scheduling.

In [12], the author discussed various ways to utilize renewable energy in order to assure the efficient usage of energy, ,cost reduction, and handling loads. The scheduling of loads in the used algorithm was depending on time and overload management using multilevel priority. Based on the need of load scheduling during peak demand hour, a duration of time was determined. The loads with medium and high priorities would be activated during this time and the load with low priority would be deactivated. All load would be deactivated in case the limit was exceeded.

3. Proposed Architecture for Energy Efficient Agro Systems

As shown in Figure 1, the proposed architecture consists of four sensors: light sensor, color sensor, soil moisture sensor and temperature/humidity sensor. The proposed architecture is used for monitoring plants' performance in agro systems. The data measured by the soil moisture sensor and temperature/humidity sensor will be sent to Central Processing Server (CPS) to decide the proper time for irrigation after comparing it with the threshold values. Regarding the other two sensors, the user will take the action required based on the received data that were measured by these sensors in case there were any up normal values detected at the CPS. The goal is to ensure the continuous operation of this system by using energy efficiently to increase the life time of the system. Figure 2 shows a proposed architecture for sensor area network (SAN1) using energy efficient technique. It depends mainly on two parts:

3.1. Solar panel or battery used as a power source

- The source of power during day is the solar panel. It is used for supplying the loads during day as it is working and the power needed by the loads is available. Some loads will be switched off in case that the solar power isn't enough for suppling all loads and the rest will be on depending on the available solar power.

- The source of power during night is the battery. The active loads will be supplied by the battery and some loads will be off during night as these loads will not highly affect the system's operation.

3.2. The loads (sensors and actuators) which are divided into categories according to priority.

- Load 1 (High priority): the high priority loads highly affect the system's operation. This load must be on most of the time so the deactivation will be during night only in case that the state of charging of the battery is less than the threshold value.

- Load 2 (Medium priority): if the power is enough for supplying medium and high priority loads, this load will be active. It will be deactivated when the power isn't enough to supply all loads and this will occur mostly during night.

- Load 3 (Low priority): it doesn't have a huge impact on the system's operation so it can be deactivated during night. The user can activate this load upon his request if needed during night after checking the battery state of charging if it is within threshold values or not.

The soil moisture sensor is considered a high priority load due to its high criticality in precise agriculture applications as stated in

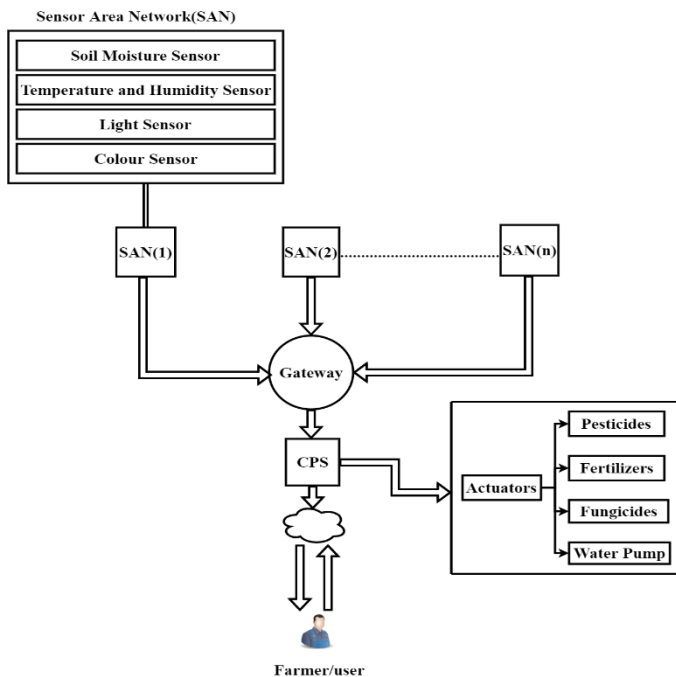
[13] .The soil moisture sensor is used in the proposed system to change the concept of scheduled irrigation to be on demand irrigation as its measured values help in deciding whether plants needs to be watered or not and based on these values irrigation takes place .The light sensor is considered a medium priority load in the proposed system due to its medium criticality as it needs to be active at specific time as it is used in the proposed algorithm to indicate whether the weather is sunny or cloudy and to indicate also whether it is day or night. Accordingly, the algorithm will switch to the power source that can be used in the current situation to supply the loads. The water quality sensor is considered a low priority load as irrigation is applied mostly during day so there is no need to schedule it to work during night but in the proposed algorithm it can be activated during night if needed upon the user request.


Figure 1: Architecture for Monitoring Agro Systems
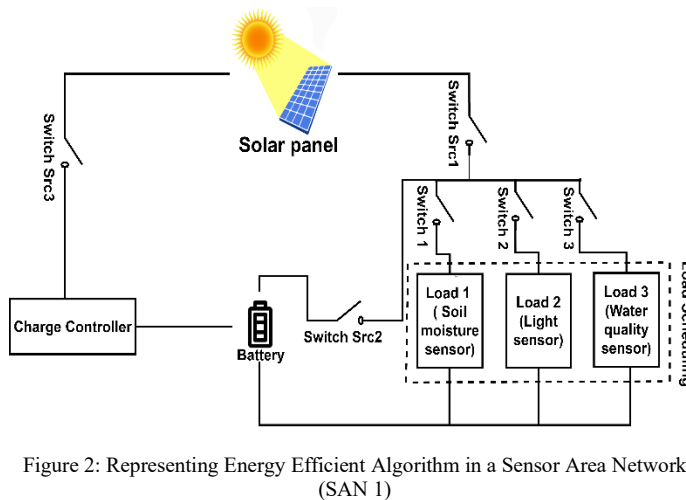

Figure 2: Representing Energy Efficient Algorithm in a Sensor Area Network (SAN 1)

4. Proposed Energy Efficient Algorithm

The proposed algorithm uses energy efficiently in agricultural applications to elongate the sensor nodes life time. The agro

devices' dormant mode will be synchronized and controlled by the proposed algorithm based on the change of day/night. This algorithm doesn't depend on the marketable power supplies so it will guarantee a sustainable environment. The battery drainage issue will be solved to some extent which will enable a sustainable power system. The proposed energy efficient algorithm is dependent on the load scheduling technique and solar energy. There are two other methods for powering the system either by using battery only or by using battery along with load scheduling.

The proposed algorithm is compared with these two methods. In the first method as shown in Figure 3, there is no enough power for supplying the loads as they are active for only five consecutive hours. In the second method, load scheduling technique is used which saves more power therefore the loads are active for longer time as shown in Figure 3. However. The problem of battery drainage still exists and the battery needs to be replaced but it is not easy to replace it in agro-applications. Replacing the battery is not necessary in the proposed algorithm as the solar panel is used during day to recharge the battery. The loads are supplied by the battery only during night. The solar panel is used to supply the loads during day therefore the battery state of charging is maintained for longer time in the proposed algorithm as shown in Figure 3. As a result of using the proposed algorithm, the life time of the sensor nodes is increased due to the increase of the battery life time.
Figure 3: State of Charging versus Day/Night for The Two Power Methods Compared with The Proposed Algorithm.

The two main parameters used in the proposed algorithm are the availability of power and the criticality index of the load. The first parameter is represented as solar irradiance or State of Charging (SoC) of the battery. The second parameter indicates whether the load is critical or not to operate in the non-scheduled time. Based on these two main parameters, the agricultural ecosystems loads are transferred to on or off state. Intelligent load Scheduling and solar power are combined in this algorithm to efficiently implement the system using IoT.

Figure 4 represents a flow chart for a combined energy efficient technique using intelligent load scheduling and solar energy. The algorithm initially checks the capacity of solar power during day to decide whether to activate or deactivate the load. It is proven in the simulation that the idle duration varies based on the availability of solar power. For example, when the solar irradiance is reduced from 1000 W/m^2 to 500 W/m^2, the idle duration is increased by Δt. The battery is the source of power during night and it takes the lead in the absence of the sun to supply all the needed loads.

The loads are transferred to on or off state based on their criticality index as the loads are classified according to priority. The loads with high and medium priority are activated if SoC of battery is more than or equal to 75% and the unnecessary loads are deactivated. According to the availability of power, the loads' idle time is tuned and calculated. By time, the idle duration increases as a function of the battery drainage. If SoC is below 40%, the load with high priority is activated and the load with medium priority is deactivated and the idle duration increases based on the drainage rate of the battery. The inactive loads can be transferred to on state if needed during night based on user request.

The idle duration levels during day and night are shown in Table 1. The first level is selected during day as it is devoted for the dynamic solar irradiance scenario in which it varies during day hours from 100 W/m^2 to 1000 W/m^2. The other levels are devoted for the battery SoC variations. According to the availability of power, the idle duration for each load changes by Δt. Table 1 shows different scenarios where the idle duration level for each load changes by Δt and according to this change, the power gain is calculated for each load. The power gain shows the state of the consumed power at the current level compared to the previous level. As shown in Figure 5, the power gain increases as the Δt increases.

Figure 4: The Flow Chart Illustrates That the Decision of Activating or Deactivating the Loads is Taken After Checking State of Charging (SoC) of The Battery and the Availability of Light.

Table 1: Representing the Power Gain and The Changes in Idle Time for Different Scenarios

Level	Scenario	Load Priority	Active Hours	Δt (Hours)	Power Gain (dBm)
1	Dynamic Irradiance	High	11	10	46.48
		Medium	5	5	45.22
		Low	4	4	44.25
2	100%	High	12	1	36.47
		Medium	6	1	38.23
		Low	0	4	44.25
3	≥75%	High	10	2	39.48
		Medium	4	2	41.25
		Low	0	0	0
4	≥50%	High	6	4	42.49
		Medium	2	2	41.25
		Low	0	0	0
5	≥40 %	High	4	2	39.48
		Medium	1	1	38.23
		Low	0	0	0
6	<40 %	High	1	3	41.25
		Medium	0	1	38.23
		Low	0	0	0

Figure 5: Power Gain versus The Change in Idle Time (Δt) for The Three Loads

It is very essential to choose the optimum sleep time (T_s) that will not affect the system operation. There are three significant parameters that must be taken into consideration while choosing T_s, State of Charging (SoC), Load current (I_L), and Load index (η). The load index (η) ranges from 0.1 to 1. The value 1 indicates high priority, 0.5 indicates medium priority and 0.1 indicates low priority. The SoC is the difference between the battery rated capacity (C_{rated}) and the used capacity by loads (C_{used}) divided by the battery rated capacity. SoC can be calculated using (2):

$$T_s = fn(SoC, I_L, \eta) \tag{1}$$

$$SoC = \frac{C_{rated} - C_{used}}{C_{rated}} \times 100 \tag{2}$$

Figure 6 represents the charging stage of the battery which shows that the battery state of charging is increasing with time. As a result the sleep duration for the loads is decreasing due to the increase of the amount of power available in the battery. Therefore the sleep duration is inversely proportional to the SoC as shown in Figure 7. Figure 8 shows that the increase in load current results in a decrease in the battery state of charging.
Figure 6: SoC Represented in a Charging Stage versus Time
Figure 7: Sleep Duration versus Time
Figure 8: State of Charging at Different Load Currents versus Time

The active duration for each load depends on the maximum current consumed by the loads (I_{Lmax}), the current consumed by load 1 (I_{L1}) and the load index (η). Equation (3) is used to calculate the active duration for each load then calculate the sleep duration using (4). The active and sleep durations for the three loads are shown in Figure 9 and 10. Figure 11 represents the sleep duration for each load versus the battery SoC.

$$T_a = \frac{I_{Lmax} \times 60 \times \eta}{2 \times I_{L1}} \tag{3}$$

$$T_s = 60 - T_a \tag{4}$$

c
Figure 12: Energy Consumed by Each Load versus Sleep duration for Each Load

1034

The energy consumed by each load for a uniform sleep duration depends on the power consumed by the load (P), the operating time (T_o), Sleep time for each load (T_s) and the number of sleep durations (n). The energy consumed by each load is calculated using (5). As shown in Figure 12, the energy consumed by each load decreases by increasing the sleep duration.

$$E = P \times T_o - P \times T_s \times n \qquad (5)$$

5. Simulation Model Results

An agro environment is simulated on a Matlab Model that is designed using one node consisting of battery, three loads and solar panel. The designed model is used to test the algorithm by testing it at different scenarios that are shown in Tables 2 and 3. The solar irradiance and the state of charging must be checked first to enable the model to select the optimal scenario based on these two parameters. This scenario selection will guarantee the efficient use of energy which will increase the battery life time. The current and power of the solar panel is affected by solar irradiance so a decrease in solar irradiance causes a decrease in the current and power as shown in Figure 13. Low solar irradiance occurs as a result of the small amount of solar energy absorbed by the solar panel which results in a decrease in power and current. Due to the change in climatic conditions as shown in Table 2, solar irradiance changes. The solar power is affected by these changes and it will have an effect during day on deciding whether to switch loads on or off.
Figure 13: Power and Current at Different Solar Irradiances

Table 2 and 3 show the different scenarios that are designed depending on the battery state of charging and the changes in solar irradiance during day. The loads are activated or deactivated based on the availability of energy provided by battery or solar panel. High priority load is represented as load 1, medium priority load is represented as load 2 and low priority load is represented as load 3. Table 2 shows the four scenarios that are used usually during night. These scenarios are designed depending on the state of charging of the battery. During night, load 1 and load 2 are active for specific hours based on priority while load 3 is deactivated.

Table 2: Represents Different Scenarios of Load Scheduling During Night

Scenario #	Scenario Description	SoC (%)	hrs	Load Scheduling Scenarios		Load Active hours (hrs)
				Priority	Status	
1		100	12	High	On	12
	Fully charged			Medium	On	6
				Low	Off	0
2	Partially charged	75	12	High	On	10
				Medium	On	4
				Low	Off	0
3	Half charged	50	12	High	On	6
				Medium	On	2
				Low	Off	0
4	Battery draining	<40		High	On	1
				Medium	Off	0
				Low	Off	0

Figure 14 shows the battery state of charging as it decreases with time. It is essential to monitor the battery state in order to select the best scenario for supplying loads during night based on amount of power remained.
Figure 14: Battery State of Charging versus Time

The solar irradiance is divided into two types static and dynamic. Static solar irradiance is represented in the first three scenarios that are shown in Table 3. These scenarios are designed for various cases that might occur during day in case of static solar irradiance. The duration is constant for the first three scenarios as it is estimated to be 12 hours.

In case the solar irradiance is dynamic during day, this is represented in the fourth scenario shown in Table 3. Scenario 4 is designed due to the change of solar irradiance during day hours. The values of solar irradiance in the previous scenarios might happen in one scenario at different hours. The first scenario in Table 2 and the fourth scenario in Table 3 are simulated and shown in Figure 16 and 17.

Figure 15 shows the changes in solar irradiance during day while during night the loads are supplied by the battery. These variations have an effect on solar power provided to the loads which will decide the status of the load.
Figure 15: Solar Irradiance versus Day /Night

Table 3: Represents Different Scenarios of Load Scheduling During Day

Scenario #	Scenario Description	Climatic Conditions	Solar Irradiance	hrs	Load Scheduling Scenarios		Load Active hours (hrs)
					Priority	Status	
1	Static Irradiance	Direct sunlight	1000 W/m2	12	High	On	12
					Medium	On	10
					Low	On	8
2	Static Irradiance	Cloudy sunlight	500 W/m2	12	High	On	6
					Medium	On	4
					Low	On	2
3	Static Irradiance	Very cloudy	100 W/m2	12	Powered by Battery Only		
4	Dynamic Irradiance	Clear direct sunlight	1000 W/m2	6	High	On	6
					Medium	On	3
					Low	On	3
		Cloudy sunlight	500 W/m2	5	High	On	5
					Medium	On	2
					Low	On	1
		Very cloudy	100 W/m2	3	Powered by Battery Only		

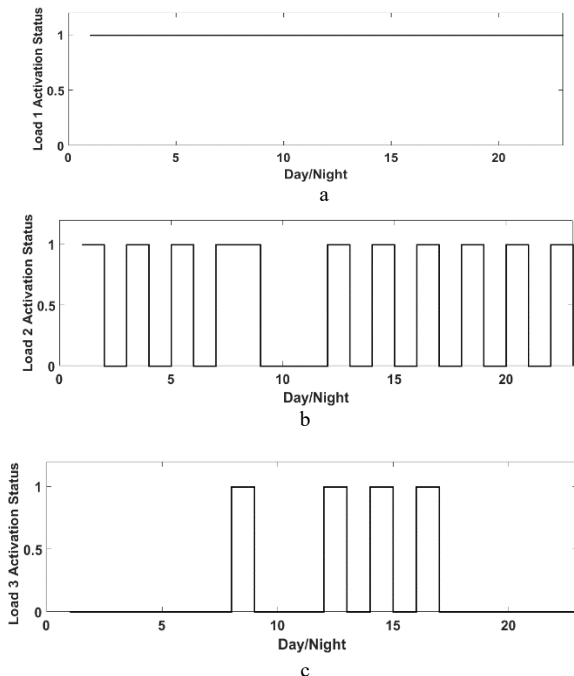
The loads' status shown in Figure 16 has an effect on its total consumed energy as it changes due to the change in loads' status during day and night. The compensation factor (CF) is shown in Figure 22 as it is calculated for the eight scenarios. It is defined as the ratio between the loads' consumed energy and the energy supplied. During day hours, the solar irradiance changes and at noon, it reaches the maximum point. The solar power at the maximum point will be enough to supply all the loads as shown in Table 3 for specific hours.


Figure 16: Loads (On/Off Status) versus Day/Night (Scenario 1 in Table 2 and Scenario 4 in Table 3)

Figure 16(a) shows the status of load 1 during day and night. During day hours, load 1 is supplied by solar and in this case the load is active. While during night, it is supplied by the battery.

Figure 16(b) shows the status of load 2, it is activated during day for only 5 hours. Load 2 is activated during night for 6 hours. Figure 16(c) shows the status of load 3, it is activated during day for only 4 hours and it is deactivated at night.

The calculation of load's consumed energy is according to the status of loads shown in Figure 16. The supplied energy either by solar or battery is efficiently consumed using the load scheduling scenarios to provide a sustainable system as shown in Figure 17.
Figure 17: Total Energy Consumed versus Day/Night (Scenario 1 in Table 2 and Scenario 4 in Table 3)

Scenario 2 in Table 2 along with scenario 4 in Table 3 are tested and shown in Figure 18 and 19. Figure 18 shows the loads on/off status during day and night. The total consumed energy by the loads is calculated based on the status of loads as shown in Figure 19.

Figure 18(a) shows that during day hours, load 1 is activated as the power is provided by solar in this case while at night, the load

is still activated and supplied by the battery. Figure 18(b) shows that during day, load 2 is activated for only 5 hours and it is activated for 4 hours at night. Figure 18(c) shows that during day, load 3 is activated for only 4 hours but at night it is deactivated.

a

b

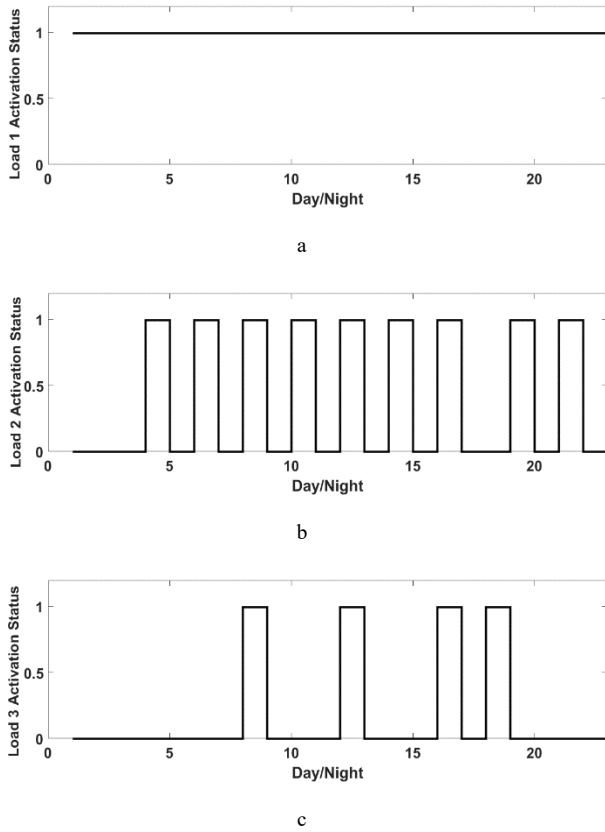
c


Figure 18: Loads (On/Off Status) versus Day/Night (Scenario 2 in Table 2 and Scenario 4 in Table 3)

The efficient usage of energy during day and night will provide a sustainable system. The total consumed energy by the loads during day and night in accordance to the loads' status is shown in Figure 19.
Figure 19: Total Energy Consumed versus Day/Night (Scenario 2 in Table 2 and Scenario 4 in Table 3)

Scenario 3 in Table 2 along with scenario 4 in Table 3 are simulated and represented in Figure 20 and 21. Figure 20 shows the status of the loads which indicates whether it is on or off during day and night. Figure 21 shows the total consumed energy by the loads during day and night based on the status of the loads.

Figure 20(a) shows the status of load 1 during day and night. During day, load 1 is activated by solar power for only 10 hours.

During night, it is activated for only 6 hours as it is supplied by the battery. Figure 20(b) shows the status of load 2 during day and night. During day, load 2 is activated for only 5 hours and at night it is inactive. Figure 20(c) shows the status of load 3 during day and night. During day, load 3 is activated for only 4 hours and at night it is inactive. The supplied energy is consumed efficiently by the loads using the designed scenarios of load scheduling. The total consumed energy by the loads during day and night is shown in Figure 21.

a

b

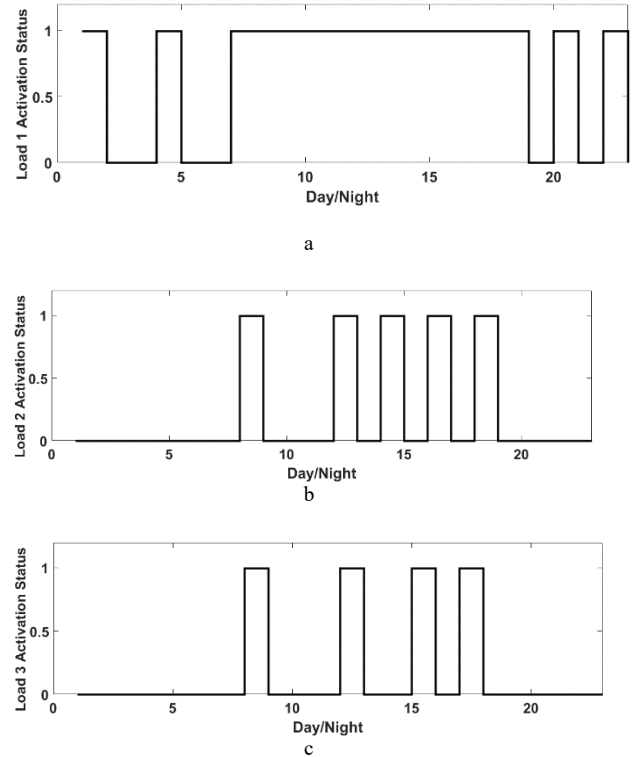
c


Figure 20: Loads (On/Off Status) versus Day/Night (Scenario 3 in Table 2 and Scenario 4 in Table 3)
Figure 21: Total Energy Consumed versus Day/Night (Scenario 3 in Table 2 and Scenario 4 in Table 3)
Figure 22: Compensation Factor (CF) versus Load Scenarios

Figure 22 represents the compensation factor (CF) which is calculated for all the designed scenarios. It is the consumed energy by the loads relative to the energy supplied by solar or battery. The compensation factor (CF) is used to show whether there will be an amount of remaining energy that can be used for battery charging or all the supplied energy is fully consumed by the loads.

6. Discussion

The proposed algorithm was simulated and its results are shown in Table 4. The main source that was used for supplying power to the loads during day is the solar panel. During day, there are four designed scenarios for load scheduling. In scenario 1, the three loads will be activated based on priority for a certain time and the energy consumed by the loads is 671.94 mWh at 1000 W/m^2. When the solar irradiance changes to 500 W/m^2, the solar power in this case isn't enough for supplying all loads so scenario 1 isn't suitable for this case as the loads activation period must be reduced.

In this case, scenario 2 is chosen as load 1 (highest priority) is activated for 6 hours while load 2 (medium priority) is activated for 4 hours and load 3 (lowest priority) is activated for 2 hours. In this scenario, the energy consumed by the loads is 184.32 mWh, the battery can be recharged during day using the remaining solar power. At 100 W/m^2, scenario 3 is selected as the loads are supplied by the battery because the solar power is not enough for supplying the loads in this case. The three solar irradiances 1000, 500 and 100 W/m^2 can vary during day so they are combined and represented in scenario 4. In scenario 4, the solar irradiance is 100 W/m^2 for 3 hours, 500 W/m^2 for 5 hours, and 1000 W/m^2 for 6 hours.

Table 4: Simulation Results for Energy Efficient Algorithm

Power Source	Scenario #	Power (mw)			Energy (mwh) for different scenarios	CF %
		Load 1	Load 2	Load 3		
Solar	1	4.62	1.65	75	671.94	81.26
	2	4.62	1.65	75	184.32	61.64
	3	4.62	1.65	75		
	4	4.62	1.65	75	359.07	71.77
		4.62	1.65	75		
		4.62	1.65	75		
Battery	1	4.62	1.65	75	65.34	93.33
	2	4.62	1.65	75	52.8	94.73
	3	4.62	1.65	75	31.02	79.93
	4	4.62	1.65	75		

During night, the algorithm was simulated by using the battery as the main source of power for supplying the loads. There are also four designed scenarios for load scheduling at night. In scenario 1, the loads are supplied by a fully charged battery so load 1 is activated for 12 hours while load 2 is activated for 6 hours as it is active for 1 hour every 2 hours and load 3 is inactive. In scenario 2, the battery SoC is 75 % so load 1 is active for 12 hours, load 2 is active for 4 hours as it is active for 1 hour every 3 hours and load 3 is inactive. Load 3 can be activated based on the user demand or it remains inactive till the availability of light. In scenario 3, the battery SoC is 50% so load 1 is active for 6 hours as it is active for 1 hour every 2 hours while load 2 is active for 2 hours as it is active for 1 hour every 6 hours and load 3 is inactive. In scenario 4, the

battery SoC is below 40% so load 1 is active for 1 hour while load 2 and 3 are switched off till the availability of light in order for the loads to be powered by the solar and for the battery to be recharged. The proposed algorithm guarantees the efficient usage of energy by using the designed scenarios for load scheduling during day and night. It provides a sustainable system as it avoids the drainage of the battery which will prolong the system life time.

7. Conclusion

As a conclusion, it is essential to monitor plants' performance as it helps in increasing and saving the agricultural production. Monitoring the performance of plants is facilitated using IoT technology as it uses wireless sensors that enables the plants to talk and express its requirements. Energy optimization is a major challenge that faces IoT. In agriculture, wireless sensors are utilized in remote areas therefore they consume high energy for continuous operation. An energy efficient technique was proposed in this paper to avoid battery drainage in order to guarantee system sustainability and continuous operation. Solar power and intelligent load scheduling are combined in the proposed algorithm. The results showed that the system operation adapts to the availability of power represented as solar irradiance or battery SoC. It operates using solar panels during day based on solar irradiance but during night, it depends on the battery SoC. During day and night, intelligent load scheduling based on priority is applied to ensure continuous operation. The proposed algorithm elongates the sensors' batteries life time as it efficiently uses energy to ensure the system sustainability. The proposed algorithm enhanced the battery life time by 79.2 %.

A B S T R A C T

This paper presents the method of simulating the personal knowledge management (PKM) processes, based on Get-Understand-Share-Connect (GUSC) Model, using real event logs data from an online learning platform. The method used in here is process discovery and conformance, which are the process mining techniques. Having the model proven at granular level of multi-agent system, this research is found significant in proving that PKM indeed exists in students' online learning behavior and needs to be monitored to ensure that they are managing knowledge in a complete cycle, to support their credibility as future graduates and knowledge workers in organizations. The ideal process starts from Get, then Understand, and followed by Share and Connect, but this study proves that the sequence may vary although the original theory is construed. This depends on the way the online activities being mapped to the Get, Understand, Share and Connect processes during the data processing stage. The results from this paper include the simulation of the GUSC model as discovered from real event logs data.

1. Introduction

Due to the habit and intuitive that they possess, the digital natives, i.e. the generation that grows up with the Internet technologies, are used to independent learning and do not rely much on physical classroom learning. It is a competition of being the most knowledgeable to them, to be able to gain more knowledge and manage their personal knowledge in as many means as they can through the Internet, hence the shift from traditional classrooms to online learning environment in many universities today.

Looking at the need to ensure that learners gained the right knowledge at the right time, and being competitive and marketable graduates, it is necessary to also ensure that they could well manage their personal knowledge. With the current experience in managing classes and teaching materials online, the data is available for analysis on online learning behavior of learners using the university online learning platform. Instead of relying on questionnaire and interview surveys that highly depend on respondents' feedback that could be bias and distorted from truth,

it is a better way to approach the case of online learning behavior directly from the data source on the server.

Recent research has proven the existence of personal knowledge management (PKM) in online learning platforms, including social media and learning management system provided by universities. However, these studies were mostly done using surveys. One significant research developed an agent-based simulation to visualize the PKM processes based on those surveys. There is a gap between these two types of previous research, in which this study intends to close this gap with its findings visualized directly from the original source, which is the event logs data from the online learning server. In doing so, this research aims to achieve the following objectives:

- to discover PKM model by visualizing the process flow in online learning environment; and

- to simulate the PKM processes using real case data for further verification on conforming the model.

This paper is an extension of work originally presented in the 6th International Conference On Research & Innovation In Information Systems (ICRIIS2019), Malaysia [1].

2.1. GUSC Model Simulation

As mentioned in the introduction, a recent research has developed an agent-based simulation on GUSC Model, a model that is proven in quite a number research before this. The abbreviation "GUSC" comes from the words Get, Understand, Share and Connect, which are the processes deem necessary for personal knowledge management (PKM). The GUSC Model was simplified from a handful of previous models on PKM by renowned authors since 2009 [2]-[4]. The only difference between GUSC Model and other models before this is the proven suitability of this model for intelligent agents modelling, in which the PKM processes can be developed at granular level for software agents to perform.

In lieu to the previous models, this PKM model is based on the following processes [4], [5]:

- *Get or Retrieve knowledge (G)*: This process simulates how learners retrieve knowledge in explicit form, in which that knowledge has been converted from tacit form by the person who shared it;

- *Understand or Analyze Knowledge (U)*: This process simulates how learners analyze the explicit knowledge that they have retrieved, and convert it to a tacit form in a way that they understand;

- *Share or Publish Knowledge (S)*: This process demonstrates how learners share or post the knowledge that they have understood in an explicit form, so that others can gain knowledge from it;

- *Connect to Knowledge Source (C)*: This process is about connecting learners to sources of knowledge, including materials and people, which may involve communication between the two, resulting in a transformation from tacit form of knowledge to another tacit form.

The decision of adopting GUSC Model for this research is due to its credibility in proving the existence of PKM in learning environment [6], smart classroom [7], [8] , social network [9] , and social messaging applications [10], [11]. In addition to that, prototypes have been developed to prove that GUSC Model can be used to design PKM platforms for individuals [12], and a simulation of GUSC Model in learning environment is developed to show and prove PKM processes among learners [13].

It was suggested in the recent research on GUSC simulation [14] to relook into the simulation itself by improving the way the measurement of each PKM process is done. There is a trend discovered from the simulation, in which there are some "learning sessions" that are not used, or termed as "non-usage". This is a significant finding that is found interesting for this research to investigate using real event logs data.

2.2. Process Model Discovery

Derived from business process management domain, process mining helps the analysis of business process based on actual data of event logs. It is often thought as the same as data mining, but it is not. Data mining algorithm is significant to process mining but the latter provides more comprehensive benefits in terms of the organizational system as a whole.

Event logs are analysed in the context of process-aware system [15], in which the full view of the case situation is being understood, hence the importance of the event logs to researchers. Process mining techniques are expected to be non-trivial because it is based on extraction of only useful information from the logs [16], which in turn could provide truthful, real data without biasness. Nevertheless, process mining can show that a real process in a system is more complex than the way it is planned to be in documents. The event logs from e-learning environments might contain huge amounts of fine granular events and process-related data, which consist of different categories that make the whole process messy and prone to producing waste of resources and useless data [17].

There are three different techniques suggested for process mining [18], as follows:

- *Process Model Discovery*: By using the event logs retrieved from the database, fuzzy miner algorithms are applied by the process mining software to produce a process model. This requires data to be readily available, in a situation where process model is not yet planned or developed in documentation.
- *Conformance Checking*: When a process model is available (either from the plans and documentation or from the discovery), the retrieved event logs are analysed to conform whether the real activities happening in the system is as how the process is modelled for, or not.
- *Process Improvement*: The purpose of this technique is to improve the existing process model using the information retrieved from the event logs. It is different than conformance checking because it measures the alignment between the model and the real online activities, hence producing an improved model that fits the condition deemed necessary.

There are several algorithms that can be used to perform process discovery including Fuzzy miner and Heuristic miner [19]. Fluxicon Disco is a recommended tool for automated process model discovery based on fuzzy miner algorithms. The strength of the fuzzy miner is the seamless process simplification and highlighting of frequent activities that are very useful for the research purpose [20]. The process model could be messy and fuzzy mining will come in handy in terms of filtering out the data and adjusting the level of details available in the model, in order to better perceive the process model.

3. Methodology

For this research, process model discovery will be used to initiate the process of discovering the GUSC Model in online learning environment and achieving the first objective. This is followed by conformance checking, to prove that GUSC processes really happen in the online environment, by simulating the processes through animated visualization, to achieve the second objective.

3.1. Case Settings

This research has chosen a case university that implements a Moodle-based online learning environment called "VLE", i.e.

virtual learning environment. The event logs data from year 2016 to 2017 was extracted from the VLE database for the purpose of this study. The event log consists online activities data that the students went through every day in the VLE. The extracted fields from the event logs data are date and time, case ID, and activity.

The students who performed the online learning activities in the selected case are those from semester three to six. They were chosen because they have experience using the VLE for more than one semester.

The selected courses for this study are from software engineering and business technology. These courses are selected to ensure that both technical and less technical contents are covered in the process model discovery, since the lecturers or instructors of both courses have their own way of delivering teaching materials online and assigning activities. For example, business technology may have a more theoretical contents compared to software engineering, hence the instructor may use discussion forum and wiki more than the latter.

Other important matters to be identified during case settings are the activities in the event log and the relevance of data to this research. Irrelevant data of less or non-relevant activities need to be omitted out, for example "register", "delete comment" and "update profile". Since the purpose of this research is to analyze PKM processes in VLE, the activities selected for analysis are those related to PKM activities only, such as "course module viewed", "quiz attempt started" and "quiz attempt summary viewed".

3.2. Process Discovery

In process discovery, the event log was extracted and imported into the chosen process mining tool (i.e. Fluxicon Disco), in which the log is automatically transformed to create a newly discovered process model using fuzzy miner algorithm. There are two ways of process discovery: play-in, i.e. from event log to process model; and play-out, i.e. from process model to event log [21].

The first step in classification of requirement is the extraction of the event log from VLE database and importing the event log into the Fluxicon Disco. Figure 1 shows the interface after the event log is imported into the tool.

From Figure 1, the event log (in *.CSV file format) that is inserted into the process mining tool needs to be classified according to the requirement, i.e. ID, Activity and Timestamp. Due to the difficulty of having process instances scattered over multiple rows (i.e. in *.CSV file), it is found that the Fluxicon Disco is a suitable tool for data extraction compared to a normal spreadsheet.

The basic data requirement for process mining is to look into the historical process data precisely, such as a "process lens". The three requirements are as follows:

i) *Case ID*: A case identifier, else called as process case ID, is important to recognize various executions of a similar process. The correctness of case ID relies on the domain of the process. For this research case, the case ID are *Get*, *Understand*, *Share* and *Connect*, i.e. the GUSC processes.

ii) *Activity*: There ought to be names for various procedure steps or status changes as activities were performed in the process. In the event that the information only appears once or in a single passage (i.e. one row) for each procedure occasion, then it could be concluded that at that point the information is not detailed enough.

iii) *Timestamp*: From the timestamp, the delays between activities can be identified as it could show the duration of each activities in a process. This could be further related to the process of a series of activities and its duration across time.

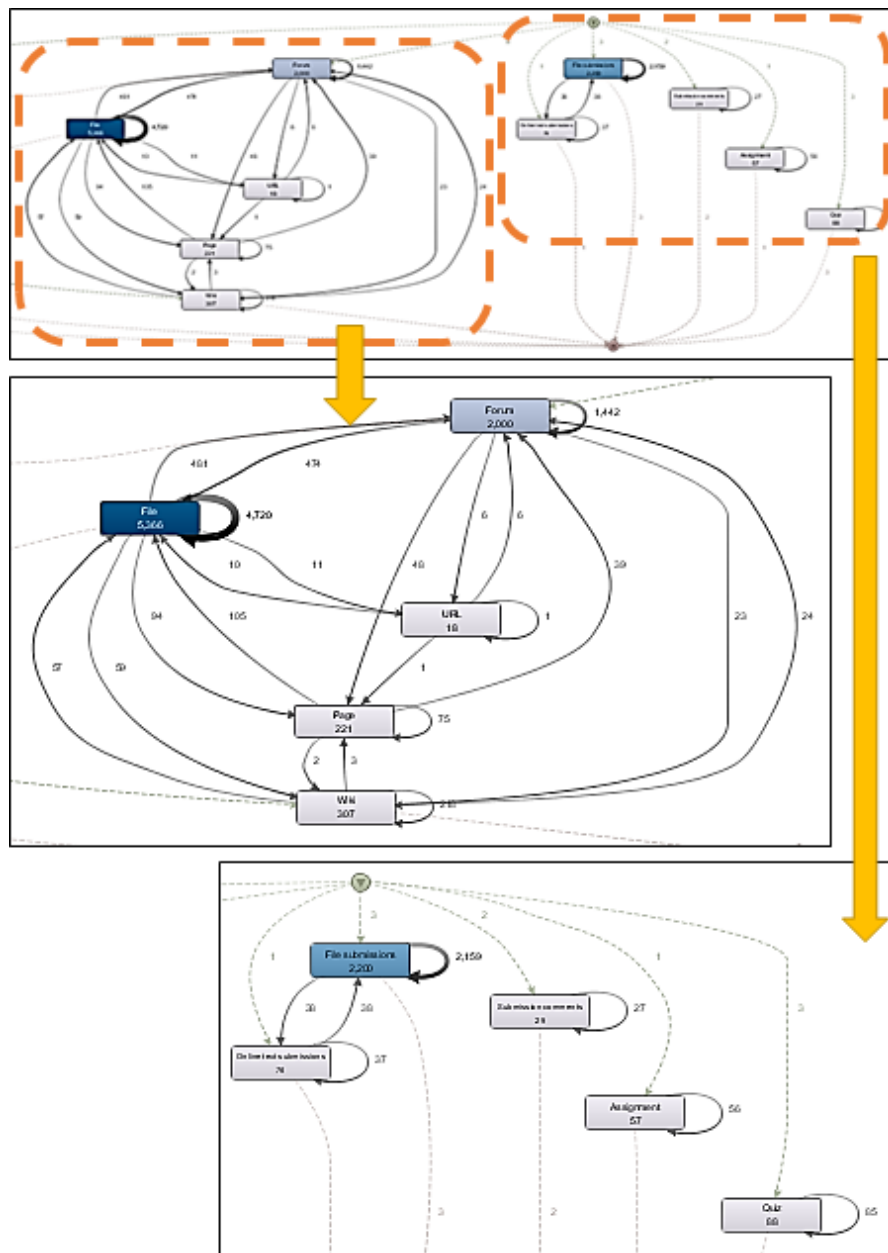
Figure 1: Event log being imported into Fluxicon Disco


Figure 2: Results after classification of requirement

3.3. Process Mapping

Figure 2 shows the result after classification of requirement has been confirmed. From the classification, a process model is developed based on the mapping that has been assigned in the event log. This process model can be manipulated by adjusting its part and activity frequency. This is to ensure that the process model is better understood, instead of merely showing the full process that involves so many paths and activities that will often be displayed as spaghetti-like process. Adjusting the activities to lower the frequency would not make the process model unreliable, but it could hide some activities that may not seem fit to the process model.

In a glance as shown in Figure 2, it is observed that there are two groups of activities being defined in the overall process. The left part of the process flow shows the learning activities over forum, file, URL, webpage and wiki, whereas the right part of the

process flow shows the assessment related activities, mainly file submission, assignment and quiz.

Filtering of data can be easily done in Fluxicon Disco, as compared to using spreadsheet. Data that is identified to be useless for the process model simulation is filtered out. The Timeframe can also be filtered according to year, month and/or day, according to the time an active process happened. For this research, the whole timeframe is taken into account to see active months and years, so that none of the activities are left behind, e.g. student logging in to VLE during mid-semester break or in semester break. Figure 3 shows the interface of filtering process in Fluxicon Disco.

The statistics interface shown in Figure 4 displays an overview of the data, which can be in a huge amount. The statistics table shows which case is frequently active in the process, and the connection between each data. The *Connect* process is identified throughout the process in a more understandable way. This table

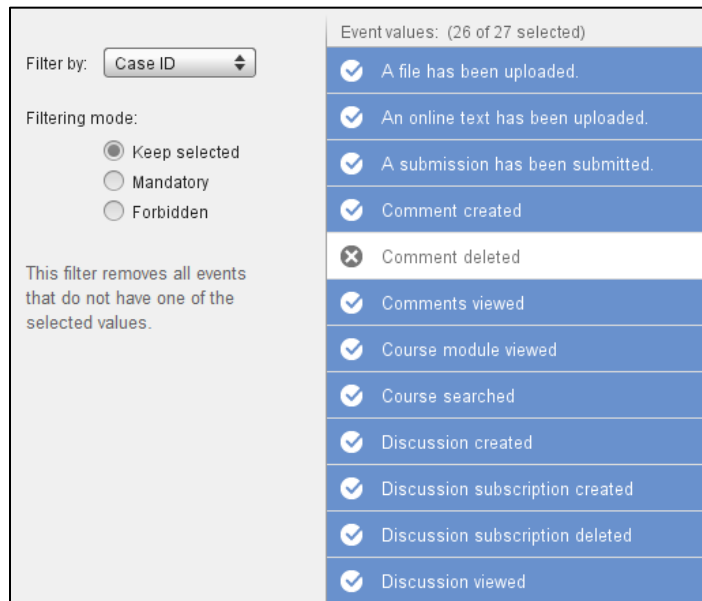
generated in Fluxicon Disco also shows the frequency of each activity that consists the number of events data. The duration of each activity can also be viewed here.


Figure 3: Filtering of data in Fluxicon Disco

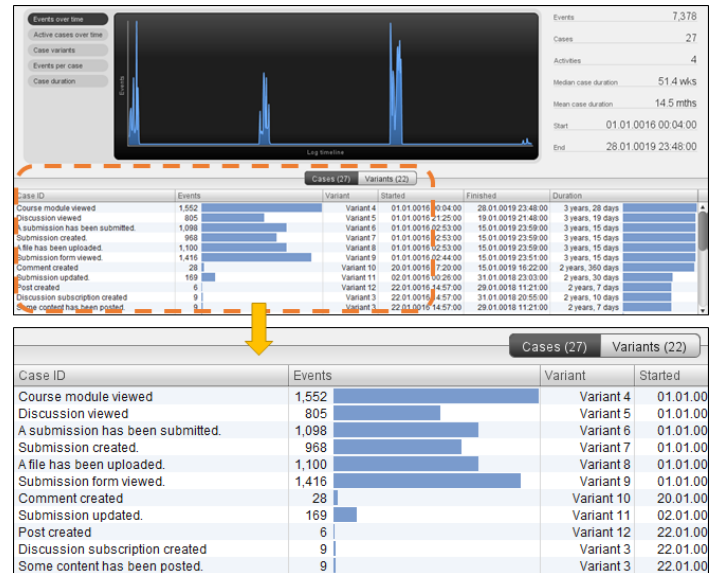
activities and their frequencies. The results shown here are presented according to three types, i.e. process model by components, by PKM process variables, and by activities that happened in the VLE.


Figure 4: Statistics of activities in Fluxicon Disco

4. GUSC Model Simulation

This section presents the results of the GUSC Model simulation using the fuzzy miner algorithm in Fluxicon Disco. The simulation results are displayed in two modes: static view of GUSC process flow; and animated view of GUSC process flow.

The process model presented here basically shows the actual process that happened in VLE, which consists of the numbers of

4.1. Static View of GUSC Process Flow

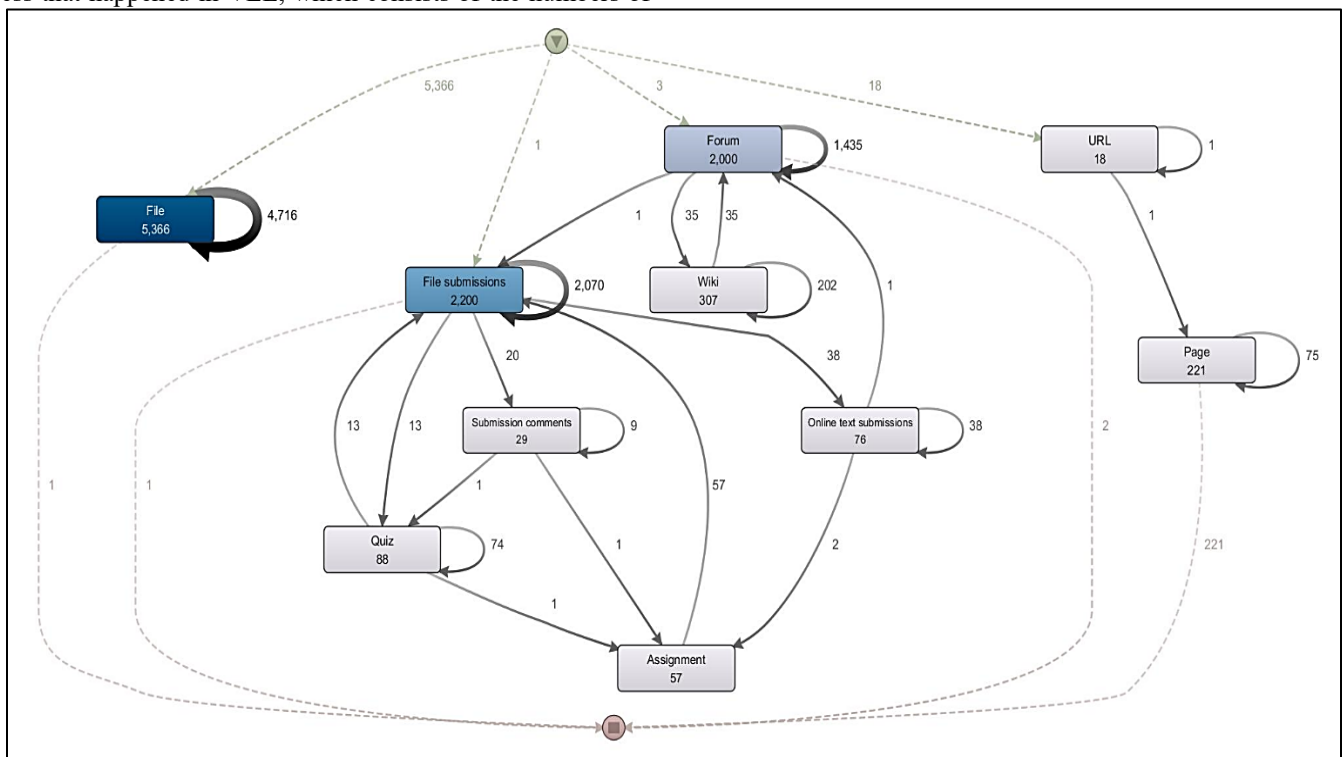
Figure 5 shows the process model that was developed according to components from the event log. In general, there are 10 components analyzed for process model discovery simulation: File; File submissions; Submission comments; Quiz; Assignment; Forum; Wiki; Online text submissions; URL; and Page.


Figure 5: GUSC process model by components

The 'File' component (shown in darkest shade in Figure 5), is the dominant one because the activities that happened on a 'File' is frequently active (i.e. 5,366 occurrences). Students' activities of downloading or uploading files would fall under this 'File' component. Activities like 'downloading notes' are quiet common in the event logs and it happens quite frequently among the students.

'URL' (18 occurrences) is a component that is posted by the lecturers, in which the URL or hyperlink of a website is shared in the VLE for students to click on and be directed to the landing page with materials to learn. A 'Page' (221 occurrences) or webpage serves the same purpose as the 'URL', but instead of directly bringing the users to an external website, it is an internal webpage created by the lecturers, in which the students can view notes and multimedia contents like a page in a website within the VLE.

Each activity has different component and each component may share the same activity name. For example, the component 'File' may have two activities in it that are 'Course module viewed' and 'Wiki page viewed', and these two activities share the same component with 'Forum', 'Page', 'URL', and 'Wiki'. This is due to the way the 'File' component is used within the other activities.

Table 1 shows the number of occurrences for each component shown in Figure 5. It also presents the number of recurrences for each component, which happened when students return to the same component during a session. Figure 5 also shows the frequencies of inflow and outflow processes, which are not presented in Table 1. However, the total number of recurrences, inflow and outflow processes for each component should be the same as the number of occurrences for each component.

Table 1: Component Occurrences in VLE

Component	Occurrence	Recurrence
File	5,366	4,716
File submissions	2,200	2,070
Submission comments	29	9
Quiz	88	74
Assignment	57	-
Forum	2,000	1,435
Wiki	307	202
Online text submissions	76	38
URL	18	1
Page	221	75

Figure 6 shows the process model that was developed according to PKM processes, based on the GUSC model. The processes are *Get*, *Understand*, *Share* and *Connect*, as stated in Section 2. These processes are mapped to the VLE activities in the imported event log data (i.e. in the *.CSV file), as the mapping was developed according to the PKM process model requirements made prior to this study.

As shown in Figure 6, the number shows the frequencies of the VLE activities that are mapped to the GUSC processes. The *Get* activity is the dominant one as compared to the other processes (shown in darkest shade in Figure 6). This result is as expected

because the *Get* activities is common to happen more frequently than *Share* or *Connect* activities. The basic idea of having VLE is to provide a platform for students to *Get* information and knowledge shared by others, especially in the form of learning materials and notes.
Figure 6: GUSC process model by PKM processes

The looping arrow displayed on *Get* process shows a number of reworks that occurred in the event. An activity that keeps looping like this basically means that students kept downloading the same notes or materials, e.g. for three days in a row. The same pattern is seen on the *Understand* process, in which the process keeps looping on the same activity as the students attempt to understand the information and knowledge in VLE. An example of this is uploading of assignment, in which students are allowed to keep uploading an assignment, or attempt multiple submissions of an assignment, as long as the deadline has not yet past.

Table 2 shows the number of occurrences and recurrences for each GUSC process derived from Figure 6. As described for Table 1, the inflow and outflow processes are not shown here, but the number of occurrences should show the total number of inflow processes, outflow processes and recurrences as a whole.

Table 2: GUSC Process Occurrences in VLE

Process	Occurrence	Recurrence
Get	7,025	6,495
Understand	2,471	2,451
Share	38	-
Connect	828	325

Figure 7 shows the overall view of the GUSC process model according to VLE activities. The most dominant activity is "File – Course module viewed – Get" with 5,366 occurrences (shown in darkest shade in Figure 7). This is followed by "Forum – Course module viewed – Get" (1,167 occurrences) and "File submissions – A file has been uploaded – Understand" (1,100 occurrences). In other words, the *Understand* process does happen in an online learning environment like VLE, even if can only be proven by uploading of files to VLE.

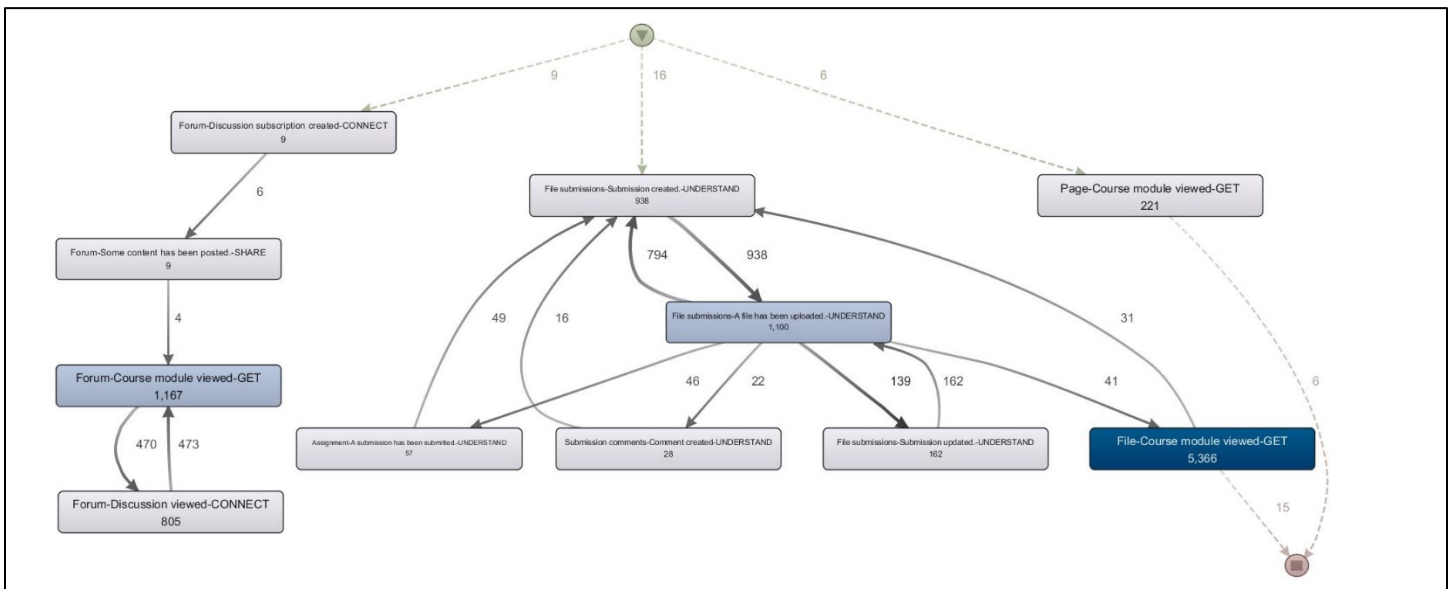
In a glance, the process model presented in Figure 7 looks quite structured. Unlike the previous two views, Figure 7 shows no recurrences of any activity. Recurrences only happened between two activities, e.g. between "Forum – Course module viewed – Get" and "Forum – Discussion viewed – Connect" (470 occurrences to, and 473 occurrences return). Table 3 shows the summary of occurrences according to the activities derived from Figure 7.


Figure 7: GUSC process model by activities

Table 3: Activity Occurrences in VLE

Activity	Occurrence
Forum – Discussion subscription created – Connect	9
Forum – Some content has been posted – Share	9
Forum – Course module viewed – Get	1,167
Forum – Discussion viewed – Connect	805
File submissions – Submission created – Understand	938
File submissions – A file has been uploaded – Understand	1,100
Assignment – Submission has been submitted – Undestand	17
Submission comments – Comment content – Understand	28
File submissions – Submission updated – Understand	102
Page - Course module viewed – Get	221
File - Course module viewed – Get	5,366

4.2. Animated View of GUSC Process Flow

The GUSC model simulation shows the movement of the processes in 'blobbing' shapes. The movement can be seen with different rhythm and speed depending on the time duration and frequency of the running processes. The thicker the line movement of the process travels, the frequent the process is. Figure 8 shows the snapshot of this animation of GUSC process model, in which the thicker line in red is where a process travels, and the yellow 'blobbing' shape shows the high volume per time unit.

As shown in Figure 8, the *Understand* process does not travel to other variables except for one way towards *Share* process, while *Get*, *Connect* and *Share* processes travel to each other. This can be explained that *Get*, *Connect* and *Share* processes happen before the *Understand* process can happen. The situation supports the findings of previous research that proved the *Get*, *Connect* and

Share are connected to each other and they are the main processes of PKM [6]. This was statistical proven to justify that an *Understand* process can only happen when a *Share* process happens (the one-way line shown from *Understand* to *Share* in Figure 8), and *Share* process happens when *Get* and *Connect* processes happen (shown in darker lines in Figure 8).

Figure 10: Timestamp in event log data

5. Discussions

Among the features available in VLE, forum is a powerful platform that can facilitate students in performing all PKM processes. It has been mapped to all four PKM processes, namely GUSC processes, and the results have shown that Forum receives high occurrences and recurrences in certain areas of PKM. Although Wiki has similar strength in providing the same PKM facilities, the exposure on its usage is still low, in which students do not find that Wiki could help in enhancing their learning capacity through collaboration and knowledge sharing. Both of these features or components require high commitment and interaction among the students, and thus the processes of *Connect* and *Understand* could be well performed on top of *Get* and *Share*.

The process model discovered through this simulation research has shown the real scenario of processes that occurred in VLE, but it is far from the expectation this research earlier perceived. A simple activity as downloading lecture notes is actually an important activity in VLE to achieve the process of *Get* knowledge, but it happens as a looping activity. In business process view, a looping activity is not good because it shows that the first time of performing the activity is not done properly. As a result, it can be concluded that the students are not managing their knowledge very well because they keep on downloading the same notes several times.

This research shows that using Forum and Wiki in VLE will not only let the students interact with each other but it can also boost the full potential of the VLE itself. Not many users know all the features in VLE that can provide the full potential benefits of managing knowledge, hence time is wasted on available precious resources. Figure 9 shows the frequency of the activities happened on Forum and Wiki, in which the process travels a lot between these two components that all the PKM processes happened in this loop simultaneously. In contrast, components like Assignment only fall under *Understand* process, as students only tend to submit their assignments once they have understood on how to complete them.

Figure 10 shows the event log data when it was first retrieved from the database. It does not show the start and end time of a process, but only the overall time when a process happened. The unavailability of both start and end timestamp in the VLE event log data has caused this limitation. This limitation has caused some difficulties in analyzing further on students' activities, especially when the duration of each activity can produce significant measurement and findings for this research, in which the duration can be derived from having two timestamps.

Overall, the use of process mining has helped in proving a theoretical model like personal knowledge management processes, without biasness of respondents' feedback. This research has proven that the same event log data can be used to analyze different theoretical models, as the same data was used in a research on self-regulated learning (SRL) model prior to this [22].

6. Conclusion

In a nutshell, this research has achieved its objectives of discovering PKM model by visualizing the process flow in online learning environment, and simulating the PKM processes using real case data for further verification on conforming the model. With the simulation views (i.e. both static and animated views), it is expected that online learning environment users can benefit in terms of knowing their status of managing knowledge. It should benefit both the lecturers (who can use the simulation to gauge students' learning behavior as well as improving teaching initiatives) and students (who can know where they can improve in terms of responding to the learning system for own future benefits). Nevertheless, the process model discovered in this research is highly dependent on how the online learning environment is used in the case organization, in which the features used by both lecturers and students reflect whether the PKM model is fully complied or not. Missing features or activities may affect the learners' capability of managing personal knowledge, as they depend on the features to exist for them to have more choices and fully utilize as part of their learning sessions.

It is recommended that the future work could improve the way this research is conducted, in terms of activity and component mapping to the PKM processes (i.e. GUSC), as well as identifying the start and end time for each activity in an online learning system to better analyze the overall PKM processes. Other opportunities

include adopting suitable techniques to perform the process mapping to activities and extending this research on other courses and case settings.

Formal Proof of Properties of a Syntax-Oriented Editor of Robotic Missions Plans

Laurent Nana*, François Monin, Sophie Gire

A R T I C L E   I N F O

A B S T R A C T

This article copes with the formal verification of properties of the missions building module of PILOT's software. PILOT is a language dedicated to remote control of robots. An incremental syntax-oriented editor was built in order to increase the dependability of PILOT's missions and we showed that, under a maximum size of plan, this editor allows building only all plans that are syntactically correct. The limitation in size was due to state space explosion problem inherent to the Model-checking approach used for the proof. In order to extend the proof to all plans without any limitation in size, we investigated the theorem-proving approach, and especially PVS (Prototype Verification System). This paper therefore focuses more on modeling of PILOT plans and related building operations and the use of PVS to verify properties of the built models, in view of proving the aforementioned properties of PILOT software's missions building module.

1. Introduction

This paper extends the work originally presented in [1]. In the prolongation of preceding works aiming at enhancing the dependability of robotic applications [2-12], it targets the use of verification systems, and especially PVS (Prototype Verification System), for properties verification of a syntax-oriented editor of missions plans conceived for PILOT, a programming language devoted to the control of robots from remote. PILOT is developed within the Laboratory of Sciences and Techniques of Information, Communication and Knowledge (Lab-STICC). Proof systems rest on methods of formal proof or verification that can be described as approaches enabling to define systems properties and check their correctness using mathematics techniques and inference rules. In an earlier work, with the help of Prolog and University of Amsterdam's SWI-Prolog tool, we proved that the syntax-oriented editor allows building all and only plans having a correct syntax. Nevertheless, we could only do this proof for plans whose size was under a maximum limit, due to the explosion of state-space inherent to the model-checking approach implemented using the SWI-Prolog tool. Theorem proving approaches and related tools such PVS should make it possible to get rid of the constraint on plans size, and to extend the proof to all plans whatever their size. PVS has been chosen because of our experiment in its use for protocol verification [13, 14]. The formal verification of properties of PILOT's syntax-oriented editor involves a proper formalization of the language syntax and of the editor's working. This article is dedicated to the modeling of PILOT plans and building operations of plans, and the use of PVS to verify properties of the built models, in view of proving the correctness of PILOT's incremental syntax-oriented editor.

The rest of this paper is structured as follows. A state of the art of robotic systems' formal verification is presented in the second section. The third section addresses preliminaries on formal proof methods and gives an overview of PVS. The language PILOT as well as PILOT plans construction and checking method are presented in the fourth section. The fifth section deals with verification of properties with the help of SWI-Prolog tool. The sixth section is dedicated to the modeling of plans and building operations of plans, and verification of properties on the models using PVS. Conclusions are presented in the seventh and last section.

2. Related works

In [15], the authors reminded, firstly that formal methods of verification were only recently introduced in the control community to assist developers in the construction of complex robotic systems' control architectures, and secondly that the hybrid nature of such systems (combination of discrete and continuous behaviors) makes their formal treatment hard and necessitates new methods that are both operational and efficient.

In [16], the authors tackle issues and outlooks in robotics. One of the issues they pinpoint is long-term mission execution

*Corresponding Author: Laurent NANA, Univ. of Brest, Computer Science Department, 20 Avenue Le Gorgeu, 29238 Brest, +33298052283, nana@univ-brest.fr

capability. Despite the fact that dependability, formal verification and fault tolerance methods are not directly referred, they are needed to reach that objective.

In [17], the authors address the inclusion of operations into the control architecture of a UUV (unmanned underwater vehicle) for the mapping and the watching of the ocean. The proposed control system integrates safety mechanisms to lessen hazards at the Mission level and necessitates to use formal verification approaches.

In [18], the authors portray an approach for the use of formal tools to verify the controllers of unmanned autonomous vehicles (UAV) working in congested areas. They mention that the design of controllers of such systems is difficult, in consequence of the required speed and responsiveness. They also notify that, since it is costly to test and compare distinct UAV controllers, formal verification is the number one phase for their performance and efficiency optimization.

In [19], the authors propound a model-checking tool for user assistance in properties checking of systems having complex behaviors. The system modeling is done with the help of a finite-state automaton. The latter is very large and its manual verification is therefore very difficult. The model-checking tool helps the user by automating part of the verification process.

In [20], the authors propose a review of research works related to the application of formal specification and verification methods to the autonomous robotic domain. They pinpoint the insufficiency of testing on real deployment or simulation of autonomous robots. Indeed, the complexity of these robotic systems and their use in safety critical applications do not allow to test some of their behaviors. The authors claim the necessity to use formal methods to guarantee the exactness of such systems.

In [21], the authors propose an integration of the modeling language Timed Rebeca in ROS, a middleware for mobile robots' program development. A conceptual model of ROS programs in Timed Rebeca is proposed and used to verify the correctness of properties defined by users on ROS programs. Timed Rebeca is based on a model checking approach.

In [22], the authors deal with the formal proof of a robotic system. Model checking approach is applied as well as theorem proving approach of higher-order logic. The first one requires the discretization of the differential equations describing the continuous dynamics of the system and therefore limits the model to an abstracted view of the system, whereas the second one allows using it in its true form and makes it possible to take into account all the real possibilities of the dynamics of the system. Different techniques used for the analysis of the robotic system are compared, based on expressiveness, accuracy and automation.

Above works show the usefulness of formal verification approaches in robotics. They also show that solutions and tools are needed to facilitate the use of formal verification methods in the robotic domain. Analysis of state of the art reveals that the majority of works on formal verification of robotic systems use model checking techniques. In [20], only 3 between 49 works related to formal verification of robotic systems use theorem proving, despite their ability to avoid the state-space explosion issue that sometimes occur when using model checking. It is necessary to develop the use of theorem provers for robotic systems, given their complexity that makes their verification with model checkers prone to the state-space explosion problem.

In the next section, preliminaries on formal proof methods are first introduced, then the theorem prover PVS is presented.

3. Preliminaries on formal proof methods and Prototype Verification System

3.1. Formal proof methods

Two main formal proof methods exist: model-checking and demonstration also called theorem proving.

In the model checking approaches (illustration in figure 1), system's state-space model is built and its properties are first specified. Both are then input to the model checking system that goes through the state space exhaustively and checks if the system satisfies the given properties. When a property is not satisfied, the model checker generates error information.
Figure 1: Model checking

In the theorem proving approaches (illustration in figure 2), system's mathematical model is built and its properties are formalized using a well-defined logic. Both are then input to the theorem proving system as theorems. Using axioms, hypothesis and deductive reasoning (inference rules), the theorem prover helps the user to develop his proof and to verify if the system satisfies the given properties. Inference rules together with theorems that have already been verified make it possible to prove new theorems. When the theorem proving relies on a decidable (propositional) logic, it can be automatic. When it is based on an un-decidable (higher-order) logic, it is interactive.
Figure 2: Theorem proving

In comparison to theorem proving, the advantage of model-checking is its entire automation. Its disadvantage is that it is subject to state-space size explosion that could cause problems due to limited computer memory space and limited computational resources.

3.2. Prototype Verification System

PVS [23] is a deductive verification system. It manages a tree of proofs and helps the user to build a full proof tree, i.e. a tree whose terminal nodes are all admitted as being true. Each non-terminal node is a goal from which children nodes are obtained by

a step of the proof. Goals are sequents having each the following shape:

$$p_1, p_2, \ldots, p_n \vdash q_1, q_2, \ldots, q_m$$

where the p_i are the antecedents and the q_i are the consequents.

PVS system uses backward reasoning: each proof step results in sequents that are at least as strong as previous ones. The root of the proof is the sequent $\vdash q$ where q is the theorem to prove.

PVS system furnishes a specification language that is strongly typed [24] as well as an interface that makes it possible to specify systems under Emacs, to formally specify properties on those systems and to prove them with the help of the proof system of PVS [25].

PVS's specification language is founded upon a logic of higher order. It provides various types and subtypes, including elementary ones (strings, numbers, predicates, etc.), abstract data and compound types (records, union, etc.). PVS system offers several useful functions for the process of formal verification. The main commands implementing the decision procedures are the following:

- *typecheck:* it makes it possible to analyze the file containing the specification of the system and to detect semantic errors.

- *prove:* it makes it possible to start the proof of properties that are non-trivial for the system.

- *flatten*: enables to flatten the structure of the current goal

- *split*: enables to separate a goal into subgoals

- *inst*: makes it possible to instantiate variables with given terms

- *expand*: enables to expand/develop a definition or an expression

- *skolem*: it makes it possible to "skolemize" quantified variables (quantifiers are removed and quantified variables are replaced by skolem constants).

- *grind/ground*: enable to launch the process of decision/simplification of a rule.

- *induct*: makes it possible to perform an induction on a variable.

- *undo*: enables to go back in the proof.

- *lemma*: makes it possible to add a lemma to the assumptions.

- More elaborated commands, such as *skosimp* that iterates the application of *skolem* and *flatten* commands on the current rule.

The next section presents the language PILOT and the method of construction and checking of plans.

4. Language PILOT and method of incremental construction and checking of missions' plans

4.1. The language PILOT

PILOT [5, 26, 27] is founded on the action concept. An action is composed of an order that the robot can execute, a rule of precondition and rules of supervising each having a tied treatment. An action is either elementary or continuous. Elementary actions

end by themselves, in general once they reach their goal, while continuous actions' termination is provoked by a parallel or a preemption primitive. Whether elementary or continuous, an action only executes if its precondition is true. Similarly, when a supervision rule of an action becomes true during its execution, the corresponding treatment is launched. For each supervising rule, the default treatment consists in stopping the related action. Precondition and supervision rules are usually conditions expressed on values of sensors. Figure 3 shows the graphical representation of elementary and continuous actions.

Figure 3: Elementary action and continuous action

In PILOT language, the following control primitives are available for missions' plans programming:

- Sequentiality: it starts by a "sequence beginning" and ends by a "sequence end". It enables to define an order of execution on other primitives of the language (actions and control primitives). A graphical symbol named "intersequence" is used to connect the primitives of the sequence. Figure 4 illustrates a sequence comprising 2 elementary actions.
Figure 4: Sequentiality

- The conditional: it is formed by branches, each composed of a Boolean expression and a sequence following it. Starting from top, the first sequence whose condition is true is the only one to be executed. Figure 5 shows an example of conditional primitive with 2 alternatives.
Figure 5: Conditional

- Iteration: it is constituted of a criterion of continuation and a sequence following it. Depending on the continuation criterion, the iteration is said to be fixed or to be conditional. In the first case, the criterion is a number of loops. In the second one, the criterion is a boolean condition. Figure 6 shows and example of fixed iteration on the left and an example of conditional iteration on the right. In the example of fixed iteration, elementary action A1 is executed 3 times. In the example of conditional iteration, elementary action A2 is executed while condition s>2 is true.
Figure 6: Fixed and conditional iterations

- Parallelism: it is composed of sequences executed in parallel. It terminates its execution when all its sequences have ended theirs. Figure 7 illustrates an example of parallel primitive. In this

example, elementary actions A1 and A2 are executed in parallel and the parallel execution ends when both actions reach the end of their execution.
Figure 7: Parallelism

• Preemption: it is composed of sequences executing in parallel, but unlike parallelism structure, the termination of its execution occurs as soon as one of the sequences ends. Figure 8 illustrates an example of preemption with 2 sequences. In this example, once one of the sequences ends, it causes the termination of the second one and leads to the end of the parallel execution.
Figure 8: Preemption

After the above presentation of the language PILOT, the next subsection describes the incremental syntax-oriented building approach of missions' plans.

4.2. Method of construction and checking of PILOT missions' plans

The syntax-oriented edition of PILOT plans guarantees that the plan is syntactically correct at each step of plan building. When the programmer starts building a mission plan, he obtains a sequence that is empty. In order to continue the construction of the plan, he uses operations *insert*, *erase* or *modify*. The *modify* operation makes it possible to change elements such as the Boolean expression of a conditional primitive, etc. Whenever an operation is applied by the user, the editor checks the syntactic validity of the plan obtained and only takes the modification into account in the positive case. When the syntax is incorrect, the editor informs the user through a message. For the purpose of ensuring the syntactic correctness of the plan whenever insertion operation is performed, the following default primitives are associated with the structures of PILOT language:

• The default conditional structure which contains a unique alternative consisting in a condition set to "false" followed by an empty sequence.

• The default iteration structure that contains a continuation criterion set to 0 followed by an empty sequence.

• The default parallelism structure which contains a unique empty sequence.

• The default preemption structure that contains a unique empty sequence.

These default structures are illustrated in the example of plan shown in Figure 11.

Assuming that:

• *plan* is the current mission plan,

• *elt* is the element to insert in the plan,

• *sel* is the element of the plan selected by the user to indicate where to insert the new element (i.e. he wants *elt* to be inserted just before *sel*),

• *cont* represents the immediate encapsulating structure containing *sel*.

• Type *(<param>)* represents the type of <param>. Type values are BS, ES, BE, NL, EA, CA, CP, IP, PP. They respectively correspond to "Beginning of Sequence", "End of Sequence", Boolean Expression", "Number of Loops", "Elementary Action", "Continuous Action", "Conditional Primitive", "Iteration Primitive", and "Parallel Primitive". Here, parallelism and preemption primitives are considered of type PP.

• PredecessorOf (<param>) represents the element preceding <param> in the plan.

• SetOfSequencesOf (<param>) defines the set of sequences of <param>. In this case <param> is supposed to be a parallel primitive.

• IsContinuousActionSequence (<param>) is true if <param> is a sequence made of a beginning of sequence, followed by a continuous action followed by an end of sequence. Otherwise, it is false.

The precondition of the implemented insertion operation can be represented as follows:

$$
\begin{aligned}
&\exists\ elt\ \wedge \\
&(\neg\exists\ sel \Rightarrow (\exists\ cont \Rightarrow (\text{Type}\ (cont) \neq \text{IP}\ \wedge \\
&\quad (\text{Type}\ (cont) = \text{PP} \Rightarrow \text{Type}\ (elt) = \text{BS})\ \wedge \\
&\quad (\text{Type}\ (cont) = \text{CP} \Rightarrow \text{Type}\ (elt) = \text{BE})))) \wedge \\
&(\exists\ sel \Rightarrow ((\text{Type}\ (sel) = \text{BS} \Rightarrow \\
&\quad (\exists\ cont \wedge \text{Type}\ (cont) = \text{PP} \wedge \text{Type}\ (elt) = \text{BS})) \wedge \\
&\quad (\text{Type}\ (sel) = \text{BE} \Rightarrow \\
&\quad (\exists\ cont \wedge \text{Type}\ (cont) = \text{CP} \wedge \text{Type}\ (elt) = \text{BE}) \wedge (\text{Type}\ (sel) \neq \text{NL}))) \wedge \\
&(\text{Type}\ (elt) = \text{CA} \Rightarrow \\
&\quad ((\exists\ cont \wedge \text{Type}\ (cont) = \text{PP})\ \wedge \\
&\quad (\exists\ sel \wedge \text{Type}\ (sel) = \text{ES} \wedge\ \text{Type}\ (\text{PredecessorOf}\ (sel)) = \text{BS})\ \wedge \\
&\quad (\exists\ seq\ /\ seq \in \text{SetOfSequencesOf}(cont) \wedge sel \notin seq\ \wedge \\
&\quad \neg\text{IsContinuousActionSequence}\ (seq))))
\end{aligned}
$$

After this presentation of PILOT and the description of the method of construction and checking of PILOT missions' plans, the next section deals with properties' proof of the latter, based on Prolog and an associated tool.

5. Verification of the method of construction and checking of PILOT missions' plans using Prolog and an associated tool

It is necessary demonstrating that the implementation of the syntax-oriented editor enables the construction of all but solely plans whose syntax is valid. For the sake of simplicity, only the

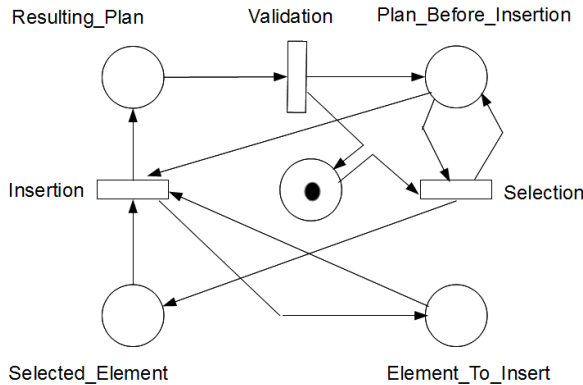
case of plans building using insertion operations is considered. In this case, the approach used for the validation can be illustrated by the colored Petri net of Figure 9. In colored Petri nets [28], colors are represented by associating values to tokens.


Figure 9: Validation approach

The initial marking of places "Plan_Before_Insertion" and "Element_To_Insert" are respectively {[beg_seq, end_seq]} and {beg_seq, end_seq, cont_act, elem_act, par, pre, iter, cond, bool_exp, loops_num}. Initially, place "Selected_Element" has an empty marking and so is place "Resulting_Plan".

The transition "Selection" (respectively "Insertion") models an element selection (respectively insertion) of (respectively in) the plan. As far as transition "Validation" is concerned, it represents the formal syntax analyzer of the language PILOT. The mechanism implemented for the syntax-oriented building of plans is free of errors if the Petri net of Figure 9 does not contain any deadlock.

For the application of this certification method to the syntax-oriented editor of PILOT plans, a syntax-checker has been built in PROLOG based on the approach suggested in [29]. Thereafter, the plan construction has been modeled and the properties hereafter have been checked:

- Are there insertions that lead to plans whose syntax is not correct?

- Are there plans with correct syntax whose construction is not possible with the proposed insertion model?

The first property aims at ensuring that the proposed syntax-oriented building mechanism disallows the construction of plans whose syntax is not correct. Regarding the second property, the goal is to make sure that the mechanism does not disallow the building of correct plans. Indeed, the checking mechanism may be too restrictive and lead to the rejection of plans that are syntactically correct.

Due to the working of PROLOG, it was necessary to limit the size of the set of plans built. If not, the PROLOG tool would have tried to generate all syntactically correct plans and this would have led to memory space problems. PROLOG parser and plan construction models were therefore modified to solely generate plans of size under a threshold. Here, the size is that of the list modeling the plan. Figure 10 shows the translation of the above properties in PROLOG, taking the size constraint into account. In this PROLOG code, *convert* converts a model representing the

graphic plan into a model which the syntax analyzer can process. *convert_set* works similarly, but applies to set of models.

```
inserion_issue (Size_Max, NG_Plan, G_Plan):-
    automated_insertions (Size_Max, G_Plans_List),
    member (G_Plan, G_Plans_List),
    convert (G_Plan, NG_Plan),
    not valid_syntax (NG_Plan,[]).
anomalous_rejection (Size_Max, NG_Plan):-
    automated_insertions (Size_Max, G_Plans_Set),
    convert_set (G_Plans_Set, NG_Plans_Set),
    valid_syntax_plans (Size_Max,Valid_NG_Plans_Set),
    member (NG_Plan, Valid_NG_Plans_Set),
    not member (NG_Plan, NG_Plans_Set).
```

Figure 10: Syntax analyzer' properties validity translation in Prolog

SWI-Prolog tool of University of Amsterdam were used for the programming. The tests performed for plans of size under 15 showed no insertion problem and no anomalous rejection. Consequently, for plans whose size is under 15, the proposed syntax-oriented building mechanism enables constructing only but all plans whose syntax is valid. For greater sizes, an exception related to lack of memory space is raised. The lack of space is caused by the exponential increase of the set of plans.

The next section presents the modeling of PILOT plans' properties as well as the modeling of plans' building operations, for their verification using Prototype Verification System. As indicated in the third section, Prototype Verification System offers a theorem proving system which enables to avoid the aforementioned memory space problem.

6. Plans and operations modeling for properties verification using Prototype Verification System

6.1. Prolog approach model analysis

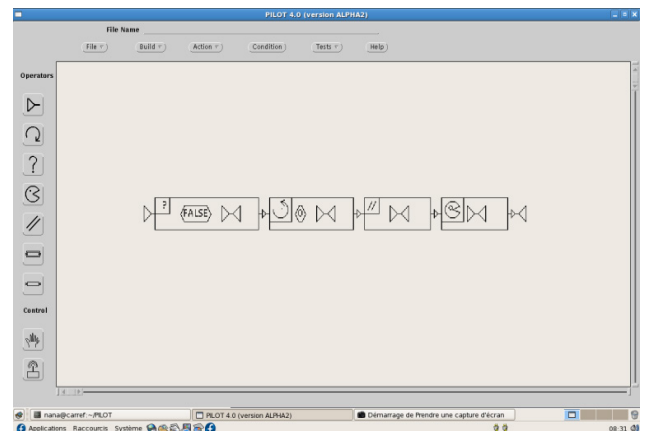
In the approach used for PILOT's syntax-oriented editor properties' proof using SWI-Prolog, plan's model is a numbered elements list, so as to be able to locate components of the plan as in its graphical version. Indeed, for operations such as insertion, it is necessary identifying where insertion is wished. In PILOT's Graphical User Interface (Figure 11), in order to insert an element in a plan, the user selects the element among the operators list on the left, then he clicks on the location of the plan before which he wants to insert the element.


Figure 11: Graphical User Interface of PILOT

The use of numbers to locate the components of the plan is suitable to produce all the plans buildable by insertion of a unique primitive of the language within a plan. Nonetheless, it becomes an obstacle to the generalization needed for theorem proving with the help of Prototype Verification System, the reasoning being done independently of the size of the plan. One of the main difficulties was therefore to find a model of representation of the plan, not based on the numbering of its elements, and making it possible to uniquely locate its elements.

Building and syntax-checking operations necessitate identification of each plan element's container. Indeed, the behavior of operations such as insertion is container-dependent. Mechanisms such as that provided by SWI-Prolog through the notation "par: number: List" make it easy to isolate blocks and locate the containers. PVS offers no similar mechanism. Therefore, the design of a solution for containers' identification is needed for PVS.

6.2. Models proposal for the proof of properties with PVS

Proving PILOT editor's properties with PVS, necessitates defining various models notably for PILOT plan, selection's container and operation "selection" that specifies where to perform the insertion in the plan. The models proposed for these different entities are presented hereafter.

a) Plan model

The plan is represented as a list of elements belonging to the set {*bs, es, e, c, exp, par, pre, condi, iter*} (see example on Figure 12). These elements refer to PILOT' syntax terminals. *bs* denotes sequence beginning, *es* sequence end, *e* (respectively *c*) elementary (respectively continuous) action, *exp* expression of conditional. *pre, par, condi* and *iter* respectively denote preemption, parallelism, conditional and iteration primitives.

Plan	PVS model
Empty sequence	cons (bs, cons (es, null))
Sequence with a single conditional primitive	cons (bs, cons (condi, cons (exp, cons (bs, cons (es, cons (es, null))))))
Sequence with a single elementary action	cons (bs, cons (e, cons (es, null)))

Figure 12: Examples of plans modeled in PVS

b) Modeling properties of syntactically correct plans

In the proposed approach, each rule of the grammar of the language is represented using a two parameters function whose first parameter is the part of the plan submitted for parsing and the second is the remainder expected after retrieving the pattern matching the rule. The output of the function is true when the real and expected remainders are identical. Otherwise, it is false. In Prolog's case, this approach enables to automatically generate the program that recognizes the language, as shown in Table 1.

Using the same approach under PVS, the program recognizing the language PILOT has the shape shown in Figure 13.

It turns out that this solution cannot be used as such under PVS. Indeed, in PVS's description language, a function call can only be done after the definition of the function. So, in figure 13, the call to seq_base in the definition of validplan isn't concretely allowed. An approach to solve this problem could be just to specify (declare) the function before the call without defining it completely, but it is disallowed in Prototype Verification System.

A first method adopted to overpower these drawbacks has been to elaborate PILOT syntax rules' dependencies graph, then using it to define the functions in the order of dependency, beginning by the functions not involving cross recursive calls, and then using the passing of functions as parameters to define functions involved in calls with cross recursion. The principle is shown hereafter through a definition of even and odd parities:

Table 1: Description of PILOT's syntax with Prolog

PILOT Syntax rules		Description in Prolog	
S	: SEQ_BASE	validplan (A,B)	:- seq_base (A,B).
SEQ_BASE	: bs L_PRIMI_BASE es	seq_base ([bs|A],B)	:- l_primi_base (A, [es|B]).

SEQ_SPECIFIC	: bs PRIMI_ACT_CONT es	seq_specific ([bs|A],B)	:- primi_act_cont (A,[es|B]).
PRIMI_ACT_CONT	: c	primi_act_cont ([c|A],A).	
PRIMI_PREEMPTION	: pre '(' LIST_SEQ ')'	primi_preemption ([pre,'('|A],B)	:- list_seq (A, [')'| B]).
PRIMI_CONDITIONAL	: condi '(' LIST_CONDITIONAL ')'	primi_conditional ([cond,'('|A],B)	:- list_conditional (A,[')',B]).
LIST_CONDITIONAL	: CONDITIONAL LIST_CONDITIONAL |	list_conditional (A,B)	:- conditional (A,C), list_conditional (C,B).
	CONDITIONAL	list_conditional (A,B)	:- conditional (A,B).
CONDITIONAL	: exp SEQ_BASE	conditional ([exp|A],B)	:- seq_base (A,B).
PRIMI_ITERATION	: iter '(' SPEC_ITER ')'	primi_iteration ([iter,'('|A],B)	:- spec_iter (A, [')'|B]).
SPEC_ITER	: CONDITIONAL |	spec_iter (A,B)	:- conditional (A,B).
	nb SEQ_BASE	spec_iter ([nb|A],B)	:- seq_base (A, B).
PRIMI_ACT_ELEM	: e	primi_act_elem ([e|A],A).	

```
% definition of types and declaration of variables
primi: type = {bs, es, …}
t: type = list [primi]
a, b, c, x, y: t
% representation of rules
validplan (a, b): bool = seq_base (a, b)
seq_base (a, b): bool = (car (a) = bs) and l_primi_base (cdr (a),
    cons (es, b))
l_primi_base (a, b): recursive bool = ((a = b) or (a /= b and a /=
    null and exists c: (primi_base (a, c) and l_primi_base (c, b))))
    measure lambda (x, y): length (x)
primi_base (a, b): bool = primi_parallel (a, b) or
    primi_preemption (a, b) or primi_conditional (a, b) or
    primi_iteration (a, b) or primi_act_elem (a, b)
```

Figure 13: Specification of PILOT syntax in PVS with same method as Prolog

$$\text{Even } (n: N): \text{Boolean} = n{=}0 \text{ or } (n \neq 0 \text{ and odd } (n{-}1))$$

$$\text{Odd } (n: N): \text{Boolean} = n{=}1 \text{ or } (n \neq 1 \text{ and even } (n{-}1))$$

This definition of even and odd functions can be transformed in PVS as shown in figure 14.

```
Even_1 (n: N, od: N -> Boolean): Boolean = n = 0 or (n ≠ 1
    and od (n-1))
Odd (n : N) : Boolean = n=1 or (n ≠ 1 and Even_1 (n-1,
    Odd))
Even (n: N) : Boolean = Even_1 (n, Odd)
```

Figure 14: Representation of even and odd functions for PVS with resolution of recursive crossed calls

Nevertheless, the syntax of PILOT contains several complex crossed calls involving more than 2 crossed calls. For example, "seq_base" refers to "l_primi_base" that refers to "primi_base" which refers in turn to "primi_parallel" that also refers to "seq_base".

Under PVS, defining a function that is recursive also necessitates adding a function called *measure* which decreases in the course of recursive calls and having a down side limit, so as to ensure recursive calls ending.

Figure 15 illustrates the representation proposed in order to solve the problem related to recursive cross calls for the example mentioned above.

A representation of PILOT's syntax under PVS has been generated with the help of this approach. For its validation, the obligations of proofs produced by Prototype Verification System were proven and a few plans' definition theorems, among which those in Figure 16, have been defined and proved with the help of PVS.

a) Modeling of plan element selection

The intention is to design a model representing the point of insertion in the PILOT plan. The following two components can

be used for characterizing the point of insertion: the clicked element and its container. The proposed model of representation of the selected element is the couple (Lbe, Laf) where Lbe corresponds to the head of the plan list ending just before the selected element, and Laf is the remaining of the plan starting from the selected element. This solution makes it possible to take advantage of the properties of concatenation of lists in the design of the models of operations that apply to the selected element. It also provides a good consistency with the syntactic rules modeling where two parts of the list representing the plan have to be distinguished, namely the part recognized by the rule and the remainder.

```
primi_parallel_i (a, b, lsq): bool = (a/= null and b /= null and
    car (a) = par and lsq (cdr (a), b))
primi_base_i (a, b, lsq): bool = primi_act_elem (a, b) or
    primi_parallel_i (a, b, lsq) or …
l_primi_base_i (lsq) (a, b): recursive bool = (a = b) or (a /=
    b and exists c: (primi_base_i (a, c, lsq) and
    l_primi_base_i (lsq) (c, b)) measure lambda (lsqf) (x, y):
    length (x)
seq_specific (a, b): bool = a = cons (bs, cons (c, cons (es,
    b)))
seq_base_i (a, b, lsq): bool = a /= null and car (a) = bs and
    l_primi_base_i (lsq) (cdr(a), cons (es, b))
seq_i (a, b, lsq): bool = seq_base_i (a, b, lsq) or seq_specific
    (a, b)
l_seq_a (a, b): recursive bool = a = b or (a /= b and exists c:
    seq_i (a, c, l_seq_a) and l_seq_a (c, b))
measure lambda (x, y): length (x)
l_seq (a, b): bool = exists c, d: (l_seq_a (a, c) and
    seq_base_i (c, d, l_seq_a) and l_seq_a (d, b))
seq_base (a, b): bool = seq_base_i (a, b, l_seq)
validplan (a): bool = seq_base (a, null)
```

Figure 15: Excerpt of PILOT's syntax description in PVS with cross recursive calls solving

In the proposed modeling, the selected element's container is frequently split in two parts, one belonging to Lbe and the other to Laf. Plan element selection model is shown in Figure 17. In this model, Lcon is the tail of the plan that starts from the selected element's container.

An extract of the PVS model of the selection operation is given in Figure 18. It shows the specification of the selection of an outermost plan's element (i.e. an element of the main sequence of the plan), as well as the case of a selection within a parallel box. In the first case, there is no container, whereas in the second case, the parallel box is the container.

P01: theorem validplan (cons (bs, cons (es, null)))

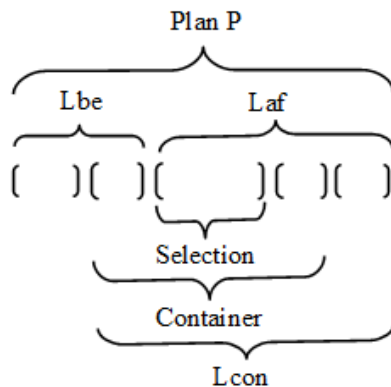
Figure 16: Samples of PVS demonstrated theorems


Figure 17: Selection model of a plan element

In this selection operation, "fusion" is an operation that performs the fusion of two lists and "seq" is such that its first parameter is a list L starting by a sequence S followed by a list LS2 of primitives.

7. Conclusion

As shown in the state of the art part of this paper, it is necessary to develop the use of theorem provers for robotic systems, given their complexity that makes their verification with model checkers prone to the state-space explosion problem. This work is a step forward in this direction, through a case study showing the limits of model-checking for the proof of properties of a robotic system, namely the syntax-oriented editor of a robotic missions programming language (PILOT), and investigating the use of the PVS theorem proving system to overcome the problem encountered with the model-checking approach.

Another goal of the work was to check out the appropriateness of Prototype Verification System for accomplishing complicated demonstrations that involve the design of models for different kinds of entities frequently encountered in robotics and more generally in control-command systems (language syntax, operations ...).

```
selection (P, Lbe, Laf, Lcon): recursive bool =
  P = fusion (Lbe, Laf) and
  ( % sequence element selected
    ( Lcon = null and (Laf = cons (es, null) or

                ( Lcon1 /= null and Lcon = fusion (Lcon1, Ls2))
              ) and
              ( Lbe = fusion (Lbepar, cons (par, fusion (Ls1, Lbe1)))
              and
                Laf = fusion (Laf1, Ls2))))))
  ) or
  % code for the other encapsulating primitives
  …
)
measure lambda (s, s1, s2, s3): length (s)
```

Figure 18: Extract of selection operation's PVS model

In order to reach these goals, PVS functions have been used to represent PILOT's syntax. The proposed model has been validated notably by verifying the obligations of proofs produced by Prototype Verification System and proving some theorems defined on PILOT plans. The modeling of recursive cross-calls has been the major issue faced during PILOT's syntax specification in PVS.

As matter of fact, contrary to Prolog, the language of specification provided by PVS disallows to use a function before its full definition. Consequently, a PVS model without cross recursivity was proposed. The specification in PVS of the selection operation of the syntax-oriented editor of PILOT has also been presented in this paper.

The results obtained at this step of the work (the representation model of the syntax rules of the language PILOT under PVS and its validation, the modeling of operations of the syntax-oriented editor of PILOT), enables to conclude in a good capacity of PVS for the modeling of aforementioned entities of control-command systems and for the achievement of further formal proofs.

Conflict of Interest

The authors declare no conflict of interest.

A B S T R A C T

In this paper, we have modeled and designed a metal mountable tag antenna that is applied to cover two major UHF RFID bands, i.e., European (EU) (865-867 MHz) and U.S. bands (902-928 MHz). It is applied for many applications, especially in the transport and logistics fields. The tag antenna configuration utilizes microstrip configuration with open bent stub feed network to attain conjugate matching w.r.t. Monza R6 chip impedance. The proposed microstrip patch-based tag antenna structure is simple without using any shorting pin/holes, thus making it easy and inexpensive to manufacture. Additionally, the proposed tag's impedance has been easily tuned in order to achieve conjugate matching in regard to the employed chip impedance. The presented tag antenna has been fabricated and experimentally characterized to measure its read-range performance in the desired bands. Further, the differential probe set up is used to measure the designed tag's impedance. Also, the designed tag read-range is measured using a reader setup and is observed to exhibit read-range up to 11 m and 9 m in European and U.S. UHF RFID bands, respectively. The tag exhibits an impedance of 9.7 – j 130 ohms at 866 MHz and 8.7 – j 124 ohms at 915 MHz. The proposed tag antenna design's performance is verified, analyzed, and optimized by CST Studio Suite software. The performances of the designed tag are evaluated and analyzed in terms of conjugate matching, reflection coefficient, and read range measurement. From the results, it is noticed that the designed tag exhibit dual-band behavior with good impedance matching, Reflection coefficient, and high read range.

1. Introduction

Ultra-High Radio Frequency Identification (UHF-RFID) technology has emerged as an efficient technique to track the objects/items/products without needing to be in the line of sight. The major RFID applications are in access control, logistics, healthcare, asset tracking owing to its advantage of long read range and compact size in comparison to Low (L.F.) and High Frequency (H.F.) bands [1]. The UHF RFID band is further divided between two major regions, i.e., European and North America/U.S.

covering (865-867 MHz) and (902-928 MHz) bandwidth with a maximum allowed transmitted power of 3.28 W and 4 W, respectively [2], [3]. To operate the tag reliably in both the regions, it is required that the designed tag must exhibit dual-band operation covering European and U.S. UHF RFID bandwidth.

The RFID tag has to be affixed on a different type of conductive and non-conductive object to be tracked. Further, the performance of the tag deteriorates significantly especially when placed on conductive items such as metals. This is attributed to the cancellation of radiations resulting from phase electromagnetic

wave reflections from the underlying metal surfaces [4-6]. To track the metallic objects efficiently, some of the recent work utilizes a microstrip patch antenna with a full ground beneath to overcome the influence of conductive objects such as metal, liquids, etc. as depicted in ref [7] and [8]. Further, the planar inverted-F antenna (PIFA) incorporating vias/ holes for the compact-sized tag is presented in [9], [10]. However, the employed vias/holes contribute to increased fabrication cost and complexity to the tag structure.

In this article, the work presented in [11] is extended further. Here, a dual-band metal mountable tag antenna having a planar structure covering European and North American UHF RFID bands is designed. The proposed tag antenna utilizes a microstrip patch antenna having a bent open stub feed. This bent feed structure offers the benefit of easy impedance tuning of the designed tag considering the complex chip impedance.

In this paper, we propose an RFID tag antenna to be integrated to track items in fundamental applications such as in the supply chain for the transport and logistics field. Effective management of this chain leads to very concrete results. To increase this efficiency, the implementation of an RFID based container-tracking system is necessary. This will contribute to real-time identification and reaching new levels of traceability and control.

To that end, and to test the performances of the UHF RFID tag developed, a real test is planned on the metal containers in airports; this test requires the deployment of a chain of readers and tags attached to the objects.

The container is the basic loading unit, usually made of aluminum alloys, with different sizes, the largest, exclusively on cargo aircraft, and the means are loaded in the holds of passenger aircraft.

For better optimization of airfreight, goods are transported in containers designed for safety reasons and to facilitate loading and unloading operations. These goods can be easily tracked using a metal mountable RFID tag. Thus, in this article, a UHF RFID tag is proposed, designed and tested for metallic objects. The designed tag is able to operate on two frequency bands EU and US to ensure interoperability of the system. This work is an extension of the work presented in [11], In this paper, the designed tag antenna's working performance on the basis of circuit analysis is represented. Further the simulated results of the tag presented in [11] are verified experimentally in terms of differential impedance and read range. Also, the designed tag's read range performance is compared for two different heights of the substrate. It is observed from a comparison table (Table II) that the designed tag has better performance with respect to other recently designed tags covering two major RFID bands at UHF range i.e., ETSI and U.S. Further, the tag is specifically designed for metal mountable applications. Also, the designed tag covers a better-measured read range of 11 m and 9.7 m in ETSI and U.S. band when mounted on metal objects.

The paper is organized as follows. The proposed tag antenna structure is introduced in Section 2. The section 3 discusses the equivalent circuit of the patch antenna. The parametric study to show its tuning capability for conjugate impedance matching is shown in Section 4. Further, the simulation performance of the

designed tag antenna is shown in Section 5. The impedance measurements for the employed RFID chip i.e. Monza R6, and the designed tag antenna is carried out in Section 6. Also, Section 7, presents the designed tag's measured read range performance. Finally, Section 8 concludes the work.

2. Proposed design

2.1. Antenna structure

The tag antenna proposed here has been designed using a microstrip patch antenna. The proposed tag antenna geometry and its dimensions are illustrated in Fig.1 and Table 1, respectively as described in [11]. It consists of two simple microstrips, a patch, and a bent feed line [8].
Figure 1: The proposed tag antenna design (Top View and Side view).

Table 1: The proposed antenna dimensions (units in mm)

Par.	L	W	Lp	W_p	L_{r1}	L_i	L_{r2}	W_{r2}
Value	85	40	42	30	30	25	36	11

The tag structure is designed with a full ground plane beneath to be mountable on metallic objects. It is fabricated using FR4 substrate having $\varepsilon r = 4.69$, $\tan \delta = 0.02$, and a thickness h=3.2 mm, with a total dimension of W*L (40 mm * 85 mm). As the size is a critical factor in designing RFID tags, and in order to reduce tag size, the bent feed line structure has been adopted for feeding the patch. The antenna size can also be reduced by opting for higher permittivity substrates. However, they lead to higher costs. Also, the open stub feed line inserted into the patch decreases the input impedance of the patch. The RFID chip is connected to the feed line and its position is optimized to obtain conjugate impedance matching. The parameters L_1 and L_{r1} are optimized to obtain conjugate matching.

3. Equivalent Circuit Model

Figure 2 illustrates the transmission line model of the designed antenna. From the figure, the global structure of the antenna model has been modeled as two transmission lines connected in series configuration [12] comprising of microstrip patch and the feed line of lengths l_1 and l_2 respectively. The antenna input impedance at the feed port can be calculated as:

$$Z_{in} = Z_{in}^1(l_1) + Z_{in}^2(l_2) \qquad (1)$$

where Z_{in}^1 represents the input impedance of the radiation patch, and Z_{in}^2 represents the input impedance of the bent open stub line.

Further, the microstrip patch input impedance is given as in [13]:

$$Z_{in}^1(l_1) = Z_0^1 \frac{R_r + jZ_0^1 \tan(\beta l_1)}{Z_0^1 + jR_r \tan(\beta l_1)} \qquad (2)$$

where R_r , Z_0^1 and β are the resistance and characteristic impedance and the propagation constant of the radiation patch.
Figure 2: Open stub patch antenna transmission line model representation

Also, the employed open stub feed's input impedance is represented by:

$$Z_{in}^2(l_2) = -jZ_0^2 \frac{1}{\tan(\beta l_2)} \qquad (3)$$

where the characteristic impedance of the open stub line is represented by Z_0^2 .

For a preliminary design of the radiating patch antenna, and before proceeding with the optimization, the dimensions were calculated using the classic rectangular patch equations expressed bellow:

$$L = Leff - \Delta L \qquad (4)$$

where L is the physical length, ΔL is the extended length due to fringing field effects and $Leff$ is its effective length. The extended length, ΔL is given by [14] as shown in equation (5).

$$\frac{\Delta L}{h} = 0.412 \frac{(\varepsilon_{eff} + 0.3)(\frac{w}{h} + 0.264)}{(\varepsilon_{eff} - 0.258)(\frac{w}{h} + 0.8)} \qquad (5)$$

where w is the width of the patch, h is the substrate height, and εeff is the effective dielectric constant.

Also, the effective dielectric constant of the patch is represented as follows:

$$\varepsilon_{eff} = \frac{(\varepsilon_r + 1)}{2} + \frac{(\varepsilon_r - 1)}{2}(1 + \frac{12h}{w})^{-1/2} \qquad (6)$$

where, ε_r is the relative dielectric constant of the substrate.

4. Parametric Study

The conjugate impedance matching is optimized by tuning the lengths of the stub, i.e., L_i and L_{r1}, respectively as explained in [11].

Further, the parametric study to investigate the influence of varying the antenna dimensions, i.e., L_{r2} and W_{r2} in order to tune the second resonant frequency, i.e., 915 MHz, is shown in Fig. 3.

It has been observed that the resonance shifts towards the right by varying these parameters simultaneously and keeping the other parameters constant.
Figure 3: Simulated reflection coefficient versus frequency of the for different values of Lr2 and Wr2.

5. Simulation results

In this context, we have designed, analyzed, simulated, and optimized the proposed tag antenna using CST Studio Suite software.

The tag antenna must exhibit conjugate impedance that matches the employed chip impedance, i.e., Impinj Monza R6 [15]. The simulated and measured S_{11} results for the designed tag antenna are shown in Fig. 4.
Figure 4: Antenna measured reflection coefficient comparison

6. Impedance Measurement of Designed Tag Antenna and Chip

The Monza R6 chip is employed here at the feeding port of the designed tag antenna and its equivalent circuit is shown in Fig. 3. The chip has a resistance, R_p, of 1200 Ω in parallel to the capacitance, C_p, of 1.43 pF and a chip sensitivity of -20 dBm. The equivalent circuit values for the chip are provided in the datasheet

for the die chip and do not take into account the parasitic impedance that includes substrate, packaging, and input power dependence. The packaged chip, i.e., LXMS21ACMF-183 from Murata is used in the designed tag prototypes. Thus, it is important to consider the chip impedance dependence with respect to frequency.
Figure. 5: Tag Chip Linearized R.F. Model

The measurements of the tag antenna and the chip impedances are obtained using vector network analyzer E5062A from Agilent. The tag antenna impedance cannot be directly measured using a 50 Ohms port directly. Therefore, to measure the differential impedance, the tag antenna has been considered as a two-port network and to measure its reflection coefficient, its differential impedance input impedance, Z_{in}, has been calculated represented as:

$$Z_{in} = \frac{2Z_0\,(1-S_{11}S_{22}+S_{12}S_{21}-S_{12}-S_{21})}{(1-S_{11})(1-S_{22})-S_{21}S_{12}} \quad (7)$$

here, Z_0 represents the coaxial cable's characteristic impedance. Figure 6 illustrates the setup to measure the impedance. The differential balun with short-circuited semi-rigid coaxial cables using λ/4 was constructed to measure the impedance. The terminals of constructed balun are soldered to the feed terminals of the designed tag antenna Further, the port extension technique has been applied while measuring differential impedance as detailed in [16].
(a)   (b)
Figure 6: Equipment for chip and antenna characterization. (a) VNA, (b) Balun

Figure 7 and fig. 8 shows the used chip input impedance measurements versus the frequency. The chip impedance is measured to be 9.7 – j 130 Ω at 866 MHz and 8.7 – j 124 Ω at 915 MHz, respectively. In comparison, the input impedances given in the datasheet are 13.6-j 127 Ω at 866 MHz and 12.2-j 120 Ω at 915 MHz [17]. As observed, the packaged chip input impedance is slightly different and also depends on the input power.

Finally, the reflection coefficient (Γ) is further calculated using measured tag antenna impedance i.e., Zin and chip impedance, i.e., Zchip respectively, and is represented as:

$$\Gamma = \frac{Z_{in}-Z_{chip}^*}{Z_{in}+Z_{chip}} \quad (8)$$

(a)

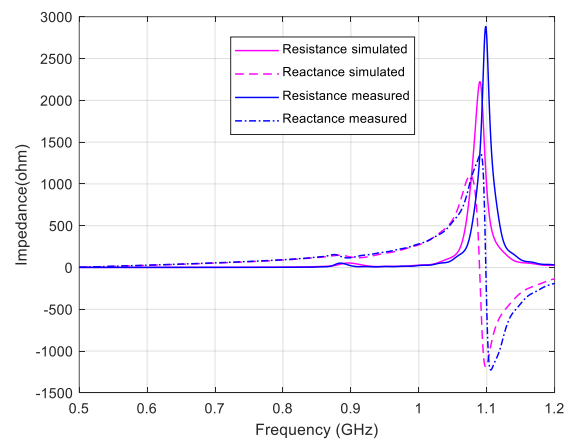
(b)
Figure 7: Chip input impedance for -20 dBm input power


Figure 8: Representation of simulated and measured results of the antenna input impedance

Figure 9 shows a comparison of the simulated and measured reflection coefficient results in the 2 required frequency bands i.e. ETSI & FCC.
Figure 9: Results of the antenna's reflection coefficient.

It can be seen that a reasonably good value for the reflection coefficient is obtained, which validates the existence of a suitable conjugate impedance matching between the chip' and the designed tag antenna impedance.

7. Read Range Measurements

The reading range or the tag range is defined as the maximum distance from which the tag can be recognized [18], and is the most important parameter for evaluating the RFID tag performance. The equation below shows this reading range following the Friis formula for free space:

$$R = \frac{\lambda}{4\pi} \sqrt{\frac{P_{EIRP} \times G_{tag} \times (1-|\Gamma|^2)}{P_{th}}} \qquad (9)$$

where PEIRP is the equivalent isotropic radiated power specified as 3.3 W in the E.U. band and 4 W in the U.S. band.

Further, λ represents the operating free-space wavelength and P_{th} indicates the chip sensitivity at the resonant frequency. The G_{tag} is defined as the antenna tag's gain and Γ is the reflection coefficient defined above in equation (8). The tag's read range can be maximized by achieving a lower-power reflection coefficient defined by $|\Gamma|^2$ and a high-gain antenna G_{tag}.

Also, the ability of the tag to transfer power to the connected chip is represented by $(1-|\Gamma|^2)$ which is also known as the power transmission coefficient of the tag.

Figure 10 describes the devices used for experimental measurement of the reading range in an anechoic chamber.

Figure 10: The Read range measurement setup

The measuring setup consists of an RFID reader, i.e., CAEN RFID, circularly polarized Reader antenna with a realized gain Gr of 8 dBi. The reader is connected to the reader antenna and a host computer. The cable losses and attenuator losses were taken into consideration.

From the measurement results, we deduced that the tag has a reading range of approximately 11 m and 9.7 m at 866 MHz and 915 MHz with an EIRP of 3.3 W, respectively, as illustrated in Fig. 11.

The gain of the tag antenna, as well as the height of the chosen substrate, strongly influences the read range of the tag. a comparison of the read range for two different substrate heights

i.e., 3.2 and 1.6 is shown in Figure 12. The read distance was observed to degrade from 11m to 4 m at 866 MHz and 9.7 m to 3.7 m at 915 MHz.
Figure 11: Results of simulated and measured antenna read range
Figure 12: Read-range for two different substrate thickness.

7.1. 3D-Radiation Pattern

As already mentioned, impedance matching between antenna and chip impedances, is a key design requirement. Therefore, its radiation pattern cannot be measured directly using a 50-ohm port. Hence, the performance of the tag antenna is also assessed based on its simulated 3 D (Dimensional) gain and radiation pattern as shown in Figure 13. It has been observed from the figure that the tag antenna exhibits a realized gain of -3 dBi. Also, to minimize the effect of mounted objects, the tag should exhibit a unidirectional radiation pattern. Thus, it is depicted from Fig. 14, that the designed tag antenna exhibits a directional radiation pattern with a directivity of 4.2 dBi. This feature is mainly desirable to design the platform tolerant tag and hence validates its application for metal mountable tracking objects.

A performance comparison of our proposed tag antenna with some previous research studies representing metal-mountable UHF RFID tags is shown in Table 2. From the table, it has been observed that the tags designed in [18-22] are larger as compared to the tag proposed in this work. Moreover, our proposed tag is

characterized by its operability in the two main frequency bands with a better reading range. On the other hand, all the other tags shown in the table cover a single UHF RFID band. Further, the tag designed in [20] is compact, however, still it covers a lower read range in a single UHF RFID band.
Figure 13: 3 D Gain pattern of the designed tag at 866 MHz
Figure 14: 3 D directivity pattern of the designed tag at 866 MHz

Table 2: A comparison table performances of UHF tags mounted on metallic items

Ref.	Transmitting EIRP Power	Circuit Size (mm)	Backing Plate Size (cm)	Max. Read Range (m)
This work	4 W	85×40×3.2	20×20	11 m (ETSI) 9.7 m (FCC)
[19]	4 W	86×41×3.2	20×20	5.6
[20]	3.3 W	88×60×0.76	15×15	5.4
[21]	4 W	30×30×3	20×20	7.2
[22]	4 W	120×60×0.4	15 × 30	10
[23]	N/A	84×126×1.28	N/A	2.5

Thus, better performances in regard to reading range, size and also covered bands, characterize our proposed RFID tag. Also, it is deduced that the designed tag may be employed for different applications such as health monitoring, logistics, and transport supply chains, and IoT (Internet of Things) network applications, etc.

8. Conclusion

In this research paper, a new planar dual-band compact platform tolerant UHF RFID tag antenna presented in [11] has been simulated, fabricated, and tested for its impedance and read range performance experimentally. To measure the real performance of metallic objects, the tag is mounted on a metal sheet. (20 m x 20 m) while measuring. Our tag antenna is modeled and designed using CST Studio Suite software. The designed tag is specifically designed to be mountable on metallic items by considering a full ground plane. The tag comprises a simple structure and does not include any vias, thus facilitating low-cost, efficient design for mass production. Further, the simulated and measured impedance, reflection coefficient, and read ranges of the tag structure have been presented and are observed to be well in agreement with each other. From the tag antenna reflection coefficient, it is realized that the designed antenna covers both major UHF RFID bands i.e., European (E.U., 865-867 MHz) and North American (the U.S., 902-928 MHz). The designed tag exhibits a read range up to 11 m at 866 MHz and 9 m at 915 MHz.

Hence, the designed tag antenna is observed to perform better in terms of conjugate impedance matching, unidirectional radiation pattern, and high read range in both the required resonant bands. Thus, it is validated that the designed tag is suitable for use in real-time applications such as transport and logistics fields and IoT network applications.

Conflict of Interest

The authors declare no conflict of interest.

A B S T R A C T

Nowadays almost every PLC manufacturer offer a so-called safety PLC. It is a specific category of PLC, which in recent years have become a commonly used means of performing safety functions, especially in industrial applications. In this area of specific applications, a maximum of SIL 3 is normally required. However, the guaranteed safety features of the PLC lead to the consideration or discussion, whether they could be used in applications with higher safety requirements. This paper deals with the possibility of using the safety PLC to implement safety functions with SIL 4. The paper presents the long-term experience of the authors in the development of control systems for railway applications with the required level of SIL4.

1. Introduction

This paper is an extension of the work originally presented at the conference [1]. Extension relates to elaboration of the impact of random and systematic failures to the safety of the safety function (SF) realized on the Safety Programmable Logic Controllers (sPLC) in the dual architecture, which is realized by this architecture. The part of realized extension is a specific application example of the realization of SF with the safety integrity level 4 (SIL 4) using two safety PLCs certified to SIL 3.

In practice (in industry, transport, medicine ...) we can quite often encounter that the ongoing process or operation of a machine or equipment can pose a risk to assets (people, environment, property damage, ...), which fall within its remit. It is necessary to deal with the risk analysis in this case. This means identifying hazards, their consequences and calculating (or estimating) the risk. Generally, the risk (R) is given by the sum of the combinations of the occurrence frequency of the i - th hazard (h_i) and its consequences (c_i), it means:

$$R = \sum_{i=1}^{n} h_i \times c_i, \tag{1}$$

where n is the number of identified hazards.

The appropriate safety measures (technical, organizational) must be applied to reduce this risk to at least a predefined tolerable value (Figure 1), if the calculated (estimated) risk is greater than the predefined tolerable risk ($R>R_T$). The technical safety measures can be passive (covers, fencing, ...) or active. Safety-relevant systems (SRSs) are used as active technical safety measures, which realize the safety functions (SFs).

Total risk (R)	
Acceptable risk (R_T)	Risk to be reduced
Residual risk (R_R)	Reduced risk
Figure 1: Relations between individual components of risk

A process (equipment, machine) is considered safe if it is valid that

$$SR_R \leq R_T. \tag{2}$$

The application of safety measures can be focused on:

- only to reduce the frequency of individual hazards;

- only to reduce the consequences of individual hazards;

- to reduce the frequency of occurrence and also to reduce the consequences of individual hazards.

This paper deals with the issue of using the technical active measures to reduce the frequency of hazards.

Based on the risk analysis, the safety functions are defined within the specification of safety requirements so that ordinarily one SF covers one hazard (or even more hazards). The aim of SF realization is to achieve risk reduction to the required value (for example, by reducing the frequency of hazards). In order to achieve this objective, the SRS must be characterized by the fact that during fault-free operation it performs the specified SFs and in case of failure the SRS must ensure that the ongoing process either remains in the given operating state (if this state does not endanger the assets within its operation), or has entered a predefined safe state (for example, disconnecting power from the motor and stopping the machine). This is a feature called "fail-safe".

Since safety cannot be understood in absolute but relatively, the possibility of SF failure must also be taken into the account. The degree to which SF is able to achieve the fail-safe property is expressed by SIL. Standard [2] defines four levels of SIL (1 to 4), SIL 4 means the most stringent safety requirements (for continuous operation, the mean frequency of a dangerous safety function failure PFH $10^{-9} \leq$ to $< 10^{-8}$ h^{-1} is required; i.e. an average of one dangerous SF failure is about 11 416 years). The required SIL for SF is determined depending on the size of the risk that SF reduces.

One of the suitable technical means for the implementation of SRS based on processor technology are also sPLCs. These are especially modified PLCs to have a fail-safe feature. These are usually modular systems with which SFs can be implemented not only with the required safety properties (with the required SIL), but also with the required reliability properties (with the required availability).

Commonly available sPLCs are mainly used for the implementation of SFs with a requirement for maximally SIL 3. This is because they are primarily developed for industrial applications where this requirement is usually sufficient (normally the SFs are implemented with desired SIL 2 or SIL 3 in the industry).

However, there are special cases of applications (e.g. in railway transport) where the implementation of SFs with SIL 4 is required, but these sPLCs are relatively expensive and do not always meet the functional requirements of the customer (for example, they do not have suitable I/O modules for wiring special components that are used in a given area of a specific application). Therefore, several manufacturers of the safety-related electronic signaling systems for railway applications are developing their own modular systems (such as generic products), which they use to realize specific applications (for example sPLC type NEXUS from the company PrvíSignalní [3]).

The efforts to increase the efficiency of the development of generic products of electronic signaling systems for railway applications have caused some manufacturers (e.g. [4], [5]) decided to develop a product for the implementation of SFs with SIL 4, which consists of two sPLCs (intended for the realization of SFs with SIL 3). It is a dual structure based on composite fail-safety with fail-safe comparison. A block diagram of such a structure is shown in Figure 2. The Equipment Under Control

(EUC) block represents the controlled equipment, resp. monitored equipment (either as a separate element or as a part of the controlled or monitored process).
Figure 2: Block diagram of a general dual structure

The technical safety principle of such a solution (Figure 2) is based on mutual exchange and comparison of the data between the unit A (one sPLC) and unit B (second sPLC). The positive result of the comparison is the sign of the correct operation of the system.

Standards [2] and [6] require to prove not only functional safety (correct performance of the function in a fault-free state), but also technical safety of SRS (represents the fail-safe feature). Although functional safety can be in principle proved by the tests, it is impossible to prove technical safety in the same way. Making technical safety prove encounters the problems that are pointed out in this article. Since the safety proves must be performed individually for each SF (SRS can generally be implemented by several SFs, whereas a different SIL may be required for each SF and each SF may be implemented by different parts of the SRS). To clarify the considerations presented in this paper, the authors accepted the simplification that the SRS implements only one SF. Under this assumption is valid, that a dangerous failure of the SRS (due to the occurrence of a failure) is equal to a dangerous failure of the SF.

2. Realization of SF with SIL 4 using sPLCs with SIL 3

SF with SIL 4 must be realized in such a way that the requirements for safety integrity (SI) level 4 are met, which result from [2] resp. [6]. These are the requirements for safety integrity against random failures (RanF-SI) and also for integrity against systematic failures (SysF-SI). In the case of RanF-SI a failure of hardware components is supposed; in the case of SysF-SI it means the software errors, whether embedded software (firmware) or application software, but the hardware failures with a common cause cannot be ruled out (one hardware failure will affect the operation of both units A and unit B).

In principle, the influence of both systematic and random faults to SF failure can be illustrated by the fault tree shown in the Figure 3.

The fault tree in Figure 3 can be described by a logical function:

$$S\_DF = S\_DRF + S\_DSF, \tag{3}$$

whereas:

$$S\_DRF = A\_RF . B\_RF, \tag{4}$$

$$S\_DSF = (A\_SFA + A\_SFE) . (B\_SFA + B\_SFE), \tag{5}$$

where S_DF is a dangerous fault of SRS (top event), S_DRF is the dangerous random failure of SRS, S_DSF is the dangerous systematic failure of SRS, A_RF (B_RF) is a random fault of unit A (B), A_SFE (B_SFE) is a systematic failure of the application software of unit A (B), A_SFE (B_SFE) is a systematic failure of the embedded software or hardware of unit A (B).

The logical function (3) expresses the fact that SRS dangerous failure can be caused by the random or systematic failure.

Figure 3: Fault tree for SRS in Figure 2

2.1. The influence of random failures on SF safety integrity

The primary construction elements of PLCs are the electronic components, which are characterized by the occurrence of the random failures. It is generally accepted that the occurrence of random failures of electronic components can be described by the exponential distribution rule. Manufacturers usually declare the failures rates for individual modules (in the case of sPLC, the dangerous failures rate). Based on this information and knowledge of the structure of SRS, the dangerous failures rate of SRS (dangerous failure rate of SF) can be calculated.

If the manufacturer declares the dangerous failure rate for the electronic system or its part (for example, the sPLC module for the implementation of SF with SIL 3), which is designed for industrial applications, then calculating the dangerous failure rate accept to assume that every second failure either alone or in combination with another failure (other failures) is dangerous [7]. Such an assumption may not be in accordance with the requirements for other applications. For example, for railway applications [6], if SIL 4 is required for an SF that is implemented

with an electronic SRS, then it is considered that any failure may be potentially dangerous. This fact must be taken into account when calculating the failure rate of SF for a specific application.

If the units A and B are physically independent of each other, then the basic events A_RF and B_RF from the fault tree in Figure 3 are independent too. The probability of the dangerous random failure of the SRS can be expressed by relation 6:

$$SP_{S\_DRF}(t) = P_{A\_RF}(t).P_{B\_RF}(t),$$

$$P_{S\_DRF}(t) = \left(1 - e^{-\lambda_{A\_RF}.t}\right).\left(1 - e^{-\lambda_{B\_RF}.t}\right), \qquad (6)$$

where the $P_{S\_DRF}(t)$ is the probability of dangerous random failure of SRS, $P_{A\_RF}(t)$ is the probability of dangerous random failure of unit A, $P_{B\_RF}(t)$ is the probability of dangerous random failure of unit B, λ_{A_RF} (λ_{B_RF}) is the dangerous random failures rate of unit A (B).

The dangerous random failure rate of SRS can be calculated using the equation:

$$\lambda_{S\_DRF}(t) = \frac{\frac{dP_{S\_DRF}(t)}{dt}}{1 - P_{S\_DRF}(t)}, \qquad (7)$$

after substituting (6) into (7) and adjusting, it can be determined that:

$$\lambda_{S_{DRF}}(t) =$$

$$\frac{\lambda_{A\_RF}.e^{-\lambda_{A\_RF}.t} + \lambda_{B\_RF}.e^{-\lambda_{B\_RF}.t} - \left(\lambda_{A_{RF}} + \lambda_{B_{RF}}\right).e^{-\left(\lambda_{A_{RF}} + \lambda_{B_{RF}}\right).t}}{e^{-\lambda_{A\_RF}.t} + e^{-\lambda_{B\_RF}.t} - e^{-\left(\lambda_{A_{RF}} + \lambda_{B_{RF}}\right).t}}. \quad (8)$$

Assuming that $\lambda_{A\_RF}.t \ll 1$ and $\lambda_{B\_RF}.t \ll 1$, then the SRS dangerous failure rate is:

$$\lambda_{S\_DRF}(t) \le 2.\lambda_{A\_RF}.\lambda_{B\_RF}.t. \qquad (9)$$

The mutual physical independence of unit A and unit B can be achieved by applying appropriate technical measures (e.g.: galvanic separation of the units, separate the power supply of unit A and unit B, ...).

SRS consists not only of sPLC, but also other elements necessary for obtaining information from the monitored (or controlled) process (equipment, machine) and elements for the realization of SF outputs. An example of a frequently used SRS wiring with sensors (S_A, S_B) and contactors (C_A, C_B) represents the Figure 4. Safe disconnection of the EUC from the power supply after affecting the sensors is the purpose of this wiring.

The wiring of sensors and contactors follows the sPLC manufacturer's recommendations and their selection depends on the specific application. In this case, contactors are used which, in addition to the coil (W_A, W_B) and the main contacts (c_{1A}, c_{1B}), also contain control contacts (c_{2A}, c_{2B}). The manufacturer must guarantee the co-operation of the main contact and the mechanically coupled auxiliary contact (it is the characteristic of relay type C according to [8]). The correct function of the

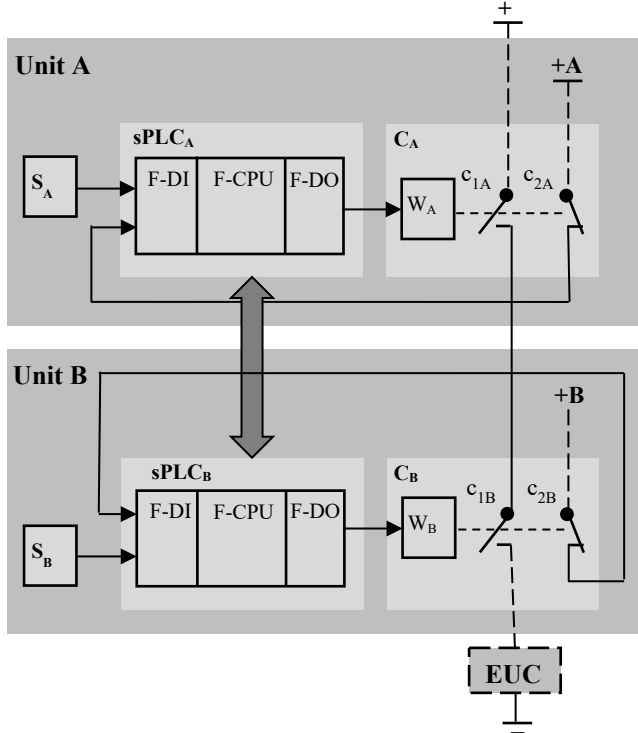
contactor is checked using feedback through application diagnostics. The feedback data is compared with the commands for the contactor in the application software. Test diagnostics in the application software and comparison of feedback data are discussed in more detail, e.g. [9] and [10]. Diagnostics can be performed in distinct forms and can cover a whole system [11], [12] or be specifically oriented on selected system parts [13], [14].


Figure 4: Wiring of the SRS

Occurrence of the dangerous failure due to random failure of SRS in Figure 4 can be described by a fault tree (Figure 5).

If the basic events of the fault tree in Figure 5 are independent (realistic and feasible assumption) then according to (9) it is valid that:

$$\lambda_{S\_DRF}(t) \leq 2.\lambda_{SA}.\lambda_{SB}.t + 2.\lambda_{SA}.\lambda_{sPLCB}.t + 2.\lambda_{SA}.\lambda_{CB}.t + 2.\lambda_{sPLCA}.\lambda_{SB}.t + 2.\lambda_{sPLCA}.\lambda_{sPLCB}.t + 2.\lambda_{sPLCA}.\lambda_{CB}.t + 2.\lambda_{CA}.\lambda_{SB}.t + 2.\lambda_{CA}.\lambda_{sPLCB}.t + 2.\lambda_{CA}.\lambda_{CB}.t, \quad (10)$$

whereas:

$$\lambda_{sPLCA} = \lambda_{D_{FDIA}} + \lambda_{D_{FCPUA}} + \lambda_{D_{FDOA}},$$
$$\lambda_{sPLCB} = \lambda_{D\_FDIB} + \lambda_{D\_FCPUB} + \lambda_{D\_FDOB}, \quad (11)$$

where λ_{SA} (λ_{SB}) is the sensor A (B) random failure rate, λ_{sPLCA} (λ_{sPLCB}) is dangerous random failure rate of sPLC$_A$ (sPLC$_B$), λ_{CA} (λ_{CB}) is random failure rate of the contactor A (B), λ_{D_FDIA} (λ_{D_FDIB}) is the module F-DI random failure rate of the unit A (B), λ_{D_FCPUA} (λ_{D_FCPUB}) is the module F-CPU random failure rate of the unit A (B), λ_{D_FDOA} (λ_{D_FDOB}) is the module F-DO random failure rate of the unit A (B).
Figure 5: The fault tree of the SRS from Figure 4

If the SF realized by SRS (Figure 4) is to meet the RanF-SI requirement for SIL 4, then it must be true that

$$\lambda_{S\_DRF}(t) \leq \lambda_{SIL4}. \quad (12)$$

It follows from (10) and (12) that

$$t_O \leq \frac{\lambda_{SIL4}}{2.X},$$
$$X = (\lambda_{SA}.\lambda_{SB} + \lambda_{SA}.\lambda_{sPLCB} + \lambda_{SA}.\lambda_{CB} + \lambda_{sPLCA}.\lambda_{SB} + \lambda_{sPLCA}.\lambda_{sPLCB} + \lambda_{sPLCA}.\lambda_{CB} + \lambda_{CA}.\lambda_{SB} + \lambda_{CA}.\lambda_{sPLCB} + \lambda_{CA}.\lambda_{CB}), \quad (13)$$

where t_O is the maximum allowed time of failure detection and negation.

2.2. Results of modeling the impact of random failures on the SF safety integrity - a case study

Let the SRS in Figure 4 implements one SF, in the implementation of which all elements participate. The failures rate, or dangerous failures rate of these elements are listed in the Table 1. Figure 6 shows the dependence of the SRS dangerous random failures rate ($\lambda_{S\_DRF}(t)$) depending on the time of failure detection and negation (t_O) calculated according to the relation (9) - curve 1 and calculated according to the relation (8) - curve 2. Maximum tolerable dangerous failure rate for SIL 4 is shown by a horizontal line. The intersection of curve 1 or 2 with this line

determines the maximum allowed time of fault detection and negation. For curve 1 it means the time 3830 h and 3845 h for curve 2. The difference between determined times is relatively small and acceptable from a safety point of view because the time determined from the simplified relationship (9) is shorter.

Table 1: The failures rates and dangerous failures rates of realized SF

Element	Failure rate	Dangerous failure rate
S_A	5.10^{-7} h^{-1}	
S_B	5.10^{-7} h^{-1}	
sPLC$_A$		4.10^{-9} h^{-1}
F-DI 16x24VDC		1.10^{-9} h^{-1}
F-CPU 1516F-3PN/DP		1.10^{-9} h^{-1}
F-DQ 8x24VDC/2A PPM		2.10^{-9} h^{-1}
sPLC$_B$		4.10^{-9} h^{-1}
F-DI 16x24VDC		1.10^{-9} h^{-1}
F-CPU 1516F-3PN/DP		1.10^{-9} h^{-1}
F-DQ 8x24VDC/2A PPM		2.10^{-9} h^{-1}
C_A	$6,4.10^{-7}$ h^{-1}	
C_B	$6,4.10^{-7}$ h^{-1}	

The diagnostic mechanisms available to the SRS must guarantee that all potentially dangerous faults are detectable (diagnostic coverage DC = 100%). Another approach must be used to calculate the dangerous failure rate of SRS if this condition is not fulfilled - for example, a model based on the Markov chain [15] (in this paper, the fault tree analysis (FTA) is used). The issue of using different methods to assess the dangerous failure rate of SRS as well as considering the influence of other factors (besides the random failures rates and DC) on the dangerous failure rate of SRS is discussed in [15]. For the sake of clarity, the fault tree analysis (FTA) method is used in this article.

It can be stated that the realization of SF with SIL 4, with respect to RanF-SI, using a dual structure is realistically achievable.
Figure 6: Dependence of the SRS dangerous random failures rate on the failure time detection and negation

2.3. The impact of systematic failures on the safety integrity of SF

While RanF-SI is a quantifiable part of SI, SysF-SI is a non-quantifiable part of SI. Probability calculations cannot be used for its evaluation (assessment), because the rate of the occurrence of the systematic failures is not known (practically, the occurrence of systematic failures is impossible to identify) and the distribution of systematic failures is not known. Achieving the required SysF-SI is based on the effective prevention of failures by applying appropriate and suitable safety measures (depending on the required SIL for SF), which are defined in the relevant standards for the given areas of applications. The evaluation (assessment) of SysF-SI is based on the assessment that the prescribed safety measures are effective and have been applied at a sufficient level [2].

The fault tree in Figure 3 shows the influence of systematic failure on the occurrence of the SRS dangerous failure. This influence is expressed by a logical function (5). In general, it should be assumed that unit A and unit B have only some mutual systematic failures, and thus it cannot be valid that the basic events A_SF, B_SF are mutually interdependent. Therefore, in this case, it must be evaluated by the general relation that:

$$P_{S\_DSF}(t) = P_{A\_SF}(t).P_{(B\_SF/A\_SF)}(t), \text{ resp.}$$
$$P_{S\_DSF}(t) = P_{B\_SF}(t).P_{(A\_SF/B\_SF)}(t), \tag{14}$$

where $P_{S\_DSF}(t)$ is the probability of dangerous systematic failure of the SRS, $P_{A\_SF}(t)$ ($P_{B\_SF}(t)$) is the probability of systematic failure of unit A (B), $P_{(B\_SF/A\_SF)}(t)$ is the conditional probability of systematic failure of unit B provided that the systematic failure of unit A has occurred and $P_{(A\_SF/B\_SF)}(t)$ is the conditional probability of systematic failure of unit A provided that the systematic failure of unit B has occurred.

In general, it is valid that

$$P_{A\_SF}(t) \leq P_{(A\_SF/B\_SF)}(t) \leq 1, \text{ resp.}$$
$$P_{B\_SF}(t) \leq P_{(B\_SF/A\_SF)}(t) \leq 1, \tag{15}$$

where $P_{(A\_SF/B\_SF)}(t) = 1$, resp. $P_{(B\_SF/A\_SF)}(t) = 1$, if the units A, B are identical (have the same systematic failures) and $P_{(A\_SF/B\_SF)}(t) = P_{A\_SF}(t)$, resp. $P_{(B\_SF/A\_SF)}(t) = P_{B\_SF}(t)$, if unit A and unit B are mutually independent (units do not have the same systematic failures).

Figure 7 shows in principle the influence of safety measures to prevent of systematic failures in consideration of the degree of interdependence of units A, B and therefore also to the on SI.

If the units A and B are HW and also SW identical (same sPLC and the same application software; Figure 7a), then it can be stated that the units A, B are dependent and the SF, which is realized by these units has the same level of SysF-IS as would have SF if it were realized only by one unit (unit A or unit B). This means that if the sPLC manufacturer states that using this sPLC can be realized SF with max. SIL 3, it must be assumed that the SysF-IS level is 3. The fact is that in such a case it does not make sense to use a dual structure.

Increasing the SysF-IS level can be in principle achieved in the following ways (safety measures):

$A\_SF = B\_SF$

$P[(A\_SF) \cap (B\_SF)] = 1$

A_SF B_SF

A_SF B_SF

$0 < P[(A\_SF) \cap (B\_SF)] \leq 1$ $P[(A\_SF) \cap (B\_SF)] = 0$
Figure 7: The illustration of the "overlapping" of the sets of systematic failures of unit A and unit B

- software diversification (different software in unit A and in unit B);
- hardware diversification (different hardware in unit A and in unit B, i.e. using of different sPLCs in unit A and in unit B);
- diversification of hardware and software.

Modifying the embedded software is a very effective safety measure to increase the SysF-IS level. However, when using sPLC, such a solution is practically impossible because this software is inaccessible to the user (this is information that the sPLC manufacturer does not provide). Diversification of application software is possible. In addition to functional algorithms related to the realized SFs, the application software can also implement mechanisms that allow the detection of a part of the systematic failures operating in a given unit. These are, for example, the following mechanisms:

- a clear, complete, and verifiable specification of requirements;
- registration of requirements using semi-formal or formal methods;
- compliance with coding standards;
- use of verified function blocks that are verified by "good" practice;
- consistent testing.

The fact is that the number of reduced systematic failures can be expected, but it cannot be demonstrated that the level of remaining systematic failures is acceptable. This is also related to the fact that the set of systematic failures is not known and therefore it is impossible to implement safety measures for their detection and subsequent negation in a targeted manner. In reality, some safety mechanisms implemented in application software may be redundant.

The aim of diversification is not to reduce the number of systematic failures in unit A, resp. unit B, but the goal is to minimize the mutual dependence (Figure 7b). This minimization is achieved by the fact that existing systematic failures do not affect the data manipulated in these units in the same way and

at the same time (by acquiring or processing or transforming or storing or transmitting data). In association with diversification, it should be noted that a powerful diagnostic tool in the dual structure presented here is the comparison of data. The larger volume of data that is the subject of the comparison and the frequency of comparison make a greater probability of detecting a failure. Diversification brings the problems of ensuring the compatibility of different sPLCs and with the synchronization requirement to be comparison possible at all. Comparison of output signals only is not considered sufficient.

The ideal situation is shown in Figure 7c, when the interpenetration of systematic failures of unit A and unit B is zero.

3. Conclusion

The use of sPLCs in dual architecture (certified to SIL 3) primarily eliminates random hardware failures. In this way, it is possible to achieve the final SIL of the realized safety functions at level 4.

Fight against the systematic failures can be done best at the embedded software level. Due to the fact that the embedded software is fixed from the user's point of view, the use of sPLC from two different manufacturers and the subsequent application of discrepancy diagnostics may be a suitable solution. Discrepancy diagnostics must be focused on a thorough comparison of internal states, memory states, etc.

Manufacturers of the sPLCs certified to SIL 4 are already starting to appear (e.g. HIMatrix product from the HIMA Company [16]). However, such products are rare and their use is precisely limited to a particular area of application. It can be assumed that in the future, the development of sPLCs will be aimed at increasing their safety and expanding their application possibilities.

Conflict of Interest

The authors declare no conflict of interest.

Prioritization of Sustainable Supply Chain Management Practices in an Automotive Elastomer Manufacturer in Thailand

Saruntorn Mongkolchaichana, Busaba Phruksaphanrat*

Thammasat University Research Unit in Industrial Statistics and Operational Research, Industrial Engineering Department, Faculty of Engineering Thammasat University, Pathum-thani, 12121, Thailand

A B S T R A C T

Nowadays the sustainable awareness trend is increasing. The consumers' attitude has changed, causing companies to pay more attention to management in a sustainable way. Effective sustainable supply chain management (SSCM) can increase social, economic, and environmental benefits. Important factors from literatures were gather and organized to be a framework for SSCM. The proposed framework incorporates the whole supply chain for both internal and external activities, which can be applied to a manufacturer. The case study factory, which is an automotive elastomer producer has planned to adopt SSCM, so it needs to know the main factors for its operations. Logarithmic fuzzy preference programming method (LFPP) was used to rank SSCM criteria. The results of ranking important criteria showed that external factors (government and competition) were the most significant criteria that the factory has determined. Government and competitors are significant drivers that initiate the company to implement SSCM. Regulations and standards were good guidelines to SSCM for the factory. Next, the Triple Bottom Line (TBL) criteria (social, economic, environment) were considered in the overall operations. Not only concerning about cost and profit, but also environmental effect and social responsibility are cooperated. Finally, internal factors (supplier, consumption, and company) were considered with low level of importance. The proposals of actions of the company were also shown as a guideline for a manufacturer.

1. Introduction

This paper is an extension of work of a similar concept presented initially in the ICIEA 2019 conference [1]. The previous work considered the criteria for green supply chain management (GSCM), while the current work extended the scope to sustainable supply chain management (SSCM). In this research, the main criteria for SSCM were collected and organized to be a new framework for an automotive elastomer factory [1–4].

The evolution of process flow management from raw materials to finished goods is known as supply chain management (SCM). SCM plays an important role in any organization's success. However, there are many operations in the supply chain, which cause environmental impact to the social communities. The concept of sustainability has gained increased popularity due to

the increase in environmental problems. Organization's management strategies have to improve and adjust to the current world situation for survival and friendly environment by not destroying the environment and not harming social communities. The use of environmentally friendly raw materials in the most effective way is one of the interesting practices [5]. Moreover, the participation of communities by corporate social responsibility (CSR) activities or developing community projects, helps to ensure the longevity of the organization.

SSCM is effective management that considers economic, environmental, and social performances at the same time in the supply chain. The basic aim of GSCM is to eliminate all wastes within the industrial system and limit use of hazardous substances. The aims of SSCM concern not only profit but also environmental and social dimensions, called a Triple Bottom Line (TBL). Companies must consider environmental effects from

processes in the supply chain such as purifying the toxic water or air emitted by the manufacturing process before releasing it to the environment to maintain good health in the community [6]. There are many pieces of research on case studies of SSCM. Some of them consider the specific operation in the supply chain such as supplier selection, reverse logistics, packing, etc [7–9]. However, the overall framework for SSCM for a supply chain needs to be clarified and important factors also need to be highlighted.

SSCM has various factors that affect the operations, which differ in each organization; also, the levels of action within each organization need to be considered differently too. Sari (2017) recommended considering inbound operations, production operations, outbound operations, and reverse logistics as primary criteria for the decision making in GSCM practices [10]. Uygun and Dede (2016) suggested a green design, green purchasing, green transformation, green logistics, and reverse logistics criteria. These activities are mainly concerned with environmental awareness [11]. Wu et al. (2020) and Mastrocinque et al. (2020) considered TBL as primary criteria throughout the SCM [12,13]. These criteria need to prioritize and formulate appropriate internal management strategies to achieve more benefit for the stakeholders in the most efficient way.

Multi-criteria decision making (MCDM) method is one of the most commonly used methods for ranking [14]. There are many methods of MCDM such as Analytical Hierarchy Process (AHP), Fuzzy Set Theory, Case-based Reasoning, Data Envelopment Analysis (DEA), Simple Multi-Attribute Rating Technique, Goal Programming, Simple Additive Weighting (SAW), and Technique for Order of Preference by Similarity to Ideal Solution (TOPSIS) [15,16]. However, in evaluation criteria, the decision-maker may not be able to precisely decide the value for the decision, so the fuzzy set concept was proposed [17]. Then, many fuzzy methods for prioritization were presented [18]; these include the logarithmic least-squares method, geometric mean method, extent analysis method, lambda-max method, fuzzy preference programming method (FPP), linear goal programming method, and logarithmic fuzzy preference programming method (LFPP). Nevertheless, these methods still have some pitfalls to avoid [19–21]. The LFPP method has been chosen in this research to prioritize the criteria for three main reasons. The first reason is realistic computation; there is not an argument about this method from literature reviews. The second reason is that the data's consistency can be calculated, and can be re-evaluated over a short evaluation time. Finally, LFPP can maintain Saaty's AHP assessment rules in all aspects.

In this research, a case study of an automotive elastomer manufacturer was studied. Currently, the case study factory has already applied GSCM, but the management team desire to get a higher level of consideration about sustainability to survive in rapidly changing societies. The new goal of the factory is to implement SSCM in order to focus on social, economic, and environmental aspects. So, the main criteria that influence SSCM implementation should be investigated initially. A new framework of SSCM for the factory is presented. The

organization's main objective is to achieve the lowest internal costs (the most profitable) and the least impact on the environment (using environmentally friendly raw materials and the most efficient use) to ensure that the product is green before releasing it to the market and consumers. Criteria were used to construct a new framework composed of SSCM factors for both internal and external factors, it can be used with any factory. All critical factors are integrated into the framework, which can satisfy the qualified policy of the factory. This research aims to prioritize the important criteria that affect the SSCM of the case study factory by use of LFPP, so that the factory can know which criteria should be emphasized and invested firstly. Then, the goals and direction can be clearly set. The proposals of actions of the factory also present in this research.

This research is organized as follows: Section 2 mentions the definition of SSCM and the detail about SSCM activities involved in the operations. Relevant literature was reviewed to determine the important criteria for SSCM of the case study. Section 3, calculation procedure by LFPP method is discussed. Section 4, the results from prioritization of the important criteria that affect the SSCM in this case study are deliberated. Conclusion, discussion, and future research are presented in section 5.

2. Sustainable Supply Chain Management

SSCM is an extension of GSCM, which mainly focuses on environmental, economic, and social dimensions [7]. These three dimensions are related to the Triple Bottom Line (TBL) principles [22], in which the perspectives are focused on the achievement and success of an organization in the economy, environment, and society as shown in Figure 1. They are the key to success of sustainable development, which needs to be balanced [13,22,23].
Figure 1: Triple bottom line for SSCM [24]

The objective of the organization previously only focused on profit, which cannot maintain sustainability. Many companies have turned to concern about people, societies, stakeholders, planet, and environmental responsibility. The TBL-based business aim is not only high profit, but also more consideration about the social and environmental problems. TBL shows profit at the top of the triangle. It is an economic dimension that almost all organizations desire.

The concept of people or humans in TBL is to emphasize fair business practices to the communities, employees, and societies by not causing harm to workers and people in the communities, but at the same time, the business has to make a profit for shareholders. Moreover, fair trade must be performed for the people dimension to balance with a social perspective.

Planet or natural dimension means a business should support sustainability and the diversity of the environment. The operations of the company must produce as little waste as possible from resources and must use recycling methods and reduce toxic gas and wastes to secure the environment and biodiversity, so the planet dimension is identical with an environmental perspective.

2.1. Sustainable activities

SSCM has comprehensive activities throughout the workflow processes. SSCM activities must care about social, economic, and environmental dimensions at the same time. These three perspectives incorporated with administrative activities start from planning strategies through to reverse logistics activities. They are described as follows:

- Sustainable strategy and planning: Strategic planning by top management is essential for organizations' initiative to improve and change [25]. If there is no strategic planning or goal setting, there is no direction that makes people understand the management intent [29, 30]. The implementation of SSCM defines the company's goal to sustainability, in which everyone should adhere to the three perspectives: social, economic, and the environment in all operations.

- Sustainable design: The design is not only for recyclable packaging or readily biodegradable products [8,28,29]; SSCM's sustainability design goes beyond that. Green design is a comprehensive design across SCM that is the best starting point for green purchasing, green production, green packaging, and green logistics. In recent years, biodegradable materials from renewable natural resources have received extensive government support.

- Sustainable purchasing: The purchasing managers need to be aware of sustainable raw materials that have to be compared among suppliers. There are many factors to be concerned about, which are cost, delivery, quality, environmentally friendly products, and value. Besides, the company also has the freedom to choose suppliers and avoid bribery from suppliers [7].

- Sustainable production: The production process design has many points to consider [8], such as a suitable location for machinery to reduce energy consumption or less fuel consumption and to get the best performance, type of source of energy, the amount of waste produced by the production [30].

- Sustainable packaging: The essential feature of product packaging is the ability to protect products from contamination damage, and deterioration. The packaging design may include special techniques to make good quality packaging, which is designed according to the 3R theory, which is recyclable (the product can be modified and reuse),

reduce (reduce the use of raw materials in the production of packaging or the product itself), and reuse (the product or packaging can be reused). Also, packaging design should be easily disassembled for digestibility and create as low waste material percentage as possible [8,28,30]. Moreover, biodegradable packaging is also a favorite choice for manufacturers.

- Sustainable logistics: The green logistics design process has many points to consider, such as the design of the distribution route for the most efficient transportation, the minimization of the number of trips [31,32], the reduction of transport cost, the volume of the empty return transport called backhauling [33], the selection of transport vehicles to reduce CO_2 emissions that cause environmental impact [34], the selection of third-party logistics service providers [35], the warehouse design for convenient loading and unloading of products without congestion, and the reduction of waiting time and administrative costs [28]. If sustainable logistics can be applied, it can cover three perspectives, which are social perspectives such as management of traffic congestion, economic perspective by reducing the transportation cost and transportation fuel consumption, and environment perspective by reducing the number of transportation trips and distances to reduce the greenhouse gas emission.

- Sustainable consumption: Determine how to consume the raw materials in the right way to minimize the processes that bring environmental pollution. The instructions must be written in words that are easily understood. The company must analyze consumer trends, consumer characteristics [36], customer green preference [37,38], and consumer purchase behavior [39] of the new generation of people who are becoming increasingly influential in the global green and sustainable market [40].

- Sustainable reverse logistics: Due to the increasing environmental impact today, various industries need more control over the amount of waste from the production processes [9]. Controlling waste is a waste management process that needs to delve into great detail to achieve the most efficient reduction in pollution and use resources efficiently [28]. Therefore, setting up a waste center is needed to receive the used products to facilitate consumers and initiate reverse logistics to be more successful [40].

2.2. Sustainable criteria for implementation

Every activity consists of essential components; for example, green purchasing has a vital role in choosing which supplier is suitable to deliver material that satisfies the company's qualification standards. Therefore, a review of the critical criteria that directly affect SSCM activities must be compiled to cover all management practices. In the previous work, the guidelines for GSCM were proposed [1]. There are 6 criteria: government, competitor, social, supplier, customer, and company to prioritize the criteria that are important to GSCM. Further pieces of literature have proposed more criteria for SSCM. These criteria can be incorporated to construct the SSCM framework for defining an action plan as shown in Table 1.

Table 1: The main criteria for SSCM implementation.

There are 8 main criteria related to SSCM; company, supplier, competition, consumption, government, social, economic, and environment.

2.3. The sustainable supply chain management framework

In the past, the SCM of an organization was not complicated and consisted of a few stakeholders. Most companies focused on developing economic efficiency, such as technical quality development, reducing cost, and improving delivery performance. However, today, business operations are more complicated, leading to a broader range of stakeholders [55]. Supply chain activities are transformed into a complicated network model [56]. The suppliers, manufacturers, distributors, and logistic providers

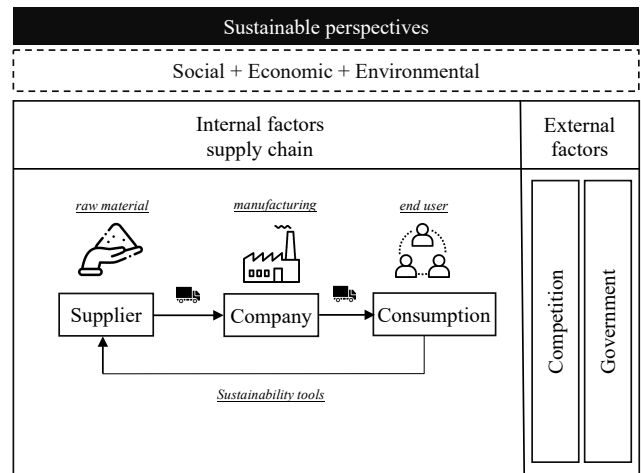
must work together to enhance their competitiveness. Meanwhile, other stakeholders such as consumers, investors, employees, and society pressure the manufacturers to be concerned about social and environmental issues that affect them. Therefore, nowadays organizations have adopted a sustainable development approach to their SCM [6,33], which considers whole parts of the operation throughout the supply chain known as SSCM. SSCM helps the organization to reduce the risk rate and enhances the competitiveness of the business. Promoting good corporate governance throughout the life cycle of products and services can improve environmental performance, social performance, operations performance, and competitiveness of an organization [57].


Figure 2: A framework of an SSCM for a manufacturer

A new framework of an SSCM is proposed in this research as shown in Figure 2. It consists of three parts. The first part is external factors, referring to surrounding factors that can indirectly affect the corporate supply chain, which are competition and government. The second part is internal factors, referring to the composition of the main parts of the supply chain, which start from supplier, to company, and end at consumption. Next, the TBL consists of environmental, social, and economic aspects. They are the basis for sustainability. Sustainability tools can be applied to the framework to support the implementation. Whitehead et al. (2020) proposed the tools, which consist of 3 groups; tools for action, tools for analysis and evaluation, and tools for communication [58]. It is also summarized tools and approaches for sustainability, which are cradle to cradle, GSCM, life cycle analysis (LCA), eco-design, reverse logistics, design for environment (DFE), Quality Function Deployment (QFD) for the environment, sustainable value analysis tool (SVAT), sustainability balanced scorecard (SBSC), corporate social responsibility (RSC) and sustainable value stream mapping (Sus-VSM) [59]. These sustainability tools can help an organization's supply chain to achieve successful SSCM. Criteria based on the framework are summarized in Figure 3. They can be described as follows.

Government is the criterion related to enacting laws to enforce and setting standards or regulations that industrial factories must follow. Government criterion is divided into two parts: enforcement of laws or policies and recommendations for

manufacturers from the government. Industries must follow the government laws; if any factory fails to follow the laws, there are penalties. Policies and recommendations from the government might be disregarded if the company is not willing to implement them. It depends on the individual organization's willingness or the opinions of executives within the organization. Many policies require action and enforcement that a business may select by itself or by the government. The role whereby a government can facilitate sustainability will depend on its authority which is different in each country. For example, a government with strong political leaders may generate models which benefit the local community and focus on supporting economic growth. In welfare-state models, the government provides services to firms and nonprofit organizations or takes on social-economic development [60]. Manufacturers determine their profit and level of energy efficiency. The government has sustainable goals that relate to saving energy, seeking profit, and increasing social welfare. Therefore, sustainability is a fundamental issue for both organizations and the government [61].

Competition in the market is one of the critical factors. Competition may be in the form of price, quality, variety of products, responsiveness, or environmental awareness, etc. In the case of SSCM implementation, social trends and substitute goods can affect consumers in making a decision. The organization should be concerned about the market trend to adapt to the competitive market. If the organization does not become active or is slow to adjust to consumption flow, it will lose market share. Competition in each type of market is different. Every organization needs fair competition as an ideal, but in the real situation, it may not be. Therefore, the rapid change of the organization is an advantage and benefit for the organization. The company's choices can affect the decisions of the firm's competitors. The firm invests in sustainability only if it can gain more revenue or reduce cost [62].

Economic sustainability has been defined as gaining more income and stability for society. In the current situation, an economy which does not disturb natural, social, and human societies is needed for sustainability [63]. If the current situation of the economy is getting worse, the investment in SSCM operations will be debated at management board level, and the SSCM operations may be delayed. On the other hand, if the economy is good, a high profit from operations or good cash flow may allow an organization to be able to start SSCM operation quickly. Moreover, the policy formulation from the government is an important factor. For example, if the government requires less tax on the green product, the product price will not be high, it will generate more incentives for consumption and produce more profit. The organization also wants to make more of the products that are best-sellers in the market. All the above result from the first criterion, which is government.

The social factor has direct and indirect effects on SSCM that start with employees on the production line. If the organization has sustainable production management, such as equipped with technology to optimize the use of resources as needed and get the most efficient outputs, minimize energy consumption and air polluting emissions [64], employees do not have the risk of direct exposure to volatile chemicals during production, production accidents will be reduced and the operators of manufacturing plant should have a good quality of life as well. Furthermore, supposing the organization has a policy to apply CSR, it will benefit the surrounding communities. The government is very important in supporting the policy by reducing tax for industrial factories that implement CSR [65, 66], which makes companies willing to undertake CSR projects.

The environment is related to various problems concerning pollutants from water [67], air, and other wastes from factories, which create increasing problems. Reduction of CO_2 emissions, energy consumption [71, 72] and wastes from the processes, products, packaging, and any substances that can increase the world's temperature, are critical issues. Different environmental regulations have started to emerge and be proposed to companies by governments. Companies must comply with environmental legislation existing in each country. Moreover, standards related to environmental consideration are one of the effective tools for the company to apply.

Selecting suppliers that market environmentally friendly raw materials without affecting the surrounding communities can help when implementing SSCM. However, this criterion is difficult to apply in order to make a significant impact on SSCM because organizations cannot enforce or control all suppliers, so choosing a supplier is yet another option in implementing SSCM within the organization. The selection of suppliers requires several factors to be considered [22, 70]. The key principles are the high quality of raw materials, reasonable prices, and on-time delivery.

Consumption can take place only if consumers are more aware of the environment and communities. The eco-label campaign is part of the approachability that can greatly appeal to consumers who are passionate about green consumption. Using its features is an important selling point. Currently, the consumer has a greater preference for healthy and environmentally friendly products [71]. Consumer perspective in sustainability is the driver for a company in the caring economy [72].

The company, including the management team, realize that the operation of SSCM requires a budget for investment [62]. Furthermore, employees within the organization have to adjust to the work with more responsibilities [73]. They must also cooperate to achieve the company strategic goal of SSCM. Moreover, organizations should provide support such as services, knowledge, information, training and facilities for them to achieve efficiency and effectiveness as soon as possible.

Criteria	
Company • Information • Top management support and motivation • Process /System operation • Strategy and goal • Incentives and rewards • Reputation loss • Business characteristics • Organizational culture • Innovation	**Government** • Laws / Regulation / Standard • Government support • Disposal green policies • Environmental policies of government • Transparency • Pressure
Supplier • Raw material use (material toxicity and chemicals) • Trade groups • Certification	**Social** • Communities • Corporate social responsibility
	Economic • Cost and benefit • Tax on green product • Production cost
Consumption • Green image • Green product • Consumers' characteristics • Reverse logistics • Feedback	**Environment** • CO_2 emission • Risk management • Pollution prevention • Energy reduction • Waste reduction
Competition • Market segment • Product pricing • Competitive advantage • Fair competition	

3. Logarithmic fuzzy preference programming method

Wang and Chin (2011) have proposed a logarithmic fuzzy preference programming method (LFPP) for finding the weight to prioritize the fuzzy number by comparing pairs of the dataset from the decision matrix [74]. The basis of this method was developed from the FPP method of Mikhailov (2004) by using nonlinear functions computation to find the weight with the following [75]:

$$ln\ \tilde{a}_{ij} \approx (ln\ l_{ij}, ln\ m_{ij}, ln\ u_{ij}), i,j = 1,..., n. \quad (1)$$

where $\tilde{a}_{ij}$ is an approximate triangular fuzzy number.

The membership function is shown below.

$$ \mu_{ij}\left(ln\left(\frac{w_i}{w_j}\right)\right) = \begin{cases} \dfrac{ln\left(\frac{w_i}{w_j}\right) - ln\ l_{ij}}{ln\ m_{ij} - ln\ l_{ij}}, ln\left(\frac{w_i}{w_j}\right) \leq ln\ m_{ij} \\ \dfrac{ln\ u_{ij} - ln\left(\frac{w_i}{w_j}\right)}{ln\ u_{ij} - ln\ m_{ij}}, ln\left(\frac{w_i}{w_j}\right) \geq ln\ m_{ij} \end{cases} $$

$$(2)$$

$\mu_{ij}(ln\ (w_i/w_j))$ is a membership of function $ln\ (w_i/w_j)$ belonging to the approximate triangular fuzzy judgment $ln\ \tilde{a}_{ij}$. A crisp priority vector to maximize the minimum membership degree $\lambda = min\{\mu_{ij}(ln(w_i/w_j)) \mid i = 1,…, n - 1; j = i + 1,.., n\}$. The subsequent model can be constructed as

Maximize λ

$$ \text{Subject to} \begin{cases} \mu_{ij}\left(ln\left(\frac{w_i}{w_j}\right)\right) \geq \lambda, i = 1,…,n-1; j = i+1,…,n, \\ w_i \geq 0, i = 1,…,n, \end{cases} $$

$$(3)$$

or as

Maximize 1 - λ

$$ \text{Subject to} \begin{cases} ln\ w_i - ln\ w_j - \lambda ln(m_{ij}/l_{ij}) \geq ln\ l_{ij}, \\ -ln w_i + ln w_j - \lambda ln(u_{ij}/m_{ij}) \geq -ln u_{ij}, \\ i = 1,…,n-1; j = i+1,…,n, \\ w_i \geq 0, i = 1,..,n. \end{cases} $$

$$(4)$$

To avoid λ from taking a negative value, Wang and Chin (2011) proposed nonnegative deviation variables δ_{ij} and η_{ij} for $i = 1,…,n-1$ and $j = i + 1,…, n$ such that they meet the following inequalities:

$\ln w_i - \ln w_j - \lambda\ln(m_{ij}/l_{ij}) + \delta_{ij} \geq \ln l_{ij}$, $i = 1,…, n - 1; j = i + 1,…, n$,

$- \ln w_i + \ln w_j - \lambda\ln(u_{ij}/m_{ij}) + \eta_{ij} \geq - \ln u_{ij}$, $i = 1,…, n - 1; j = i + 1,…, n$.

Then, the model to maximize the minimum membership degree becomes

MODEL: LFPP

$$Minimize J = (1 - \lambda)^2 + M \cdot \sum_{i=1}^{n-1} \sum_{j=i+1}^{n} \left(\delta_{ij}^2 + \eta_{ij}^2\right)$$

$$Subject\ to \begin{cases} x_i - x_j - \lambda ln\ (m_{ij}/l_{ij}) + \delta_{ij} \geq ln l_{ij}\ , \\ \quad i = 1,…, n - 1; j = i + 1,…, n, \\ -x_i + x_j - \lambda ln\ (u_{ij}/m_{ij}) + \eta_{ij} \geq -ln u_{ij}\ , \\ \quad i = 1,…, n - 1; j = i + 1,…, n, \\ \lambda, x_i \geq 0, i = 1,…, n, \\ \delta_{ij}, \eta_{ij} \geq 0, i = 1,…, n - 1; \\ \quad j = i + 1,…, n, \end{cases}$$

(5)

Let $x_i = ln\ w_i$ for $i = 1,…, n - 1$,

M is a large constant value, x_i^* is an optimal solution, λ is a membership degree, δ_{ij}, η_{ij} are nonnegative deviation variables for $i = 1,…, n-1$ and $j = i + 1,…, n$ and

$l_{ij} = 1/u_{ji}, m_{ij} = 1/m_{ji}, u_{ij} = 1/l_{ji}$ and $0 < l_{ij} \leq m_{ij} \leq u_{ij}$ for all $i,j = 1,. . .,n; j - i$.

Normalize the value of x_i^* and sorting fuzzy pairwise comparison matrices by (6)

$$w_i^* = exp(x_i^*)/ \sum_{j=1}^{n} exp(x_i^*), i = 1,…, n. \qquad (6)$$

where $exp(\ )$ is the function of exponential for which the calculation is $exp(x_i^*) = e^{x_i^*}$ for $i = 1,…, n$.

w_i^* is the weight of each criterion from $i = 1,…, n$.

The following equation is used to check the consistency of data.

$$l_{ij} \leq w_i/w_j \leq u_{ij}, i = 1,…, n-1, j = i + 1,…, n. \qquad (7)$$

4. Prioritizing of SSCM criteria for the case study

The SCM process of an automotive elastomer manufacturer has a flow chart as shown in Figure 2. The supply chain flow process begins with the purchasing process, where sources of the best raw materials for the company such as a polymer, fillers, softeners, and other additives are procured. A supplier who has the lowest cost, which high-quality products and delivery on time was selected. After receiving raw materials, the production is done according to production planning. After the products are finished and pass the quality inspection, they are transferred to the packing process. Then, finished goods are delivered to customers.

There are environmental concerns in all of the above activities, which need to be reviewed through three aspects: social, economic, and environmental. These processes are internal factors of the SCM. Additionally, the process would not be complete if it did not take the external factors into account. The external factors are competitors and the government. The competition between the companies is considered in terms of price, quality, strategies, and market share. Also, the company needs to follow the laws and regulations of the government. However, the government also provides support to the company to reach international standards. The three sustainable perspectives are integrated with both internal and external factors. The company can control all processes by setting the procedures for each aspect by using sustainability tools that can help an organization's supply chain to achieve successful SSCM.

The automotive elastomer manufacturer has decided to apply SSCM in the company, so the importance of each criterion needs to be clarified. Then, everyone in the company can move in the same direction emphasizing the critical criteria. Eight criteria in the previous section were considered and ranked. A fuzzy decision matrix was constructed and evaluated by five experts who are key men in the factory: the procurement supervisor, planning supervisor, quality control supervisor, production engineer, and research and development engineer who has worked in this company for more than 10 years. The decision matrix is shown in Table 2. Model in equation (5) for this fuzzy pairwise comparison matrix can be written as

$$Minimize\ J = (1 - \lambda)^2 + M \cdot \sum_{i=1}^{7} \sum_{j=i+1}^{8} \left(\delta_{ij}^2 + \eta_{ij}^2\right)$$

$$Subject\ to \begin{cases} x_1 - x_2 - \lambda \ln\left(\frac{0.35}{0.26}\right) + \delta_{12} \geq \ln(0.26), \\ -x_1 + x_2 - \lambda \ln\left(\frac{0.57}{0.35}\right) + \eta_{12} \geq -\ln(0.57), \\ x_1 - x_3 - \lambda \ln\left(\frac{0.34}{0.24}\right) + \delta_{13} \geq \ln(0.24), \\ -x_1 + x_3 - \lambda \ln\left(\frac{0.46}{0.34}\right) + \eta_{13} \geq -\ln(0.46), \\ x_1 - x_4 - \lambda \ln\left(\frac{1.52}{0.80}\right) + \delta_{14} \geq \ln(0.80), \\ -x_1 + x_4 - \lambda \ln\left(\frac{2.41}{1.52}\right) + \eta_{14} \geq -\ln(2.41), \\ \quad\quad\quad\quad \vdots \\ x_7 - x_8 - \lambda \ln\left(\frac{2.09}{0.99}\right) + \delta_{78} \geq \ln(0.99), \\ -x_7 + x_8 - \lambda \ln\left(\frac{3.19}{2.09}\right) + \eta_{78} \geq -\ln(3.19), \\ \lambda, x_1, x_2, x_3, …, x_8 \geq 0, \\ \delta_{12}, \delta_{13}, \delta_{14}, …, \delta_{78} \geq 0, \\ \eta_{12}, \eta_{13}, \eta_{14}, …, \eta_{78} \geq 0. \end{cases}$$

(8)

Taking a sufficiently large number for M, say M=1000, to solve this model with Lingo 17.0 as shown in Figure 4, the optimal solution can be obtained as

Table 2: Fuzzy comparison matrix of the aggregated weights of the criteria

| Criteria | | C_1 | | | C_2 | | | C_3 | | | C_4 | | |
		Company			Supplier			Competition			Consumption

Figure 4: The result obtained from Lingo 17.0.

$$x_1^* = 0, x_2^* = 0.4656, x_3^* = 1.1459, \dots, x_8^* = 0.5329,$$

$$\delta_{12}^*, \delta_{13}^*, \delta_{14}^*, \dots, \delta_{78}^* = 0,$$

$$\eta_{12}^* = 0.0889, \eta_{13}^*, \eta_{14}^*, \dots, \eta_{78}^* = 0,$$

based on which, normalization of LFPP priorities as

$$w_1^* = \frac{EXP(x_1^*)}{\sum_{i=1}^{8} EXP(x_i^*)} = 0.0620,$$

$$w_2^* = \frac{EXP(x_2^*)}{\sum_{i=1}^{8} EXP(x_i^*)} = 0.0988,$$

$$w_3^* = \frac{EXP(x_3^*)}{\sum_{i=1}^{8} EXP(x_i^*)} = 0.1951,$$

$$\dots,$$

$$w_8^* = \frac{EXP(x_8^*)}{\sum_{i=1}^{8} EXP(x_i^*)} = 0.1057.$$

According to (7), the results of the consistent test found that there were four pairs outside the specified limits: a_{12}, a_{15}, a_{23}, and a_{25}, so the decision-makers needed to reevaluate the pairwise comparison judgment as shown in Table 3.

After reevaluating, weights were found and the importance could be sorted as shown in Table 4 and Figure 5. Lingo 17.0 with Intel (R) Core (TM) i5-3570 CPU @ 3.40GHz RAM 8.00 GB 64-bit was used to calculate weights of each criteria. The total calculation time for weights criteria was 0.06 seconds.

The prioritizing results clearly show that external factors, which are government and competition, are the main criteria for applying SSCM in the factory. Then, the economic, social, and environment criteria, which are TBL factors for sustainability, are considered. Their weights are similar which means that the emphasis of the factory on TBL is balanced. Finally, supplier, consumption, and company, which are internal factors have lower weightings.

Table 3: Reevaluate fuzzy comparison matrix

Criteria		C_1 Company			C_2 Supplier			C_3 Competition			C_4 Consumption		
C_1	Company	1.00	1.00	1.00	0.26	0.35	0.65	0.24	0.34	0.46	0.80	1.52	2.41

Figure 5: SSCM criteria weights

External pressures from the government and competitors' impact on SSCM for the automotive elastomer manufacturer in Thailand. There are some regulations and laws that control environmental problems that are caused by small particles and hazardous chemicals. The factory has followed the standards of the Ministry of Industry and certified ISO 14001:2015 for many years. The environmental issue is one of the company's strategies. It has an operation plan to protect the environment such as use fewer chemical substances, reduce wastes and pollution, etc. These two factors are very important in leading the factory to the implementation of SSCM.

In the competitive market with rapid change, the factory needs to adjust itself to satisfy the target market, which is the global market. Most of the management team in this factory are foreigners who mainly focus on the global trend. Sustainable awareness for the manufacturer is currently in practice.

The economic issue is important for all profit organizations to survive. However, it should be balanced with social and environment issues. Every project about sustainable management in the factory has to be evaluated by feasibility analysis before implementing it.

The company implemented GSCM before desiring to switch to SSCM, so environmental concerns have existed in almost all of the supply chain. It has been certified to ISO14001:2015 for many years and still keeps track to reduce environmental problems of the factory.

The factory has a policy to select high-quality suppliers. These selected suppliers can help the company to improve the firm's competitiveness across its supply chain. Reasonable price, high quality of raw materials, and fast response are the main factors of the selection. The existing suppliers rarely consider sustainability.

Most customers of the factory are foreign customers, who have less concern about the sustainability of the products. The company products are small parts for automotive manufacturers. Most of the automotive manufacturers are considering clean technology involving combustion in the engine, which is not related to the case study company's products.

The company has the least weight of importance for SSCM. It operates for maximizing profits but the regulations, standards, laws, and stakeholders have forced the company to be concerned not only with profit but also the environment and social issues.

5. Conclusions

This research proposes a framework for SSCM that combines the whole supply chain. It is applied to the case study factory, which is an automotive elastomer producer. Criteria are collected and factors (government and competition), TBL factors (environment, rearranged into the framework, which is suitable for a manufacturer. Three main groups of criteria, which are external social, and economic), and internal factors (supplier, company, and customer) are reviewed. These factors are prioritized by the LFPP method, which has advantages over other methods. Government and competition are the most important criteria for the case study factory that force it to implement SSCM. Laws, regulations, and standards are carefully determined and set for the company to achieve. They are set has the highest priority for the company to achieve. Market and competitors are studied and the operation plan related to these criteria is defined. Environment, social, and economic criteria are the next factors that the factory is concerned about. They are considered to be at the same level of importance, which is balanced according to the concept of SSCM. Profit is still the goal that the factory wants to achieve, but there is also an environmental concern and the certified environmental standard to be satisfied. Moreover, the factory has plans for corporate social responsibility activities with the communities in its action plan. Existing SCM involves suppliers, the company, and customers. They are considered as the less important criteria. The proposals of actions of the case study factory was shown as an example for the other factories.

For future research, the level of SSCM performance in each practice tool should be evaluated to know the efficient tools for the implementation of SSCM.

A B S T R A C T

Nowadays, the Internet has become an indispensable tool for the realization and continuity of activity at a different time, place, and technological context (e.g., mobile, pc, tablet), so that interaction techniques through the use of multi-device support have become of great interest. From this perspective, continuity in interactions is an essential concept in the face of changes in context environments where an interaction develops. There are works related to the continuity and support of multi-device environments through software platforms that are useful to improve continuity support; however, reducing steps to resume an activity on a different device is an aspect that needs to be studied in greater detail. In support of the above, this paper presents an exploratory study that shows that continuity is a useful feature for users; however, there are still aspects that need to be studied. Therefore, in this paper, we propose a platform to implement continuity in a workflow that reduces the steps necessary to continue and resume activity in a different device context and a case study which serves as a method to evaluate the platform proposal and the models on which it is based.

1. Introduction

The Internet has become one of the main tools for carrying out different activities in various sectors, for example, work, entertainment and communication [1]. The evolution of the Internet has had effects in many areas of information and communication technologies such as computers [2] that make use of it, and the paradigms and models of software development [3].

The evolution of computers towards small devices with considerable computing capacity and intelligence, have brought about changes in the design and interaction paradigms seeking a better integration in our environments [4]. The constant evolution of computers towards small devices with considerable computing capacity and intelligence, have brought about changes in the design and interaction paradigms seeking a better integration in our environments [5]. In general, these developments use tools that make it easier to carry out software projects.

Interaction techniques through the use of platforms with support for multi-device environments have become one of the fields of greatest interest thanks to the great adoption of the internet and the evolution of information and communication technologies, taking advantage of its advantages [6]. The tools that have emerged derived from these techniques are broad and useful, focusing on different areas of interaction such as the use

of single sign-on systems, the use of multiple devices to interact with the same system at the same time, and the ability to continue certain activities with a long duration across different contexts [2].

In multi-device interactions, an activity can be carried out through different devices and in other contexts; this is much more complex to keep a user-focused on an activity and recover the activity's status was left. For example, a student who writes a document on a computer at his school may interrupt his work and continue it later from a different computer at home. This activity implies having to transfer the information from one computer to another and recovering the last state (e.g., page of a document where the student was, available tools, and information on the clipboard).

Continuity has become an essential concept in recent years for commercial information systems. We can find these systems such as Netflix, Amazon Video, and Spotify, which allow through a login and constant synchronization between devices to maintain a state between them and allowing the user to resume their activity (playback of some content multimedia) in a different context. Similarly occurs with Apple operating systems, which, in the case of system-specific applications, allow resuming an activity between devices, omitting several additional steps to do so.

Continuity has been one response to the interruptions brought by changes in context, reducing the number of steps necessary to

*Corresponding Author: Luis G. Montané-Jiménez, Email: lmontane@uv.mx

continue an activity; however, its implementation is complex due to multiple aspects [4], [6]. Therefore, we propose a conceptual platform that helps implement continuity in a software project, and it helps reduce the number of steps necessary to continue an activity when changing context. This proposed platform allows programmers and designers to focus their efforts completely on said design and reducing the workload to implement continuity. It also reduces the users' cognitive load in applications complex by quickly migrating an activity between different devices, reducing interruptions in the workflow.

This paper is structured as follows. Section 2 reviews the terms related to continuity in the workflow, and Section 3 presents a comparison of the work related to continuity and workflow. Section 4 presents a study of continuity in commercial applications. Section 5 presents a conceptual model of continuity in software projects. Section 6 presents a case study where the platform was implemented for testing. Finally, Section 7 presents the conclusions and future work.

2. Continuity in workflow

2.1. Workflow

The term workflow is a concept applicable to all areas where the human being develops. Specifically, information systems refer to a series of tasks that must be followed and completed so that a user can obtain a result (e.g., complete an activity). In [7], the authors refer to the workflow simply as flow. The workflow tends to be confused with the activity itself. This activity is the aim pursued by the user. For example, when someone to read a book, the workflow is necessary to complete it: i) read chapter 1, ii) read chapter 2, among others. The workflow has the characteristics shown in Table 1.

2.2. Interaction between devices

Adopting multiple devices in people's daily lives creates an environment where information is easily shared between them [8]. Currently, users are not limited to owning only a computer and a mobile phone, systems that in most cases are isolated from each other. In these environments, a user can have multiple computers that are used in different places and with other devices such as tablets or Smart TVs that have tools and applications that have the ability to interact and communicate with each other to offer the user a user interface that is seen as a whole, regardless of the equipment or device where users perform an activity.

Interaction between devices is an emerging branch of Human-Computer Interaction (IHC) focused on the way in which users interact between the different devices to which they have access, as well as the way in which applications take advantage of these forms interaction to offer much more dynamic user experiences [9]. There are two types of interaction between devices, i) interaction with multiple devices and ii) interaction across multiple devices [6]. The i) interaction with multiple devices is based on the ability of each of the devices to operate a system or application at the same time [10], allowing to create an environment where each device takes a specific role within the application and thereby better distributing the options and capabilities of the system. It focuses especially on collaborative environments where each person can take a specific role within the application, adapting the interface to each role and thereby

avoiding overloading the interface with unnecessary elements. On the other hand, ii) interaction through multiple devices focuses especially on monitoring activities that were started on a certain device, and due their duration, it may need to be interrupted and continued on a different device [7], facilitating the change of context for the user using concepts such as continuity and workflow to provide better user experiences.

Table 1: Workflow characteristics

Characteristic	Description
Divisible in tasks	The activities can be divided into more specific and shorter tasks, the completion of these tasks has the consequence of approaching the end of the activity.
Duration	It is an important factor in the definition of an activity and its flow, it defines the time that is invested in carrying out the activity and generally greatly affects the methods and moments of interaction.
Focus	It refers to the number of people involved in the activity; it affects the way in which the activities are carried out. It is possible to catalog the activity flows in two: one user and multi-user.

2.3. Continuity

The continuity term is defined as the ability to perform an activity on devices used sequentially and without presenting major interruptions in their workflow (context changes) [6]. It is a capacity and characteristic that we can find present in many commercial systems and applications and that take advantage of the benefits of the Internet and the capabilities of the devices with which we interact to reduce the steps necessary to continue an activity between them.

The experiences that implement continuity have 6 main characteristics that can be seen as objectives to be achieved [6]: i) Privacy, provide the user with the assurance that the data is safeguarded. ii) Appropriation, operate inherently in conjunction with the user and their work context. iii) Personalization, provide users with the possibility to choose which and when the continuity functions are activated. iv) Awareness, ability to "infer" the next steps that the user will perform. v) Inclusion, broad compatibility with current and future devices of the user, increasing interaction possibilities. Finally, vi) Troubleshooting, offering the ability to solve problems arising from the use of continuity to the user.

In a specific context in which a user interacts with a system that implements continuity and requires interrupting their work and continuing it in a different context, it is possible to distinguish two types of continuity [7]: monoactivity, and sequential activities. In monoactivity, continuity refers to activities such as: reading a book, watching a movie, or writing a text that may require a long time to complete. The advent of technology and the great expansion of mobile devices have contributed significantly to users changing how they performed these actions [2]. These activities can be carried out in short periods, where the context of use and the time available have an essential effect on the

interaction. Continuity in one-time activities focuses on this type of interaction, trying to minimize the necessary steps so that a user who left an activity pending completion can resume it when he deems it appropriate.

Continuity in sequential activities refers to when the user faces activities whose time and necessary effort allow them to be divided into the performance of sub-activities [7]. The continuity in these types of activities does not depend on being able to carry out the same activity through different contexts, but rather on maintaining a state between all the sub-activities, allowing the user to minimize the mental processes necessary to continue working. The design of these interactions is not based on its duration but rather on the place where a sub-activity occupies the general activity. In general, these types of interaction focus on offering the user information related to the last time they interacted with the system rather than minimizing the steps necessary to continue with the activities.

3. Continuity related work analysis

Multi-device environments and the accelerated evolution of information and communication technologies have led to the development of a great variety of works with multi-device and continuity implications; each of them has its characteristics and qualities. Among the works carried out, the most noteworthy include frameworks, development tools, and evaluations of applications that implement continuity.

3.1. Frameworks

The frameworks are a recurring theme in computer science because they allow us to establish future work bases and propose different approaches to solve a problem. In the multi-device and continuity field, there are several works where proposals for theoretical frameworks are presented. Recent works conceptually propose a framework for co-located devices in the same environment distributing the interface of an application through the users' roles when using the interface simultaneously [10].

In [11] propose a conceptual framework where for each device a role must be established and used in some way within the adaptation process, continuity is included at the conceptual level. More recent works introduce the concept of continuity as in "Design a framework to support the development of smart cross-device applications" [9], where a framework is proposed which provides guidelines and tools to distribute interfaces through nearby devices. Continuity is introduced as a state maintenance that improves the user experience.

A recurring theme in framework development is maintaining state through different methods. In [12,13] present frameworks that allow data to be automatically migrated between applications. However, they do not have current tools that maintain the state completely. On the other hand, [14] propose a tool to migrate data through interaction with Kinect to migrate data during a work session with several devices easily.

3.2. Development tools

Application development is a complex task that uses many tools to facilitate the process. In the field of continuity and multi-device interaction, work has also been carried out based on tools' development.

In [15] present a studio-type tool focused on the design of multi-device interfaces, and focused on its interactivity. The tool focuses on designing web-based interfaces that can be distributed and function in a coordinated manner between various devices; it also allows defining contexts for the devices to adapt according to them.

Several tools focus on data migration; among them, we can find tools that allow data to be migrated between "neighboring" applications of a mobile device [16]. In [2] propose a tool that allows for migrating information searches between different devices while maintaining history. On the other hand, there are works such as present in [17–19] that allow for migrating the state through different triggers such as biometric sensors and JavaScript methods. Finally, in [20] present a tool that allows data to be migrated through NFC tags, mainly focused on web searches.

Other authors have focused on the development of tools that support the internal procedures of the applications. In [5], the author propose a middleware type tool to implement a single sign-on between devices; continuity is a crucial part of the tool since, through this sign-on, the state can be transferred between devices.

3.3. Evaluations to applications

Continuity is a tool that has been implemented in both software projects and projects for the commercial field, verifying the effectiveness of applications that implement continuity. A multimedia application prototype to continue multimedia consumption through different devices was developed in [21]. This prototyping's main objective is to demonstrate the interaction techniques' effectiveness between the most used devices. Through the study and the prototype, it was possible to demonstrate that it developed software with a user-centered approach is necessary. However, there are still processes that can be implemented to improve interaction.

On the other hand, a conceptual model is presented in [22] where long-term searches on the web are supported across different devices; their approach is not just based on allowing long-term searches across different devices. It also provides intelligence by offering suggestions based on search patterns. The study carried out on the model showed significant differences in user interaction, depending on the context and type of device used.

In [6], the author evaluated one of the most representative applications of continuity in a commercial context: *Apple Continuity*. The study carried out contrasts the characteristics of Apple's service against user comments; the results indicate that continuity is accepted and desired by users in general. However, adapting to these new interaction methods can become complex, so the focus on user-based development is important to avoid such complexity. Further, [23] present an evaluation of automatic code generation to implement continuity with a strong emphasis on commercial applications.

Finally, there are work that present the applications of a method developed by authors to evaluate the migratory aspect of multi-device application such as presented by [24], [25].

3.4. Continuity related work comparative

By reviewing the work related to continuity and multi-device applications, Table 2 is presented, which shows that several

elements come into play when continuity is implemented in devices and systems.

The concept of multi-devices is applied in many ways throughout the different jobs, allowing the creation of different forms of interaction in the systems. It is also proven that it is a key point to give way to the continuity of activities in applications.

Table 2: Comparative of papers related to continuity

Paper	Year	Type	Emphasis	Multi-device	Continuity	
					Explicit	Implicit
Mobile to TV migration	2008	Tool	Backend	Yes	Yes	Yes
Remote AppBus	2009	Tool	Backend	Yes	Yes	No
Flexible framework	2009	Framework	Backend	Yes	No	Yes
JavaScript state	2011	Tool	Frontend	No	No	Yes
Multimedia prototype	2011	Evaluation	Frontend	Yes	Yes	Yes
Deepshot	2011	Framework	Backend	Yes	Yes	Yes
Single session start	2012	Tool	Backend	Yes	No	Yes
Virtual Browser	2012	Tool	Backend	No	Yes	No
Taskshadow-W	2013	Tool	Backend	No	Yes	Yes
Communication evaluation	2013	Evaluation	Backend	Yes	Yes	Yes
Interface IDE	2014	Tool	Frontend	No	No	No
XDKinect	2014	Framework	Backend	Yes	Yes	Yes
Search model for continuity	2015	Evaluation	Backend	Yes	Yes	No
Code generator	2015	Evaluation	Backend	Yes	Yes	No
Apple Continuity	2016	Evaluation	Frontend	Yes	Yes	Depends
CustomConsole	2016	Framework	Backend	Yes	No	No
Moving context kit	2017	Framework	Backend	Yes	Yes	No
Yanux framework	2018	Framework	Frontend	Yes	No	Yes
CORMORANT	2019	Tool	Backend	Yes	Yes	Yes
Model 4C's	2019	Framework	Backend	Yes	No	Yes

In the same way, works have been created that support the implementation of a part of continuity in applications. The main problem found in them is the poor compatibility with applications due to their focus on a specific aspect makes it difficult for continuity to be implemented by developers except in the aspects for which these tools were developed. It is also noteworthy that, in recent years, jobs such as [9–11] have focused on the creation of frameworks both at a conceptual and technical level for the creation of tools with interactions in continuity, showing a huge advantage over applications because they allow developers to expand the range of end uses that may have an application.

Based on the information presented in Table 2 and the reviewed works, we can see that, although explicit continuity and implicit continuity (called by many authors as maintenance of a state) are characteristics that do not always go hand in hand. The results, especially from those studies focused on evaluations of continuity implementations, suggest maintaining a state in applications that implement continuity is a very desirable feature.

With the analysis of the related works, it can be affirmed that one of the ways to implement continuity in the applications is through a framework or technological platform that provides developers with the necessary tools to create ecosystems with continuity characteristics. Although forays into these types of work have previously been made, there are aspects that remain to be covered, such as compatibility with modern platforms and with future platforms and the generalization of activities.

One of the most desirable features in continuity is maintaining an application state, which, in the long run, reduces the steps to resume an activity. This aspect is a topic little explored by researchers.

4. Exploratory study

In support of the points identified in the review of works, an exploratory study was designed to identify points of improvement in the user experience in multi-device applications, with a specific focus on applications that implement one or more aspects of continuity. The methods and materials used for this study are described below.

4.1. Experiment design

For this study, an exploratory experiment was designed and executed using the Google Forms tool; a questionnaire was constructed with a total of 20 items or questions that encompassed four different categories. Users were chosen randomly, regardless of their age, gender, or degree of academic studies. A total of 30 people were chosen for the application of the study.

The categories considered for the exploratory study are the following: i) general user data for classification and future consideration during data analysis; ii) continuity analysis in multi-device applications focused on music streaming; iii) continuity analysis in multi-device video streaming applications; and iv) continuity analysis in multi-device applications for document editing.

4.2. Evaluation tools

For the study, a questionnaire with 20 items was designed, the first four dedicated to categorical information from the user; the rest are described in Table 3. For its execution, the Google Docs tool was used; specifically, the Google Forms application allowed the questionnaire to be distributed quickly and effectively to the respondents. Another reason for its choice is that it provides a graphical analysis of the results and avoids the results' repetition by monitoring the respondents with their email.

Table 3: Questions applied in the exploratory study

ID	Question	Detail
5	How often do you use these devices to play music?	Question on Likert 5 points scale

6	It would be useful if the application automatically changes places to play your music on the most suitable device	Question on Likert 5 points scale
7	Would you like the application to be displayed as you interrupted it on another device when changing devices?	Question on Likert 5 points scale
8	What would you expect your player app to do when you want to switch devices?	Multiple option question
9	How often do you use these devices to play video?	Question on Likert 5 points scale
10	Of the following characteristics of an application for video playback, which of them are most important to you	Multiple option question
11	Is it useful to you that a video player application allows you to continue a movie / series right where you left off?	Question on Likert 5 points scale
12	You would like a video application to allow you to continue with a movie / series on another device only by turning it on and opening the application	Question on Likert 5 points scale
13	When it comes to playback across multiple devices, what would you improve on a video app?	Open question
14	How often do you use these devices to work on a document?	Question on Likert 5 points scale
15	Have you ever used the "pick up where you left off" feature in Microsoft Office	Multiple option question
16	How useful is this feature for you when switching from one workplace to another or between different devices?	Question on Likert 5 points scale
17	How much would you like Microsoft Office to allow you to continue a document without having to indicate it using the "continue where you left off" function?	Question on Likert 5 points scale
18	Would it be useful for you if, in addition to taking you to the section where you worked in the document, also the settings, clipboard and tools kept their last state?	Question on Likert 5 points scale
19	Would you like that when you open the Microsoft application (Office, Excel, PowerPoint) it would automatically open the last document you had open?	Question on Likert 5 points scale
20	When it comes to writing documents, what would you expect from an application when switching between contexts or devices?	Open question

4.3. Process

The participants' selection was carried out randomly, a short introduction to the subject of the study was given, and the instructions for filling out the tool; their participation was completely voluntary.

The tool was sent by electronic means to the users chosen for the test who had the approximate time of 1 day to answer them without affecting their working hours or daily activities. Finally, after a week, the data obtained through the platform was collected for subsequent analysis.

4.4. Results

Regarding music playback applications, it is notable that one of the characteristics most sought after by users is the "intelligence" of the application to play on the most suitable device available.

The results translate into that it would be instrumental for most users if they are playing music, and this automatically chooses the most appropriate device to play on. For example, a user who plays content on their cell phone, and when they get to Your home could automatically transfer this playback to your TV or computer, without the need for intermediate steps.
Figure 1: Opportunities of continuity in music streaming apps
Figure 2: Continuity in video streaming apps

In addition, an aspect that music applications lack and that users expect from applications is the maintenance of a state, that is, that the application remembers where it was stopped the last time it was used, as can be seen in the second graph of Figure 1.

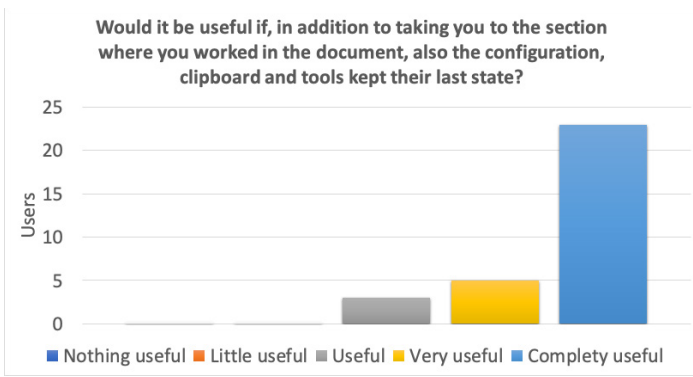
Regarding video applications, continuity has a greater presence in the application processes and turns out to be one of the characteristics that users like the most, as shown in Figure 2. In the same way as playback applications, music users are interested in the possibility of maintaining the state of the content reproduction when exchanging between devices. However, the approach applied in implicit continuity is not as relevant for users as seen in the second and third graphs of the survey conducted. Finally, for productivity applications, an analysis of the continuity implementation was carried out for an office suite widely used in the world and whose continuity implementation is explicit. Each time the user starts the application and opens a document you have been working on recently, you are presented with a button to go directly to the place where you last edited the document.


Figure 3: Continuity in document edition apps

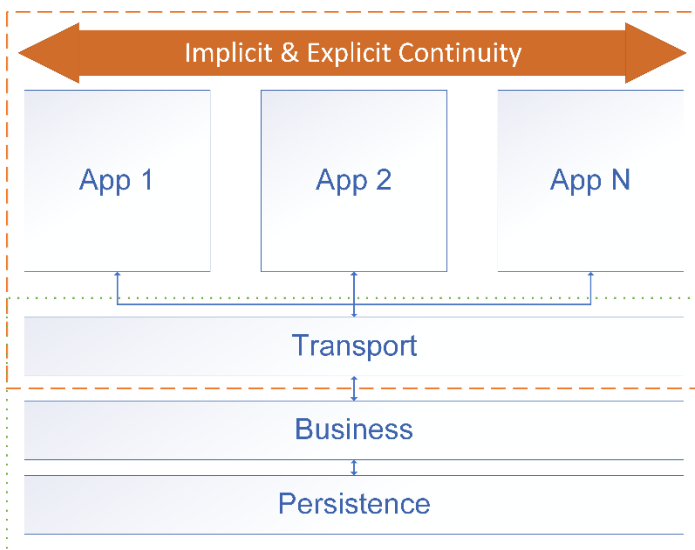
In this type of application, two important aspects can be distinguished with regard to continuity. An important aspect mentioned by users is that the application directly remembers the status of the application with the documents they are working on, without the need for this function to be explicitly activated by the users. On the other hand, users would also find it useful to retrieve the configuration of tools for editing documents such as clipboards, temporary settings of the application, and additional tools such as a calculator or a browser; the results of the latter can see in Figure 3. With what was previously described, some users differ in the case that the application implements implicit continuity. It could be noted in the review of the comments made by the users; not all agree that the last document worked should be opened.


Figure 4: General model of the platform for implementation of continuity

5. Conceptual model for continuity implementation in software projects

Based on the models proposed by [5,9–11,15] and in the results of the continuity study carried out, a technological platform proposal was made at a conceptual level for the implementation of continuity in the activity flows shown in Figure 4 and detailed in its components in Figure 5. This model proposes an architecture for a platform where applications compatible with different devices can be easily implemented, and one of its goals is to allow its users to continue their task in a simple way when faced with a context change. The objective and the structure of the model for

the platform allows the reduction of steps necessary to continue an activity between several devices, that is, to facilitate the implementation of implicit continuity in several applications.

In Figure 4, the general behavior of the platform can be observed. Through a set of layers, the necessary support is provided to create multi-device environments, taking advantage of the possibilities of explicit continuity and, above all, of implicit continuity, regardless of the type and number of applications being developed.

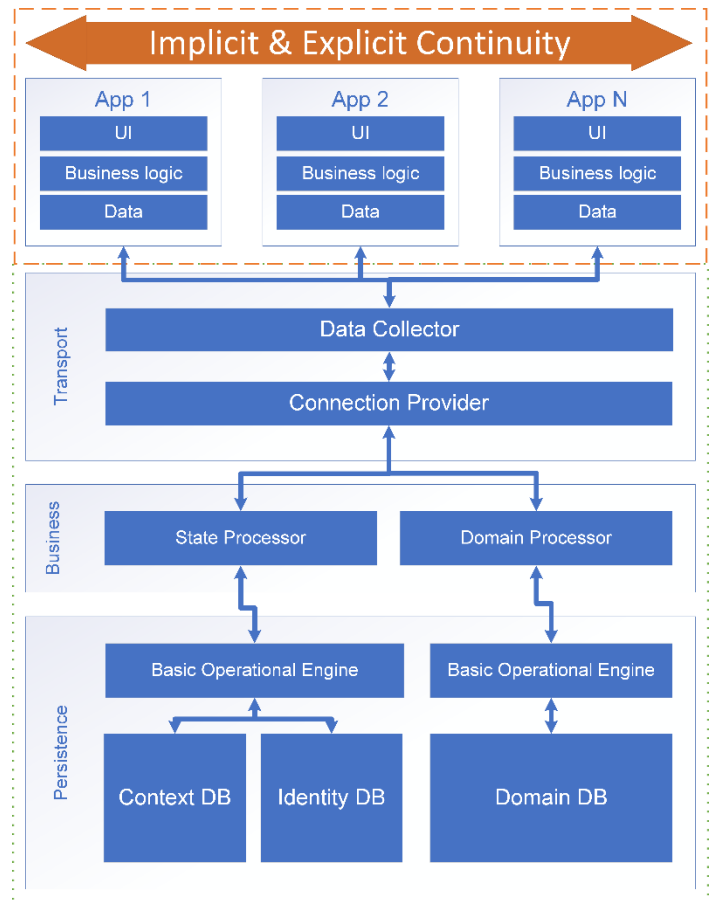
The persistence layer focuses on the storage of information corresponding to the application domain and the context where it operates (for example, the type of device used and the environment where it is done), typically composed of three elements, i) the application's usage status data, that is, configuration and usage information, this data contains information about how the last device was used ii) the device status data that considers device-specific details such as type of last device or the app version used which helps to adapt the interface of next used device and iii) the domain data referring to the application's own information (documents, photos, among others) which is used to present the data that were working, is based on unstructured language for the storage of information. This layer also contains the basic operational engine, which provides essential functions (create, update, delete, and read) over the data storage in order to operate with the basic application information.


Figure 5: Components of the technological platform for the implementation of continuity in software projects

Table 4: Description of the conceptual model of a technological platform for the implementation of continuity in workflow

Characteristic	Description
Context DB	Storage component that allows to save the information of the context of use of the devices, it is a long-term data storage software, it contains elements that function as tools for the selection of device sequence and the configuration of interfaces
Identity DB	Storage component that stores information corresponding to users and that is used as a starting point to create state representations, this database must contain data from the user that help to identify the information that is stored in the context and domain database, its purpose is to maintain control over the information that the platform operates
Domain DB	Storage component focused on the operational information of the applications, it contains representations of the information that the user enters or obtains from the application.
Basic Operational Engine	It is a logical component that provides access to the basic functions on the storage components, the proposed implementation design defines an engine for domain data and another for identification and context information in order to reduce workloads over other components.
State Processor	Logical component that allows composing and decomposing the state representations and the information obtained from the operational engines and sending that information to the next layer depending on whether it is retrieved or entered into the platform, its purpose is to offer an interpreter for both directions of the platform.
Domain Processor	Logical component that provides functionality on domain information and that must establish the data transformation bases for the changes that are necessary between the jumps of multiple applications. This element works as a translator when it is necessary. It must also be responsible for communicating the domain data to the upper and lower layers in order to reduce the information contained by state representations
Connection provider	High-level component that functions as a data input to the lower layers, receives the information from the data collector and is responsible for passing it to one of the two processors of the business layer. This component is proposed to function as an API in order to be able to be integrated into software projects without having to modify the base structure of the project
Data Collector	Its a high-level component that is proposed to be responsible for direct communication with the final applications, it must be in charge of obtaining the necessary information to create the representation of the state that will be sent to the connection provider and also of presenting the information when a representation is retrieved from the platform towards a final device, It is proposed that this element be built as libraries for the specific programming languages of each final application
App 1,2… N	These are the final applications where the platform can be implemented, which can go from 1 to N, each one can have its own logic processes, information storage media and graphic interface.

The persistence layer communicates with the business layer, which comprises two processing services (state and domain logic). These processing elements are responsible for making the necessary changes to the data; being the most important elements since a large part of the adaptation depends on them. Finally, in the highest part, the transport layer is composed of two elements (data collector and connection provider). These elements are those that are exposed to the developers and are integrated into the final applications, built in the form of APIs, extracting the necessary information from the applications and sending them to the processing models so that the rest of the platform works. It is also are responsible for making the necessary changes to the application interfaces. It is through these two elements that applications reduce the steps necessary to resume activities. These elements have to be able to scale to serve as many final applications as a program has been developed.

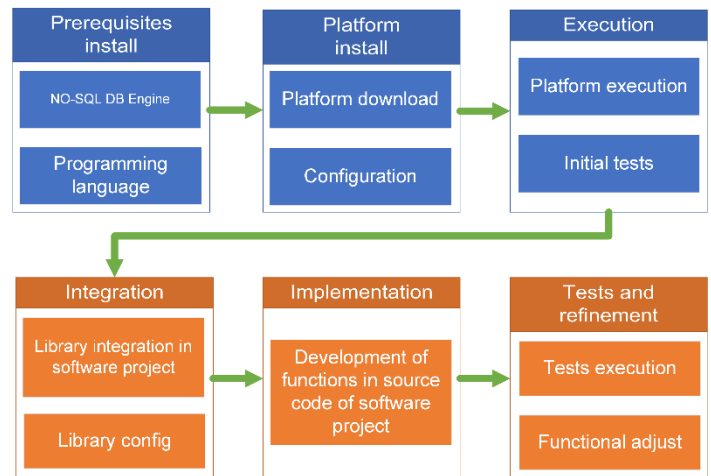
In order to support the understanding of this platform, a diagram was developed with the components of the model and which is presented in Figure 5, as well as the description of these components which is found in Table 4.


Figure 6: Platform implementation roadmap

In Figure 6, the platform implementation is shown; in the upper part the work stages are shown directly on the platform which are: i) pre-requisite installation in which the execution environment of the platform through the configuration of tools for database management and the programming language used by the platform, ii) installation of the platform that consists of downloading the platform code and its configuration with the database management tool, iii) Execution which consists of the start-up and rapid tests of the correct operation of the platform.

At the bottom of the implementation sheet, the steps after the installation of the platform are shown, which apply directly to the software project; these steps are: iv) Integration where the libraries that are added to the software projects allow communication to the platform and its configuration, v) Implementation where the views and functions of the software are developed, and it is indicated where the platform libraries will work and vi) Testing and refinement where the tests should be carried out on each final application and adjusting functions in case these changes are necessary.

6. Case Study

The platform is an intermediate software that communicates with the different components of other applications; due to the nature of this type of software. It is impossible to carry out functional and use tests directly on its construction, so the software is implemented in a Case study where both the function and the user experience when using continuity could be evaluated.
Figure 7: Implementation architecture for study case

The selected case study is an application that allows you to create exams according to a catalog of questions previously evaluated and approved. The process of editing an exam can be a complex task for those who take it, and because of this, in many cases, it is necessary to move it between one device and another.

The case study has three elements: a direct administration system that allows the question catalog to be generated, edited, and debugged. A web application is attached to the administration system to generate the exams from any browser. Finally, an Android application that also allows generating the exams.

The structure of the selected application makes it perfect to test the proposed solution because it's possible to change between two different types of apps and two different contexts, also, the selected applications can be executed in many modern mobile devices and even in any device that can accessing internet through a web browser.

On the other hand, the limitations of this case study are that it does not allow the analysis of an interaction that is too deep, such as using a text editor, in addition to the fact that it is an application in its final stages of development, so an error that is not related to the use of continuity and biases the study in a certain way.

Two libraries were built that allowed to integrate the platform in the case study, the first in JavaScript for the web sections and the second in Java-Android for the android section of the case study. Figure 7 shows in detail the structure and elements that make up the platform in its implementation for the case study.

The persistence layer is implemented through two databases that represent the storage components, one for the domain and one for the state. These connect a first layer of python that offers basic functions on databases (basic functional engines). At the second level there is a business layer that implements methods and processes to arm and disarm the state representations and finally the transport layer is responsible for implementing a RESTful-type web service and the two libraries mentioned above, while the REST service receives and sends the information when the

libraries so require, the libraries control directly and in a practically automatic way the events in the applications of the case study that save and retrieve the information.

7. Conclusions and future work

The development of computer systems has changed over time, adapting to the different tools that arise daily. The notable increase in the use of mobile devices is one of the main reasons that have led to the emergence of new interaction and development paradigms.

One of the main topics that researchers and the market related to systems development have focused on is multi-device interaction. Continuity arises as part of the multiple ways in which a multi-device interaction occurs. The possibilities that continuity offers to improve the different ways in which a user interacts with a system are vast, yet there is still a long way to go.

One of the problems that researchers currently focus on solving through the use of continuity is the minimization of interruptions in the flow of an activity, something that could be seen through the review of works related to this research and the exploratory study carried out is a feature that users are beginning to expect from the systems.

The design of a platform to implement this type of interaction is complex due to the components that are required for correct operation, as well as the very logical structure that is required to maintain the state of the applications between the changes made by the user.

The results obtained once the implementation was carried out in the case study were favorable, the platform facilitated the continuity implementation in the case study and also allowed to reduce the necessary steps to resume an activity, which facilitated context changes for users.

In contrast to other works that were reviewed during the writing of this document, we can see that a platform that provides full support for continuity has a deeper impact than applications such

as [2,4,5,12–14], whose emphasis is strongly focused on the login and the migration of user data over the migration of operation data.

On the other hand, a better performance can also be noted than the proposals made by authors such as [3,9,11,16,18], where migration Information is a present feature, but small details such as the configuration or the last view requested are not considered, forcing the user to have to remember this when resuming an activity. It is still necessary to make improvements with respect to the platform's ability to adapt based on usage preferences and configurations that affect continuity, as well as to carry out tests that guarantee its effectiveness, with continuity being a useful tool in different contexts of use. However, it still requires a long and dedicated development process.

Finally, as part of the future work, it is expected to carry out a series of tests through the case study in order to validate the functionality and design of the Platform.

Conflict of Interest

The authors declare no conflict of interest.

Evolution of Cardiovascular Risk Indicators in Elderly Hypertensive Men from a Health Facility in North Lima

Rosa Perez-Siguas[*], Hernan Matta-Solis, Eduardo Matta-Solis

Research and Intellectual Creativity Direction, Universidad María Auxiliadora, 15408, Lima-Perú

A R T I C L E   I N F O

A B S T R A C T

Cardiovascular risk today is one of the non-communicable diseases that occurs in the population of the third age where risk factors further compromise its health, therefore the objective of the study is to determine the evolution of the Cardiovascular Risk indicators in hypertensive elderly from a facility in North Lima. This is a quantitative, non-experimental, descriptive, and cross-sectional study, with a population of 47 hypertensive elderly people over 60 years of age, whose cardiovascular risk was determined with the PAHO cardiovascular risk calculator. In the results, we can see that in the month of January, 17 (36.2%) presented a moderate risk, 19 (40.4%) presented high risk, 8 (17%) presented very high risk and 3 (6.4 %) presented critical risk, in June, 17 (36.2%) presented low risk, 24 (51.1%) presented moderate risk, 4 (8.5%) presented high risk, 2 (2.1 %) presented very high risk and 1 (2.1%) presented critical risk and in December, 25 (53.2%) presented low risk, 17 (36.2%) presented moderate risk, 4 (8.5%) presented high risk and 1 (2.1%) presented critical risk. In conclusion, prevention of cardiovascular problems in the elderly should be expanded, to contribute to their health status and quality of life due to the increase in population.

1. Introduction

Cardiovascular risk is the probability that the individual presents cardiac problems in a certain time, and this will depend fundamentally on factors that predispose the individual's risk, these factors can be modifiable and non-modifiable, whose function varies in relation to the present risk, which can be qualitatively (high, intermediate or low) or quantitatively (numerical probability of suffering a complication in a given period) [1].

In the population, aging worldwide is increasingly accelerated, whereas of 2015 the amount of the population of older adults in the world has doubled, going from 12% to 22%, it is also underestimated that within 2 years the number of the age group of the elderly will be higher than children under 5 years of age. Likewise, in the near future, the majority of older adults will be concentrated in countries with low to middle income [2], therefore it should be taken into account that the aging process is usually accompanied by chronic diseases, among which stand out heart disease [3].

Worldwide, cardiovascular diseases (CVD) are responsible for approximately 17 million deaths per year, among them

complications from high blood pressure produce 9.4 million deaths annually. The worldwide prevalence of hypertension (HT) is estimated to be 35% [4]. For its part, the Pan American Health Organization (PAHO) estimates that hypertension affects between 20-40% of the adult population in the Americas. At the Peruvian level, 16.5% are affected [5]. Focusing on the elderly, HT affects 67% of those over 60 years of age in the United States and in Peru the prevalence is 43.3% in those over 60 years of age. The foregoing shows that hypertension is a growing public health problem, in the context of epidemiological transition that the country is going through [6].

In a study carried out in Peru [7], they observed that in patients older than 80 years of age with a history of HT, the main risk factors were that 10.07% of older adults were smokers and it was more frequent in men. As for women, 33% had high cholesterol in both sexes, diabetes mellitus in 16.63% and 14.29% were obese, these last two risk factors were seen more in women than men.

In a study carried out in Brazil [8], they showed in their results cardiovascular factors in patients older than 60 years in relation to the cardiovascular disease they suffered and their lifestyle habits, where 53% had high blood pressure, 25% diabetes mellitus and 8% already suffered from a cardiovascular disease,

in relation to their life habits, 68% of older adults carried out physical activity, 35% were alcoholics and 50% were smokers, therefore risk factors such as alcoholism and smoking occurred more in men than women, and therefore cardiovascular diseases appeared early in men.

In a study carried out in Brazil [9], they observed in their results that 64.9% of adults older than 60 years with a history of arterial hypertension were obese, also it was found that 70.8% of older adults had a metabolic syndrome, 27.2 % had a low cardiovascular risk, 46.8% moderate and 26% high, interpreting that older adults who presented metabolic syndrome had a high probability of having a high cardiovascular risk.

The present study is important because it will provide relevant and real data about the cardiovascular risks of hypertensive elderly people since the elderly makes them more vulnerable to contracting metabolic and cardiovascular diseases.

2.   Methodology

It is an applicative study where the evolution of cardiovascular risk indicators in hypertensive older adults will be detailed, also 3 measurements will be given in their assessment in the months of January, June, and December, to analyze the evolution and observe if hypertensive older adults present cardiovascular risk factors.

2.1. Research type and Design

The present study, due to its characteristics, way of collecting data and measuring the variables involved, has a quantitative approach. Regarding the methodological design, it is a non-experimental, descriptive, cross-sectional study [10].

2.2. Population

In the present study, the population is made up of 47 hypertensive elderly men over 60 years of age who attend a health facility in North Lima.

2.3. Inclusion Criteria

- Older adult patients suffering from arterial hypertension
- Patients who attend at least 3 check-ups at the health facility.
- Older adult patients who have signed the informed consent according to the principles of ethics of charity, non-maleficence, justice, and autonomy.

2.4. Technique and Instrument

To carry out this research work, the Cardiovascular Risk Calculator of the Pan American Health Organization (PAHO) was used, which aims to determine the risk in the elderly, this instrument was used because the study was exploratory and only required the use of the PAHO Calculator. The Cardiovascular Risk Calculator is administered to assess whether the patient has a cardiovascular risk, this calculator will determine the risk depending on sex, age, blood pressure, history of diabetes mellitus, cholesterol and risk factors such as smoking, in this way it is determined whether the patient is at low, moderate, high, very high, and critical risk; when calculating the parameters, it is estimated that there may be a risk of presenting some

cardiovascular disease - to establish the values, the incidence of less than 10% at 10 years is considered low risk, that is, less than 1% per year. Another way to read it is to consider that of a group of 100 people in this situation, one will develop a disease each year, thus reaching 10 people in a decade. At the other extreme, very high risk greater than 40% at 10 years, indicates that of 100 people in this condition, 4 will have events annually and 40 will have them in the next 10 years; almost one in two [11].

The Calculator is more accurate if cholesterol levels are reported, although it may not be considered if the data is not reported. Once the risk estimate has been obtained, it can be evaluated to what extent the risk could be modified by correcting factors such as smoking, high blood pressure and hypercholesterolemia. It is considered ideal not to smoke, blood pressure values less than 140/90 mmHg and total cholesterol less than 200 mg / dl. In some cases, it is possible that the desired cholesterol may be much lower than that, depending on the presence of other risk factors. In such a way that the person may notice that when they quit smoking their risk drops by half, or that it transforms from very high to low by correcting the three factors that we can influence in this calculator. Age and gender cannot be changed, and diabetes status is taken upon knowledge of its diagnosis but is not based on blood glucose levels or other parameters.

It refers to low risk to carry out all its preventive control activities; moderate risk when it performs its controls but not daily; high risk, when the patient barely performs its preventive controls; very high risk when the patient scarcely performs its preventive controls and presents symptoms product of the disease; and critical risk when the patient does not perform any preventive control and the symptoms present to the disease tend to complicate.

2.5. Place and Application of the Instrument

To carry out the Development of the cardiovascular risk calculator in hypertensive elderly patients, it was carried out in a Health Facility in North Lima

First, the permits were coordinated with the head of the establishment to carry out the research, then the permission to the patient explaining about what was going to be developed and why the research work will be carried out.

It was developed during the mornings with an approximate time of 10 minutes for each elderly hypertensive patient, concluding a good satisfaction since they supported the research work.

It is important to emphasize the presence of health personnel during the development of the research work, because the patient as an older adult with hypertension there is the possibility that signs, and symptoms of the disease may occur and thus the necessary treatment can be administered to be able to stabilize it.

3.   Results

The results of hypertensive elderly patients corresponding to the research work will be shown below:

CARDIOVASCULAR RISK IN HYPERTENSIVE ELDERLY
Figure 1: Semiannual comparison of the Evolution of cardiovascular risk indicators in hypertensive elderly from a facility in North Lima

Figure 1 shows the six-monthly comparison of the evolution of cardiovascular risk indicators in hypertensive elderly people from a health facility in North Lima, where in January, 17 (36.2%) presented a moderate risk, 19 (40.4%) presented high risk, 8 (17%) presented very high risk and 3 (6.4%) presented critical risk, in June, 17 (36.2%) presented low risk, 24 (51.1%) presented moderate risk, 4 (8.5%) presented high risk, 2 (2.1%) presented very high risk and 1 (2.1%) presented critical risk and in the month of December, 25 (53.2%) presented low risk, 17 (36.2%) presented moderate risk, 4 (8.5%) presented high risk and 1 ((2.1%) presented critical risk.

In Table 1, it is observed that in moderate cardiovascular risk, within the hypertensive elderly population, 17 (100%) do low physical activity, at high cardiovascular risk, 9 (47.4%) do low physical activity and 10 (52.6%) do not do physical activity, at very high cardiovascular risk, 3 (37.5%) do low physical activity and 5 (62.5&) do not do physical activity, and at critical risk 3 (100%) do not do physical activity, in relation to weight, the hypertensive elderly had a weight between 70 kg and 99 kg respectively with a height of 155 cm to 171 cm, taking their BMI where in moderate cardiovascular risk 17 (100%) were overweight, in high cardiovascular risk 19 (100%) were obese, at very high cardiovascular risk 5 (62.5%) were overweight and 3 (37.5%) were obese, in relation to smoking, at moderate cardiovascular risk 8 (47.1%) were smokers and 9 (52.9%) were not smokers, in relation to cardiovascular risk and diabetes mellitus, at moderate risk 13 (76.5%) suffered of diabetes and 4 (23.5%) do not have diabetes, at high risk 17 (89.5%) have diabetes and 2 (10.5%) do not have diabetes, at very high risk 6 (75%) suffer from diabetes and 2 (25%) do not have diabetes and at critical risk 3 (100%) do not suffer from diabetes, in relation to blood pressure in hypertensive elderly, they had a blood pressure between 120 mmHG to 180 mmHG and in relation to cholesterol, the hypertensive elderly had a cholesterol level between 180 mg/dl and 300 mg/dl.

In Table 2, it is observed that in low cardiovascular risk within the hypertensive elderly population, 14 (82.4%) do medium physical activity, 3 (17.6%) do low physical activity, and moderate cardiovascular risk 2 (8.3%) do medium physical activity and 22 (91.7%) do low physical activity, at high cardiovascular risk 2 (50%) do low physical activity and 2 (50%) do not do physical activity, in very high cardiovascular risk 1 (100%) does not do physical activity and in critical cardiovascular risk 1 (100%) does not do physical activity, in relation to weight, hypertensive elderly had a weight between 60 kg and 91 kg respectively with a height from 155 cm to 171 cm, taking their BMI where the low cardiovascular risk 6 (35.3%) were within the normal range, 10 (58.8%) were overweight and 1 (5.9%) was obese, at moderate cardiovascular risk, 1 (4.2%) is within the normal range and 23 (95.8%) were overweight, at high cardiovascular risk, 4 (100%) were obese, at very high cardiovascular risk 1 (100%) was obese and at critical cardiovascular risk 1 (100%) was obese, in relation to smoking, at low cardiovascular risk 1 (5.9%) was a smoker and 16 (94.1%) were non-smokers, at moderate cardiovascular risk 13 (54.2%) were smokers and 11 (45.8%) were non-smokers, at high cardiovascular risk 1 (25%) was a smoker and 3 (75%) were not smokers, at very high cardiovascular risk 1 (100%) was a smoker and at critical cardiovascular risk 1 (100%) was a smoker, in relation to cardiovascular risk and diabetes mellitus, at low cardiovascular risk 12 (70.6 %) suffer from diabetes and 5 (29.4) do not have diabetes, at moderate cardiovascular risk 21 (87.5%) have diabetes and 3 (12.5) do not have diabetes, at high cardiovascular risk 4 (100 %) suffer from diabetes mellitus, at very high cardiovascular risk 1 (100%) suffers from diabetes and at critical cardiovascular risk 1 (100%) suffers from diabetes, in relation to blood pressure in hypertensive elderly, they had a blood pressure between 112 mmHG to 155 mmHG, and lastly, in relation to cholesterol in the hypertensive elderly, they presented a cholesterol level between 178 mg/dl to 285 mg/dl.

Table 1: Cardiovascular Risk in Hypertensive elderly in relation to Risk Factors for the Month of January of a Health Facility in North Lima

Cardiovascular risk	Physical Activity		Weight (KG)	Height (cm)	Body Mass Index (BMI)		Smoking		Diabetes		Maximum Systolic Pressure (mmHg)	Cholesterol
	Low	Do not			Overweight	Obese	YES	NO	YES	NO		
Low risk	-	-			-	-	-	-	-	-		
Moderate risk	17 (100%)	0	≥70KG a ≤99KG	≥155cm ≤171 cm	17 (100%)	0	8 (47,1%)	9 (52,9%)	13 (76,5)	4 (23,5%)	≥120 mmHG a ≤180mmHG	≥188mg/dl a ≤300mg/dl
High risk	9 (47,4%)	10 (52,6%)			0	19 (100%)	12 (63,2%)	7 (36,8%)	17 (89,5%)	2 (10,5%)		
Very high risk	3 (37,5%)	5 (62,5%)			5 (62,5%)	3 (37,5%)	5 (62,5%)	3 (37,5%)	6 (75%)	2 (25%)		
Critical risk	0	3 (100%)			0	3(100%)	3(100%)	0	3 (100%)	0		

Table 2: Cardiovascular Risk in Hypertensive Elderly in relation to Risk Factors for the Month of June in a Health Facility in North Lima

Cardiovascular risk 2	Physical Activity			Weight (KG)	Height (cm)	Body Mass Index (BMI)			Smoking		Diabetes		Maximum Systolic Pressure (mmHg)	Cholesterol
	Medium	Low	Do not			Normal	Overweight	Obese	YES	NO	YES	NO		
Low risk	14 (82,4%)	3 (17,6%)	-	≥ 60 Kg a ≤ 91 Kg	≥ 155 cm a ≤ 171 cm	6 (35,3%)	10 (58,8%)	1 (5,9%)	1 (5,9%)	16 (94,1%)	12 (70,6%)	5 (29,4%)	≥ 112 mmHG a ≤ 155 mmHG	≥ 178 mg/dl a ≤ 285 mg/dl
Moderate risk	2 (8,3%)	22 (91,7%)	-			1 (4,2%)	23 (95,8%)	0	13 (54,2%)	11 (45,8%)	21 (87,5%)	3 (12,5%)		
High risk	0	2 (50%)	2 (50%)			0	0	4 (100%)	1 (25%)	3 (75%)	4 (100%)	0		
Very high risk	0	0	1 (100%)			0	0	1 (100%)	1 (100%)	0	1 (100%)	0		
Critical risk	0	0	1 (100%)			0	0	1 (100%)	1 (100%)	0	1 (100%)	0		

Table 3: Cardiovascular risk in hypertensive elderly in relation to risk factors for the month of December in a health facility in north lima

Cardiovascular risk 3	Physical Activity			Weight (KG)	Height (cm)	Body Mass Index (BMI)			Smoking		Diabetes		Maximum Systolic Pressure (mmHg)	Cholesterol
	Medium	Low	Do not			Normal	Overweight	Obese	YES	NO	YES	NO		
Low risk	23 (92%)	2 (8%)	0	≥55 Kg a	≥ 155 cm a	22 (88%)	2 (8%)	1 (4%)	2 (8%)	23 (92%)	18 (72%)	7 (28%)	≥ 100mmHG a	≥160 mg/dl a ≤ 265
Moderate risk	6 (35,3%)	11 (64,7%)	0			1 (5,9%)	16 (94,1%)	0	11 (64,7%)	6(35,3%)	17 (100%)	0		
High risk	0	3 (75%)	1 (25%)			0	1 (25%)	3 (75%)	4 (100%)	0	3 (75%)	1 (25%)		

Very high risk	-	-	-	≤ 92Kg	≤171 cm	-	-	-	-	-	-	-	≤ 150mmHG	mg/dl
Critical risk	0	1 (100%)	0			0	0	1 (100%)	1 (100%)	0	1 (100%)	0		

In Table 1, it is observed that in low cardiovascular risk, within the hypertensive elderly population, 23 (92%) do medium physical activity and 2 (8%) do low physical activity, in moderate cardiovascular risk 6 (35.3%) do medium physical activity and 11 (64.7%) do low physical activity, at high cardiovascular risk, 3 (75) do low physical activity and 1 (25%) do not perform physical activity, at risk Critical cardiovascular 1 (100%) do low physical activity, in relation to weight, hypertensive elderly had a weight between 55 kg to 92 kg respectively with a height of 155 cm to 171 cm, taking their BMI where in low cardiovascular risk, 22 (88%) are within the normal range, 2 (8%) were overweight and 1 (4%) was obese, at moderate cardiovascular risk, 1 (5.9%) is within the normal range and 16 (94.1 %) were overweight, at high cardiovascular risk, 1 (25%) was overweight and 3 (75%) were obese, at critical cardiovascular risk 1 (100%) was obese, in relation to smoking, at low cardiovascular risk 2 (8%) were smokers and 23 (92%) were non-smokers, at moderate cardiovascular risk 11 (64.7%) were smokers and 6 (35.3%) were not were smokers, at high cardiovascular risk 4 (100%) were smokers and at critical cardiovascular risk 1 (100%) was a smoker, in relation to cardiovascular risk and diabetes mellitus, at low cardiovascular risk, 18 (72%) suffered from diabetes and 7 (28%) do not suffer from diabetes, at moderate cardiovascular risk 17 (100%) have diabetes, at high cardiovascular risk, 3 (75%) have diabetes and 1 (25%) does not have diabetes, at cardiovascular risk Critical 1 (100%) suffers from diabetes, in relation to blood pressure in hypertensive elderly, they had a blood pressure between 100 mmHG to 150 mmHG and lastly in relation to cholesterol in hypertensive elderly, they had a cholesterol level between 160mg / dl to 265mg / dl.

Among the results obtained, it is important to consider the months of difference in which it will allow us if hypertensive elderly people can reduce cardiovascular risk by performing physical activities such as passive exercises, walks, yoga, muscle stretching, and the communication with the family as it will allow to see if have any symptoms that decrease their health well-being.

4. Discussion

In this research work, an approach is given to the public health of hypertensive elderly people in a health facility, where factors and conditioning factors in them, such as the elderly population, increase the probabilities of having cardiovascular risks.

In the results on the cardiovascular risks distributed every six months in the months of January, June, and December, we can verify that in the initial month of January, the patients presented a high cardiovascular risk, this is because as adults of the third age, because of their gender male, increases the chances of suffering some type of cardiovascular risk. In [8], they argued that life habits in the elderly population related to cardiovascular risk are influenced by sociodemographic and clinical factors, where sex, smoking and alcoholism; the presence of diabetes mellitus and

arterial hypertension were more associated with the patient's desire to be able to control the disease and the alteration of blood pressure, where they do physical activities and control their own disease. Likewise, in [12], they argued that arterial hypertension is a cardiovascular risk factor with the greatest burden in the male population, therefore, with regard to chronic diseases, it is associated with diseases such as cardiovascular mortality and ischemic heart disease that can compromise the individual's health.

In the same way, the factors that put the health of hypertensive elderly at risk make available the probabilities that they suffer from heart disease or even die as a result. In [7], the authors mentioned that risk factors such as high blood pressure, smoking, diabetes, overweight or obesity and physical inactivity, are factors that compromise the elderly to be vulnerable and increase the chances of dying from heart disease. Likewise, in [13], the authors argued that older adults with cardiovascular risk factors are more associated with suffering an acute myocardial infarction since sedentary lifestyle and arterial hypertension can happen

For this reason, physical activity, a healthy diet, not consuming products that compromise your health, allow the elderly to have a better quality of life, a good life expectancy, all of which will allow the elderly to improve and live a life healthy. In the same way, in [14], the authors maintain that a change in lifestyle, regular physical activity, having a balanced diet, will allow the elderly to improve their quality of life. In [15], the authors argued that a good quality of life in the elderly is due to the fact that the level of physical activity is associated with a lower prevalence of presenting a cardiovascular risk factor. In [16], the authors mentioned in their systematic review that increasing the level of physical activity, balancing the diet, and eliminating tobacco and alcohol habits allows older adults to improve their quality of life.

For all this to be carried out, a plan is needed that allows it to be put into practice in the elderly to maintain a healthy life and that cardiovascular risks can be prevented. For this, 4 steps have been carried out as a plan to prevent cardiovascular risks:

- Reduction or elimination of tobacco consumption: Quitting smoking and not using smokeless tobacco is one of the best options for the heart, since the chemical substances in tobacco damage the heart and blood vessels reducing oxygen in the blood, thereby increasing blood pressure and the heart must work more than it does usually. Although the cardiovascular risk decreases in the person one day after they stop smoking, so if after a year without tobacco, it will decrease half the risk of a smoker.

- Daily physical activity: In the elderly, regular physical activity is important since it allows them to reduce cardiovascular risk, since it allows weight control, and reduces other conditions

such as high blood pressure, high cholesterol, and type 2 diabetes mellitus; so, they should do aerobic exercises a week, and activities that strengthen their muscles, since these activities offer benefits for the heart.

- Healthy Eating: A balanced diet helps protect the heart, prevents high blood pressure, cholesterol and reduces the risk of contracting type 2 diabetes mellitus, limiting the intake of salt, sugar, carbohydrates, alcohol, and saturated fat, all of which will allow them to have a good health.

- Maintain a healthy weight: For one to have a healthy lifestyle, one must perform physical activities along with a healthy diet, since physical activity helps maintain weight, lowers high blood pressure, reduces the risks of type 2 diabetes, among other risks All this with a healthy diet that is low in calories, and more nutritious, allows their weight to be preserved and stay healthy.

5. Conclusions

It is concluded that primary prevention strategies should be considered in elderly patients with high cardiovascular risk and have secondary prevention

It is concluded that prevention of cardiovascular problems should be expanded in the elderly, to contribute to their health and quality of life due to the increase in the population.

It is required to provide counseling on food and nutrition that motivates the elderly and their family to learn about the benefits of a healthy diet.

It is concluded that an adequate diagnosis and control of risky diseases must be carried out, especially acting on the risk factors identified at an early age, to achieve a better quality of life when one is an older adult.

The limitation of this research work is due to the situation due to the COVID-19 pandemic that could not take more elderly patients for the study, since the population depended only on one health center, so it was taken only 47 elderly patients who were the most recurrent to their controls in the same.

Conflicts of Interest
The authors declare that they have no conflict of interest.

A B S T R A C T

The article presents some results of the research of the LoRa module. These modules can be the basis of possible IoT technologies are implementing, providing enough good range of receiving and transmitting messages. The SX1276 transceiver has been testing to determine the signal loss in the propagation channel. These experiments took in a highly-populated Kyiv district and one of the passageways of a Podbryantsevsky salt mine near the Solar town. The measured parameters are the maximum radio communication range in the mine, the signal-to-noise ratio, the number of bit errors and losses of the signal transmission. The data of the study we plan to use for the engineering of the radio-messaging networks based on LoRa radio modules.

1. Introduction

Multipath propagation is obtaining as a result of re-reflections of the signal source antenna beam from ground objects. Namely from buildings, a large number of rooms and corridors inside them, hills, vegetation, mine tunnels, etc., which create except the one direct some indirect directions of arrival of the beam. The receiving signal is an additive mixture of signals with different amplitudes, phases, and arrival directions. Multipath propagation of radio signals results in signal fading and frequency shift of the receiving signal.

Multipath propagation decreases the quality of the data reception. In the same circumstances, radar reception is resolved by introducing a small frequency additive into the low power oscillator of the frequency converter then receiving signal frequency deviation is synchronous with the transmitting signal frequency. The next way is the creation of additional reception channels. Another situation arises in technique for communicating, where noise has a strong effect, and the signal-to-noise ratio (SNR) is less than unity. A natural solution pointed problem is the complication of the receiving set by introducing additional receive channels and complex signal processing. However, this approach is not acceptable for the Internet of Things (IoT) technology. The peculiarity of the application of this technology in mines is the small size of antennas and equipment, also low power consumption.

Optimal filtering is one way to expand the SNR at the receiver output. However, in processing technology, this approach is not always suitable. The signal spectrum expands due to interference, and by increasing the acceptance threshold, and the signal may be lost. In this case, for improving the signal quality at the input of the matched filter, the noise protection is offered. Unluckily, well-known methods of suppression of narrow-band interference do not apply as well.

Due to its ability to maintain communications and lighting simultaneously, some authors consider the visible light communications (VLC) system like potential opportunity to implement effective communications in mines, which is basing on the phenomenon of light propagation. In this case, the quality of communication devices is highly dependent on the available channel propagation models, including long-term fading, which was critical for the project and assessing the operation of VLC systems. But, the basic features of the VLCs have not yet been enough explored. Also, dust and moisture block the propagation of light signals.

This paper is an extended version of our work [1] presented at the 2019 IEEE International Scientific-Practical Conference Problems of Infocommunications, Science and Technology (PIC S&T) in which the research purpose was to study the features of LoRa (Long Range) signal processing in multipath propagation. The remaining part of the paper is organized as follows: Section 2 presents the works that provide an overview of the subject area; Section 3 devotes the general formulation of the problem; Section 4 briefly describes the features of the radio module when used in free space. Section 5 presents the results of module tests in multipath conditions, and conclusions from the studies are presented in Section 6.

2. Paper Review

Due to frequent disasters that occur in mining sites caused by landslides and rockslides of underground mine workings, the creation of a reliable system for communication in places of underground mining has recently become important.

In this case, the traditional solution is the use of radio communication systems. In the document [2], prepared in response to the MINER Act, an analysis of existing communication systems in different frequency ranges has been presented, and the basic requirements for existing radio communication facilities are formulating. Their functions are not only messaging but also tracking the actions of miners. Thus, radio communication is recognizing as the principal method of communication. In this respect, it is also worth noting that the work to establish the requirements for frequency ranges and radio communication range based on the study of the average attenuation characteristics of radio signals in mines of various types of minerals by this time was partially done (for example, see [3, 4]).

Reviews of communication facilities in underground mines have also presented in papers [5, 6], where were manifest the problems of wireless communication under the ground, associated with attenuation and loss of communication that is greater than when they have on the surface. The attenuation parameter for a frequency of 900 MHz has been refined in [7] and was concluding the possibility of using mobile communications in coal mines.

Recently, as an alternative to conventional wired and radio transmitting systems, researchers [8-11] are considering the possibility of using visible light as a means of communication for mine communication. So, in the article [8], based on this approach, a method is proposed for modeling the visible light propagation channel for two types of underground utilities: directly at the bottom hole and on the roadway, and the results of studies of the number of indicators spread signal in the visible light channel have presented. The main achievement of the authors of [9] is assessment loss as a function of distance.

In [10], the use of angular diversity receivers has been proposed that was focus on reducing inter-cell interference. It also considers new mathematical models of light distribution: pyramidal and hemi-dodecahedral. Numerical values for data rate, signal energy, and signal-to-noise-plus-interference ratio have also been presented, which can be useful for evaluating new solutions.

It is worth noting, the use of optics for communication has studied earlier. One of the earliest sources for time division multiple access (TDMA) broadcast communications dates back to 2005 [11]. Described here are a malfunction resistant system start and restart of the system with the dynamic self-configuration capability and a controlled internal diagnostic system.

The authors of [12, 13] propose the technology of detecting personnel and equipment in tunnels of underground manufactories by data transmission through light-emitting diodes and a photodetector; their approach also uses the trilateration method. So, in [12], an algorithm for determining the location of targeting objects is proposed. It is built based on data from several VLC systems located on the cover of an underground tunnel, as well as VLC mobile devices placed in the interests of ensuring the safety of miners, and the same problem is solved in three-dimensional space by authors [13].

To detect underground facilities, it is also possible to use ground penetration radar (GPR). So, in [14], it is proposed to divide the transmission paths into two types of signals: blocked and unblocked. Since the volume of blockaded signals is less than the estimated signal space, their routes are using in signal processing. A similar approach was proposed by the authors [15] based on the ULF (Ultra Low Frequency) radio channel for a mine specializing in the extraction of non-ferrous metals. In [16], GPR was used to assess soil moisture in the interests of agriculture. However, the range of propagation of electromagnetic waves underground is not long, does not exceed several meters; their use is advisable only in the interests of agriculture, which has been established by numerous studies and is confirming in [17 - 19]. The article [20] discusses the problems of robot navigation for coal mines.

This research continues the work presented in [21, 22].

3. Problem Statement

A multipath reception for a receiver based on LoRa technology is considering. In an open space, the module manufacturer guarantees the service of remote users at a distance of up to 20 km for a long life of the time, which makes the technology comparable with common Wi-Fi and LTE (Long-Term Evolution) [1].

The set of modules forms a system for picking reports from users and transmitting them to the server for further treatment and, maybe, answering queries. The messages exchanged between users; the service is providing by the open air at frequencies below GHz.

A message is a data package, which includes a preamble, a header and a payload, its size is dependent on the spreading factor

(S_f). Length of the package varied from 51 to 256 bits. The information transfer rate is between 22 and 27 kbps. The selection of this parameter depends upon the range, bandwidth and expansion factor. The signal that is emitted is a chirp signal, which is now assumed as the standard in the area of short-range wireless communication systems (IEEE 802.15.4a).

A distinguishing characteristic of signal receiving in multipath propagation is a significant deterioration in the signal quality, up to its complete loss. Examples of single radiation without interference and the total effect of four chirp signals without interference shown in Fig. 1, 2.
Figure 1: The one chirp signal
Figure 2: The four chirp signal with different phase shifts

A traditional study in the course of multipath reception is to clarify losses in the transmitter-receiver section and guarantee the receiving range [23]

$$R = \sqrt{\frac{P_t F(\theta) G_t A_r e^{-2\alpha d}}{4\pi P_r}}$$

(1)

where R is the radio communication range; P_t is the transmitter signal power; $F(\theta)$ is the antenna directivity in the θ direction, $F(0) = 1$; G_t is the transmitting antenna gain; A_r is the effective receiver area; P_r is the signal power at the receiving set input; α is

the attenuation of the signal along the path of the beam propagation, taking into account the free space and propagation environment; d is the distance between two antennas.

Channel losses determine the budgeting of the wireless communication channel, which is calculated by the formula [23]:

$$P_r = P_t + G_t - L_s - L_{ch} - M$$

(2)

where G_t is the gain determined by the directivity of the antennas, L_s is the system's loss (for instance, in short antennas used in most remote devices), etc.; L_{ch} is the loss in the signal spillover channel, M is the attenuation signal is computed by empirical data. All values in the equation are expressing in dB.

If we know value R radio communication ranges in free space and the range in the loss conditions D, the value of losses in dB can be specified using the formula

$$L = 40 \lg\left(\frac{D}{R}\right)$$

(3)

SNR and bit error (BER) rates are auxiliary indicators of reception quality. The SNR is determining as follows

$$SNR = P_{signal} / P_{noise} = (a_{signal} / a_{noise})^2$$

(4)

The purpose of the research is to assess the effectiveness of using LoRa modules in a confined space, where it is possible to observe multipath propagation.

4. Preliminary remarks

A typical LoRaWAN radio network integrates end devices into architecture type a star. Messages are underlying double encrypted to ensure security. Devices that have small power consumption are ensuring by using a short time for transferring in a comparatively long time interval when the terminal device is in a "sleep" regime. Information is transferring both asynchronous and synchronous modes. The information from the end node of the network is spreading through the gateway to the network server and then deliver to the application server. LoRa modules have better receiver sensitivity because it uses chirp signals, error correction, high transmit noise immunity and insensibility to frequency changes of resonators.

In experiments, we used a module based on the SX1276 microcircuit (Fig. 3), in which messages are transmitting at a frequency of 868 MHz. Other parameters of the transceiver based on the SX1276 microcircuit [24] are presented in Table 1.

Table 1: Some parameters of SX1276

Option	Value
Δf, kHz	20.8
S_f	8
BR, bps	1562
P_r, dBm	− 128

The channel budget, calculated by the formula (2), for a transmitter with a power of 100 mW in the case of ideal transmit-receive dipoles, for which the gain was chosen to be 2.1 dB and the minimum loss and signal attenuation turns out to be 130 dB.

The maximum range of radio communication in line-of-sight conditions for a lifting height of the receiving and transmitting antennas of 1 m under experiment conditions and normal refraction does not exceed 25 km.
Figure 3: The module SX1276

The force of the received signal as a function of the range without interference [25, formula (5.15)] has shown in Fig. 4 with a blue line; the threshold sensitivity of the studied module is a black straight line. Crossing the lines gives the radio communication range corresponding to the real sensitivity of the receiving module, which turns out to be 4.8 km.
Figure 4: Estimation of the maximum radio communication range for a given sensitivity

5. Research results

The LoRa chipset study consisted of a sequence of surface experiments in a highly-populated city spot, where mobile communications and radio internet interfere with the receiving channel, and underground, in a mine where spurious radiation is absent. Ground tests based on a point-to-point scheme and a point-gateway with treatment on a remote server and underground tests were according to a point-to-point layout.

5.1. Interference radio

In the beginning, the transmitter installs on the last floor of a hard-wall building in Kyiv. A few Wi-Fi networks were deploying inside this building, on the roof of the building were also installed antennas of three operators' mobile communication. The indicator

of the receiving device showed the message quality. At the experiment, the LoRa radio module was deposited from the 11th floor of the building to the first floor and to the downstairs located two floors below the first floor for creating multipath reception. The measurement framework reveals in Fig. 5. In Fig. 5, the abbreviations MS are used for the marking of the antenna of the stations of mobile operators, Tr is the transmitting module, Rc is the receiving device.
Figure 5: Layout of devices in the experiment

Rooftop antennas of mobile communications and Wi-Fi routers causing interference. These signals create a noise background, which chose as the "white". Crosstalk is causing by multiple reflections of beams inside the building from reinforced concrete structures. Using signal and noise level were fixed on every building floor, and the legibility of the text message was controlled as well. Additional documenting of the measurements has been carried out by a panoramic receiver, which chose as a reference. A initial report of the interference condition presents in Table 2.

The functioning of the transceiver in the "point-to-gateway" regime is fundamentally no different from the "point-to-point." The main difference is data processing, which carries out on a cloud server, and therefore the information has been slightly delayed (tens of milliseconds) compared to the point-to-point regime. In measurements, an auxiliary radio communication

channel was used by a mobile phone. The results of measurements of the BER and SNR for the LoRa radio module shows in Fig. 6, 7.

Table 2: Interference Condition

Type of sources	Frequency, MHz	Power, W	Effect
CDMA	800-900	2-60	strong
LTE	900-2400	2-60	middle
Wi-Fi	2400	0,1	weak
Other	400-5000	<0,01	weak
Figure 6: BER as a function of the number of the floor
Figure 7: SNR as a function of the number of the floor.

By the experiment results, it has established that text messages receive on all floors and within 2 m from the staircase in the basement; the loss connection was at a distance of 8-10 m from the stairs.

5.2. Using the LoRa module in a mine

This subsection contains data on the results of measurements of the quality of message reception by the LoRa radio module at the conveyor slope of the Podbryantsevsky salt mine, located in the vicinity of the Soledar town.

The measurements were fulfilled in tunnels of the mine, in which are two parallel corridors connected by passages, Fig. 8. The experiment was carried out by step-by-step removal of the receiving set from a stationary transmitter with a fixed distance. The motion has been done from the initial point, corresponding to

the transmitter location, clockwise around the salt layer 23 m wide. The transmitter has installed 100 m from the comer.
Figure 8: Section of the Podbryantsevsky formation mine, where measurements have been done

Point A in the diagram corresponds to a growth in the signal level around the comer, point B matches the signal maximum, and point C to a total signal loss. Also, the information in the mine was transmitted by voice; it was also repeated by the Motorola radio station functioning in the decimeter range and its output signal power of 1 W.

The quality of communication in LoRa assesses by the number of packets received and by voice; the last way was estimated according to the degree of intelligibility of radio phrases. The results of the measurements present in Table 3, where value D is the distance from the LoRa receiving set to the transmitter antenna (T); Received Signal Strength Indicator (RSSI) serves as an indicator of the signal level at the receiving set input; Packets is the number of transmitted packets; Quality of Receiving is a category parameter of reception. The last parameter was the estimated sign "+" in case of satisfying reception, and "-" otherwise.

Table 3: Report of Receiving Quality

D, m	RSSI, dBm	Packets	Quality of Receiving
100	-94	4	+
115	-96	4	+
129	-107	4	+
162 (A)	-98	4	+
187	-97	4	+
211	-96	4	+
230 (B)	-93	4	+
243	-101	4	+
263	-113	4	+
283	-124	-	±
303 (C)	-128	-	−

Based on the measurement data, a graph of the loss function $L(D)$ is built, where D is the range from the signal source to the

measurement point, Fig. 9. The resonant character of the curve in Fig. 9 is a consequence of the superposition of beams resulting from multipath propagation. Signal power losses in the section of indirect signal propagation with a length of 150-230 m have an average value of 15 dB.
Figure 9: Graph of the function *L* (*D*).

Analysis of various forms of communication in mine made it possible to establish that the range of voice communication, with due regard for phrasal awareness, no more than 30 m; the distance of radio communication no more than 100 m; the transmission range by LoRa reached 150 m.

6. Conclusions

The paper presents a study of the LoRa module on two models of multipath propagation with external interference in a city building and without them in a salt mine. In the course of the studies carried out in a high-rise building, it was found that for the LoRa transmitter with a decrease in the SNR by 70 dB, the BER deteriorates by only 15%. The transmission range of messages in the mine with indirect beam propagation (Rayleigh channel) exceeded the distance of conventional radio communications by 30%, voice communications by five times. The average loss at the frequency under consideration is 15 dB for a Rayleigh radio propagation channel, provided the messages are intelligible. These results are planning to be the basis for the choice of the LoRaWAN radio network topology as an element of mine communication.

Conflict of Interest

The authors declare no conflict of interest.

Acknowledgment

The authors thank both the authorities of the Taras Shevchenko National University, and National Aviation University the especially leadership of the Faculty of Cybersecurity, Computer and Software Engineering for their support during the preparation of this paper. The authors also thank the anonymous reviewers, whose comments significantly improved the content of the paper.

A R T I C L E I N F O	A B S T R A C T
	The research paper aims to focus on the issues and challenges in developing a sustainable model of an ideal heritage village project by using descriptive and empirical investigation methods. To capture the perception and understanding of the concept of sustainability of a Heritage Village, a mixed-methods approach was conducted by the researcher where document where reviewed, observations were done, structured interviews and a questionnaire survey was conducted involving resident's in the heritage villages of Pragpur and Garli in Himachal Pradesh, India. Through this research, the objective was to catalogues the resident's outlook and understand their belongingness towards their rural settlement. The analysis conducted, was also to understand their attachment to the heritage fabric which would act as a catalyst for their sustainable development. Due to the diversification in terms of architecture, social and cultural aspects, it was important to analyze the resident's perception towards the built heritage as it may vary to be more or less important to different people, community groups, or generations.

1. Introduction

The term "Heritage" proposes a wider based concept that includes both tangible and intangible heritage as well as the natural ecosystem of the settlement. It includes built environment, historic places and monuments, settlement pattern, settlement morphology, heritage collections, past and present cultural practices including living experiences of the residents of these villages. It can act as a catalyst for the overall sustainable growth and change in these rural settlements [1]. The collective memory of each locality or community or a particular heritage is unique. The preservation, conservation, documentation, presentation of the built heritage, and cultural diversity of any particular place are important challenges.

Manmade structures which possess heritage character and significance should become a part of the built heritage of any settlement and the society [2]. Due to the rapid modernization of the built environment, there is a need for focusing attention to preserve the cultural and architectural heritage, before it disappears completely. Buildings and settlements of historic or architectural value in all urban and rural areas are disappearing

very fast due to neglect and decay or reconstruction in newer materials which results in changing the specific characters of these village cores, leading to monotonous and repetitive new modern constructions.

The built heritage is the prominent aspect to transform the current situation of rural areas because it has the potential to diversify people's perception and acts as a common denominator for the development of these settlements. Heritage can act as a catalyst for the future development and sustainability of a village [3]. It indicates that by enhancing the heritage character of a village, a sustainable tool can be devised for the residents who live in these settlements to make them part of the rural development process. Additionally, the tool is likely to give rural areas a positive, vibrant image and in this way, a trend can be developed for bringing the migrated youth back into these rural areas. It also indicates that cultural meanings and construction assets such as vernacular construction techniques can be mobilized for rural and regional development, and cultural identities can become important for uplifting local economies.

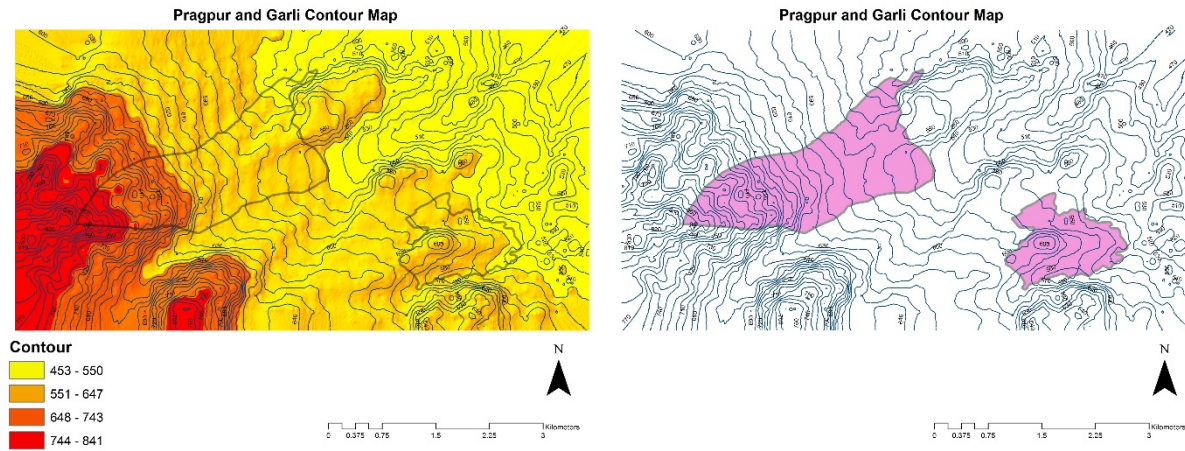

Figure1: Contour Map of Pragpur and Garli geo-referenced on GIS

2. Methodology

In the following study, a mixed method of analysis is conducted to investigate the status quo of these villages and also to understand the perception of the residents. In this mixed method of analysis, a three-stage layered analysis is conducted where the first stage is to conduct a spatial analysis using GIS, and then a descriptive and empirical analysis is conducted upon the responses received from the entire sample area. Questionnaire Surveys and interview-based surveys were used as tools to obtain variables. The relevance and public reaction to the concept of being a "Heritage village "models and theories regarding the sustainable built environment were questioned primarily. A total of 100 responses were gathered from these two villages and Turkey Post-Hoc test was conducted on the responses gathered using a five-point Likert scale. The questionnaire was developed on seven major parameters as Economic Viability, Infrastructure, Heritage, Social and cultural Character, Governance/ Policy framework, Environment, Settlement Pattern.

3. Study Area

The villages of Pragpur and Garli in Himachal Pradesh are situated at two thousand feet which are approx. 550 Meters above sea level, it comes under the region of district Kangra, Himachal Pradesh. The heritage-based settlement of Pragpur and Garli with a pristine view ideally suited to explore the distinct characteristics of Kangra valley. This area has several water channels that mix into river Beas with its pleasant and comfortable climate, better connectivity, rich flora, and fauna (Figure 1). The Dhauladhar mountain range raised behind this picture of pastoral perfection and needy frames it with tall peaks that are draped with snow for the better part of the year. Recognized as Heritage Village by a notification dated 9th December 1997 the state Government has classified Pragpur and Garli as a "Heritage Zone".

Heritage villages of Pragpur and Garli also fall under the ecozone, ideal for the development of tourism. These villages are also promoted by the administration as an example for community development in the hospitality sector. The core area of Pragpur is notified as "Heritage Villages" by the state government. This makes it one of the villages in India with such a distinctive title. Understanding the unique architectural style and settlement pattern the Government has declared the creation of SADA

(Special Area Development Authority) for improving the infrastructure in the area in the field of tourism[4][5].
Figure 2: Land use percentage for the village of Pragpur and Garli

4. Architectural features of the built form

Pragpur and Garli can be divided into three major sectors based on the activities, such as residential, commercial, and tourism-based buildings (Figure 2). The Residential area is the zone where all the heritage-based residences are built[6]. The commercial area is where all the small-scale activities such as retail activity, weavers, shoemakers, etc. are housed. Tourism based infrastructure is where the residential houses have been converted into small scale hotel. Some of the major features that can be observed within the settlement are,15ft. that main street is around 15 feet in width which also acts as the main spine for connectivity from the urban centres.7-10 ft wide secondary streets are used for core connectivity towards the interior of the settlement having around 6010 feet width. Low height structures can be observed along the main street usually used for retail purposes.

The layout of the streets is in a linear pattern and the secondary roads radiate from the main street along the natural contour of the settlement. The main axial road of the village consists of built with variable land uses. As per the land use characteristics observed it was seen that the ground floors are used for commercial and retail. The lower floors are designed such as to create a recessed structure and the above floors act as cantilevers. A row of the columnar corridor is constructed supporting the projected floors of the upper storey. A colonnaded facade is recessed which provides easy entry and forms a semi-

transparent visual screen that creates a unified image of the structures. These plinth areas or semi-open areas act as recreational spots for the shop owners. The upper cantilever storey is used for residential purposes. Most of the residential and commercial structures are not more than two stories. A series of residences having vernacular architectural characteristics are built along the connecting streets of the village which diverge from the main spine. Many of these houses have a central courtyard. The common material used for the construction of these heritage houses are mud plaster, dry and seasoned bamboos with a layer of bitumen for roofing purposes. In the case of repetitive floors, the floors are finished with mud mixed with reed or bhusa to create a thick paste-like consistency. Wood is primarily used for doors and windows. The balustrades on all floors are constructed using seasoned timber. The doors, windows, and even the railings have magnificent ornamentation and carvings designed on them. The door frames are also adorned with carved patterns such as local flowers and flowering buds, animal frescos, and geometrical patterns. Window and door arches are constructed to support the lintel beams. A mixed variety of arches are observed such as segmental arches, flat arches, gothic spires, etc. The chajjas over the openings are also intricately carved. The streets are designed using cobbled stone in interesting patterns. The verandas are also constructed using stones in various patterns like linear, rectangular and circular patterns. The houses are arranged in a row formation around an open to sky courtyard. On the upper floors, the windows are reduced gradually in size. Half-timbered construction is mainly observed in these villages for the construction of residential buildings.

The half-timber construction method is, in which the external and internal walls are constructed using the timber-framed structure and the space between them is filled with materials such as mud plaster, brick, or daub and wattle. In these hilly regions the half-timber construction is usually made of squared oak timbers joined by rafters, tenons, mortises, and wooden pegs; the building's structural skeleton is strengthened using braces in the corners (Table 1).

To understand the evolution of the rural settlement and to catalogue its existence in the rural areas, the help of GIS (Geographic Information System) is taken. First, we created a base map of the spatial database of the Garli village. Then specific attributes such as the timeline of the construction, the year of the last restorations or reconstructions over time, etc. were attached to each vector. The main objective was to identify the residential buildings which were constructed through vernacular style and which residential buildings were renovated with their material study used in construction. In this way, it was possible to generate several maps that emphasize the old village system and the houses which have been abandoned by its residents (Figure 3 and 4). This attribute and the database are updated in real-time, and in this way the government can decide their restoration policies in a more precise way, comparing with the traditional methods. The updated data regarding the preservation and conservation status of residential houses represent an important factor in monitoring, protection and documentation of local heritage and, at the same time, offer the possibility to involve the local community in heritage management for sustainable development.

Table 1: Visual Survey of Pragpur and Garli depicting architectural features

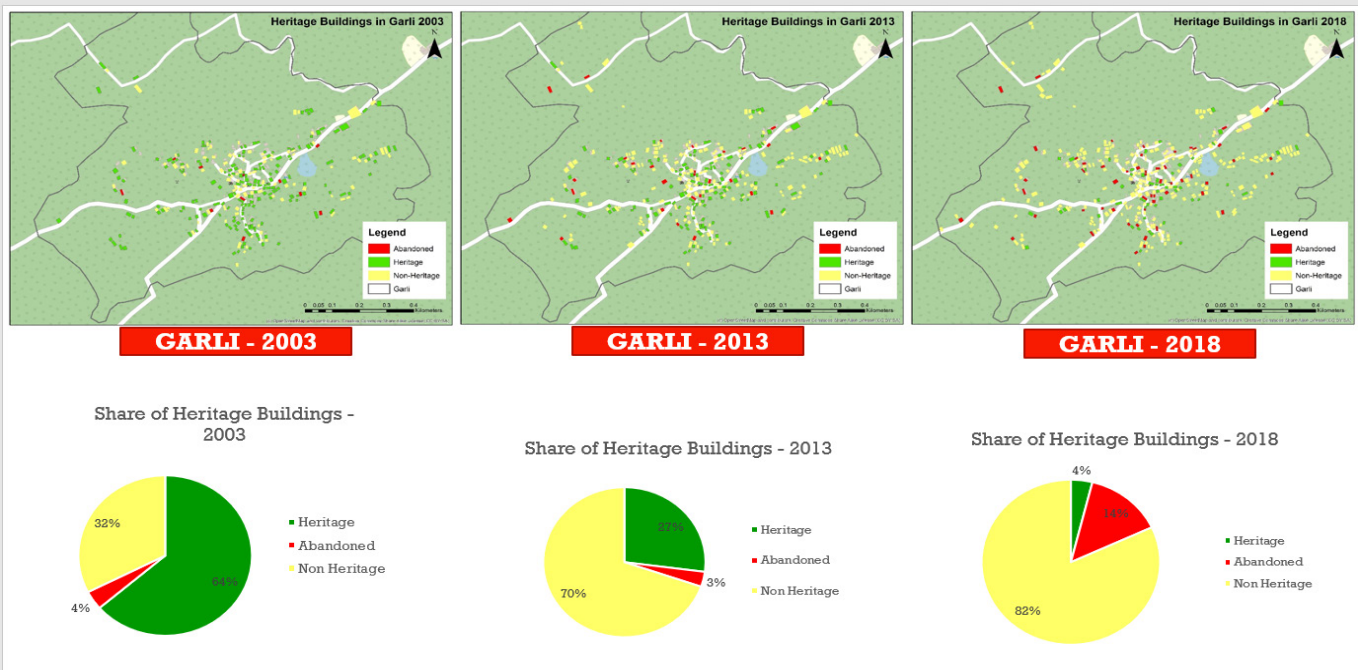
Parameters	Images	Architectural Features
Settlement pattern		1. Streets paved with dressed cobbled stone.
Buildings		2. Gothic spires 3. Gables with decorative and ornate finials 4. Wooden pillars and heavy wooden beams 5. Roofs are sloping, made of local slate on wooden framework 6. Gabbled and cross gabbled
Materials		7. Mud plastered 8. Slate roofed houses 9. Bamboo 10. Reed or bhusa 11. Cobbled stone


Figure 3- Settlement mapping of built heritage for year 2003,2013,2018 of Garli
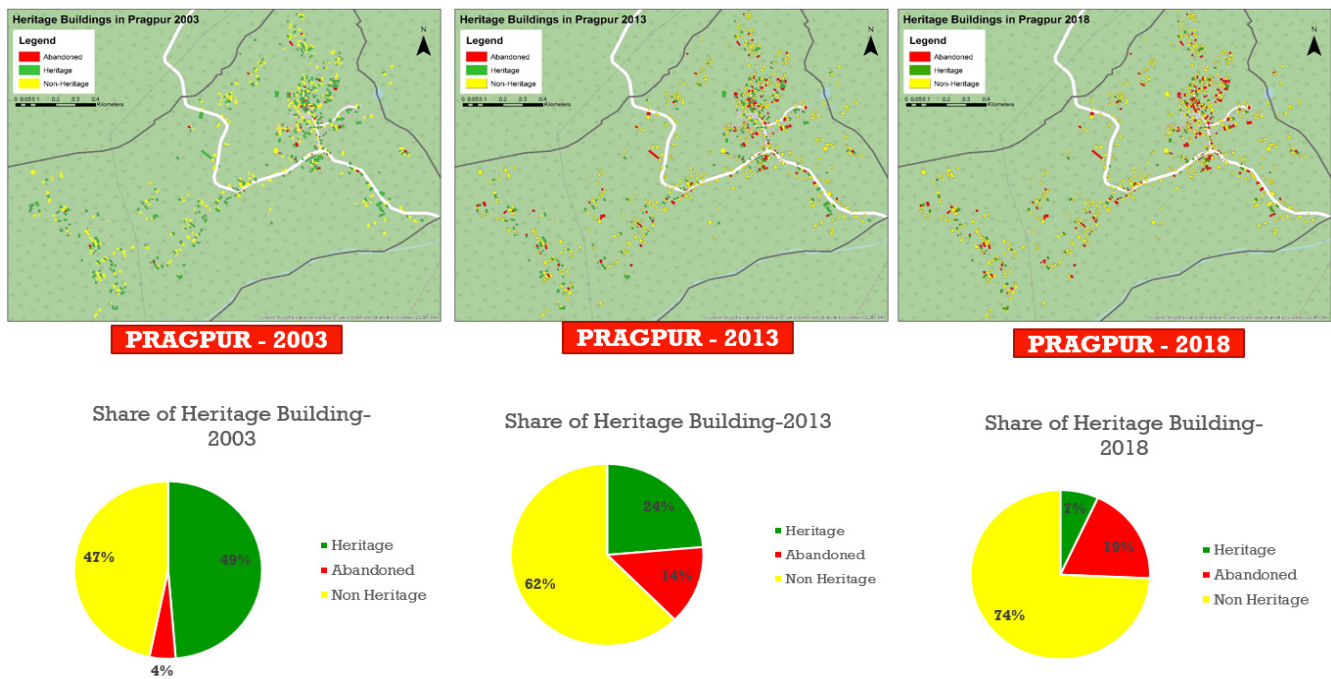

Figure 4: Settlement mapping of built heritage for year 2003,2013,2018 of Pragpur

5. Data Collection

To attain a holistic view, 100 interviews (50 in Pragpur and 50 in Garli) were carried out with groups of specialists (including academicians and conservationist), cultural reference groups (including community heads or chieftains, heritage managers, cultural groups, the private hospitality sector, and local NGOs). It is also important to understand that these traditional villages are located near the core and buffer zones of their urban district[7]. The composition of the sample of respondents was taken according to people who have a direct impact due to the development of these villages (Table 2).

The respondents were asked varied questions regarding the status of a "Heritage Village". Also, it reflects the understanding of the respondents as to whether after getting the said status whether the employment opportunities have increased[8]. This study also aims to enrich the literature with an empirical investigation on issues and challenges in developing a sustainable model of heritage village projects[9]. Thus, the objectives are to identify the most common and fundamental issues and challenges that currently exist in these villages and to determine if these issues can be resolved with certain interventions[10].
Figure 5: Descriptive analysis for the responses

Table 2: Sample size for the questionnaire survey in Pragpur and Garli

	Pragpur	Garli
Total Residential Buildings	354	118
Heritage Building	93	21
New Construction	261	97
Abandoned Residences	67	17
Sample Size for Survey	50	50

5.1. Statistical analysis

Statistical analysis is performed by using descriptive and inferential statistics. Pearson correlation was applied to see the relationship between the variables. One-way Anova followed by Tukeys HSD post-hoc test for multiple comparisons was applied to see the mean difference between the villages.

Correlation in the broadest sense is a measure of an association between variables. In correlated data, the change in the magnitude of 1 variable is associated with a change in the magnitude of another variable, either in the same (positive correlation) or in the opposite (negative correlation) direction. The Pearson correlation coefficient is typically used for jointly normally distributed data. Then to understand the study One-way Anova was used.

- To compute large and varied data sets, which included data collected from two different villages and having varied responses. It was also done to verify the variability of the data acquired.

- To test which method yields the most suitable result in the sample of data collected. The sample consisted of stakeholders comprising of the residents, government officials, and tourists in these two villages.

If data are analyzed using ANOVA, and a significant F value obtained, a more detailed analysis of the differences between the

treatment means will be required. In this case, the P-value is less than 0.05 considered as significant at 95% confidence level.

The statistical software SPSS version 24.0 was used in the analysis. The questions in the questionnaire invited them to indicate the level of agreement of each factor in relation to the seven main parameters based on a five-point scaling, i.e., Strongly Agree = 5, Agree = 4, neutral = 3, Disagree = 2, and Strongly disagree = 1.

6. Result and Discussion

The Economic Viability parameter, the focus was to correlate the economic fabric [11]of these villages as a community and whether this can act as a prominent factor that governs the sustainable development of a rural area[12]. The Infrastructure parameter focuses on the infrastructure needed for developing a sustainable village model which may include roads, tourism infrastructure, connectivity, etc. The parameter also addresses the negative impact of creating an ideal village model and that may hamper the heritage fabric of the villages[13]. Understanding the relationship and assessing the loss and degradation of the core's-built heritage is the focus behind the Heritage parameter. This is to analyse, investigate, and discuss, the concerns, obstacles, and issues of sustainability to this rural heritage conservation. In the Social and cultural Character parameter the focus is to examine the influence of socio-cultural factors on the formation of architectural spaces in Heritage based villages by applying a descriptive-analytical method and using literature study.

The results of this study indicate that the structural system of traditional houses is based on a hierarchical system and is intricate for the development of the settlement. The Governance/Policy Framework parameter attempts to focus on the holistic system or dynamic model to analyze the interaction of the social–economic–heritage sectors to examine policies to achieve the goal of development and conservation. The Literature study shows that conservation alone cannot lead to its own goal. Economic development strategies or policies could be a better choice if the development is carefully planned and effectively controlled to avoid over-consuming resources.

Table 3: Statistical analysis

		N	Mean	Std. Deviation	Std. Error	95% Confidence Interval for Mean		Minimum	Maximum	p-value

Understanding the influence of human behavior on the landscape is the prime objective of the Environment parameter. Also, to analyze the reason for village landscape transition which come from road construction, the transformation of building materials, higher living level, the inflection of family structure and social relationship, different culture and self-identity [14]. To investigate or to identify the challenges and hurdles towards the growth or deterioration of the settlement of heritage villages, it was gathered that through cataloguing the settlement pattern the evolution of the community and its historical background can be documented with its various changes in all its bearings.

To understand the aim of the Economic Viability parameter was to determine their economic status of the respondents and whether they have benefitted from the status of "heritage village" [15]. The respondents of the villages of Garli and Pragpur had major concerns while developing their residential buildings. The families owning these houses lacked the economic resources and finances to maintain these houses [16]. While enquiring about the infrastructure development the residents were not content and strongly disagrees with the increase in any land value in villages of Garli and Pragpur in Himachal where the circle rate for 100 sq. meters are around 886 Rs and 1751 Rs (District Kangra, Government of India website) respectively from last one decade.

It indicated the stagnation in terms of development. In these villages, it was also observed that mostly the migrant population is residing in the heritage houses were on a rental basis [17]. They are mostly not aware of the heritage status and do not have the economical means to maintain these residential buildings. The infrastructure needed to sustain and develop a heritage village was not visible in these Villages.

Community Participation has been observed as a major factor for the sustainable development of a settlement [18]. In villages like Garli, some residential patrons have tried to restore their residential buildings and convert them into commercial and recreational spaces for the tourist, parallel developing the village

and generating employment for the locals. The basic amenities such as fire protection and police protection also lack in these villages. The villagers were governed under Panchayat System and they themselves resolve the petty issues related to the governance of the villages [19].

The villages lacked the basic infrastructure to support a tourist influx. It was determined by the study that, many people outside of these villages are not aware of the heritage status. The upkeep the vernacular architectural style of the residences, not many skilled labours are available. The construction and maintenance in these villages are done according to the new construction style using materials such as RCC and Bricks. In Pragpur and Garli, timber construction and wood such as teak and sheesham were used for the construction of residential houses.

7. Findings

The major factors highlighted in this study were as detailed below:

- The first major criteria were to identify the heritage-based settlements through the extensive literature study. A multidisciplinary approach was initiated where along with the architectural characters certain parameters were combined such as economy, social conditions, settlement morphology, etc.

- It was also observed that different policy development schemes or frameworks for the inclusion of rural heritage preservation measures is not highlighted or mentioned. There is no incorporation of heritage-based rural development in the physical planning processes as part of a holistic approach towards sustainable development [20]. This research wants to focus on and promote the inclusion of preservation of heritage-based residential buildings representing the local architectural style.

- Finally the study wants to highlight the importance of heritage in rural development. Through the descriptive and empirical study of the data, it was found that for the development of these types of settlements the role of the local residents and community plays an important part [21]. There is a need for introducing public awareness as a tool to generate employment in these rural areas.

The data acquired through the questionnaire survey along with the interview survey gave many insights to identify the hurdles and challenges while implementation of heritage-based development policy. A multidisciplinary approach as mentioned earlier can be used where collaboration with tourism, hospitality industry all related sectors can be initiated [22]. This was considered important to resolve any issues which may cause the undermining preservation of the built resources. It is also stressed that preservation of cultural and natural heritage should be perceived together and they must not be promoted with activities that can cause hindrances towards sustainability. To make the residents conscious about the values of rural heritage certain programs can be initiates such as studies on vernacular architecture, promotion of knowledge, and training about traditional techniques and materials.

It was also observed during the survey that the majority of participants were of the suggestion that a balance should be maintained between the retained heritage-built fabric and its economic viability. The entire exercise was conducted to understand the importance of the residential buildings and should actually be protected. Secondly, it was to address its importance for the future generations of these villages. The second factor also ponders upon the different methods of adaptability and reuse of these heritage buildings. The process also helped to understand the hurdles along with the decision-making towards the protection and conservation of these buildings. Many respondents have also agreed that the policymakers and government officials should ensure that if the value of a residential building is under heritage significance then relevant heritage policies and bye-laws should be formulated.

8. Conclusion

Through the extensive literature study regarding the preservation of this built heritage, the researcher had identified core parameters that are vital for sustainable development. The qualitative study and empirical study evaluated the study and the observation done to understand the ground reality. The major parameters were categorized into several sub-parts depending on the focus, such as historical value, economic viability, infrastructure, socio-cultural characteristics, and the overall aesthetic value. The research aimed to understand the perception of the local community and analyse their approach and consensus to further develop a holistic policy framework. The detailed analysis led to the determination that the infrastructure lacks the capacity to promote tourism or hospitality industry to create a sustainable model to promote the heritage of that area. In very few cases, the architectural value (vernacular architectural style) is also considered but all are linked to the history of a particular settlement along with its cultural values.

It is evident from the analysis from the sample groups and interviews that diversity plays an important role when discussing the importance of their heritage settlement. It varies across the communities, geographical location. It also varied because of their economic status, socio- cultural parameters as seen in these villages of Pragpur and Garli. As per the investigation, it was also highlighted that administration plays an important role as policymakers and implementors. It is important for the local government to create awareness towards the importance of these heritage-based residential buildings and that they may gain value in the future.

Electronically Tunable Triple-Input Single-Output Voltage-Mode Biquadratic Filter Implemented with Single Integrated Circuit Package

Natchanai Roongmuanpha, Taweepol Suesut, Worapong Tangsrirat[*]

School of Engineering, King Mongkut's Institute of Technology Ladkrabang (KMITL), Bangkok 10520, Thailand

A R T I C L E I N F O	A B S T R A C T
	This article proposes a compact and simple design of electronically adjustable voltage-mode biquadratic filter using fundamental active cell implemented on a single integrated circuit (IC) package as LT1228. The proposed circuit having triple inputs and single output (TISO) employs namely one resistor and two capacitors as the passive components. All the five possible biquadratic filtering responses, namely low-pass (LP), band-pass (BP), high-pass (HP), band-stop (BS) and all-pass (AP), are realized by the appropriate selection of the relevant input signals. The pole angular frequency and the quality factor of the proposed TISO filter are electronically tunable through the bias current of the IC chip LT1228. Non-ideal effects and sensitivity performance are carried out. The theoretical results are satisfactorily validated by both PSPICE simulation results and experimental measurements using commercially available LT1228.

1. Introduction

Over the decade, analog filters always play a role in many important analog signal processing applications, i.e. communication systems, measurement and instrumentation systems, etc. Nowadays, the realization of an active analog filter using versatile active building blocks has been focused by many researchers due to many advantage features, such as simple circuitry, high linearity, and wide dynamic range. In the literature, many modern active electronic elements have been utilized in analog active filter design, such as current conveyor (CC) [1–7], differential difference current conveyor (DDCC) [8–12], differential voltage current conveyor (DVCC) [13–16], fully differential second-generation current conveyor (FDCCII) [17], current differencing buffered amplifier (CDBA) [18–20], current feedback operational amplifier (CFOA) [21–27], current follower transconductance amplifier (CFTA) [28–29], operational transconductance amplifier (OTA) [30–34], voltage differencing buffered amplifier (VDBA) [35–36], voltage differencing inverting buffered amplifier (VDIBA) [37], fully balanced voltage differencing buffered amplifier (FB-VDBA) [38], voltage differencing transconductance amplifier (VDTA) [39–41], and voltage differencing gain amplifier (VDGA) [42–44]. However, so many of them require at least two or more active elements for

their realizations [1–5, 7, 8, 10, 11, 13, 18–27, 30–39, 41, 43, 44]. Moreover, the voltage-mode filters presented in [1–17, 19–29, 38, 42] need a large number of passive resistors, while the articles in [1, 4, 16, 22] also contain three passive capacitors. It is also to be emphasized that the realizations of [1–27] suffer from the lack of electronic tuning capability of their important parameters. Even though some similar works were developed by based on various active building blocks in either bipolar junction transistor or (BJT) or complementary metal oxide semiconductor (CMOS) technologies, they are not commercially available chips and reachable in general. Besides, the performances of the research developments in [1–4, 7–20, 22, 24, 25, 28–37, 39–44] have been demonstrated through only simulation results.

In this communication, an electronically tunable voltage-mode biquadratic filter with three input and one output terminals (TISO) consisting of only single active IC package LT1228, one resistor and two capacitors is introduced. The proposed TISO filter can realize the five standard biquadratic filtering responses, namely low-pass (LP), band-pass (BP), high-pass (HP), band-stop (BS) and all-pass (AP), all at a single output terminal without modifying a circuit structure. It also provides an electronic adjustability of its pole angular frequency (ω_o) and quality factor (Q) via the external bias current of the LT1228 IC chip. The theoretical propositions are confirmed by PSPICE simulations with LT1228's model parameters, and the simulated results corroborate the theory. In addition, all conclusions discussed in this work are also verified by

the measurement results of an experimentally test circuit with a single IC package LT1228, and the experimental findings are found to be in agreement with the theoretical values.

2. Description of IC Package LT1228

Our design utilizes only one active cell of a commercially available IC LT1228 from Linear Technology Company [46]. An active cell LT1228 is internally a combination of an operational transconductance amplifier (OTA) and a current feedback operational amplifier (CFA) in 8-pin IC package, as demonstrated in Figure 1. This device has three high impedance input terminals (p, n, and z), and one low impedance output terminal (o). It provides the output current i_z at intermediate terminal z which is the difference of two input voltages v_p and v_n ($v_p - v_n$) multiplied by transconductance gain (g_m). An external impedance Z_z is connected to the terminal z, and the potential v_z developed across Z_z will transfer to the output voltage v_o at the terminal o by the CFA. Its ideal terminal characteristics can be described as:

$$\begin{bmatrix} i_p \\ i_n \\ i_z \\ v_o \end{bmatrix} = \begin{bmatrix} 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ g_m & -g_m & 0 & 0 \\ 0 & 0 & 1 & 0 \end{bmatrix} \cdot \begin{bmatrix} v_p \\ v_n \\ v_z \\ i_o \end{bmatrix} . \qquad (1)$$

Thanks to the LT1228 manufacturing, the g_m-value can be altered to the desired value through the external DC bias current I_B by the following relation: [46]

$$g_m = 10 I_B . \qquad (2)$$

(a)

(c) equivalent circuit.

3. Proposed TISO Biquadratic Filter

The realization of an electronically tunable TISO voltage-mode biquadratic filter is given in Figure 2. The proposed TISO filter is implemented with a single LT1228 together with one resistor and two capacitors. A straightforward analysis of the proposed TISO filter reveals the following output voltage function:

$$V_{out}(s) = \frac{s^2 R_1 C_1 C_2 V_3 + s C_1 V_2 + g_m V_1}{D(s)} , \qquad (3)$$

where the denominator $D(s)$ is found to be:

$$D(s) = s^2 R_1 C_1 C_2 + s C_1 + g_m . \qquad (4)$$

From an inspection of Equations (3)-(4), it appears the five standard biquadratic filter functions can be obtained all at the terminal v_{out} of the proposed circuit by the following conditions.

(i)   The LP response is obtained by setting $v_{in} = v_1$ (input voltage signal) and $v_2 = v_3 = 0$ (grounded).

(ii) The BP response is obtained by setting $v_{in} = v_2$ and $v_1 = v_3 = 0$.

(iii) The HP response is obtained by setting $v_{in} = v_3$ and $v_1 = v_2 = 0$.

(iv) The BS response is obtained by setting $v_{in} = v_1 = v_3$ and $v_2 = 0$.

(v)   The AP response is obtained by setting $v_{in} = v_1 = -v_2 = v_3$.
Figure 2: Proposed electronically tunable TISO biquad implementation employing single LT1228.

Therefore, the proposed TISO filter of Figure 2 does not require any element matching conditions or equality constraints for the desired filter function realizations. In all types, the important characteristics ω_o, and Q are respectively found as:

$$\omega_o = 2\pi f_o = \sqrt{\frac{g_m}{R_1 C_1 C_2}} , \qquad (5)$$

and

$$Q = \sqrt{\frac{g_m R_1 C_2}{C_1}} . \qquad (6)$$

In case of practical design, if $C = C_1 = C_2$, then the ω_o and Q simplify to:

$$\omega_o = \frac{1}{C}\sqrt{\frac{g_m}{R_1}} , \qquad (7)$$

and

$$Q = \sqrt{g_m R_1} . \qquad (8)$$

In view of the above expressions, the parameters ω_o and Q of the proposed TISO filter can be altered electronically by means of g_m-value. According to Equation (2), the g_m variation can be obtained by an adjustment of the bias current. Also note that since the major contribution of this work is to design a compact and

minimum configuration voltage-mode TISO filter with electronic tunability, an orthogonal control of ω_o or Q is not expected.

4. Non-Ideal Analysis and Sensitivity Performance

In consideration of the non-ideal behavior, the terminal behaviors of LT1228 can be rewritten as:

$$
\begin{bmatrix} i_p \\ i_n \\ i_z \\ v_o \end{bmatrix} = \begin{bmatrix} 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ \alpha g_m & -\alpha g_m & 0 & 0 \\ 0 & 0 & \beta & 0 \end{bmatrix} \cdot \begin{bmatrix} v_p \\ v_n \\ v_z \\ i_o \end{bmatrix} , \tag{9}
$$

where $\alpha = (1 - \varepsilon_{gm})$ and $\beta = (1 - \varepsilon_v)$, where $|\varepsilon_{gm}| << 1$ and $|\varepsilon_v| << 1$ are the transconductance inaccuracy and the voltage transfer error, respectively. Taking this effect into account, the characteristics ω_o and Q given in Equations (5) and (6) are modified to:

$$
\omega_o = \sqrt{\frac{\alpha\beta g_m}{R_1 C_1 C_2}} , \tag{10}
$$

and

$$
Q = \sqrt{\frac{\alpha\beta g_m R_1 C_2}{C_1}} . \tag{11}
$$

In this case, all sensitivity coefficients of ω_o and Q with respect to the active and passive components are derived and found to be as follows:

$$
S_\alpha^{\omega_o} = S_\beta^{\omega_o} = S_{g_m}^{\omega_o} = \frac{1}{2} , \tag{12}
$$

$$
S_{R_1}^{\omega_o} = S_{C_1}^{\omega_o} = S_{C_2}^{\omega_o} = -\frac{1}{2} , \tag{13}
$$

$$
S_\alpha^Q = S_\beta^Q = S_{g_m}^Q = S_{R_1}^Q = S_{C_2}^Q = \frac{1}{2} , \tag{14}
$$

and

$$
S_{C_1}^Q = -\frac{1}{2} . \tag{15}
$$

It is clear from Equations (12)-(15) that the absolute values of the ω_o- and Q-sensitivities are all equal to 0.5. These values ensure that the sensitivity performance of the circuit is to be of low value.

5. Simulation Results

In this section, the proposed circuit and its filtering responses are simulated and discussed through the PSPICE simulation program. For ideal simulation, the LT1228 macro-model parameters obtained from Linear Technology Company and DC supply voltages of ±5V were employed. To demonstrate the functionality of the proposed filter, the circuit is designed for $f_o = 159.15$ kHz and $Q = 1$. In this case, the various component values have been set as $I_B = 100$ μA for $g_m = 1$ mA/V, $R_1 = 1$ kΩ and $C_1 = C_2 = 1$ nF. The simulation results for all filter responses are shown in Figures 3-7, which demonstrates very close agreement with the theoretical responses. For time-domain responses, a 159-kHz sine-wave input voltage with 50 mV peak amplitude was applied to the filter. The simulation results show that the error in f_o-value was found to be less than 1%.
Figure 3: Ideal and simulated LP characteristics

Figure 6: Ideal and simulated BS characteristics
(a) time-domain responses   (b) frequency responses

Figure 7: Ideal and simulated AP characteristics
(a) time-domain responses   (b) frequency responses

Furthermore, the electronic tuning of gain characteristic for BP filter concerning I_B is observed. The related gain expressions of the proposed BP filter, as shown in Figure 8, are plotted for $I_B = 50$ μA, 200 μA, and 500 μA, which resulted in $g_m = 0.5$ mA/V, 2 mA/V, and 5 mA/V, respectively. From Figure 8, the simulation conditions, and corresponding theoretical and simulated f_o and Q are summarized in Table 1.
Figure 8: Ideal and simulated frequency responses of the proposed BP filter with an adjustment of I_B.

6. Experimental Results

To further validate the practical workability of the TISO biquadratic filter in Figure 2, the prototype circuit built with readily available IC element LT1228 and discrete passive elements were used to execute experimentally laboratory tests. The circuit was measured using Keysight EDUX1002G digital storage oscilloscope. All of the measured results were performed

Table 1: f_o and Q adjustment of the proposed filter by varying I_B

I_B (μA)	g_m (mA/V)	R_1 (kΩ)	C (nF)	Q	f_o (kHz) Simulated	f_o (kHz) Ideal	% f_o deviation
50	0.5	1	1	0.7	111.43	112.54	0.99
100	1	1	1	1	157.70	159.15	0.91
200	2	1	1	1.4	222.84	225.08	0.99
500	5	1	1	2.2	352.37	355.88	0.99

at symmetrical supply voltages of ±5 V, and I_B = 100 μA (g_m = 1 mA/V), R_1 = 1 kΩ, and $C_1 = C_2 = 1$ nF. This results in f_o = 159.15 kHz and Q = 1. To observed transient response, the measurement was carried out with a 159-kHz sine-wave signal input of 50 mV peak amplitude. The experimental results for the transient and frequency responses as well as the associated frequency spectrums are displayed in Figures 9-13. Also from Figures 9(c)-13(c), the measured results of the percentage total harmonic distortion (%THD) of the v_{out} for each filtering responses are noted in Table 2. It can be concluded that the measured results are close to the theoretical analysis, and also verify the functionality of the proposed circuit.

Table 2: Total harmonic distortions of v_{out} in Figure 2.

Filter	THD (%)
LP	0.67
BP	4.47
HP	0.73
BS	2.4
AP	0.32

Another set of measurements have been carried out to examine the electronic adjustability of the proposed TISO filter. BP filter response is used for illustrative purposes. Figure 14 illustrates the measured BP frequency responses for various bias current I_B. The g_m-values of the considered filter have been set as 0.5 mA/V, 2 mA/V, and 5 mA/V, for I_B = 50 μA, 200 μA, and 500 μA, respectively. As follows from Equations (5) and (6), the f_o values have been obtained as 112.54 kHz, 225.08 kHz, and 355.88 kHz, while the Q values have been obtained as 0.7, 1.4, and 2.2, respectively.

7. Conclusions

This contribution describes the practical implementation of an electronically tunable voltage-mode biquadratic filter with triple input terminals and single output terminal. The proposed filter employs only a single commercially available IC LT1228 together with one resistor and two capacitors. The filter can realize all five standard biquadratic filtering functions all at a single output terminal by an appropriate input signal selection. The characteristics of ω_o and Q can be controlled electronically and linearly in an electronic manner via the external bias current. Simulation results obtained from the PSPICE macro-model of the LT1228 by Linear Technology as well as constructed in prototype hardware using commercially available IC LT1228 are performed to confirm the properties of the proposed circuit.

Conflict of Interest

The authors declare that they have no conflict of interest.

The use of heuristic methods in teaching is not possible without the cooperation of all or part of the students' academic group. That is, the teacher who made the decision to apply the heuristic method de facto solves the issues of organizing project method in teaching. There are a large number of indications on the relationship between the effectiveness of the use of heuristic methods, taking into account the personality differences of students. As well as the importance of taking into account the personality differences in the project method. However, there is a lack of information about experimental studies in which three components: the project method, the heuristic method and the Myers Briggs personality types methodology, would be considered simultaneously. This prompted us to conduct this study. As part of the project method, a tournament among students of prospective mathematics teachers was held during 2014-2020. Teams of three types to participate in the competition were formed. There was a team whose members were not previously trained. The team whose members studied the heuristic method - "Creativity enhancement method". And also a team whose members, along with the study of the heuristic method, were selected in a special way. Students included in this group had personality types most suitable for performing heuristic techniques, which are components of the heuristic method. The task of the tournament was to compile a set of educational problems in geometry that can be used in the school curriculum. The problems developed by the team were evaluated by the panel. Members of other teams acted as opponents and reviewers. Using the heuristic method allowed teams to prepare more problems and systematize them. The best results in the use of the heuristic method showed the team, the composition of which was selected in a special way. The survey conducted according to the results of the tournament showed an increase in students' interest both in the studied discipline and in the project method, as well as a willingness to use the project method in their future work.

1. Literature review

1.1. Problem-based learning

The experiment on the application of the project method in the study of the discipline "Mathematics training methodology" was carried out from 2014 to 2020 year. This article is a generalization and continuation of the work originally presented at the International Conference on High Technologies for Sustainable Development, which describes the 2014-2018 experiment [1].

Problem-based learning (PBL) is a widely spread teaching method. This method has the following features: using collaboratively work in groups or teams, using principle "learning by doing", increased motivation and interest in learning outcomes [2].

*Corresponding Author: Viktor Ivanov, Email: ivv@opu.ua

Creative techniques are also used [2]. In its turn, principle "learning by doing" include such techniques: learning by trial and error, evidence in practice, experience versus book learning, discovery versus instruction [3]. Another point of view on the main features of PBL in [4] is as follows: the method involves solving a problem posed by the student, initiative of a group of students by the form of study, results of research and activities in the form of the final product, long-term project, and teachers are used only as consultants. The PBL is considered as three principal approaches: learning, contents and social [5]. The term learning means cognitive learning, which have follows peculiarities: the problem is focused on learning, learning versus experiment, enhancement motivation and study within the framework of the project. These peculiarities are the same that point out above. The content approach first of all implies interdisciplinary learning. The social approach is mean that student organize in project team and get project management skills.

At all source mentioned above indicate such features of PBL; cognitive character of learning (including heuristic methods [5]); student should be organized in group; the goal is to solve the problem (this solution to the problem is carried out within the framework of the project [4, 5]). One author is using term a group [4], another is using both term group and team [2]. It is more clearly stated in [5] - the project team is working on the project. Direct link to project management is here.

1.2. Elements of role-playing projects in PBL

In this and other publications, the project method is equated to PBL. But, according to [6], there are four types of projects: construction, enjoyment, problem and specific learning. Thus PBL is only a third type of project. The "construction" project constructs the interaction of the project team members according to certain circumstances. This means that role projects, as well as their well-known variety - a business game - are construction projects. We believe that all types of projects include elements of construction project and PBL. When considering PBL projects, at least the role of the teacher and the role of the team leader are highlighted. Also, the size of the team is usually taken into account.

In [2] the team contract is considered to be an interesting PBL tool. This contract contains the project rules namely: objective of the project, communication between team members, rules and procedures for meetings, etc. At this contract experience of project method is used. As example, a resource and time management elements are include. The team role distribution is considered at item - define the responsibilities of each team member. The role of the teacher is described as a facilitator of the learning process in [2]. Group size guidelines are given. Students which study engineering in framework of PBL perform project tasks in industry. The teacher acted as a mediator among the student group and employees of the firm. The number of assistant lecturers should be limited [7].

In the case of real project, special employee of the company – an instructor can be assigned. He selects a project topic, prepares the presentation of the project for a group of students with a statement of the problem and meets regularly with the members of the group [7]. But inspector should not execute the project instead of students or impose their opinion on them. It is also considered necessary to have an instructor who must prepare important data

and organize information for students [2]. The instructor ensures a link between educational tasks with real problems. Another problem is that the use of the project method to solve real problems presupposes the existence of a core of good academic standing and conscientious students. Lack such of core creates an incredible administrative struggle to compensate for lack of student's motivation and to maintain the quality of the final product for the client [7]. Also, the potential problem for the implementation of real projects should be limited in scope so that the task does not exceed academic terms - a quarter or a semester.

In [8] example of student's group from 5 to 45 is provided. But note that more often groups of 5-7 are applied. It is point out that two faculty advisers should provide the work of student's group [8]. In [9] teaching roles in problem-based learning is described as a process-oriented supervisor.

PBL uses the results of research in the field of cognitive psychology to enhance creativity and increase interest [10]. The size of group is considered; note that for most purposes 3-5 members feasible is recommended. But this recommendation is not based on scientific analysis, but only on experience. Regarding the long-term project, it is indicated that most of the project terms are four years, when the whole process of studying at the university is performed on one project [10]. It should be noted that the work of the project team is provided by one or two teachers [10].

1.3. The role of teacher

The role of teachers is advisory, rather than authoritarian. Teachers used teaching assistant as mentors. On a final stage the report to the client is prepared with help a research assistant [10]. In [11] it was concluded that the group size and team tenure don't influence at the team performance. Note that both the term group and command are used in [10] and [11].

At the each publication mention above the role of a teacher is discussed. In detail the teacher's role is investigated in [12]. This role changes according to stage of a project. At the preparatory stage, the teacher motivates the students, helps in setting the goals of the project. When performing the main stage teacher directs the process. At the final stage the teacher is involved in summarizing works as an independent expert [12]. There are notes that it is very difficult for a teacher to plan or execute projects with students and control them at the same time. In [10] for decided this problem the senior seminar students as mentors are used. In order to avoid the monitoring problems, the teacher may assign a leader for each group of students. Collective execution of the project may lead to the fact that the poor academic standing students avoid academic work. Therefore, the teacher can use individual evaluations, along with a general evaluation of the performance of the group [7]. Such an evaluation can also be given by the instructor (research assistant) and each member of the group can evaluate the contribution of his colleagues during the various stages of the project [7]. In [13] identifies various ways of organizing the work of the teacher: with open (explicit) coordination or with hidden coordination (including the coordinator in the work on the project). In [14] refer different options for the distribution of roles between the teacher and students. In the case that the total amount of work can be divided into independent parts for each student, the role of the co-ordinator falls upon the teacher. In the case when it is possible to identify the main and auxiliary tasks, and also when the

final distribution of tasks between students occurs in the process of performing assignments, the role of the co-ordinator falls upon the teacher and one of the students. Such a distribution of roles exists when performing of integrated master's theses when several students develop one topic [14].

The main sources mentioned above are connected project approach with creating a group. In [15] note that obviously, the group is fundamentally and, when possible, students should be grouped. It is important to give students time to study group behaviour and performance. A study of the work in the student group showed that although the teacher's intervention and management led to improved student satisfaction with the results of the project, this negatively affected group unity [15]. An interesting variant in which the function of the co-ordinator is entrust to one of the students. This student co-ordinator is usually chosen from among the most successful students [16]. In general, many researchers distribute students into "strong" and "week", meaning only their academic achievements. For election of co-ordinator, such a feature as a high sense of responsibility, can take into account, for example [15].

In [11] pays attention to the need to take into account the personal differences of students while monitoring their academic achievements. So, students in different ways can show themselves in oral or written evaluation. To take account of these differences is proposed to use socionics typology [17]. Refer that the project method is also assumed control of academic achievements. In [18] insists that the same teaching method gives different results for students with different personality types. He invited to divide students into small groups so that each group included representatives of only one personality types. [18].

1.4. Student competition

The foregoing article consider different aspect of project method at education; these are: increasing creativity, "learning by doing", increased motivation, results of research and activities in the form of the final product, teacher's role, size of group and selection team members in according there personality types. Depending on the type of project, this or that moment turns out to be very important. It is consider the projects, which included this entire item. These projects are based on student's competitions.

The Formula Student team includes from 40 to 50 members typically [19]. This large team is parted into sub-teams of 3 or 4 participants. A large project team has a leader called the captain. Usually this role is performed by a graduate student. The formalized roles are systems engineer and managers responsible for marketing and financial matters [19]. The captain and faculty member is controlled financial issues, also. An adviser and industry mentor supported each large team. In this case is realized problem learning study: team solve problem of automobile design with final product - racing car. As well role-playing project is realized. The students are performed role of design division of automobile company.

The same examples when there is a PBL project and a role project and also the final product are World Robot Olympiad and Robot Soccer World Cup. Another example is student tournaments. International Natural Sciences Tournament (INST) is including following specializations: Chemistry, Material Science,

Geography, and Engineering. University students can participate in the team. The researcher or doctoral student acts as a trainer. Separate tournaments in mathematics (International Tournament of Young Mathematicians) and physics (International Physicists' Tournament) are held.

The International Physicists' Tournament (IPT) has the most established and regulated rules for conducting [20]. The IPT preparatory work on the formation of tasks carried out group of teachers, which is then not in contact with students. The other teachers, usually four of them, are panel members. Each team has the adviser - PhD student. Team is headed by the captain; he is one of a student. Teams of six students receive a list of tasks that can be solved experimentally or theoretically. In a round of a tournament, each team plays one of the following roles: speaker, opponent, and reviewer. Each task consists of three rounds, i.e. each team must play all three roles. Along with the team competition, the participant's personal contribution is assessed. Speakers and Opponents who receive an above average grade for their performances receive personal points. Individual winners of the Tournament are determined by the total amount of personal points.

Point out that in a number of cases, the work result of the project team may be not only in obtaining certain knowledge and skills, but it have practical result. Practical result is important when:

- A project is real and results of which will be used in practice;
- Competition between projects groups, for example - Formula Student, IPT, INST, etc.;
- Business games, when the insufficient level of results breaks the plot of the game and does not allow achieving the necessary knowledge and skills;
- This is the study of heuristic methods, when the absence of a result will not allow to fully revealing the content of the topic.

1.5. The results of the review and the objectives of the study

The effectiveness of the application of project method, as reviewed by the literature sources, is related to the features of the formation and work of project teams. Recommendations for the size of the project team are very different - from 2 to 12 members. Note that there are usually 15-25 students in an academic group. The size of the project team depends on the size of the academic group, due to organizational factors. Conveniently if all students of an academic group are included in the project team or two teams are formed from this academic group. The most common recommendation is that the project team should be small, but for more teams, more teachers should be involved than a lecturer and assistant.

In two cases, it is important to distribute roles between students in the project team - in the implementation of long-term projects and in student team tournaments. Long-term projects can be implemented for execution of a bachelor's degree project, a master's degree project and a term paper formed to work for a long period of time. The project team can be formed for a year or more for implementing collaborative interdisciplinary or research projects. In [11], it was concluded that group size does not affect team performance. We assumed this was due to the fact that team members were selected without regard to their personal

differences. Extensive experience in the formation and organization of project team interaction has been accumulated in project management. As a rule, the distribution of roles between students of the team members is spontaneous: someone is chosen for the role of leader, someone is a generator of ideas, and someone is responsible for processing the results of the work. Sometimes students themselves are called to perform certain functions in the team. However, there are various scientifically valid typologies of team roles. This distribution can be performed on the basis of the project management theory. The terminology accepted in project management, namely: project team, teamwork, team roles, is also expedient to use. The heuristic nature of the design method is often noted. The content of the project method can be the work of the team to study and apply the heuristic method [21]. In this case the distribution of team roles should be performed on the basis of personality type's methodologies [21]. The important question is about the role of the teacher in the project method. The roles of teachers vary. Teachers prepare material and project rules. They are advisers and evaluate students. Is teacher outside the project team or its member? Usually it depends on which project we are considering. In a short-term project, the teacher is out of the project. If the subject of the study is a long-term project, then the teacher can be an advisor and even be a member of the project team.

The study includes a preparatory stage, which consists of building project teams, teaching students to use the heuristic method and surveys to determine their personality type. The experiment itself included the organization of a tournament, work with the use of a heuristic method, including taking into account the personality type of students. As well as the panel's assessment of the teams' work results and a survey of the participants about the experiment results. At the analysis stage, the performance of the project teams, and the effectiveness of using individual techniques of the heuristic method by students with certain personality types were compared.

2. The methodology of experiment

2.1. The hypothesis of the study

The project method is widely used in education. The scientific basis of this method was developed in project management. The guidelines for team size and selection of team members were generally developed based on the team role methodology. Often the purpose of forming a project team is to ensure teamwork within the heuristic method. The methodology of personality types is more suitable for selecting group members and organizing the interaction of team members in the case when the application of the heuristic method is the reason for the formation of the project team. The lack of data on the combination of personality type's methodology, heuristic method and project method should make up for this experiment.

The following statement is accepted as hypotheses of a study:

- H_a - The use of the heuristic method, allows to improve the performance of the team.
- H_b - The formation of a project team, taking into account the personality types of students, allows to improve the performance of the team.

- H_c - The use of the project method in the form of team competition increases the interest of team members in the application of this method.

2.2. Tools are used to test these hypotheses of a study

The Keirsey Temperament Sorter. Student's personality types were determined using the Keirsey questionnaire [22]. The first test was conducted six months before the tournament. The second test was performed immediately before the tournament. Along with personality types, their brightness was determined. The test was carried out on the basis of an adapted version of the test in Ukrainian (http://ibib.ltd.ua/2211-test-keyrsi-tekst-35784.html). Two academic groups consisting of 15-20 students in each took part in testing. The coincidence of the results of the first and second tests was in the range of 76–81%, which is within the acceptable range (75–90%) in accordance with [23]. Students with personality types necessary for the execution of the heuristic method algorithm were selected to the first group. Of the students with the same personality types, preference was given to the participants with the brighter type.

The expert evaluation. The teacher and two PhD students prepared tasks for the tournament and became members of the panel. The panel members evaluate each problem based on a report and discussion. The maximum score is 100 points. The problem was evaluated on four items: correctness of composing and solving the problem (40), completeness of methodological recommendations (20), compliance with the requirements of the educational set of problems (20), consistency, clarity and validity of each stage in the presentation of the problem (20).The maximum number of points for each item is indicated in parentheses. The individual contribution of each participant was also assessed. The maximum score also is 100 points. The problem was evaluated on five items: ability to report, ability to debate, quickness in correcting your mistakes, finding mistakes in opponents, the ability to analyze the proposed sets of problems from a methodological point of view. The maximum score of each item is 20 points.

The survey. A survey was conducted following the experiment. All students answer the questions "Do you like the project method?" and "Will you use the project method in your future work?". The members of first and second team answer the questions "Do you like the heuristic method?" and "Will you use the heuristic method in your future work?". The members only of first team answer the questions "Do you like the distribution team role due personality type?" and "Will you use the distribution team role due personality type in your future work?".

2.3. The heuristic method

It was decided to use as a heuristic method "creativity enhancement method" [21]. This method included several heuristic techniques, namely: collective discussion, pause between the presentation of ideas and their criticism, random associations, analogy, expert evaluation, using a matrix. The sequence of heuristic techniques is follow. At first is applied three techniques collective discussion, pause between the presentation of ideas and their criticism, expert evaluation. This three techniques is represented a all known brainstorming. The main difference of a creativity enhancement method in contradistinction to another

method based on brainstorming is using matrix. The purpose of the first three heuristics is to determine what sense should be given to the row and column. Second part of heuristic techniques follows. These are random associations, analogy and expert evaluation. The goal of techniques random associations and analogy is to generate ideas about the semantic content of the first row and first column elements. Expert evaluation technique is used to select better variant of ideas. Third part of heuristic techniques grouped around the matrix. These are using a matrix, collective discussion and expert evaluation. The combination of elements first row and first column give a content of each matrix cells [24]. Each cells can contain a possible solve of problem. But in fact, many combinations give impossible options or options that are not implemented under given restrictions. The cells that are have sense the material of collective discussion. The final selection is performed using expert evaluation techniques.

2.4. The personality types selection

The preparation of students to use creativity enhancement method one lecture session and one practical session were provide.

According to the method especially selected students performed determination techniques. The moderator of discussion should be with personality type ENTJ or ESTJ [21, 22]. For collective discussion the ENTJ, ENTP, ESTJ and INTJ personality types are recommended [22, 25, 26]. These types are arranged in the order in which they are best suited for this technique. For criticism the types sequences in order of their degree of preferable: ISTP, INTP, ISTJ, ESTJ [25, 27, 28]. For expert evaluation the same type can be used only at another sequences their degree of preferable. For technique of random associations the types ENTP and ENTJ should be added to discussion group [21, 26]. For technique of analogy a type INTJ should be used [22, 25].

3. The results of the experiment

The experiment was attended by students of SUNPU - prospective teachers of mathematics. Every year, the subject studied two academic groups. The experiment was carried out during 2014-2020. Students were assigned to two or three project teams. The academic group was reorganized into a project team if the number of students was less than 15 or two project teams if the number of students was more than 15. Thus, there were two or three project teams. The teams were of three types. The third project team were participants, who were doing methodical task without special preparatory training for this task. The members of the first project team took additional sessions to learn the creativity enhancement method. The participant of this team especially selected on the base of their personality type. The types, which corresponded with personality type to need a heuristic technique of method, were included in team. Members of the second project team are also studying the heuristic method. Students of the third project team didn't have additional classes. In total, sixteen project teams were created: a fifth team of the first type, three teams of the second type, and three teams of the third type (Table 1).

The total number of problems prepared by the teams is presented in Figure 2. The tournament was organized for project teams as part of the study of the discipline «Mathematics training methodology». IPT rules were used for the competition. If there were three teams, then each of the teams consistently acted as a

speaker, opponent and reviewer. In the competition between the two teams, there were only speakers and opponents. The teams were tasked with developing a set of geometric problems, namely, a planimetry subsection. The topic of these problems set is established the same for all teams. This set of problems can be used in the school curricula. Specific requirements for this set are established: definite purpose of using, the arrangement of the problems in increasing order of difficulty and the availability of the alternate problems (with the same level of difficulty as well as methodical recommendations).

Table 1: Types of team per year

Year / Types of team	2014	2015	2016	2017	2018	2019	2020
First type	■	■	■	■	■	■	■
Second type	■			■		■	■
Third type	■	■	■		■		■

The work of teams of the first and second types was organized in accordance with the heuristic method algorithm. The collective discussion group included from 5 to 10 people, depending on the number of project team members. The ideas put forward by them were discussed by a group of critics of 3-5 people, together with some of discussion group participants. The final decision is made by an expert evaluation group of three people, one of whom is a moderator. Then the team was divided into two parts, one discussed the specific content of the rows, the second columns. Groups is performed this task using free association and analogy techniques. Based on the results of the discussion, a matrix was drawn up. Schemes of problems were depicted in the corresponding cells of the matrix. The discussion group is selected problems for further development. Then, the team, to increase productivity, split into parts and worked on selected problems. For each problem it was necessary to find several solutions and develop methodological recommendations. The expert evaluation group with high-achieving students selected problems that could be presented.

Figure 1: Example of a table with options for problems

An example of a fragment of one of the matrices obtained by the command of the second team type is presented in Figure 1. The

elements that need to be found are marked in red. These are the medians drawn to the three sides of the triangle. The first row of the matrix is location options of medians (LOM). The first column contains the given triangle elements (GTE). Each cell of the second row corresponds to a triangle with all sides are given.

Of the three options for the location of the median, only one was chosen, since in all three cases the solution algorithm is the same. In the third row, there are triangles in which two sides and the angle between them are known. Two options are selected when the median is drawn from a known angle and when it is drawn from an unknown angle. In the fourth row, there are triangles in which two sides and angle are known but the angle is not located between them. Two variants are also chosen when the median is drawn from a known angle and when it is drawn from an unknown angle. Further, in the matrix considered triangles in which one side is known. These rows are not shown. For each of the triangles marked with a yellow background, the team developed several solutions with explanations, as well as recommendations for the teacher on how to apply these problems in the school curricula.

The total number of problems prepared by the teams is presented in Figure 2 and Table 2. The team reported the results, usually there were several speakers. Students preparing the problem presented it. The panel evaluated the team members who participated in the presentation individually. The members of the opponent's team who participated in the discussion were also individually assessed. The participants of the opposing team looked for inaccuracies in the solution and deficiencies in the explanation. They raised objections to methodological recommendations and to the possibility of using the problem in the school course. On the basis of the report and discussion, the panel evaluated each of a set of problems. Problems with more than 100 points were selected for use in the school course. The number of problems selected by the panel is shown in Figure 3 and Table 2.
Figure 2: Total number of problems by year
Figure 3: Selected number of problems per year

Table 2: Team performance

Team No \ Year	Team 1		Team 2		Team 3	
	Total	Se-lected	Total	Se-lected	Total	Se-lected
2014	34	14	24	9	12	5
2015	31	12	-	-	11	4
2016	25	13	-	-	5	4
2017	22	10	18	7	-	-
2018	17	7	19	8	-	-
2019	29	13	22	8	9	6
2020	24	12	20	10	-	-

The results of the student survey showed an increase in the interest of team's members of all types in the project method and the heuristic method. The students of the first type of team showed enthusiasm for defining their personality types and organizing the team work based on this data. As for the prospects for using the acquired skills in further work, everything is not so unequivocally. Most of the students of the first type team are not going to use the knowledge gained about personality types in their further work. Almost half of them are ready to use the heuristic method in the future, in contrast to participants from teams of the second type. The project method of work was assessed by the students of teams of three types as the most deserving of use in the work of a teacher (Table 3).

Table 3: Types of team per year

Survey questions \ Team types	First team	Second team	Third team
Do you like the project method?	89%	84%	73%
Do you like the heuristic method?	77%	69%	-
Do you like the distribution team role due personality type?	82%	-	-
Will you use the project method in your future work?	65%	71%	58%
Will you use the heuristic method in your future work?	44%	24%	-
Will you use the distribution team role due personality type in your future work?	23%	-	-
Has interest in studying the discipline increased due to innovations in the form of education?	81%	73%	67%

4. Analysis of experiment result and discussion

The performance of the second type team, which used the heuristic method, is higher than the performance of the third type team. Teams of the second type developed 24 problems. The average number of problems in a set is 8. The third type team developed 13 problems. The average number of problems in a set is 4,3. Thus, the results of the experiment confirmed the hypothesis H_a.

The application of the heuristic method requires special training. One lecture and one practical session are the minimum time to explain the essence of the method. It would be desirable to have more time for this. But there is a problem associated with the allocation of even this short time. If the heuristic method were used in teaching several disciplines, then there would be an opportunity for additional training. The method is quite complex, and several times the teams invented the contents of the matrix during brainstorming and heuristic techniques of random associations and analogies are not used. Heuristic techniques of random associations and analogies can be used to search for the contents of rows and columns. If one technique does not work, the other can be used additionally. It is promising to use the heuristic method in long-term projects carried out during a semester or longer.

The performance of the first type team, which was formed taking into account the personality types of students, is higher than the performance of the second type team and much higher than the performance of the third type team. The first type of team developed sets of 56 problems. The average number of problems in a set is 11,2. The experimental results confirmed the hypothesis of H_b. This means that the selection of performers for the execution of heuristic techniques was performed correctly.

It is very difficult to select the necessary personality types for the project teams, considering the level of knowledge, motivation and the personal interaction and relationships due to the small number of students learning a certain subject. For to form first type team in some cases it was necessary to include the students that had rare personality types ENTJ (moderator) ENTP (discussion group) from another academic group. This reduced the performance of teams of the second and third types. Experience has shown the academic achievements of the students can be more important than the exact matching of their personality types with their role in the creativity enhancement method. Sometimes we had to include the students from different academic groups into the project teams to strike a balance between the levels of their knowledge. The correct selection of team members of the first type allows students to understand the advantages of the method through a successful result. The project team included not only students with a personality type that is suitable for performers of heuristic techniques. Thus, it was necessary to find a model of participation for those who have a different personality type. Experience shows that the ENFP can act as a moderator, facilitating discussion through one's own imagination and enthusiasm. The personality type ENFJ can substitute INTJ in the discussion group because of their ability to generate the ideas. The personality type ENFJ can also fulfil the role of the teacher assistant when teaching creativity enhancement method. Having the big number of the representatives of personality types ISTJ, INTJ, INTP, ISTP, in the discussion group, it makes sense to give the students time to make the record of their ideas before the beginning of the discussion. A higher level of students' knowledge is created the prerequisites for the effective execution of the chosen role when working in a project team. However, this students, who did not have high grades earlier with the matching of their personality type with the appointed role surprisingly enough showed a better efficiency. For example, a student of personality type ISTJ, with an average level of academic achievement, working as a critic in a project team, enthusiastically is joined the work in detail analyzing the proposals of other team members. This

is allowed him to systematize and deepen his knowledge and skills appropriate way for him. The personality types of students, who show high results in the experiment, usually coincide with the typical personality types for STEM specialties: ISTJ, INTP, ESTJ, INTJ, ENTP, and ENTJ.

The survey showed that the members of the three types of teams were enthusiastic about the project method implemented in the form of competition. 82% of the total number of students liked the participation in the project. Students, who are going to use the project method in their profession - 64,7%. Thus, hypothesis H_c is confirmed.

The number of students in project teams is higher than recommended by the majority of research. This is due to the lack of teachers to conduct the research. Another problem of the project method was the organization of teamwork in such a way that all team members took an active part in it. We did not have this problem with the work of the first type of teams, unlike the second and third type teams. This serves as an indirect confirmation of the success of team interaction based on personal types. When using project method, there has always been the problem of assessing the personal contribution of team members and, accordingly, evaluating their academic achievements. Not all students presented solutions to problems and participated in the discussion. In the first type team, the students, in particular, the moderator, were involved in the assessment, which contributed to its objectivity and validity. The fact that students who solved the problem represent it is good for their self-realization, but it can be bad for the team score. From the point of view of higher score of the team, it is advisable to entrust the presentation of problems to students with high academic achievements.

5. Conclusion

The experiment was conducted in the form of a tournament, which made it possible to implement the PBL project and at the same time the role-playing project. The project had the final product - a set of geometry problems. Students studied the creativity enhancement method using the principle of "learning by doing". Thus, the project was comprehensive. Three types of project team took part at competition. Students of first and second project team are learned the heuristic method. Students of third project team haven't special training. It was found that the use of the project method in the form of a team competition aroused increased interest among students. It has been established also that the use of the heuristic method improves the performance of the project team. Members of first project team were selected according to their personality types. It was proven that the selection of students with certain personality types to the project team, the most suitable for the implementation of the heuristic techniques of the method, allowed increasing the performance of the project team. This confirms the correctness of the recommendations for the selection of personality types corresponding to a certain heuristic techniques. It is best to choose students with the ENTJ personality type for the role of moderator. It is recommended to choose personality types ENTP, ENTJ, INTJ for discussion and generation of ideas. The ISTP, INTP and ISTJ personality types should be used as criticisms. Several members of a collective discussion group must necessarily be at the group of critics. However, among the critics, there should be several

members of the project team who did not participate in the discussion, for unbiased analysis of the proposed solutions. Academic achievement affects the performance of teams along with the personality types of students. This is important to consider when choosing a moderator and discussion group members. For this reason, the preferred ENTJ types can be replaced with ESTJ as the moderator, and ENTP can be replaced with INTP in the discussion group.

Conflict of Interest

The authors declare no conflict of interest.

A B S T R A C T

Wireless sensor networks (WSNs) are having large demands in enormous applications for the decade. The main issue in WSNs is estimating the exact location of unknown nodes. All applications are dependent on the location information of unknown nodes in WSNs. Location information of mobile anchor node is used to estimate the location of unknown nodes. A new approach is implemented in this paper for the localization of unknown nodes using Artificial Neural Networks. Specifically, a neural feed network is used for the indoor position process. Also several neural network configuration sets have been tested, which includes Bayesian regularisation (BR), Levenberg-Marquardt (LM), resilient back propagation (RP), Scaled Conjugate Gradient (SCG) and Degree Descent (SCG),etc. At the end results are simulated using MATLAB and Mean Square Error is calculated and compared with other existing approaches. The proposed approach is energy efficient and uses only a two-way message to obtain inputs for the localization. Even the cost is minimized as in the proposed system only one mobile anchor node is used.

1. Introduction

With the development of new applications in numerous areas, wireless sensor networks (WSNs) have gained a vast reaction from academia and industry. Applications for the future include monitoring of vegetation and the environment, search and rescue processes, object tracking in hospitals, monitoring of patients, and military applications. Because of technological development, small, cheaper sensor nodes have been developed that consume less power and feature capabilities like sensing, data storage, computer technology, and wireless communication.

Localization among others, architecture, deployment, synchronization, calibration, quality of service, and security are the key and difficult part of many WSN applications. The sensor data has to be attached to measured data in order to make this important for location since it is essential to monitor and record broad information like acoustic, visual, thermal, and seismic or any other type of measured observation. For example, the place or part of the farm from which the data is collected would be required for the person monitoring a big vegetation farm, with a wide variety of vegetables, since various vegetables have different special needs. Reporting Object origin, node location is required so as to support or answer group querying, routing and network coverage questions. Research into the problem of node location has provided a number of solutions over the course of the decade.

Overall, most of the time there is a compromise between localization accuracy, computer complexity, and technology energy efficiency according to their application needs.

A large number of space-dispersed sensor nodes is usually used in a WSN such that the location of the sensor node when the nodes are used is unable and inefficient. Sensor nodes may also be relocated from their original position. An algorithm is therefore necessary for an independent assessment of the location of the node. In this research paper, a new location scheme for neural network-based nodes is proposed. In order to address the node location problem, the Received Signal Strength Indicator (RSSI), is utilized to evaluate the coordinates and location of WSN nodes. Contributions are as follows:

Is RSSI an appropriate component for WSN node location? We use RSSI to determine where the sensor nodes are located and explain how RSSI is suitable for locations. There will not be a need for additional hardware because sensor nodes are openly outfitted with RF modules for wireless communication. Multi track fading and noise, however, can contaminate the RF signal and thus affect the RSSI value through a noise-to-signal correction.

Also, of the utmost importance is the choice of the evaluation model. A 2D indoor environment that is determined by the x and y co-ordinates is considered in this research. A single node of anchor requires directional steering antennas, which directly

boosts the sensors' cost and electricity consumption. Therefore, the two or more anchor nodes with different configurations explain the best configuration used for the anchor nodes.

A new 2D indoor locating system based on a neural network is introduced. For an accurate localization, the global positioning system can be used. The use of GPS does require the attachment of external hardware to the sensor nodes, thereby increasing cost and electricity consumption. In addition, a GPS viewing line is required and is therefore not applicable to indoor environments.

A neural feed network is used for the proposed indoor position process. A variety of neural network configuration sets have been tested, and Bayesian regularisation (BR), Levenberg-Marquardt (LM), resilient back propagation (RP), Scaled Conjugate Gradient (SCG) and Degree Descent (SCG) are the best neural network training and implementation (GD).

2. Literature survey

In [1], the authors presented a survey on machine learning algorithms for WSNs. They have presented techniques to identify intrusion by merging clustering and deep neural network methods and discussed machine learning-based localization techniques for WSN such as fuzzy logic, k-means + fuzzy-c-means, CNN+SVM, ANN, SVM. Also discussed ML-based congestion control strategies. Logic-based cram detection and control systems have been configured for efficient and active queue management as the basis for minimizing packet loss. It can be carried out in three stages. Second, it senses congestion in the second it modifies congestion control and by balancing the flow it recovers from the congestion.

In [2], the authors have suggested a new distance measuring capability using the Adaptive Neural Fuzzy Inference Scheme to render model, map RSSI to the precise T-R distance and experiments prove feasible.

In [3], the authors has proposed an adaptable model dependent on the neural organization and lattice sensor preparing stage for exact limitation of sensors. Recreation results show that the area exactness can be expanded by expanding the framework sensor thickness and the number of passages. The author proposed and explored a confinement procedure for WSNs utilizing NN. They think about NN for building adaptable planning among RSS and the situation of the sensor hubs. In this method, the NN is prepared to utilize the RSS estimations of the lattice sensors. The positive highlights of the framework are its dependence against the adjustment in the RSS estimations with time and no requirement for the additional course of action of equipment. The organization's preparation is refreshed with a standard timespan to limit area mistake. Simulation experiments demonstrate that the area exactness can be expanded by expanding the matrix sensors' density and APs.

Nowadays for enhancing the accuracy of localization in the Range-Free approach is more focused. In [4], the authors introduced many algorithms to improve accuracy such as BP artificial neural network (BP ANN). Rather than the amorphous algorithm is very easy to develop, and it will generate huge errors in the localization procedure. For resolving the issue and to diminish localization error, presented an improved localization algorithm. A widely utilized model in neural networks (NN) is BP NN. BP algorithm is a NN of three-level. The methodology used for the detection of network weight and the threshold between BP algorithms with minimal error and recursive technology is known

as the deepest descent. BP ANN practitioners are incredibly self-organizing and self-learning, error replication, and a minimal theory of error in error optimization.

In [5], authors presented a study on localization in WSN by utilizing neural networks (NN). This study analyses localization algorithms and their advantages and disadvantages. They Discussed localization, localization classification methods, localization classification algorithms, and the pros and cons.

In [6], authors submitted comparable analyses of the localization WSN localization networks of Sigmoidal Feed ANN (SFFANNs) and Radial Base Function (RBF). The system proposed uses the Obtained Signal Force Indicator (RSSI), a static node calculated on a grid of 100 x 100 m2 of the three anchor nodes. The key aim of the SFFANNs' and RBF network system comparative analysis is the development of an efficient WSN localization structure. Both ANN models approximate the position error by using RSSI values. Quality comparison has been done with respect to standard deviations, mean position errors, and statistical parameters of R-square. MLP has the best efficiency, shown by simulation outcomes, where accuracy is considered.

In [7], the RBF network has been reviewed by the authors for the implementation of the WSN position method. For reasons of faster convergence and the lowest measurement rate, the RBF-based localization architecture should be evaluated. The analyses of RBF in this paper have been a probabilistic NN and general regression NN. For designing an efficient localization method, the suggested technique may be used. To minimize position errors, the predictive location algorithm proposed by the authors [8] relies on RBF NN. An algorithm detains moving node standards inherent in it and learns them from them. A field of mobile nodes can be expected by removed traveling highlights. Reproduction findings confirm that these calculations will be more reliable in the visually impaired interval to understand detailed localizations.

In [9], the authors proposed computationally – cheap arrangements rely upon support vector machine (SVM) and twin SVM learning algorithms where network nodes right off wanted signal. At that point, the network is trained to determine nodes in the region of source; subsequently, locale of the function is distinguished. At last, centroid of event region is assessment of source area. Re-enactments show the productivity of the proposed techniques. SVMs are integral tools for regression and classification which depend on the statistical learning hypothesis. Contrasted and other ML strategies, for example, ANNS, SVMs have a superior speculation ensure. SVM separates the data tests of 2 classes by deciding a particular hyperplane in input space. This hyperplane boosts the partition among 2 classes by taking care of a quadratic programming issue whose arrangement is around the globally optimal.

In [10], the author has examine the reasonableness of a portion of these algorithms while investigating diverse compromises. In particular, authors initially figure new method of characterizing many feature vectors for planning localizing issues onto diverse AI models. Instead of regarding localization as a classification issue, as accomplished in the majority of detailed work, authors treat it as a regression problem. Authors have contemplated an effect of varying network parameters, for example, anchor population, network size, transmitted signal power, and remote channel quality, on confining precision of the models. Authors have additionally considered the effect of sending anchor nodes in the framework as opposed to putting the nodes arbitrarily in

deployment areas. Their outcomes have uncovered fascinating experiences while utilizing the multivariate regression model and SVM regression model with an RBF. Various models have been characterized for various ML algorithms. A portion of the normally utilized models incorporates neural networks, multiple linear regression model, linear regression model, SVM with various kinds of kernels, Logistic regressions or classifications, k-nearest neighbours (KNN), and random forest (RF) clustering.

In order to address the Wireless Sensor Networks (WSN) localization accuracy problem in [11], the authors have suggested the latest Methodology for Localization Backpropagation Network (BPNN). At first, node localization calculations are provided with range intervals and signal power, and on BPNN the parameters solve easily. In a simulation experiment, the main factors of NS2 and MATLAB are also evaluated. The results show that this technique is successful in comparison with other localization algorithms and can minimize localization errors effectively.

In [12], the authors proposed ANNs way to deal with localization in WSN through change of ANNs structures utilizing Genetic Algorithms. Populace of feed forward ANNs composing their structure in genetic code is developed more than 20 ages. Every individual is assessed through the preparation of training of ANN and further estimation of its root mean square error for all testing set. The RSSI estimations were utilized as ANN inputs to localize hubs. The methodology is to collect information from the ANNs under an input reactivated static 26 x 26 meter indoor organizational climate, which consists of eight anchor hubs, under a reactivation of the static 26x26 meter indoor organization environment. The methodology has been used. Hereditary calculations of MATLAB and fake neural organizations were used for stashing tools.

In [13], the authors emphasise the comparison and study of MLPNN and RBFNN for the creation of a position system in WSNs. Various sensor node collection were evaluated using both MLPNN and RBFNN along with the mean square error of various input data sets. Their simulation findings effectively suggest that MLPNN is more reliable with respect to localization than RBFNN.Use the "Insert Citation" button to add citations to this document.

In [14], the authors suggest a new algorithm for localizing the sensor nodes using virtual anchor nodes. VAN is located in its system with minimum anchor nodes. The goal of their work is to improve the accuracy of the position by optimizing the location ratio and minimizing the costs of several anchor nodes.

In [15], the author explained the localization based on ANN in WSN. Localization refers to the issue of finding the location or position of sensor nodes in a network. But localization problem is still an open challenge in WSN. Author analyzed and classified existing works on localization algorithms that uses ANN. ANN algorithms were identified based on how they were utilized in the localization processes; noise characterization, model construction, training phase optimization, clustering, and prediction. Author also discussed about the features and related work about it and how to improve the accuracy of previous localization using ANN.

In [16], the authors proposed an approach known as ANN approach for moderating the reaction of mixed noise sources and harsh factory conditions on the localization of the wireless sensors. They have focused on investigating the effect of blockage

and ambient conditions on the accuracy of mobile node localization. They have added a simulator for simulating the noisy and dynamic shop conditions of manufacturing environments, also for analyzing the proposed neural network.

In particular, in networks with sparse anchor deployment, cooperative localization improves the accuracy of position estimates. In [17], the authors presented implementation of it in low-cost WSN that are low-power. A WSN hardware platform with ultra-wideband range and communication is shown and the implementation of a cooperative localization algorithm based on belief propagation is addressed. The key sources of error are addressed and indoor tests of the device are performed using a simple channel access scheme and a standard ranging process.

In [18], the authors presented an enhanced centroid localization algorithm for WSN. One of the main technologies in the WSN is node localization. The center position algorithm depends entirely on the size and distribution density of the anchor nodes, but they are distributed randomly and their density is small. Given the conventional centroid localization algorithm, an enhanced centroid localization algorithm is vulnerable to the effect of network deployment status and the current situation of low positioning accuracy. Second, the idea of reference anchor nodes is implemented by bringing weight thought into the measurement method of node coordinates.

This template, modified in MS Word 2007 provides authors with most of the formatting specifications needed for preparing electronic versions of their papers. All standard paper components have been specified for three reasons: (1) ease of use when formatting individual papers, (2) automatic compliance to electronic requirements that facilitate the concurrent or later production of electronic products, and (3) conformity of style throughout the conference proceedings. Margins, column widths, line spacing, and type styles are built-in; examples of the type styles are provided throughout this document and are identified in italic type, within parentheses, following the example. Some components, such as multi-leveled equations, graphics, and tables are not prescribed, although the various table text styles are provided. The formatter will need to create these components, incorporating the applicable criteria that follow.

3. Methodology

An ANN, also known as the network of neurons, offers a simple way of revealing valued and true functions as examples. ANN uses a supervised curriculum. Inputs and outputs to the ANN are given to learn and create a correct model. The classification and regression dilemma is normally tackled. Typically, the artificial neuron network has 3 layers, input layer, hidden layer(s), and finally output layers.

Neural feedback and feedback networks form two classes of neural networks. In a neural feed network, the outcome is fed from one layer of neurons to the next layer, no layers are skipped during this process, and the system has no feedback. The position is composed of three major neural networks: MLP, the Recurrent Neural Network and, the RBF.

It is to be noted that RSSI values are very unpredictable and vary under ambient noise and sensor mobility. The benefit of a neural network is that prior environmental and noise propagation is not needed. More precision is achieved through a neural network compared to other approaches such as Kalman filters. Comparing other neural network types, for the study the

compromise between MLP neural accuracy and the network memory requirement was chosen.
Figure 1: A general feed-forward neural network structure with four inputs and three outputs.

3.1. Network Model

WSN model for region assessment of static sensor nodes. Static nodes are moved to region of recognition and the node of mobile
Figure 2: Illustration of broadcasting and reception of beacon signal from a Mobile Anchor and static sensor node respectively.

anchor (MA) ready for intersection. In addition, in the fig, the way MA navigates. 2.

It is assumed that R is a contact range of the MA hub. MA has a GPS recipient and knows its location often. The MA is sending beacon signal at a fixed "Live" interval with an id, transmission radius, current location, transmission power and format shown in figure 2. Before the MA node moves around the sensor area, the administrator determines the 'alternative' intervals.

Figure 3: Packet format of beacon message

Any static sensor node in MA node's "R" range receives a signal from the beacon. A table called Mobil Anchor Location (MAP), as represented in Table 1, is retained in every static sensor Node.

When static sensor node beacon signals are obtained, X-y coordinate values are extracted from signal and stored in the MAP table in corresponding fields. The distance is determined according to the signal power obtained and stored in the Chart Table.

Consider scenario in Figure 2, let $\alpha_a, \alpha_b, \alpha_c$ and α_d be the MA positions throughout its traversal time and having (x_1, y_1),

(x_2, y_2), (x_3, y_3) and (x_4, y_4) as their coordinates. Static sensor node S1, at position δ whose co-ordinate is (x_0, y_0), receives beacon signals when MA is at position $\alpha_a, \alpha_b, \alpha_c$ and α_d and stores their x-y co-ordinate values into MAP table. Similarly, S1 receives beacon signals when it comes into MA node proximity. Eventually, x-y co-ordinate values are extracted from received signal and stored into MAP table.

3.2. RSS Measurement

Distance from the MA node at position I to the static node S1 at position (x0, y0) is referred to as a correspondence to r (i), as seen in the following equations; (R2) The noise free RSS or received power at S1, denoted by P_i^r

$$P_i^r = k_i \frac{P_i^t}{d_i^\alpha}, i = 1,2,3, \ldots., m \qquad (1)$$

$$d_i^\alpha = k_i \frac{P_i^t}{P_i^r}, i = 1,2,3, \ldots., m \qquad (2)$$

If the beacon signals received by the static node i=1, 2... m number, the transmitted power is P_i^t, the power received is P_i^r, and the propagation constant is α, k (i)denotes other environmental variables that influence the received power. Range related measurement can be modeled, as expressed in (R1)

$$r_i = k_i \frac{P_i^t}{P_i^r} \qquad (3)$$

$$r_i = d_i^\alpha + \eta_i \qquad (4)$$

Every static node calculates r_i for each received beacon signal and stores into MAP table as demonstrated in table 1.

Table 1: MA Positions stored at static sensor node

X-co-ordinate	Y-co-ordinate	Distance (r)
(x_1)	(y_1)	r_1
(x_2)	(y_2)	r_2
(x_3)	(y_3)	r_3
(x_4)	(y_4)	r_4
•	•	•
•	•	•
(x_m)	(y_m)	r_m
Figure 4: Multi-layer perceptron neural network

3.3. Multi-Layer Perceptron Neural Network Model

Neural network model (framework), initially trained with training dataset. Proposed system consisting of Multilayer Perceptron neural network [MLPNN] model having input layer, one or more hidden layers and output layer.

Nine inputs are passing to MLPNN, consisting of three different positions of MA with respect to distance from sensor node. Hidden layer having various neurons. Each neuron, having transfer function to find out weights of each connection between inputs to hidden layer neurons. Output layer having two neurons produces the location coordinates of unknown sensor node. Activation function (linear or nonlinear) is used to calculate location of sensor nodes.

3.4. Algorithm

The multilayer perceptron algorithm is as follows:

Step 1: Initialization: Arbitrary values are used to trigger all networks and thresholds, which are consistently distributed across a limited range. If these values are 0, gradients will also be computed to 0, if and only if there will be no direct relation between input and output and network. More training trials, with various initial weights, are planned to have the best cost-effectiveness. If the initial values are sufficiently high, however these units appear to be saturated.

Step 2: A new period of formation: an era means all the examples are presented in the training set. Training on the network typically requires further training times. The weights are calibrated for statistical rigour, only after the test vectors are applied on the network. Therefore, after each model in the training set and after the end of the training stage, weights must be memorised and adjusted, the weights changed only once. There is a "online version, simpler, which directly updates weights, in which case there may be the order in which the network vectors are displayed. Both weight gradients and current error have been initialised at 0 (alternative to 0) and E=0).

Step 3: The forward propagation of the signal

An example from the training set is applied to the inputs. Outcomes of neurons from hidden layer are computed:

$$y_j(p) = f\left(\sum_{i=1}^{n} x_i(p) . w_{ij} - \theta_j\right) \quad (5)$$

Where n is hidden layer number of inputs for neuron j and f is sigmoid activation.

Real network outputs are measured:

$$y_k(p) = f\left(\sum_{i=1}^{n} x_{jk}(p) . w_{jk} - \theta_k\right) \quad (6)$$

Where m is the input number from the output layer of neuron k.

Error updated by epoch:

$$E = E + \frac{(e_k(p))^2}{2} \quad (7)$$

Step 4: Backward error propagation and weight correction. Neuron error gradients are computed in the output layer:

$$\delta_k(p) = f'e_k(p) \quad (8)$$

where f' is the activation derivative function. A mistake occurs as

$$e_k(p) = y_{d,k}(p) - y_k(p) \quad (9)$$

If we use the single-pole sigmoid (equation 1, its derived is:

$$f'(x) = \frac{e^{-x}}{(1+e^{-x})^2} = f(x).(1 - f(x)) \quad (10)$$

Furthermore, the single-pole sigmoid is the function used. Then it becomes equation (10):

$$\delta_k(p) = y_k(p).(1 - y_k(p)).e_k(p) \quad (11)$$

The weight gradients from the secret layer to the output layer are updated:

$$\Delta w_{jk}(p) = \Delta w_{jk}(p) + y_j(p).\delta_k(p) \quad (12)$$

The gradients of the neuron errors are determined in the secret layer:

$$\delta_j(p) = y_j(p).\left(1 - y_j(p)\right).\sum_{k=1}^{l} \delta_k(p) w_{jk}(p) \quad (13)$$

where l is the number of network outputs.
The weight gradients of the input layer are modified with the hidden stage.

$$\Delta w_{ij}(p) = \Delta w_{ij}(p) + x_i(p).\delta_j(p) \quad (14)$$

Step 5: A new version. A new one. If the current training cycle still has test vectors, pass stage 3. If not the weights of all the links are changed according to the weight gradients:

$$w_{ij} = w_{ij} + \eta . \Delta w_{ij} \quad (15)$$

Where μ is the rate of analysis. When a stage is over, we check if it meets the termination condition ($E < E_{max}$ or a maximum number of periods of training have been achieved). Otherwise, we will move on to phase 2. If so, the MLP algorithm is over.

3.5. Simulations

On a PC with an i5 processor with an 8 GB RAM processing speed of 3.50 GHz, simulations can be brought. Sensor nodes are positioned on the grid intersection points and are first learned to locate as seen in the Figure. 5.
Figure 5: Illustrate the deployment of Sensor nodes and Mobile anchor node

The trained network with numerous training algorithms has placed localised sensor nodes on arbitrary points on the grid. The research is conducted. The node position is determined with the positioning information of the moving anchor node. The network is taught and checked using a handheld anchor node with the initial position to determine network efficacy (0.5, 0.5).

The sensor nodes are initially installed in a fixed location on the grid during testing. The handheld anchor node that has a set network gap has been deployed. Each mobile anchor node interval 't' sends its present position (X and Y coordinates) to sensor nodes that fall within its radio frequency spectrum. Each sensor node shall compute its current position using the proposed position algorithm by obtaining a minimum of three separate location information from mobile anchor node positions.

To determine the position of sensor nodes in the same grid, a further test of the qualified network is carried out. The nodes of the sensor were spread around the test grid uniformly. The testing is seen via the coordinate grid.

4. Results and discussion

For this study 5 different training algorithms BR, LM, RP, GD and SCG have been used for formation of the neural network, requiring supervised learning.
Figure 6: Illustration of Mobile anchor node with random deployment of sensor nodes

A neural network. Several testing functions with a different number of layers and nodes have been conducted. There are optimal results from network of 3 layers with a 9-12-2 structure. There were 9 neurons in input layer, hidden layer with 12 neurons and two in the output layers. Hyperbolic sigmoid tangent activation function for hidden layers, whereas pure line function in output layer has been used. This structure was utilized for the evaluation of the performance of the following anchor node configurations with different numbers of anchors.

An experiment was performed. 5 different BR, LM, RP, GD and SCG training algorithms for the formation of a neural

network that require supervised learning have been used to this study. A network of neural components. A number of test functions have been performed with different layers and nodes. A network of three layers with a structure 9-12-2 produces optimal results.

$$e = \sum_{i=1}^{n} \frac{1}{n} \sqrt{(x_i - x_{oi})^2 + (y_i - y_{oi})^2}$$

where n is the overall number of test sets and exact position (x_{oi}, y_{oi}) and estimated position of sensor node in i^{th} test dataset is (x_i, y_i).

The above mobile anchor node configurations were used for assessments of the performance of various anchor numbers. The average location error during this phase is illustrated in Figure 7. Figure 8 shows the time required for the network to train using different training algorithms.
Figure 7: Illustration of localization error of different training algorithm with mobile anchor.

In Figure 7, Depicts different training algorithms have compares with localization error. The BR training algorithm is having less average error as compared to other training algorithms.
Figure 8: Illustrate time taken to train neural network for different training algorithms with mobile anchor

In Figure 8. Shows the training time taken by the ANNN model for different training algorithms. LM, RP and SCG are taking less training time and BR and GC training algorithms are taking more training time.

Cost of the network will be reduced with using one mobile anchor agent. Estimated Mean Localization Error (Meters) for different number of sensor nodes using BR training algorithm is shown in Figure 9 for the communication range of mobile anchor node that is R=40 meters, 60 meters and 80 meters.
Figure 9: Estimation error when varying communication range.

In Figure 10. Depicts convergence accuracy of mobile anchor node with different time stamps for broadcasting their location information to static sensor nodes using BR training algorithm.
Figure 10: Convergence accuracy for various regular intervals.

5. Conclusions

The use of ANN has been suggested for an effective 2D localization algorithm for WSN. The RSSI signal values from the mobile anchor node are the entry to the proposed process. Since every mobile anchor node is fitted with wireless RF modules, no

external hardware is necessary. The approach proposed is therefore , energy-efficient and uses just a two-way message to obtain the location inputs. As in the proposed system, only one mobile anchor node is used, even the cost is minimized. It is however, advisable to use the RSSI value of the mobile-based anchor Node beacon request signals, which may further reduce the location error. The following is recommended.

In order to obtain the finest neural network for localization, the BR training algorithm is evaluated to give the best results. Hence, the training time for this algorithm is quite high compared to other methods such as LM, RP, and SCG. It is therefore recommended that the BR method is used when offline training is performed as in this case. The LM method is recommended for applications requiring online training.

Conflict of Interest

The authors declare no conflict of interest related to this paper.

ARTICLE INFO	ABSTRACT
	The objective of this paper is to allocate transmission congestion cost to responsible generators using a novel method. Deregulation of the electrical power system leads to the compulsion of open access to the transmission system for all entities of the power system. There is a trend to utilize cheaper generators by all loads. This leads to a violation of the operational and physical constraints of transmission corridors connected to those generators. It is not possible to utilize cheaper generators all the time due to the operational and physical constraints of the transmission lines. Hence there is an increase in the cost of energy produced. This increase in energy cost is taken into account as total congestion cost. Allocation of total congestion costs among various entities is always a complex task. Here, generators liable for the increase in total congestion cost identified using Bialek's algorithm. Bialek's upstream algorithm was applied to allocate congestion costs to generators. Results are obtained on IEEE-14 bus and IEEE-30 bus standard test systems.

1. Introduction

The electric power industry was operated as a *"regulated monopoly"* up to the nineties decade. Then after the structure of the electric power industry took a major shift and all its operations were unbundled, i.e. de-regulated. Because of the restructuring of the power utilities, the power industry is becoming turbulently competitive, and going through technological and regulatory changes, which affect its planning, operation, control, and services to customers. It is important to spot the consequences and impacts of those changes on the planning, operation, control and cost of the power system. In a deregulated power system, the transmission system must be available to all users without any discrimination. Due to physical and operating constraints of transmission corridors, not all the load be served by the cheaper generators, leading to the increased generation cost. The system operator (SO) must identify the responsible entity for this increase in cost. Determination of congestion cost and distribution of this among all participants is a crucial issue with the operation of a deregulated power grid.

Market-based methods are methods that used either dispatch methods, generator rescheduling, load management or nodal pricing based methods. Pool and contract dispatch models with a priority of load curtailment applied using social welfare and contracts between generators and load [1, 2]. Optimal bus price-based simple methods were proposed [3] to calculate congestion cost supported the very fact that additional flow increases congestion. Various dispatch methodologies introduce [4] for open access of transmission line by representing a conceptual model of pool dispatch, bilateral dispatch and multilateral dispatch alongside the need for dispatch coordination between these models. Effectiveness of congestion clusters method for congestion management discussed for cost and loss minimization [5] with the definition of transmission congestion distribution factors (TCDFs) which used to evaluate the change in the flow of a rise in the injection of power at any bus. Two sets of sensitivity indices: Real Power transmission Congestion distribution Factors (PTCDFs) and Reactive Power transmission Congestion Distribution Factors (QTCDFs) used for congestion management [6] during which selection and participation of generators depend upon both their reactive sensitivity and bid price for up/downregulation. A simplified approach proposed [7] for

security-oriented power system operation in which the first contribution of each generator for a particular overloaded line is identified and then based on the relative electric distance (RED) concept the specified proportion of generation for the specified overload relieving obtained. A combined objective function [8] was obtained using the generation cost function and congestion management cost function incorporating additional penalty factors that were further solved by a bacterial foraging algorithm. A multi-objective congestion management framework with optimization of congestion management cost, voltage security and dynamic security called augmented ε-constraint technique discussed in which the first objective function is that the cost of congestion management while the second and third objective function is of voltage stability margin (VSM) and Corrected Transient Energy Margin (CTEM) [9]. Simple indices introduced [10] for effective and agreeable load curtailment in congested lines because of the sensitivity of load to a congested branch, economic incentives to reduce consumption and customer willingness to curtail load during congestion. These indices are achieved by mathematical formulation for maximizing social welfare, the overall index for possible load management and generator re-dispatch. Zonal congestion management approach discussed in[11,12], using real and reactive power sensitivity index as well as balancing energy up/down service settlement and other similar factors. Based on the calculation of the congestion cost index (CCI) total congestion cost index (TCCI) is minimized for a given number of buses [13]. CCI is obtained by difference of bidding rate and power during the pre-dispatch and re-dispatch era. Security constraint optimal power flow (SCOPF) with and without line flow constraints [14] used to determine total congestion cost which further distributed into line-wise congestion cost, whereas same SCOPF with inputs from energy management system (EMS) and state estimator applied iteratively [15] with contingency analysis used to estimate the actual cost of congestion. The participation of generators and loads within the use of the transmission network is decided employing a modified z-bus matrix [16]. The modified z-bus matrix is formed by modeling both generators and loads as constant admittances in the network considering them separately. A novel topological approach to MW-Mile proposed based on electricity tracing method [17]. The equation for topological generation distribution factor almost like that of generalized generation distribution factor defined, which further used for formation of supplement transmission charge of any generator in the network. Distributed energy sources (DERs) plays important role for alleviating transmission congestion cost. The usage based transmission cost division method is introduced in which transmission capacity is divided into four capacities to gauge the contribution of DERs to transmission cost [18]. A modified inage domain method for power flow tracing [19] used to allocate transmission cost and advance congestion management. Power tracking coefficient developed [20]with the help of kirchof's law for the active power flow tracking and revenue collected by individual generator determined. A method [21] suggested allocating the transmission fixed charge based on the modification of the impedance matrix in which real power flow through the line expressed in terms of load current also as electrical distance and voltage injection at the bus. Iteratively one by one impact of every generator selected on the network using the z-bus of the network [22] and transmission congestion cost determined based on the current decomposition method. A DC power flow based problem [23] using generation

shift factor is defined as a lossless system to work out contribution-based congestion cost allocation methods in a bilateral market.

A fair allocation of transmission congestion cost to the generation companies is required in poolco market where generator dispatch pattern changes due to congestion. Here in this work transmission line congestion is identified by observing the value of the dual variable associated with constraints [14]. Total congestion cost (TCC) evaluated by generator re-dispatch method with and without constraints. The dual variable associated with the congested line is utilized to find the line allocation factor. Line-wise congestion cost (LWCC) of each congested line is evaluated with help of the line allocation factor. For power flow tracing, results obtained from common methods like graph method and node method are not accurate and it takes more computational time. To allocate congestion cost, the cost associated with congested lines should only be considered. A novel method discussed here using bialek's upstream algorithm [17,24] to allocate this TCC to all generators as well as the generator's contribution to supplying the load of the system.

2. Problem formulation

2.1. Total Congestion Cost (TCC) and Allocation to Line

A simple method to evaluate TCC is the generator re-dispatch method. In this method, optimal power flow (OPF) is applied with and without line flow constraints. The difference in evaluated costs of both cases is identified as TCC. This TCC is allocated to the lines under congestion. Generalized optimal power flow problem with constraints is formulated as:

$$C(P_{Gi}) = \sum_{i \in N_{gi}}(a_i P_{Gi}^2 + b_i P_{Gi} + C_i) \qquad (1)$$

where,

N_{Gi} = Number of generators in the system

The above optimized problem is with several constraints as follows:

$$P_{Gi} - P_{Di} - P_{loss} = 0 \qquad (2)$$

$$P_{Gimin} \leq P_{Gi} \leq P_{Gimax} \qquad (3)$$

$$Q_{Gimin} \leq Q_{Gi} \leq Q_{Gimax} \qquad (4)$$

$$V_{imin} \leq V_i \leq V_{imax} \qquad (5)$$

$$P_{ij} \leq P_{ijmax} \qquad (6)$$

where,

P_{Gi} = Active power generation in *MW* at bus *i*.

P_{Di} = Load in *MW* at bus *i*.

P_{Gimin} = Minimum limit of active power generation at bus *i*.

P_{Gimax} = Maximum limit of active power generation at bus *i*.

Q_{Gimin} = Minimum limit of reactive power generation at bus *i*.

Q_{Gimax} = Maximum limit of reactive power generation at bus *i*

V_{Gi} = Voltage at bus *i*

V_{Gimax} = Maximum voltage limit at bus *i*

V_{Gimin} = Minimum voltage limit at bus *i*

P_{ij} = Power flow in MW between bus i and j

P_{ijmax} = Power flow limit in MW between bus i and j

In the above constraints (2) is power balance constraint whereas (3) to (6) are inequality constraints.

Following are steps to evaluated TCC and its allocation to the congested line:

1. Run optimal line flow without and line flow constraints and obtain total generation cost (*TGC*) as per (1).

2. With line flow constraints, repeat optimal power flow for obtaining a revised total generation cost (*TGC'*).

3. Total congestion cost (*TCC*) is evaluated as:

$$TCC = TGC' - TGC \qquad (7)$$

4. The dual variable associated with the constraint of (6) is utilized to obtain the line allocation factor L_{ij} as [14],

$$L_{ij} = \frac{\mu_{ij}(S_{ijmax} - S_{ij})}{\sum \mu_{ij}(S_{ijmax} - S_{ij})} \qquad (8)$$

where,

μ_{ij} = Dual variable associated with constrained line

S_{ij} = Actual line flow between bus i and j

S_{ijmax} = Maximum line flow limit between bus i and j

5. Congested cost allocated to the constrained line is evaluated as:

$$LWCC_{ij} = TCC * L_{ij} \qquad (9)$$

Equation (9) determines the line-wise congestion cost allocated to the constrained line from that of TCC.

2.2. Generator share to line congestion cost

In poolco model of the deregulated power system, it requires to identify generators (suppliers) liable for line congestion as well as the allocation of congestion cost to those generators is equally important. For fair allocation of congestion cost to the generators, generator share to line flow is to be determined. Here bialek's upstream algorithm [17,24] is employed to spot generators participation for the corresponding line flows from congested lines. The subsequent steps demonstrate to determine the sharing of line congestion cost to generators:

1. After carrying out OPF, convert net real power into lossless line flows $|P_{i-j}|$.

2. Next to determine node injection power as,

$$P_i = \sum_j |P_{i-j}| + P_{Gi} \qquad (10)$$
For $i = 1, 2 \dots n$ n = number of buses

where,

n = number of buses
j = node directly supplying to the node I

3. The ratio of line flow to the node injection power, Generation cost coefficient (GCC), determined as,

$$C_{ji} = \frac{|P_{j-i}|}{P_i} \qquad (11)$$

4. An up-stream distribution matrix A_u evaluated whose elements are determined as,

$$[A_u]_{ji} = \begin{cases} 1 & for\ i = j \\ -C_{ji} & for\ j\ supplyinng\ to\ node\ i \\ 0 & other\ wies \end{cases} \qquad (12)$$

5. Take the inverse of the upstream distribution matrix evaluated with help of (12).

6. Determine the topological distribution factor by,

$$D_{i-l,k}^{g\ fact} = \frac{|P_{i-l}|[A_u^{-1}]_{ik}}{P_i} \qquad (13)$$

7. Generator share to line flow is determined as,

$$|P_{i-l}| = \sum_{k=1}^{n} (D_{i-l,k}^{g\ fact}) P_{GK} \qquad (14)$$

8. Line congestion cost allocated to generators as,

$$P_{gcc} = \frac{|P_{i-l}|}{P_{ij}} LWCC_{ij} \qquad (15)$$

Distribution of line congestion cost to the generators on the proportional sharing base is obtained by (15).

2.3. Generator participation to supply each load

With help of the same upstream algorithm suggested by bialek, generator participation to supply the load can be determined. Following are steps to be followed for evaluating the same.

1. Power outflow from each node is determined as,

$$P_i^{ndout} = \sum_j P_{i-j} \qquad (16)$$
For every node j connected to node i.

2. The ratio of net power flow to the node injection power P_i is given as,

$$P_i^{ndration} = \frac{P_i - P_i^{ndout}}{P_i} \qquad (17)$$

3. Generator at node I participation to each load at bus j is calculated as,

$$P_{i-j}^{GL} = [A_u]_{j,i}^{-1} P_j^{ndratio} P_{Gi} \qquad (18)$$

where,

P_{Gi} = Power generation at bus i
$[A_u]_{j,i}^{-1}$ = Upstream distribution matrix evaluated in section 2.2

3. Results and Analysis

The problem formulated during the previous section was solved with help of MATLAB programming. Initially, test results are obtained on small test bus systems like 6-bus and 9-bus test systems. Then after standard IEEE-14 and IEEE-30 test bus systems are used for obtaining results. In this section, the results of higher test bus systems are discussed. These test results are obtained for TCC, line congestion cost, and share of generators to TCC as well as line congestion cost.

3.1. IEEE-14 bus test results

IEEE-14 bus test system is with 20 lines and 5 generators. Figure 1 shows the line diagram of IEEE-14 bus system. OPF is

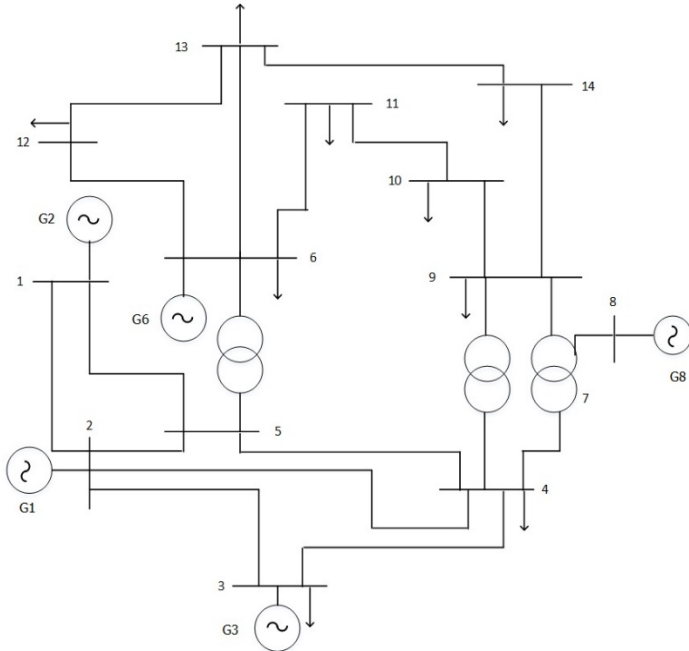
carried out without line flow constraints then after imposing line flow on line number 1 (connecting bus 1 and 2) and 4 (connecting bus 2 and 4). Generators' cost function is of 3rd order polynomial function. Bus number 1 is considered as slack bus for OPF. After that TCC, line congestion cost and generator share to the TCC as well as generator participation to each load are obtained as described in the previous section.


Figure 1: IEEE-14 bus test system

Table 1 shows the results obtained for the line congestion cost. Power flow without line flow constraints is 129.667 MW through line 1. With an imposing line flow limit of 110 MW, it is reduced to 109.94 MW. Similarly, for line number 4, after imposing a line flow limit of 40 MW, line flow is reduced to 38.392 MW from that of 55.3137 MW.

Table 1: IEEE-14 bus results for line congestion cost

Line no	Fbus	Tbus	Pflow w/o constraints in MW	Pflow with constraints in MW	Max line flow in MW	Line constraints allocation factor	Line congestion cost in $/hr	Total congestion cost in $/hr
1	1	2	129.667	109.94	110	0.493	28.53	57.88
4	2	4	55.3137	38.392	40	0.507	29.34	

Total congestion cost is 57.88 $/hr, further allocated to the congested line from line constraints allocation factor is 28.53 $/hr and 29.35 $/hr. Equation (14) is for identifying generator share to line flows. For IEEE-14 bus system, the generator share to the line flows is shown in Figure 2.

As shown in Figure 2, generator 1 at bus 1 is responsible for the major contribution to the line flow because the generation of the generator is remarkably high compared to all other generators. Subsequent contributor to the line flow is generator 2 connected at bus 2, whereas other generators are contributing very less to the line flow. Table 2 shows the allocation of congestion cost to the generators from that of line congestion cost.
Figure 2: IEEE-14 bus generator share to line flows

Table 2: IEEE-14 bus line congestion cost allocated to generators

From bus	To bus	G1	G2	G3	G6	G8	Total	Line Cong Cost
1	2	28.532	0	0	0	0	28.532	28.532
2	4	22.175	7.173	0	0	0	29.348	29.348
Total Cost		50.707	7.173	0	0	0	57.880	57.880

All congestion costs are in $/hr in Table 2. As described in Table 2, generator 1 is sharing most of the line congestion cost as it is a major supplier to the load. It is observed that the summation of congestion cost shared by generators is equal to the total of the line congestion cost as well as that of TCC. Hence results of TCC and line congestion costs allocated to generators are self validated.

Generation participation to the system load is identified with help of bialek's upstream algorithm described in section 2.3. . The total load of the IEEE-14 bus system is 259 MW and the total generation of the system is 264.13 MW. Following Figure 3 is depicting how each load of the system is shared by individual generators.
Figure 3: IEEE-14 bus load share by individual generators

Pd2, Pd3… Pd14 are the power demands (loads) at corresponding buses of the system. It is observed that generator 1 is sharing most load of the system followed by generator 2. This is in line with the sharing of line flow by all generators. Generation of generator 1 is 162.15 MW and so it serves a total load of 162.15 MW of the system with maximum sharing of 50 MW load connected at bus 2. Generators connected at bus numbers 1, 2 and

3 are supplying a load of 227.03 MW load, almost 85% of the system load.

3.2. IEEE-30 bus test results

Another standard test bus system, IEEE-30 bus system is used to get similar results as obtained on IEEE-14 bus system. As shown in Figure 4, IEEE-30 bus system having 41 lines along with six generators. The entire load connected to the system is 283.4 MW.
Figure 4: IEEE-30 bus system

TCC and line congestion costs are evaluated for the IEEE-30 bus system and the result obtained are tabulated in Table 3. Here, OPF is carried out without line flow constraints and then imposing line flow constraints on line one (connecting bus 1 and 2) and seven (connecting bus 4 and 6) to identify TCC. Allocation of TCC to line congestion cost is shown in Table 3.

Table 3: IEEE-30 bus results for line congestion cost

Line no	Fbus	Tbus	Pflow w/o constraints in MW	Pflow with constraints in MW	Max line flow in MW	Line constraints allocation factor	Line congestion cost in $/hr	Total congestion cost in $/hr
1	1	2	139.115	99.997	100	0.0511	8.16	159.48
7	4	6	55.314	38.393	40	0.9489	151.32	

Here it is revealed that after imposing line flow limits, power flow reduced to 99.99 MW and 38.39 MW through line numbers one and seven. TCC evaluated is 159.48 $/hr due to congestion. With help of line allocation factors of every congested line, this TCC was further allocated as 8.16 $/hr for line number 1 and 151.32 $/hr for line number 7.

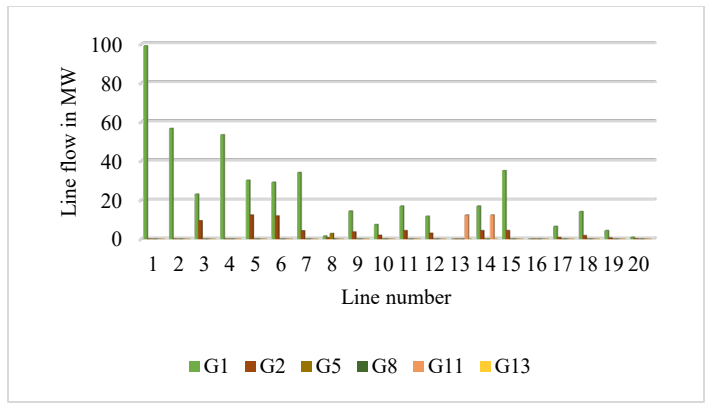
Figure 5 shows the line flow share of generators up to line number 20. Again in this case also generator 1 is sharing the remarkable load of the system, hence the line flow share of generator 1 is high compared to all other generators. For the remainder of the lines, it is noticed that only except that of generator 2, a generator connected at bus 4 (generator 4) is sharing somewhat of line flow particularly of line number 36 and 40.


Figure 5: IEEE-30 bus generator share to line flows (up to line 20)

Table 4: IEEE-30 bus line congestion cost allocated to generators

From bus	To bus	G1	G2	G3	G4	G8	Total	Line Cong Cost
1	2	8.16	0	0	0	0	8.16	8.16
4	6	134.84	16.48	0	0	0	151.32	151.32
Total Cost		143.0	16.48	0	0	0	159.48	159.48

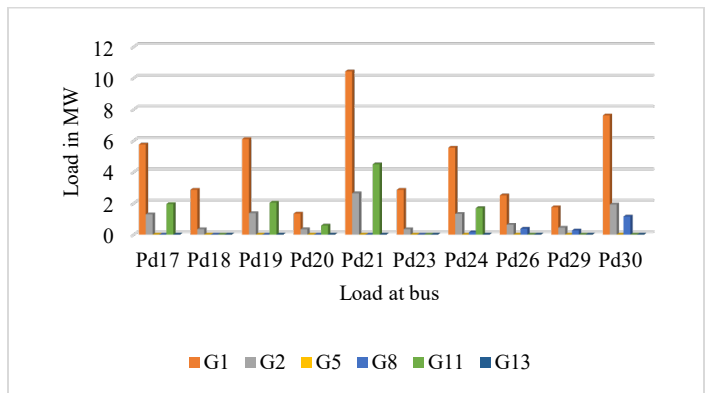
Table 4 states line flow congestion cost allocation to individual generators. Although IEEE-30 bus system contains a total of six generators, Table 4 shows five generators as only two generators (at bus numbers 1 and 2) are sharing line congestion cost. Here also the summation of individual sharing of line congestion cost by generators is equal to TTC and summation of line congestion cost.
Figure 6: IEEE-30 bus load share by individual generators (first 11 loads)


Figure 7: IEEE-30 bus load share by individual generators (Rest 10 loads)

Figure 6 and Figure 7, show the load participating by all generators of IEEE-30 bus system. There are a total of 21 loads connected to various buses as shown in Figure 5 and Figure 6. Out of a total system load of 283.4 MW, generator 1 is sharing 155.2 MW of load, and generator 3 is connected at bus 5 sharing a load of 57.13 MW.

4. Conclusion

In this paper, a method is proposed to allocate TCC to congested lines with help of a dual variable associated with these congested lines. Further, a novel method discussed to allocate these line congestion costs to generators with help of bialek's upstream algorithm of tracing the flow of electricity. Also, with help of the same algorithm formulation is done for the participation of system generators to each load connected to the system. Results are obtained for IEEE-14 bus and IEEE-30 bus test systems. Results obtained are self-validictory, and reveal that TCC is equal to the summation of individual line congestion cost as well as equal to the summation of individual congestion cost shared by all accountable generators.

	In this paper, we investigate and analyze parameters degradation in a typical photovoltaic (PV) cell, which lead to power loss under dark as well as light condition using measured current-voltage (I-V) data. A nonlinear least squares method to extract the parameters such as the reverse saturation currents, the ideality factors, the series and shunt resistances of the cell from the dark current-voltage (I-V) curves is used. In order to analysis the sensitivity of the dark current-voltage (I-V) measurement to each of the six extracted parameters as a function of the voltage as well as the temperature and the density current, we simulate the operation of a silicon solar cell (KXB0022-12X1F). The analysis of the dark current-voltage (I-V) curves permit us to detect variation as small as 15% in the series resistance. We also extends the use of dark as well as light current-voltage (I-V) measurements to modules configurations of cells and uses a nonlinear least squares method to evaluate the cell efficiency parameters in the modules. Results obtained show a degradation of the values of the maximum power (Pmax) as compared to initial values by about 12, 3%, 12, 06% and 10, 21 % respectively in Total-Cross-Tied (TCT), Bridge-Link (BL) and Honey-Comb (HC) configurations.

1. Introduction

The analysis of the current-voltage curves of solar cells parameters is an important tool for quality control and evaluation of their efficiency. Though photovoltaic (PV) cells are a very important source of electrical energy, some studies [1-5] show that in a number of ways, the photovoltaic (PV) cells/modules can fail. In the circumstances; it is very important to understand the origin and behavior of these faults, before trying to improve them. However, the analysis approach required for determining the source of power loss within a solar cell depend on the fault itself, and may necessitate an analysis process which adds to system operation costs and may not always be feasible [6-8]. Authors in [9] have classified the degradation of PV cells into groups such as early degradation and long-term degradation. Early degradation are defined as encapsulant discoloration and delamination; cracks in the cell [7, 8], burnt cell caused by hot spot; soiling and shading cell, defect in anti-reflective [9]. The early degradation are also inspected in long-term field-aged PV cells/modules. Long-term degradation can be defined as corrosion of solar joint or crack in

solder joint of the PV cells connection [9]. Understanding the cause of PV cell fault and how they affect the efficiency of the PV cells is essential to improve their dependability.

In this paper, we will focus on investigating and analyzing some parameters degradation that lead to power loss in PV cells under dark/light condition using measured I-V data. The 2-diodes equivalent circuit is used to describe the electronic properties of the solar cell. A set of analyzed parameters are determined from the dark/light I-V characteristics that can identify some fault of the PV modules aggregation of electrical components and solar cells, as well as shunting and recombination losses occurring due to cell cracks, shading cell [8, 10]. An experimental setup for measuring both dark and light I-V characteristics of solar cells is performed for this purpose. It is a complementary study of a previous work in which parameters of a typical solar cell named KX0B22-12X1F have been extracted under dark condition. This work also extends the use of dark as well as light I-V measurements to modules configurations of cells and uses a nonlinear least squares method [11] to evaluate the cell efficiency parameters in the modules. Results obtained are used to analyze

*Corresponding Author D. Bonkoungou, P.O. Box 243 Ouaga 10, contact: 00226 78 61 52 85 & Email: dominique.bonkoung@gmail.com

the shade impact in the PV cell efficiency and the effect of the cell imperfection on PV module efficiency.

2. Experiment

We have made measurement on 270 mm² silicon solar cell (KXB0022-12X1F). The I-V characteristics of the cell have been measured with a system according to international standard consisting of a Keithley 2400 multimeters; a sol-UV simulator (Oriel 81192/ 1000 W); an arc lamp source (Oriel -68920). A desktop computer is used to processes the measured data using LABVIEW. To measure the I-V curve under dark we used the procedure described into [11]. For light I-V curve measurements, the cell is illuminated by a halogen (ORIEL) .This last is fed by a halogen power supply. We performed two experiments for the measurements with homogeneous as well as heterogeneous impacts on light I-V curves. Pictures of the experiment approach are displayed in figure 1. Under dark condition, the data are measured in the forward and reverse direction using a power supply. For the power supply, the voltage is measured from – 5 Volts to 1 Volt with a resolution of 0.01 Volt. The maximum current was 1 A, which corresponds to 42.4 mA/cm².

Figure 1: Experimental setup

3. Parameters extraction and fault analysis

3.1. I-V characteristics under dark condition

The 2-diodes model is used to describe the dark I-V curves of the PV cell [11].

$$I = \frac{V - R_S I}{R_p} + I_{02}\left[\exp\left(\frac{V - R_S I}{n_2 U_{th}}\right) - 1\right] + I_{01}\left[\exp\left(\frac{V - R_S I}{n_1 U_{th}}\right) - 1\right] \quad (1)$$

where $U_{th} = \frac{KT}{q}$ is the thermal voltage, q is the electron charge, K is the Boltzmann's constant, T is the temperature; R_s is the series resistance; $I_{0i}(i=1,2)$ is the dark saturation current of the diode; R_p is the shunt resistance; $n_i(i=1,2)$ is the ideality factor. In our previous work [11], the six parameters like $[I_{0i}(i=1,2); n_i(i=1,2); R_s; R_p]$ are obtained by fitting (1) to a set of measured data using a nonlinear squares method of dark I-V measurement data. The standard deviation (SD) between computed and measured data is less than 3% [11].

3.2. I-V characteristics under illuminated condition

To analyze the results obtained for the various parameters $[I_{0i}(i=1,2); n_i(i=1,2); R_s; R_p]$ under dark condition [11], we have made additional measurements in light condition. Under illuminated condition, the PV cell generate a photocurrent I_{light} and this last has to be added to (1) expressed by (2):

$$I + I_{light} = \frac{V - R_S I}{R_p} + I_{02}\left[\exp\left(\frac{V - R_S I}{n_2 U_{th}}\right) - 1\right] + I_{01}\left[\exp\left(\frac{V - R_S I}{n_1 U_{th}}\right) - 1\right] \quad (2)$$

All the parameters are defined previously. To study the efficiency of the PV cell in light condition, it is important to analyze the following parameters such as: the open circuit voltage (V_{OC}), the short circuit photo-generated current (I_{SC}) and the fill factor (FF) [3]. For the determination of the cell parameters under illumination, we proceeded as follows. We have determined the I_{SC} value by assuming that the short circuit condition is verified i.e. for $V = 0$ and $I = I_{SC}$. We get the following equation:

$$I_{SC} + I_{light} = \frac{0 - R_S I_{SC}}{R_p} + I_{02}\left[\exp\left(\frac{0 - R_S I_{SC}}{n_2 U_{th}}\right) - 1\right] + I_{01}\left[\exp\left(\frac{0 - R_S I_{SC}}{n_1 U_{th}}\right) - 1\right] \quad (3)$$

Likewise, for $V = V_{OC}$ and $I = 0$ at open circuit condition, we obtain:

$$I_{light} = \frac{V_{OC}}{R_p} + I_{02}\left[\exp\left(\frac{V_{OC}}{n_2 U_{th}}\right) - 1\right] + I_{01}\left[\exp\left(\frac{V_{OC}}{n_1 U_{th}}\right) - 1\right] \quad (4)$$

Using (3) and (4), we yield a relationship between V_{OC} and I_{SC} given by equation 5:

$$V_{OC} + R_S I_{SC} = R_P[I_{01}(\exp(-\beta_1 R_S I_{SC}) - \exp(\beta_1 V_{OC})) + I_{02}(\exp(-\beta_2 R_S I_{SC}) - \exp(\beta_2 V_{OC}))] \quad (5)$$

where $\beta_i = \frac{1}{n_i U_{th}}$ $(i=1,2)$. To fitting the illuminated I-V characteristics, we inserted the parameters values obtained in dark condition into (2) and determined V_{OC} as well as I_{SC}. For I_{light}, we have exploited the value of I given by (1) whose expansion for low voltages allows us to establish the following relation:

$$I_{Light} = I_{SC}\left(1 + \frac{R_S}{R_P}\right) \quad (6)$$

The fill factor (FF) can be calculated by means of the definition:

$$FF = (V_{mp} I_{mp})/(V_{OC} I_{SC}) \quad (7)$$

where $(V_{mp}.I_{mp})$ is the upper value of the voltage-current (V.I) product.

4. Results and Discussion

4.1. PV cell parameters sensitivity analysis both in dark and light condition

In order to analysis the sensitiveness of the dark current-voltage measurement to each of the six parameters as a function

R_P, R_S are relatively neglected. We analyze the different power losses by progressively degrading the parameters of the cell, one at a time. We varied the parameters such as I_{01}, I_{02}, R_S and n_2 by increasing their value. During this time, we decreased the value of R_P and n_1. It can be seen in Figure.2 that increased I_{02} impact the low value voltage as well as the medium voltage region of the dark I-V curve. This phenomenon can be explained by the increase of the number of fault in the cell junction. Unlike I_{02}, the increase in I_{01} affects both the medium and the high voltage ranges of the dark I-V curve. The sensitivity to R_P and n_2 are important at low and medium voltage ranges. We can conclude that the increase in I_{01}, I_{02}, R_P and n_2 affect and present distinct curvatures in the low and medium voltage ranges of the curve.

Figure 3: Sensitivity analysis of each extracted parameter $\left[I_{0i} (i=1,2); n_i (i=1,2); R_s; R_p \right]$ as a function of density current

The increase of the value of R_S drastically affect the high current and voltage regions shown in Figure 4. This shows that the analysis of the dark I-V characteristics of a solar cell is a very important tool which permit us to detect variations as small as 15% in R_S. Besides, the disturbance of R_S under dark condition made it possible to identify the faults which hinder the proper functioning of the PV cell, when we realize that the R_S in a particular PV cell as well as module would have to double before a 5% drop in power resulted [12]. The analysis of disturbances in the other parameters such as $I_{0i} (i=1,2); n_i (i=1,2); R_p$ can allow us to identify certain operating faults. And it could make easier to modify the manufacturing process to improve cell performance.

Figure 2: Dark I-V curves of a particular solar cell (KX0B22-12X1F) affected by variant faults

Then, an exhaustive analysis of these different variations (see Figure 1) can make it possible to detect operating faults. Using the measured dark I-V characteristics, we analyzed the sensitivity of each extracted parameter as a function of the current, shown in Figure 3. The parameter β is defined as being the sensitivity ratio described as follow: $\beta = \dfrac{\delta V}{\delta \alpha_i} * \alpha_i$ where $\alpha_i (i=1,2,3,4,5,6)$ represents the different parameters i.e. $\alpha_1 = I_{01}$, $\alpha_2 = I_{02}$, $\alpha_3 = R_P$, $\alpha_4 = R_S$, $\alpha_5 = n_1$ and $\alpha_6 = n_2$. These sensitivity coefficients show the dependencies of the solar cell parameters on the current level. As can be observed that for currents smaller than 400 mA/cm² , the sensitivity coefficient to R_P rises to 0, 3% as well as 0, 45% for n_2. And at high current ranges, the sensitivity to R_S increases from 0% to 0, 15% in the studied interval.

Figure 4: Effects of series resistance on the semilog plot of the dark I-V curves

Figure 5 presents the fitted and measured I-V characteristics of the PV cell in light condition. As can be noted that the fitted I-V curve agreed very well to the measured I-V characteristic. From this figure, one has determined the values of I_{SC} and V_{OC} by extrapolation to $V = 0$ axis respectively to $I = 0$ and FF by using equation 7.

The different parameters V_{OC}, I_{SC} and FF are directly obtained from the light I-V curve. The values of these parameters are given in Table1. In this table, we compares the fitted and

measured data at room temperature. We can remark that the results obtained reveal a good approximation with the two I_{sc}-V_{oc} characteristics.
Figure 5. Fitted and measured light I-V curves at 300K.

Table 1: Measured and fitted parameters of the studied PV cell under illumination condition

Parameters	I_{SC} (mA/cm²)	V_{OC} (mV)	FF (%)
Measured data	-42,39	629,87	72, 21
Fitted data	-42,39	628,76	71,32
Deviation (%)	0	-0,27	-1,2

The plots in Figure 6 present the effects of temperature on the light I-V characteristics of a particular silicon solar cell. The plot clearly demonstrates that the open circuit voltage (V_{OC}) decreases with increasing temperature; whereas the short circuit current (I_{SC}) remains unchanged throughout the temperature range studied i.e. $I_{SC} \cong 42,40$ mA/cm². This shows that V_{OC} considerably depends on the temperature.
Figure 6: Density current I_{SC} versus voltage V_{OC} for variant temperatures

In order to analyze the effect of partial or total shading on the studied PV cell, we performed two experiments for the measurements with homogeneous as well as heterogeneous impacts on light I-V curves. Firstly, we measured the light I-V curves of the PV cell with uniform irradiances at Standard Test Condition (STC: 1000 W/², 25° C; AM.1.5) shown in Figure 7; these data are used as a baseline for the future analysis.
Figure 7: measured I-V characteristic of the studied PV cell under illumination in direct (a) and reverse (b) bias at STC

Secondly, we covered 25% (respectively 50% and 75%) of the area of the PV cell with a light-tight lid. Afterwards, the PV cell was illuminated over about 25% (respectively 50% and 75%) of its area. Results can be observed in Figure 8. It can be noted that the increase in the rate of shading of the cell produces a higher reduction of short circuit current I_{SC}, which causes a reduction in maximum power. It clearly demonstrate that the cell generated current is a function of the rate of light transmittance.
Figure 8: effect of partial shading of the studied PV cell on light I-V characteristics

4.2. Analysis of three (3) types cell interconnections under partial shade conditions

This section offers an extensive study of different reconfigurations of PV cells operating under partial shade conditions. For this purpose, we have studied the shading rate of 3 types of configurations such as Total-Cross-Tied (TCT),

Bridge-Link (BL) and Honey-Comb (HC) of PV cells shown in Figure 9.

a)   TCT

b)   BL

c)   HC
Figure 9: Types of 36 PV cells interconnection in a typical PV module

The results of shading rate of these configurations have been analyzed by shading completely selected cells in the PV module. Two experiments are made: firstly, one of the 6 X 6 PV cells is 100% shade for each type of configuration; secondly, nine (9) cells are 100% shaded and twenty-seven (27) working properly. I-V and P-V characteristics of these conditions are shown in Figures 10 and 11. First thing that can be observed is that there is a degradation of the power produced depending of the type of configuration. For the first experiment, shading one cell involve an efficiency decrease; for the second case, shading nine (9) cells involve efficiency to decrease further. We can note that in Figure 10, the values of the maximum power (Pmax) decreased as compared to initial values by about 12, 3%, 12, 06% and 10, 21 % respectively in TCT, HC and BL interconnections. Figure 11 proves that the decrease of Pmax can be imputed to the decrease of the short circuit current I_{SC}. The reduction in I_{SC} is explained by the rate of shading cells which limit the light transmittance. The influence of the number of shaded cell is presented in bar

chart form in Figure 12. The TCT and BL configurations exhibit themself as the most
Figure 10: effect of shading one cell in a typical PV module (36cells) for three various configurations: (a) I-V curve and (b) P-V curve
Figure 11: effect of shading nine cells in a typical PV module (36cells) for three various configurations: (a) I-V curve and (b) P-V curve
Figure 12: effect of the number of shaded cells on power losses

5. Conclusion

In this paper, an analysis parameters degradation in a typical PV cell, which lead to power loss under dark as well as light condition using measured I-V data was made. In order to analysis the sensitivity of the dark I-V measurement to each of the six extracted parameters as a function of the voltage as well as the temperature and the density current, we simulated the operation of a silicon solar cell (KXB0022-12X1F). The analysis of the dark I-V curves permit us to detect variation as small as 15% in the series resistance. We have also extended the use of dark as well as light I-V measurements to modules configurations of cells and uses a nonlinear least squares method to evaluate the cell efficiency parameters in the modules. Results obtained have shown a degradation of the values of the maximum power (Pmax) as compared to initial values by about 12, 3%, 12, 06% and 10, 21 % respectively in Total-Cross-Tied (TCT), Bridge-Link (BL) and Honey-Comb (HC) configurations. The decrease of Pmax could be imputed to the decrease of the short circuit current Isc. The reduction in Isc is explained by the rate of shading cells which limit the light transmittance.

Conflict of Interest

The authors declare no conflict of interest.

ARTICLE INFO	ABSTRACT
	As a result of digitalization, services become highly dependent on information systems thus increasing the criticality of security management. However, with system complexity and the involvement of more human resources, it becomes more arduous to monitor and track tasks and responsibilities. This creates a lack of visibility hindering decision making. To support operational monitoring, we propose a method composed of i) a core of security concepts from International Standard Organization (ISO) standards ii) a graphical modeling language iii) a guiding process and iv) a tool that provides verification through formal Object Constraint Language (OCL) queries. Applying this method to the case of the Capital One data breach showcases incident prevention through task supervision. The resulting work product is a formal comprehensive map of assets, actors, tasks and responsibilities. The SysML formalism allows different actors to extract information from the map using OCL queries. This allows for regular task and responsibility verification thus closing any window of attack possible.

1. Introduction

With the advent of digitalization era, the widespread dependence on information systems (IS) rose as well. This new age was kick started by technological developments especially in IoT, Big Data and Cloud, paving the way for newer services and spreading IS use to more diverse fields (Industry-science research alliance). However, this dependence translated into an increase in criticality levels of assets and tasks. Fields such as health, energy, or e-Government, which were already dealing with critical information or physical assets, are facing greater challenges in security management. As a response, practices of security management had been thoroughly addressed by corporations, standardizing organizations and academia. The quest for security approaches and methods to apply systematically to specific situations fueled the creation of best practices, standards and maturity models. The popular ISO 27000 standard series stood out for the creation and management of Information Security Management Systems (ISMS) (ISO 27000). ISO provides baseline requirements in ISO 27001, best practices in ISO 27002, security risk management in ISO 27005 or even specialized recommendation for network security in ISO 27033. Additionally, a plethora of security maturity models were created between 2007

and 2018 to support continuous improvement of security in diverse fields. However, our systematic review [1] of the literature showed that even if many standards and approaches are available, implementation remains problematic. The lack of implementation feedback further makes the study of a real case such as the Capital One Financial Corporation breach [2] more appealing to discuss. We postulate that this issue is due to two major aspects: system complexity and human behavior.

Dealing with increased complexity created between interacting systems, we find it necessary to adhere to a high level of formalism to ensure rigor and precision to tackle one of the four dimensions of human factors in information security: responsibility [3]. Taking root in the system engineering paradigm, our solution is based on the standard system formalization language SysML. We propose a scalable formal representation of security responsibilities in accordance with complex system composition that supports traceability and management. This formalism provided by extended SysML profiles, enables the use of formal verification languages such as OCL to support supervision. We also provide a guiding procedure based on continuous improvement for iterative applications as well as a supporting tool. This method would provide security managers with proper knowledge to track fundamental causes, such as asset vulnerabilities, unaccomplished tasks and accountabilities. In our previous studies, we described

our generic framework dedicated to information security management, extracted security concepts for SysML profiles [4] as well their application in security requirement management [5]. In this paper, we examine the responsibility issue and illustrate it using a case study.

We present and discuss the case of a data breach that occurred in Capital One in order to analyze the consequences of an informal specification of responsibilities and therefore prove the relevance of the problem we tackle. Next, we apply our method to the case to highlight its advantages. Through the Capital One case study we will address the following research questions:

- RQ1: How did Capital One track the chain of responsibility for their data breach?
- RQ2: How did Capital One security managers verify the implementation of security controls?
- RQ3: How to model tasks and responsibilities in a multi-scale information system?
- RQ4: How to formalize operational monitoring in a multi-scale information system?

In the following sections, we detail the context of our study highlighting the problem that our method aims to solve and how it fits within the existing body of work. Next, we present the components of our proposed method. Lastly, we present the Capital One Case followed by the application of our solution to highlight its applicability and its ability to prevent similar cases.

2. Related Works & Problematic

Information system complexity introduced heterogeneous components with a high connectivity level. In the complex system paradigm [6,7], systems can be decomposed into smaller autonomous collaborating sub-systems. This entails that security breaches and by consequence security management become pervasive. This means that measures taken to address security matters must be propagated to other collaborating systems. Similarly, this complexity makes responsibility harder to pinpoint and necessary tasks less apparent. On the other hand, the transition from theoretical and generic standard recommendations or requirements to practical application by human resources reveals a substantial gap. In 1996, including human behavior was considered as a novel conceptual stance within security management [8]. Since then, both academia and standardizing organizations have provided a plethora of references for security management that take human behavior as an important variable.

On one hand, standardizing organizations such as NIST and ISO provide thorough and well recognized references like the NIST Cybersecurity Framework, ISO 27001 and ISO 21827. These standards have either stood the test of time or have been periodically updated. We consider these standards as an important body of knowledge and procedures for our studies. We position ourselves as an extension of these standards providing the method to guide implementation that is out of their scope. On the other hand, academia has also produced countless information security maturity models such as SOASMM for SOA architecture [9], MMISS-SME [10] for small and medium enterprises, CCSMM for American governmental entities [11] or ISMM-PCI [12] for the payment card industry. Through our systematic literature review [1], we became aware of the lack of implementation and validation

results for academic security maturity models. We also perceived that the academic shift towards specialization is also related to the implementation issue, hence why our solution intervenes at the implementation phase.

This implementation issue was due to the impact of human behavior on information security as asserted by both academia and standardizing organizations. According to research [13], human resources are considered the weakest link in securing information systems. In studying the impact of habits in following security policy [14], the authors highlight the effect of individual beliefs, thoughts, actions, attitudes, awareness, and training among others on policy compliance. ISO 27001 and 21827 standards also emphasize the importance of awareness building and skill development for all interested parties. In addition, as system complexity also entails more stakeholders, responsibilities become pervasive and contain multiple levels of accountability. In this context, the problem, firstly, is that actors have difficulties proficiently managing their responsibilities within their own scope of action. While the standard recommendations are clear, organizations have difficulties down-scaling them into actionable tasks and responsibilities [15]. Secondly, managers don't have a multi-scale visibility over the system to insure monitoring adapted to scalability. In fact, we currently rely on individual manager capability for tracking tasks using natural language management tools and renowned methods such as responsibility assignment matrices [16].

As the Design Science [17] method entails, the next step is the production of artifacts to put this knowledge to use. Our method aims to bridge this gap by addressing operational monitoring for security management with a scalable vision, focusing on human behavior. In their study of non-malicious security violations, the authors [18] clear up that while employees are goal centered, job performance is the end goal rather than security. Sharing this view, we perceive that providing managers with the adequate tool to operate is the way forward. Also, studies on the social impact on information security address the influence of external systems in their culture models [19] demonstrating the need for the multi-scale visibility our solution provides. Finally, formalizing human involvement in applying security processes as well as supporting diversity of security approaches through genericity are essential. In order to achieve this, we rely on the prevalent system modeling language SysML. As a matter of fact, several studies use SysML as their basis for security risk assessment [20], secure system design [21] for model transformations [22]. We share the same system engineering vision for security management as these studies to address a different aspect of security that is operational management. Other modeling languages such as KAOS [23] offer the possibility for responsibility modeling but lacks the formalism necessary for supervision. Whereas, our solution enables a formal and complete representation of security related information. As a result, it will help test and verification using OCL, allowing for day to day monitoring, the cornerstone of Agile's [24] success in software engineering.

3. The operational responsibility and task monitoring method

As information systems' complexity blurs the lines of responsibility, we provide a generic method for responsibility, task

and vulnerability traceability. By definition, a method is composed of a set of concepts, a language, a procedure and a tool to support it all. In the following sub-sections, we will detail each component as well as their provenance.

3.1. Core concept

In order to populate our modeling language, we need to introduce information security concepts. We can rely on existing references such as standards or prominent security maturity models in order to extract these concepts. In fact, we analyzed and compared the main security concepts used in the security maturity models we found through our systematic literature review [1]. We have found that these models are highly connected to the ISO 27001 and ISO 27002 standards [4]. Seeing that the ISO standards are aligned, we compared the security concepts used in ISO 21827 to prominent academic and governmental security maturity models. We concluded that the ISO standards are comprehensive sources for information security concepts. The concepts that we put to use in this monitoring method are listed in Table 1.

Table 1: Core of Information security concept list

Concept Name	Semantic Meaning	Example
System	Smart building, Energy grid, Network	Smart building, Energy grid, Network
Asset	Anything of value to the organization	Software, Building, Server, Information, Process
Human Resource	An actor implicated with the system	Client, Chief of security, System Owner
Task	A set of actions assigned to a human resource that must be executed	Log data analysis, Configuration update
Responsibility	The obligation to oversee, take care of a specific asset	Security responsibility, Maintenance responsibility, Access responsibility
Vulnerability	The state of exposure to the possibility of being attacked, damaged or tampered with	ragility, Open port, Plain text storage, Weak password

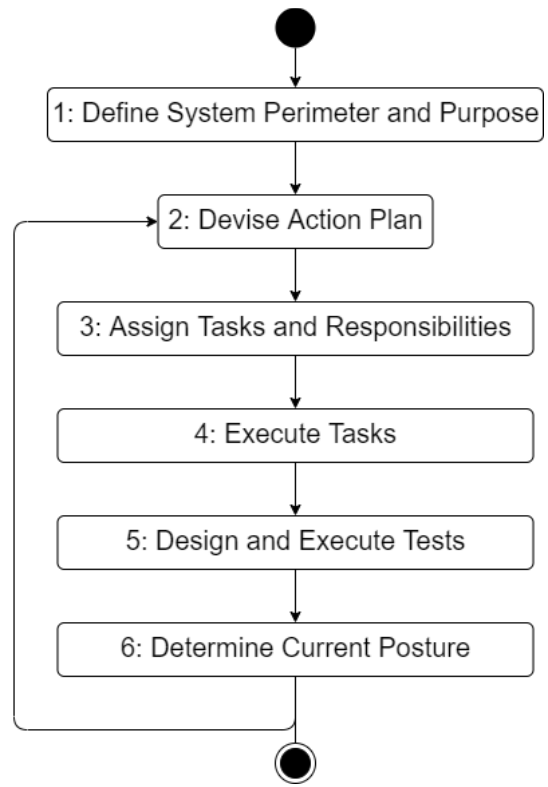
3.2. Language

In order to provide a graphical modeling language tailored to our concepts, we chose to extend SysML, the standard system modeling language. It supports specification, analysis, modeling, verification and validation of complex systems. It is defined as an extension of the well-known UML language used in software engineering. Another upside for choosing UML is the Object Constraint Language (OCL). OCL is a formal textual language that

allows constraint and object query expressions. It is a key point to the testing needed for monitoring. In addition, we can extend the SysML basic concepts by adding our security core concepts by the mean of profiles. This leads to define a new block diagram that includes security concepts. It allows us to define newer associations between these concepts for the necessary interactions. This ensures that we profit fully from the richness of the predefined SysML block diagram concepts. Our profile consists of the security concepts in Table 1 coupled with five new associations added to define new relationships between them. In Table 2 we specify the composition of our profile as well as the properties required for traceability.

Table 2: Security Responsibility Profile Elements

Concept Name	Relationship	Properties
System	Systems contain one or many Assets. Systems can interact with one another.	Owner Purpose
Interact With	Association linking two systems	Influence StartDate EndDate
Asset	Assets collaborate with one another. Assets Belong to one or many systems. Assets have one or many responsibles. Assets have one or many vulnerabilities.	ID Description IsActive LastActiveDate
Belong To	Association between assets and systems	Criticality level
Collaborate With	Association between assets	Nature Description CollabDuration CollabStartDate
Vulnerability	A Vulnerability belongs to one or many assets	Existence likelihood Description Recommendation
Human Resource	A human resource can be responsible for one or many assets. A human resource is a specialization of an asset. A human resource can execute one or many tasks.	Organizational unit
Responsible for	Association linking a human resource to one or many assets.	RespDuration RespStart LastResp RespNature

Execute	Association linking a task to a human resource.	StartDate EndDate
Task	A task can be executed by a human resource. An influence from an external system can impact a task.	ID Description IsExecuted Deadline Nature Criticality level


3.3. Procedure

The third part of our operational monitoring method is a procedure to guide step by step the usage of the modeling language. Drawing from the existing base of knowledge, continuous improvement is a central aspect of the ISO security standards. This translates into a cyclical security management procedure [5]. Using a PDCA cycle [25], operational monitoring would take place during the "Do" and "Check" phases. However, with the facilities enabled by the formal language, we can have a higher frequency of verification.

This is reflected in more frequent cycles of verification and testing. In Figure 1, we zoom into the "Do" and "Check" phase of the overall security management in order to highlight the usage of our method in operational monitoring.

First Step: The system definition resembles that of a general security management approach. It allows us to determine the scope of the system we plan to assess and aim to protect. This also clarifies the borders of the system properly defining the flow of interactions with other systems. The resulting work product is a mapped out system through a security block diagram. This diagram would present assets including their characteristics and collaborations, human resources involved and systems with which the system in question interacts.

Second Step: The organizations must devise an action plan that aligns with their internal goals and security requirements. That action plan is then adapted depending on existing resources and human resources capabilities.

Third Step: The action plan is down-scaled into actionable assignments. These duties and responsibilities are then allocated to the different actors within the system bounds with specific deadlines. This is where, traditionally, managers would use classic management tools defining tasks using User Stories that can be translated into model elements: "As a *Responsibility* I must *Task* by *Deadline*". This information is used to complete the previously mentioned security diagram.

Fourth Step: Human resources execute the tasks allocated to them. Task execution duration is task dependent and supervisions needs to be adapted accordingly.

Fifth Step: Supervisors and managers can design OCL tests to monitor task execution or do bulk monitoring. These tests can immediately yield undone tasks, return human resource work load or other tasks where manual verification would be arduous.

Sixth Step: These managers can determine, through multiple pre-designed tests, the current operational posture for their responsibilities within the system. The cycle then restarts, devising a new action plan based on previous results and future goals.

Figure 1: Operational monitoring procedure steps

3.4. Tool

In order to produce a functioning graphic editor for our language to support our method, we set out to find an existing well renowned modeling tool to extend. In Table 3, we set out to find a free and open source modeling solution.

Table 3: Renowned Modeling Tool Comparison

Modeling Tool	Author	OpenSource	Free
Modelio	Modelio Corp.	Yes	No
Entreprise Architect	Sparx Systems	No	No
MagicDraw	NoMagic	No	No
Eclipse Papyrus	Eclipse Foundation	Yes	Yes
Eclipse Sirius	Eclipse Foundation	Yes	Yes

Both Sirius and Papyrus are adequate choices, the scale tipped in favor of Papyrus for the availability of support and documentation. After this selection, the profile for the security SysML extension is created in a separate project. It is meant to act as a new extension point to be added to the profile list. This gives us, through the option of palette configuration, the possibility to add the profile elements. We can also define their graphical syntax

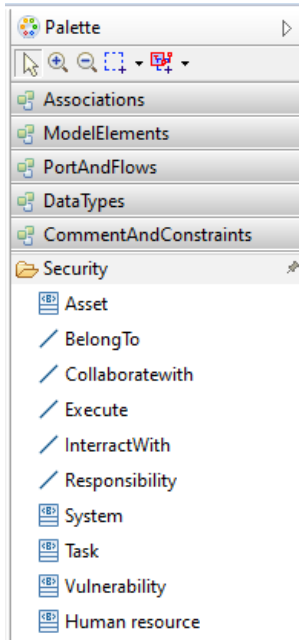
i.e. new shapes if needed, we elected to leave the original block shape with their respective stereotype. The resulting palette is shown in Figure 2. As it is for tests through OCL, Eclipse Papyrus supports the addition and execution of any OCL queries written in all Papyrus projects. By right clicking within the project, Eclipse allows the addition of OCL files, their execution and validation through the drop-down menu in Figure 3.


Figure 2: Security Responsibility Palette
Figure 3: Dropdown Menu for OCL

4. Capital One Breach Case Study

In this section, we follow the operational responsibility and task monitoring method in analyzing the Capital One data breach. At first, we analyze the impact of Capital One's monitoring practices. Secondly, we use the data breach as a case study to apply the steps of this method. Finally, we highlight the lessons learned from this case study.

4.1. Methodological Consideration

Because of the rarity of details concerning information security management, analyzing the detailed study [2] would yield interesting insights. Their study aligns with our vision since their initial hypothesis: Renowned standards do not provide enough guidance for organizations for implementation nor incident management. Also, organizations aren't capable of implementing and maintaining security controls. One of the recommendations made was to find a way to manage the time frame between control implementation, evaluation and audit. This is precisely where our study intervenes analyzing task and responsibility operational

monitoring. As per the typology provided in [26] and [27], our units of analysis in this "Descriptive Case Study" are the tasks or responsibilities of a single human resource. Our conceptual framework is that of our proposed solution, detailed in section 3. 1., as we will be studying the different human resources and assets intervening in Capital One's systems as well as the different responsibilities and tasks. We will address them through the research questions previously presented in the introduction:

- RQ1: How did Capital One track the chain of responsibility in their data breach?

- RQ2: How did Capital One security managers verify the implementation of security controls?

- RQ3: How to model tasks and responsibilities in a multi-scale information system?

- RQ4: How to formalize operational monitoring in a multi-scale information system?

4.2. Procedure

Capital One is ranked eighth largest bank overall with a revenue of around 28 billion dollars in 2018. Technology implementation and consistent progress are considered driving ideologies within Capital One. As it is the case in banking, they abide by several security standards such as the New York Stock Exchange corporate governance rules, as well as being one of the participants in supplementing the NIST security standards. Capital One are considered pioneers in migrating their data centers to a cloud environment, environment from which the breach stemmed later. In spite of all their efforts, a breach disclosing the personal data of around 106 million individuals was discovered in July the 19th, 2019. According to the investigations that followed, an employee for the cloud storage service provider Amazon Web Service (AWS) created a scanning tool that allowed the culprit to recognize servers with firewall misconfigurations allowing access to buckets of data. This permitted the later execution of a set of scripts to retrieve access credentials then copy the now available data.

4.3. Analysis

Following the steps of our procedure described in section 3.3, we address primarily the failure in the implementation of technical security controls from Capital One's side. In the **First step**, we describe the contents of the Capital One Security Management System. They have invested in hiring a renowned Chief Information Security Officer (CISO), talented security engineers as well as on other security related investments for tool development.

Secondly, the bank's action plan allegedly revolves around implementing information security standards such as the NYSE requirement or NIST security controls. This meant that the CISO had the duty of choosing the security controls he deems adequate to protect his system. He then had to specify the time and resources allocated for each security control as well as defining the evaluation and audit periodicity. This is also when he's supposed to decide the means by which the controls are to be satisfied. First of all, a Web Application Firewall (WAF) needs to be implemented and configured to block any entry from malicious

proxy servers or from TOR exit nodes. Secondly, set up proper periodic vulnerability scans for the WAF. Lastly, revoke administrative account access credentials in case of internal changes. In the *third step*, the CISO should assign these duties to the security engineer and the security manager. In the case as we understand it, there was time window in which the attack occurred and that is between task execution in *step four* and the monitoring test that would have identified the failed NIST controls in *step five*.

Research Question 1: In an article by The Wall Street Journal, Capital One attributes the problem to an error in its own infrastructure. However, in a second article in the same journal, interviewing Capital One employees reported that multiple issues are at the root of this breach. Prior to the incident, there have been complaints that employees have raised concerns that they required more software to spot breaches. This delay is caused by the difference in skillset between IT professionals and governance professionals. As systems become more interconnected, all involved parties must acquire multidisciplinary skills so that governance professionals understand the necessary requirements in terms of technology to be able to provide them within a smaller timeframe. This could also be linked to failures to stay within budget lines despite hefty investments. This shows that Capital One failed to trace back the source of their infrastructural issues that is managerial and financial at its core.

Research Question 2: A second issue voiced by employees was low morale due to an increase in number of employee terminations. This is also due to budget issues that later became detrimental to routine security control implementation. Employees also reported an internal practice giving liberties to programmers the freedom to code in whatever language they choose if it would help complicate breaking into their systems in turn complicating pen-testing. These two incidents reflect that Capital One also lacked visibility as well as control over the tasks executed inside its scope. The Capital One security managers knew the necessary security controls to implement, however, they lacked regular verification of their implementation. This is what created the timeframe the culprit needed to execute his attack.

4.4. Lessons Learned

In the previous subsection, we clarified that Capital One had issues regarding task and responsibility tracking. Now, we will address these issues through discussing the second set of research questions.

Research Question 3: In our previous analysis, the first issue was the lack of multi-scale visibility coupled with lack of understanding between engineers in the security management system and their higher-ups in top management. This an aspect that our solution addresses via a complex system vision, where multiple systems interact with one another and therefore influencing one another. Using our method, in the first step, we can model Capital One as two systems "Governance System" and "Security Management System" each containing their respective human resources. As is shown in Figure 4, we can model the budget that the first system provides to the next or how the financial issues can influence security management. In this case, any employee dismissed must be removed from the model. Carrying on, we add to each human resource their set of tasks to which we assign deadlines and the attribute *Isexecuted* to be set to

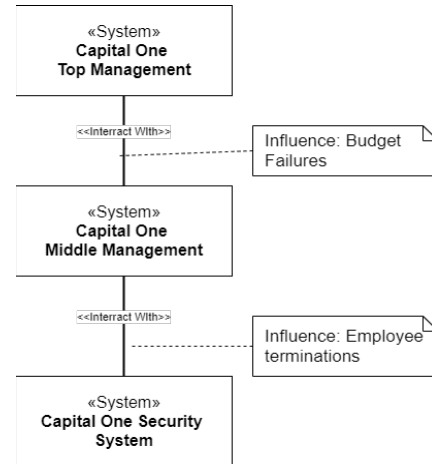
"True" when it's done. Figure 5 shows the different security tasks and their responsible. Each task is the implementation of a necessary NIST security control [2]. In the case of the layoffs and human resource removal, the tasks would remain and it would be apparent that they need to be reassigned in order to maintain security controls. Verification for human resource task load and tasks with no *responsible* association can be done through OCL tests. In addition, each human resource can find her own tasks by executing a script. This script would return all tasks that are assigned to the human resource with a *responsible* association.


Figure 4: System Influence Diagram

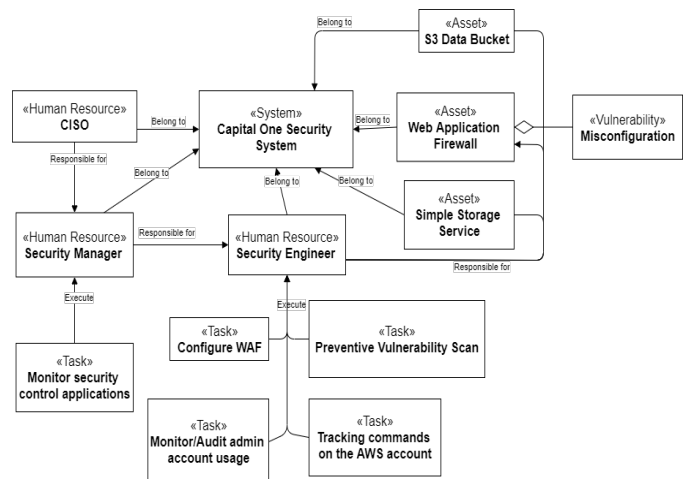
Research Question 4: Following task modeling and responsibility assignment, it is the managers' duties to design tests for task supervision. This would normally be achieved by individually verifying each task accomplishment manually. Through the formal modeling of each task and responsibility, we now have the possibility of designing tests where we can list all tasks that have the attribute *IsExecuted* set to "False" and compare the current date to the deadlines. This would also link us immediately to the person responsible for this task execution. Since the day to day supervision tests don't have to be re-written, this makes monitoring less time consuming and therefore more efficient opening the possibility for day to day supervision. In the case of Capital One, this would have resulted in the revocation of the culprit's access credentials earlier as well as reassigning other employee's tasks in time. In turn, this would have closed any timeframe required to conduct the attack.


Figure 5: Operational Traceability diagram for Capital One Case

5. Conclusion

This paper presents a method for operational security monitoring applied to a security breach case. It aims to bridge the gap identified between security control identification and implementation. We have presented the components of our method that provide a much-needed formalism in security management. We have built this method using prominent modeling and security management standards in the base of knowledge. We have chosen to extend the SysML modeling standard with security monitoring concepts. This allows the creation of specialized block diagrams that model the actors and assets within a system as well as the tasks and responsibilities. The resulting diagram is a map capable of capturing complex system composition and interaction. Furthermore, this formalism provides the ability to use OCL for proper monitoring and supervision even for complex systems. In fact, the information depicted is of different use to different actors. OCL queries allow managers to regularly verify task execution and manage task loads. They also allow security engineers to see which new tasks were assigned to them or whether undone tasks still remain. Moreover, we have highlighted through our procedure the issues usually faced during the "Do" and "Check" phases of the Deming wheel. This allowed us to showcase the importance and applicability of our method for security management onto a high profile case. The described case study provided a high level of detail that allowed us to properly study the applicability and utility of our proposed method. Our method does not circumvent the complexity of the systems studied, it retains all the necessary information for operational monitoring. It aims to provide the tools that different actors need to carry out their roles in security management.

For future studies, we intend to include this study within a bigger whole designed for security management to reach "security by design". We also plan to further improve the modeling tool facilitating tests and creating a plugin to be featured in Eclipse Marketplace for public usage.

Performance Evaluation of a Gamified Physical Rehabilitation Balance Platform through System Usability and Intrinsic Motivation Metrics

A B S T R A C T

Motivation significantly influences the outcome in the rehabilitation of patients. Several developments have been made to assess and increase patient motivation by addressing factors linked to motivation such as the personality of the patient, professional administering rehabilitation, and the rehabilitation environment. The main objective of the study is to evaluate the reliability of a gamified environment for the rehabilitation of stroke patients by testing its functionalities within standard physical therapy time and intervals. To achieve this, calibration was characterized. Also, user feedback was taken in the form of questionnaires based on the System usability scale (SUS) and Intrinsic Motivation Inventory (IMI). Based on the SUS scale, results show that the game manipulability is good, the game concept and design is satisfactory, and the game comprehensibility is also good based on the qualitative conclusion per SUS score. For the IMI ratings, it was found out that the highest rating was the perceived choice which indicates their voluntary participation in the game. Some improvements can still be added to the game itself to increase the motivation of patients. The balance board manipulability and the recalibration time interval can be further improved for comfort and ease of use by the patients.

1. Introduction

Balance deficiency is one of the common issues for post-stroke and post-injury patients, as well as for individuals who wish to train his/her balance even without deficits (e.g. athletes). Out-patients who had such deficiency will undergo a balance therapy program. In the current setting, a patient will attend therapy sessions about six to ten times. Each session, the patient will perform various balance exercises such as static balance, dynamic balance, and manual perturbation exercises using balance board, wobble board, balance rails, and mirrors extensively assisted by physical therapists. The patient will then perform the exercise, but most of the time, the patient will feel the pain of such exercises as well as boredom due to its repetitive nature. Also, the therapist will record the patient's balance quality according to what is observed, making several corrections to the number of balance sessions as well as the physician's initial observation. This also introduces an inconsistency problem when a different therapist observes the patient and records the score for interpretation. Finally, the patient has to rely on his/her safety on

the therapist, since the current tools do not have robust feedback for the patient to observe his/her balance performance. With these, the patient is usually discouraged and unmotivated to attend another therapy session as well as not trying to perform them by himself/herself.

In line with this, one of the determinants that greatly affect the success rate of undergoing physical rehabilitation is the motivation level of the patient. Motivation has been identified to be influenced by a variety of factors such as the personality of the patient, the professional administering rehabilitation, and the rehabilitation environment. Research work integrating the use of the Microsoft Kinect or the Wii Fit Board with various games to change the rehabilitation environment has proven to be effective in increasing patient motivation and overall affecting the outcomes on a more positive result [1, 2]. However, improvements on these previous researches can still be made, such as creating a more affordable and open-sourced design of the hardware and incorporating more game elements that engage the patient which will aid in the success rate of the physical rehabilitation.

[*]Corresponding Author: Rosula Reyes, rsjreyes@ateneo.edu

Balance-on-action-Team (BOAT) implements affordable hardware and open-source software to enable a wider reach in the utilization of gamification in physical rehabilitation. It is an automated balance board medical device with a gamified element for conducting balance exercises for patients undergoing balance rehabilitation therapy. The overall goal is to provide rehabilitation centers, sports clinics, and personal trainers with safer, faster, and more engaging means of conducting balance training and therapy. In this way, balance exercises in the Philippines setting will become faster, more consistent from therapist-to-therapist, and more fun to perform.

The main objective of the study is to evaluate the reliability of the equipment (calibration and functionalities) based on the standard physical therapy time and intervals. Furthermore, conduct surveys to evaluate the game's impact on motivation.

This paper describes the various studies related to rehabilitation and patient motivation in Section 2 of the Review of Related Literature. Section 3 discusses the Methodology which focuses on the hardware and software implementation in Section 3.1 and the testing procedure in Section 3.2, using different metrics. The results are shown and discussed in Section 4 which includes the calibration in Section 4.1, Game Self Evaluation in Section 4.2, Motivation Analysis in Section 4.3, and Game Walkthrough Evaluation in Section 4.4. Lastly, the Conclusion and Recommendation can be found in Section 5.

2. Review of Related Literature

Several studies have been conducted on the rehabilitation of stroke patients using varying platforms, approaches, and frameworks. A similar balancing platform was studied by [3] where the focus is on utilizing the Nintendo Wii Balance Board for rehabilitation. The study developed a *WeHab* system that added visual biofeedback based on the center of pressure location. This system also allows for multiple balanced boards to be used together, customization of activities and difficulty level, and integration with a webcam to capture video footage during the sessions. Similarly, visual biofeedback was also used by [4] using Microsoft Kinect for postural rehabilitation. This allows the system to determine if the patient performed the correct postural exercises through the built-in capabilities of the Kinect in movement and gesture recognition. Another type of balancing platform that can be used is a wobble board which was studied by [5]. Here, the instrumented wobble board is used to create multidirectional perturbations and obtain vibrotactile feedback for training dynamic sitting balance. This research work also uses a microprocessor and an inertial measurement unit but has an added eight vibrating tractors. Aside from these approaches, the rehabilitation of patients can also be monitored using EMG on the lower limbs, such as in the work of [6]. In this case, a balance board was also used but accompanied with obtaining sEMGs signals to analyze how the muscle activity reacts from dynamic leaning caused by balance reactions.

Assessing patient motivation and system usability have been determined to help improve rehabilitation for chronic stroke patients. Instead of balance exercises used in this research, the study by [7] evaluates the feasibility of a new technology-supported task-oriented arm training regime (T-TOAT) for chronic stroke patients. The system is comprised of movement tracking sensors, an exercise board, and a software-based toolkit used for skills training. The patient motivation was assessed on the Health Care Self Determination Questionnaire (HCSDT) based on the self-determination theory. Furthermore, system usability was also assessed and was found to be rated good by the users. After performing various tests, it was discovered that the T-TOAT approach improved arm-hand performance significantly for the duration of the post-training. Similar to this work, system usability and motivation were evaluated through various questionnaires and assessment tools for improving rehabilitation.

Another patient motivation assessment tool applied in this work is the Intrinsic Motivation metrics which was also conducted in a study by [8]. This study aims to characterize motivation based on the information of activities for smart wearable health equipment applications. The participants in the study were tasked to solve a computer-generated puzzle under one of the four random conditions including the long-term feedback (LFB), long term graphical feedback (LGFB), short term feedback (SFB), and non-feedback for the trend of correct answers. Intrinsic motivation was then measured using both a 12-item version of the Intrinsic Motivation Inventory and the time it takes the participant to solve the puzzle. Based on these, it was observed that the most desirable type of feedback is one that improves perceived competence, which can then be adapted to health equipment displaying methods.

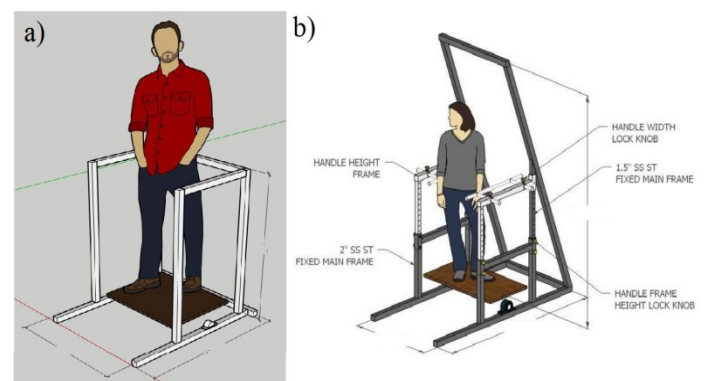
The BOAT is a research project that was conceptualized and developed through the collaboration between the Ateneo de Manila University and the Philippine Orthopedic Center. The gamified environment was initially developed by [9] using an inertial measurement unit. The goal was to provide the gamified elements in the form of quests and rewards system for providing an interactive and fun rehabilitation process. The hardware prototype was developed and tested in [10] using intervention techniques, motivation, and game design analysis. This was then continued by [11] through a comparative game design analysis. Several changes have been made for the hardware design, shown in Figure 1, and software game mechanics implementation by [12]. The research work added more customizability, and personalized information from the patients to help the physician perform better assessments. This research focuses on evaluating the gamified rehabilitation platform of [12] through various metrics such as system usability and intrinsic motivation metrics.


Figure 1: Hardware Changes from the Prototype [6] to the Commercialized [8]

3. Methodology

3.1. Design of the System

For the software, the gamified environment of the balance board lets the user experience a seamlessly integrated, open-world seafaring game integrated with a quest system [12]. The quest system allows the patient to perform physical rehabilitation exercises under the guise of the game. There are three quests or game modes designed to correspond with different physical rehabilitation exercises and specific metrics from the Tinetti Balance Assessment Tool and the Equilibrium Score. Each game mode and its corresponding mechanics are shown in Table 1.

Table 1: Game Modes and Mechanics [12]

Game Mode	Mechanics	Player Input
Collect the Crates	The player must be able to collect as much trash (in the form of crates) as possible within a certain amount of time	Lateral Dynamic Balance Exercise. The player must be able to challenge himself/herself a postural sway and recover from it as much as possible using lateral movements.
Avoid the Bombs	The player must be able to avoid all possible bombs within the boat's path in a certain amount of time	Static Balance Exercise. Players must be able to stand still as much as possible to avoid the bombs.
Follow the Light	The player must be able to follow the light in front of the boat without getting too near or too far from it	Posterior-Anterior Dynamic Balance Exercise. The player must be able to challenge himself/herself a postural sway and recover from it as much as possible using posterior-anterior movements.

The hardware design includes the following components: the frame, balance board, accelerometer, and Gizduino Uno. Most of the hardware components were mounted on the frame which features adjustable mechanisms and can be disassembled. The balance board is commonly used in physical rehabilitation for static and dynamic exercises, especially in the Philippine Orthopedic Center. There are two types of balance boards, the two-directional balance board which was used in this study, and the multi-dimensional balance board or wobble board. Relatively, the bidirectional balance board provides more accurate data from the accelerometer readings since only two directions are measured and the rest are disregarded. Several adjustable components are used to cater to different characteristics and categories of patients. One of these is the stopper which adjusts the maximum tilting angle of the balance board for both sides with increments of 5°. This allows the physician to change the maximum angle depending on the patient's capabilities. Furthermore, this helps in stabilizing the platform at 0° before running the application. Also, the handrails where the patient will hold on to when playing the game can be raised or lowered to compensate for patients with different heights. Each consecutive hole for moving the handrail is about 2 inches apart. Lastly, the friction of the balance board can be altered using the tension control knobs with a range of 1 to

8 for each side. Adjusting the magnitude of the sway of the board will help more balance-challenged patients gradually adapt to the game mechanics.

As a safety precaution, the patient is advised to wear a harness that is attached to an adjustable lanyard, presented in Figure 2. The lanyard is then mounted on the hooks of a metal bar which can be rotated 360° along the vertical axis to allow a smoother transition for the dynamic posterior-anterior to lateral sway and vice versa. Moreover, wearing the harness greatly minimizes the risk of falling from the balance board.

Figure 2: Harness for Lateral (a) and Posterior-Anterior (b) Movement

For the improvements tracking, the calibration of the equipment is accomplished through linear regression using two data points from the sensor readings. From the generated equation in slope-intercept form, the slope and y-intercept will be saved in a .txt file inside the Results folder on the desktop. This will enable the user to see any variations in calibration.

Similarly, the game metrics are recorded in the form of a .txt format in the Results folder. It publishes the patient's name, the date and time when the exercise is completed, the quest played, the type of balance exercise, their in-game score, the Equilibrium Score (ES), the maximum posterior-anterior sway, maximum lateral sway, and game settings information. This information allows the physician to track and evaluate the progress of the patients after engaging in the physical rehabilitation procedure.

Data from each game mode are recorded in the form of the ES, shown in (1), which indicates their quality-of-balance progress as patients play the game. The ES is the probability of fall in which a score of 100 indicates a 0% chance of fall while a score of 0 indicates a 100% chance of fall.

$$\text{ES} = \frac{\gamma - (\theta_{max} - \theta_{min})}{\gamma} \text{ X } 100\% \qquad (1)$$

where θ_{max} is the maximum postural sway relative to the vertical

θ_{min} is the minimum postural sway relative to the vertical (natural standing angle)

γ is the limits of stability angle for the clinical setting

3.2. Testing the System

To fully test the reliability of the system, several methodologies were adapted based on metrics related to the study, which includes the following:

An SUS (System Usability Scale) is a self-rated scoring system that measures the usability of a certain device or software. It is usually a ten-item test that has open-ended statements with user responses from "Strongly Disagree" to "Strongly Agree". Each item is scored on a 5 (or 7) point scale. To prevent purely positive or purely negative responses, this questionnaire is designed to have alternate positive-worded and negative-worded statements. Thus, the following rules for computing the SUS are the following:

- For every negative statement (odd-numbered items for this test): take the max score (e.g. 7) and subtract it by the raw score (e.g. raw score = 3, SUS score = 7 – 3 = 4)
- For every positive statement (even-numbered items for this test): take the raw score then subtract by 1 (e.g. raw score = 6, SUS score = 6 – 1 = 5)
- Add all of the SUS scores of every item. The maximum score should be:

$$(\text{max points} - 1) * \text{max items} \qquad (2)$$

- Depending on the maximum number of items, the overall SUS score should be on a scale of 0 to 100. Therefore, for a 10-item questionnaire with 7 as maximum points, the entire sum should be divided by 0.6 since the maximum score is 60.
- The overall SUS score is then tallied and averaged. Normalization is considered for the average therefore a score of 68 and above is a favorable result, while a score of below 68 is an unfavorable result. Figure 3 shows how the scores will be interpreted qualitatively in the conclusion.

SUS Score						
0 - 50	51 - 60	61 - 67	68	69 - 74	75 - 85	86 - 100
Poor	Bad	Unsatisfactory	Average	Satisfactory	Good	Excellent
Figure 3: SUS Score Equivalent

The Intrinsic Motivational Inventory (IMI) measures the motivation of the test subjects in playing the game. All 22 questions are modified from the template provided by the Self-Determination Theory Organization but have the same measurement (http://www.selfdeterminationtheory.org). For determining the IMI Score of the test subjects, the following procedures are done.

- The responses for items 2, 9, 11, 14, 19, and 21 are reversed. That is, the item score is equal to 8 minus the response (item score = 8 – response).
- These subscale scores in Table 2 are added together:

Table 2: IMI Subscales

Interest/Enjoyment	Items 1, 5, 8, 10, 14, 17, 20
Perceived Competence	Items 4, 7, 12, 16, 22
Perceived Choice	Items 3, 11, 15, 19, 21
Pressure/Tension	Items 2, 6, 9, 13, 18

- The subscale scores are analyzed as follows:
- o Interest/Enjoyment, Perceived Competence, and Perceived Choice is summed up into the IMI score for the subject's motivation. This sum is high if the test subject is motivated enough to perform the balance exercises through the game
- o Pressure/Tension is the IMI score for the subject's loss of motivation. This score is high if the test subject is not motivated enough to do the balancing exercise even if the game is played.

The Motivation-to-No-Motivation (MNM) ratio is then determined to check how much the test subjects are motivated based on their responses on the IMI. MNM is achieved by applying the equation:

$$\text{MNM} = \frac{IE+PCT+PCH}{IE+PCT+PCH+PT} \qquad (3)$$

where MNM = Motivation-to-no-Motivation ratio,

IE = IMI subscale score for Interest/Enjoyment,

PCT = IMI subscale score for Perceived Competence,

PCH = IMI subscale score for Perceived Choice, and

PT = IMI subscale for Pressure/Tension.

4. Results and Discussion

The reliability of the prototype was evaluated to assess the accuracy and precision of the components based on the calibration values before and after using the balance board. The test was also conducted with twenty (20) healthy test subjects consisting of 10 males and 10 females within an age range of 20-30 years old. Each subject has no history of stroke and no injury 6 months prior.

4.1. Calibration

Calibration evaluates and adjusts the precision and accuracy of the balance board. In calibrating, the balance board was referenced at +20 and -20 degrees, and sensor values of the MPU 6050 were then recorded on these angles to calculate the slope.

For the reliability of the balance board based on calibration, the slope was recorded before and after the game based on the following parameters: 10min (Game)-15min (Rest), 15min (Game)-20min (Rest), varying tension control, and varying weight of the test subjects.
Figure 4: Slope Percentage Error vs. Time Graph: (a) 10min (game) – 15min (rest), (b) 15min (game) – 20min (rest)

Figure 4 shows the percentage error of the balance board slope as time increases. The percentage error was computed using this equation

$$\text{Error (\%)} = \frac{2\,|x-y|}{x+y} *100 \qquad (4)$$

where *x* is the initial slope while *y* is the value of the slope after some time. With *3.5%* as the maximum percentage error (4) at around *105 minutes*, it is safe to say the calibration of the prototype is still precise after turning it on for around *1 hour and 30 min.*

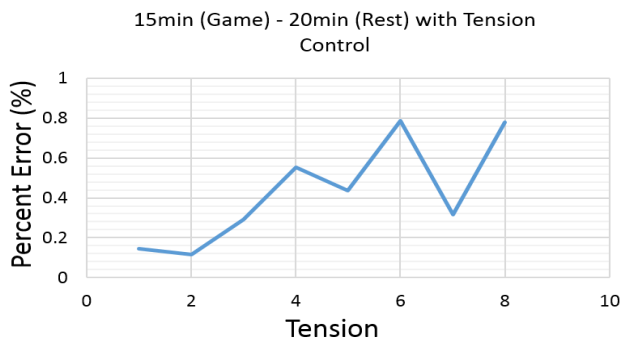
The slope of the balance board was also recorded as the tension control adjusts from 1(low friction) to 8(high friction). The correlation between the percentage error of the slope and the tension control is shown in Figure 5. Since the maximum percentage error is around *0.8%*, it shows that the calibration value is still precise even if the tension control is varied.


Figure 5: Slope Percentage Error vs Tension

Figure 6 shows the percentage error of the slope before and after doing the game testing as the weight (kg) of the test subject varies. Based on the figure, we can say that there is no correlation between the weight of the person doing the test and the slope percentage error. It also shows that the person's weight doesn't affect the calibration of the balance board with a maximum error of around *1.5%.*
Figure 6: Slope Percentage Error vs Weight

4.2. Game Self Evaluation

Game Self Evaluation is an SUS questionnaire to be filled out by the test subjects for their evaluation of both the hardware and the game. It is divided into four groups: Balance Board Manipulability Measures, Game Manipulability Measures, Game Concept and Design Measures, and Game Comprehensibility Measures.

The Balance Board Manipulability Measures is a self-rated survey on how the balance board is used to them. This is collated and calculated based on SUS. For Balance Board Manipulability Measures, the average SUS for all 20 test subjects is 64.06, which is 5.89% lower than the average SUS score of 68. Overall, the result is unsatisfactory and the balance board manipulability measures can be improved.

The lowest SUS is 35.42 while the highest is 93.75. The highest-rated item is #1 (I thought the board was too high for me to use) with an average SUS of 5 (0 being the lowest and 6 being the highest). This is because the handle on the sides of the balance board can be adjusted depending on the height of the test subject. The lowest rated item is #8 (I felt it did not need any much muscle effort in using this platform) with an average SUS of 2.55. This is because the platform was tested for healthy patients while the level of difficulty of the game was intended for post-stroke and post-injury patients. Improvements can be made by adding a motor on the balance board to assist the test subjects when they feel tired or when they executed too much muscle effort.

The Game Manipulability Measures part of the evaluation is based on how playable the game is for the test subjects. The results are also collated and calculated on an SUS basis. The average SUS for all 20 test subjects on Game Manipulability Measures is around *75.94%,* which is *11.67%* higher than the average SUS score of *68.* Based on the results, we can say that game manipulability is good.

The lowest SUS is *47.92* while the highest is *100.* Item #8 (I thought the game was simple and uncomplicated) is the highest rated item with an average SUS rate of 5.65. The lowest rated item is #7 (My legs got tired very easily when playing the game) with an average SUS rate of 3.6.

The Game Concept and Design Measures is a self-rated survey on how enjoyable and how appropriate the game is for balance board rehabilitation. The results are collated and calculated on an SUS basis. The average SUS for all 20 test subjects on Game Concept and Design Measures is around *70.64%,* which is *3.88%* higher than the average SUS score of *68.* Based on the results, we can say that the game's concept and design are satisfactory.

The lowest SUS is *51.28* while the highest is *96.15.* Item #1 (I thought the game was too hard for me) is the highest rated item with an average SUS rate of 5.7. This proves that the game is easy to play and understand by the test subjects. The lowest rated item is #3 (I got bored at this game) with an average SUS rate of 2.75. This might be because the gameplay was a bit easy for healthy test subjects but it might be challenging for post-stroke and post-injury patients.

The Game Comprehensibility Measures is a self-rated survey on how easy and understandable the instructions of the game when playing, which is collated and calculated based on SUS. Based on the results of 20 test subjects, the average SUS is around *80.42,* which is *18.26%* higher than the average SUS of *68.* This shows that the game comprehensibility measures are on a good level based on the qualitative conclusion per SUS score.

The lowest SUS is *63.89* while the highest is *100*. Item #2 (I thought the amount of information to follow this game was enough) is the highest rated item with an average SUS rate of 5.39. The lowest rated item is #11 (The sound was too loud or too soft, or had an annoying burst of sound) with an average SUS rate of 4.17, which is still above the average possible score of 3.

4.3. Motivation Analysis

In this project, all twenty (20) test subjects' responses had been collated and analyzed based on the IMI subscales. Table 3 shows the IMI results while Figure 7 shows a graph of the IMI rate in each IMI subgroup.

Table 3: IMI Results

IMI Subscale	Average	IMI rate (%)	Highest Score	Lowest Score
Interest/Enjoyment	35.25	71.94 %	49	21
Perceived Competence	29.7	84.86 %	35	19
Perceived Choice	30.3	86.57 %	35	18
Pressure/Tension	12.5	35.71 %	22	5
Figure 7: Qualitative Conclusion per Metrics Reading for MNM

In calculating their IMI scores, the average MNM is *0.88* with a minimum MNM of *0.78* and a maximum MNM of *0.95*. Results show that the average motivation of all 20 test subjects is in Good/Successful rating based on qualitative conclusion on metrics rating (Figure 7). This indicates that overall, the test subjects have good motivation in performing the balance exercises.

On all the IMI subscales as shown in Figure 8, the perceived choice is their highest response rate with *86.57%*, which indicates that they rated their voluntary participation and continued participation of playing the game. It is followed by perceived competence with *84.86%*. This means that the test subjects are skilled and they felt competent in playing the game. Interest/enjoyment which is another motivation subscale is also rated high with *71.94%*. The graph also shows that the test subjects didn't feel any pressure/tense and they feel relaxed while playing the game since the Pressure/Tension subscale only has a rate of *35.71%* and is below the average rate of *50%.*
Figure 8: IMI Bar Graph

Game Walkthrough Evaluation is a self-rated survey consisting of short answers on what the test subjects thought of the game. Each item is analyzed and compared with other metrics to find out which part of the game is easy or hard, and what would be the difficulty in using the game.

4.4. Game Walkthrough Evaluation

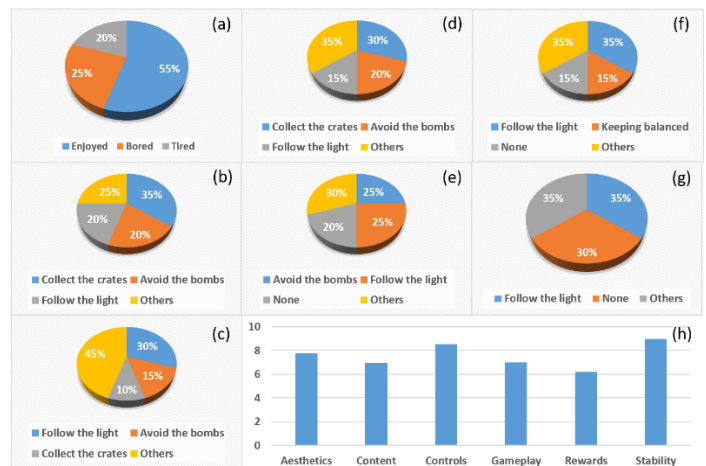
Figure 9 shows the feedback of the test subjects while playing the game. The figure shows that most of the test subjects enjoyed while experimenting. They considered "Collect the crates" as their favorite part of the game while Follow the light was the most disliked one. Also, "Collect the crates" was the easiest part of the game while "Avoid the bombs" and "Follow the lights" tied to be the hardest part of the game. Additionally, the participants considered "Follow the lights" as the most tiring game, and difficult to control.


Figure 9: Game Walkthrough Evaluation Results: (a) Feeling after playing the game, (b) Favorite part of the game, (c) Disliked part of the game, (d) Easiest part of the game, (e) the hardest part of the game, (f) Tiring part of the game, (g) Control difficulty in the game, (h) Game overall Score.

The game is scored 7.58 over 10 (shown in Figure 9 (h)), with stability being the strongest feature (9) and rewards being its weakest feature (6.2). The participants also noticed some bugs/errors while playing like delayed movement on the projector screen, squeaking noise during the game, slow pace on the levels, monotonous gameplay, small text on the screen, etc. These need to be improved to increase overall game satisfaction.

5. Conclusion

The gamified environment and balancing platform were successfully tested on twenty individuals in compliance with the standard physical therapy time and procedures. Based on tests with varying tensions and weights, the equipment was observed to require recalibration every 1 hr and 30 minutes. The users also gave feedback based on a rating from the System usability scale (SUS) and IMI (Intrinsic Motivation Inventory) with regards to the different aspects of the game and equipment. The overall evaluation of the game got a score of *7.58* with stability as the strongest feature and rewards as the lowest one.

Further improvements can be made on the overall system such as the need for technical adjustments in the current build such as bugs, glitches, and sounds, adding a "Congratulations" instead of "Game Over" to increase motivation, integrating more natural

special effects (e.g. fish, seagulls, rain, etc.) and also, make the subject immersed in a relaxing-natural coastal area where the endpoint is a docking area/lighthouse. Lastly, testing the system with post-stroke and post-injury patients of different age groups, height, and body mass index (BMI) instead of healthy individuals would yield a more accurate and better reliability evaluation of the platform.

Conflict of Interest

The authors declare no conflict of interest.

An algorithm for Peruvian counterfeit Banknote Detection based on Digital Image Processing and SVM

Bryan Huaytalla, Diego Humari, Guillermo Kemper[*]

Faculty of Engineering, School of Electronic Engineering, Universidad Peruana de Ciencias Aplicadas, Lima 15023, Peru

A R T I C L E I N F O	A B S T R A C T
	In this work we propose an algorithm for Peruvian counterfeit banknotes detection. Our algorithm operates in banknotes with 50, 100 and 200 soles denominations that were manufactured from 2009 onwards. This algorithm offers an automatic diagnosis based on digital image processing and support vector machines (SVM). Current Peruvian counterfeit detection systems are specially designed to analyze relevant characteristics in dollars and euros. Then, some counterfeiters can fool these systems. We made our detection system robust because we focus on the image acquisition and the segmentation of intaglio marks engraved over the banknotes. After segmentation, we applied embossing and Sobel filters followed by an aperture morphological operation to obtain special characteristics that were then classified by an SVM. We have validated our methodology using real and fake banknotes from a dataset of 240 samples provided by Central Reserve Bank of Peru (BCRP). Our final identification accuracy was 96.5%.

1. Introduction

In order to properly introduce the proposed algorithm, it's been divided into three sections: motivation and incitement, literature review and contribution.

1.1. Motivation and incitement

In Peru, counterfeiting money is a well-known fraud method. In fact, according to the Central Office Against Counterfeiting Money from Peru, the amounts of fraudulent banknotes have reached millionaire quantities (Oficina Central de Lucha contra la Falsificación de Numerario – OCN – Peru: "Principales operativos contra la falsificación" Available: http://www.ocn.gob.pe). As a result, the annual report of the United States Secret Service, an entity with which the Peruvian National Police works together to combat national and foreign banknote counterfeiting, places Peru as the main banknote counterfeiter country worldwide, surpassing other South American countries such as Colombia , which had this title before.

In Peru, this type of practice is especially problematic and constitutes an attack on society, because it makes people to lose trust on currency in circulation which increases money transaction time. Even worse, this distrust in Peruvian money hurts the economic growth and, in the long term, it could also lead to inflation because, as there is more money circulating than the amount the government can handle, people purchasing power increases, which would turn into an increase in prices. Finally, this ends up affecting the economy of any person or any company that receives the fradulent banknotes, especially when those banknotes are the ones with the highest denomination.

In this context, some enterprises offer solutions in the form of counterfeit banknote detectors. However, most of these detectors are based on foreign banknote manufacturing technologies, such as the "Elwic BC 3500 UV / MG next-generation banknote counter" or "PREZZOPAZZO DST-38D banknote detector", which use verification parameters such as magnetism, infrared or banknote thickness, all of which have already been fooled by Peruvian banknotes counterfeiters.

A common method used by scammers is to discolorate low-denomination banknotes (i.e. 10 or 20 soles banknotes), and then overprint them with high-denomination banknote values (i.e. 50, 100 or 200 soles banknote values). These overprints can be of very high detail so they successfully fool the aforementioned verification parameters used by commercial detectors. However these type of techniques are less common on lower denomination banknote (10 and 20 soles) as they would be less cost effective.

Our algorithm focuses on intaglio marks which are distinctive for Peruvian banknotes and whose imitations have not reached such a high level of sophistication.

[*]Corresponding Author: Guillermo Kemper, Av. Prolongación Primavera 2390, Monterrico, Santiago de Surco, Lima 15023, Peru, email: guillermo.kemper@upc.pe

The focus of the algorithm is on the higher denomination banknotes (50, 100 and 200 soles) since these are the more commonly counterfeited and the more damaging to the victims.

Some other commercial detectors are aimed to serve more as inspection tools for the user, using ultraviolet lights or magnifying glasses as is in the case of "Elwic Professional Banknote Detector IRD-2200" or the "Anizun Magnifying glass mini microscope". These solutions do not provide a clear detection verdict. Rather, they are based on users' prior knowledge of the distinctive marks and details that a legitimate banknote must have. By relying on the human senses, these methods have an intrinsic error. Furthermore, counterfeiters are capable of mimicking several of the most distinctive characteristics of authentic banknotes, such as fluorescent markings or some images that give the illusion of being seen against the light (Arjowiggins Security. "Security features: Watermarks, security fibres and security threads" Available: https://securitypapers.arjowiggins.com). Compared to these detection tools, our method offers a clear and readable verdict on the denomination and legitimacy of the analyzed banknote.

Another common counterfeit technique used in Peruvian banknotes is the removal of security bands from 100 and 200 soles banknotes. These bands are manually removed from a legitimate banknote and placed on a falsified one, then the legitimate but damaged banknote can be exchanged for a new one in banks. This way, counterfeiters have a fake one with a security band that would pass even a meticulous examination. Our algorithm can tackle this problem as it uses banknotes intaglio marks that cannot be removed and placed in falsified ones.

1.2. Literature review

We reviewed various scientific publications related to banknote analysis.

For example in [1] and [2] the authors tackled the automatic banknote denomination recognition problem by using digital image processing techniques. However in our proposed algorithm we not only determine banknote denomination but, in addition, perform a procedure aimed to identify the veracity of the banknote by analyzing intaglio marks with digital image processing techniques.

On the other hand, in [3] and [4] the authors were concerned about banknotes veracity but did not contemplate the use of an enclosure to standardize image light conditions. In comparison, our proposed solution does use an enclosure to ensure uniform illumination across all processed training and validation images.

Publications such as [5] and [6] that are based on digital image processing techniques have some flaws, as they did not consider the use of supervised learning algorithms to solve the classification task. On the contrary, our proposed solution uses a support vector machine (SVM) to tackle the classification problem after a training process performed with labeled images.

Some recent publications include the use of artificial intelligence [7] and deep learning [8] to detect counterfeit currency. However, these algorithms were designed and tested to work on other currencies such as dollars, euros, etc. Its performance on peruvian banknote has not been tested and they

don't use the intanglio marks as a classification parameter, which is the most difficult detail to forge.

Likewise, convolution techniques and neural networks are used in [8] which demand a lot of computational load and therefore requires to be implemented in hardware boards such as Jetson TX2. In contrast, we propose a low complexity algorithm that can be easily implemented on a small single-board computer (such as Raspberry Pi 3) with very satisfactory results.

1.3. Contribution and paper organization

Given that intaglio marks (Banco Central de Reserva del Perú, BCRP: "Elementos de seguridad de los billetes de 100 soles", Available: http://www.bcrp.gob.pe) are banknotes difficult-to-falsificate features we decided to design an algorithm that analyzes them (see Figure 1 for a view of some intaglio marks). In order to analyze intaglio marks we capture banknote images using a digital camera and an enclosure to guarantee proper light conditions. These images are then analyzed and enhanced using image processing techniques and a support vector machine (SVM) to determine whether the image corresponds to a legitimate or a fake banknote. Thus, our proposed system offers an automatic diagnostic on the veracity of the banknote analyzed.
Figure 1: Intaglio marks [9].

Taking all these considerations into account, our methodology was able to perform a 96.5% of detection over the image dataset comprising 240 banknotes provided by the Central Reserve Bank of Peru (BCRP).

The amount of 240 samples was the result of the source of information provided by the Central Reserve Bank of Peru.

The selection of these samples had the following filters.

- The number of samples for the indicated denominations is reduced to 2 groups.
- The first group is confirmed by banknotes that did not enter into circulation, i.e., that did not deceive people.
- The second group of banknotes belongs to the group that entered circulation, i.e. the user did not detect the counterfeit banknote at the beginning.

For the validation process the second group was selected. In this case, BCRP specialists selected the banknotes that presented the greatest difficulty in detecting counterfeits. The details of the proposed algorithm, the results of the tests and the conclusions will be described in the following sections.

2. Proposed algorithm

For a better understanding, the distinctive characteristics of Peruvian banknotes will be first described and then a discussion of the main blocks of our algorithm will be presented.

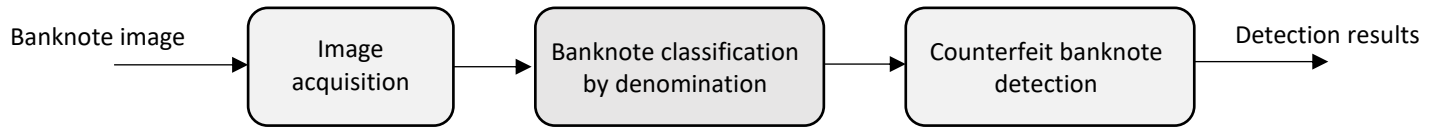
(a)   (b)   (c)
Figure 2: Intaglio marks for a (a) Fifty soles banknote, (b) One-hundred soles banknote, (c) Two-hundred soles banknote.


Figure 3: Block diagram of the proposed algorithm

2.1. Banknotes characteristics

We will focus our analysis on the intaglio marks from 50, 100 and 200 soles banknotes (Banco Central de Reserva del Perú, BCRP: "Nuevos billetes de 50, 100 y 200 soles", Available: http://www.bcrp.gob.pe). These marks can be appreciated by the human eye only if banknotes are positioned as in Figure 2 and with good illumination conditions. These marks depend on the banknote denomination, for this reason it is important to first determine the banknote denomination before proceeding with the analysis of intaglio marks.

In Figure 3 we present the block diagram of the proposed algorithm. In the following sections we will describe each block.

(a)   (b)

(c)

Figure 4: Sample of acquired images for (a) Fifty soles banknote, (b) One-hundred soles banknote, (c) Two-hundred soles banknote.

2.1. Image acquisicion

We used a closed enclosure to control light conditions, the enclosure was illuminated by a 3W white light LED. To capture the intaglio marks, every picture was taken from the right side of the banknote obverse. The sample banknotes are placed into the enclosure using mechanical guides that help with their correct and quick placement. LED lights were positioned so the area of interest would be distinguished more clearly.

A Raspberry v1 camera was used to take the picture, this camera has a CMOS OmniVision OV56476 with 5 megapixels (2592 x 1944 pixels resolution). The banknotes region of interest has RGB format (true color, 24 bits per pixel). Each primary component is defined as $I_R(x,y)$, $I_G(x,y)$ and $I_B(x,y)$, where (x,y) are the spatial coordinates.

All the computations were made by the Raspberry Pi 3B + single board computer which is compatible with the camera used and can perform all the required processing steps in less than 3 seconds with low power consumption (5 V /2.5 A). The acquired image is set to M=1644 rows and N=2592 columns.

In Figure 4 we showed 50, 100 and 200 soles banknotes taken under the described conditions.

2.2. Banknote classification by denomination

Given the captured images, we defined three regions of interest that were fixed so we can identify relevant characteristics in each banknote. These regions of interest can be expressed as:

Region 1:

$$I1_R(x,y) = I_R(x+400, y+500) \tag{1}$$

$$I1_G(x,y) = I_G(x+400, y+500) \tag{2}$$

$$I1_B(x,y) = I_B(x+400, y+500) \tag{3}$$

where:

$$x = 0,1,\dots,600$$
$$y = 0,1,\dots,500$$

Region 2:

$$I2_R(x,y) = I_R(x+780, y+750) \tag{4}$$

$$I2_G(x,y) = I_G(x+780, y+750) \tag{5}$$

$$I2_B(x,y) = I_B(x+780, y+750) \tag{6}$$

where:

$$x = 0,1,\dots,519$$
$$y = 0,1,\dots,699$$

Region 3:

$$I3_R(x,y) = I_R(x + 780, y + 1500) \qquad (7)$$

$$I3_G(x,y) = I_G(x + 780, y + 1500) \qquad (8)$$

$$I3_B(x,y) = I_B(x + 780, y + 1500) \qquad (9)$$

where:

$$x = 0,1, \dots, 519$$
$$y = 0,1, \dots, 1024$$

These regions were chosen because they allow us to differentiate between banknotes denomination by their coloration (See Fig. 5 for an example in a 200 soles banknote).

Figure 5: Two-hundred soles banknote with the three regions of interest (red boxes).

We averaged color components in every region of interest as features. To compute these averages, we use the following equations:

$$P1_R = \frac{1}{M1 \times N1} \sum_{x=0}^{M1-1} \sum_{y=0}^{N1-1} I1_R(x,y) \qquad (10)$$

$$P1_G = \frac{1}{M1 \times N1} \sum_{x=0}^{M1-1} \sum_{y=0}^{N1-1} I1_G(x,y) \qquad (11)$$

$$P1_B = \frac{1}{M1 \times N1} \sum_{x=0}^{M1-1} \sum_{y=0}^{N1-1} I1_B(x,y) \qquad (12)$$

where M1 = 601 and N1 = 501

$$P2_R = \frac{1}{M2 \times N2} \sum_{x=0}^{M2-1} \sum_{y=0}^{N2-1} I2_R(x,y) \qquad (13)$$

$$P2_G = \frac{1}{M2 \times N2} \sum_{x=0}^{M2-1} \sum_{y=0}^{N2-1} I2_G(x,y) \qquad (14)$$

$$P2_B = \frac{1}{M2 \times N2} \sum_{x=0}^{M2-1} \sum_{y=0}^{N2-1} I2_B(x,y) \qquad (15)$$

where M2 = 520 and N2 = 650

$$P3_R = \frac{1}{M3 \times N3} \sum_{x=0}^{M3-1} \sum_{y=0}^{N3-1} I3_R(x,y) \qquad (16)$$

$$P3_G = \frac{1}{M3 \times N3} \sum_{x=0}^{M3-1} \sum_{y=0}^{N3-1} I3_G(x,y) \qquad (17)$$

$$P3_B = \frac{1}{M3 \times N3} \sum_{x=0}^{M3-1} \sum_{y=0}^{N3-1} I3_B(x,y) \qquad (18)$$

where M3 = 520 and N3 = 1025

We compound this averages in a feature vector V_{C1} defined as:

$$V_{C1} = [P1_R \ P1_G \ P1_B \ P2_R \ P2_G \ P2_B \ P3_R \ P3_G \ P3_B] \qquad (19)$$

The compound feature vector V_{C1} is then classified using a Support Vector Machine (SVM) with a radial basis function kernel [10]. This kernel, which is described as a Gaussian function, was chosen because of its high performance to classify nonlinear data, as it is in our case. SVM was selected as the classifier because of its better performance compared with other techniques like KNN and because of its robustness to classify nonlinear data [11]. We used 70% of the banknotes for training and 30% for testing. We obtained a 99% of accuracy in this task as will be detailed in the results section.

2.3. Counterfeit banknote detection

After banknote classification by denomination, we now proceed to determine if the banknote is false or legitimate. To do so, we first isolate a counterfeit detection region of interest per banknote denomination as follows:

For fifty soles banknotes:

$$I4_R(x,y) = I_R(x + 760, y + 1460) \qquad (20)$$

$$I4_G(x,y) = I_G(x + 760, y + 1460) \qquad (21)$$

$$I4_B(x,y) = I_B(x + 760, y + 1460) \qquad (22)$$

where:

$$x = 0,1, \dots, 520$$
$$y = 0,1, \dots, 365$$

For hundred soles banknotes:

$$I4_R(x,y) = I_R(x + 630, y + 465) \qquad (23)$$

$$I4_G(x,y) = I_G(x + 630, y + 465) \qquad (24)$$

$$I4_B(x,y) = I_B(x + 630, y + 465) \qquad (25)$$

where:

$$x = 0,1, \dots, 295$$
$$y = 0,1, \dots, 550$$

For two-hundred soles banknotes:

$$I4_R(x,y) = I_R(x + 200, y + 545) \qquad (26)$$

$$I4_G(x,y) = I_G(x + 200, y + 545) \qquad (27)$$

$$I4_B(x,y) = I_B(x + 200, y + 545) \qquad (28)$$

where:

$$x = 0,1, \dots, 500$$
$$y = 0,1, \dots, 255$$

In Figure 6, we zoom in these regions of interest.

After the selection of the counterfeit detection region of interest, we compute averages in each component using the following equations:

$$P4_R = \frac{1}{M4 \times N4} \sum_{x=0}^{M4-1} \sum_{y=0}^{N4-1} I4_R(x,y) \tag{29}$$

$$P4_G = \frac{1}{M4 \times N4} \sum_{x=0}^{M4-1} \sum_{y=0}^{N4-1} I4_G(x,y) \tag{30}$$

(a)   (b)

(c)
Figure 6: Amplified regions of interest for counterfeit banknote detection in the case of a (a) Fifty soles banknote, (b) One-hundred soles banknote, (c) Two-hundred soles banknote.

$$P4_B = \frac{1}{M4 \times N4} \sum_{x=0}^{M4-1} \sum_{y=0}^{N4-1} I4_B(x,y) \tag{31}$$

Every color component is then enhanced using an embossing filter [12] which is designed according to the banknote denomination, as is shown in equations (32), (33) and (34).

$$H1_{50} = \begin{bmatrix} -2 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 2 \end{bmatrix} \tag{32}$$

$$H1_{100} = \begin{bmatrix} -3 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 3 \end{bmatrix} \tag{33}$$

$$H1_{200} = \begin{bmatrix} -2 & 0 & -2 \\ 0 & 1 & 0 \\ 2 & 0 & 2 \end{bmatrix} \tag{34}$$

We then obtain the filtered components $I4'_R(x,y)$, $I4'_G(x,y)$ and $I4'_B(x,y)$ which have highlighted textures as can be seen in Figure 7.
Figure 7: Results of the embossing filter in every region of interest for 50,100 and 200 soles banknotes.

To magnify edges, we applied Sobel filters [13] over the embossing components. In the case of the one-hundred banknote, we used a sobel variation filter due to the diagonal orientation of intaglio marks in this banknote. Final sobel filters are defined in equations (35), (36) and (37).

$$H2_{50} = \begin{bmatrix} 1 & 2 & 1 \\ 0 & 1 & 0 \\ -1 & -2 & 1 \end{bmatrix} \times 0.5 \tag{35}$$

$$H2_{100} = \begin{bmatrix} 2 & 0 & 0 \\ 2 & 0 & -10 \\ 0 & 0 & 2 \end{bmatrix} \times 0.7 \tag{36}$$

$$H2_{200} = \begin{bmatrix} 1 & 2 & 1 \\ 0 & 1 & 0 \\ -1 & -2 & -1 \end{bmatrix} \times 0.5 \tag{37}$$

After this step, we obtain as results $I4''_R(x,y)$, $I4''_G(x,y)$ and $I4''_B(x,y)$. Sobel filters are designed to sharp edges and variations [14], as we can see in Figure 8.

Figure 8: Sobel filter results for 50, 100 and 200 soles banknotes.

Now, the components are binarized using a threshold that varies with the banknote denomination [15]. Since constant illumination conditions are guaranteed, constant thresholds are used for each denomination in the binarization process. The resulting components are expressed using the following equations:

For fifty soles banknotes:

$$V4_R(x,y) = \begin{cases} 1, & I4''_R(x,y) \geq 40 \\ 0, & I4''_R(x,y) < 40 \end{cases} \tag{38}$$

$$V4_G(x,y) = \begin{cases} 1, & I4''_G(x,y) \geq 40 \\ 0, & I4''_G(x,y) < 40 \end{cases} \tag{39}$$

$$V4_B(x,y) = \begin{cases} 1, & I4''_B(x,y) \geq 40 \\ 0, & I4''_B(x,y) < 40 \end{cases} \tag{40}$$

For one-hundred soles banknotes:

$$V4_R(x,y) = \begin{cases} 1, & I4''_R(x,y) \geq 130 \\ 0, & I4''_R(x,y) < 130 \end{cases} \tag{41}$$

$$V4_G(x,y) = \begin{cases} 1, & I4''_G(x,y) \geq 130 \\ 0, & I4''_G(x,y) < 130 \end{cases} \tag{42}$$

$$V4_B(x,y) = \begin{cases} 1, & I4''_B(x,y) \geq 130 \\ 0, & I4''_B(x,y) < 130 \end{cases} \tag{43}$$

For two-hundred soles banknotes:

$$V4_R(x,y) = \begin{cases} 1, & I4''_R(x,y) \geq 150 \\ 0, & I4''_R(x,y) < 150 \end{cases} \tag{44}$$

$$V4_G(x,y) = \begin{cases} 1, & I4''_G(x,y) \geq 150 \\ 0, & I4''_G(x,y) < 150 \end{cases} \tag{45}$$

$$V4_B(x,y) = \begin{cases} 1, & I4''_B(x,y) \geq 150 \\ 0, & I4''_B(x,y) < 150 \end{cases} \tag{46}$$

The binarization process allowed us to reduce information from grayscale images [16]. Instead of an 8-bit image, now we have a 1-bit image, as seen in Figure 9.

Figure 9: Results from the binarization process

After this, we filtered the results using the aperture morphological operation. We do this to eliminate some noisy elements and enhance visibility of objects of interest (intaglio marks) [17]. Structuring elements are designed depending on the banknote denomination as follows.

$$\mathbf{H3_{50}} = \begin{bmatrix} 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 \\ 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 \end{bmatrix} \tag{47}$$

$$\mathbf{H3_{100}} = \begin{bmatrix} 0 & 0 & 1 \\ 0 & 1 & 0 \\ 1 & 0 & 0 \end{bmatrix} \tag{48}$$

$$\mathbf{H3_{200}} = \begin{bmatrix} 1 & 1 & 0 \\ 1 & 0 & 1 \\ 0 & 1 & 1 \end{bmatrix} \tag{49}$$

$$\mathbf{I4'''_n} = (\mathbf{V4_n} \ominus \mathbf{H3_n}) \oplus \mathbf{H3_n} = \mathbf{V4_n}°\mathbf{H3_n} \tag{50}$$

Thus, we obtain new image components $\mathbf{I4'''_R}$, $\mathbf{I4'''_G}$ and $\mathbf{I4'''_B}$. Figure 10 shows some results.

We then apply connectivity 4 to count the number of objects in each component. The number of objects per component are denominated $K4_R$, $K4_G$ y $K4_B$. We use these values to create a new compound feature vector V_{C2} as follows:

$$V_{C2} = [P4_R \ P4_G \ P4_B \ K4_R \ K4_G \ K4_B] \tag{51}$$

This feature vector is classified using an SVM trained per each banknote denomination (i.e. we used 3 SVMs). Thus, we used independent hyperplanes to perform our classification for our 6-dimensional vector [18]. Again, we used a radial basis function kernel [11] and 70% of the banknotes for training and 30% for testing.

Figure 10: Results after aperture morphological operation using specially designed structural elements.

3. Results

In this section we present our results for the classification and detection tasks using our 240 banknote dataset which are distributed as shown in Table 1. The ground-truth veracity of the banknotes was determined by a specialist of the BCRP.

Result for the banknote classification by denomination task are presented in Table 2. As we used 70% of the data to train the SVM classifier these results correspond to the remaining 30%. To compute our performance metric we divide the number of correct results by total number of samples.

As we can see, the results from this step were almost perfect, we only had one mistake in the classification of a one-hundred soles banknote.

In Table 3 we show the results for the detection process.

Results obtained in the detection process are satisfactory. There was only one mistake on a 50 soles banknote and another one on a 100 soles banknote.

Table 1: Banknotes distribution

Denomination	Veracity	Number of samples
50	Legitimate	32
	Fake	50
100	Legitimate	40
	Fake	49
200	Legitimate	32
	Fake	37

Table 2: Results for the classification process

Denomination	Number of test samples	Correctly classified samples	Performance
50	22	22	100%
100	33	32	97%
200	21	21	100%

Table 3: Results for the detection process.

Denomination	Number of test samples	Correctly detected samples	Percentage of correct detection
50	25	24	96%
100	28	27	96.4%
200	21	21	100%

In Tables 4, 5 and 6, we show correct and incorrect detections of the true and false banknote by denomination. In Table 4, a legitimate 50 soles banknote was incorrectly detected as false. This was caused by a deteriorated banknote that was bent on several places. In Table 5, a legitimate 100 soles banknote was incorrectly detected as false. This was caused by an incorrect insertion of the banknote on the image acquisition zone.

Table 4: Results for the 50 soles banknote detection process

Sample\Result	Legitimate	Fake
Legitimate	14	1
Fake	0	10

Table 5: Results for the 100 soles banknote detection process

Sample\Result	Legitimate	Fake
Legitimate	14	1
Fake	0	12

Table 6: Results for the 200 soles banknote detection process

Sample\Result	Legitimate	Fake
Legitimate	7	0
Fake	0	14

The average performance (according with Table 3) is then 97.47%. We observed that mistakes were generated because of banknote positioning problems (they were not inserted correctly or maybe the banknote was bent so its image could not be acquired correctly).

According to Table 3, the average detection performance of the proposed algorithm is 97.47%. The detection errors were mainly generated by banknote positioning problems, i.e. the banknotes were not inserted correctly or perhaps the banknote was bent, so its image could not be acquired correctly.

These problems could be solved by the use of additional hardware or by training the SVM classifier with images with these imperfections.

Finally, the total effectiveness of our algorithm $P_{(A)}$ (including classification and detection) is computed using the following equation:

$$P_{(A)} = P_{(B)} \times P_{(C/B)} \qquad (52)$$

where $P_{(B)}$ is the percentage of correct classifications, $P_{(C/B)}$ is the percentage of correct detections given a correct classification. Table 7 summarizes our final results.

Then, the total effectiveness average is 96.5%, which are results that could improve with a bigger sample. Compared to other studies with different currencies, it reached a higher percentage than Ballado's (95%) [6] and a lower percentage than Han's (100%) [7].

Table 7: Total effectiveness

Denomination	$P_{(B)}$	$P_{(C/B)}$	$P_{(A)}$
50	100%	96%	96%
100	97%	96.4%	93.5%
200	100%	100%	100%

4. Conclusions

The proposed algorithm was able to identify the denomination and veracity of Peruvian banknotes that were manufactured from 2009 onwards using the intanglio marks as a deciding factor, and support vector machines (SVM). The practical operation of this algorithm was validated by specialists from the Central Reserve Bank of Peru (BCRP). The few cases in which the algorithm failed were caused by the deteriorated state of the banknote. It is suggested not to use banknote that is ripped or folded in order to avoid missreadings.

Our automatic algorithm was efficient and can be used by any user who needs to determine the veracity of Peruvian 50, 100 or 200 soles banknotes.

The algorithm was entirely developed in Python and was embedded into a Raspberry single board computer. Additionally, does not consume high computational resources.

As we increase the number of training samples we can improve SVM performance for classification.

Conflict of Interest

The authors declare no conflict of interest.

Quality of Life in People with Type 2 Diabetes Residing in a Vulnerable Area in the Los Olivos district - Lima

Rosa Perez-Siguas*, Eduardo Matta-Solis, Hernan Matta-Solis

Research Directorate, Universidad María Auxiliadora, 15408, Lima-Perú

ABSTRACT

Non-communicable chronic diseases are more frequent in developing countries, having a significant impact on morbidity, mortality, health care costs and productivity. A study indicates that physical exercise, glucose control, complications, hypertension, duration of diabetes, diet and depression are associated with the quality of life in patients with type 2 diabetes. The purpose of the study is to determine the quality of life in people with Type 2 Diabetes who reside in a vulnerable area of Los Olivos. The focus of this study is quantitative, its design is descriptive because it allows the study population to be described at a given moment. The population was 173 people with type 2 diabetes, from the Juan Pablo II Confraternity Maternal and Child Center in Los Olivos. The diabetes 39 questionnaire (D-39) was applied, made up of 39 items grouped into five dimensions, which measures the quality of life in diabetes. The results showed a half quality of life (51.4%), followed by high (26%) and low (22.5%). These results support the importance of promoting and educating about healthy habits in the diabetic patient, so that they can maintain an adequate quality of life. Type 2 diabetes is a silent and progressive disease in its initial stage, public health systems must increase efforts to make timely diagnoses, where the disease can be controlled avoiding the presence of complications and sequelae that can be fatal for the patient.

1. Introduction

Worldwide, the total number of people detected with type 2 diabetes mellitus (DM2) has increased considerably in the last three decades, although we know that diabetes mellitus is one of the noncommunicable diseases that can cause death [1].

DM2 is well known globally, since the rapid increase in the prevalence of this disease is evidenced and it has been confirmed that in 2019, 488 million in the ages of 20 to 99 years old suffer from this disease. Where the last decade the countries of type two diabetes mellitus have been the countries of China, India, the United States, Pakistan and Brazil respectively [2].

Diabetes is an incessant chronic condition where it causes a high level of sugar in the blood [3]. This is due to the decrease in the mechanism of beta cells of the pancreas [4], generating various stimuli in various parts of the body, among them, they are pancreatic failure, increased risk of cardiovascular system diseases, hypertension, kidney failure, neuropathy, problems with foot vascularization, ketoacidosis, visual problems, among others [5], [6].

The International Diabetes Federation (IDF) warned that the number of people with T2DM disease will rise worldwide from 325 million in 2017 to 629 million with diabetes in 2045 [7].

In Latin America, the IDF estimated that 9.4% of adults had diabetes and 7.9% had impaired fasting blood glucose (IFG) in 2015, and these numbers are expected to increase to 11.9 % and 9.4%, respectively, in 2040 [7].

In Latin America and the Caribbean, since 2015 it has been calculated in people aged 20 years and over, who suffered from DM2. Therefore, DM2 has represented an economic burden in the countries of Latin America and the Caribbean in 2015 [8].

The factors that mainly compromise health and cause DM2 worldwide are overweight and obesity, sedentary lifestyle and an inadequate diet [9][10]. Also, complications at the cardiovascular level in people with DM2 due to the factors that compromise their health are the main causes of morbidity and mortality, in addition to the kidney complications present in diabetic people [1].

Although, when you have DM2 and other cardiovascular diseases that occur at a younger age, they tend to develop

aggressively, compromising the health of the diabetic person [11]. It can also lead to low life expectancy and this as a consequence causes a decline in quality of life [12].

In the same way, heart disease and other cardiovascular diseases can be generated quickly if the diabetic patient is depressed, mental health in diabetic patients is important since it maintains life expectancy and thus there is no complications in the patient [13].

In [14], the authors mentioned differences between social overload and sexual behavior, where they specified that sexual behavior had a high impact on the quality of life of the Brazilian population in the study and that social burden affected the quality of life, out of shame to present DM2, to be called diabetic and to present DM2 interrupting their family life.

In [15], the authors mentioned in their study the evaluation of the quality of life in people with DM2 and that in their results it is observed that the social burden domain is the one that has the highest incidence in quality of life (56.26 ± 12.07) followed by the domain of sexual functioning (54.35 ± 9.47), the domain of anxiety and worry (54.33 ± 7.76), the domain of energy and mobility (51.46 ± 8.73) and the domain of diabetes control (50.08 ± 10.84) concluding that the Sex life and mobility of the diabetic person is affected by age.

In [16], it was observed in the results of quality of life in the participants where 62.3% had an average quality of life, regarding the subjective perception of the state of health, 46.7% considered having adequate health well-being, expressing that a healthy diet, physical activities and a controlled treatment will allow an improvement in the quality of life in diabetic patients in the long term.

In [17], the authors interpreted that patients who have regular consultations and treatments for diabetes control, expressed that they improved their quality of life, on the other hand, in patients with comorbidities they demonstrated a considerable decrease in their quality of life. Its systematic review study, it was observed in 31 studies in patients with DM2, that 50% of the studies reported that diabetic patients received some treatment to control their disease.

In [18], the authors in their study of quality of life and depression in patients with diabetes, interpreted that 54.1% of the majority of participants perceived depression with the Patient Health Questionnaire-9 (PHQ-9)score of 6.15 ± 5.01 on a scale of 0-27. On a scale of 0 to 100, the highest mean quality of life score was reported in the social relationship domain (57.32 ± 11.83), followed by the environment domain (54.71 ± 7.74), psychological health (53.25 ± 10.32) and physical health (50.74 ± 11.83). Concluding that a study should be carried out on depression, since this factor affects more the quality of life, being associated with negativity, affecting its treatment and glycemic control of diabetes. In the absence of a timely and pertinent detection of depression, emotional problems may be exacerbated, and therefore the quality of life and well-being would be affected, all this will ultimately trigger an oversight in the health of the diabetic, and their adherence to treatment and control of the disease will not be fully assumed. This could be translated into the presence of hyperglycemia symptoms, which is the beginning for the irreversible damage to the target organs of the disease to be evident.

Diabetes is a health problem that affects global public health, in Perú, the care and monitoring of people affected with this disease is essential, since it will allow this disease not to evolve and generate sequelae or death in the person. Valuing the quality of life allows generating scientific evidence that serves as a basis to improve health strategies aimed at the care and care of these patients who become vulnerable due to the systemic damage that is characteristic of this type of metabolic disease. This non-communicable disease is considered one of the 11 health problems (health problem no. 3: metabolic and cardiovascular diseases) indicated in the document Prioridades Nacionales de Investigación en Salud en Perú 2019-2023, prepared by the Instituto Nacional de Salud and the endorsement of the Ministerio de Salud of our country.

The main objective of the research work is to determine the quality of life in people with Type 2 Diabetes who reside in a vulnerable area of Los Olivos. Due to the complications and costs that type 2 diabetes generates for the patient, the family, and the country; it is of utmost importance to take care of the health of these patients, it is necessary that they come to their medical control periodically where their levels of glycemia, weight and the impact of the medication are mainly valued. But it knows that the disease and its pathophysiology generate an impact in other areas such as social, emotional, limitations in the development of activities of daily living, etc., therefore it is important to assess the quality of life related to the health of these people, because, it will have evidence of how the disease affects other dimensions of the patient's life. It means a scientific evidence that allows health and nursing personnel to improve their professional practice aimed at the care and self-care of these people affected by this systemic disease.

Therefore, the objective of the research work is to determine the quality of life in people with Type 2 Diabetes living in a vulnerable area of Los Olivos - Lima.

The hypothesis of the research work is that type 2 diabetes mellitus negatively affects the quality of life of the patient, even though they have knowledge about the risk of the disease reported in their routine controls.

2. Methods

2.1. Research type and Design

The present study is of a quantitative approach, since the main variable will be measured with a quantitative data collection instrument and will be used for the analysis of the data collected, mainly descriptive statistical processes. The methodological design is a descriptive and cross-sectional research, it is descriptive because reality is described as it is presented and it is transversal because the process of measuring the variable was carried out only once in time by each participant [19].

2.2. Population and sample

We worked with the sample of the total population of diabetic patients in the jurisdiction of each health center. According to the

initial standard, 187 participants with type 2 diabetes were identified, then 14 of them did not decide to participate by their own decision or did not meet some of the selection criteria (inclusion and exclusion) indicated below, finally the population was made up of 173 patients diagnosed with type 2 diabetes.

Table 1: Sociodemographic data in people with type 2 diabetes residing in a vulnerable area in Los Olivos (n=173)

Information of the participants	Total		Value Sig. (p)
	n	**%**	
Total	173	100	
Age			0.000
Adult (30 to 59 years old)	91	52.6%	
Older Adult (60 and over)	82	47.4%	
Sex			0.730
Female	88	50.9	
Male	85	49.1	
Marital Status			0.171
Single	6	3.5	
Married	92	53.2	
Widowed	9	5.2	
Cohabitant	55	31.8	
Divorced	11	6.4	
Types of Family			0.578
Nuclear	104	60.1	
Extended	32	18.5	
Expanded	26	15.0	
Single Parent	9	5.2	
Reconstituted	2	1.2	
Degree of Study			0.093
No Education	1	0.6	
Primary Education	18	10.4	
Secondary Education	140	80.9	
Higher University Education	2	1.2	
Higher Non-university Education	12	6.9	
Occupation Condition			0.138
Stable Worker	4	3.2	
Eventual	114	65.9	
No Occupation	44	25.4	
Retired	11	6.4	

In Table I, it has the sociodemographic data of the study participants, there were 173 people affected with diabetes. The minimum age was 38 years old; the maximum was 77 years old and the mean was 58.35 years.

Regarding the participant's sex, 88 that represent 50.9% correspond to female and 85 that represent 49.1% correspond to male. Regarding the degree of study, 140 participants representing 80.9% have secondary education, 18 participants representing 10.4% have primary education, 12 participants representing 6.9% have Higher non-university education, 2 participants representing 1.2% have higher university education and 1 participant representing 0.6% have no education. Regarding marital status, the married with 92 (53.2%) cases predominate, followed by the

cohabitant with 55 (31.8%) cases, divorced with 11 (6.4%) cases, widowed with nine (5.2 %) cases and finally single with 6 (3.5%) cases. Regarding the type of family, nuclear families predominate with 104 (60.1%) cases, followed by extended families with 32 (18.5%) cases, expanded with 26 (15%) cases, single parent with nine (5.2%) cases and reconstituted with two (1.2%) cases. Regarding the occupation condition, the eventual prevails with 114 (65.9%) cases followed by the no occupation with 44 (25.4%) cases, retired with 11 (6.4%) cases, and finally stable worker four (2.4%) cases.

One aspect to highlight is that within the sociodemographic data. It was found that there is a significant relationship between age and quality of life with a (p=0.000).

2.3. Inclusion Criteria

The inclusion criteria are adults (30 to 59 years old) and older adults (60 to more years old) with a medical diagnosis of type 2 diabetes, also who are in treatment and are continuing patients (have at least one control medical consultation) in the health center of the jurisdiction. Moreover, participants who are residents in the area with their own home, also who voluntarily agreed to participate in the study and agreed to sign the informed consent and finally, those who did not meet at least one of the selection criteria were not included in the study.

2.4. Technique and Instrument

To measure the quality of life in Diabetes, the data collection instrument called the Diabetes 39 questionnaire was used. Before its application in the field work, its validity and reliability were verified.

To measure the quality of life in Diabetes, the data collection instrument called the Diabetes 39 Questionnaire was used, this is an instrument originally developed in the English language and specifically designed to determine the health-related quality of life of people with diabetes type 2 mellitus. It has currently been validated and translated into the Spanish language and its use is widespread in many other languages. This instrument is made up of 39 items which are distributed in 5 dimensions or factors: Energy-Mobility, which refers to the limitation of the level of energy and daily activities, decrease in visual acuity and disturbed sleep (consisting of 15 items); Diabetes control, which refers to the impact of medical treatment based on the therapeutic plan, glycemic control and diet (consisting of 12 items); Anxiety-concern, which are the concerns that the person has about economic issues, life stresses and future life (consisting of 4 items); Social burden, which refers to the limitations of diabetes mellitus that interfere with family and friends life (made up of 5 items) and sexual functioning, which refers to the impact of diabetes on sexual abilities and functioning (made up of three items) [20][21].

Validity was determined by expert judgment, consulting five health professionals about the content and statements of the instrument used in this study. The content validity of the instrument was 86.2%, which is interpreted as good. Then a pilot study was developed in which 30 people between adults and older adults participated. Statistical validity and reliability were calculated with this sample. Statistical validity was obtained using the Kaiser-Meyer-Olkin (KMO) sample adequacy tests and the

Bartlett sphericity test. The sample adequacy test gave a score of 0.963 (KMO>0.5) and the Bartlett specificity test gave a significance level of 0.000 (p<0.001). Both tests affirm the instrument's validity hypothesis. The reliability of the instrument was determined based on the Cronbach's alpha coefficient. A high value of internal consistency was obtained between the results of the instrument which is 0.996 (α>0.6), confirming the reliability of the measuring instrument.

Participants answer how much their quality of life has affected in the last month by an action expressed by each item, marking an X on a modified visual analog type scale, whose scale of values goes from one to seven, where one corresponds if it is not affected at all and seven corresponds to extremely affected quality of life [20].

2.5. Place and Application of the Instrument

The data collection process was carried out during the last quarter of 2019. Prior, coordination was carried out to obtain data on patients with type 2 diabetes who live in the jurisdiction of the Health Establishment called the Centro Materno Infantil Confraternidad - Juan Pablo II located in the Los Olivos district. Each participant was visited at home, spending with each of them an approximate time of 15 to 20 minutes to complete the data sheet. Nursing staff was the one who mainly participated in the work of filling in data sheets, this due to their important participation in Primary Health Care areas such as Family Health, Community Health and Health Promotion. In addition, it had the support of the health promoters in the area, who facilitated the identification of the participants' homes. At the end of completing each data sheet, it was revised to ensure that it has its complete data coding and entry.

For the data analysis, a guide to the diabetes instrument Diabetes 39 was used, which gives details of how the quality of life in diabetes is evaluated for each of the five dimensions. The software used for data entry and management were Excel and the Statistical Package for the Social Sciences (SPSS).

3. Results

In Table 2, it can see the quality of life in people with type 2 diabetes, where the medium quality of life predominates with 51.4% (n = 89), followed by the high quality of life with 26% (n=45), and finally the low quality of life with 22.5% (n = 39).

Table 2: Quality of Life in people with Type 2 Diabetes residing in a vulnerable area in Los Olivos (n=173)

Quality of life	n	%
Low quality of life	39	22.5
Medium quality of life	89	51.4
High quality of life	45	26.0
Total	173	100.0

In Table 3, it can see the quality of life in its energy and mobility dimension, where the medium quality of life predominates with 69.4% (n = 120), followed by the high quality of life with 26% (n = 45), and finally the low quality of life with 4.6% (n = 8).

In Table 4, it can see the quality of life in its diabetes control dimension, where the medium quality of life predominates with

51.4% (n = 89), followed by the high quality of life with 26% (n = 45), and finally the low quality of life with 22.5% (n = 39).

Table 3: Quality of life according to its energy and mobility dimension, in people with type 2 Diabetes residing in a vulnerable area in Los Olivos (n=173)

Energy and mobility	n	%
Low quality of life	8	4.6
Medium quality of life	120	69.4
High quality of life	45	26.0
Total	173	100.0

Table 4: Quality of life according to its diabetes control dimension, in people with type 2 diabetes residing in a vulnerable area in Los Olivos (n=173)

Diabetes control	n	%
Low quality of life	39	22.5
Medium quality of life	89	51.4
High quality of life	45	26.0
Total	173	100.0

In Table 5, it can see the quality of life in its anxiety and concern dimension, where the medium quality of life predominates with 52% (n = 90), followed by the high quality of life with 26% (n = 45), and finally the low quality of life with 22% (n = 38).

Table 5: Quality of life according to its anxiety and concern dimension, in people with type 2 Diabetes residing in a vulnerable area in Los Olivos (n=173)

Anxiety and concern	n	%
Low quality of life	38	22.0
Medium quality of life	90	52.0
High quality of life	45	26.0
Total	173	100.0

In Table 6, it can see the quality of life in its social burden dimension, where the medium quality of life predominates with 52% (n = 90), followed by the high quality of life with 26% (n = 45), and finally the low quality of life with 22% (n = 38).

Table 6: Quality of life according to its social burden dimension, in people with type 2 Diabetes residing in a vulnerable area in Los Olivos (n=173)

Social Burden	n	%
Low quality of life	38	22.0
Medium quality of life	90	52.0
High quality of life	45	26.0
Total	173	100.0

The results of this study constitute scientific evidence that allows to understand the health situation of these patients with type 2 diabetes in a greater dimension, which allows a more holistic and comprehensive assessment of the evolution of their disease, thus the professional health will make more timely and relevant decisions that translate into improving their well-being.

4. Discussion

This research work on quality of life in diabetes is part of the research line of chronic non-communicable diseases, this one has an approach from the perspective of health promotion that should be promoted from primary health care.

Regarding the quality of life in people with diabetes, the medium quality of life prevailed, therefore, the hypothesis established in the research work is accepted, that is, the person

with diabetes mellitus has an unsatisfactory quality of life, even though they have knowledge about the risks that this disease generates.

The results interpret that diabetes mellitus negatively exposes the quality of life of the person, factors such as sedentary lifestyle and inadequate nutrition further compromise the well-being of the person. In [16], the authors argue that the quality of life in people with diabetes mellitus is not only based on rigorous treatment and physical activity in order to maintain their health, but also on the emotional support they have from their family in order to maintain their mental health and thus allow them to improve their quality of life.

In [15], the authors observed that the diabetes control dimension is affected by the time of the disease and the degree of education of the patient.

The results of glycemic control observed in patients with DM2 is low, so an approach is considered where a strategy is sought to improve knowledge about their disease and their adherence to treatment [4]. DM2 is one of the diseases that is most associated with cardiovascular diseases; studies have shown that glycemic control reduces diabetic vascular complications [3]. In [17], the authors reported that the control of diabetes and continuous treatment is very important because it allows the prevention of certain comorbidities since patients with DM2 are exposed to contracting diseases that are mainly cardiovascular.

In [14], they indicated that the quality of life was greatly affected in the items related to the social burden dimension: shame of having diabetes, being called diabetic and having diabetes interfering in their family life. This result deserves special attention in diabetes, where educational programs are carried out, to incorporate strategies that facilitate the approach of aspects related to the impact of diabetes.

Life-altering change is a diagnosis of type 2 diabetes, people must cope with the diagnosis to accept type 2 diabetes. Anxiety, depression, stress, and angst from diabetes were identified as key influential psychosocial factors. The emotional responses to the diagnosis were related to depression and anxiety. Negative styles of resignation, protest, or isolation were higher in women and were associated with poorer quality of life, while avoidance was associated with increased diabetes-related distress and depressive symptoms [10]. In [18], they argued that depression and anxiety are factors that predispose diabetic patients to a poor quality of life, because their psycho-emotional health is altered by suffering from the disease and also having a negative attitude, sadness and shame as this interrupts their daily routines.

People with DM2 express concern due to insulin prices, therefore, it generates a negative impact on their state of mind [11], since personal care and living with complications related to DM2, causes negativity at a psychosocial level affecting health in it.

The frequency of depression in patients with diabetes raises the need to consider depression as an additive factor to the disease burden of this condition. Type 2 diabetes is a silent and progressive disease in its initial stage, public health systems must increase efforts to make timely diagnoses, where the disease can be controlled avoiding the presence of complications and sequelae that can be fatal for the patient [13].

5. Conclusions

It is concluded that the nursing staff has an important role in educating and guiding diabetics, with its science of care, it must contribute to generating behavioral changes in this type of patients, only in this way, it could guarantee that they have a controlled disease and carry a full and quality life.

It is concluded that nutritional counseling for patients should be considered mainly for the families of older adults and thus they are oriented in what needs the older adult is going to present at home.

It is concluded that patients must have a correct management of the disease, as well as psychological support, both family and professional, to improve their quality of life.

The limitation in the present research work is that it was considered that in Peru there is little research on quality of life in patients with diabetes, so it is necessary that several studies be carried out to improve knowledge about the quality of life in patients with diabetes.

Conflicts of Interest

The authors declare that they have no conflict of interest.

Psychological Anguish in Families due to Positive Cases of COVID-19 in the Puente Piedra District Home

Rosa Perez-Siguas*, Eduardo Matta-Solis, Hernan Matta-Solis

Research Directorate, Universidad María Auxiliadora, 15408, Lima-Perú

ARTICLE INFO

ABSTRACT

The psychological impact is alarming in families since they are exposed to high risks of contagion because their mental health is altered, therefore, the objective of the research study is to determine the Psychological Impact on families due to positive cases of COVID - 19 in the Puente Piedra district, 2020. This is a quantitative, non-experimental, descriptive, and cross-sectional study, with a population of 22 families with household members infected with COVID - 19 from the Puente Piedra district, who answered a questionnaire with sociodemographic data and the Depression, Anxiety and Stress Scale (DASS-21). In the results where can be observed, with respect to the sex data of the head of the family to whom the questionnaire was carried out, where we can observe with respect to the psychological impact on families by positive cases of COVID-19 at home in the district of Puente Piedra, where the male head of the family 13 (76.5%) of the total have a medium psychological impact and 4 (23.5%) have a low psychological impact, in the female head of the family 4 (80 %) of the total have a medium psychological impact and 1 (20%) have a low psychological impact. In conclusion, greater attention should be paid to vulnerable groups such as the young, the elderly, and women since they are more prone to contracting the disease.

1. Introduction

Concerns about the new coronavirus (COVID - 19) in the world population are becoming more alarming, because it has negative psycho-emotional and psychosocial effects on them [1], therefore the World Health Organization (WHO), maintains that the psychological impact has generated an increase in anxiety, depression and stress in the population as a result of isolation and quarantine as a result of the coronavirus pandemic [2].

In this way, the world population has had a strong impact on their daily lives, likewise while the isolation and quarantine due to the pandemic continues, the population will be experiencing different mental disorders such as nervousness, fear, anxiety, depression and insomnia, all of which can long-term impact if the pandemic can be extended for a long time [3], [4]. More concern in public health is increasing due to the increase in COVID-19 cases in the country, which has generated physical, socioeconomic and psychological impacts on the entire population [5].

Likewise, the pandemic not only affects the daily life of the world population but also has negative impacts on the person as a result of unemployment and the closure of businesses [6], and on

the family as a result of isolation at home without any visit, all this has been planned to stop the rapid spread of the coronavirus, still interrupting the daily routines of the person and family where it plays an important role in their health and physical and mental well-being [7], [8].

All this generates on a large scale forms of prevention or strategies that allow protection against this disease [9], [10], where the government implemented measures that allow the population to take care of themselves, therefore strategies such as personal protection measures, correct hygiene hands, home isolation and social distance, are measures that the population will choose in their prevention of contagion by COVID – 19 [11].

In China, it was evidenced in 1210 participants on the mental health of the general population in China, where the results showed that 53.8% had moderate and severe psychological impact, 16.5% with depressive symptoms, 28.8% with anxiety symptoms and 8.1% presented stress and each of them was between moderate and severe, concluding that women are more likely to present psychological impact than men [12].

In India, an online survey was conducted with a total of 1106 among male and female participants from 64 cities in the country,

where the data obtained in their results, the majority of respondents 66.8% presented a minimal psychological impact, 15% mild psychological impact, 5.5% moderate psychological impact and 12.7% severe psychological impact, finding that the psychological impact in women is considerably higher than in men [13].

In Spain, through a questionnaire, it was observed in 1014 participants of the general population, in relation to the threat of COVID-19 and their emotional state during quarantine, giving in their results that 51% of the population presented sadness and depression, 54.7% anxiety and 29.3% hostility; product of the threat of the coronavirus, which is reflected in the population at a cognitive and emotional level (affective and mental) as a result of the quarantine in prevention of the pandemic [14].

Another study in Spain, a study was carried out in 1161 participants between the ages of 19 to 84 years of age, which, in the results, it was observed that the psychological impact was more reflected in the fear of COVID-19, sleep problems , stress, anxiety and depression are factors that were prioritized more because they alter the mental health of the participants during confinement by COVID – 19 [15].

The objective of the research work is to determine a psychological impact on families due to positive cases of COVID-19 in the Puente Piedra district, 2020, in which, it will allow us to observe what is the psychological impact that exists in families of in the Puente Piedra district.

Therefore, the hypothesis maintains that the psychological impact on families with positive cases for COVID-19 considerably affects the psycho-emotional level in family members.

This study is important since it provides us with data based on the reality of families that are mentally vulnerable caused by the COVID-19 pandemic.

2. Methodology

2.1. Type of Study

It is a study with a quantitative approach, with a descriptive, non-experimental and cross-sectional study methodology [16].

2.2. Population

In the research work, it was made up of 22 families from the Puente Piedra district of the Micaela Bastidas Association.

2.3. Inclusion criteria

- Families with one or more family members infected with COVID - 19 at home.
- Families who signed the informed consent.

2.4. Technique and instrument

The survey was used as a data collection technique, including the DASS - 21 instrument with the objective of measuring the psychological impact in families with positive cases of COVID - 19.

The depression, anxiety, and stress scale (DASS-21), each of the three DASS scales contains 14 items, divided into subscales of 2 to 5 items with similar content. The depression scale assesses dysphoria, hopelessness, devaluation of life, self-loathing, lack of interest or participation, anhedonia, and inertia. The anxiety scale assesses autonomic arousal, skeletal muscle effects, situational anxiety, and the subjective experience of anxious affect. The stress scale is sensitive to levels of non-specific chronic arousal. It evaluates the difficulty to relax, the nervous excitement and the discomfort, agitation, or irritation, over reactivity and impatience. It consists of 4 answer alternatives, 0 "not at all", 1 "sometimes", 2 "most of the time" and 3 "most of the time" that serve to rate the degree to which they have experienced each state during last week. To obtain the final score of the DASS-21, the total score obtained must be multiplied by two (data x2) [17].

At the statistical level, the instrument was validated using the Kaiser-Meyer-Olkin (KMO) test, resulting in a sample adequacy of 0.203 and the Bartlett's Sphericity Test of 0.000 ($x^2 = 353.725$; gl = 210; p <0, 05), and to determine the reliability of the instrument, it was performed using Cronbach's Alpha statistical test, determining an internal consistency index of 0.802 ($\alpha > 0.6$).

For data processing, a matrix drawn up in the statistical program Statistics Base 26.0 (SPSS) was entered, where the analysis was carried out for the elaboration of tabulations and figures for the interpretation in their respective results and discussions.

2.5. Place and application of the instrument

The questionnaire carried out to measure the psychological impact on families due to positive cases of COVID-19 at home, was carried out in North Lima, in the Puente Piedra district, of the Micaela Bastidas - Zapallal Association.

It was coordinated respectively for the study with the head of the family to carry out the survey, once this, it was explained what the study is about and why the research survey was carried out.

The survey was carried out during the presence of the head of the household with a certain time for filling in the survey of approximately 15 minutes, concluding with satisfaction when collecting the surveys since the families supported our study.

It is important to emphasize the presence of the family at the time of filling in the questionnaire, since they were also given information about questionnaire, and why it is being carried out, all this was done to generate trust with the family allowing to carry out the present research work.

3. Results

Below is a summary table of the surveys carried out following the guidelines corresponding to the research work:

In Table I, the psychological impact in relation to the sex of the head of the family is related, in which it is determined with the Pearson chi-square test (X^2), the significance level of the test obtained a value of 1.14 (p > 0.05) ($X^2 = 0.869$; df = 1). therefore, a hypothesis of association between variables is not rejected, which is why it is verified that there is a relationship between the psychological impact and the sex of the head of the family.

Table 1: Psychological Impact on Families in relation to the head of the family for positive cases of COVID - 19 in the Puente Piedra district, 2020

			Total psychological impact		
			Low	Medium	Total
Sex of the Head of Household	Male	Count	4	13	17
		% within Sex of the Head of Household	23,5%	76,5%	100,0%
	Female	Count	1	4	5
		% within Sex of the Head of Household	20,0%	80,0%	100,0%
Total		Count	5	17	22
		% within Sex of the Head of Household	22,7%	77,3%	100,0%

Chi-square tests

	Value	df	Asymptotic significance(bilateral)	Exact significance (bilateral)	Exact significance (unilateral)
Pearson's Chi-square	,027[a]	1	,869		
Continuity correction[b]	,000	1	1,000		
Likelihood ratio	,028	1	,867		
Fisher's exact test				1,000	,687
Linear by linear association	,026	1	,872		
N° of valid cases	22				

a. 3 cells (75.0%) have expected a count less than 5. The minimum expected count is 1.14.
b. It has only been calculated for a 2x2 table
Figure 1: Psychological Impact on Families in relation to the Type of Family for positive cases of COVID-19 in the Puente Piedra district Home, 2020

Therefore, it can be interpreted that the sex data of the head of the family to whom the questionnaire was carried out, where we can observe with respect to the psychological impact on families due to positive cases of COVID-19 in the Puente Piedra district, where the Male head of household 13 (76.5%) of the total have a medium psychological impact and 4 (23.5%) have low psychological impact, in the female head of household 4 (80%) of the total have an impact medium psychological impact and 1 (20%) has low psychological impact.

Figure 1 shows the data in relation to the type of family, where it can see that 9 (100%) of the nuclear family type has a high psychological impact, 3 (25%) of the nuclear family type has a low psychological impact , 3 (100%) of the single parent type have a high psychological impact, 3 (60%) of the extended family type have a high psychological impact, 2 (40%) of the extended family type have a low psychological impact, 1 (100%) of the expanded family type has a high psychological impact and 1 (100%) of the reconstituted family type has a high psychological impact.
Figure 2: Psychological Impact on its Depression Dimension in families due to positive cases of COVID-19 in the Puente Piedra district, 2020

In Figure 2, the data are shown in relation to the depression dimension, where 17 (77.3%) of the total presented mild depression, 3 (13.6%) of the total presented normal depression and 2 (9.1%) of the total presented moderate depression.

In Figure 3, the results of the anxiety dimension are observed, where 13 (59.1%) of the total presented moderate anxiety, 6 (27.3%) of the total presented mild anxiety and 3 (13.6%) of the total presented normal anxiety.

In Figure 4, the results of the stress dimension are observed, where 19 (86.4%) of the total presented normal stress and 3 (13.6%) of the total presented mild stress.

4. Discussion

In this study, emphasis the psychological impact from the point of view of promoting mental health in families, in which it

seeks to contribute programs that allow families to benefit to face situations that generate an alteration in their mental health allowing cope with this emergency due to the COVID - 19 pandemic.
Figure 3: Psychological Impact on the Anxiety Dimension in Families due to positive cases of COVID-19 in the Puente Piedra District, 2020
Figure 4: Psychological Impact on the Stress Dimension in Families due to positive cases of COVID-19 in the Puente Piedra district, 2020

These results that were obtained reflect the mental health that families have during the outbreak of the COVID-19 pandemic in Peruvian families, making them susceptible to depression, anxiety, and stress. In the head of the family, it was observed that the psychological impact occurred more in men than in women, this is since the male as head of the family must support the family economically and emotionally, therefore when he sees that one of his relatives infected by COVID - 19, their mental health is altered. In [12], they argue that women are the most vulnerable than men, since age, sex, being a student and presenting some physical symptoms of their own health, are factors of high psychological impact and that increase anxiety levels, stress and

depression. In the same way in [13], they argue that women have a greater psychological impact due to the COVID-19 pandemic than men because physical comorbidities were predictors of having a greater psychological impact in response to the pandemic. Comparing the results with the studies discussed, we can see that in the statistical samplings in our results it is observed that men have more psychological impact than women, on the other hand, in the studies that are discussed, women represent the majority of the population with a high psychological impact where the pictures of depression, anxiety and stress turn out to be highly elevated.

In relation to the type of family, the nuclear type of family is the most altered, because the COVID-19 pandemic has been crucial in the family, factors such as isolation within the home, unemployment, job instability due to the pandemic, the fear of contracting the disease when leaving the home have generated a certain degree of anxiety and stress in the parents. In [4], they argue that single mothers without support during the pandemic have had high rates of depression, anxiety and stress, therefore, this implies the importance of family support to face the COVID-19 epidemic. In [18], argue that loneliness, social isolation and financial stress are risk factors that affect poor physical and mental health, where the well-being of the person and the family are vulnerable to becoming infected with COVID - 19.

In its dimensions, the most altered was anxiety, this is because the family must face this crisis product of the COVID-19 pandemic where one of their relatives has been infected, where the isolation of the family member infected by COVID-19 has generated a feeling of nervousness and tension in the family members who take care of it, likewise in [12], they maintain that the female sex as the main member of the household at the same time that the male sex presents symptoms such as myalgia, dizziness, coryza, maintaining that they do not have an adequate perception of their well-being of their own health that avoids contagion by COVID - 19. In [14], they argue that the cognitive and emotional states of people as a result of quarantine, make people perceive the threat of COVID - 19 in a highly negative way, where emotional states, such as sadness, depression, anxiety and irritability, aggravate the psychological well-being of the person, damaging their well-being of the same and of the s family members. In the studies discussed, it is observed that in China 28.8% of its population shows a high index of anxiety and in Spain 54.7%, in comparison with our study 59.1% have a moderate index of symptoms anxiety, all this is based on how they can handle or face quarantine without affecting their mental health, therefore the management of strategies that allow them to maintain their mental health in perfect condition.

5. Conclusion

It is concluded that the family due to COVID-19 must have the ability to cope when one of their relatives contracts the disease and be able to emotionally cope with this situation without disturbing the other members of the family.

It is concluded that greater attention should be paid to vulnerable groups such as the young, the elderly, and women since they are more prone to contracting the disease.

It is concluded that the accessibility of health services for the family on prevention and coping strategies on mental health due to the COVID-19 pandemic should be considered.

We can conclude that in our country the susceptibility of presenting symptoms of depression, anxiety and stress is higher than in comparison to other countries

It is concluded that anxiety is a primary factor that more compromises people who already have a mental condition for this reason, in our study we can observe that the majority of the population presents symptoms of anxiety compared to other studies that manage strategies that allow to reduce the anxiety.

Health strategies that allow families to have access to virtual mental health care are recommended

The importance of preventive measures focused on the mental health of people during epidemics, which are developed by mental health personnel, is recommended, suggesting that mainly risk groups be identified for their care.

This research work will be beneficial for future studies, since the COVID-19 pandemic will leave consequences on people's mental health, and thus the consequences that COVID-19 will allow the development of research strategies that allow establish preventive measures on themselves.

Conflict of Interest

The authors declare no conflict of interest.

[2]*Vietnam National University, Ho Chi Minh City, 71308, Vietnam*

A B S T R A C T

In this paper, a novel approach to design a Process Design Kit Digital for CMOS 180nm process is presented. This work proposes a detailed flow to design a PDK Digital using Ocean language, which is a vital element in the semi-custom design and applied in education purposes in universities in Vietnam. The PDK digital includes Standard Cell Library containing 47 standard cells and Wire-Load Model. The library is designed based on the CMOS 180nm process with a supply voltage of 1.8V.

1   Introduction

CMOS technology has been developing in recent years due to its benefits such as high integration density, low fabrication cost, etc. Many new techniques of circuit design have been given ranging from RFIC [1]–[5] to mm-Wave IC design [6], [7].

In the past, the full custom design took many resources, efforts, and design time for designing a big chip. Meanwhile, the semi-custom design has significant decreased in the design and verification time for chip design by using the Electronic Design Automation (EDA) tools and PDK digital [8]. Especially, the latter provides a considerable decrease in design time, decreasing around 25% to 50%. Moreover, the latter would be applying for many more complex designs than the former [9].

Focusing on the PDK digital, the one consists of Synopsys library and P&R library [10]. While the former is applied for timing, power consumption, and noise analysis, the latter is used for place and route design in a design flow [11]. There are two ways to design an SCL. The first one uses the Liberty NCX tool of Synopsys. The Liberty NCX determines the function of standard cells. Following this, the tool creates the complete simulations by using HSPICE that would make the liberty file for each logic cell in the library [12], [13]. The second way performs characterization for all standard cells manually using the Spectre tool. The process of characterization consists of many simulations where the transition of the input and the capacitance of output load are varied. Timing and other parameters would be extracted, and outputted as a liberty format file.

The license of the Liberty NCX tool is unavailable at universities in developing countries due to its cost. Therefore, designing an SCL using this tool is almost impossible [13]. With regards to the manual characterization, the challenge is that we have to do many simulations to generate timing, power consumption, etc [14]. This way takes much time to design each logic cell. For instance, to design an INV logic cell, we have to do 7x7 simulations and 49x6 calculations to generate all parameters for the liberty file.

In this work, the Ocean language is proposed to solve problems about the licensing and running manually many simulations. The language is an extension of the Skill language used to control Analog simulation. The flow automatically performs parametric simulations of each logic cell and generates output parameters with the format as the liberty file [15]. Regarding the Wire-Load Model (WLM), this paper proposed a method and used accuracy formulas to design a complete model.

The authors presented ideas about designing a PDK Digital for CMOS technology in the "2019 19th International Symposium on

Communications and Information Technologies (ISCIT)" [1] and the following paper is an extension of this work.

The remainder of this paper is organized as follows: Section II shows the SCL design flow from the transistor level. This section also gives the schematic design, Euler rules for layout design, DRC/LVS definition, etc. A detailed liberty format generation flow is given in section III. Section IV shows how to design a wire-load model. Finally, section V presents the conclusion.

2   Standard Cell Library Design

An SCL is made up of combinational logic cells such as INV, AND, FA, sequential logic cells such as DFF, Latch, and physical cells, etc. The design flow is composed of many steps. To begin with the front-end design stage, firstly, the schematic of all standard cells in the library are designed from transistor level. After that, symbol creation and do simulation at corners [16]. Next, in the back-end design stage, to optimize the layout design in term of area and routing, the layout design needs to have some rules as follows:

1. All the input and output pins must be placed on the intersections of the vertical and horizontal routing tracks with the special exception for power and ground pins.

2. All the cells in the library are designed to be multiple of the unit tile which is defined by a library developer. The height of the cells must be equal and be multiple of the unit tile's height.

3. This work uses M1 and M2 for the layout design.

4. Minimize the width of all standard cells in the library.

5. Optimize pins access to prevent the routing congestion in place and route stage.

6. Some special cells such as filler, decap cells can be put in the library to make sure the connection of supply trails and N-well.

The figure below shows the schematic, Euler path for optimization, and layout design of an AOI22 cell in the library. The layout should follow the considerations as above.
Figure 1: a. Schematic design, b. Euler path, c. Layout design

The Physical Verification process will be performed after the layout design. This process will accomplish sequentially Design Rule Check (DRC) verification and Layout Versus Schematic (LVS) verification.

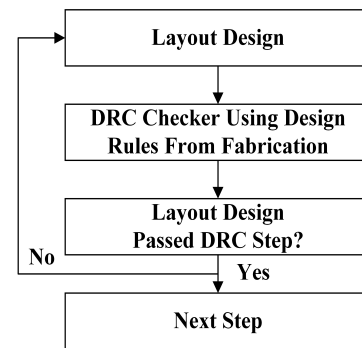
Firstly, by using the rules from the fabricators, the layout design is checked to ensure no potential violation, which is called DRC verification. The design rules are supplied by the manufacturers to ensure the chip will function properly when fabricated. The design rules include many rules such as the minimal critical dimensions, shape angles, pattern density requirements, etc [17]. The DRC flow chart is shown in Figure 2 and the example design rules are presented in Figure 3.


Figure 2: DRC flow chart

For example, the resolution rules for metal 1 and metal 2 layers are 0.23μm and 0.28μm, respectively. With regards to the rules for poly layer, the min.poly width is 0.18μm, min.gate to contact spacing is 0.375μm, and the min.poly overlap of diffusion is 0.22μm. For contact rules, the exact size and min.contact overlap are 0.22μm and 0.12μm, respectively.
Figure 3: The example rules are used for DRC check

Followed by the LVS verification, which is the more critical verification step. Particularly, the LVS compares any combination of physical or schematic designs.

Depending on the layout design, so different parasitic components can be generated. These parasitic parameters can make the functionality and characteristic of the layout design different from schematic design. For that reason, if the whole parameters in the schematic design are different from the parasitic parameters of the layout design, which makes it impossible to complete the LVS step. Hence, this verification proves the chip after being fabricated will function as the schematic design [17]. When the LVS errors occur, we have to fix the layout design and perform the DRC step again to complete the LVS step without errors. The LVS flow chart is shown in Figure 4.
Figure 4: LVS flow chart

The Physical Verification process plays a vital role in the design flow. Therefore, the designers ensure that each cell in the library passed the DRC and LVS without any violations [18]. After the Physical Verification process, the post-layout simulation at corners will be executed before the cell characterization step. Next, Layout Parasitic Extraction (LPE) step is performed. Afterward, the post-layout simulations at corners are performed by using the parasitic parameters extracted. Therefore, the characterization of the standard cells will be calculated [19]. The post-layout simulation becomes possible and correct only after the LVS step is completed, then the extracted parameters are accurate. The post-layout simulation process will be shown in Figure 5.
Figure 5: Post Layout Simulation Process Flow chart

Finally, the characterization step is divided into Liberty Format Generation step and Abstract View & GDS step. While the timing models, power models including dynamic and static power are extracted by the former to make the liberty file (*.lib) [20]. The Synopsys internal database format (*.db) may be translated from the

liberty file by the Library Compile tool of Synopsys. The latter is used to create the library exchange format (*.lef) file by abstracting from the layout design, and the last step is the generating GDS file [21]. The block diagram in the figure below (Figure 6) illustrates the SCL design flow.
Figure 6: SCL design flow chart

3 Liberty Format Generation

After the post-layout simulation process, the standard cell characterization process is performed. Especially, the liberty format generation process, this process will generate an output file (*.lib) which is one of the most important files in the standard cell library design. The liberty file includes structural information, functional information, timing information, power information, and environmental information of each standard cell.

Firstly, the structural one declares connectivity of a logic cell including cell, bus, and in-out pin descriptions. Secondly, the functional one describes the logical function of each output pin of each cell. Thirdly, timing models are given including cell rise delay, cell fall delay, rise transition, fall transition. Next, power models give the dynamic and static power consumption of each cell. Finally, environmental information describes the manufacturing process, temperature of operation, supply voltage, etc.

In this part, to perform cell characterization and generate output file same as the liberty file's format, all cells in the library will have the same load capacitance C_{load} = 2 fF, 5 fF, 6 fF, 7 fF, 8 fF, 9 fF, 9.5 fF, the input slew of the waveform $slope$ = 0.01 ns, 0.02 ns, 0.04 ns, 0.06 ns, 0.08 ns, 0.09 ns, 0.095 ns [22]. The load capacitance and input slew are declared in the Ocean file to create 7x7 = 49 simulation times and extract the timing model and dynamic power

consumption for each cell.

These figures below (Figure 7 and Figure 8) show the testbench circuits for the Ocean script run and the results of a NAND gate cell with two inputs.

(a)

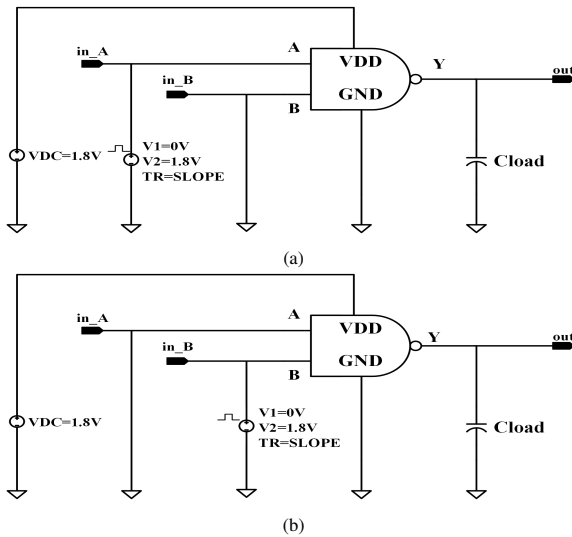
(b)


Figure 7: Testbench circuits for characterization
Figure 8: Waveform results

3.1 Input capacitance

In SCL design, one of the most important parameters that we need to calculate is input capacitance. The output capacitance of each cell can be determined but in most cases, the capacitance is specified only for the inputs and not for the outputs, which means that the output pin capacitance is zero in the library design [23].

The following formula illustrates the relationship between input capacitance, current, and supply voltage at an input pin.

$$I = C\frac{dV}{dt} \tag{1}$$

where I is the current at the input pin, V is the supply voltage and it is equal to 1.8V in this paper. By inputting a pulse power to the

input pin and calculating the current, the input capacitance value is determined as the formula below:

$$C_{input} = \frac{\int_t^{t+\Delta t} I dt}{\int_t^{t+\Delta t} dV} = \frac{\int_t^{t+\Delta t} I dt}{VDD} = \frac{\int_t^{t+\Delta t} I dt}{1.8} \tag{2}$$

where Δt is the time when the voltage at each input pin changes the logic level.

The two tables below show the capacitance of each input pin of the NAND2 cell. These tables also provide the rise power and fall power which are presented in the next section.

3.2 Timing models

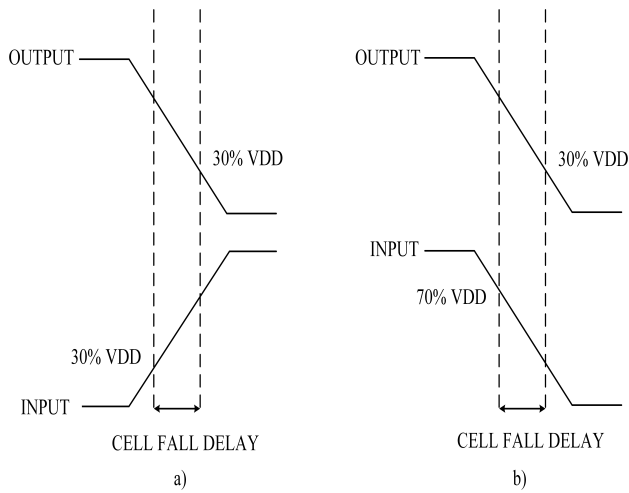
All the timing arcs of the cell are declared in the timing model. There are two types of timing models that are linear and non-linear timing. Whereas the former provides less accurate for the sub-micron process, the latter is better. Therefore, most standard cell libraries use the latter. [20]. The definitions of all the timing arcs in the timing model are given in these figures as follows (Figure 9-11):
Figure 9: a. Cell rise delay at negative unate case, b. Cell rise delay at positive unate case


Figure 10: a. Cell fall delay at negative unate case, b. Cell fall delay at positive unate case
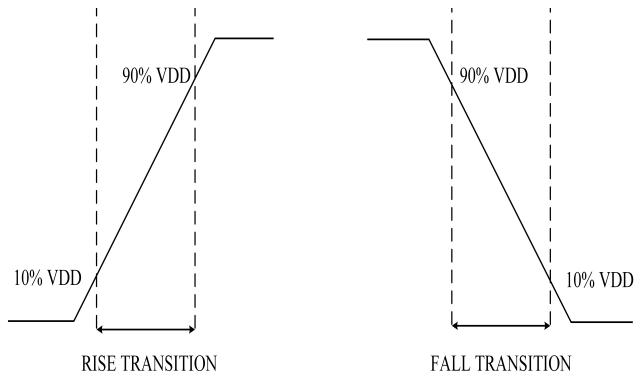

Figure 11: a. Rise transition time, b. Fall transition time

In this work, threshold values for timing arc calculation are 30%, 70% for cell rise/fall delay calculation and 10%, 90% for rise/fall transition calculation. These values are declared in the header section of the liberty file [24]. These four tables below show the timing arc results of the NAND2 cell after the characterizing step.

3.3 Power models

There are two types of power in the power model that are dynamic power and static power consumption. For dynamic power, this one

includes rise power and fall power. While the former is calculated in the time when output changes from 0 to VDD. The latter is determined when output goes from VDD to 0. The formula below shows the dynamic power calculation.

$$VDD^* integ(i("/V0/PLUS"), t, t + \Delta t)/(1e - 9) \tag{3}$$

These two tables (Table 7 and Table 8) above give the dynamic power consumption of the NAND2 cell after the characterizing step.

In contrast, the static power consumption occurs when the cell is in inactive condition. There are many leakage currents caused the cell has this power consumption such as sub-threshold current which is the main component of the currents, tunneling current through the gate oxide [25]. Static power consumption can be shown as the following formula:

$$LEAKAGE\ POWER = \sum I_{LEAKAGE}.VDD \tag{4}$$

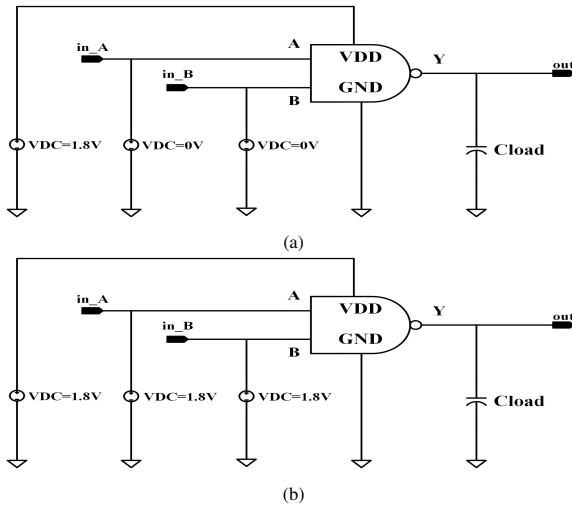
With regards to calculate the static power, firstly, a testbench circuit is designed with all inputs are pulled down as Figure 12a and calculate the power. Next, a testbench circuit is designed with all inputs are pulled up as Figure 12b and then calculate the power. Finally, taking the bigger power number to represent the static power of a cell.


Figure 12: Testbench circuits for static power calculation, (a) Testbench circuit for static power calculation in pull down condition, (b) Testbench circuit for static power calculation in pull up condition

4 Wire-Load Model Design

The wire delays must be estimated during the timing analysis before placement and routing. Using a wire-load model is the simplest method of estimation. The wire-load model gets a rough value of the total wire capacitance based on the size of the chip and the fanout of the net [26]. The wire-load model is specified in the Liberty file.

In this work, the wire capacitance is computed by using the results of T. Sakurai and K. Tamaru's paper [27]. The accuracy of these formulas is practically sufficient for a wide range of wire thickness, wire width, and inter-wire spacing. When two or three nets are placed on bulk silicon, the total capacitance of one net includes the "coupling" capacitance between lines C_{side} and "ground"

capacitance between the net and the ground C_{plate}. Below are the detailed steps to determine the wire capacitance of a net.

First, the coupling capacitance C_{plate} between line and bulk silicon is given as formula:

$$C_{plate} = E_{ox}(1.15(\frac{W_{int}}{T_{fox}}) + 2.8(\frac{T_{int}}{T_{fox}})^{0.222}) \tag{5}$$

Next, the coupling capacitance C_{side} between lines is shown as:

$$C_{side} = 2E_{ox}(0.03\frac{W_{int}}{T_{fox}} + 0.83\frac{W_{int}}{T_{fox}} - 0.07\frac{W_{int}}{T_{fox}}^{0.222})(\frac{W_{sp}}{T_{fox}})^{-1.34} \tag{6}$$

Where E_{ox} is a dielectronic constant of SiO_2. It is given as:

$$E_{ox} = E_0 K_r = 3.9x8.85xE^{-03} = 0.035(\frac{fF}{\mu m}) \tag{7}$$

Final, the total capacitance or wire capacitance is determined as:

$$C_{total} = C_{plate} + MFC.C_{side} (\frac{fF}{\mu m}) \tag{8}$$

Where Miller Coupling Factor (MFC) is equal to 1.5 in this work.

Regarding the resistance of a interconnect net, this value is computed by the formula as below:

$$R_{total} = \rho\frac{L}{S} = \rho\frac{L}{W_{int}T_{int}} (\frac{\Omega}{\mu m}) \tag{9}$$

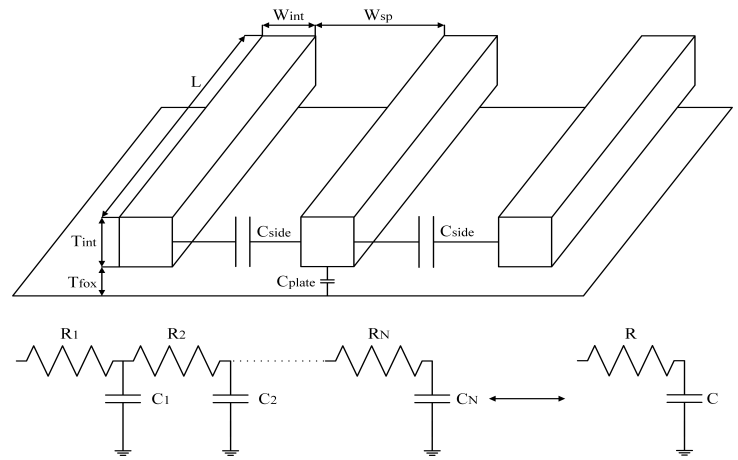
The figure below defines all variables used in the formulas above.


Figure 13: Variables definition used to compute the wire capacitance

This work is performed based on the CMOS 180nm process which has six metal layers. The following table provides the values of all variables defined in the formulas above.

Table 9: Values Of Variables For Wire Capacitance Calculation

Metal Layer	W_{INT} (μm)	W_{SP} (μm)	T_{INT} (μm)	T_{FOX} (μm)	C_{side} ($\frac{fF}{\mu m}$)	C_{plate} ($\frac{fF}{\mu m}$)
M1	0.23	0.23	0.53	0.003981	0.019	1.456
M2	0.28	0.28	0.53	0.003981	0.015	1.737
M3	0.28	0.28	0.53	0.003981	0.015	1.737
M4	0.28	0.28	0.53	0.003981	0.015	1.737
M5	0.28	0.28	0.53	0.003981	0.015	1.737
M6	1.50	1.50	2.34	0.003981	0.007	8.665

The table below shows the results of wire capacitance and resistance with the unit length of $1\mu m$. In addition, the delay of each metal layer is computed by the following formula:

$$t_{delay} = 4^*RC \tag{10}$$

Table 10: Values Of Wire Capacitance, Resistance, Delay

Metal Layer	Length (μm)	Capacitance (fF)	Resistance ($ohms$)	Delay (ps)
M1	1	1.484	0.164	0.097
M2	1	1.759	0.135	0.095
M3	1	1.759	0.135	0.095
M4	1	1.759	0.135	0.095
M5	1	1.759	0.135	0.095
M6	1	8.675	0.006	0.020

Based on the results above, the resistance and capacitance of a net will be calculated as the following formulas:

$$R = length.R_{unitlength} \tag{11}$$

$$C = length.C_{unitlength} \tag{12}$$

The tool in the timing analysis stage, especially the synthesis stage will calculate the capacitance and resistance of a interconnect net based on the particular *length* value.

5   Conclusion

In this paper, a novel approach to design a Process Design Kit (PDK) Digital for CMOS 180nm process is presented. For the Standard Cell Library design, by using the Ocean language, this work solved the problems about the licensing of the Liberty NCX tool which is unavailable in universities in developing countries, especially Vietnam, and running manually many simulations when the tool is not applied. Regarding the Wire-Load Model, this paper proposed a method and used accuracy formulas to design a complete model.

Conflict of Interest   The authors declare no conflict of interest.

Fiber-Wireless (FiWi) network is an integration of fiber optic and wireless connections in the same network. It is one of the best solutions to overcome rapid increment of Internet users and bandwidth-hungry services. To facilitate fundamental knowledge and further understanding on FiWi for students and researchers at the university level, this article proposes the development of a fast integration and scalable FiWi router testbed using Raspberry Pis as the embedded system-based hardware for lab-scale experiments. The performance of the router testbed in terms of end-to-end delay and throughput for upstream and downstream are evaluated. The delay values comply with IEEE 802.15.4 routing scheme. The performance of the router testbed is compared with the industrial grade off-the-shelf router in terms of throughput for each network. A testbed stress test is conducted by sending two data traffics simultaneously, and the performance test is repeated for Wireless-Fiber-Wireless and Fiber-Wireless-Fiber network architecture. The results show the proposed router testbed is scalable, flexible, and capable of fast integration.

1. Introduction

This paper is an extension of work originally presented in 2020 IEEE 8th International Conference on Photonics (ICP) [1]. However, in that work, fiber connection alone would not be able to accommodate all connections, especially to mobile and smart devices that are rapidly increasing. Furthermore, the demand for Internet and leased line bandwidth are growing continuously at more than 20% per year due to more video streaming, cloud computing, social media and mobile data delivery [2]. By 2020, the bandwidth demand will continue to grow due to an enhancement of video quality such as 8K Ultra High Definition (UHD) and increasing number of user subscriptions. Because of that, the estimated traffic in terms of mobile data and fixed systems will be 2600 times more than the traffic in 2010 [2]. This growth is accelerated by the new type of communication services such as device-to-device (D2D) and machine-to-machine (M2M) [3]. Therefore, to ensure users experience are at the same level of Quality of Service (QoS) regardless the time and location while the

demand is increasing, Fiber-Wireless (FiWi) deployment has become a necessity because it can cover a large area and support large number of users. According to [4], FiWi is still an ongoing study and there are plenty of rooms for improvement.

It is important to equip fundamental knowledge and further understanding on FiWi for students and researchers at the university level. Therefore, to facilitate this, it is essential to have a scalable FiWi testbed with fast integration capability, which is proposed in this article. FiWi network is a combination of fiber and wireless connection in the same network [5, 6] to provide fixed and mobile services [7-11]. A typical FiWi network consists of high-capacity passive optical network (PON) as backhaul comprising of Optical Line Terminal (OLT) and multiple Optical Network Units (ONU), connected to a cluster of wireless front end routers [12]. ONU is integrated with a wireless gateway that provides wide-area connectivity to users. At the optical backhaul, the OLT at the central office (CO) forms a root connected to the optical backbone via fiber link to provide cloud computing services. ONU is connected to the OLT via 1 : N (N = 32, 64) splitter to form a leaf-shaped nodes. The CO is responsible to manage the information

transmission between mobile devices with ONUs and acts as a gateway to other networks [13]. In the wireless end of FiWi network, mobile devices such as smart phones [14, 15], virtual reality (VR) glasses [16], smart watches and other Internet of Things (IoT) devices [16-18] have access to the Internet either via ONU or multi-hop wireless mesh network. Based on a study by [19], one of the advantages of FiWi is that it provides high speed optical backhaul for a wireless mesh network. In [20] stated that the network has a broadband access where it uses wide range of frequencies enabling a large number of data to communicate simultaneously. Whereas, mobile backhaul combines reliability and capacity of Ethernet-based optical backhaul with the wide range of coverage and flexibility of Ethernet-based wireless devices. By utilizing the efficacy of both optical fiber and wireless, a fast speed and low cost of service areas can be achieved [21]. It provides cost effectiveness, robustness, flexibility, high capacity, reliability and self-organization compared to fiber or wireless connection alone [22-24] Another advantage of having FiWi network is the combination of fiber optic and radio access technologies in multi-tier Radio Access Network (RAN) [2].

Radio access technologies will be used to deliver wireless services with high capacity, high link speed, and low latency [25]. The multi-tier RAN will improve the cell edge performance for mobile fronthaul and backhaul, resource sharing, and centralization of multiple standards with different frequency bands and modulation formats. FiWi network is a promising technology to support high demand of bandwidth and large number of users in different types of topologies and geographical environments.

Over the years, research communities have been working hard to improve the performance of FiWi network. Hence, in order to study and perform an extensive performance evaluation, testbeds are needed. Testbed is known as a prototype for proof-of-concept of any technology features where further studies can still be conducted [26]. There are various types of testbed in various platforms such as lab-scale testbed and field testbed. According to [27], built in lab-scale testbed is portable, which means, it can easily be packed away, securely stored and safely transported. The testbed can also be reused and assembled by other researchers in the future. For field testbeds, they consist of high-end setup which require installation by trained professionals and usually require large spaces. For example, in [28], an experiment was conducted consisting of 64 massive multiple-input multiple-output (MIMO) antennas for the FiWi testbed setup. The setup is comparing with collocated massive MIMO to simultaneously serves many users using the same time-frequency resource. For educational module, a simpler setup is preferable because fast integration capability is an important criterion for an educational testbed. This will speed up the installation of the testbed and the lecturers can have more time on explaining rather than focusing on testbed installation.

A testbed can have flexible architecture to be connected to any devices such as multiple sensors [29]. Despite of its compactness, it has powerful local computation unit. A testbed can also be reconfigured to different topologies as required. A review on two types of router testbeds (commercial-based and embedded system-based) were presented in [30]. The commercial-based are store-bought off-the-shelf routers [31, 32]. Some examples of embedded system-based routers are using netFPGA [33], Banana Pi [34] and Raspberry Pi [35-37]. From the study in [30], the embedded

system-based routers are reconfigurable, reprogrammable, scalable and cost less than the commercial routers. These advantages will be a suitable choice for the lab-scale router testbed in research and academic field.

Developing a lab-scale testbed is also one of the practical ways of studying and experimenting a particular technology before an actual implementation due to its portability and flexibility. This article describes the development of a FiWi router testbed with the said advantages, with several additional features: fast integration capability, scalable and flexible. The proposed router testbed uses Raspberry Pi for its programmable function (coded in Python language) to be a router. The details of the router structure will be described in the following section.

2. Hybrid Fiber-Wireless Router Testbed

Figure 1 shows a flowchart that reflects the overview of technical development for the proposed router testbed. Firstly, after the proposed routers in the testbed are connected with one another in FiWi architecture, connection reliability test is done by sending a packet from one client to another client. If the packet is not received by the client, an additional processing delay is increased in the proposed router. This delay is an additional time for the router to process the packets including label injecting, label checking, and packet forwarding. The process is repeated until the clients are able to receive the packet without fail. Afterwards, the performance of the proposed router is tested in FiWi architecture in terms of throughput and end-to-end delay in order to validate its correctness and comply with the current communication standards. After it is validated, a stress test is done by sending two traffics at a time to test the stability of the proposed router. Then, the architecture is changed to Fi-WiFi and Wi-FiWi in order to test its flexibility and scalability.

The proposed FiWi router testbed is using Raspberry Pi 3B+ to support data transmission for research and education purposes. It consists of four routers that are connected in tree topology and may be varied accordingly, as shown in Figure 2. It is a typical topology for FiWi network [12, 13]. Each router is an integration of four Raspberry Pi 3B+; one Header Pi and three Forwarding Pis. The three Forwarding Pis are to emulate the real router, with each of them having a unique static IP address. To form a router, the Raspberry Pis will be connected to two Ethernet switches via CAT5e Ethernet cable, as illustrated in Figure 3. Ethernet Switch 1 is to represent the internal connection of the routers (between Header Pi and Forwarding Pis). While Ethernet Switch 2 representing the external connection between routers. An Access Point (AP) is added as an element to the router structure to support wireless transmission.

2.1. Topology

The router testbed is set up in tree topology consisting of four proposed routers for the default FiWi architecture, as shown in Figure 2. The connection between routers is using single mode fiber optic patch cord. Since Raspberry Pi has only one Ethernet port, a Fiber Media Converter (FMC) is needed as an adapter. Then, the architecture is expanded to Fi-WiFi and Wi-FiWi as shown in Figure 4 and Figure 5, respectively. Compared to other topologies such as ring and mesh, the flexibility and stability of the proposed router can be observed after going through a number of

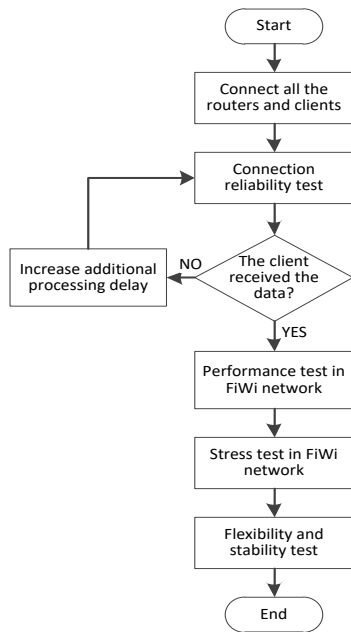
medium changes from wireless to fiber and vice versa in tree topology. Moreover, the purpose of these setups is to test the scalability of the testbed.


Figure 1: The overall flowchart of this work
Figure 2: The architecture of FiWi router testbed

The architecture of this testbed can be scaled easily to Fi-WiFi and Wi-FiWi without any tedious hardware rearrangement. The routing mechanism for FiWi, Fi-WiFi and Wi-FiWi can be achieved by changing the label for each client, Header Pi and Forwarding Pi in the router program code. The labels for routers and clients in any of the three architectures (FiWi, Fi-WiFi and Wi-FiWi) must be unique to prevent misinterpretation of data destination by the router.

2.2. Routing Mechanism

The flowcharts of the testbed routing mechanism are shown in Figure 6, 7 and 8, for the client, Header Pi and Forwarding Pi, respectively. When a client sends a packet of data to the destination, a pre-label is added to the payload of the packet to indicate where the data should end. The client sends the data to Header Pi. Then, the Header Pi checks the label to know the beginning (source) and end (destination) of the data. After the Header Pi has identified the destination of the data, it replaces the old label with a new label onto the payload and then broadcast the data to each Forwarding Pis. Each of the Forwarding Pi has its own unique label because each identity label corresponds to one destination only. When the Forwarding Pi receives data from

Header Pi, it will check the label on the payload of the packet with its own identity label. If both labels are the same, the Forwarding Pi will continue to forward the data to desired destination set by the client. Otherwise, if both labels are not the same, the Forwarding Pi turns the data to zero and drops the packet.

Figure 5: The architecture for Wi-FiWi router testbed

2.3. Experimental Setup

2.3.1. FiWi Router Testbed Performance Test

For this test, Raspberry Pi client is used to send a packet to another client via a combination of fiber and wireless transmission as in Figure 2. The initial data size transmitted is at 100 bytes for proof of concept [38]. Then, the data size is increased by 100 bytes each time until 1445 bytes. The performance of the experiment in terms of end-to-end delay and throughput are plotted on the graph. The proposed router is compared with industrial grade router to check its functionality and to observe its correctness. The setup for the industrial grade router is using the same topology as the proposed testbed. The upstream and downstream transmissions are done by using two computers. The throughput of the proposed router testbed is validated with industrial grade router. The bandwidth of the industrial grade router is set to 1 Gbps. However,

the initial data size is set to 10 kB and increased by 10 kB for each transmission until 100 kB. This is because the industrial grade router is connected to an access point with similar specification to the proposed testbed setup, limiting the actual bandwidth to 1 Mbps. Then, the throughput of the experiment for upstream and downstream are captured using Wireshark.

Figure 6: Client flowchart

Figure 7: Header Pi flowchart

Figure 8: Forwarding Pi flowchart (label example for A)

2.3.2. FiWi Router Testbed Stress Test

The limit of the FiWi router testbed is tested by sending two traffics simultaneously from one router to another. This stress test is done by connecting two clients for each proposed router. The performance will be analysed in terms of the end-to-end delay and throughput for downstream and upstream for two simultaneous traffic transmission. The purpose of this test is to evaluate the stability of the proposed testbed.

2.3.3. Scalability Test

Scalability is defined as the ability for the testbed to adapt to a new architecture or arrangement easily and its ability to expand the number of new components. In order to add or remove a component in the testbed, minor changes need to be done to its arrangement. In this case, the testbed architecture is changed to Fi-WiFi and Wi-FiWi to test its scalability performance and to prove the testbed is flexible to work in various architecture. The scalability test presents the performance for Fi-WiFi and Wi-FiWi in terms of end-to-end delay and throughput. Hence, the purpose of this section is to analyse the scalability performance and to compare which architecture is better for the testbed.

2.4. Parameters

2.4.1. Design

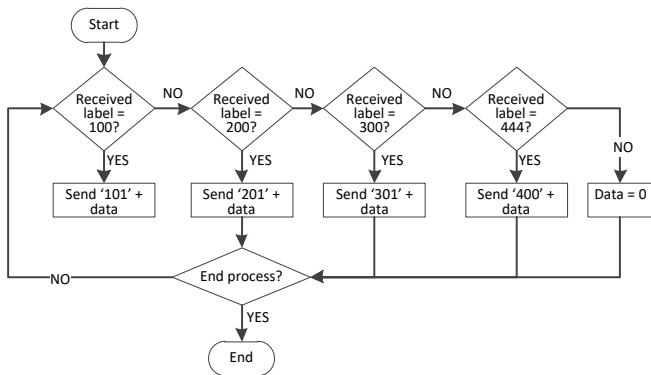
Design parameters are defined as the input for the testbed; the data size and the end-to-end delay. The data size is the length of data in bytes (B). It can be varied easily by the user at the client side. In this experiment, the increment of the transmitted data size is 100 bytes for each transmission. The summary of data size and corresponding throughput scale used in the experiment are listed in Table 1. The data size affects the end-to-end delay where greater data size may result in greater end-to-end delay. The end-to-end delay is used to study the throughput of the testbed.

Table 1: Summary of data size and throughput scale used in the testbed experiment

	Start	Data size increment	End	Throughput scale
Proposed testbed	100 bytes	100 bytes	1445 bytes	linearly
Industrial grade router	10 kB	10 kB	100 kB	1

2.4.2. Performance

Performance parameters are the output of the testbed which indicate its performance. Two performance parameters are taken into consideration; end-to-end delay and throughput. End-to-end delay is the time taken when the user sends the data from a client to another client. Throughput is the overall performance of the testbed in bit per second (bps) when the data size in bit (b) is divided by end-to-end delay, L, in second (s). The throughput, Th_{TL} calculation is summarized in (1) [39], where D_T is data transmitted and D_L is data loss.

$$Th_{TL} = \frac{D_T - D_L}{L} \qquad (1)$$


3. Results and Discussion

3.1. Fiber-Wireless Performance Test

Figure 9 shows the throughput for downstream and upstream transmissions. The purpose of this validation is to observe the correctness of the router testbed. The throughput of the testbed is scaled up to match the throughput industrial grade router. Based on the figure, the throughput of the proposed testbed has similar increasing trend as the industrial grade router, thus validates the correctness. The downstream throughput for proposed testbed increases from 0 bps at 0% offered load to 719 kbps at 100% offered load. The throughput of industrial grade router increases from 0 bps at 0% offered load to 697 kbps at 90%, then decreases at 100% offered load when reaching its bandwidth limit. This situation is due to the QoS algorithm in the industrial grade router limits the maximum throughput.

Similar trend is observed for upstream transmission, where the throughput of the proposed testbed increases as the offered load increases from 0 bps to 770.351 kbps at 0% to 100% offered load. The throughput for industrial grade router is also increasing from 0 bps to 774 kbps at 0% to 100% offered load.

For both downstream and upstream transmissions, industrial grade router is able to transmit data up to 700 kbps and 774 kbps respectively at 100% offered with 1445 bytes of in each packet. But the proposed testbed can only transmit for one packet of 1445 bytes, up to 52.097 kbps for downstream transmission and 54.335 kbps for upstream transmission. Hence, if the proposed testbed sends as many packets as the industrial grade router, the transmitted data in the proposed testbed is vertically scaled up by factor of 13.436 (700 kbps/59.097 kbps = 13.436) for downstream and 12.883 for upstream (774 kbps/59.097 kbps = 13.436). Vertical scaling is a method to translate a graph without losing the original properties where all y-values in the graph are multiplied by a specific factor. Therefore, for the proposed testbed, the throughput for each offered load is multiplied with 13.436 and 12.883 for downstream and upstream respectively.

Overall, the throughput of the proposed testbed is slightly lesser than the industrial grade router due to its lower technical specification, bandwidth and processing power but is adequate enough for lab-scale experiment. From the graphs, we can conclude that the trend of the proposed testbed is correct.
Figure 9: FiWi downstream and upstream throughput for the proposed router (PR) testbed and the industrial grade router (IGR)

Figure 10 shows the end-to-end delay for downstream and upstream transmission in FiWi architecture. For downstream, the minimum and maximum end-to-end delay are 0.1246 s and 0.14484 s at 100 bytes and 1445 bytes, respectively. For upstream, the minimum end-to-end delay is 0.12193 s at 100 bytes, and the maximum is 0.12430 s at 1445 bytes. The increased delay is due to testbed takes longer time to process the data. The subtle differences in the graphs caused by very small data size for a large bandwidth of fiber (1 Gbps). Furthermore, the data is transmitted by using light pulses in fiber. Hence, it transmits faster compared to electrical pulses in copper. For example, during downstream transmission, the end-to-end delay at 100 bytes is 0.1246 s, whereas at 200 bytes the end-to-end delay is 0.1250 s. The end-to-end delay is expected to be higher in the proposed router testbed compared to a typical fiber-supported router like industrial grade router, also because of hardware limitation. This is acceptable as part of the aim of this article is to create a reconfigurable router testbed that supports fiber-wireless transmission for educational module.
Figure 10: FiWi downstream and upstream end-to-end delay
Figure 11: FiWi stress test downstream and upstream throughput for 1-traffic and 2-traffics transmissions

3.2. Fiber-Wireless Stress Test

Figure 11 shows the throughput for downstream and upstream transmissions. The throughput is still increasing gradually with the data size. The minimum and maximum throughput are 3.210 kbps at 100 bytes and 40.047 kbps at 1400 bytes. For downstream

with 2 traffics, the throughput decreases at 1445 bytes from 40 kbps to 39.5 kbps due to the end-limit of the testbed. Compared with the throughput of a single traffic, the throughput of two traffics is about half of the throughput of single traffics. The reason of this occurrence is two traffics causing the proposed testbed to process the data twice. For example, at 100 bytes in downstream transmission, the throughput for a single traffic is 6.42 kbps whereas the throughput for two traffics is 3.21 kbps. This statement is supported by [40] where more traffics contribute to less throughput.

Figure 12 shows the downstream and upstream end-to-end delay graphs. For downstream, the trend of the graph is increasing with the data size, from 0.249 s at 100 bytes to 0.293 s at 1445 bytes. At 1445 bytes, there is a sudden increase of end-to-end delay, due to the testbed's end-limit. Theoretically, when number of traffics increases, the end-to-end delay also increases [41]. Therefore, comparing the plots for downstream, the end-to-end delay of two traffics is twice as big as single traffic, because testbed needs to process the data twice. For example, the end-to-end delay at 1445 bytes for single traffic and two traffics are 144.838 ms and 293.01 ms, respectively.

The trend for upstream end-to-end delay is also similar where the delay increases from 243.863 ms at 100 bytes to 248.591 ms at 1445 bytes. At 1445 bytes, the end-to-end delay for two traffics and single traffic are 248.591 ms and 124.296 ms, respectively. Even though the trends of the graphs are almost constant, it is actually increasing as the data increases. The constant trends of the graphs are due to the presence of fiber which make the difference in end-to-end delay between two data such as 100 bytes and 200 bytes are not significant.
Figure 12: FiWi stress test downstream and upstream end-to-end delay for 1-traffic and 2-traffics transmissions

3.3. Scalability Test

3.3.1. Fiber-Wireless-Fiber

The plot for Fi-WiFi downstream and upstream throughput is shown in Figure 13. The downstream throughput increases with the data size from 2.626 kbps at 100 bytes to 22.403 kbps at 1445 bytes. For upstream, the throughput is increasing up until 1100 bytes only, unstable at 1200 bytes to 1300 bytes, then continue to decrease from 1400 bytes to 1455 bytes. Even though the

downstream throughput is increasing, but the graph gradient is gradually decreasing starting at 700 bytes. Whereas the upstream throughput becomes unstable at 1200 bytes to 1300 bytes because the proposed testbed is almost at its limit, resulting in greater graph gradient. Then, the throughput decreases at 1400 bytes and 1445 bytes due to the sudden increase of upstream end-to-end delay at 1400 bytes in and the delay continues to increase until 1445 bytes.

The downstream and upstream end-to-end delay for Fi-WiFi architecture is shown in Figure 14. The downstream delay increases with the data size from 0.609 s at 100 bytes to 1.032 at 1445 bytes. For upstream, the increases from 0.505 s at 100 bytes to 0.948 s at 1445 bytes. The end-to-end delay for this setup is higher than the FiWi architecture because the data has to undergo multiple routers and medium conversions from fiber to wireless and then wireless to fiber [42]. For downstream transmission, there is a sudden increase in end-to-end delay at 1400 bytes due to the end-limit of the proposed testbed, thus the longer processing time.

3.3.2. Wireless-Fiber-Wireless

The downstream and upstream throughput for Wi-FiWi architecture can be seen in Figure 13. The trend of the downstream throughput increases with the transmitted data size from 2.833 kbps at 100 bytes to 38.09 kbps at 1445 bytes. For upstream, the throughput increases from 2.81 kbps at 100 bytes to 38.348 kbps at 1445 bytes. At 100 bytes, the throughput for upstream transmission is slightly lower than downstream. However, as the transmitted data increases, the throughput for upstream transmission is higher than downstream: the throughput at 1100 bytes is 29.754 kbps (upstream) and 29.941 kbps (downstream). However, starting 1200 bytes, the throughput for upstream transmission is 32.276 kbps, while for downstream is 32.087 kbps. At 1445 bytes, the performance for both transmissions are slightly decreased due to the end-limit of the testbed, referring to the slope of the graph at this point. The slight differences in the throughput values proving that the proposed testbed in Wi-FiWi architecture is stable for both transmissions. This proposed router testbed is therefore suitable to be a scalable testbed.

Figure 14 shows the end-to-end delay of downstream and upstream transmissions respectively for Wi-FiWi architecture. The downstream end-to-end delay increases with the transmitted data size from 0.565 s at 100 bytes to 0.607 s at 1445 bytes. There is a sudden increase to the downstream end-to-end delay at 1200 bytes, because the proposed testbed is approaching its limit. Hence, the data processing time takes longer at this point. For upstream, the end-to-end delay is also increasing with the transmitted data, from 0.569 s at 100 bytes to 0.603 s at 1445 bytes. It can be observed that the downstream and upstream end-to-end delay for Wi-FiWi architecture is also higher than the FiWi because there are more medium changes in between clients. Therefore, the process of medium conversion contributes to higher end-to-end delay.

3.3.3. Fi-WiFi versus Wi-FiWi

Figure 13 clearly shows the comparisons in terms of throughput between Fi-WiFi and Wi-FiWi architectures for downstream and upstream transmissions from 100 bytes to 1445 bytes. The performance for Wi-FiWi is more stable than Fi-WiFi based on the behaviour of the graphs. This is because Fi-WiFi has more conversion from electrical pulses to light pulses and vice versa compared to Wi-FiWi causing the instability in Fi-WiFi.

Thus, the overall performance in Wi-FiWi is more stable because it has better observable graphs compared to Fi-WiFi.

Figure 14 shows the end-to-end delay comparisons between Fi-WiFi and Wi-FiWi architectures for downstream and upstream transmissions. Both have increasing end-to-end delay when the transmitted data size increased from 100 bytes to 1445 bytes. However, Fi-WiFi architecture has higher delay than Wi-FiWi because of the higher number of FMCs in Fi-WiFi. Hence, the medium conversions from light pulses to electrical pulses or vice versa is more than Wi-FiWi, thus contributes to more delay. From the graphs, we can conclude that Wi-FiWi has more stable transmission because throughout the transmissions, the end-to-end delay changes subtly. The summary of the throughput and end-to-end delay results at full load (1445 bytes) for all experiments using the proposed router testbed are listed in Table 2. Throughput results for FiWi architecture are not scaled, to fairly compare with other experiments.
Figure 13: Fi-WiFi vs Wi-FiWi throughput
Figure 14: Fi-WiFi vs Wi-FiWi end-to-end delay

4. Conclusion

FiWi is seen to be one of the best technologies for future global data communication network architecture due to the advantages of providing robustness and mobility to the consumers by deploying FIber and wireless in one network. To equip fundamental knowledge and further understanding on FiWi for students and researchers at the university level, this article proposed a FiWi router testbed. It is a fast integration and scalable, which is essential for an educational module testbed. The focus of this research is on lab-scale environment router testbed in FiWi architecture to provide a proof-of-concept solution on reconfigurable router testbed in FiWi network. Raspberry Pi is chosen to be the embedded system hardware in this research for the development of scalable and reconfigurable FiWi router testbed. It has a socket module which enables the user to program Raspberry Pi to communicate with each other using IP addresses.

The proposed FiWi testbed throughput performance has been validated with industrial grade router to prove the correctness. As the proposed testbed approaches its limit, the throughput is maintained with no further increment. For the end-to-end delay, it increases with the data size with acceptable measure and its behaviour satisfies the end-to-end delay of IEEE 802.15.4 routing scheme. Hence, the proposed testbed is suitable to serve as an educational module FiWi testbed due to its simplicity, reconfigurable and fast implementation. A stress test shows that the end-to-end delay for two traffics is twice as high as single traffic due to the twice data processing. This causes the throughput for two traffics is halved of the single traffic throughput. For scalability performance test, the end-to-end delay in Fi- WiFi is higher than Wi-FiWi architecture due to more electrical pulses to light pulses conversion and vice versa from FMC in Fi-WiFi. Furthermore, Wi-FiWi is more stable compared to Fi-WiFi, thus making the testbed flexible and scalable for various possible setups. The proposed router testbed also shows a promising stability, a huge advantage to test various architectures.

Table 2: Summary of throughput and end-to-end delay results at full load (1445 bytes) for all experiments

| Experiment | Parameters | | | |
| | Throughput (kbps) | | End-to-end delay (s) | |
	Up stream	Down stream	Up stream	Down stream
FiWi	54.34	59.10	0.124	0.144
FiWi stress test	46.50	39.45	0.250	0.290
Fi-WiFi	24.40	22.40	0.948	1.030
Wi-FiWi	38.35	38.09	0.600	0.610

Conflict of Interest

The authors declare no conflict of interest.

[2]*Faculty of Management, Canadian University of Dubai, Dubai, 12346, UAE*

ARTICLE INFO	ABSTRACT
	The emergence of new digital payment technologies has introduced both opportunities and challenges across all industries. This research aims to examine the significant factors that influence the adoption of new e-payment technologies, specifically in smart cities, as in Dubai. A comprehensive theoretical framework based on several previous studies included the following factors; Perceived Usefulness, Perceived Trust, Perceived Personal Innovativeness, Perceived Ease of Use, Perceived Risk, and Generation Cohort. The results of this research confirm that all proposed factors significantly affect the adoption of e-payment in Dubai as a case of a smart city; however, the perceived usefulness is not as significant as the other factors. Moreover, comparative analysis across the three generations showed almost similar patterns of adopting e-payment systems.

1. Introduction

E-payment is among the revolutionary changes caused by technology in the field of financial services that tremendously changed humans' life by making them simpler and easier than before. Currently, e-payments have taken over the entire world of financial transactions whether these are meant for personal or commercial use [1] because it offers numerous benefits to the consumers including cost-effectiveness and conservation of time and energy. The UAE in general, and Dubai in particular, has extensively adopted new innovative e-payment systems with over 25 e-payment service providers offering more than 250 payment services for traffic fines, electricity bills, parking fines, university fees, etc... [2]. Moreover, the e-payment transactions in the UAE increased by 21% between 2015 and 2016, which represents $12.4 billion of goods and services [3] due to the Dubai government's vision of creating the perfect smart city.

Despite their rapid growth, e-payment systems are not perfect. Some disfavors easily noticed, such as hacking risks, the high cost of setting-up, and upgrading the system. These disadvantages prevent some individuals from adopting e-payment systems. This paper investigates the key factors that influence the adoption of new e-payment technologies across several generations in smart cities such as Dubai. Consequently, help the organizations in

Dubai, facilitating the adoption of innovative e-payment services through smart and effective design that is more conscious about the essential factors in the adoption criteria. The expansion of new e-payment adoption research allows companies and organizations to spend less effort and time, which can be invested in developing new e-payment services with more significant opportunities in the market.

A large number of studies employed the TAM or UTAUT models to investigate the factors affecting e-payment adoption. However, the framework proposed in [4] is considered more suitable for the goals of the current research. The study investigated the Malaysian consumers' perception of e-payment and recommended the Benefits, Trust, Self-Efficacy, Ease of Use, and Security as the most critical factors affecting the consumers' perception of e-payment. This research extended the previous frameworks by proposing the following factors: Perceived Usefulness, Perceived Trust, Perceived Personal Innovativeness, Perceived Ease of Use, and Perceived Risk. Moreover, the effect of age cohorts (X, Y, and Z Generations) on the previous factors and the users' perception to adopt the e-payment system in Dubai is to be examined.

The research in [5], is the sole study among past studies that shed light on how Age influences the factors of e-payment adoption. However, only some of the factors (Perceived Ease of Use and Perceived Usefulness) were considered by the researchers, overlooking the impact of other significant factors.

[*]Corresponding Author: Anas Najdawi, Amity University, Dubai, UAE, anajdawi@amityuniversity.ae

In [6], the authors explored the factors affecting the adoption of e-payment systems among university students in the UAE. In this study, the researchers employed a modified TAM model in which the factor of trust was also incorporated. However, the population studied in this paper is limited to the university's students only. Therefore, the age factor was not being taken into consideration. The authors addressed students residing in all the emirates of UAE.

In [7], the authors adds to the previous work the demographic variables and e-payment channel adoption in the UAE. The current paper is organized as follows. Section 2 is dedicated to reviewing the previous works. Section 3 will represent our framework. The next section will be the description of the methodology used in order to accept or reject the proposed hypotheses. After that, the results are listed and discussed in Sections 5 and 6. The conclusions and different implications are provided in Section 7. Finally, the research limitations and recommendations for future studies are stated in Section 8.

2. Literature Review

2.1. E-payment systems

Similarly to all e-services, an electronic platform is essential for the functioning of e-payment systems. The e-payment supports various kinds of monetary transactions [1], including regular transactions like paying for grocery or utility bills as well as B2B transactions besides others, and thus, it enables the buyer and seller to reap the benefits of a faster and more convenient payments system [2].

Various modes of payment, including e-money, debit or credit cards, and internet banking, may be considered as E-payment [3]. Moreover, another important revolution in this context is the introduction of mobile money by various organizations. For instance, two of the most successful companies in terms of mobile money are Apple pay and Samsung pay [4].

The e-payment systems have numerous advantages. For instance, they offer faster monetary transactions waiving the need for long queues and waiting periods for payments and receipt of money. People can remotely perform the payment and receipt of money through their cell phones or another mode of payment. Additionally, the fees related to financial transactions when using e-payment systems are far less than transaction fees when using traditional ways in most countries, especially in Dubai. Even in the absence of direct fees, the consumer may have to bear indirect fees, such as transportation fees, to go to the bank to withdraw money or go to the store to buy goods and services.

However, e-payment systems also have some disadvantages, for instance, the security threat that users face when using the e-payment system, the Risk of hacking the system, which causes a loss of money and personal information. Another disadvantage would be the cost; although the cost will be less for users, some costs related to securing the system and installing or upgrading it could be relatively high.

2.2. Generations X Y Z characteristics

The ICTs are changing and transforming individuals and society in general. Various generations are characterized by different traits, preferences, behaviors, principles, and concerns [5]. Therefore, all people with the same characteristics are grouped in what is called a cohort.

The author serves as the bridge that connects the previous and current generations [8]. One of the prominent attributes of Gen X is its reliance on reviews of other people. They make purchase decisions only after thorough research and review of feedback posted by others to make better decisions regarding the purchase [9]. However, they witnessed ICT development and then information society; hence, they became more familiarized with technology [10]. They are adapting to technology very fast.

The author evolved amidst technological advancements and internet growth, allowing them to acquire tons of information without hassle. Gen Y has been introduced to the internet and technology since childhood; hence, they are thoroughly familiar with technology [11], [10], and Media is part and parcel of their lives since they grew in the era of information [12]; therefore, they are comfortable with technology and would prefer to communicate with e-mail or text than talking face-to-face [13] and focus significantly on technical information [14].

Using computers and the internet is part and parcel of Gen Z's lives, who deem social media platforms as the basis of communication and interaction [10]. Therefore, they are excellent with all the digital devices, and they are almost unable to exist without these devices [15].

2.3. Related frameworks and theories

TAM stands for Technology Acceptance Model, which was developed by Davis with the aim to determine and forecast the factors that affect a system before implementing it. TAM was employed by the majority of researchers to develop the framework in order to investigate the factors that influence e-payment adoption. The TAM model identified two major factors; Perceived Usefulness and Perceived Ease of Use, which can be affected by external variables [16]. Later, it was adapted to include more factors; some researchers included Perceived risk, Security, Perceived advantage, Trust, Web assurance seals and Usability [17]. Others, adopted the Perceived Risk and Information on e-payment as additional factors. Adopted Trust, Self-efficacy, and Security as additional factors [18].

In [19], the author performing research on the e-payment adoption in the context of Iran, the factors of Usability (Perceived Ease of use) and Technological and transaction system, as well as access to protection rules (Perceived Usefulness), were used by the authors. Moreover, Technical security, Security reports, Transaction system, and Personal experience pertaining to e-payment systems were identified in [20] as external variables. While the Age was added as a moderating factor in [21].

Other researchers adapted the UTAUT model to incorporate the factor of trust while discarding the factor of user behavior. Another change made in this model was the substitution of Behavioral intention with Continuance Intention [22]

3. Research model and hypotheses

The theoretical framework employed for the current research is shown in Figure 1. This study is carried out to investigate the

factors affecting the Emirate of Dubai residents' perception of using e-payment. The relationships between the factors affecting the residents' perception of using e-payment are used to develop the hypotheses in the following subsections. The factors we used in our conceptual model in light of prior findings from the literature are the following:
Figure 1: The Extended and Adopted Conceptual Framework

3.1. Perceived usefulness

Perceived usefulness implies the consumer's perception regarding the effectiveness and convenience offered by e-payment systems in simplifying his daily transactions [23]. In other words, it is the benefits that a person can get from e-payment systems. E-payment systems provide the user with a convenient mean of payment and the ability to store and transport a currency value [24].

Moreover, e-payment systems can provide other benefits such as time and cost-saving. Usefulness is one of the most important factors for e-payment systems use [17], [18], [25], [26]. However, as per some researchers, considerable time and effort may have to be invested by the consumer to learn how to use the e-payment system [27]; therefore, e-payment systems may be costly rather than cost-saving systems. Thus, it is hypothesized that:

H1 - There is a significant relationship between perceived usefulness and consumers' perception toward e-payments.

3.2. Perceived Trust

Perceived Trust in the context of e-payment systems implies the confidence bestowed by the user in the system regarding the reliability of the system in protecting the user's personal data and money from misuse and theft [28] , [29].

Many researchers stated that a high level of trust is essential for an e-payment system adoption [29], [22]. Similarly, users' concern over data privacy, internet security, etc., leads to a low level of trust, and thus, it will impact the adoption of e-payment systems negatively [32].

However, some researchers argue that trust alone is not sufficient to attract individuals adopting e-payment systems; for instance, if a reputed organization offers e-payment functions, the consumer will willingly use them; However, the user will hesitate in using the e-payment services provided by an untrustworthy organization [17]. Others found that trust is not significantly associated with individuals' perception toward e-payment [20] [31]. Thus, it is hypothesized that:

H2 - There is a significant relationship between consumers' perceived trust and perception toward e-payments.

3.3. Perceived personal innovation

Innovativeness is defined as the extent to which individuals consider themselves as technology leaders and pioneers [33]. This factor has been considered as an important factor influencing user's adoption of e-payment systems [18], [34], [35]. Thus, it is hypothesized that:

H3 - There is a significant relationship between perceived personal innovativeness and consumers' perception toward e-payments.

3.4. Perceived ease of use

Ease of use is defined as to which extent a person will not spend effort while using an e-payment system [23]. It can be attained via several factors, such as the content, design [29], information management, and speed [36]. E-payments systems can be affected significantly by these factors [37]. Previous researchers found that ease of use has a positive effect on the adoption of e-payment systems [18], [21]. Thus, it is hypothesized that:

H4: There is a significant relationship between perceived ease of use and consumers' perception toward e-payments.

3.5. Perceived Risk

Risk is defined as the individual's uncertainty about e-payment systems [38], due to their concern about fraud, theft, hacking, misuse of personal information, etc... Individuals may feel hesitant about the e-payment system due to Risk as an important factor influencing the adoption of the e-payment systems [39]. And the individuals' concern about the system may be a barrier to its adoption [40].

Contrary to most studies, some researchers argue that there is no relation between Risk and intention to adopt e-payment systems; although the Risk affects the payment system's adoption, it has no direct link; thus, individuals may use the system despite their concern [17]. Therefore, it is hypothesized that:

H5: There is a significant relationship between the perceived Risk and consumers' perception toward e-payments.

3.6. Consumer's perception towards the actual use of e-payment

User's attitudes toward IT systems represent a paramount factor that influences a particular system's actual use by individuals [16]. Thus, it is hypothesized that:

H6: Consumers' perception toward e-payment has a positive effect on the actual use of e-payments

3.7. Generations XYZ

In the current study, the generation cohorts will be defined based on the results from the literature review as follow:

- Generation X (Gen X), born between 1965 and 1979

- Generation Y (Gen Y), born between 1980 and 1994, this generation is also commonly known as 'Millennials' and sometimes as 'the children of Globalization' [41].

- Generation Z (Gen Z), born between 1995 and Nowadays, this generation is also known as the "silent generation," the iGeneration, generation quiet, and the next generation" [13].

The researchers believe that people from different generations do things differently when it comes to adopting e-payment systems in Dubai. Thus, it is hypothesized that:

H7: There are no significant differences among different generations toward the actual use of e-payments.

4. Methodology

The participants in this study were using e-payment in the emirate of Dubai. In this research, a nonprobability sample technique is used for collecting responses. Convenience sampling is a type of non-probability sampling where population elements are selected for inclusion in the sample based on access ease. In some cases, judgment sampling is used where the researchers' judgment is used for selecting participants who are considered as representative of the population.

The survey was carried out using a self-administered online questionnaire, which consisted of two major sections. The first section comprises 10 questions intended to collect demographic information and some information about the use of e-payment. The second section contains 28 statements meant to examine those factors that influence the perception of using the e-payment. This section's items essentially required the respondents to choose to what extent they agreed with each statement. The items were close-ended questions based on a 5-point Likert scale that each spectrum includes strongly disagree, disagree, no idea, agree, and strongly agree.

The proposed factors in accordance with the above hypotheses and the conceptual research framework constructed in section 3 are; Perceived Usefulness (abbreviated as PU), Perceived Trust (PT), Perceived Personal Innovation (PPI), Perceived Ease of Use (PEOU), Perceived Risk (PR), and Consumers' Perception toward e-payment (CP). Notably, items of the questionnaire for each one of these factors were cautiously adapted from prior studies. However, the wording was kept as similar as possible across studies.

The pilot study was done on 20 consumers prior to its dissemination to satisfy face validity. Cronbach Alpha, which is a measure of reliability based on the internal consistency of the constructs, was calculated for each factor. The reliability for each factor was higher than the acceptable 0.75 limit that [42] suggests. The Cronbach Alpha for the data instrument in total was 0.913, indicating that the questionnaire has attained a rather high level of reliability. Hence, all items are retained.

Before the regression analysis, 7 variables were created. The items relating to each factor were added together for each respondent, and the average was found. The mean scores ranged from a possible score of 1 to 5, with 1 representing total

disagreement with all stated items, and 5 representing total agreement with all stated items—two types of variables available in the research - dependent variable and independent variables. The main objective of this research is to investigate the predictors/variables that would determine the consumers' perception of the use of e-payment in Dubai. In this study the independent variables are the PU, PEOU, PT, PR, PPI, and CP. These six independent variables would be tested to identify whether these variables possess an influence on the dependent variable, which is the actual use of e-payments (UEP).

5. Analyses and Results

5.1. Descriptive findings

We conducted an online survey to investigate factors affecting consumers' perception of e-payment differences via generations based on our proposed conceptual framework. A total of 379 respondents visited the survey's link, and 242 respondents (63.8%) completed the survey. Of the 242 respondents, 207 respondents (85.5%) were considered eligible for this study after we removed respondents who answered that they are not currently using any of the e-payment methods.

Table 1. Shows the demographic characteristics of the e-payment users in the Emirate of Dubai who use e-payment. From the respondents to the questionnaire, 52.9 % were male, and 47.1 % were female. 12.6 % of the participants have a year of birth less than 1980 (Generation X), 33.3% between 1980 and 1994 (Generation Y), and 54.1% born in 1995 or above (Generation Z). Twenty-two percent of the participants were married, and in terms of the current professional position, 12.1 % were Executive, 10.1% Non-executive, 2.4% Housewife, 61.4% students, 5.3% Self-employed, and 8.7% were in other positions. Also, 30 % of the participants had High school or lower, 12.6 Diploma, 37.7% Bachelor's degree, 10.1% Masters and 9.7% Ph.D. holders. In term of the monthly income, the study found that 55.2% of the respondents having income below 10000 Dirhams, 14.3% between 10000 and 20000, 18.2% between 20000 and 30000, 5.9% between 30000 and 40000 and 6.3% having a monthly income above 40000 Dirhams

Table 1: Demographic characteristics of the sample (n=207)

Criterion	Category	Frequency	%
Gender	Male	109	52.9
	Female	97	47.1
Generation	X	26	12.6
	Y	69	33.3
	Z	112	54.1
Marital Status	Single	161	77.8
	Married	46	22.2
Current Professional Position	Executive	25	12.1
	Non-executive	21	10.1
	Housewife	5	2.4
	Student	127	61.4
	Self-employed	11	5.3
	Others	178	8.7
Education	High school or lower	62	30.0

	College (2 years program)	26	12.6
	Bachelor's degree	78	37.7
	Masters	21	10.1
	Ph.D.	20	9.7
Monthly Income	Below 10000	113	55.2
	10000 up to less than 20000	29	14.3
	20000 up to less than 30000	38	18.2
	30000 up to less than 40000	12	5.9
	40000 or above	14	6.4
Total:		207	100

5.2. Relationships between the factors affecting the Consumers' perception towards e-payment

Table 2 shows the results of the regression model we have done so far using SPSS after we checked the assumptions of regression analysis. From these outputs, we conclude that the factors under investigation explained 78.2% of the variance of the consumers' perception to use e-payments in Dubai. The remaining 21.8% of the variance can be explained by other factors not listed in our conceptual framework. As shown in the ANOVA table (Table 3), the minimal significance F indicates that our regression model is valid at a 0.05 significant level.

Table 2. Regression Model Summary

Model	R	R Square	Adjusted R Square	Std. Error of the Estimate
1	.782[a]	.611	.602	.40269
a. Predictors: (Constant), PR, PEOU, PPI, PT, PU				

Table 3. ANOVA Table

Model		Sum of Squares	Df	Mean Square	F	Sig.
1	Regression	51.303	5	10.261	63.274	.000[b]
	Residual	32.595	201	.162		
	Total	83.898	206			
a. Dependent Variable: CP						
b. Predictors: (Constant), PR, PEOU, PPI, PT, PU						

Table 4 shows the estimations of regression coefficients along with their t-ratios and probability values. It is seen that PEOU, PT, and PPI have a positive and statistically significant effect on the CP. In contrast, the PR has a negative and statistically significant effect on the CP. However, the results of Table 4 indicate that there is no significant relationship between PU and the CP (p-value 0.057). Therefore, hypotheses H2, H3, H4, and H5 of the present research have been validated, but there is no strong evidence to accept H1 at a 5% level of significance.

The sixth hypothesis of the study assumes that the consumers' perception toward e-payment has a positive effect on the actual use of e-payment. To test this hypothesis, we used a correlation analysis. The result of the Pearson's correlation coefficient between the consumers' perception toward e-payment and the actual use of e-payments is significant at 0.01 level (r = 0.452, p-value=0.000). The findings support the stated hypothesis H6 and confirm that consumers' perception toward e-payment has a positive effect on the actual use of e-payments

Table 4: Regression coefficients of the factors affecting consumers' perception of e-payment

Model		Unstandardized Coefficients		Standardized Coefficients	T	Sig.
		B	Std. Error	Beta		
1	Constant	.656	.239		2.742	.007
	PU	.144	.076	.143	1.911	.057
	PT	.116	.056	.110	2.073	.039
	PEOU	.446	.077	.452	5.782	.000
	PPI	.219	.048	.238	4.529	.000
	PR	-.096	.034	-.127	-2.797	.006
a. Dependent Variable: CP						

5.3. Differences among generations towards the use of e-payments

This section discusses the differences among generations towards the use of e-payments. As indicated in Table 5, the findings show that the respondents of generation X have a better agreement in using e-payments (average 4.10) than that of generation Y (with an average of 3.88) and of generation Z (with an average of 3.99). However, the value of the standard deviation (SD), reveals no significant differences between the respondents of generation X (SD=0.69) and the respondents of generation Z (SD=0.65). This contrasts with the respondents of generation Y (SD=0.97). This means there is a more significant difference among generation Y than the two other generations in regards to their perception to use e-payments.

Moreover, we used ANOVA test to verify the seventh and final hypothesis (H7). The hypothesis assumes a statistically significant difference in the consumers' perception of respondents from different generations toward the use of e-payment. As illustrated in Table 6, the p-value is above 0.05 (Sig. = 0.425). This indicates that there are no significant differences in the consumers' perception of respondents from different generations toward the use of e-payment. Therefore, the seventh hypothesis H7 is supported.

Table 5: Averages and Std. deviations of respondents from different generations toward the use of e-payment

Gen.	N	Mean	Std. Deviation	Std. Error	95% Confidence Interval for Mean		Min.	Max.
					Lower Bound	Upper Bound		
X	26	4.1026	.69134	.13558	3.8233	4.3818	2.33	5.00
Y	69	3.8841	.97991	.11797	3.6487	4.1195	1.00	5.00
Z	112	3.9970	.65070	.06149	3.8752	4.1189	2.33	5.00
Tot.	207	3.9726	.77987	.05420	3.8658	4.0795	1.00	5.00

Table 6: ANOVA Table of the respondents from different generations toward the use of e-payment

	Sum of Squares	df	Mean Square	F	Sig.
Between Groups	1.047	2	.523	.859	.425
Within Groups	124.242	204	.609		
Total	125.289	206			

6. Discussion

In the first hypothesis H1, Perceived Usefulness was found not to have a significant relationship with the consumers' actual use of

e-payment in Dubai. The finding was consistent with previous studies [27]. The result implied that regardless of the persons' belief that using an e-payment system will enhance the performance of his day to day activities; consumers are more likely to use e-payment.

In the second hypothesis, H2, Perceived Trust was found to have a significant relationship with the consumers' actual use of e-payment in Dubai. Similar results were demonstrated from previous studies [22], [29]-[32]. And this implied that a high level of trust is essential for an e-payment adoption.

Perceived personal innovation was found to have a significant relationship with the consumers' actual use of e-payment in Dubai, which supported the third hypothesis H3, which was in line with many past studies. [18], [34], [35]. And this implied that the extent to which individuals consider themselves as technology leaders and pioneers is considered an important factor influencing the user's adoption of e-payment.

Perceived Ease of Use was found to have a significant relationship with the consumers' actual use of e-payment in Dubai, which supported the fourth hypothesis H4, which was in line with many past studies [18], [21], [37]. And this implies that ease to use of handling e-payment, such as convenience, speed, flexibility, simplicity, accessibility, and availability, is also considered a vital factor influencing the user's adoption of e-payment.

Perceived Risk was found to have a significant negative impact found to have a significant relationship with the consumers' actual use of e-payment in Dubai, which supported the fifth hypothesis H5. This was in line with many past studies [39], [40]. This implies that individuals' concern about the system may be a barrier to its adoption.

In the sixth hypothesis, H6, the Consumers' Perception toward e-payment was found to have a significant positive relationship with the consumers' actual use of e-payment in Dubai. And this implied that the user's attitude toward IT systems represents a paramount factor that influences the actual use of e-payment.

Finally, this study's results did not show significant differences among the different generations toward the use of e-payment, which supported our seventh hypothesis, H7. This might be indicated that most consumers in Dubai, as a smart city, are sufficiently familiar with using e-payment and accepting any new technologies easily.

7. Conclusion and implications

In this paper, the researchers studied the effect of some factors that might affect the adoption of new e-payment services and technologies. Based on an extended framework that captures the unique status of smart cities such as Dubai that move faster in digital transformation rather than less developed ones. The extended framework included all of Perceived Usefulness, Perceived Trust, Perceived Personal Innovativeness, Perceived Ease of Use and Perceived Risk on the adoption of e-payment systems in Dubai while considering the age cohorts (X, Y, and Z generations).

The results show that most of the factors used in the study are indeed critical and significant to the users' adoption of e-payment systems in Dubai. However, perceived usefulness is not as

significant as the other factors; we think it is because some users care more about the system being easy to use than to be useful.

Unexpectedly, we found no serious differences between the generation cohorts regarding the adoption of e-payment in Dubai. We think that this due to the government of Dubai's efforts to in digital transformation of all of its E-Government services, and the adoption of digital payments toward a cashless economy might be a reason. The results imply that the government's strategies encourage consumers to use technologies in general as e-payment systems are working fine. This research will help future studies that focus on more recent technologies in the region based, such as adopting cryptocurrencies by individuals and businesses in the Middle East's smart city context.

8. Study limitations and recommendation for future work

This study is not free from some limitations. And to begin with, the sample employed in our empirical analysis is collected by nonprobability sampling techniques. The use of a convenient sample limits the research results to the specific sample, which means that the findings cannot be generalized to a larger population [43]. Other factors and dimensions, including the individual differences, system characteristics, social influence, and facilitating conditions missing in this study, will be considered in future research.

Additionally, the exact e-payment channels and factors toward adoption in Dubai and the preferred e-payment methods should be conducted to understand how Dubai as a smart city is moving toward the digital transformation of e-payment channels and their diffusion among the consumers; this will compared to other smart cities in the region including Saudia Arabia and Singapore [44], [45] and my be focused on specific sector such as banking [46]. The expected results will be useful to financial institutions, government, and e-payment technology providers in this region and marketers and, will encourage the innovative design of e-payment services that are most likely will be adopted by individuals, businesses, and governments.

Conflict of Interest

The authors declare no conflict of interest.

Computer Science Department, BINUS Graduate Program – Master of Computer Science, Bina Nusantara University, Jakarta, 11480, Indonesia

A R T I C L E I N F O	A B S T R A C T
	Music is one of the most popular entertainments, and the music industry continues to increase over time. There are many types of genres in music, and everyone has their own choice of the type of music they want to listen to. The recommendation system is an important function in the application, especially when there are a large number of choices for a particular item. With a good recommendation system, users will be able to get help from the suggestions given and can improve the user experience of the application. By using collaborative filtering (CF) methods to recommend products related to personal preference history, this feature can be better provided. However, the CF method still lacks in integrating complex user data. Hybrid technology may be a solution to perfect the CF method. The combination of neural network and CF also called NCF is better than using CF alone. The focus of this research is a CF method combined with neural networks or neural collaborative filtering. In this study, we use 20,000 users, 6,000 songs, and 470,000 records of ratings then predict the score using CF and NCF approach. We aim to compare the recommendation systems using CF and NCF. The study shows that NCF is better in gathering certain playlists according to one's preferences, but it takes more time to build compared to user-based collaborative filtering.

1. Introduction

Music is one of the most popular entertainments. There are 1.15 trillion users who stream video and audio-based music on digital platforms in 2019 and increased by 29.3% from the previous year. The increasing number of users are based on the fact that music could control people's emotions, moods, or physiological arousal [1]. Besides users, music content also increases a lot every year. Large numbers of music content are making it hard for people to search relevant music, especially when it is unorganized. Therefore, there is a need to organize all music content, but it is very time consuming to do manually. In order to simplify this process, some music applications like Spotify and Youtube Music implement recommendation mechanisms or systems [2]. This recommendation system can suggest a list of relevant music from the library and becoming popular nowadays and crucial to prevent their customer to move on to another service [3].

Recommendation systems use two main approaches, content based and collaborative filtering (CF). Content based approach focuses on item metadata or attributes. For example, a music described by genre, singer, producer, etc. Otherwise, CF approaches focus on user preferences and are called as personalized recommendation systems. This approach analyzes the relationship between user and item. Similar users tend to be interested in similar items. User similarity can be measured by their history or review. Afterwards, user-item relation is used to predict what item might be liked by other users similar to him. Suggested items may vary for each user, due to different interests. Thus, CF approach has become popular and widely used in recommending items [4].

In CF, matrix factorization (MF) becomes one of the most popular techniques besides neighbour-based using similarity metric. Unfortunately, MF performance impeded due to inadequately capturing an advanced structure of user interaction data. Thus, it is required to develop another technique by using MF approach to obtain better results [5]. Recommendation system nowadays widely implements hybrid techniques in order to overcome limitations of the CF approach [2, 3]. An approach by combining both CF and neural networks is one of the hybrid

techniques used widely for learning the interaction function from data [5].

Collaborative filtering approach combined with neural network or called neural collaborative filtering (NCF) enthrall this study. The aim of this study is to compare NCF with user-based CF. In this paper, we also implement collaborative filtering and neural collaborative filtering in a digital online music application. After a user logged in, the system will provide recommendations with the two methods along with the predicted rating.

This paper consists of 5 sections starting from the review from previous work in section 2, followed by methodology in section 3. In section 4, we discuss the experiment results of neural collaborative filtering compared with user-based collaborative filtering. Finally, we concluded our study with suggestions for future research in section 5.

2. Related Work

Recommendation system is a system that is used to predict an object as a suggestion to a related user. Suggested item expected to be liked or relevant to user's interest. It consists of two different strategies, which are the content-based approach and CF. Content-based approach, did its job by distinguishing the product's nature. CF on the other hand relies only on past user behavior. It then complicates the use in the beginning since it is unable to address products new to the system, and so called the cold start problem [6].

Collaborative filtering uses two types of input, those are explicit and implicit feedback. Those feedbacks are used as user-item interaction. For explicit feedback, data acquired explicitly from user input in response to portray if the user is interested in an item. However, not every user likes to give their thoughts about an item, so explicit data is not always available. This underlines the reason why we need to observe user behavior to acquire the implicit feedback. Examples of implicit feedback are mouse click, the number of times a video or music played, etc. An implicit feedback has an inherently noisy nature, it requires appropriate measures for evaluation, and the numerical value indicates confidence [6].

The CF approach is widely used in e-commerce, movie/video/music platform, food application, and social media - Facebook, Instagram, Twitter. There are two types in CF approach, those are: user-based and item-based. User and item-based CF are alike, where user-based search the items that a user interacted with. While item-based search which users interacted with this item. Collaborative filtering approaches are used widely nowadays. Research by [5,7–11] implemented CF and showed that CF resulted in high accuracy and suitable for recommendation systems. This approach has for about 2 thousand users, and the accuracy is 80-90% [9]. While research by [12] gives 0.8 and 4.5 as the highest RMSE and MAE value, respectively.

The principal in creating a neighbour-based CF recommendation system is to identify user similarity from their preferred items, then select top most similar k users [5,10,11]. Neighbour-based CF provides good recommendations. Research by [12] shows that multiple processes to predict rating with k=1 and use the average of item's ratings gives better performance in terms of precision, recall, accuracy, MAE, MSE, etc. Research by [3,11] shows that a recommendation system with kNN-based CF does well in predicting rating of song given the attributes with a small error value. Another method for CF is using latent vectors to represent users and items, called matrix factorization (MF) [7]. In this process, the inner product of those latent vectors become the interaction between user and item, or ratings. Latent-vectors factors are learned in MF method by minimizing the loss or difference between actual and predicted ratings [13]. Deep learning like recurrent neural network (RNN) can represent better user interest from the latent-vectors factors [14].

Even though those techniques perform well, it also has its deficiency. Therefore, fusing one technique to the others could be more promising in providing better recommendation. Nowadays, combining/hybrid techniques are used widely in machine learning and also recommendation systems. By combining technique, each technique is expected to overcome others' limitations [2,3,15]. One of which is by combining with neural networks for learning the interaction function from data. It is supported by a paper that stated that neural collaborative filtering (NCF) or combination of MF with neural network shows that NCF with 4 layers results in greater HR@10 and NDCG@10 value [5]. Another hybrid approach proposed by [14] called multiple user interest representation (MUIR), combined CF and content based filtering aspects using deep learning which resulted in better precision, recall, NDCG values compared to content based filtering and other methods. Based on those hybrid techniques, it shows that combined techniques produce better results and complement one's weakness.

3. Methodology

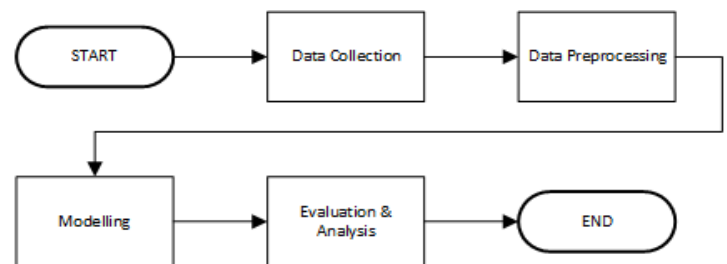
In this section, we will explain our steps on building a song recommendation system using user-based collaborative filtering and neural collaborative filtering as shown in Figure 1.


Figure 1: Steps of the Music Recommendation System Research

3.1. Data Collection

Data used in this study consist of users, music, and the total number of times the music was played. There are over 20,000 users, 6,105 music, and 470,759 records about the number of times music was played.

Figure 2 shows the ERD used in our digital online music application. The "playlistcount" (3rd) table contains the implicit feedback of the number of times each user heard a song. The "playlistrating" (4th) table shows the rating data of each user for a song that is heard. The 3rd table has a close relationship with 4th table where the rating is obtained from normalizing the number of times a user listens to a song. Calculation of normalization will be discussed in Chapter 3.2.
Figure 2: Entity Relationship Diagram of Music Data

3.2. Data Preprocessing

We need to normalize the number of times the music is played c_{ui} due to different habits each user is likely listening to. The normalize value then considered as rating r_{ui} – the rating from user u for item i as shown in Eq. (1):

$$r_{ui} = \frac{c_{ui}}{Max(c_u)} \times 100 \qquad (1)$$

The denominator of Eq. (1) search maximum number of times user u listened to a music. The rating value is then stored in the database on the 4th table as shown in Figure 2 and used for suggesting music content to each user. It is ranging from 0-100.

3.3. Modelling

To predict personalized music rating, we use two techniques, that is: user-based collaborative filtering and neural collaborative filtering. For those techniques we use the same preprocessed data discussed before. All models were run on Google Colaboratory with its GPU runtime.

3.3.1. User-based Collaborative Filtering

For user-based collaborative filtering, we first choose a user u, then we find similar user candidates by seeing if they have listened to the same music. Due to lots of users in the database, we use sample candidates of n users. Next, compute correlation or similarity between user u and similar users' candidate. In calculating the similarity of two objects, we can use similarity metrics, such as cosine similarity, pearson correlation coefficient (PCC), and mean square distance (MSD). In this study, we use PCC formula [7–9,12] as shown in Eq. (2):

$$r = \frac{\sum_{i=1}^{n}(x_i - \bar{x})(y_i - \bar{y})}{\sqrt{\sum_{i=1}^{n}(x_i - \bar{x})^2}\sqrt{\sum_{i=1}^{n}(y_i - \bar{y})^2}} \qquad (2)$$

In Eq. (2), x represents ratings from user 1, while y represents ratings from user 2. The output of pearson correlation (r) ranges from -1 to 1 representing how similar is user 1 and user 2. The value of r = -1 when there is a perfect negative correlation, r = 0 means there is no correlation at all, and r = 1 means there is a perfect correlation. Next, we sort similarity users in descending order as it represents the most similar preference with user u and choose the top 50 users. After that, we predict the rating.

There are several methods for predicting rating, such as weighted average (WA), mean centering (MC), and Z-Score (ZS) [12]. In this study, we use the weighted average method. Correlation value with the top 50 users then used as a weighting factor in order to calculate predicted rating by weighted average as shown in Eq. (3) [12]:

$$\dot{r}_{ui} = \frac{\sum_{j=1}^{n_{ui}} sim(i,j) * r_{ju}}{\sum_{j=1}^{n_{ui}} |sim(i,j)|} \qquad (3)$$

where:

- $sim(i,j)$ is the output of PCC of user i and j similarity
- r_{ju} is actual rating from user j of item u
- $\dot{r}_{ui}$ is predicted rating from user u of item i

In CF, we split data into two sections: training and testing. First, we take 5 given ratings by each user and use it as a testing data. Therefore, we have 376,617 as training data and 100,000 as testing data. While predicting test data, the model could output NaN values, so we do not consider when calculating errors.

3.3.2. Neural Collaborative Filtering

Neural collaborative filtering approaches combine general matrix factorization with neural network matrix factorization as shown in Figure 3. This model combines linearity of GMF and non-linearity of neural network in modelling user-item interaction. This model was built by using Keras. Extra preprocessing was implemented when building this model because our input data consist of strings. We then use labelencoder provided by the sklearn library to encode and decode user and music id. Encode is necessary to build the model while decode is used when predicting rating for the user.

For each input, that is: users and music, we create embedding or latent factor with a size of 64 for each item. Then, we multiply item and user embedding as a layer for general matrix factorization (GMF). For the neural network layer, it aims to learn user-item interaction representing predicted rating matrix. Concatenating the item vector with the user vector has been widely used in multimodal deep learning network. However, it does not consider user-item interaction [5]. So, we use a multi layer perceptron (MLP) to learn the interaction function. First, we concatenate item and user embedding and use four hidden layers

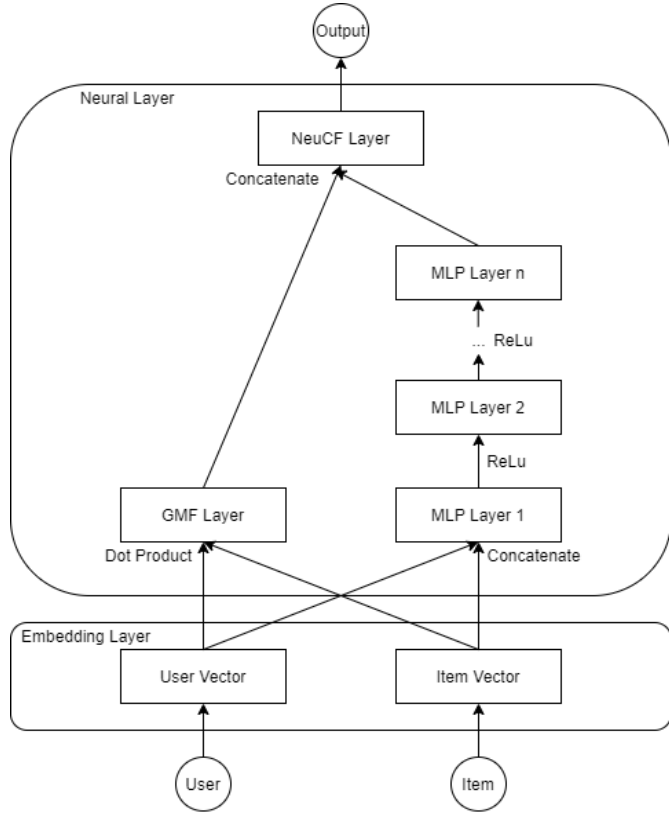
with 0.25 as a dropout rate. For each hidden layer we implement a linear activation function, ReLu R(x) as shown in Eq. (4). The value of R(x) ranges from 0 to infinite. Then, we concatenate GMF results with the matrix generated from the MLP layer as NeuCF layer. Last, the output of NCF is given by using ReLu activation function on NeuCF layer's output. The formula used in NCF model are shown in Eq. (5) - Eq. (7) [5].


Figure 3: Structure of Neural Collaborative Filtering

$$R(x) = \max(0, x) \tag{4}$$

$$GMF = p_u \cdot q_i \tag{5}$$

$$\text{MLP} = \alpha_L \left(W_L^T \left(\alpha_{L-1} \left(\dots \alpha_2 \left(W_L^T \begin{bmatrix} p_u \\ q_i \end{bmatrix} + b_2 \right) .. \right) \right) + b_L \right) \tag{6}$$

$$y_{ui} = R \left(h^T \begin{bmatrix} GMF \\ MLP \end{bmatrix} \right) \tag{7}$$

For all formulas above, p_u and q_i denotes user and item embedding respectively. We define this task as a linear regression problem as we intend the output of NCF is the predicted rating value. Therefore, we use mean square error (MSE) as the loss function. Parameters used in this model are shown in Table 1.

Table 1: NCF Model Parameters

Variable	Value
Batch size	64
Epoch	10
Learning rate	0.001
Optimizer	ADAM

In the neural collaborative filtering approach, we split the data into training, validation, and testing data. The percentage of testing data is 20% of all data and 80% for training. The training data is then split into training and validation, with a percentage of the total data validation of 20% of the training data. Therefore, we have 301,285 as training data, 75,322 as validation data, and 94,152 as testing data.

3.4. Evaluation

Since the recommendation system output is predicted rating, we use regression evaluation metrics. We use mean absolute error (MAE), Mean Absolute Percentage Error (MAPE), mean square error (MSE), and root mean square error (RMSE) for the calculation. The evaluation and comparison of our music recommendation system presented as a value of actual and predicted music rating. The formula of each evaluation metrics is shown in Eq. (8) - Eq. (11):

$$\text{MAE} = \frac{\sum_{i=1}^{n} |y_i - x_i|}{n} \tag{8}$$

$$\text{MAPE} = \frac{\sum_{i=1}^{n} \frac{|y_i - x_i|}{y_i}}{n} \times 100\% \tag{9}$$

$$\text{MSE} = \frac{\sum_{i=1}^{n} (y_i - x_i)^2}{n} \tag{10}$$

$$\text{RMSE} = \sqrt{\frac{\sum_{i=1}^{n} (y_i - x_i)^2}{n}} \tag{11}$$

Where x and y represent predicted and actual value respectively.

4. Experiments

Our experiments take two steps, which are searching the best architecture used for NCF and comparing it with user-based CF. Table 2 and Figure 4 below shows the performance of NCF given different architecture on validation data. We test the model using 32, 64, and 128 latent vector factors or dimensions with 3 and 4 hidden layers. We use 3 and 4 hidden layers based on experiments by [5] which shows that 4 hidden layers results in better NDCG@10 value and 3 hidden layers once give the best NDCG@10 value. For every number of latent vector dimension, it is true that 4 hidden layers model gives less error than with 3 hidden layers. It also showed that 64 latent factor dimensions gives better error performance with about 5 value difference between the lowest error of 32 and 64 latent factors.

Table 2: Neural Collaborative Filtering Performance with Different Architecture

Layers	Factor	Highest Error	Lowest Error	Average Time to Build
3	32	29.123	20.271	13 minutes
	64	26.097	16.480	29 minutes
	128	25.655	24.086	55 minutes
4	32	25.799	15.879	15 minutes
	64	25.201	15.697	30 minutes
	128	25.397	23.676	57 minutes
Figure 4: RMSE of Neural Collaborative Filtering on Testing Data

Evaluation metrics of CF and NCF shown in Table 3 below are calculated based on the 94,152-test data. Based on the result, it is shown that NCF is better than user-based CF, as it has lower error calculated with MAE, MAPE, MSE, and RMSE. Other than that, CF error has a big difference with NCF with about two times larger. These errors seem to be larger than other research mentioned before because we use a wider range of 0-100 for each rating. It is not surprising since there are some limitations in PCC. Some of the important limitations by PCC are that similar users could only be calculated if there is an overlap over the rated items and due to CF sparse data makes PCC results NaN measure [15].

Table 3: Collaborative Filtering and Neural Collaborative Filtering Performance

Method	MAE	MAPE	MSE	RMSE
CF	14.866	66.118	645.786	26.107
NCF	7.933	28.591	246.422	15.697

Table 4 below shows the predicted rating by using CF and NCF. We use 3 users given 7 sample music to see the difference between actual and predicted rating by both CF and NCF. The closest difference means that the framework predicts better results. NCF framework gets a 21/27 score and reflects that NCF provides more appropriate and optimal recommendations compared to CF.

Table 3: Sample of Recommendation Score

# User	# Song	Actual	CF Score	NCF Score	Winner
1	1	34	43.666	25.124	NCF
	2	13	28.5	10.368	NCF
	3	20	54.75	40.449	NCF
	4	17	13.3	18.745	CF
	5	17	19.66	22.226	CF
	6	3	27	25.456	NCF
	7	6	26.8	25.338	NCF
2	1	5	20.4	17.052	NCF
	2	50	58	51.9	NCF
	3	20	54.75	40.449	NCF
	4	5	13.5	13.961	CF
	5	5	17.666	6.296	NCF
	6	5	23.375	6.747	NCF
	7	11	85	34.424	NCF
3	1	33	30.2	26.475	CF
	2	33	23.25	29.868	NCF
	3	66	44	26.472	CF
	4	33	16.666	30.487	NCF
5		33	37.5	39.8	CF
6		33	13.666	40.82	NCF
7		66	33.2	44.707	NCF

Table 3 and 4 represent NCF framework is better than CF alone as it gets less error in predicting rating. Unfortunately, NCF needs more time to build a model with approximately 25-30 minutes with our model using Google Colaboratory GPU runtime. However, it is worth implementing NCF as it predicts more accurately and faster than user-based CF when using pre-build NCF model. The NCF model needs 5.24 seconds while CF needs 12.16 seconds in recommending music. Therefore, the NCF model must be trained first and stored so that in its application, it is only necessary to load the model.

The experimental results were obtained by following the stages, methods, and architecture described in Chapter 3. The parameters described in Chapter 3 are the best parameters to get optimum results based on several experiments such as changing the number of latent factor dimensions and the number of hidden layers. Other than that, we also consider the time to build the model with the difference of the errors.
Figure 5: Application Workflow

The disadvantage of doing a load model is that it cannot cope with significantly changing conditions. The model is trained with existing data, if there is a change in behaviors, the model cannot handle it. To overcome this, the model must be trained regularly so that changes in user habits can be learned and the system provides appropriate recommendations. In this application, model training is carried out periodically using recurring jobs. With the recurring jobs that carry out training with the latest data, it is hoped that it can overcome significant changes in user behaviours.

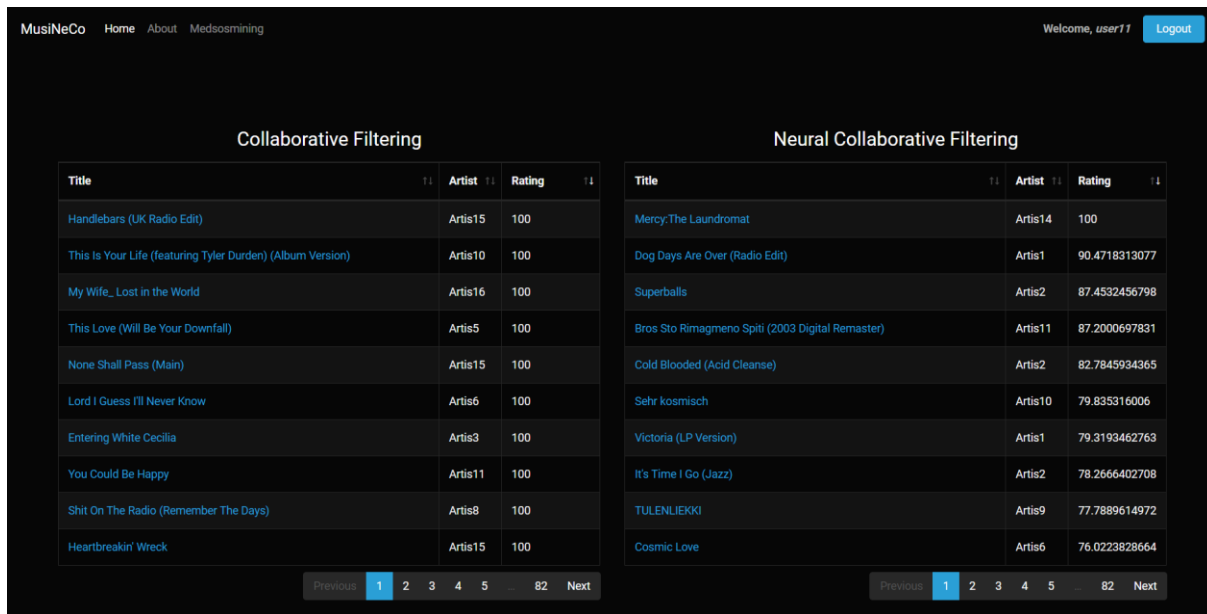
An example of a user interface of our application can be seen in Figure 6. After the user logs in, 2 recommendation options will be given, using CF and NCF, this process on our application shown in Figure 5. On that page, the predicted rating for each recommended music is also displayed. There is no identical music on the top 9 recommendations based on CF and NCF. In NCF the predicted ratings are more varied rather than CF results.


Figure 6: Music Recommendation Application

5. Conclusion

Our study focuses on NCF then compared with CF approach on music dataset. From the results discussed in Chapter 4, it can be concluded that NCF produces better recommendations than CF in terms of errors, predicting ratings, and time used to predict. It is unsurprising that NCF gives better performance since it learns the user and music embeddings that more similar users in the context of preferred music are closer to each other in the embedding space rather than single correlation calculation performed on CF. Moreover, recommendation model from NCF could be used repeatedly on giving recommendation without recalculating similarity between users when needed. However, building NCF model needs more powerful computation power due to massive matrix manipulation needed.

In addition to making comparisons between CF and NCF, we also make comparisons with several model parameters to the NCF model in order to obtain an optimal model. Model with more hidden layer may converge in a higher level of abstraction. It is proved in this study that four hidden layers model gives smaller error paired with small time difference when building the model compared with three hidden layers model. The result of this study can be implied to increase people's engagement with digital online music applications as it provides sufficient recommendations according to the user preference.

Although neural collaborative filtering has better results than collaborative filtering, this method has a weakness in terms of preparation time because it has to go through the build and training model stages. This stage takes a long time, so the alternative is to save the trained model and load the model to get recommendations. To solve the process time problem, the implementation of the application does not do real-time training instead, it loads a trained model. Further research on recommendation systems could contribute in proposing a new approach or combining several approaches to improve system performance, either in terms of times, effectiveness, errors, accuracy, or other performance metrics.

Conflict of Interest

The authors declare no conflict of interest.

A R T I C L E I N F O	A B S T R A C T
	The Bolivian higher education system comprises 59 universities; these institutions have the challenge of increasing their scientific production since it is one of the factors to provide quality education and meet one of the 17 Sustainable Development Goals (SDGs). But currently, the GDP assigned to the research and development (R&D) sector of Bolivia is 0.16%. In this regard, this research aims to develop a scientific production assessment of the publications generated by Bolivian universities and indexed in SCOPUS in the last ten years. On the other hand, the universities included in the 2020 SIR World and SIR Iber rankings will be identified, and their scientific production will be reviewed. After conducting the analysis, it was observed that the country still has a low scientific production compared to the rest of the countries in the region, with a total of 3,451 publications indexed in SCOPUS and 303.97 publications per million inhabitants in the last ten years. The 2020 SIR World ranking shows that only one Bolivian university is in the ranking and holds the 774th position. For their part, 26 Bolivian universities entered the 2020 SIR Iber ranking. Among all these institutions, they produced 1,010 publications indexed in SCOPUS for the five years analyzed.

1. Introduction

The United Nations (UN) indicates that one of the 17 sustainable development goals is to provide quality education [1]; it is essential to speak of higher education for sustainable development in this context. That is why universities are encouraged to fulfill the mission of becoming centers of learning and research for sustainable development within their communities [2].

However, according to [3, 4], Bolivia's universities, together with other countries of the Andean region such as Ecuador and Peru, have not been structured in their beginning from substantial scientific communities. For this reason, the higher education systems of the three countries did not develop enough scientific bases, so they suffer from academic weakness at the institutional level [5].

Bolivia is a country located in South America; it is an Andean country with 11,353,100 inhabitants, according to data from the World Bank [6]. The GDP assigned to the research and development (R&D) sector in Bolivia is 0.16%, according to

UNESCO (United Nations Educational, Scientific and Cultural Organization) [7]. The country's higher education system comprises 59 universities registered in the Vice Ministry of Higher Education for Professional Training [8]. Bolivian universities are classified into autonomous public universities (11), private universities attached to the Executive Committee of the Bolivian University - CEUB (3), private universities (39), indigenous universities (3), and exceptional regime universities (3).

According to [9], one of the challenges of the Bolivian higher education system is that there is a difference between Bolivian public universities since they try to focus on three functions of higher education: training, research, and interaction, and contrarily private universities tend to focus on their teaching activities without focusing on doing research. The main reason [2, 10] is that most university teachers, especially in private universities, do not work full-time, which prevents them from getting involved in scientific research development. It is also mentioned in [5] that university teachers are overloaded with teaching hours and administrative work.

Given this limitation, according to [5] until 2006, many universities have promoted research infrastructure creation.

According to records, 17 research centers belong to private universities, 25 research institutes belong to government organizations, and 141 belong to the public university system, giving 183 research and development centers located mainly in three departments La Paz, Cochabamba, and Santa Cruz.

Besides, according to [11], there have been national policies to increase human resources in research, for example, the increase in postgraduate programs, both masters and doctoral programs in Bolivia, which left a total of 1,015 research professors and 631 research assistants, in addition to 4,014 completed investigations until 2014. However, these statistics do not include data from private universities. According to UNESCO, for the year 2020, the country has 2,218 full-time equivalent researchers [7].

Another important aspect is the number of Bolivian academic-scientific journals indexed in SciELO, RedALyC, and SCOPUS databases. According to [12], until 2011, Bolivia had six journals indexed in SciELO and one journal indexed in SCOPUS; these shows a scarce presence and not in all sources. However, these seven scientific journals included in prestigious databases for the scientific community at the regional and international levels increase Bolivian scientific production's visibility.

In this sense, scientific research and production are essential not only because they allow innovation, the resolution of social demands, and the country's technological development. Also, because there are metrics to classify universities, in which scientific production is an essential factor. This situation is the case of the Scimago Institutions Rankings (SIR) that develops two annual reports. One is SIR World, an institutional ranking of organizations from different sectors that produce research in the world. The other is SIR Iber, which shows the scientific activity of higher education institutions in Ibero-America [13, 14]. For an institution to enter SIR World, it needs a scientific production of at least 100 research articles indexed in the SCOPUS database per year. Also, to enter SIR Iber, the institution must have at least one document published and indexed in SCOPUS. Additionally, the Academic Ranking of World Universities (ARWU) uses different indicators, including the number of former students and staff who won Nobel prizes, scientific production, and the citation index [15].

The present research seeks to analyze the scientific production developed by Bolivian universities and indexed in SCOPUS from 2010 to mid-2020 and compare it with other countries' scientific production in the South American region. Moreover, the SIR World and SIR Iber report for 2020 will be analyzed to identify the Bolivian universities included in these rankings. Finally, the scientific production indexed in SCOPUS in 2019 and part of 2020 of the five Bolivian universities with the highest scientific production in Bolivia according to SIR Iber 2020 will be presented.

2. Methodology

2.1. Data sources

The data necessary for the development of this research work are the following:

- Scientific production: The data on scientific production in Bolivia and the rest of South American countries were extracted from SCOPUS, which is an international database that indexes scientific publications, covers scientific journals

and books from various publishers [12, 16]. SCOPUS belongs to Elsevier, a modern global information analysis publisher specializing in science and health [17].

Scientific production data were extracted from 2010 to the end of July 2020. Moreover, due to the constant updating of the database, it was decided to collect scientific production data on the same date, 07/27/2020, for all countries and institutions analyzed in this study.

- Population data: The number of inhabitants of the South American countries was extracted from the open-access data catalog prepared by the World Bank data team [6]; this catalog contains world population data. In all the South American countries analyzed in this study, the population data are updated until 2018.

- Bolivian universities: The list of Bolivian universities was extracted from the guide of universities of the Plurinational State of Bolivia [8], prepared by the Vice-Ministry of Higher Education for Professional Training; this Vice-Ministry is part of the Ministry of Education of Bolivia. This guide is the latest version published and is updated to the year 2016.

- Classification of Bolivian universities by scientific production, this list was extracted from Scimago Institutions Rankings (SIR) from both the SIR World report and the SIR Iber report; both reports correspond to the year 2020 and can be consulted at https://www.scimagoir.com/rankings.php. It should be mentioned that, although both rankings correspond to 2020, they are prepared based on data from five years from 2014 to 2018 [13].

2.2. Data preparation and analysis

In South America, there are 13 countries, all of which are culturally diverse, and their higher education systems have gone through different historical processes, so they present different scientific production levels. These factors added to the fact that all the regional countries have different sizes and amounts of inhabitants.

Therefore, to develop a fair comparison, this study proposes comparing South American countries' scientific production per million inhabitants.

$$P_i = \frac{P_S}{N_i} \, x \, 1\,000\,000 \qquad (1)$$

where:

P_i = Publications per million of inhabitants
P_S = Number of Publications indexed in SCOPUS
N_i = Number of inhabitants

As can be seen, the previous equation will allow a proper classification of the countries by their scientific production indexed in SCOPUS.

3. Results

The results obtained after processing and analyzing the collected data were divided into two sections for better understanding. The first section will show a comparative analysis of the scientific production indexed in SCOPUS in the 13 countries of South America. The second section will show the Bolivian

universities' scientific production indexed in SCOPUS and how they are positioned in Ibero-America and the country.

3.1. Scientific Production in South America

It is intended to analyze and compare the entire scientific South American region's scientific production to observe its evolution over the last ten years and, above all, to identify and diagnose the growth of scientific production in Bolivia.

Therefore, to develop a fair comparison, this study proposes comparing South American countries' scientific production per million inhabitants. As mentioned in the methodology section, the scientific production data was consulted on July 27, 2020.

According to the data obtained in the last column of Publications per million inhabitants (Pi), it can be observed that the country in the region with the highest scientific production per million inhabitants is Chile, with a total of 6,597.13 articles per million inhabitants. Secondly is Uruguay, with a total of 4,427.85 articles per million inhabitants. In the third position is Brazil, with 3,567.35 articles per million inhabitants. Then, there is Trinidad and Tobago, with 3,205.99 articles per million inhabitants. Argentina follows it with 3,193.68 articles per million inhabitants.

Subsequently, it is located in Table 1 Colombia, with 2,024.73 articles per million inhabitants. After Colombia, Ecuador can be found with 1,378.45 articles per million inhabitants. In the eighth position is Peru, with 791.61 articles per million inhabitants. Subsequently, Suriname is found with 776.05 articles per million inhabitants. Venezuela follows with 664.87 articles per million inhabitants. In the eleventh position is Guyana, with 587.93 articles per million inhabitants. Afterward is Paraguay with 343.58 scientific articles per million inhabitants and finally Bolivia with 303.97 articles per million inhabitants.

Figure 1 shows the difference between the total scientific production of the South American countries from 2010 to 2020 (A) and the scientific production per million inhabitants (B) during the same period.

As shown in Fig. 1 A), if only the total number of scientific publications were counted, Brazil would be found in the first place by a significant difference. However, when considering the

population factor, it can be observed in Fig 1. B) that Chile rises to first place. Another compelling case to comment on is one of Peru and Ecuador. It can be seen in Table 1 that Peru, until 2015, had higher scientific production than Ecuador. But as can be observed in 2016, Ecuador begins to increase its scientific production and exceeded the Peruvian scientific production. Additionally, it can be observed that Trinidad and Tobago, despite having a reduced scientific production that remains relatively constant throughout the ten years of study. When considering the number of inhabitants to calculate scientific production per million of inhabitants, this country is located in a good position within Table 1. Finally, Venezuela, unlike the rest of the countries in the region that are increasing their scientific production year after year, can be observed that Venezuela is decreasing its scientific production.
Figure 1: Scientific Production in the South American countries A) Total number of publications from 2010 to 2020 B) Publications per million of inhabitants (Pi)

Table 1: Scientific Production in the South American countries

Country	Number of inhabitants	2010	2011	2012	2013	2014	2015	2016	2017	2018	2019	2020	TOTAL	Pi
Chile	18,729,200	7,147	7,889	8,994	9,426	11,134	11,788	13,462	13,675	15,016	15,818	9,210	123,559	6,597.13
Uruguay	3,449,300	948	1,096	1,113	1,176	1,472	1,393	1,613	1,598	1,833	1,935	1,096	15,273	4,427.85
Brazil	209,469,300	51,028	55,492	61,532	64,848	68,472	70,543	75,270	79,505	84,090	86,815	49,655	747,250	3,567.35

Bolivia	11,353,100	251	262	254	286	314	329	353	310	388	430	274	3,451	303.97

Source: SCOPUS database

In Bolivia's case, it can be observed that, although it is in the last position concerning the other countries of the region if the number of inhabitants is taken into account Fig. 1 B). However, it climbs ranks in Table 1, reaching the tenth position if only the total scientific production over ten years is taken into account Fig. 1 A), with a total of 3,471 scientific articles indexed in SCOPUS from 2010 to mid-2020.

Besides, from 2010 to 2017, Bolivia shows a growth in scientific production that remained relatively constant over time; Bolivia presents two decreases registered, one in 2012 with a reduction of 3.05% and another reduction of 12.18% in 2017. Also, it can be observed that there has been a growth in scientific production, especially during the last two years, since Bolivia presented an increase of 25.16% in 2018, which is the highest percentage of growth registered in the previous ten years. It has been possible to observe another increase reported in 2019 of 10.82%.

Finally, it can be seen that by the end of July 2020, Bolivia already presents a total of 274 publications indexed in SCOPUS, which represents 63.72% of the total scientific production of 2019. This percentage leads to thinking that this year will present growth in scientific production compared to what was obtained the previous year.

3.2. Scientific Production in the Bolivian Universities

As explained in the methodology section, the SIR World and SIR Iber reports were consulted to identify Bolivia's higher education institutions with the necessary scientific production to enter one or both rankings.

Consulting the SIR World 2020 report, it was found that only one Bolivian university is present in the ranking, in the 774th position was the Universidad Mayor de San Andrés (UMSA). This university is an autonomous public university located in La Paz, which is the seat of Bolivia's government. It is essential to mention that it is the first time that a Bolivian university has managed to overcome the fence of 100 publications and enter this ranking. The UMSA in 2018 managed to reach 110 scientific publications

indexed in SCOPUS, the reason that allowed it to represent the country in this ranking.

As consulted in SIR World [18], the Universidad Mayor de San Andrés published in 85 scientific journals and different areas of research, as can be seen in Fig. 2:
Figure 2: Research topics of the Universidad Mayor de San Andrés (UMSA) [18]

In Fig. 2, each circle's spatial position represents the scientific article's research topic; for its part, the colored spots indicate the research areas. The circles' size represents the value of the SCImago Journal & Country Rank (SJR) of the publication. It can be seen that there is a predominance of publishing in the areas of biology and medicine.

Furthermore, when consulting the SIR Iber 2020 report, the list of 26 Bolivian universities that accomplished to enter that Ibero-American ranking was compiled, as can be seen in Table 2:

Table 2: Bolivian universities in SIR Iber 2020

Source: SIR Iber 2020 [14]

Table 2 shows the 26 Bolivian universities present in the SIR Iber 2020 ranking. Also, it can be seen in the respective position of the institution in Ibero-America (IBE) in Latin America (LAC) and in the country itself (CO) according to its scientific production. Besides, in column (O), the institution's total number of publications indexed in SCOPUS can be observed. Also, in the column (IC), the percentage of the institution's international collaboration with other scientific networks can be seen to develop joint research. Likewise, in the column (% Q1), it can be observed the percentage of scientific publications produced by the institution that are published in journals that are located in the highest quartile of each category of knowledge, according to the SCImago Journal Rank. Finally, in the column (% Lead), it can be seen the percentage of papers published by the institution whose principal researcher, that is, the corresponding author of the document belongs to that institution.

Also, it can be observed that the university in the first place is the Universidad Mayor de San Andrés, with a total of 497 publications indexed in SCOPUS. Followed by the Universidad Mayor de San Simón with 214 publications and in third place in the country is the Universidad Autónoma Gabriel René Moreno with a total of 86 publications indexed in SCOPUS.

It is essential to mention that most institutions have a high percentage of international collaboration (IC), except for four universities. This factor is favorable for Bolivian scientific production since it is crucial to forming scientific networks to carry out research and inter-institutional publications.

Besides, it can be observed that in the case of the Universidad Autónoma del Beni Jose Ballivián presents a total of 26 publications indexed in SCOPUS, of which 73.08% are published in journals that are located in the first quartile of the SCImago Journal Rank. This factor is an indicator of its scientific production's institutional capacity to reach a high expected impact level.

Finally, an essential aspect of analyzing is institutional leadership in scientific production. It can be seen that of the five institutions that lead the ranking in the country that the Universidad Mayor de San Simón is the one that presents the highest percentage of leadership with 37.85%. However, it can be observed that it is a low percentage, which means that although the institution is developing publications, the principal author, the corresponding author of the scientific publications, does not belong to the institution. Contrarily, there are universities with less scientific

production but with high leadership percentages, such as the Universidad Privada Franz Tamayo.

As consulted in the SIR Iber 2020 report and as summarized in Table 2, it can be indicated that six higher education institutions represent the first five places in the ranking of scientific production in Bolivia. There are six because there is a third-place tie between the Universidad Autónoma Gabriel René Moreno and the Universidad Católica Boliviana San Pablo with 86 publications indexed in SCOPUS.

Consequently, in Table 3, it can be seen the scientific production for 2019 and 2020 of the institutions corresponding to the top five positions in the country:

Table 3: Scientific production of Bolivian universities

University	Scientific Production indexed in SCOPUS	
	2019	2020
Universidad Mayor de San Andrés	99	84
Universidad Mayor de San Simón	51	27
Universidad Autónoma Gabriel Rene Moreno	14	14
Universidad Católica Boliviana San Pablo	21	11
Universidad San Francisco Xavier de Chuquisaca	10	3
Universidad Privada Boliviana	23	12

Source: SCOPUS Database

As previously mentioned, the SIR Iber report is a ranking that takes into account five years to perform its analysis. In this case, the 2020 report was prepared to take into account indicators corresponding to five years from 2014 to 2018. For this reason, Table 3 has been compiled the total number of publications indexed in SCOPUS for the year 2019 and part of 2020 to be able to observe the scientific production developed by the universities located in the top five positions in the country in recent years.

Therefore, in Table 3, it can be observed that the Universidad Mayor de San Andrés has registered for 2019 a total of 99 publications indexed in SCOPUS and for 2020 a total of 84 publications. If this institution keeps working, in the same way, it could reach the 100 scientific publications to be included again in the ranking SIR World.

Moreover, it can be seen that the Universidad de San Simón has a total of 51 and 27 indexed publications for the years 2019 and 2020, respectively. It can also be observed that the Universidad Autónoma Gabriel René Moreno had 14 indexed publications for

2019 and 14 publications so far in 2020. Subsequently, the Universidad Católica Boliviana San Pablo can be observed. It is essential to mention that this university is the first private university in the top five; this university has a scientific production of 21 indexed publications for 2019 and 11 publications for 2020. Also, it can be seen that the Universidad San Francisco Xavier de Chuquisaca presents a scientific production of 10 and 3 publications indexed in SCOPUS for 2019 and 2020, respectively. Finally, the second private university in the top 5 is the Universidad Privada Boliviana, with a scientific production of 23 indexed publications for 2019 and 12 indexed publications so far in 2020. If this university maintains the same production rhythm can ascend positions in the next SIR Iber report.

4. Discussion and Conclusions

Higher education institutions are called to guarantee the sustainable development goal of quality education, for which, in addition to teaching activities, they must concentrate on research and scientific production.

The scientific production in Bolivia is compared with the production of the other countries of the South American region for ten years from 2010 to the present; it can be seen that the country is among the last positions with a total of 3,451 publications indexed in SCOPUS and 303.97 publications per million inhabitants.

As has been observed, the scientific production indexed in SCOPUS of Bolivia has had a growth of 71.32% from 2010 to 2019. Still, to know if this growth has been accelerated or slow, it is necessary to compare Bolivia's case with another country's scientific production. For developing this comparison, Peru was chosen, an Andean and neighbor country. Peru presents a growth of 283.72% from 2010 to 2019; it could be said that its scientific production indexed in SCOPUS has almost quadrupled.

To analyze Peru's growth, it is necessary to mention that there have been fundamental changes in two of the three pillars that support research; since there have been changes at the State level and at the university level that strengthen its scientific production. Starting in 2013, the National Council of Science, Technology, and Innovation (CONCYTEC) have provided more funds for two large programs. The first is the development of theoretical and applied research by Peruvian universities, and the second is aimed at the repatriation of Peruvian scientists. Likewise, in 2014 the new university law was approved. With this, it was urged that all Peruvian universities could comply with the necessary quality conditions (CBC) to obtain a license granted by the National Superintendency of Higher University Education (SUNEDU) and continue in operation [19]. This law's critical point is that one of the necessary quality conditions required by SUNEDU is research. This condition has allowed the creation of research lines related to professional careers, increased teachers who carry out research, students with research skills, and a more significant presence of Peruvian universities in international rankings.

The low growth in Bolivia's scientific production could be due to several factors. For example, the Vice Ministry of Science and Technology (VCyT), which belongs to the Ministry of Education, focuses on strengthening science education programs and scientific dissemination. Still, it must expand its scope to the management and distribution of competitive funds for research. Furthermore, most university teachers, especially in private universities, do not work full-time. Additionally, teachers are overloaded with teaching hours and administrative work [2, 5, 10]. Besides, there is a lack of a repatriation program for Bolivian scientists specialized abroad, causing the loss of Bolivian talents. The impact of these factors is evidenced in the low quantity of full-time equivalent researchers in the country, which, according to UNESCO, are 2,218 full-time equivalent researchers for the year 2020 [7]. Finally, it can also be mentioned scarce funds to finance research projects and centralization of research infrastructure, since 183 research and development centers are located mainly in three Bolivia departments: La Paz, Cochabamba, and Santa Cruz [5].

However, the Bolivian government has identified some aspects that it must strengthen to increase its scientific production. In that sense, in 2016, it organized the First Meeting of Bolivian Scientists Living Abroad for Scientific and Technological Liberation [20], in which 54 researchers based in different parts of the world have participated together with representatives from ministries and private companies. This meeting had the objective of exchanging proposals and ideas to identify actions and mechanisms to strengthen science, technology, and innovation in Bolivia in the short, medium, and long term. It is essential to follow up and begin to implement the suggested strategic mechanisms.

Besides, it could be seen that of a total of 59 universities that constitute the university higher education system in Bolivia, only one institution could enter the SIR World report for the year 2020, ranking in the position 774th. Also, 26 universities are present in the SIR Iber 2020 report, which means that only 44.07% of the country's existing higher education institutions entered this ranking. They produced a total of 1,010 publications indexed in SCOPUS for the period analyzed. These scientific publications from higher education institutions represent 61% of the national total.

Besides, it was possible to observe that of all the institutions present in the SIR Iber ranking, 11 were autonomous public universities, 12 were private universities, and 3 were private universities attached to CEUB. This situation shows that 100% of autonomous public universities and private universities attached to CEUB managed to enter the SIR Iber 2020 report. Only 30.77% of Bolivian private universities managed to enter the ranking. Moreover, it has been possible to establish, as can be seen in Fig.3, that autonomous public universities have developed 84.36% of scientific production. In comparison, private universities attached to the CEUB have produced 8.92% of publications. Private universities have generated only 6.72% of the scientific production reported in the five years analyzed, which shows that 27 of the 39 private universities in Bolivia are not prioritizing research. This situation is evidence that, for the moment, private universities are not taking advantage of the existing relationship that some of these institutions have in a more significant way with the business production system of Bolivia. This factor is essential since a synergy could be generated; it would create spaces for research, innovation, and learning for both companies and universities.

It is essential to mention that at the time of compiling Bolivian universities' scientific production data in the SCOPUS database, it was possible to reveal that 89.83% of the country's universities

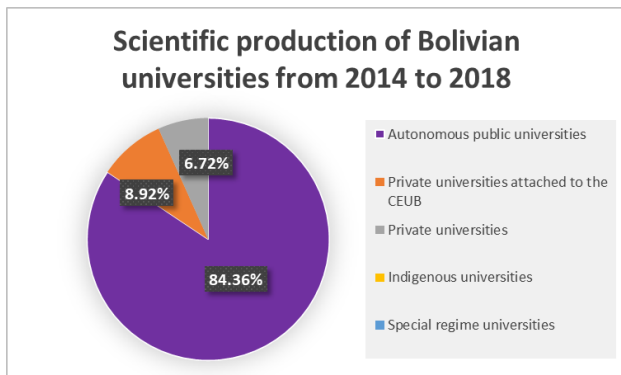
have not created their institutional profile. This factor is challenging to verify each institution's number of publications; in this sense, it is recommended that all higher education institutions in the country create their institutional profile in SCOPUS.


Figure 3: Scientific production of Bolivian universities from 2014 to 2018

Finally, analyzing the scientific production indexed in SCOPUS of 2019 and 2020, it can be observed that the Universidad Mayor de San Andrés is emerging to overcome the fence of 100 publications once again and represent Bolivia in the SIR Wolrd ranking.

We believe that Bolivia should begin to propose changes in a country's research tripod's policies and mechanisms, including the Bolivian state, universities, and industry, to strengthen scientific and research activities. It is also crucial to enhance the Vice Ministry of Science and Technology activities, which should begin by identifying national strategic priorities and calling on universities and other entities to develop research in those defined lines to achieve sustainable development.

It is crucial that in the future, the country can define national policies to promote scientific activities in higher education institutions, both in public universities and private universities.

Moreover, it is essential to start considering the implementation of programs for the repatriation of scientists to avoid the brain drain, which is a phenomenon that is currently observed in Bolivia. It is also necessary to strengthen existing postgraduate programs and create new ones, as this will allow increasing the research-trained resources in the country.

Finally, other countries' steps in the region can be analyzed and followed. For example, Ecuador and Peru's case, whose firsts steps were to define priority research lines in the country and develop calls for competitive funds to finance research projects following those research lines.

Conflict of Interest

The authors declare no conflict of interest.

	Everyone needs fast response or output against its request or need. Therefore, technologies are used to make the processing fast and accurate according to our needs. But in some situations, still we need to do more. Especially, when we need to process a massive or huge crowd of people in limited time frame such as at airport, religious gatherings, at stations etc. As the verification time increases crowd also increases and causing problems such as missing of the next flight, causality in religious gathering. Also, percentage of usefulness of verification system decreases and vice versa. Currently, different approaches are being employed to reduce verification time such as decentralized, distributed, queuing etc. But each of the approach has its merits and demerits. In order to minimize this problem, one of the solutions is to perform group (cluster) based verification. The reason behind is that as religious or tourist visits are done in groups, therefore, we can easily perform the group verification to make the verification fast in context of time. Further, we can set the limit where we need the group verification and where we can go through the normal verification (one by one). In this paper, we presented a Wireless Sensor Network (WSN) simulation model to calculate verification time in the groups form for massive crowd. We discussed the different scenarios for a group such as all group (cluster) members (CMs) are same and within the range or out of the range of cluster head (CH), CMs and non-CMs are within the range or out of range of the CH. We considered the pilgrimage as use case to compare the verification time taken by existing system and proposed system in context of time. We also compared the verification time with respect to verified and unverified CMs (CMs) in a group verification model. By optimizing the number of CM members in a group will decrease the number of unverified CMs (the drop rate), hence the performance of the group verification will be increased by minimizing the group verification time.

1. Introduction

We need to develop a new system or setup to achieve some important factors such as reducing the time, cost, improving the quality and increasing the security. Time is an important factor among the other factors to measure the usefulness of a system. In the verification systems, if verification time is increased its percentage of usefulness is decreased and vice versa. Especially, in time constrained or real time systems, margin for time delay is very low among the other systems. Nowadays, everyone needs fast response or output against its request or need. We are using

* Corresponding Author: Naeem A Nawaz, Ummal Qura University, nanawaz@uqu.edu.sa

technologies to make the verification fast and accurate according to our needs. But in some situations, still we need to improve, especially, when we need to process a massive or huge crowd of people in context of time. When a crowd exceeds from its given limit in term of capacity then it is called massive crowd. Standard size of massive crowd varies according to the nature of the crowd as given in [1]. Some places cause congestion or bottle neck when verification is required such as at airport, at stations, religious gatherings etc. In order to make the verification fast, distributed verification is introduced and it requires verification at different places. For instance, in case of airport, verification will be done first at country of departure and then at country of arrival. As the verification is done one by one by using the new technologies, it

makes the verification fast but not fast enough in case of massive crowd. Even then there become long queues and cause problems such as missing of the next flight at airports, causality in at religious places during religious gathering or sports gathering in stadiums. To minimize this problem one of the solutions is to verify the crowd in in group form. The group verification will provide help to reduce the time for crowd verification at public area hence provides safety from causality, stampede and terrorist attacks. In order to adjust the massive crowd according to the capacity of the area an approach is discussed in which capacity estimation is done by counting the number of the persons getting in and out from the specific area according to capacity by using WSN [2]. In WSN based identification model, grouping technique and different operational phases are discussed and has been compared with existing system [3]. WSN architecture is an efficient solution to problem by exploiting the capabilities of wireless sensor network to collect required data in the form of clusters. Supplying of food is done in cluster form according to a given limit of time [4]. The time series clustering is presented it also include general-purpose clustering algorithms. In time series clustering studies, general-purpose clustering algorithms are used to evaluate the performance of the clustering results. Results can be obtained either in the forms of raw data, extracted features, or some model parameters. On the basis of results, comparison between two time series can be done [5]. The conceptual model for WSN based smart movement is discussed by [6]. At node level energy is consumed by sensing-module to sense the data, microprocessor process the data and data is forwarded by radio communication. This consumption of energy causes other limitation such as network life- time and limited abilities to perform different task. To increase the performance of WSN, one of the solutions is to make the clustering of sensors [7].

The cities of Makkah and Madinah are crowded during Hajj and Umrah. Therefore, the crowd needs to be managed in these days. The problem of such a crowd is that how to make verification of pilgrims at different place as pilgrims are moving from place to place and between cities. This goal can be achieved by verifying the crowd in group form with the help of WSN.

Other technologies will also provide help to achieve the goal. For example Cloud computing system can facilitate the pilgrims to access data, it does not matter how far away are they from the physical location of the resources of the hardware and software. [8]. Internet of Things (IoT) allows pilgrims to connect with anyone, at any time, at anyplace with the help of devices by using Internet services [9]. In the same way, it helps the government to used management approach not only optimizing data but also considers prominent governance structures planning [10].

In this paper, single group scenarios, their designs and simulations are discussed to calculate the verification time for optimal number of CMs (pilgrims) in a single group. At the end, comparison of the existing system and proposed system verification time is performed.

1.1. Paper Layout

In section 2, we briefly discuss the background. Section 3 presents verification of the crowd approaches or strategies. Section 4 depicts the proposed group (cluster) verification model according to single Group (cluster) approach and operational

phases. Section 5 elaborates the proposed scenarios for single group (cluster) verification approach, section 6 offers design of algorithms for CH and CMs, section 7 gives the simulation setup for proposed model. Section 8, simulation scenarios in Contiki/Cooja and a brief review of the existing system. Section 9 explains the simulation results and comparison between existing and proposed system verification time. Section 10 represents the conclusion and future directions.

2. Background

In this section, we present the previous work and the technologies involved to improve the verification time for massive crowd. A solution is proposed to solve the storage problem by using the distributed collection of the data collection [11]. An Adaptive Collection scheme based on Matrix Completion (ACMC) is proposed and compared with other data collection schemes to reduce delay and to improve the energy utilization of the network. [12]. Manufacturing Internet of Things (MIoT), provides the data analytics about massive volume of data, heterogeneous data and real-time velocity of manufacturing data [13]. The clustering of the WSN is a problem because of diversity of WSN applications. In order to evaluate clustering different parameters are considered. After comparisons with different techniques they concluded that with low energy consumption, high data delivery rate centralized clustering solutions based on the Swarm Intelligence paradigm are more efficient for applications [14], [15]. The concept of local density to find each point of density to avoid the connecting the clusters having different capacities. They used Hadoop platform running MapReduce, clustering big data with varied density [16]. Nearest Point with Indexing Ration (NPIR) tries to solve some limitations of clustering by using non-spherical clusters, clusters with unusual shapes, or clusters with different densities. NPIR is evaluated real and artificial data sets of different levels of complexity, number of clusters and points. Results showed that NPIR performance is good Homogeneity Score, Completeness Score, V-measure, and Adjusted Rand Index [17]. A review and analysis the method is used to find the better clustering mechanism to get high efficiency. Different methods have been studied and discussed their advantages are highlighted to provide help the selection of and efficient clustering mechanism [18]. The possibilities of a Wireless Sensor Network support (WSN) for a Fog computing system in disposable intelligent wireless sensors is presented. With the coordination of augmented reality, an environmental monitoring system and communication infrastructure, in the framework of a next-generation emergency management system can be developed. [19]. A strategy Wireless Power Transfer (WPT) is used to divide the load of the CH. Each CM node in the cluster will transfer a specific amount of energy to get red the CH from a whole load instead it will bear a part of the whole load in this way lifetime of WSN is increased [20]. The concept of mobile as a service model is explored as "tri-opt". "Tri-Opt" means electric powertrains, new model cars and growth in smart cities [21]. The capacity estimation in the context of dynamic position and events by using zones and levels is done to process the crowd [1].

The definition of the IoT covering the different application from different field such healthcare, transport, verification, education, transport, and also provide help to crowd [22].

Simulator can be used efficiently if we evaluate the things from the top level. Because topologies, data collection and protocols give better performance at top level and are the best for simulation [23]. An emulator is used to run the test bed to evaluate WSN applications in primarily level. If test bed is successful, then large scenario is used in real time environment. We will work on the software level for the implementation, but in future, the same scenario can be implemented on a hardware device. Full Function Devices (FFDs) and Reduced Function Devices (RFDs) are two standard classes of an LR-WPAN devices. FFDs have the advanced capabilities such as synchronization of nodes and forward data packets in multi-hop communications. But the job RFDs is to communicate with FFD [24]. Link layer acknowledgments do not result from packets that are sent a broadcast. But in principle of Contiki MAC, during full wake-up interval, the sender sends the packets repeatedly to make ensure that it is received by all neighbors [25]. An inexpensive Clear Channel Assessment (CCA) mechanism used by Contiki MAC wake-up. It checks an indication of radioactivity on the channel with the help of Signal Strength Indicator (RSSI) of the radio transceiver. It compares RSSI with a given threshold and returns positive if the RSSI is below. This indicates that the channel is clear. If RSSI is above the given threshold then it returns negative result. This indicates that the channel is busy [26]. If it is considered that each receiver has a specific time period of wake-up interval, then sender can optimize the sending of data by using the wake-up phase time period. The receiver can read the link layer acknowledgement to get information about receiver's wake-up time. To overcome this problem, we have used multi-hop communication between CMs and their respective CH [27].

Due to one by one individual verification, the existing system is unable to process the crowd speedily or it goes for random identification and verification. Furthermore, if crowd verification is done in group (cluster) form and data is pre-written on the devices, the crowd verification time can be reduced. By using group (cluster) verification for crowd, we do not need the random identification and verification because group (cluster) verification minimizes the time.

3. Present Implementation of Crowd Verification

The present verification process for crowd or religious crowd is done person by person at different points such as entrance points of the country borders, airports of departure and airports of arrival, entry points at city or the entry points of the religious places. This verification process is needed again and again because after verification people travel on the routes or stay at the places where other unverified people are staying. For example, in case of Hajj (Pilgrimage) crowd stays among the people without Hajj permit. Therefore, on crossing the city of the Holy Makkah border again, they need verification of Hajj permit again. When the pilgrims go to the Hajj events places (Al-mushier), they again need verification so that people without Hajj permit can be prohibited. Currently verification process is divided among the airport of departure and airport of arrival for some countries. But in case of any internet problem or hacking among the countries of departure and arrival, it causes a big problem.

We mused about the other technologies such as smart cards, mobile phone and WSN devices with queue verification to handle the crowd but as mentioned the nature of the crowd they are not good users of technologies and also smart mobile will increase the cost that is not affordable for every pilgrim. Subsequently, we pondered about cluster approach and pre-stored data because data are collected and stored a long time before the pilgrimage process. Group (cluster) of pilgrims will be controlled by the well-trained person as a CH. Each CM has the simple reusable sensing device and proactive approach to pre-stored the data on CM device for verification. Simple reusable device means it has few buttons with different color and functions, there is no special expertise required to use it. Reusable means on the return of the device data can be burnt for new pilgrims and it is a cost-effective solution.

4. Proposed Group Verification for Massive Crowd

The proposed group (cluster) verification for crowd is an idea taken from sensing as a service model to minimize the crowd verification time by performing the verification in group (cluster) form not one by one. The distinguishing feature of this proposed group verification model is that it enables the verification of pre-stored data in cluster form. Consequently, we minimize the verification time for crowd. The use of sensor devices is multiple purposes other than data collection and transmission. The current crowd verification implementations usually take more time and therefore at some checkpoints it is done randomly. However, the proposed model can benefit in many ways, the most important of which is cluster verification, pre-stored data storage and fast crowd verification. For instance, if the proposed model is unable to implement to the whole crowd then it can be implemented at a specific part or aged pilgrims. It can be implemented according to the nature of the crowd where fast verification is required and it is compulsory such as in case of COVID-19. Because verification is slow it causes massive crowd according to the space available and it became difficult to maintain social distancing.

The proposed group verification for crowd (Pilgrims) steps at the airport as a use case are:

- At the time of biometric, identification along with CM device and passport interchange is done. CM devices are already indexed according to the arrival schedule of pilgrims.
- Data verification from CMs to CH
- Data verification from Cluster Head (CH) to server (immigration system)

The step to verify visa number by scanning the passport or entering the visa number of pilgrims will be done automatically in group (cluster) form by CH, as CH has pre-stored data of pilgrims. After group (cluster) verification by immigration, pilgrims will be free to collect their luggage. The remaining steps, printing of sticker for schedule, pasting of schedule, writing of reference number and entry stamp on passport will be done by the immigration in cluster (bulk) form. The passport, after entry stamp will be collected by the company from the immigration department. Because as a rule, passports of the pilgrims are possessed by the company not by the pilgrims. In this way, group verification will minimize the waiting time for pilgrims and further steps minimize the significant amount of crowd verification time.

In the last decade a lot of research has been done to improve the WSNs architecture and protocols to get efficient results in the implementation of different applications. Technologies are on the way and have provided cheaper, powerful and smaller wireless devices. These cheaper, powerful and smaller wireless devices are supporting to the multiplicity applications of WSNs in low-power standard [28].

The combination of different technologies with WSN will provide strength to different applications in different fields of life such as smart home, smart cities, smart cars, healthcare, education, online smart marketing etc. The time verification process involves different phases such as; sensor registration, sensor dispatching, sensor grouping or clustering [3]. Our main focus is on the group (cluster) verification with respect to time. As mentioned in the previous phases that the sensor devices are registered from the servers. The CH will generate the list of its CMs by using the CM_ID and CM will response its request. When CM_ID will be verified, then status will be updated by the name of entry point.

5. Group Verification Scenarios for Massive Crowd

In a single group verification approach, we discussed different for a single group (cluster) with CH and its CMs. In different group verification scenarios, we used different numbers of the CMs within a single CH transmission range. Further, we discussed the scenarios to check the performance, if some of the CMs are out of the transmission range of the CH, if there are CMs and non-CMs, but within and out of range of the single CH transmission range. We write the algorithms to handle different scenarios for a single group.

5.1. Different number of CMs (5, 10, 15, …, 50) within single CH range

We used different numbers of the CMs (5, 10, 15, ….) within a single CH transmission range, as illustrated in Figure 1. This provides us the maximum number of CMs that can be supported by a single CH. It also provides us with the maximum number of the CM verified by a single CH. By this approach, we can fix the number of the pilgrims (people) in one group for the best or optimize group scenario. Implementation of this scenario as a use case is at the airport in the immigration hall where group (cluster) formation area is allocated.
Figure 1: Different Number of CMs (5, 10, 15, …, 50) Within Single CH Range

5.2. CM Devices Belong to Single Group (cluster) but some out of CH Range

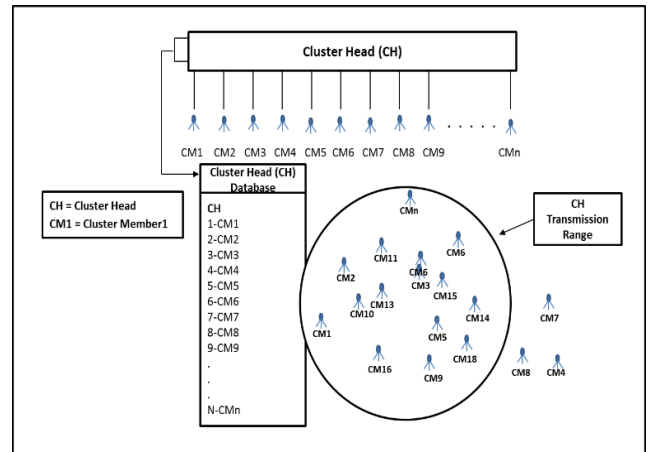
The scenario given in Figure 2 is considered at the places where CMs of the single CH are in scattered form. Some of them may be out of transmission range of the CH. For example, CMs are scattered or misplaced at the airport and are waiting in lounge. In such situations, the out of transmission range CMs can be communicated via nearby CMs with the help of multi-hop communication to pass the message. In this way, all CMs can be communicated for any activity or verification. If we want to identify our CMs, then the verification message can be generated and as a verification, CM_LED turns green (flag sets to 1).


Figure 2: CMs Devices Belong to Single Group (cluster) but Some Out of CH Range
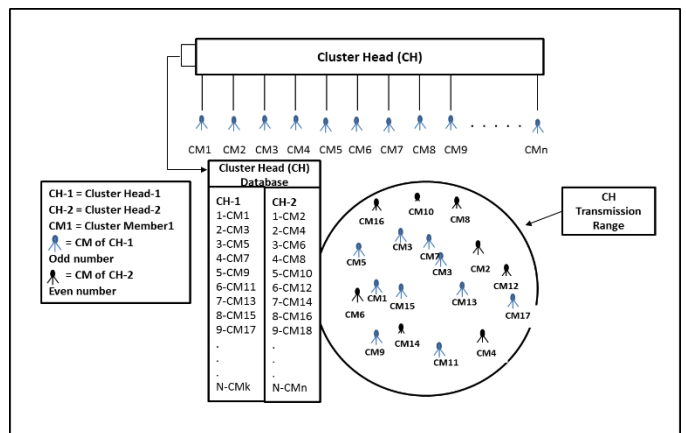

Figure 3: Single CH Having Different CMs Devices Within Range

5.3. CH having different CMs devices within range

The scenario given in the Figure 3, discussed to check the performance of the CH, if some non-CMs become within the transmission range of a CH. With the help of this scenario not only we check the performance, but also in the future we extend the feature that the CH identifies the non-CM's CH and inform to the concerned CH via server that one of CMs is within my group (cluster) range. This will provide help, in case the pilgrims lost and mixed with another group, then it can be easily identified by the current location. For example, CM_2 belongs to the CH-2 but currently, it is under the CH-1, then CH-1 will inform CH-2 that

one of your CM_2 is with me at this location. In another case, CH-1 can detect the location of CH-2 and guide CM_2 about the location of its original CH (CH-2). CMs belong to different groups (clusters) are represented by light and dark color scheme.

5.4. Different CMs devices but some out of CH range

The scenario given in the Figure 4, discusses the performance if there are CMs and non-CMs and some CMs remain outside the CH transmission range. By this scenario, we see the communication effect between CH and CMs outside the transmission range in presence of non-CMs. This scenario is applicable when CMs of the different group (cluster) mixed with each other and some of them are out of range.
Figure 4: Different CMs Devices but Some out of CH Range

6. Design of Algorithm

There are different ways of verifying pilgrims (people) in a crowd: manual checking, biometric verification, facial recognition, scanners and by querying from the database system. These processes do verification one by one and consume a lot of time. In this section, we discuss the algorithm for group (cluster) verification to minimize verification time for crowd. In order to achieve the objective of the research, we need to write some algorithms for different scenarios of the proposed model. The algorithm is written to send, receive, store, forward, verify and drop the unverified packet. To make a better understanding, we write pseudo code so that latter on code can easily be run on the simulation tool and we can get the results. The algorithm representing different scenario is given in the next section. The multi-hop group (cluster) verification algorithm is developed after the study of [29] concept of multi-hop and [30] collaboration by neighbor table.

6.1. Single group (group) verification algorithms

In single group (cluster) verification algorithm, we discuss the algorithm that represents the different situations (scenarios) of a single group and its CMs. Different group (cluster) situations (scenarios) represented such as; all CMs those belong to the same group (cluster) and are within the transmission range of the CH; all CMs those belong to the same CH, but some are out of the

transmission range of CH; CMs and non-CMs within the range of a single CH; and some CMs are outside the CH range. According to the given algorithm, we write code to handle the different scenarios.

Algorithm 1 Verification by CH	
Step-1	Begin
Step-2	GET value for Max NCM
Step-3	GET list of the CMs and Broadcast
Step-4	While(Simulation on AND Number of CM <= Max NCM)
Step-5	IF(CM_ID (In CH list) == CM_ID (Response from CM)
Step-6	Add CM_ID in the verified list
Step-7	GOTO Step-4
Step-8	ELSE
Step-9	Drop the packet
Step-10	GOTO Step-4
Step-11	Endif
Step-12	Endwhile
Step-13	End

Algorithm 1 discusses the CH side verification. The CH has a list of CMs with maximum number of CMs (Max NCM) and CH broadcast the list CM_ID. If the response received from CM (CM_ID) matches with CH list, then CH adds the CM_ID in verified list. Otherwise drops the data packet. This verification process carries on until Max NCM verified or simulation time is out.

Algorithm 2 Response by CM	
Step-1	Begin
Step-2	GET value for Max Hops
Step-3	While(Simulation is On)
Step-4	IF(CM_ID (Received) == CM_ID (Current CM))
Step-5	Response to CH
Step-6	Store in Log
Step-7	Display the LED Green
Step-8	ELSE
Step-9	IF(Number of Hops <= Max Hops)
Step-10	Store in neighbor Table
Step-11	Forward To next CM
Step-12	ELSE
Step-13	Drop packet
Step-14	Endif
Step-15	Endif
Step-16	Endwhile
Step-17	End

Algorithm 2 discusses the scenario in CM side. CMs set by the maximum number of the hops (Max Hops). If the CM_ID receive from the CH matches the CM_ID of the current CM then its response to CH, store it in log file and turn LED into Green for CM device. Otherwise it checks current number of hops is less than the Max Hops then it stores information in the neighbor table, and forward data packet to the next CM. If it exceeds the maximum number of hops, then it drops the packet. This process carries on until the simulation time is out.

7. Simulation Setup for Proposed Group Verification for Crowd

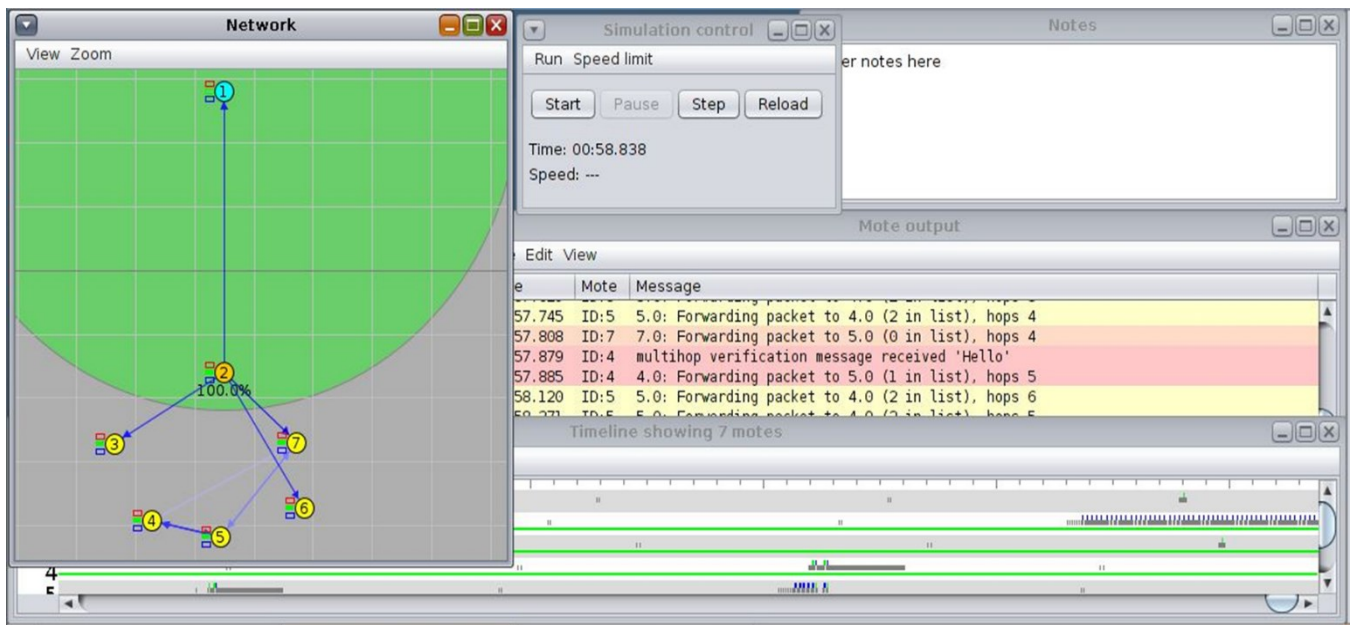
Contiki OS is a lightweight open source operating system for sensor network. It was designed by Adam Dunkels, at the Swedish Institute of Computer Sciences. C programming language is used in both Contiki OS and its programs. Contiki is flexibly portable OS and it has been ported to different platforms. Cooja is Java based Contiki network simulator with a graphical user interface


Figure 5: Full view of the Contiki/Cooja simulator

(GUI). It integrates to simulate with the external tools to provide additional features to the large and small networks. Motes can be emulated, which is faster and allows simulation of larger networks, or at the hardware level. Two emulator software packages are contained by this tool: Avrora and MSPSim. Cooja can emulate multiple platforms like: TelosB/SkyMote, MicaZ mote, Zolertia Z1 mote, ESB, Wismote [31].

The Figure 5 shows full screen view of Contiki/Cooja simulator. Network simulator "Contiki/Cooja" is separated into small windows such as: Network Window, Notes Window, Simulation Control Window and Mote Output Window.
Figure 6: Scenario for Flow and Functions of Nodes

We took the simple scenario to make understanding of the flow and function of each node as given in Figure 6. Server function is to keep the record and status of the pre-registered CMs. Antelope is a relational database management system (RDBMS) and it facilitate a sensor to work as a database server. It provides help to create dynamic databases and to run complex queries [1].

7.1. Client Interface

The client interface to insert data in the Antelope database is shown in the Figure 7. Client interface in Antelope DBMS provides help to store the record by using the client interface.

Figure 7: CLIENT Interface to Insert Data

7.2. Server Interface

The server interface displays the output result in Mote output screen for each query is shown in Figure 8. The function of the CH node is to keep a list of CM IDs, send, receive, verify CM IDs. We fetch the group of CM IDs by compiling the code on the CH node.

7.3. Multi-Hop Communication for Nodes

The multi-hop communication initializes the memory and initializes the list for the neighbor table entries used for the neighbor table. Open a multi-hop connection on Rime channel and Register an announcement ID. As multi-hop connection is set open sensor buttons are Activated. Sensor buttons are used to

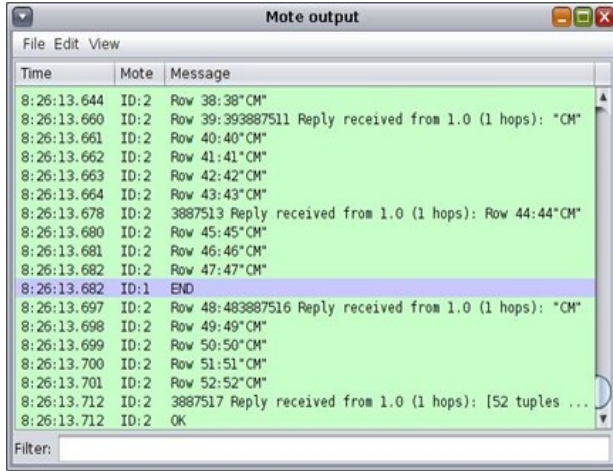
drive the traffic. When button click option is used sensor device transmit the data. Multi-hop also has a function to check the neighbor table. If the neighbor is not present in the list, a new neighbor table entry is added to the neighbor table. CM function is to verify the CM_ID by replying I am here, and to update the memory storage.


Figure 8: Server Interface Showing Query Process

Table 1: Simulation parameters

Simulation Parameters	Values
Number of Group (cluster) Members	5, 10, 15, 20, 25, 30, 35, 40, 45, 50
Transmission Range	50 m X 100 m
Startup Delay	1000 ms (1 sec)
Neighbor Timeout	60 sec
Max Neighbor	16
Position	Random
Simulation Time	5 min
Communication	Multi hop
Radio Channel	26
Protocol	CSMA MAC Contiki

7.4. Simulation Parameters

The algorithms are implemented on WSN based scenarios that are developed to validate the proposed simulation model. At first, the results for different number of CMs a group (cluster) are presented. The optimal number of CMs in a group is 20, where all of the CMs are verified and unverified number of CMs (drop rate) is zero. As then number of CMs increases from 20 to 25, unverified number of CMs increases which increases the group verification time for a crowd. The verified and unverified rate shows that WSN based model can verify CMs in group (cluster) form that leads to minimize group verification time and hence minimize crowd verification time. The results for verified and unverified CMs in a group (cluster) are explained by controlling and varying the number of CMs in group (cluster). The results for proposed system are calculated and estimated in terms of total number of CMs verified and unverified. The verification time

results have shown in Table 2 and Figure 17 only include the verified CMs. But the verification time results have shown in Table 3 and Figure 18 include both verified and unverified CMs. The simulation environment with parameters is given in the Table 1.

To study the validity of proposed model, Cooja/Contiki Simulator is used. In Table 1, the simulations parameters are mentioned for simulating the proposed group verification to calculate the number of verified, unverified CMs and verification time for crowd in group (cluster) form.

- **Number of CMs:** The number of CMs existing (populated) in a single group (cluster)
- **Transmission Range:** The coverage area of the CH
- **Startup Delay:** Simulation startup delay to get ready for communication
- **Neighbor Timeout:** The time at which the old neighbor entry will be removed so that the table doesn't overflow.
- **Max Neighbor:** The maximum number of neighbors that can be supported. As the number of neighbors is increased, the number entry in the table will increase. It will require more memory and causes more delay.
- **Position:** The x and y coordinate of the CM's position. It can be defined as linear, elliptical, random or manually.
- **Simulation Time:** The time at which the simulation is completed to get required results.
- **Communication:** The multi-hop communication will help to forward the packet to the next neighbor if the destination CM is at a longer distance and in this way save the energy of CM. It will also help deliver the packet if the node is out of the CH's range.
- **Radio Channel:** Cooja/contiki support different radio channels for communication.
- **Protocol:** CSMA MAC is a Contiki lightweight protocol designed for low power, low memory and low verification power wireless sensor network.

8. Contiki/Cooja Simulation Scenarios

There are different performance metrics to evaluate crowd verification in group (cluster) form. Most of them include number of verified and unverified CMs in a group (cluster).

8.1. Different number of CMs (5, 10, 15, ..., 50) within single CH range

In a single group (cluster) scenario, the number of CMs increases by multiples of 5 in each simulation. The maximum number of the CMs support by the Contiki/Cooja is 45 CMs in our scenario. Some of the scenarios are shown in the Figures 9, 10 and 11. Results are obtained from log file taken from Contiki/Cooja.

In Figure 8, there is one server, one CH and 5 CMs. The CH has generated the signals (CM_ID) for verification. All 5 CMs are verified and as a result of verification their LED color turns into Green (flag sets to 1).

In Figure 10, There are 25 CMs for group verification. Out of 25 CMs, 22 CMs are verified but CMs having CM_ID 23, 24 and

27 remain unverified. LEDs of Verified CMs turn into green while LEDs of unverified CMs remains off.
Figure 9: Single Group (cluster) Having 5CMs

Figure 10: Single Group (cluster) Having 25

Figure 11: Single Group (cluster) Having 45 CMs

In Figure 11, only 14 out of 45 CMs verified but 31 CMs remain unverified. LEDs of Verified CMs turn into Green while for unverified CMs they remain off.

8.2. CM Devices Belong to Single Group (cluster) but some out of CH Range

In Figure 12, CMs number 4, 14, 15, 17, 19, 20, 23 and 24 are out of transmission range of CH. CMs number 4, 15, 20 and 24 are verified but CMs number 14, 17, 19 and 23 remain unverified. This means 4 out of 8 CMs out of transmission range of CH are verified. This showed that multi-hop also works out of transmission range but the number of verified CMs decreased and time for verification increased. The best result for the single group (cluster) is provided when CMs are within the transmission range of CH.

Figure 12: Out of 25 CMs Some are Out of CH Range

Figure 13: CH having CMs and non-CMs

8.3. CH having different CMs devices within range

In Figure 13, CH having 10 CMs and 5 non-CMs. All CMs from CM 3 to 12 are verified but all non-CMs from CMs13 to 17 remain unverified. This means CH can verified the CMs in the presence of the non-Ms.

8.4. Different CMs devices but some out of CH range

In Figure 14, 15, and 16, different views of CH having CMs, non-CMs and some out of range are shown. All the CMs within the range are verified and their LEDs turn into green. But in case of non-CMs all non-CMs remain unverified and their LEDs remain off either within the range or outside the range of CH. The CMs 18, 19 and 20 are out of range. The CMs 18 and 19 are verified but CM 20 remain unverified. That means 2 out of 3 are verified outside of CH range by using the multi-hop communication.

Figure 14: Coverage area by server

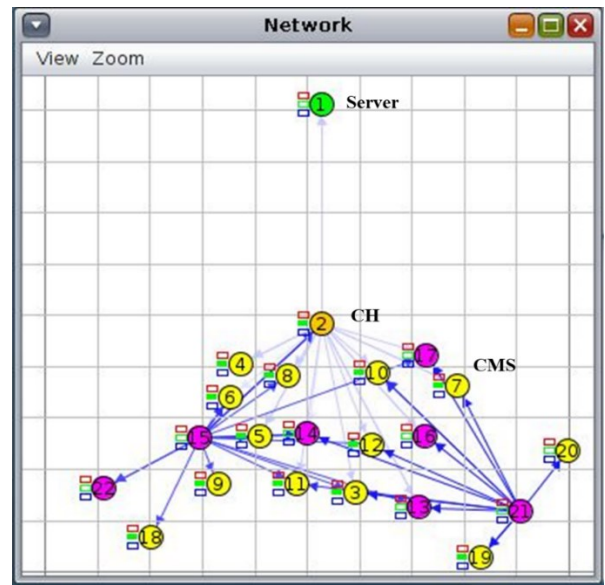
Figure 15: Coverage area by CH


Figure 16: Without coverage area

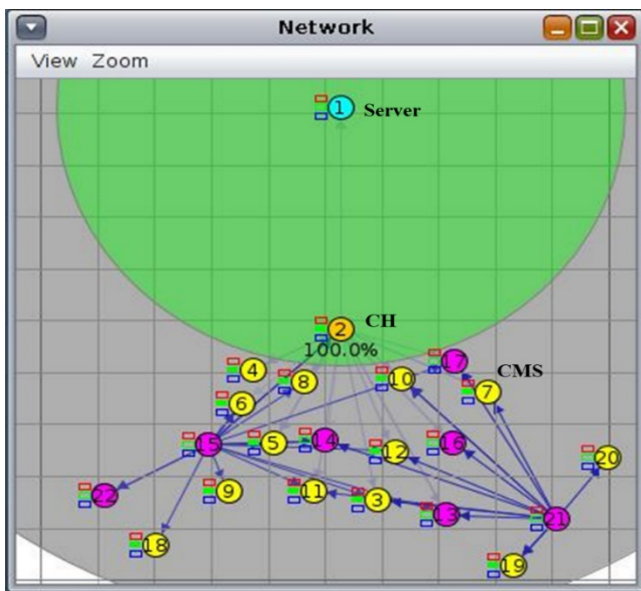
9. Verification Time for Existing and proposed Systems

Currently verification is done in queue form one by one or person by person. There are different steps involved for the process of verification. This verification of crowd in queue form causes a long queue and delay. Time Taken by Verified CMs by existing system is given in Table 2 and 3 columns have heading "Time Taken by Verified CMs in Min" is calculated by observation and well-planned interview is given in "Unpublished" [33].

Verification time is compared with the existing system verification time. In first step, verification times for only verified number of CMs in a group (cluster) are compared. In the second step, verification times for verified and unverified (go through the normal process) CMs in a group (cluster) are compared.

9.1. Verification Time for Single Group (cluster) by Proposed Vs Existing System (Only Verified CMs)

In this case, we evaluated the single group (cluster)'s verification time by proposed and existing systems, but only considered the number of verified CMs. As represented in Table 2 and Figure 17, we found the number of verified CMs by proposed system and calculated the verification time on the basis of simulation from log file generated by the Contiki/Cooja tool. By data collection, we calculated the existing system minimum, average and maximum verification time per person and are 5 minutes, 7 minutes and 12 minutes respectively. But we considered minimum verification time (5 minutes) by the existing system to compare with proposed system verification time. Therefore, to get total verification time taken by the existing system, we multiply the number of verified CMs by 5. As represented in the Figure 17, the minimum verification time is 0.4 minutes by the proposed system, but by existing system is 25 minutes, when number of verified CMs for the single group (cluster) are 5. The maximum verification time by the proposed system is 4.9 minutes, but the existing system has a maximum verification time of 110 minutes. The optimal time for verification by the proposed system is 3.3 minutes, when numbers of verified


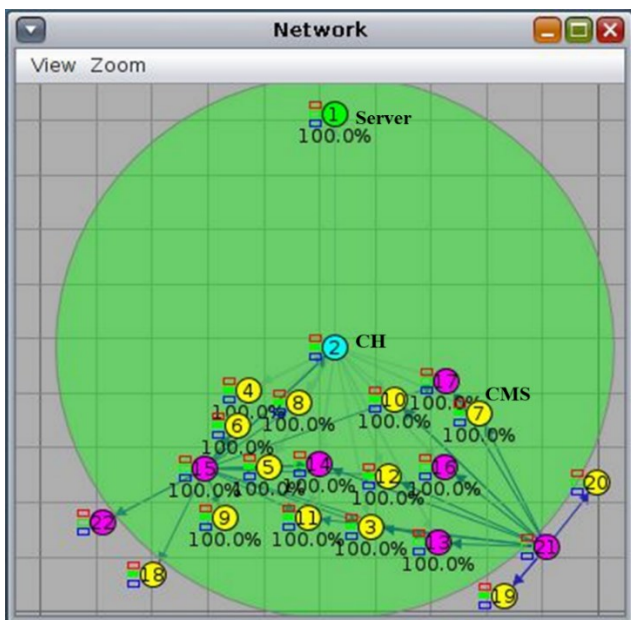


Table 2: Verification Time for Single Group (cluster) by Proposed VS Existing System (Only Verified CMs)

Number of CMs in a Group (cluster)	Number of Verified CMs	Time Taken by Verified CMS in Min (Proposed System)	Time Taken by Verified CMs in Min (Existing System)
5	5	0.4	25
10	10	0.9	50
15	15	2.5	75
20	20	3.3	100
25	22	3.9	110
30	17	4.2	85
35	15	4.7	75
40	15	4.9	75
45	14	4.6	70
50	13	4.6	65
Figure 17: Verification Time for Single Group (cluster) by Proposed VS Existing System (Only Verified CMs)

CMs are 20. But when number of verified CMs are 20, the verification time by the existing system becomes 100 minutes. Such a large difference validates our proposed system.

From this analysis, we conclude that our proposed system is better and suitable for the single group (cluster) having 20 CMs. The maximum number of CMs verified is 22 out of 25 and the verification time is 3.9 Minutes by the proposed system but for the existing system is 110 minutes. If we increase the number of CMs in a group (cluster), it affects the performance of the proposed system and verification time increases. The reasons for this increase are discussed in section 9.3.

9.2. Verification Time for Single Group (cluster) by Proposed vs. Existing System (Verified &Unverified CMs)

In this case, we evaluated the crowd verification time by proposed and existing system, but we considered both verified and unverified number of CMs. As represented in Table 3 and Figure 18, we found the number of verified and unverified CMs by the proposed system on the basis of simulation from log file generated by Contiki/Cooja tool. We calculated the total verification time by the proposed system by the addition of time taken for verification by verified CMs on the base of simulation and time taken for verification by unverified CMs on the base of minimum time by data collection (existing system). To get total verification time taken by the existing system, we multiply the

number of verified and unverified CMs by 5, as per person verification time by existing system is 5 minutes. As represented in the Figure 18, when number of verified CMs are 5, the minimum verification time is 0.4 minutes by the proposed system and that of the existing system is 25 minutes. The maximum verification time by the proposed system is 184.6 minutes and that of the existing system 250 minutes, when the number of CMs in the group (cluster) is 50.

The optimal time for verification by the proposed system is 3.3 minutes, when the number of verified CMs is 20. But verification time by the existing system is 100 minutes. Such a large difference validates our proposed system. If we increase the number of CMs to more than 20 i.e. 25 in a group (cluster), then some CMs are unverified. These CMs have to go for verification by an existing system which increases the verification time to 18.9 minutes.

After 18.9 minutes, verification time of the proposed system increases with big differences, 69.2, 109.7, 129.9, 164.6 and 184.6 minutes because the number of unverified CMs increases into 13, 20, 25, 31 and 37 CMs. As the number of CMs increases, the unverified CMs rate also increases and that increases the verification time. In this way, unverified CMs affect the performance and verification time increases. Reasons for this increase in verification time are discussed in the section 9.3.

Table 3: Verification Time for Single Group (cluster) by Proposed VS Existing System (Verified & Unverified CMs)

Number of CMs in a Group (cluster)	Time for Verified CMs (Min)	Time for Unverified CMs (Min)	Total Time for Verified and Unverified CMs (Min)	Total Time Taken by Existing system (Min)
5	0.4	0	0.4	25
10	0.9	0	0.9	50
15	2.5	0	2.5	75
20	3.3	0	3.3	100
25	3.9	15	18.9	125
30	4.2	65	69.2	150
35	4.7	105	109.7	175
40	4.9	125	129.9	200
45	4.6	160	164.6	225
50	4.6	180	184.6	250
Figure 18: Verification Time for Single Group (cluster) by Proposed VS Existing System (Verified & Unverified CMs)

9.3. Reasons of Increment and Decrement of Group (cluster) Verification Time

First reason, by increasing the number of CMs increases the number of neighbor's entries in the neighbor table (The table in which each CM keeps a record of its neighbor). When it exceeds the maximum number of entries in a neighbor table or neighbor time out, it causes dropping or removing of the entries from the neighbor table. The dropping of entries causes the incomplete route to destination, therefore, packet drops. The second reason is that the packet is forwarded neighbor to neighbor and it exceeds the maximum number of neighbors and hence drops the packet to save the energy. In our case, the limit of maximum number of the neighbors is 16.

The third reason is that the group (cluster) verification model works on the MAC layer and it uses the CSMA Contiki protocol. CSMA does not support collision detection, but when collision happens, it retransmits the packets after a certain time period. It causes a delay in packet delivery and hence increases the crowd verification processing time. As we increase the number of CMs, it increases the traffic that increases the chances of greater number of collisions and hence packet drops before reaching the destination.

10. Conclusion and Future Directions

This article provides an overview of the simulation model for group (cluster) verification and its application. We discussed the present verification approaches and proposed a model to calculate the verification time for verified and unverified CMs. We also explain the different scenarios of CMs and as well algorithms for CMs and CH. If simulation-based group (cluster) time verification model is implemented, it provides many application scenarios. In time specific verification application, such as at stadium, airports, trains etc. To avoid the CVID-19, after taking the temperature, verification can be done in group (cluster) form (while maintaining the social distance) to minimize the verification time. To optimize the number of CMs in group (cluster) for fast verification to reduce the massive crowd.

This research shows some simulation results and on the basis of simulation results, needs to be further expanded to test the WSN sensing emulation model into the laboratory and then in real environment. According to our knowledge, this is the one of the limitations that there is no such complete practically implemented model. The Internet and WSN communication causes dropping of packets due to low memory, less processing power and low energy. Therefore, factors affecting the packet dropping need to be identified and improved for efficient packet delivery. Furthermore, there is no such mechanism to identify that the person carrying the CM device is his own device or it has taken from another person (friend) or it is using lost device. In any case misplace or misuse of CM device causes a great risk in security viewpoint. An algorithm can be designed to maintain the social distance to avoid the COVID-19 attack.

A R T I C L E   I N F O

A B S T R A C T

The study aims to verify the capacity of Facebook Translation Service in translating English Facebook posts into Arabic in terms of two criteria: adequacy and fluency in line with the Translation Automation User Society (TAUS) scales. To ensure consistency and objectivity as recommended by TAUS, six evaluators, native speakers of Arabic and near-native speakers of English, rated the same data on each scale. The evaluators were acquainted with fluency and adequacy scales along with MT limitations and potentials. Once the corpus was uploaded and sent to the evaluators using TAUS tools, they had to assign scores online on 1-4 rating scales. Then, each report was displayed online on the TAUS reports tool. Evaluators' responses were combined in thematic categories and were calculated to obtain frequencies and percentages. The study found that FTS provided fluent output with highest percentage of the scale good equal to 3 on a scale from 1 to 4, where the output is assessed as flowing smoothly with minor linguistic errors. Moreover, FTS succeeded in generating an adequate output with the highest percentage of responses as 'most' equal to 3 on a scale from 1 to 4, where almost the full meaning of the source is deemed to be transferred in the target language. This study is useful since it highlights the role of Facebook Translation service in translating, educating the public and fighting COVID-19. Consequently, such research would encourage the use and research on the potentiality of MT and FTS in dealing with abrupt crises, such as COVID-19.

1. Introduction

Translation is a medium of human communications. It bridges the gap between human communities and ensures the best way of communicating among global communities[1]. Nowadays, the world is facing the most frightening Coronavirus (COVID-19) outbreak in the last decade. The health authorities, international health organizations, political leaders, healthcare providers and the public have social media sites at their disposal. They post information regarding COVID-19 daily. The flow of social media posts about COVID-19 is unprecedented, and would be beyond the capacity of human translation, let alone an economically viable proposition to have them translated by humans. During lockdowns around the globe, Machine Translation (MT) helped to translate such posts into Arabic. The author in [2] states, "The challenge is how to communicate rapidly changing data across language

borders so that essential information is not lost in translation". In this regard, he goes as far as stating that machine translation is a strong ally in the fight against COVID-19. Social media sites have become popular among young Arabs, who tend to use them daily. The [3] shows that Facebook is the most popular social media site in the Middle East with 200 million daily users, representing almost 70% of Middle East population. Facebook has a translation service, which offers translation for more than 80 languages.

Facebook wide use makes it necessary to evaluate the content and verify its effectiveness and limitations to the end users. English ranks as the top language of social media with 25% of internet.

This means that many Arab Facebookers will be exposed to posts written in English with some able to read and understand it, and a large portion of those who are not competent in English. Facebook has been offering their own translation service since 2011, FTS.

Users can easily activate the translation service on their profiles in two ways. They can click on top right hand of their page and select setting and privacy, then choose language and region. After that, users have to click on the language into which they would like to have posts translated into. The current study scrutinizes FTS in terms of adequacy and fluency in rendering English posts into Arabic during the COVID-19 lockdown.

1.1. Machine Translation

Machine Translation (MT) is the study of the computer systems or online applications in transferring the Natural Languages from one language into another. Author in [1] shows that MT systems are "applications or online services that use machine-learning technologies to translate large amounts of text from and to any of their supported languages. The service translates a "source" text from one language to a different "target" language". The availability of such online systems for free or at low costs makes it necessary to verify the effectiveness of MT systems in dealing with natural languages especially with the languages which belong to different families such as English and Arabic.

Translation has been integrated into technology thanks to the giant technological progress of the last 70 years, starting with the first successful MT project at the University of Georgetown in 1954 as a result of collaboration between Georgetown University and International Business Machines (IBM). The [2] indicates that the success of the first experiment "attracted a great deal of media attention in the United States. Although the system had little scientific value, its output was sufficiently impressive to stimulate the large scale funding of MT research in the USA and to inspire the initiation of MT projects elsewhere in the world and notably in the USSR".

Research in [3] shows that 1980 is considered a flagship moment of MT with new developments emerging whilst "more dramatic development took place in MT in the 1990 since computers became more powerful with much higher storage capabilities". This crowned with the invention of the internet, a source of translation for the general public [4]. Automatic translation tools available on the Internet translate billions of documents daily, which would take human translators months. Whereas MT service was not free in the early history of the Internet, nowadays, we have a set of MT platforms that provide translation service for free such as Google Translate, Microsoft Translator, FTS and others. The author in [5] states, "Machine Translation (MT) is being deployed for a range of use-cases by millions of people on a daily basis. Google Translate and Facebook provide billions of translations daily across many languages".

1.2. Facebook Translation

The author in [5] indicates that Google translate and Facebook Translation users reach more than 1 billion monthly. The research in [6] shows that Facebook, firstly, used Google Translate service to translate comments into 50 languages. Facebook launched its first Translation Service in 2011, called In-line Translation Facebook Tool [7]. Where [8] states, "After Google integrated the "translate" feature into its social network, which allows users to translate posts and comments into 50 different languages, Facebook, as usual has followed the footprints of Google+, and quietly announced the launch of "translate" button – powered by Microsoft's Bing", setting itself apart from Google. The author in [9] describes the first Facebook Translation tool, "Facebook has quietly introduced a new tool that makes instant inline language translations appear with a single click". For instance, if a non-Spanish user on a Facebook public page gets across a post in Spanish, then he/she will click on the translation button and then he/she will be able to see the translation of the post in his/her language. FTS works on individual posts on Facebook and not on users' profiles yet, including comments. Currently, FTS offers translation service for 89 languages and they will continue to add more languages.

FTS adopted phrase to phrase MT approach, thus translating whole sequences of words of differing lengths. The author in [10], the founder of Facebook, explained that translation is the best mean to connect human globally. "Understanding someone's language brings you closer to them, and I'm looking forward to making universal translation a reality. To help us get there faster, we're sharing our work publicly so that all researchers can use it to build better translation tools". In the same year, Facebook research team developed a new MT approach using Convolutional Neural Networks (CNNs), allowing to translate languages more accurately (read: increase quality on a BLEU scale) and up to nine times faster than the traditional Recurrent Neural Networks (RNNs). The author in [11] describes the new MT approach as "Today we're publishing research on how AI can deliver better language translations. With a new neural network, our AI research team was able to translate more accurately between languages, while also being nine times faster than current methods", a superior speed confirmed by [12]. The author in [13] has shown that "CNNs have been very successful in several machine learning fields, such as image processing. However, Recurrent Neural Networks (RNNs) are the incumbent technology for text applications and have been the top choice for language translation because of their high accuracy".

In the late of 2019, Facebook research has declared new advances in NLP, which boost the accuracy of Facebook Translation. They have also introduced a new self-supervised pretraining approach, RoBERTa, that surpassed all existing Natural Language Understanding (NLU) systems on several language comprehension tasks. They have also collaborated with New York University (NYU), DeepMind Technologies, and the University of Washington (UW) to promote their future research [14].

In a first study on Facebook Translation evaluation, it evaluated Facebook translation service in handling low-resources languages: Lao, Kazakh, Haitian, Oromo, and Burmese. They evaluated the translation of English posts into these languages. They implemented different strategies: LASER, back-translations, self-training, multilingual modeling, to improve the translation from English to low source languages. "For instance, Sinhala to English and Nepali to English translations on Facebook have improved from "useful," which are just accurate enough to understand the meaning, to "good," which generate full meaning but may have typos or grammatical errors"[15].

The study is mainly concerned with Facebook translation of English posts related to COVID-19 released by international

organizations such as WHO, political leaders, medical specialists and the general public. The study aims to verify the efficiency of FTS in translating posts from English into Arabic and provides constructive feedback about the degree of fluency and adequacy of FTS and whether FTS is considered a reliable source of information or not.

1.3. Machine Translation Evaluation

MT systems Evaluation (MTE) is crucial to the development of MT systems. The author in [4] shows that the evaluation of MT is central to determine the effectiveness and performance of MT systems. Machine Translation Evaluation is essential to all end-users: researchers, designers and users to select the best system to use [16]. In similar way, the development of MT systems depends on the evaluation of MT systems, limitations and strengths of the systems. MT evaluation sheds light on the capacity of the system: what the system can or cannot do. The author in [17]emphasizes that the evaluation of MT system shows accuracy and fluency sought for the audience and purpose and complies with the other features negotiated between the requester and supplier, taking into consideration end-user needs".

Many evaluation methods have been used over the history of MTE. The first MT evaluation dated back to 1954 to assess the ability to translate 250 words from Russian into English, and they succeeded in translating this small number of words. The success of the experiment attracted a lot of funding. Consequently, in 1962 the first committee, the Automatic Language Processing Advisory Committee (ALPAC), was formed for evaluation. They found that it was not worthy to spend more money on useful MT system. The report ended with nine recommendations to evaluate MT, three of them encouraged to do further research on MT systems [18].

MT systems have achieved high performance close to human accuracy. The authors in [19], [20] shown that MT systems 'performance have achieved near human level performance. Moreover, the widespread of MT reached millions and therefore it has become a source of information for millions of people. In [3] Google Translate has been used by 500 million daily. However, many studies have highlighted the shortcomings of MT in dealing with Natural language processing (NLP). The have indicated that the main challenge of MT is having large parallel corpora. However, these corpora are not available in all NL [21]-[23]. There are very limited parallel corpora for the majority of language pairs. On the other hand, most of the previous studies depend on monolingual corpora in each language [24], [25]. According to [23] the success of the previsions of MT research is about using inferred bilingual dictionary. Moreover, it is indicated that the success of the previous studies is about using model training in sequence to sequence systems [26]-[28]. Previous studies have adopted back translation strategy in supervising i.e. generating inputs to train the target models and vice versa. Despite the fact that there are many methods designed for evaluation, there is still no generally accepted methodology to evaluate MT systems. Yet, MT needs evaluation, which can be done manually and automatically [22].

To assess MT system, there are three stages to evaluate their performance and efficiency: firstly, the design of the system; secondly, the development of the system; and thirdly, the evaluation of the system by potential customers [27]. With regards to the third point, MT evaluation is divided into three categories. The first is adequacy, which is used to assess the end user's needs, such as readability and costs. The second is diagnostic evaluation, where the designers and developers examine the output of MT and its relevance to the input. The third is the performance evaluation in order to assess the systems' performance in specific areas to assist the developers and the designers of the system [28].

MT could be evaluated manually and automatically [29], [30]. The author in [31] states manual evaluation investigates the systems' usability via human participants by means of Error Analysis […], whereas automatic evaluation examines MT outputs through the text's similarity to a referenced translation. Similarly, MT evaluation has two aspects: intrinsic and extrinsic. The former highlights the language quality, while the former highlights the capacity and efficiency of the system. He also adds that there are two ways to evaluate MT output: automatic and manual evaluation. Automatic evaluation relies on the usage of metrics that could approximate the similarity between the output and the human referenced translation without human interventions, while manual evaluation depends on human evaluators to assess and rank MT output [32]. The author in [15] sums up the advantages of automatic evaluation as fast and cheap: there is no need for bilingual speakers, it requires minimal human labor and can be used as an ongoing evaluation process during the design of the system.

MT could be evaluated automatically in terms of Edit-Distance metrics, Precision and Recall, F-Measure and Word Order. The author in [33] indicates that Edit Distance evaluates MT in terms of additions, omissions, substitutions, which are the requirements for adequate output. Precision and Recall evaluates the degree of n-gram matching between MT and human translation based on referenced translation, such as BLEU and NIST. The F measure is used to measure the overall quality performance. The word order counts the word order sequence between the source sentence and the output of MT. The author in [34] reminds us why BLEU is the most popular metrics among researchers:

> *one of the reasons why the metric is popular in the community seems to be for its simplicity for MT developers at least. Another reason why BLEU is widely used is that it has the best correlations with human judgments of translation quality. It estimates the similarity between the translated sentence and the referenced sentence.*

In fact, automatic evaluation has some advantages, but its shortcomings outweigh its advantages. Automatic evaluation assesses the text similarity between the output and the referenced human translation. It does not look for the meaning transference from the ST to the TT, which is a fundamental requirement for accuracy in translation. Bilingual Evaluation Understudy (BLUE) looks for n-gram similarity not meaning [35]. The author in [36] further argues that BLEU evaluates text similarity rather than meaning. Moreover, the Translation Automation User Society [37] agrees that automatic evaluation could provide one side of quality, which could not reflect the genuine quality of MT output. For these reasons and others, the current study adopts manual methods in evaluating MT output holistically in terms of adequacy and fluency scales provided by TAUS, rather than automated evaluations using BLEU for instance.

In fact, manual evaluation of MT is considered as golden standard to evaluate MT and cannot be overwhelmed by automatic evaluation. Manual evaluation of MT could be done in terms of quality assessment, translation ranking, error analysis, information extraction, comprehension test and post editing. Translation ranking results provide the end users with the degree of the output intelligibility.

In the same vein, [36] developed several tools for MT quality evaluation. They offered these tools on their website to conduct MT evaluation in terms of adequacy and fluency. The adequacy tool enables the evaluators to assess the output based on 1-4 rating scales to verify how much of the meaning is contained in the TT as shown in Table 1 & 2.

Table 1: Adequacy Rating Scale [34]

Adequacy Rating Scales		
4	Everything	All of the meaning in the source is contained, no more, no less
3	Most	Almost all the meaning in the source is contained in the translation.
2	Little	Fragments of the meaning in the source are contained in the translation.
1	None	None of the meaning in the source is contained in the translation.

On the other hand, [36] also provides a fluency tool to evaluate MT output in terms of structural rules as accepted by native speakers of the TL. Fluency evaluates MT output in terms of 1-4 rating scales.

Table 2: Fluency Rating Scale [34]

Fluency Rating scales		
4	Flawless	Refers to a perfectly flowing text with no errors.
3	Good	Refers to a smoothly flowing text even when a number of minor errors are present.
2	Disfluent	Refers to a text that is poorly written and difficult to understand.
1	Incomprehensible	Refers to a very poorly written text that is impossible to understand.

The present study aims to verify the best results of MT output in terms of adequacy and fluency scales provided by TAUS. The study has adopted TAUS since it provides a constructive feedback of the Facebook Machine Translation. Such feedback helps the system's developers to improve the efficiency of the systems and provide the users with insights about how much is the FTS is adequate and fluent.

2. Literature Review

As discussed above, MTE is essential in evaluating MT output to provide the end users with feedback about the strength and limitations of the systems. Facebook is the most prominent social media sites globally. It is also classed as the most popular social media site in the Arab region. Therefore, Facebook has become a major source of information for the majority of Facebookers during the COVID-19 outbreak. No research to date has been conducted to evaluate the efficiency of Facebook Translation in rendering English posts into Arabic in general and COVID-19 in particular.

The author in [37] conducted a study to trace the percentage of FTS usage among Jordanian during COVID-19 lockdown. They found that 94.3% use Facebook daily; 87.1% of the participants activated Facebook Translation Service (FTS). Moreover, 62.2% of the participants considered Facebook as a primary source of information regarding COVID-19 and 27.8% as secondary source. The authors in [38] have conducted a descriptive study on medical students in Jordan to assess knowledge, attitude, perceptions and precautionary measures toward COVID-19 among a sample of students in Jordan. They have found that 83.4% used social media sites as their preferred source of information regarding COVID-19. Moreover, [39] have conducted another study in Jordan to assess knowledge, practice and attitude of university students regardless of their majors. They have found that the sources of information for the University students are social media, internet and television. No significant difference was noticed between medical and non-medical college students on the sources of their information.

On the other hand, [40] has shown the social media sites have become a useful tool in confronting the crisis and connecting people together during the crisis. Moreover, public health experts have used social media sites to educate the public about the effects of COVID-19 and to discuss COVID-19 with specialists. The acceleration in the digital life changes the way of approaching the health information. She shows public health experts will use social media sites to spread correct information regarding health problems [41]. The author in [42] shows that Facebook has become a source of discussion and information exchange for 100,000 health care providers regarding the COVID-19 outbreak.

Social media sites have become platforms for survival against social isolation during the COVID-19 to "help people avoid the detrimental effects of social isolation during this pandemic" [42], with Facebook playing a major role as well. Social networks usage has rocketed covering different aspects of our life, including medicine, geography and business growth. Facebook has been used widely during COVID-19 as a platform for business, charity, and community service [43]. The [44] goes as far as suggesting that social media sites during the crisis preached religion to the followers and provided a form of religious instruction and support. On the other hand, social media have become the platform for sharing hurtful messages for people of China. They blamed China as a source of the crisis [45]. However, Facebook and other social media clamped down the spread of fake news concerning COVID-19 and fake news

This research brings the importance of MT systems in handling translation across languages during world crises. The next part highlights the methodology used in assessing MT role during COVID-19 Crisis.

3. Methodology

The study evaluates the effectiveness FTS has in providing adequate and fluent output for English posts related to Coronavirus into Arabic. It provides an answer to the following question: To what extent is FTS capable in providing adequate and fluent translation for English COVID-19 posts into Arabic? To answer this question, six evaluators evaluated the output of FTS in terms of the above TAUS adequacy and fluency scales.

The corpus of the study consists of 300 English posts related to COVID-19, collected over March and April 2020, the peak months of the pandemic. The posts were selected from various Facebook pages that belonged to political leaders, healthcare providers, medical specialists and the public. To ensure consistency and objectivity as recommended by TAUS creators, six evaluators, native speakers of Arabic and near-native speakers of English rated the same data on each scale. The evaluators were acquainted with fluency and adequacy scales along with MT limitations and potentials. Once the corpus was uploaded and sent to the evaluators using TAUS tools, they had to assign scores online on 1-4 rating scales. Then, each report was displayed online on the TAUS reports tool. The data were analyzed using SPSS Statistics to get Pearson interrater agreement among evaluators in ranking the output at two different times. The results showed that there is a high inter-rater reliability among the rators.

Table 3. Interrater correlation

N	Fluency	Adequacy
1	.947**	.969**
2	.973**	.936**
3	.931**	.967**
4	.839**	.782**
5	.976**	.867**
6	.944**	.985**

The above table shows Interrater correlation using Person Correlation between first and second evaluation for each rater, resulting in a statistically significant strong correlation between first and second evaluations for each rater.

4. Results and Discussion

4.1. Fluency

The following example illustrates how FTS translated a World Health Organization (WHO) COVID-19 instructional post into Arabic.

Example 1

Source Text: Many people are making great sacrifices to stay home and protect their health and that of others from COVID-19.

FTS output: الكثير من الناس يقدمون تضحيات كبيرة للبقاء في المنزل وحماية صحتهم وصحة الاخرين من كوفيد-19

alkthyr mn alnas yqdmwn tdhyat kbyrh llbqa' fy almnzl whmayh shthm wshh alakhryn mn kwfyd-19

Back translation: many people are offering great sacrifices to stay home and protect their health and that of other from COVID-19.

This example shows how FTS rendered the English WHO post into Arabic. The analysis shows that FTS rendered the posts fluently. Moreover, four of the raters gave the above example a rate of 4, flawless, while two of them ranked it as 3, Good. The analysis shows that FTS provided intelligible and fluent output.

Example 2

Source Text: Now, anyone returning from overseas is being forced into quarantine for 14 days when they arrive back in Australia. This is mostly occurring in hotels, and at Government expense.

FTS output: الان، اي شخص عائد من الخارج يجبر الى الحجر الصحي لمدة 14 ايام عندما يعود الى استراليا. يحدث هذا في الغالب في الفنادق، وعلى نفقة الحكومة.

alan, ay shkhs 'ea'ed mn alkharj yjbr ala alhjr alshy lmdh 14 ayam 'endma y'ewd ala astralya. yhdth hda fy alghalb fy alfnadq, w'ela nfqh alhkwmh.

Back Translation: Now, anyone returning from abroad is being forced into quarantine for 14 days when they return to Australia. This is mostly occurring in hotels, and at Government expense.

The above example shows how FTS rendered into Arabic a Facebook post of Mark McGowan, Premier of Western Australia, regarding the quarantine for arrivals to Australia. The analysis shows that the raters rated the post in a balanced way. Three of raters rated the output as flawless, where the post is perfectly translated. Moreover, three of them ranked FTS output as Good, where the sentence is fluently translated despite minor errors. In fact, these minor errors did not inhibit the intelligibility of the text.
Figure 1: FTS Fluency

The above chart illustrates the degree of fluency obtained by FTS in providing fluent translation for English posts related to COVID-19 into Arabic. The highest fluency scale goes for *good* among the six evaluators with a percentage of 55.33%, where FTS output is easily understood without difficulty even when a number of minor errors are present. The lowest scale goes for incomprehensible scale, where the output is poor and impossible to understand which is equal to 0.67%. The first and second raters had similar evaluation. They indicated that the FTS output is held between *good* where the output has minor errors with 55.33% and *flawless* with 29.67%, a perfect output with no errors. The other four raters ranked FTS as *good*, followed by Flawless and then *disfluent*, where the text is poorly written and difficult to understand. According to the raters, FTS is mostly adequate in

conveying Source the ST to the TT where the target side translation is grammatically well informed, without spelling errors and experienced as using natural/intuitive language by a native speaker.

Adequacy

Example 3

Source Text: The conclusion I reached is that the Government should end the lockdown after Easter and return to a mitigation strategy,   with
self-quarantining limited to those most at risk" writes Toby Young.

FTS Output: الاستنتاج الذي توصلت اليه هو انه ينبغي للحكومة انهاء الاغلاق بعد عيد الفصح والعودة الى استراتيجية التخفيف، مع الحجر الصحي الذاتي, يقتصر على اولئك الاكثر عرضة للخطر, يكتب توبي يونغ.

alastntaj aldy twslt alyh hw anh ynbghy llhkwmh anha' alaghlaq b'ed 'eyd alfsh wal'ewdh ala astratyjyh altkhfyf, m'e alhjr alshy aldaty, yqtsr 'ela awl'ek alakthr 'erdh llkhtr, yktb twby ywngh.

Back Translation: The conclusion I reached is that the government should end the lockdown after Easter and returned to mitigation strategy, with self-quarantining limited to those at most risks, writes Toby Young.

This example shows how FTS rendered the Telegraph Facebook Posts into Arabic. The results show that the source text meaning is contained in the output translation. The four raters rated the FTS output as Most, where almost all the meaning in the source text is contained in the translation. However, two raters gave a scale of 4 Everything. The current study concurs with the last rating, Everything, that all the information contained in the source text is found in the target output.

Example 4

Source Text: When the world's doctors come together, amazing things can happen. We're all hopeful that plasma therapy can help treat COVID-19.

I'm glad Bloomberg Philanthropies can play our part to support Arturo Casadevall's research.

FTS Output:

عندما يجتمع اطباء العالم معا، يمكن ان تحدث اشياء مذهلة. نحن جميعا نامل ان العلاج بالبلازما يمكن ان يساعد في علاج كوفيد-19.

Bloomberg Philanthropies يمكن ان يلعب دورنا لدعم ابحاث ارتورو كاسادفال انا سعيد ان

'endma yjtm'e atba' al'ealm m'ea, ymkn an thdth ashya' mdhlh. nhn jmy'ea naml an al'elaj balblazma ymkn an ysa'ed fy 'elaj kwfyd-19.

ymkn an yl'eb dwrna ld'em abhath artwrw kasadfal Bloomberg Philanthropies ana s'eyd an

Back Translation: When the world's doctors come together, amazing things can happen. We are hopeful that Plasma thereby can help cure COVID-19. I happy that Bloomberg Philanthropies can take part in supporting Arturo Casadevall's research.

The example shows how FTS transferred the English post into Arabic. The six assessors ranked the output differently. Four of them rated it as Most, while the other two raters ranked it as Little. The study correlates with the four raters that almost all the meaning in the source text is contained in the translation. However, the study indicates that keeping the noun 'Bloomberg Philanthropies' untranslated does not inhibit the intelligibility of the text
Figure 2: Adequacy Scales
Figure 3: FTS Fluency and Adequacy Performance

The above chart shows the degree of adequacy obtained by FTS in providing adequate translation for English Facebook Posts related to COVID-19 into Arabic. The analysis shows that the highest adequacy scale goes for *most* scale with a percentage of 47%%, where almost all of source text meaning is contained in the target text, while the lowest scale goes for *none*, none of the meaning is contained in the translation which is equal to 5.33%. The six raters had similar views that most of the outputs are scaled as *most*, followed by *everything*, all the meaning of the source text is contained in the translation, and then little in the third rank and None with lowest rate. The chart below illustrates FTS performance based on TAUS adequacy and Fluency.

The above chart illustrates the ratings of fluency and adequacy obtained by FTS in rendering English Facebook posts related to COVID-19 into Arabic. The analysis shows that the highest degree of adequacy achieved by FTS is Most, with a percentage of 46.33, followed by Everything and then Little and None, indicating that almost all of the ST meaning is contained in

the TL. Similarly, the highest degree of fluency achieved by FTS is Good, where FTS succeeded in providing Fluent output with minor grammatical categories, followed by Flawless, Disfluent and then Incomprehensible. These two degrees indicate the FTS could provide fluent and adequate translation to the end users.

The results of the study have indicated that Facebook have conducted rigorous research to ensure the best translation quality for the end users. The study has shown that FTS has achieved a high degree of fluency starting with **good** scale, followed by *flawless*, **disfluent and *incomprehensible***. The study has shown that FTS achieved a higher degree of adequacy starting with **most**, followed by **everything**, **little** and **none**. These results agree with [11] that Facebook introduced Neural Machine Translation (NMT) to provide an accurate translation for the end users. Moreover, the study confirms the findings by [37], that the NMT introduction enhances the accuracy and the speed of MT across languages. The study correlates with [13] that back-translations, self-training, multilingual modeling could improve Facebook translation accuracy across human languages.

5. Conclusion

This research is the first research to fill a gap in the literature about the FTS degree of adequacy in contributing to translate the English Facebook posts related to COVID-19 into Arabic. It provides useful data on FTS adequacy and fluency criteria.

Overall, Facebook translation service obtained a high degree of adequacy and fluency. This is because FTS is trained well to deal with Arabic content. More importantly, we could benefit from FTS with Human Assisted Machine Translation (HAMT), in which a computer system does most of the translation, appealing in case of difficulty to a human translator for post editing services. Therefore, FTS helps in fighting COVID-19 since it facilitates the process of information exchange. Moreover, the study recommends further studies to conduct diachronic evaluation for FTS output over a period of time, since the current study is limited to assess FTS output during the COVID-19 outbreak in Jordan. Despite the fact that FTS achieved a higher degree of adequacy and fluency scales, the current analysis does not cover all genres and therefore there is a lack of integrative evaluation studies that pave the research for the holistic analysis and the error analysis studies. The FTS is still far from reaching fully adequate and fluent translation of a quality obtained by human translators.

6. Limitation and Study Forward

This study has some limitations as it investigates the adequacy and fluency of Facebook Translation Service during COVID-19 on a particular topic, namely COVID-19, from the instructors' perspective, within a defined timeframe (post COVID-19 era), and geographical context (Jordan) to answer three research questions. Consequently, further research will be necessary to examine the adequacy and fluency of FTS in other fields and different timeframes. That the current study focuses on the period of the outbreak of the COVID-19 pandemic, it is recommended that other researchers examine the long-term adequacy and fluency of FTS in all fields. It is also recommended that researchers conduct similar research on the adequacy and fluency of FTS in translating from English into their languages at different situations.

Determinants that Influence Consumers' Intention to Purchase Smart Watches in the UAE: A Case of University Students

Nasser Abdo Saif Almuraqab[*]

Dubai Business School, University of Dubai, Dubai, 14143, UAE

A R T I C L E I N F O	A B S T R A C T
	It has been observed that the smartwatches have emerged quickly on the digital era with the ability to significantly influence daily life and improve users' wellbeing, decisions, and behaviour. Nonetheless they are in their stages of adoption, smartwatches are marked the most widespread type of wearable technologies. Considering this, present work has been carried out to intensify the scholarly understanding of determinants that affecting consumers' behaviour of purchasing intention, to reach this objective, an integrated model based on Technology Acceptance Model (TAM) was designed and examined. An online questionnaire was utilized for the collected data (n=106). The empirical analysis based on partial least square method, using SmartPLS software. The findings exposed that visibility, social influence, and perceived ease of use are the proximate factors that drive adoption intention. Further, the analysis reveals that Consumers' purchasing intention is significantly influenced by intention to use and cost. The extent of these factors is influenced by consumers' perception of smartwatches as a technology and as a fashion accessory. Present study has also attempted to scholarly discuss the theoretical and managerial implications.

1. Introduction

The contemporary technological improvements and global penetration of mobile devices such as smartwatches and smartphones have resulted in anytime-anywhere real time accessibility to information. In addition, the concept of 'mobility' is advancing from simply carriable to seamlessly wearable technology. Consequently, expanding the ubiquity of personal communication to higher level. Technically, wearables are those smart electronic devices and computers that can be integrated into various kinds of daily used accessories of clothing and can be wore on or attached to the body [1]. Such devices are designed to provide consumers with a seamless and integrated experience. The major function of wearable gadgets is to help users achieve a state of self-connected by using sensors and software that simplify communication, data exchange, and instantaneously information access. Consequently, wearable devices have become a prominent part of internet of things (IOT) [2–5].

In particular, smartwatches by e.g. (Samsung, Apple, Huawei) have been highly publicized for many features and functions that attract wide range of consumers' interests, containing health-monitoring, fitness, and location tracking and extended smart features such as communications [6]. As per the results revealed

by different recent surveys regarding smartwatch adoption, the marketplace for smartwatches will continue to grow exponentially by 2020 to be around 373 million units will be sold out globally [7, 8].

Regardless Of smartwatches' high scores on the 'hype-o-meter', empirical examinations on how consumers' view and behavior of purchasing intention of these devices have not been satisfactorily conducted, and related research are still precursive. To fill this identified gap, present research has examined number of proximate psychological factors such as social influence, visibility, and cost that how these factors affect the determination of the user adoption and purchasing intention of smartwatches by assimilating them with technology acceptance model. This research thus aims to design a research model permitting a systematic estimation of smartwatch adoption and purchasing intention, with significant implications for manufacturers, marketing, and policy makers toward future wearable technology adoption.

2. Literature review

2.1. Wearable devices and smartwatches

A study conducted by [1] exposed that the terms 'wearable devices' or 'Wearable technologies', or just 'wearables' refers to

contemporary micro-electronics or even computers that are smartly integrated into daily use accessories relevant to clothing and hence can be wore or attached to body. These characteristics deliver the consumers a seamless and integrated experience. It has been commonly observed that wearable devices provide significant convenience when compared to laptops and mobile phones. This quality can be rightly attribute to their light weight, easily accessible in nature, can be used while moving, non-keyboard commands and control such as voice and gesture. Another worth mentioned significance of these devices is that they are simultaneously considered as technology and fashion by large number of users [9]. Further, in terms of performance, these devices can outperform than laptops and a smart phone, consequently the researcher thinks that they can easily replace the competitors in future. The author in [10] argues that awareness and knowledge these devices have been increased, which is positively affecting manufacturers intentions to release new versions of wearable technologies to the market. It has been argued that wearable devices possess significant potential for dramatically changing the landscape for societies and businesses as they can largely add to individuals' wellbeing and ultimately help them to make relatively batter and rational decision. Such as, smart wearable's in medical centers can help through providing most accurate health information that will ultimately increase patients' safety and success of medical operations.

The relevant published research does not provide any clarifying description of smartwatch technology. Such as, [8] discussed number of wearable's involving Samsung Galaxy Gear and Fitbit Flex, as smartwatches. While most of these are wrist-worn technologies, and technically other distinctions are required to mark them as smartwatches. Such as smart bracelets, smart wristband or fitness tracker are technically made for tracking the physical functions of the user and provide limited information in small displays. Hence these devices are primarily designed for compilation of limited data that a user can perform some analysis using laptop or smartphone. Further the capabilities of these are very limited in terms of presentation of information's such as pulse or time; also, the wristbands do not allow the installation of new applications. Contrary to that the smartwatches have relatively larger display and are mostly designed in larger size then traditional watches. In-addition, smartwatches are equipped with advance technology of touch screens, they allowed the users to install new apps. Another remarkable difference in wristband and smartwatches is that the latter provide extra functionality when user is connected to Internet. Smartwatches are capable for providing Facebook notifications, emails etc. while the primary function of wristbands is to gather data. In line with the conclusion of [11] our discussion reveals that smartwatches are relatively good choice as compare to wristbands hence, present work defines smartwatches as a device that is wore similar to regular watch and permits for apps installation and utilize the relevant features. In addition, an academic work was conducted by [12] on the wearable technologies and smartwatches' adoption, highlighting the impact of usefulness and visibility, their study revealed that perceived usefulness and visibility are important determinants that influence adoption among consumers. However, their study didn't test or examine consumers' intention to purchase the smartwatches, and the impact of adoption intention on purchasing

decision. Which this study will reveal and tend to contribute and fill this literature gap.

2.2. Theoretical framework and research model development

The contemporary era has been experiencing the invention and innovation of different types of technologies; the technologies are commercialized on large scales that are leading to the development of different theoretical and conceptual models to explain the technology acceptance. One of the frequently discussed and used theoretical models is Technology Acceptance Model (TAM) that provides insights into final user's acceptance of ICT. This model postulate that the primary and prominent psychological factors of intention to use (ITU) are perceived ease of use (PEOU) and perceived usefulness (PU) [13,14]. It has been argued that when final end users perceived that a service is relatively easy to use and operate, they will use the technology. Number of earlier works done in the current area of interests suggests that TAM framework has the advantage of explanatory power and follow a parsimonious approach, this has been proved through many research works on the user adoption of several mobile-services and technologies, including m-government or smart government apps, tablet computers, e-book readers, mobile cloud computing, long-term evolution services (LTE), and digital currencies [8,15–21]. Consequently, TAM has been adopted as the primary theoretical framework to investigate the user acceptance of smartwatches. The following hypotheses have been developed in the current study.

H1: Perceived usefulness (PU) will have positive effect on users' intentions to use smartwatches (ITU).
H2: Perceived ease of use (PEOU) will have positive effect on users' intentions to use smartwatches (ITU).

2.3. Visibility

In contemporaneous societies, clothing, trinkets, and makeup are considered as important and prominent determinants of persons' imprint development e.g., [22–24]. A study carried out by [25] outlined first person verdicts as instant rejoinders during first meetings and considered that the noticeable factors of ones' personality plays an important role in impression structure. Earlier studies on possessions and branding exposed the ideology that visible components of personality can be used for impression and gathering data about others e. g. [26,27]. Hence, a user using a brand, or possession or product to reveal a facet of her/himself to others, wants to make sure that other people acknowledge such possession. As concluded by [28] "visible products and services are the bases for inferences about the status, personality, and disposition of the owner or consumer of these goods." As a contemporary trend, people tend to purchase products with high social status [29], the study presumes that people with more information's and awareness regarding visibility have a positive mindset towards a technology, others' influence may enhance consumers' intention [12,30–32]. Following this prior explanation, it is hypothesized:

H3: Visibility (VB) will have a positive effect on users' intention to use smartwatches (ITU).

2.4. Social influence

It has been observed that social influence is a significantly important factor, considering the technology has fashion factor

involved as well. This is the case with most of the wearable devices such as smartwatches. Consequently, as soon as users tend to buy something, they do consider their social circles and social networks. Number of earlier relevant studies included social influence as a critical factor of the consumer buying behavior [15,33]. Two independent studies conducted by [34,35] investigate the adoption of wearable devices by passengers and concluded that social influence significantly affect behavioral intention. They further discussed that the social influence can greatly affect these systems because people normally tend to notice and that these devices will greatly increase their survival chances. Other studies have also confirmed that same for other wearable technologies such as smart clothing [36], smart glasses [37,38], and fitness/health wearable technologies [39–42]. Hence, it is hypothesized:

H4: Social influence (SI) will have a positive effect on users' intention to use smartwatches (ITU).

2.5. Cost

Cost is also considered as a vital factor in previous studies. whether consumers think that the smartwatches are costly or reasonable? whether they are willing to pay or not? Manufactures and all those concerns give high weightage to these questions because they know that consumer buying behavior is greatly influenced by consumers' opinions of cost. In fact, [43] attempted to analyze the nexus between cost and acceptance of m-banking. They reach to the conclusion that higher the cost of a service, less the consumers will be willing to purchase it. Similar results were exposed by number of other studies such as in case of m-commerce [44,45]. Considering the above, cost of smartwatches has been included as an explanatory variable with the following hypothesis to test its validity:

H5: Cost (CT) will have negative effect on intentions to purchase smartwatches (PI).

2.6. Purchase intention

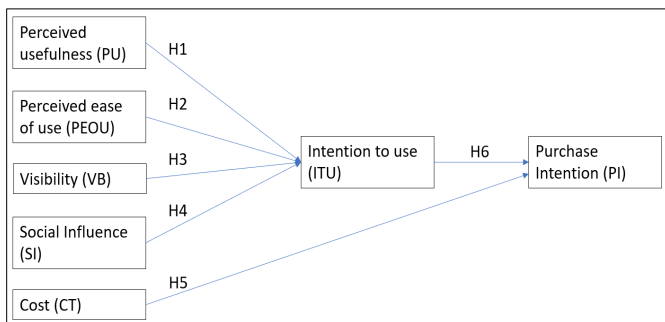
Attitudes towards technology (i.e. intention to use) are the only determinants of purchasing intention, claims [46]. Costa-Font, [47] also articulate that certain attitudes encourage consumers' choice of a product. These claims are widely supported in literature on technology adoption. These claims are well validated by empirical results showing strong associations [48,49]. Also, based on Davis' technology acceptance model, the author will test the correlation between intention to use and purchase intention. **H6:** Intention to use (ITU) smartwatches will have a positive effect on consumers' purchasing intention (PI).


Figure 1: Conceptual framework of the research

3. Methodology

To the best of author's awareness, this is a pioneering empirical study that has exclusively attempted to scholarly examined the determinants of smartwatches buying intention of the people in the context of UAE. Present study has adopted an empirical approach for testing the model used, a well-designed and pretested questionnaire has been used for collecting the desired data on the proposed variables.

3.1. Instruments

The questionnaire served in this study has been divided into three sections. Introduction to the study and objectives of the study are given in first section, this was inevitable as respondents were UAE citizens (expats and locals). The next section was composed of questions related to demographic information's such as age, education, gender, and possession. And the final section was composed to 23 questions that measured seven variables drawn from relevant studies. All this has added significantly to the validity of instrument and ultimately to the reliability. Present study has extended the TAM model through inclusion of PU and PEOU to the predicted variables from the available literature, which are cost, social influence, and visibility. Table 2 has been allocated to the items' distribution that contains means and standard deviations of the items. It has been observed that this technique has added significantly in enhancement the consistency and strength of study's model.

3.2. Sampling process

The survey used in this research has been developed as follow: initially the researcher conducted a reliability test through collecting data from limited number participant from the target population (50 to 60) minimum. For this purpose, Cronbach's alpha was obtained from SmartPLS3. For justification of and deciding upon sample size, the researcher pre-planned that the survey will be distributed through electronic targeting to connect minimum 50 responses if possible. Consequently, to compel with the SmartPLS3 criteria of 10-times larger formative indicator for measuring single construct, or even highest order structural path that was indicated by the construct in the structural model.

Followed by that, the scholar has shared the survey link to the participants using the email list given by the University of Dubai. This simple random sampling method resulted in 106 responses after discarding incomplete responses, that is sufficient for the generalization and of results and sustainability of terms. Table 1 has been allocated to presents the sample demographics.

3.3. Analysis of the results

Partial least squares analysis which is based on structural equation modelling (SEM) [50]. SEM methodology has the advantage of assessing the measurement and structuring model simultaneously, hence factor analysis and hypothesis testing are done concurrently [51]. Further, PLS was used instead of covariance-based SEM as it is more appropriate for exploratory study [51]. For ensuring significant perceivability of the items used in the model, the Likert scale with responses recorded from 1 to 5 has been used. Table 2 presents information regarding loadings, cross-loadings, standard deviation, and means of all the variables used in the model.

Table 1: Sample Table

Gender	Frequency	Percentage
Male	65	61%
Female	41	39%
Education		
High school	3	3%
Diploma	8	8%
Bachelor	52	49%
Postgraduate	43	41%
Age		
>18	1	1%
18-24	26	25%
25-34	32	30%
35-44	38	36%
45-54	7	7%
55-64	2	2%

The scholar has properly measured the discriminant and convergent validities for examining the research model used in the research. For verification and validity of convergent strength, the average variance extracted was performed, for internal consistency Cronbach's Alpha and item loadings were obtained. All of these statistics were higher than 0.70 for composite reliabilities, the Cronbach's Alpha was above 50 percent, the statistic for item loadings was 0.70 [52] all these are given in Table 2 and 3. Further, Table 2 shows that average loading of variables is higher than 70 percent; this is desirable in social sciences. Further, the acceptable level dependency of all variables has been shown by Cronbach's alpha (suggested value 0.8, acceptable value 0.6) the details of these values are given in Table 2.

Technically, prior to responding the research question, the scholar should examine and test for the possible correlation. Agreeing to [53] for the discriminant validity, as compare to a construct correlation with other variables, the AVE must be larger for every construct. Table 3 present the results for inter-construct correlation matrix, with bold values representing the respective square root AVE.

A Simultaneous equation model test has been applied using SmartPLS3 to add further to the results shown and to properly achieve the research aim. Technically, the non-parametric bootstrapping procedure is used by PLS-SEM for statistically testing the model under consideration. In simple words, numbers of sub-samples out of the study sample are produced and are tested for the verification and validity of model best fit. The University of Dubai has its own licensed SmartPLS3 tool that is used by the scholars. The output is presented in Table 3.

A great significance of SmartPLS3 tool is that it simultaneously computes the t-statistic and exact probability value p-value for each hypothesis tested. The results are provided in Table 4.

For obtaining the t-values, the bootstrapping procedure was utilized. The coefficient of determination R^2 value of 0.69

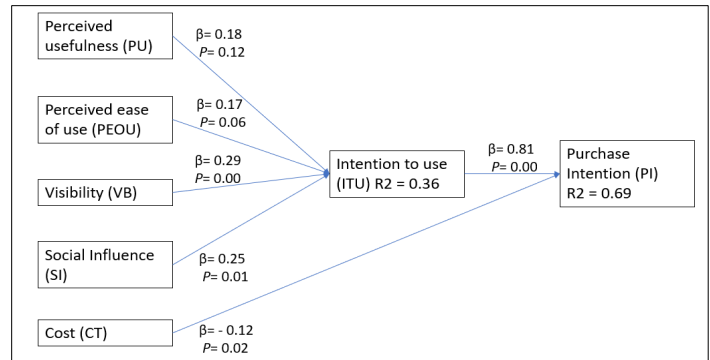
suggests that the model is good fit. Further, Figure 2 provides partial coefficient values along with their respective 't' and 'p' values.


Figure 2. Hypotheses' *b*- and *p*-values

4. Discussion

As users' interest in smartwatches has lately become obvious, increasing assurance has been placed on the determinants that facilitate consumers' experience and boost greater adoption of smartwatches. Consequently, this research investigates smartwatches' key psychological and technological determinants trying to understand consumers' behavior, and explores their effect on smartwatches purchasing intention, by designing and confirming an integrated user adoption model. The model explains that people at the UAE will tend to purchase smartwatches for less cost (CT) of course, and other factors mediated by intention to use (ITU), which are visibility (VB), social influence (SI) and of course such technology should be easy to use (PEOU). The first variable (PI) is a well-explored construct that is used as a surrogate for smartwatch purchasing. In this study, PI was predicted by two major variables (ITU) and (CT), with a varying degree of significance. It was found that three out of four variables mediated by (ITU) which have significant indirect effect on (PI), these are (PEOU), (SI), and (VB). Only one of the variables was found not to be significant, which is (PU).

The analysis reveals that the prominent construct of PI is the intention to use (ITU), with partial coefficient value of 0.81. This suggests that the more the people of UAE have the intention to use technology, the more they will purchase smartwatches. Further, the analysis shows that, cost (CT) is another dominant explanatory factor of PI, with partial coefficient value of -0.12. This suggests that higher the cost, lower will be purchase intent of the people and vice versa, as the peoples in UAE consider price or cost to be a major factor that shape their future buying decision. In addition, and as per the results analysis above, there were critical predictors have significant indirect influence on people purchasing intention, mediated by ITU. These are VB, SI, PEOU in order. Visibility found to be important predictor with beta value 0.29. This suggests that in the context of UAE, people care about visibility (VB) of wearable technologies, i.e., they care about how people will notice in case they wear smartwatch and they do believe that smartwatches are more visible and prominent. Consequently, they have greater intention to use smartwatches. Similar finding was discussed by [12] on the significance of VB on ITU. These results support the findings of [12] that smartwatches, merge technology and fashion aspects.

ITU ⟶ PI	0.81	23.05	0.00	Supported ***

* p≤0.1 -- ** p≤ 0.05 -- *** p≤ 0.01

The analysis exposed that social influence (SI) has significant impact on PI with the partial coefficient value of 0.25. This outcome leads us to conclude that in the context of UAE economy, peoples attach more importance to social influence and will have more intention to purchase smartwatches if they consider the influence of closed or important ones, such as family, relatives, colleagues, and important people at the society such as social influencers. A person in UAE will purchase smartwatch, if s/he notice that people important in her/his life thinks that s/he should have a smartwatch. Technically, bandwagon effect can be observed in case of smartwatches purchases in UAE.

Similarly, the analysis suggests that perceived ease of use (PEOU) significantly influence ITU with a partial coefficient value of 0.17, suggesting that ease of use is as major determinant of buying behavior in UAE. People give importance to acquiring knowledge about how to use and operate smartwatches. It has been observed that perceived usefulness (PU) has no significant relationship with (PI) in the context of UAE economy. This outcome can be explained by number of factors involved, first, most of the peoples think that smartwatches are not important as have already been receiving notifications through their mobile phones, further facilities such as heartbeat rate is available in most of the smart phones as well as in most of other wearable technologies. Further, battery drain is a significant problem as people do not like to charge their smartwatches on daily basis or even every next day. All these explains why PU is not a significant factor in the context of UAE economy, and Similar finding was reported [8].

The analysis suggests that 69% of the variation in PI is explained by the included variables in the model, in social sciences that is considered as a substantial level of prediction. Out of the six variables included in the model as predictors of intention to use (ITU), four variables namely CT, PEOU, SI, were found to have statistically significant relationship with ITU and one variable PU was found not significant. Further, table 5 suggests that all but (H1) of the proposed hypotheses were supported.

Most the variables included in the present study are significantly important for analyzing smartwatch adoption and purchasing behavior in the context of UAE. The findings of the current study are in line with the findings of the earlier studies in the field.

The study suggests that visibility and social influence play critical roles in shaping purchasing intention of the peoples in UAE; people are close together and influence each other via social perceptions. Further, in the context of UAE, people also care about others' impression on their wearable devices. Moreover, prior research works have also reported that cost of smartwatches is also important and is negatively influencing purchasing decision. Hence, manufacturers should give significant importance to prices of their products and should try to produce different types of products with different prices. Finally, it has been found that ease of use is another important determinant and consumer mostly prefers simple and easy to use smartwatches in terms of features and applications. However, perceived usefulness does not influence consumers' intention to use smartwatches, subsequently buying behavior them. As many people believed that smartwatches are not mature enough to replace some or main functions of smart phones yet, and it has some drawbacks discussed earlier.

5. Conclusion

5.1. Theoretical Contribution

This research contributes two-folds to the existing stock of knowledge on the present area of interest. First, published scholarly research on smartwatches is relatively limited, and this study is an addition to limited research. Specifically, it added and validated the importance of technology acceptance utilizing (TAM) to predict the purchasing intention. In addition, TAM was combined with more variables such as cost, social influence to explain consumers' purchasing intention. Second, this work provides technical insights for understanding smartwatches, which are observed as from a technology and psychology viewpoint. Analysis suggests that most people consider smartwatches to be a combination of technology and fashion. Hence, visibility is an important determinant of adoption intention, and subsequently influence consumers' purchasing decision. However, TAM has not yet tackled the visibility part, while related aspects, such as image have been shown to be relevant in some contexts. The outcomes of the this study are in line with the previous work, which suggest that consumers perceive smartwatches on two dimensions: technology and fashion [12,33]. Generally, when exploring the adoption of purchasing intention of wearable technologies, using TAM, other variables i.e. (social influence, visibility, and cost) should be considered. Just as, any smart T-shirt or smart shoes may be considered relatively more fashion related than technology. Consequently, the relevant

theories about fashion adoption may work more appropriately in this case.

5.2. Practical contribution

It has been argued that smartwatches are a combination of technology and fashion, and they are supposed to accordingly be well-designed, affordable, and meet social needs of their targeted consumers. Despite limited customization of the design, majority of smartwatches offer technical customizations through installation of applications. To take full advantage of their market competitiveness, manufacturers are offering their products in variety of colors or wristband, whereas other are advertising various virtual background on the screen. In addition, manufacturers, should pay attention to the cost factor, which is critical, or they might introduce different models with differ prices. While the focus of this study is on smartwatches, it provides a guidance and managerial implications for decision makers for manufacturers and their marketing, not only on smartwatches, but also, on other wearable devices, for example smart glasses, smart shoes, or smart clothing.

6. Limitation and Future Research

Similar to other scholarly works, present study has number of delimitations that needs to be addressed in future research. First, as current study has taken sample from single country, the allows the researcher to control number of exogenous factors, which results an increase in internal validity, and thus limits the generalizability of the study. Although, previous studies carried out in this regard exposed that TAM [54] and other models associated with visibility [55,56] are considerably steady in varying samples and contexts, making this restriction less threatening for the sustainability of present study. furthermore, the inclusion of non-branded smartwatches allows consumers to express openly the influence on their intention without being potentially biased by a particular smartwatches brand.

Nevertheless, this advantage relates to the limitation with brand related issues, for instance brand loyalty, was not considered. For example, it was argued that a user with high brand attachment [57] or brand love [58] to Apple, would purchase any product of Apple. Upcoming studies should concentrate on tackling such limitations. Moreover, further evaluation of the significance of visibility is necessary. For example, particular design features i.e., color, shape, size) might be examined to verify the ideal strategy and improve the understanding of the desired visibility.

Correspondingly, the functions of smartwatches and its benefits, could be further studied to expose perceived usefulness (PU). Lastly, forthcoming studies might apply resistance models i.e. [59] to recognize the resistance to smartwatches and/wearable technologies. These models might be crucial in situation where smartwatches substitute conventional watches.

Conflict of Interest

The authors declare no conflict of interest.

	This paper proposes a new method of implementation of the part of SIFT (Scale-Invariant Feature Transform) algorithm used to extract the feature of an image of a size 256×256 of pixels, which is mainly based on the using the LEON3 soft core processor .With this method it is possible to detect points of interest and so perform matching. This process allows several real time applications as robotic navigation, stereovision, object recognition etc. Obtained results show a very robustness in rotation, scale invariant as well as luminosity change. SIFT algorithm saw big success in various applications of computer vision. However, its high computation complexity has been a challenge for the most part of embedded implementations. This paper presents a partial implementation of the SIFT algorithm, which is to implement just the extraction of the characteristics that is based on the LEON3 processor. This implementation method overcomes the existing problems, in particular, the high dependence of existing implementations on the hardware architecture used. Indeed, the high flexibility of the processor allows the possibility to develop the application independent of the target board.

1. Introduction

The detection and the description of stable local features are two fundamentals components of many object recognition algorithms. In this context, Moravec and Harris were the first who proposed algorithms for the detection of interest points. Over time, several improvements have been applied to these algorithms until the appearance of the SIFT algorithm. This was a big success in various applications of computer vision.

In the computer vision field, it is interesting to extract features of an image for use in various applications such as image recognition, autonomous navigation of robots, and face recognition.

A significant progress has been developed in this axis. One of the most interesting works of characterization that gives good results was carried out in 2004 [1]: Features extracted by SIFT (Scale Invariant Feature Transform) are largely invariant to rotation, change of scale, change illumination, noise and small changes in views.

The main disadvantage of the SIFT algorithm is its high computational cost. This is the result of the complex iterative process used to obtain the invariance to changes and transformations mentioned above. An effective solution to this problem is to move to embedding this algorithm on hardware platforms, to improve the execution time.

In the second section of this paper, related works are presented. Section 3 shows briefly explanation of the principles of SIFT algorithm. In section 4, proposed method is developed. The experimental results are shown in Section 5, and a conclusion summarizes proposed work and suggests some ways to improve results.

2. Related works

The SIFT algorithm has succeeded in a large number of applications; however, its high computational complexity has been a challenge for embedded implementations. Several works have overcome this problem while developing hardware architectures based on very powerful development platform, which allows improving the running time and the precision of the results. In fact, they have benefited from the hardware parallelism offered by (Field-Programmable Gate Arrays) FPGAs. Some studies have only implemented the detection portion of points of interest based

*Corresponding Author: Nasr Rashid, +201001652392 & Email: nasrrashid34.el@azhar.edu.eg

only on a purely hardware architecture. Other works are based on a mixed architecture (hardware /software), where the software part is designed using a softcore (Nios II) or a Digital Signal Processor (DSP). A full hardware implementation was presented in 2008 [2].

The author proposed a parallel hardware architecture for detecting of points of interest based on the SIFT algorithm applied to the Simultaneous Localization and Map-building (SLAM) problem. That architecture was based on specific hardware optimizations considered fundamental to include such a robotic control system on a chip. The proposed architecture was completely independent and able to detect features from 30 images/second. They calculated the descriptor through the Nios II processor. Another architecture was proposed in 2009 [3]. Authors modified the original version of the SIFT algorithm to increase the processing speed and reduce the used hardware resources. They used two octaves where each one was formed by four scales, instead of three octaves each one was formed by five scales. This choice has degraded the mapping results, but it has optimized the use of material resources. They also reduced the size of the descriptor, in order to reduce the execution time; they went from a size of 128 to a size of 72. With this optimization, the proposed system was able to detect the features of an image of a size of 640 × 480 pixels in 31 milliseconds. In [4], the authors presented a partial implementation of the SIFT algorithm, where they only implemented a feature extraction part. The proposed architecture is able to detect points of interest from an image of 320 × 240 pixels in 11 ms.

In [5], the author described a low-cost embedded system based on a new architecture that successfully integrates an FPGA and a DSP. The step of detecting characteristics was implemented using a fully parallel architecture based on FPGA. However, the description step was performed using a fixed-point DSP. With this new design, it allowed both reducing the used hardware resources and to accelerating treatment. It was able to detect characteristics in 10ms from images of a size of a 320 × 256 pixels (without convolution step). Despite the optimizations made by the authors during the design of their architecture, the latter mismatched compared with the result obtained by the executable in [6]. This defect was caused by the loss in accuracy due to the representation of the data relating to the magnitudes and orientations in a fixed point format.

All these works have benefited from hardware parallelism offered by FPGAs to optimize the computation time and increase accuracy. But the developed architectures are dedicated to a very specific FPGA [2], [7], [8] and if you want to change the target FPGA card, you must make changes that can take a lot of time; as the example of [2] where architecture will be implemented on the FPGA of the Altera family. This paper presents a partial implementation of the SIFT algorithm, which is to implement just the extraction of the characteristics that is based on the LEON3 processor. This implementation method overcomes the existing problems in the methods presented above. Indeed, the high flexibility of the processor allows the possibility to develop the application independent of the target board.

3. Description of SIFT Algorithm

The SIFT algorithm was proposed in 2004 [1], it has been used mainly in the field of computer vision for recognizing object, people and faces. This algorithm is decomposed into four parts:

- Detection of extrema in the scale space
- Precise localization of points of interest
- Assignment orientations
- Descriptor Calculation

In this article, only the first and second step of the algorithm are considered.

3.1. Detection of extrema in space scales

This step is to determine the location of the invariant point scale change through a continuous scaling function called scale space. This function was provided in 1984 [9]. In fact, it is the result of the convolution of the Gaussian function $G(x, y, \sigma)$ with an $I(x, y)$ input image:

$$L(x,y,s) = G(x,y,s) * I(x,y) \tag{1}$$

$$G(x,y,s) = \frac{1}{2ps^2}e^{-(x^2+y^2)/2} \tag{2}$$

After determining the scale space, Lowe proposed to calculate the difference of the Gaussian (DOG) to determine the points of interest invariant to scale changes. Unlike the Gaussian is calculated from the difference between two adjacent scales separated by the constant factor k.

$$D(x,y,s) = (G(x,y,s) - G(x,y,ks)) * I(x,y) \tag{3}$$

Below is a detailed demonstration of this approximation:

$$\frac{\P G}{\P s} = s \tilde{N} G^2 \tag{4}$$

then

$$\frac{\P G}{\P s} = \frac{(G(x,y,s) - G(x,y,ks))}{ks - s} \tag{5}$$

from (3) and (5):

$$G(x,y,s) - G(x,y,ks) = s(k - 1)\tilde{N} G^2 \tag{6}$$

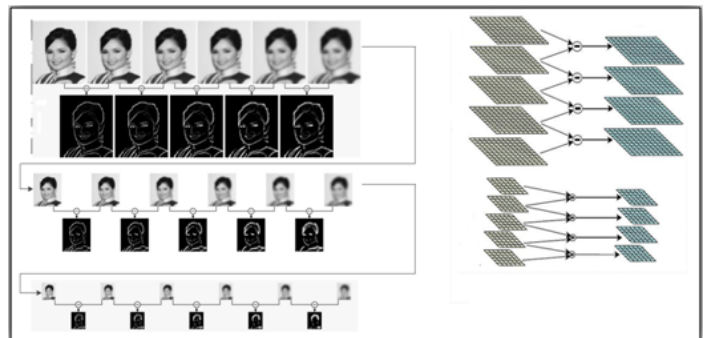
The factor *(k−1)* in the equation is a constant that affects neither the location nor the stability of the points of interest.


Figure 1: Detection of extrema in space scales: steps of forming the pyramid

The above steps will form a single octave. However, Lowe proposed to determine the point of interest within a pyramid which is a set of octaves. So, to form a new octave, it reduces the size of the original image of the previous octave and the process is repeated. Figure 1 shows the steps of forming the pyramid.

Indeed, the original image is sampled down by a factor of two, and then by a factor of four in order to form the basic image of each octave. Then, inside each octave, the initial image is convolutional   with a Gaussian is to produce all the images of the scale space. Finally, the adjacent images of the same octave are subtracted to produce difference of Gaussian (DOG).

To detect the local maxima and minima of *D(x, y, σ)*, each point is compared with its eight neighbors in the current image and the scale in its nine neighbors in the above and below scales. It will be chosen only if it is larger or smaller than all of these neighbors. Figure 2 shows a detailed explanation of this step.
Figure 2: Detection of extrema in space scales: detailed explanation

3.2. Precise localization of points of interest

The previous step has generated a set of points, some of which are unstable. For this, an elimination should be performed for low contrast points and points situated on the edges because they are unstable. To eliminate weak points of contrast, the Taylor expansion to order one of the DOG functions is performed. A point of interest is considered unstable if $D(X) < 0.03$. A point of interest that is located in the edges is removed if the primary curve along the contour of which it is positioned is greater than the curvature in the orthogonal direction. The main curve is represented by the eigenvalues of the Hessian matrix H of 2×2 sizes given by the following expression:

$$Tr(\mathbf{H}) = D_{xx} + D_{yy} = a + b \qquad (7)$$

To avoid the calculation of eigenvalues, users exploited, in general, the approach proposed by Harris and Stephens (1988). Let α is the largest eigenvalues and β the smallest:

$$Tr(\mathbf{H}) = D_{xx} + D_{yy} = a + b \qquad (8)$$

$$Det(\mathbf{H}) = D_{xx}D_{yy} - (D_{xy})^2 = ab \qquad (9)$$

Let *r* be the ratio between the two eigenvalues ($\alpha = r\beta$), using two expressions (8) and (9), then:

$$\frac{[Tr(\mathbf{H})]^2}{Det(\mathbf{H})} = \frac{(a+b)^2}{ab} = \frac{(rb+b)^2}{rb^2} = \frac{(r+1)^2}{r} \qquad (10)$$

A point is retained if it satisfies the following condition:

$$\frac{[Tr(\mathbf{H})]^2}{Det(\mathbf{H})} < \frac{(r+1)^2}{r}$$

4. Proposed Method

To implement the feature extraction part, a C code is developed which allows the creation of space DOG space and extract the features of an image of a size of 256 × 256 pixels. The code is developed in accordance with the original version of the SIFT algorithm, where there is three octaves and where each

consists of five scales. Also, a Gaussian filter with size 7 × 7 is used. This code is implemented on the FPGA cyclone that hosts the LEON3 processor.

4.1. LEON3 processor

LEON3 [10] is a 32-bit RISC processor provided as a synthesizable VHDL model on digital ASIC or FPGA circuits. The model is highly configurable. In fact, the user can set many features of LEON3 according to his needs. The LEON3 version can be used under the GPL, allowing free use for research. ASIC LEON3 versions have been developed specifically to operate ionizing medium VHDL model and a fault tolerant LEON3-FT. Figure 3 shows the architecture of the LEON3 processor which is formed by two separate and reconfigurable cache instruction and data, 7 pipeline stages, and cabled MAC unit, multipliers and dividers. LEON3 is supplied with an IP grouped together in the "GRLIB IP" library [11] which includes a set of VHDL libraries from which the cores (IP) are instantiated in a local design. The architectures provided by this library are based on the AMBA (Advanced Microcontroller Bus Architecture) bus. There are two distinct types of buses at the AMBA. The AMBA / AHB bus used for the interconnection between the IP that requires a high data throughput as the LEON3 processor, the memory controller and the JTAG. The AMBA/APB bus (AMBA Advanced Peripheral Bus) on which the units that require a low data rate as timers and UART connect. These two buses are interfaced through the AHB/APB Bridge. Furthermore, it contains several LEON3 models designated for different FPGA board. This ensures the LEON3 processor great flexibility. The GRLIB also contains a configurable design for a multiprocessor architecture based on the LEON3. LEON3 makes available to the designer tools facilitating its rapid development (e.g.; through graphical configuration utility). This prevents wasted time in an arduous and time consuming development. For embedded applications, it is fully synthesizable, and can be implemented with a number up to 16 hearts.

4.2. Development platform

NIOSII is a dedicated embedded hardware platform application. Figure 4 shows the development platform, which is formed equipped with a EP1C20400C700 FPGA. It is also equipped with a set of memory media: flash memory (8 Moctet) SRAM (1 MB) and SDRAM (16 Moctet). In addition, this kit includes a set of communication tools: JTAG, two serial communication ports. Figure 5 shows algorithm flowchart. Step 1 presents convolution product computing. Step 2 compute the difference of Gaussians DoG. Finally, step 3 is dedicated to interest point extraction.

5.   Test and verification

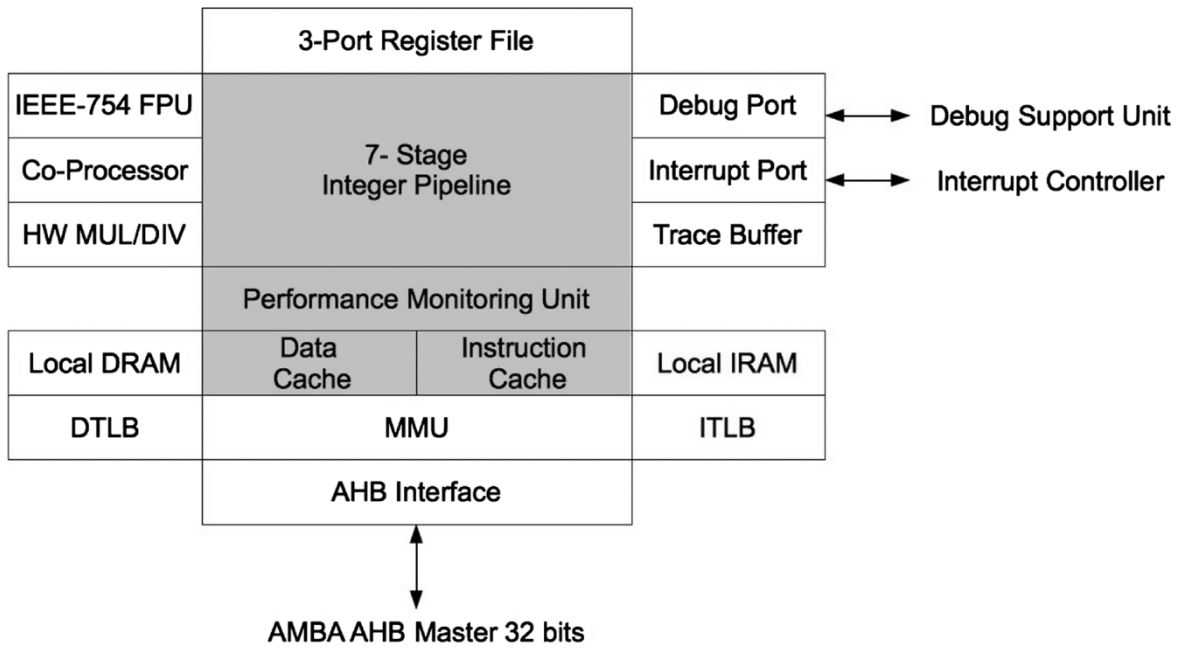
To test proposed approach, LEON3 processor should be configured ; this step can be performed either under UNIX or Windows with Cygwin. Then the VHDL code of the processor is compiled in the Altera Quartus environment and finally the transfer to the card is done using the Altera programmer. Now to transfer the code to the card and run it by the LEON3 processor the GRMON tool [12] is employed, this is a debug monitor used for debugging SoC based on the LEON3 processor. The latter supports the following debugging interfaces: UART, PCI, JTAG and Ethernet. JTAG is selected for this step.


Figure 3: Architecture of the LEON3 processor
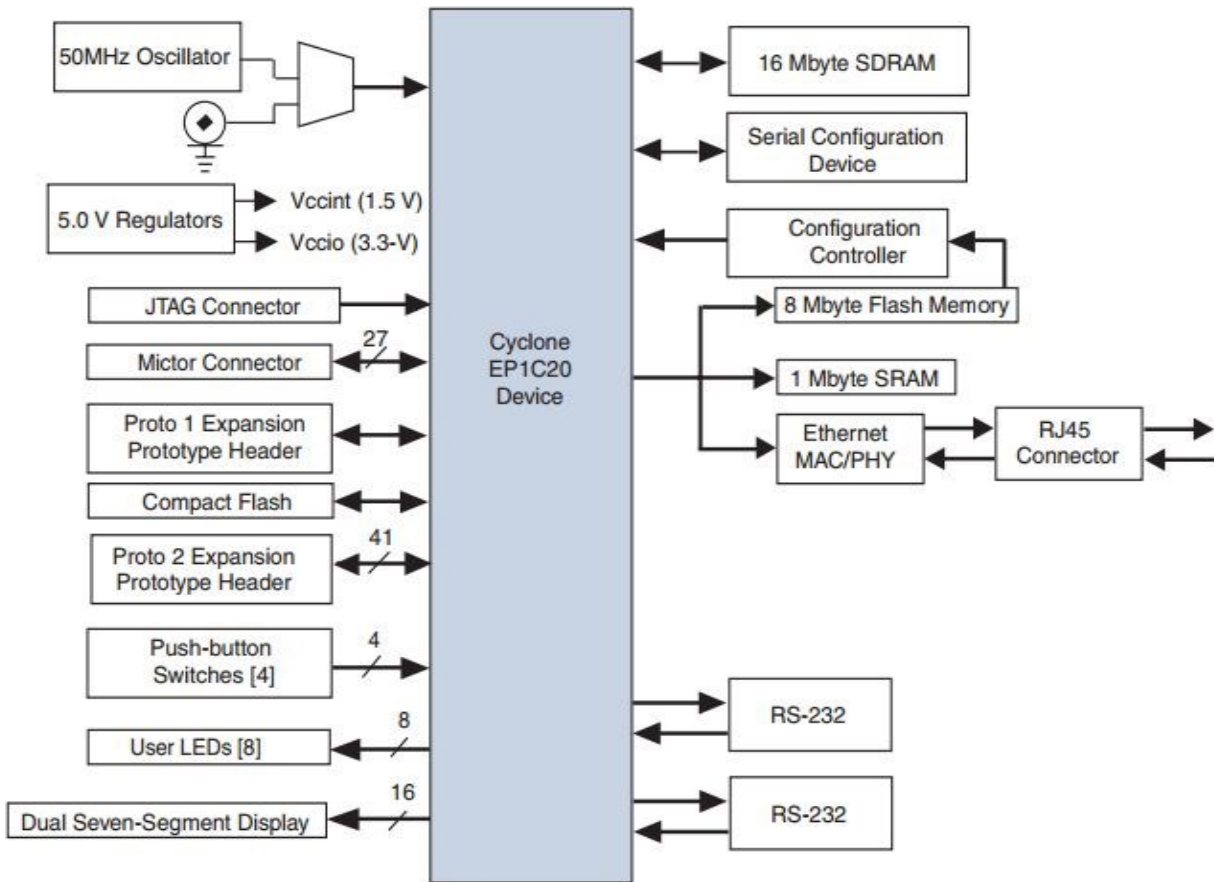

Figure 4: Development platform
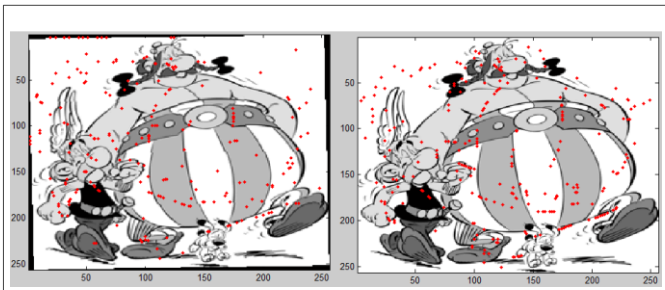
Figure 5: Algorithm flowchart
(1) Scale change 15%
(2) 256×256 vs 512×512


(3) Rotation -10°

(4) Rotation -10°

Figure 6: Experimental Results

For validation, proposed algorithm is performed on a set of images that have undergone various transformations such as: scaling, rotation, brightness and also images that are taken randomly from the internet. The test results are given in Figure 6. To judge the results; a visual inspection as well as quantitative measures are used. The objective of this evaluation is to locate points of interest on the same position at the same image that undergoes different processing. All these tests confirm that have been able to successfully implement the detection points of interest. SIFT code is running on the FPGA card reliably, but with an execution time equal to 3.06mn. To reduce the execution time, we benefit from a high configurability offered by the LEON3 processor that allows us to quickly design a multiprocessor architecture. This approach consists in subdividing the image into a set of blocks where each block will be executed by a single processor. Thus the run time is equal to the time taken by one processor to determine the points of interest at a single block. The Convolution was included. Process input was a grey level image and process output was SIFT points coordinate. Point description was not included (vector with 128 values) as like the majority of similar work. Embedded code stops at the generation of points. To validate this approach image is divided into four blocks, each of a size of 64×64 pixels. Where the execution time becomes 9s instead of 3.06 mn. It is to be mentioned that at this article we have used the FPGA Cyclone I, whereas nowadays the FPGA cards are performed in terms of frequency and the number of logical blocks programmable this card as Cyclone III, Vertex V, etc.... In fact, the use of this card increases over the size of the LEON3 processor cache hence reducing memory access time and thus decreasing the execution time. Figure 7 and Figure 8 show statistical result of the detection process as well as matching rate results. Matching rate is computed by dividing number of matched points by minimum between right and left detected points. Obtained rate allows any ego-motion model estimation using rejection sampling for example. It can be used as a recognition support as well.
Figure 7: Number of SIFT detected points
Figure 8: Matching rate

6. Conclusion

The objective in this work is to establish a detailed study of the SIFT algorithm and to propose a solution to implement it on a reconfigurable platform. This paper presented the different methods of extracting and describing points of interest, before focusing the study on the SIFT algorithm. SIFT is characterized by a very high algorithmic complexity due to the intensive use of iterative operations in order to guarantee invariance to the different types of change Rotation, scale ..., etc.

Thus, a new method was proposed based on LEON3 which has enabled us, through software programming in C language, to embed the part of extracting points of interest on an FPGA platform. Once the method is implemented, its validation will take place while being based on multiple images. The proposed approach showed very encouraging results.

In order to improve obtained results, a number of perspectives can be considered. In order to increase the size of the processor cache, FPGA boards which have a high integration capacity such as Virtex V, startixII can be used. In order to embed the FPGA platform supporting the SIFT algorithm on board a mobile robot, we propose to refine the results of the point of interest extraction step and program the description part. The main objective still to guarantee the robot's autonomous navigation (trajectory monitoring, obstacle detection, SLAM…etc.).

ARTICLE INFO

ABSTRACT

Autonomous vehicles (AVs) technology is expected to provide many benefits for the society such as providing safe transportation to the community and reducing the number of accidents on the roads. With the emergence of AVs, the conventional safety infrastructure in which humans drive their vehicles will need to be upgraded in order to take full advantage of the new technology. AVs are responsible for the different aspects of driving, namely: perception, decision making and taking action. Capturing data and diagnosing issues becomes imperative in this new transportation system because an error might be an indication of a systemic problem which may lead to future accidents or failures. Therefore, any AV accident must be dealt with seriously. Unfortunately, current procedures and the type of data collected during the investigation of an accident is not sufficient; For example, AV minor accidents are not investigated in depth as it is with AV major accidents and therefore, if the cause of the accident is a systemic issue, then it might cause more accidents in the future. The main goal of this paper is to explore the requirements for accident reports for incidents involving AVs and the procedures to escalate issues to avoid systemic risks. All the information available about AV accidents, regardless of the severity of the accident, will be analyzed and studied. This paper will present three recommendations; An updated law enforcement accident report, an escalation procedure that depends on the diagnosis of the fault and a database of AV accidents to enable ongoing learning to find systemic issues.

1 Introduction

1.1 Conventional Automobile Regulation

There is a desire everywhere to reduce the number of car accidents on our roads due to its effects on the communities and the economy. This paper is an extension of work originally presented in [1] in which we studied a number of autonomous vehicle's accidents and analyzed them in order to understand the behaviour of autonomous vehicles and to locate the root causes of these accidents. Studying traffic accidents is not new. Actually, accidents have been a concern for societies since the first recorded fatality back in 1869 [2]. There are different causes of accidents such as the weather, obstructions on the roads, mechanical problems with the vehicles, etc. However, the main causes are the drivers themselves who might be drowsy, intoxicated or over speeding [3]–[4]. Problems of traffic congestion and road accidents have increased due to the increase in the demands of vehicles [5]. Nowadays, over a million people lose their lives due to road traffic crashes world wide and these

crashes cost most countries 3% of their gross domestic product [6]. Some advanced driving assistance systems helped in improving the safety of vehicles on the roads such as Adaptive Cruise Control. The current goal that manufactures are working on now is to have fully automated vehicles on roads within the foreseeable time and this will reduce the number of accidents significantly on the roads [7]. These autonomous vehicles are in their experimental phase where they operate on the roads along with a backup (safety drivers) to take control as needed and to avoid accidents.

In order to manage automobile accidents, one must consider a number of involved parties, such as local law enforcement, insurance companies, state licensing authorities and federal authorities [1]. The driving process can be divided into three aspects: Perception, Decision Making and Action. Currently, the human driver operating a traditional vehicle is responsible of the perception as well as the decision making of the driving process. The manufacturer of the vehicle is responsible for the action aspect of the driving process. When an accident occurs, an accident report is produced by the law enforcement who are the first engagement entity in the

creation of the accident report. Law enforcement investigate the accident and includes the following information:

- Location and timing of the accident.

- Identifying information of drivers and vehicles.

- Description of the accident based on drivers, passengers, and other witnesses.

- Description of property damages and medical issues.

- Occasionally, weather conditions are included

The investigation of the accident determines the direct cause of the accident and determines which party is at fault. The fault can be related to drivers or the vehicle itself. Then the other entities, including insurance companies, lawyers and court system, would intervene to solve the financial consequences of the accident. However, if the vehicle itself is at fault then the National Highway Traffic Safety Administration (NHTSA) gets involved [8]. One of the main tasks of NHTSA is to license vehicles, offer feedback on safety of vehicles and to locate systemic vehicle issues and fix them. The Crash Investigation Sampling System (CISS) or the Office of Defects Investigation (ODI) are usually the initiators of the NHTSA investigations.

It is note worthy that the Federal Aviation Administration (FAA) has been very successful in their accident investigation methods where there is a requirement to include a flight data recorder (FDR) and a cockpit voice recorder (CVR) inside what is referred to as "a black box". Besides that, safety concerns are confidentially gathered for further analysis.

Vehicles have similar technology to the FDR, namely, the Event Data Recorder (EDR). The EDR is a device installed in a motor vehicle to record technical vehicle and occupant information for a brief period of time before, during and after a crash [9]. However, it is not required by the Federal Government to install it in all vehicles [10]. The official definition of the EDR and the minimal list of parameters that must be recorded was produced by the NHTSA in 2019. The recorded parameters include longitudinal and latitudinal speeds and accelerations, engine throttle and RPM, time, ABS activity, air bags deployment status, role angle of the vehicle, occupants position and many more which are recorded until a fraction of a second before an event or accident [11]. Furthermore, EDR technology has been voluntarily used with almost 92% of new light automobiles since 2012.

1.2 AV Accident Reports

The traditional driving system assumes that the perception and decision making aspects of the driving process are the responsibility of the human driver. However, with an AV system, the responsibility for perception and decision making is shifted to the vehicle itself. This transition from humans to AVs requires developing new procedures and laws (regulations) that can answer some of the new challenging questions such as how to determine who owns liability in case of an accident, how to license AVs, and how NHTSA can certify a fleet of AVs.

In the United States, a number of local states authorities have adopted different laws to regulate AV as a driver. For example, California's Department of Motor Vehicle (DMV) adopted regulations for testing AVs in 2014. In a followup amendment in 2018 [12], the laws requires the manufacturers to submit an AV collision report within a period 10 days of any accidents (minor or major). The report includes the following information: Manufacturer's information, cars involved (time, location of the accident, description of damage, etc.), property damage, a description of the accident, a check list that contains information about the weather, lightning, road way surface (wet, ery, etc) and road way conditions (flooded, holes, etc). Moreover, for each vehicle involved in the collision, the report contains information about movement preceding collision (stopped, backing, etc), type of collision (head-on, side swipe, etc) and associated factors (such as vision obstruction).

Besides the collision reports, every manufacturer is required to submit an annual report, by January 1st of each year, that contains all the disengagements of the AV technology during testing their AVs on California's public roads. These reports show how often the vehicles were disengaged from autonomous mode during test. The disengagements could be because of technology failures or simply because the backup driver wanted to safely operate the vehicle.

Beyond California, none of the other states provide guidance on AV accident reports.

1.3 Related Work

Different aspects related to Autonomous vehicle's accidents and safety have been studied such as Collision Avoidance [13], the ethical decision-making during crashes [14] and the Automated Vehicles Safety in Lane-Change Scenarios [15]. However, studies of real AV's crashes have been limited to collecting and analyzing AV crash data from a limited number of accident's reports [16], [17]. There is an agreement between the researchers in this field that the current AV crash reports are unstructured and sparse which results in impeding the learning and analysis work. The importance of the information in the accident reports help in capturing systemic problems that might exist even in what seems to be minor accidents.

In [1], a database was built using reports collected on 94 minor and major accidents involving AVs. The data was statistically analyzed and that helped in building a foundation for a proposed accident report that meets the AV needs. In this work, we expanded the database to include 200 accidents and the analysis has been performed on all of these accidents.

This paper focuses on suggestions and mechanisms to determine and capture the necessary data that is needed in order to capture any systemic issues. This is important in the verification of AVs where the accidents can be simulated by creating the same scenarios which led to the accidents. This is helpful to determine if the decision made by the AV involved in the accident was as expected or not. The real crash data is valuable with this regard.

This paper follows the following outline; Section 2 describes the core architecture of AV systems. The analysis of current crashes from the point-of-view of developing a safety methodology is in Section 3. Our recommendations for an improved AV ecosystem infrastructure is presented in Section 4 and finally, Section 5, offers conclusions.

2   The AV system Architecture

The key to understanding the reasons behind the accidents that involve AVs is understanding the structure of the systems that the AV is comprised of. As mentioned briefly before, the AV operates using the three standard stages of driving: Perception, Decision Making and Action. Figure 1 presents the major components of the AV system where the components are divided with respect to their contribution to each of the driving stages. When a human driver is in control of a traditional vehicles, the perception stage and decision making stage are the responsibility of the driver, while the action is performed by the vehicle. The automotive industry has over 100 years of experience in making certain that the action is performed in an optimum manner. Comparatively, the perception phase through the use of sensors is very recent. Sensing the environment is accomplished using sensors such as cameras, radar and lidar technologies. All the inputs of these components are combined with object recognition artificial intelligence engines. Perception also combines the sensory input with communication from other vehicles (V2V) and the surrounding infrastructure (V2I). The internal model of the surrounding environment of the AV is finally created by combining all these inputs.
Figure 1: Autonomous vehicle technology architecture

In the context of reports on accidents involving AV's, the gathering of sufficient amount of information is imperative so that it can be analyzed to understand what the AV perceived and the reason behind the decision it made. Looking at the architecture of AVs, when an accident occurs, several open questions arise. These include:

- Are the sensors functioning as required and as intended ?
- What is the accuracy level of the the sensor fusion/object recognition?
- Is the threat assessment and the analysis of any obstruction correct?
- Assuming perfect input, is the AV making the correct decision?
- What is the accuracy of the internal maps?
- Is the communication between the vehicle and the environment (V2I) and between the vehicle and other vehicles (V2V) understood properly?

We will now examine whether we can diagnose these issues with current information.

3   Analysis of Current Accidents

An analysis of all reported AV accidents up to the present date was carried out with the objective being to understand the needs of future accident reports regardless of the automation level at this point. These AVs are being tested on the roads and they require a safety driver while the AVs perform driving.

3.1   Data collection

After mining the public records of the Department of Motor Vehicles in California in addition to multiple sources from the press, a database of accidents involving AVs was built. The database included details in the following categories:

- Information about the road and environment

    - The location of the accident using GPS coordinates
    - Atmospheric and weather conditions
    - Types of the roads and road structure (intersections, highways, etc)

- Information about the accident

    - Description of the traffic at the time of the accident
    - Manner of accident (rear-ending, side swiped, etc)
    - Date and time of the incident
    - The speeds of the involved vehicles
    - The road speed limit
    - Severity/fatality level of accident

- Information about the AV

    - The manufacturing company operating the AV
    - Vehicles' models
    - The autonomous mode used during the incident

As faced by other researchers in this area, converting the unstructured loose textual data into formats which would enable analysis on a deeper level is vital but quite challenging. The database was populated with all the information that was available, however, the data was incomplete in many cases, specially in the cases of minor accidents. To fill in some of the missing information, such as the type of roads and number of lanes , Google Earth was used based on the location of accidents provided in the accident reports (location of an accident is given as an address or as a cross street in the report).

3.2 Detailed review of minor accidents

The earliest record we have of an accident involving an autonomous vehicle dates back to May of 2010, since then there has been many other accidents. However, getting access to up-to-date information and records of these accidents to create a database has been quite challenging. We have looked and gathered information on about 200 accidents with 189 of these accidents in the state of California. That is due to the fact that the state of California was one of the first states to put into place a law that allows the AVs to be tested on public roads and that allows police officers to write accident reports for all accidents involving AVs and make these reports available as public records. In addition, most of the manufacturers and Technology Developers are based in California and they were testing vehicles close to their facilities. In Figure 2, is a list of all manufacturers and developers we have in our database and their percentages of accidents. As anticipated, manufacturers and developers with larger fleets of AVs, such as GM Cruise and Google (Waymo), have had bigger share of accidents with 46% and 37% (combined) respectively. It is also worth noting that the number of companies investing and working in this field has increased in the last 2 years [1].
Figure 2: Percentages of crashes by AV Developers

The accident reports were not consistent, and in many cases the reports were missing many pieces of information which are necessary to truly understand what caused the accident and all the parameters that were involved.

There are many characteristics of an accident that will be much more important now that AVs are on the roads performing the perception, decision making, and the mechanics of the driving process. Characteristics such as speeds of all vehicles involved in the accident and the speed limit, as well as the road structure, just to name a few, are specially important, to be able to simulate the accidents accurately and understand the cause. Even minor accidents could be caused by a systemic error in the decision making algorithms which could cause much bigger issues later. However, many of these characteristics are either missing or not required by the current accidents report forms.

In the construction of our database, much effort and time was spent analyzing accident reports and filling in missing information. We

have found that the AV speed was unknown in 51% of the accidents, 63.5% of the accidents speed of the second elements in the crash (vehicle or object) was not listed. In 83.5% of the accidents, the speed limit for the road on which the accident happened was not recorded. Also, the type of road on which the accident occurred was not clear in 6.25% of the reports.

Figure 3, illustrates the accidents sorted by road type as listed on the accidents' reports. The majority of the accidents happened at intersections, especially at four-way intersections where 68.5% of all the crashes occurred. These accidents could be caused by a failure of the sensors or the algorithms which are supposed to gather sensor input and fuse it together in order for the AV to have an accurate model of the environment around it. Furthermore, it is worth noting that the environment at intersections is quite complex.
Figure 3: Types of roads where accidents happened

The chart in Figure 4 shows the speed ranges of vehicles (elements) involved in the crashes and the percentage of crashes that happened in these ranges. As mentioned previously, the speeds for AV and the other element or vehicle was not recorded in many reports. However, out of the ones that were recorded we observed that the majority of crashes happened at low to idling speeds. This was not surprising since the vast majority of accidents happened at intersections where the vehicles were either stopping or just starting to move from a full stop. In addition, AV testing has been limited to nice weather and low speed situations.
Figure 4: The percentage of accidents corresponding to speed range

Table 1: Accidents types and percentages and the status of the AV system.

Type of Accident	AV Mode	
	Engaged	Disengaged
Taxi Driver slapped a window	0.0%	1.3%
A vehicle backed into AV	0.0%	1.3%
A vehicle rear ended the AV	67.8%	38.0%
Angle	9.1%	7.6%
A vehicle struck the AV's rear bumper	0.0%	1.3%
AV Backed into another vehicle	0.0%	1.3%
AV rear ended another car	0.8%	2.5%
Broadside	2.5%	7.6%
Head-on	0.0%	5.1%
Hit by Pedestrian	0.8%	1.3%
Hit Object	0.8%	3.8%
Perpendicular	1.7%	3.8%
Rear end, Head on	0.0%	2.5%
Side swipe	9.1%	22.8%
A car made slight contact AV's side	0.8%	0.0%
A pedestrian struck.	0.8%	0.0%
Radar Clipped by a passing truck	0.8%	0.0%
AV Front to back of firetruck	0.8%	0.0%
Rear ended a fire truck	0.8%	0.0%
The AV crossed the red light	0.8%	0.0%
NA	2.5%	0.0%

It was surprising to find that the vast majority of AV accidents are actually humans hitting AVs (see Table 1). Furthermore, when also considering the type of accident and speeds at which the accidents happen, one may conjecture that a portion of these accidents could have happened because of a lack of understanding of the behavior of the AV. For instance, 67.8% of the crashes were involving another vehicle rear-ending the AV while it was slowing down to turn right at an intersection. The AV's are required to make a full stop before turning right when there is a red light or a stop sign while the human driver in the vehicle behind it might have predicted that the AV will just slow down and make the turn.

3.3 Major accidents

Autonomous Vehicle's major accidents with severe damage, injury or fatalities occurrence are very important to analyze. The information obtained from any accident can be used to understand the behavior (actions) of AVs under different circumstances. In [1], three fatal accidents were analyzed. These accidents took place in three different states in USA and were reported in media: Florida, California and Arizona between 2016 and 2018. Each major accident happened under different scenarios from the other ones. For instance, the autonomous vehicles were driving at different speeds ranging from 43 up to 74 mph at the time of the accident. However, we noticed one common thing between these accidents which is that the object (truck, road barrier or a pedestrian) that the AVs collided with was either stopping or moving at very low speed.

Upon analyzing these major accidents, we found out the following findings:

- Autonomous Vehicles, in some cases, were able to sense the objects in front of them few seconds before the accident but did not recognize it as a threat. For example, the software on Uber's AV system, back in 2018, initially classified the pedestrian crossing the road in front of Uber as an another vehicle moving in the same direction before reclassifying the pedestrian as a bicycle that was static.

- Some procedures for risk assessment were not appropriate including oversight of the backup drivers.

- Threat analysis is a critical in the development of AVs.

- When the autopilot is used to follow a leading car, while navigating other traffic and road curvature conditions, there is a need for continuous perception and a stable feedback system with the leading car under all conditions. If that feedback is interrupted then a back up plan should be implemented.

- Autonomous vehicles, under experimental driving, issue warnings to the human back up drivers in some situations. An action plan must be implemented when the human driver ignore these warnings. For example, in Uber accident, The National Transportation Safety Board (NTSB) determined that one of the main causes of the accident was the failure of the Uber backup driver to monitor the road.

- There is a lack of system prevention measures to prevent the possibility of misuses of technology by the drivers specially when drivers lack the understanding of the limitations of the autopilot.

- There is a need to record and take instant action when complains are received from the users of the vehicles because that could reveal a systemic problem. As an example, in California's Tesla accident, the driver had complained few times that his Model X vehicle would drift of its lane in the same location where the collision occurred while using the autopilot.

- Manufacturers should be involved in order to get an independent analysis and verification of the data associated with the vehicle's crashes. Also, the data must be standardized and retrievable. This retrieved information is extremely important to detect if an issue is an indication of a systemic risk.

In 2019, another fatal major accident took place in Florida, USA and it is discussed in this paper.

Details of Accident: On March 1, 2019, about 6:17 a.m, A fatal crash occurred when a 2018 Tesla Model 3 under-rode a truck (truck-tractor in combination with a semitrailer) which resulted in the death of the Tesla driver. This accident took place in State Highway 441 in Delray Beach, Florida. The accident happened when Tesla, driving southbound at 68 mph on a 55 mph speed limit road, came across a truck that pulled out of a private driveway on the right hand side of the road and blocked Tesla's path. The NTSB's preliminary report stated that the truck slowed down as it crossed Tesla's lane and blocked Tesla's path. The truck was trying to make a left turn into northbound lanes and Tesla's ADAS didn't execute an evasive maneuvers to stop or change direction of the car. The car came to a stop on the highway's earthen median, about 1,600 feet away [18]. Besides that, the NTSB report states that the driver of Tesla engaged the autopilot 10 seconds before the impact and that the driver's hands weren't detected on the steering wheel from less than 8 seconds to the crash. This accident reminds us of the 2016 Tesla crash that took place in Florida. Both of the accidents involved tractor-trailer trucks with similar scenarios and both resulted in the unfortunate death of the drivers. In both accidents, the autopilots were engaged.

The accident in 2016 took place when a semi-autonomous Tesla Model S70D collided with a tractor-trailer while approaching an intersection. The tractor was making a left turn across the path of the Tesla, but Tesla did not stop and crashed into the trailer [1]. Tesla was using a black and white camera and there is a possibility that the computer was believed incorrectly that the road in front of the Tesla was clear. This accident might have been avoided if a LIDAR sensor was used instead of the camera since the colors would not have mattered [19]. Also, the autopilot system was tuned to ignore more of the radar inputs at high speed in order to avoid false positives.[20].

Similarities of both accidents: Despite the time difference between the two accidents and also despite the software updates that have been applied to the autopilot (AP1 to AP2) since the first accident [21], there are major similarities between the two accidents: both of accidents involved hitting stationary truck-trailers at high speed and the semi-autonomous vehicles didn't attempt to stop. Also, both of the accidents happened in sunny and clear skies days.

These two accidents show that a safety challenge still exists with the autopilots and how they deal with stationary objects at high speeds. Correct AV's perception of the environment is critically im-

portant for safety. In the above mentioned crashes, it seems that the autopilot failed to perceive the truck-trailors as objects blocking the path of the AV. On the other hand, a false perception could also lead to dangerous accidents. For example, an AV mistakenly perceives a moving object as a stationary object. This situation could trigger the autopilot to stop the car completely and that is a dangerous action specially if the vehicle is travelling at high speed on the freeway which might cause other vehicles to rear end the AV.

These accidents highlight the need to understand the perception aspect of the AV. If the perception engine is fooled then that might lead to accidents. The communication between vehicles themselves on the road (vehicle to vehicle,V2V) and also with the infrastructure (V2I) might be necessary to avoid accidents. Also, it might be useful to use more accurate sensors such as LIDARS instead of cameras in order to reduce the risk of misconception by the vehicle.

Analysing the accident and understanding why the AV took the decision is extremely important to locate the problem and work on solving it to prevent it from happening again in the future. Therefore, the data collected from these accidents are important.

4 Recommendations on AV EcoSystem Infrastructure

The creation of an ecosystem or road environments in which AVs can operate at a higher level of efficiency requires upgrades in three major areas. This is based on analysing the accidents up to the present date and the methods by which information was gathered, as well as, the operational fundamentals of AVs. The areas in need of improvement are:

- Utilization of data from Event Data Recorders (EDRs) for vehicles and infrastructure

- Update and supplement Vehicle Accident Report

- Upgrade Fatality Analysis Reporting System (FARS) and an Automated Storage Retrieval System (ASRS) system

4.1 EDR Information

As mentioned earlier, Event Data Recorders are currently available in over 92% of vehicles on the road. However, EDRs are needed as a requirement for all AVs. Regardless of the model, an EDR collects and record the current vehicle dynamics. However, an EDR in an AV (AV-EDR) need to capture additional AV critical data. The AV critical data include raw sensor inputs, all communications (V2V and V2I), the ongoing object model of the surrounding environmental produced by the perception stage, and finally the threat annotations of the object model.

The time-based unmodified recordings of all the sensors (Camera, Lidar, Radar, etc) together with the vehicle dynamics produce the mathematical model for the AV. Using this mathematical model and information, issues or faults related to manufacturing, electromagnetic interference, or weather can be detected.

One of critical components for understanding faults of object recognition is details and accurate recording of the perceived object model and its corresponding threat annotations. The core AI sitting

at the center of the AV systems are possibly the most challenging to construct and test. If the AI system has a fundamental error, then it is likely that this error will reveal itself in other circumstance. Therefore, such errors can give rise to systemic risks beyond the current incident.

Moreover, recording all the communication between the vehicles and with the environment (V2V and V2I) information is essential to identify issues in the case where communication was planned but failed. Also, to determine if errors occurred due to the actual message contained within the communication is faulty or if communication is compromised.

Finally, AV-EDR data should be recorded locally and on the cloud in standard formats. The combination of EDR recordings for the AV and the environment form a reasonably complete package information for any accident of that is automatically collected. In the case of an accident, law enforcement at the scene should have instant access to the EDR information.

4.2 AV Police Accident Report

The current accident report procedure has been optimized to handle human related traffic accidents. However, in order to deal with this upcoming technology, the accident procedure needs to be updated in three main areas; severity, the interview with the driver, and interviews with other humans. For severity, since the human beings behaviour is well understood, current minor accidents are treated lightly. On the other hand, when an AV is involved in minor incidents it could be an indication of a systematic fault or safety issues that may cause major accident in the future. Hence, law enforcement will need to put additional focus on all accidents involving AVs even the minor accidents.

Normally, law enforcement officers interview the drivers of all vehicles involved in an accident. However, the driving AI of an AV cannot be interviewed. Therefore, police officers need to understand what the AV was "seeing" to understand the decision that was made. To understand the perception, our recommendation is pictures to be taken from the point of view of the AV. Determine if there is any significant activity that might affect the Lidar, Radar or any other sensor of the AV. For instance weather conditions, radio equipment, or power lines could have some influence on the sensors. Moreover, to understand the decision made by the AV, the officers may need to consider all activities in the surrounding environment that may deceive the AV. Examples of activities include actions made by pedestrians or small animals on the side of the road or on the road itself, as well as the actions of trucks or scooters or other vehicles that may move in way different than the AV.

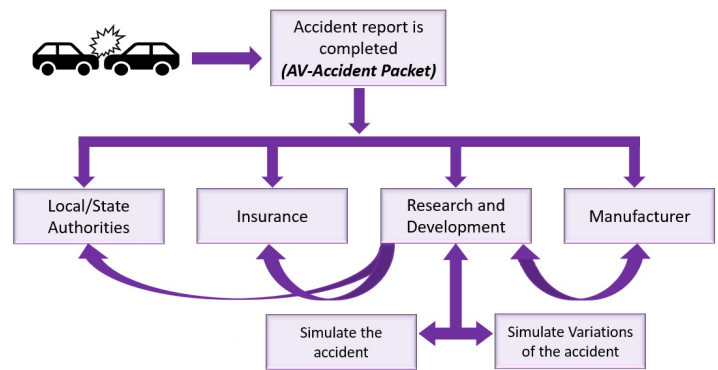
Lastly, when accidents are caused by other humans due to their perception of an AV then it is imperative to know what the AV did to communicate its intent to the other humans in the surrounding environment. If someone perceives the AV as behaving erratically then it is as dangerous as any other erratic driver. Additionally, interviewing other drivers is of particular importance in instances where the other drivers collide with an AV even if it a minor scrape or a fender bender.


Figure 5: The accident report and the information flow

4.3 Learning Flow

By including the EDR recordings of the AV and environmental parameters along with the law enforcement input in the accident report, which we will call the *AV-Accident Packet*, we can analyze and understand how an accident happened and its causes. In this manner, systemic errors can be identified early and procedures can be created to escalate the issues and find remedies for it. The most critical concerns are those caused by algorithmic issues since they would be replicated across all the vehicles sharing the same software. These types of concerns need to be determined and the issues need to have a swift escalated response. On the other hand, hardware failures such as sensors or other components are also very important and can indicate reliability issues on the long term. However, hardware issues are very unlikely to be the reason behind systemic errors. Additionally, if an accident occurs where a human driver hit an AV then it is not probable that the cause requires to be escalated immediately, although the accident should be carefully considered.

To establish an overall safety model, manufactures and other involved parties must be able to utilize all the accidents' data efficiently in the production and testing of AVs. Furthermore, a database of accidents should be built and made available to be mined for possible systemic errors that wouldn't be easily identified if the data is just considered locally.

4.4 Importance of Completed Accident reports (AV-Accident Packet)

The rate at which automotive technology is growing is very rapid. The addition of all of this technology into the vehicles has had an affect on the way traffic is understood. Finally, the introduction of AVs in normal traffic is going to continue to change traffic behaviour which requires the reassessment of the procedures used to report accidents and how the information within the report flows (see Figure 5).

The importance of the AV-Accident Packet, as defined above, includes, but not limited to, the following main points:

- Research and Development:
  - Analyzing the data to understand the causes of the accident.

– Recreate accidents by simulation using similar scenario and extend that to include variations of parameters included (actors, road types, weather, etc.)

– Expanding the database of accidents to be used for verification and validation of AV systems.

• Manufacturers and developers

– In addition to the items listed above, the makers of AVs will have the highest interest in the performance of their product.

– Provide software updates and maybe hardware replacements.

• Insurance

– Determine Liability.

– Run risk assessments to determine the cost of insurance. For example, a company with lots of AV accidents means the cost will be higher.

• Local/State Authorities

– Collect data and analyze the statistics about accidents.

– Provide policies and regulations based on accurate information.

– Organize appropriate response in case of an accident; For instance, AVs communicate with the authorities upon the occurrence of accidents and provide an initial report.

Once the AV-Accident Packets are available, accidents can then be re-created within a simulation, and this is indispensable for multiple reasons. One is to improve the process of diagnosing errors. Also, when a correct decision is achieved which would avoid the accident or at least reduce its severity, then a validation platform, such as the one discussed in [22], can be used to check the validity of decision or action. Additionally, various test cases can be derived and simulated easily to find similar issues and fix them. Hence, this approach generates an essential feedback loop in the verification of the safety of AVs.

Presently, traditional accident data is collected and used by FARS to find systemic problems. However, this database must be enlarged to keep records and follow issues for AVs. For instance the database must include parameter measuring the reliability of sensors, conditions for edge-cases causing problems in the perception or threat recognition. It is also reasonable to have a weather index similar to the heat index of boating safety index that would give a measure on the effect of extreme weather phenomenon on the AV systems.

There is still a need to learn the process of building, deploying and regulating AV systems. Therefore, there is a substantial need that all parties involved must share information and thus build a system of gathering input and data which can provide a confidential way for any source to share input in order to help insure the public does not have to face unsafe conditions.

5 Conclusion

Stakeholders will sooner or later transform the complete picture of our roads into a fully AV-controlled environment. Undoubtedly, this promises immense range of benefits including safe transportation, to our community. Because of the differences between conventional driving and AV driving, we should treat AV accidents differently. In the AV world, the risk of systematic problems exist and it is extremely important to capture these problems at an early stage. One of the methods to capture these problems and risks is by the analysis of the current AV accidents regardless of their severity. The nature of AV systems requires capturing an incredible amount of date in order to operate (perception, decision making and action). Therefore, in order to understand the cause of an accident, a prior to the accident data must be available. In this paper, we looked at the architecture of an AV system, collected data for almost 200 AV accidents and then we analyzed them in order to understand the root cause of these accidents. The accidents can be simulated by using the collected data to create similar scenarios of the accidents and that is vital in the verification and validation of AV systems.

However, with the current accident reports, some important information related to AV systems is still missing from the current accident reporting system. The current conventional automobile infrastructure must be upgraded to meet the AV needs and this paper proposes three upgrades: First, an updated law enforcement accident report that incorporates the EDR recording and sufficient details on the environment surrounding the accident. Second, a procedure for escalation which depends on the analysis of the error. Lastly, a well organized database of related AV accidents must be available to stakeholders to enable ongoing learning to find systemic issues.

A B S T R A C T

Diploma certificate and transcript forgery is a serious issue in education. The government is still finding the best way to prevent and minimize this issue in the future. The diploma certificate and transcript are very easy to duplicate, not only from third parties. Even the university can easily produce a fake diploma certification and transcript for their benefit. Blockchain technology is a new technology and now can be used to prevent the fake graduation documents. This research shows the simulation of blockchain technology used (Multichain) for data recording of academic transcript as one of the graduation documents. FGD has been carried out by inviting several reputable universities to validate the prototype. As a result, the FGD participants validated the prototype and agreed if it possible to be implemented in university, especially for recording the academic transcript data. Recording the academic transcript on blockchain technology can contribute to prevent forgery.

1. Introduction

Diploma Certification forgery is not a new issue in Indonesia. Recently, in 2020 as reported from serambinews.com, it involved a Rector Candidate from one of Higher Education in Indonesia. A diploma certificate is still important in Indonesia for several positions. It is easy for university to produce the certification without any data validation [1]. This is not a new problem in Indonesia. Since 2015, there are many cases of diploma certification forgery. Many people got in this case and public figure and people in government too [2]. The publisher of this fake graduate information can be from a third party or even a legal university.

Looking at this problem, producing a certification for people that not even come and study to the university is very easy. The information is easily manipulated, and the user only needs to enter and create the data without any validation. So, data integrity is very important, every process that happens during university study needs to be locked, approved, and validated by stakeholder inside the university. Any data is not approved cannot be processed and every data in the application is immutable and unchangeable.

If this integrity is maintained in University, the graduation document will be hard to be duplicated or be falsified. Talking about this data integrity, blockchain is a technology that sure make this happen, mainly because of the features and capabilities of blockchain such as the security, reliability, integrity, and the concept of decentralization. Founded in 2008 by a group or person called Satoshi Nakamoto, blockchain is very popular and used in many areas, not only cryptocurrency [3]. Several studies show blockchain technology can be used as technology that can prevent the graduation documents forgery [4]-[7]. Blockchain also can be combined with IoT (Internet of Things) to support the educational systems and create more interactive communication among students, teachers, employers, and other stakeholders [8]. Despite blockchain's ability and ensuring data integrity, there is still lack of research showing how this blockchain can prevent the fake diploma and academic transcript. This study simulates the process of academic transcript record using blockchain technology (multichain). This research used a qualitative method and conducted lab as a media to show the blockchain implementation on transcript data records.

This research is continuing from the previous study [9]. The previous study discussed about the process and value chain in academic transcript. The process was confirmed by all users in

Focus Group Discussion. This research will show the simulation of data recording of academic transcript in Blockchain (Multichain) after all process is done.

The structure of this paper divided into several sections. The first section is introduction, which describes the background of the study and the issue or problem discussed and solved in this research. The second section is Literature Review which discuss about the theoretical background to support this research. The third section is Methodology which explain the research design and technique used in this research. The fourth section is Result and Discussion, which describes the prototype and result of Focus Group Discussion. The last section is conclusion as the overall information, contribution, and further research.

2. Literature Review

2.1. Blockchain in Higher Education

Blockchain is the concept of a decentralized network and was first found in 2008 by a group or person named Satoshi Nakamoto [3]. It was first used for cryptocurrency and bitcoin was the first cryptocurrency and gained popularity for years by using blockchain technology. Since then, blockchain is popular and widely used. Blockchain using peer – to – peer ledger for all transaction registration. Blockchain is still categorized as a new technology but the popularity makes many other fields want to adopt blockchain, this mainly because of its capabilities such as immutable, unchangeable, data integrity and transparency. There are several studies discussed about blockchain technology and education, many application proposed such as application to issue diploma certificate, student academic transcript, and other students track record [4].

Blockchain in education field can be found critically important because of the asset is student. They need to be recognized for every track record they made during their study. Not only for the internal university, this data also used by government and company [9].

Some current applications of blockchain in education such as: Open Blockchain for Digital certificate application [10] which provide controls to student certificate for storing and keep the credential. Also support service application and Earning Application which connect between learning and earning [11].

2.2. Multichain

Multichain is a blockchain platform first introduced in [12]. Multichain is categorized as private blockchain. Multichain could solve privacy problems, and the management of user permissions by ensuring all activity and transaction inside the blockchain is only visible to the chosen users who have permission. In multichain, user will randomly generate their private key which has a mathematical public address.

Multichain can also be implemented for many blockchain technology based and successfully implemented agricultural food for food tracking, food tracing, and the lifecycle of the food production [13].

2.3. User Centered Design Method

User-Centered Design is a methodology that aims to gaining deep understanding about the user needs [14]. User Centered Design (UCD) can be done by using questionnaires, focus group discussions, interviews, paper prototyping, and so on as long as users contribute in the process [15]. UCD will engage user closely with the project in designing the solution and put the user as the center of design. This research using User Centered Design Method and several Focus Group Discussion is done for this research.

UCD contains of four phases, they are [16]:

- Phase 1 is Specify Context of Use, in this phase, observation and literature review was carried out to gather the requirements.
- Phase 2 is Specify Requirement, in this phase, after all information is gathered, Focus Group Discussion (FGD) with users is conducted to specify the requirements and make categorization based on the result in the first phase
- Phase 3 is Produce Design Solution. After knowing about the requirements, the design prototype is created in this phase and Focus Group Discussion is also conducted to show the prototype to users and gather the feedback.
- Phase 4 is Evaluate Design, this phase is the evaluation phase after the prototype is created. This evaluation will involve the user as the center of this methodology.

2.4. Simulation

Simulation is a process for conducting trials close to the actual situation and is often used because they are fast and cheap [17]. Simulation is used to ensure the information can be recorded in blockchain (Multichain).

Focus group discussion was conducted by inviting 7 universities. FGD aims to show the prototype flow simulation to the users/participants and get the feedback for future development.

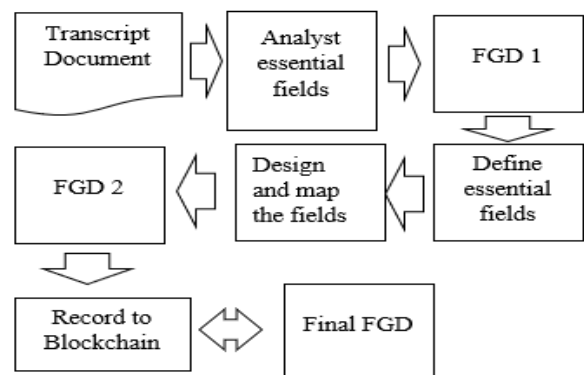
The overall process of the simulation is shown in figure 2 below:


Figure 1. Simulation Phase

- Transcript Document used for this simulation is the original transcript provided from one university, it is used to resemble the real condition
- Analyst essential fields & FGD 1, the important fields were discussed in the document transcript and FGD confirmed the results with other people who have the same interest.
- Define essential fields, at this stage a decision has been made on which fields are important in this simulation
- Design and Map the fields. At this stage the fields that have been agreed are mapped into the blockchain (Multichain)
- Record to Blockchain, at this stage all information is entry directly into the Blockchain
- Final FGD, in this process the final data or information validation is carried out in the system to ensure that the data or information stored is following user needs and has been agreed upon.

3. Methodology

This research also using User Centered Design (UCD) concept and method by exploring the user needs and requirements [14]. Using this concept, users will understand the technology and the prototype built more easily, and we will easily get what the users need the most. We conducted several Focus Group Discussion (FGD) to know more about the user needs, by inviting 7 universities and to validate and confirm the process in their universities.

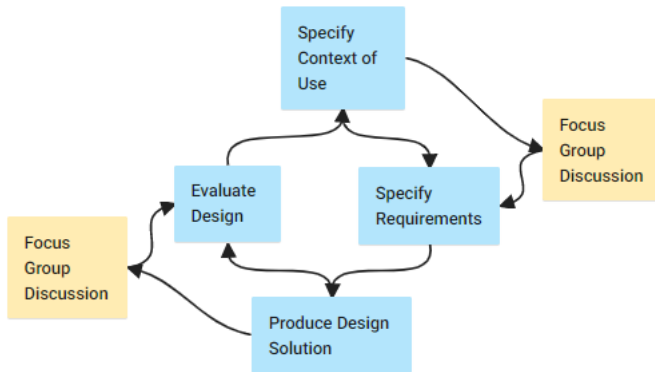
The research design and simulation steps using User Centered Design (UCD) are explained in this figure for more details:


Figure 2: Research Design & Simulation Steps

4. Result and Discussion

This research is the continue study from the previous research. The previous research discussed about the value chain and activity process in producing academic transcript [9]. This research will not discuss about the process and raw data before the data recording (smart contract process), meanwhile, the discussion is about the simulation of data record in Blockchain (Multichain).

The diploma certificate also recorded in this multichain of blockchain from previous research [3]. Diploma certificate is defined as the asset in Blockchain (Multichain) and this research

will discuss another asset of graduation document, which is academic transcript.

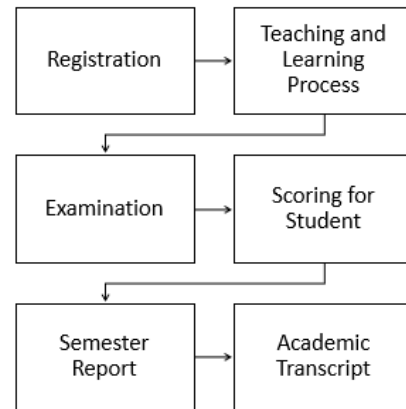
To highlight the business process of how academic transcript is created will be described on figure 3 [9]:


Figure 3: Process of Academic Transcript

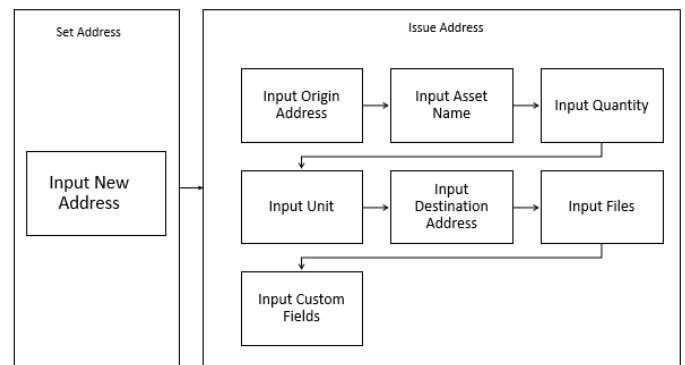
To highlight the application process, can be seen on figure 4:


Figure 4. System Process

The more detail explanation of each component will be described below.

Figure 5: Node

4.1. Node and Address

Just review about the Node and Address in the Blockchain (Multichain), the node is one private blockchain and many

addresses can be created in this node. Every address can have several assets, example: diploma certificate, academic transcript, achievement certificate, etc.

The configuration for this simulation using Node name "chain1", version 1.0.9, protocol 10011, node address represents the entity (university, student). The more detail is shown on figure 5. As presented in Figure 5, it is the node used in the blockchain.

Exhibit at Figure 6, presenting the example of address in blockchain node, this address could be represented the university or students.

Figure 6: Address in Blockchain

Once the address is recorded on the blockchain, the user can create asset for each address. The Asset for example diploma certificate, academic transcript, etc.

Exhibit at Figure 7 and 8, show the process of data entry for academic transcript.

In this simulation (using as-is Multichain), to process the data record into Blockchain (Multichain), the academic transcript data is divided into two assets. The first asset describes the student general information, and the second asset describe about the detail grade and course information. The figure 4 and 5 show the input process.

This simulation is done manually for easy process understanding. The first step, user need to ensure the first entity (From Address) is the university, then create the asset name (ex: TranscriptSeri1). User also need to determine the quantity and unit of the Asset. Then choose the address (to Address which represent student). The field can be seen on Figure 7. The first transcript named TranskripSeri1

Figure 7 (a): Issue Asset TranscriptSeri1 Part 1

User then need to fill out the fields as the important parameter on the academic transcript. For more detail information of the

fields to be entry. It exhibits in figure 7b. The data is presented in Indonesian Language as real data.

Figure 7 (b): Issue Asset TranscriptSeri1 Part 2

Figure 8 (a): Issue Asset TranscriptSeri2 Part 1

Figure 8b: Issue Asset TranscriptSeri2 Part 2

Based on FGD Result, some fields are important in Academic Transcript. The fields are then filled to the blockchain as exhibit in figure 5b, all fields on figure 7b presented in Indonesian Language as the real simulation:

- Paper No (No_Surat)
- Name (Nama)

- Student ID (NIM)
- Date of Birth (Tempat Tgl Lahir)
- Faculty (Fakultas)
- Study Program (Prodi)
- Program (Program)

Figure 11: Example of Real (Current) Printed Academic Transcript
The data on the picture was blurred for confidential purpose

The simulation and the result are presented to the FGD participant on November 5th and 12th 2020. Several feedbacks from FGD regarding to the issue of security, training for university users, and the data synchronization with government. The participants of FGD are from Binus University, Indonesia Open University, Darma Persada University, Pelita Harapan University, Kalbis University, STP Trisakti, and Universitas Negeri Jakarta with all total of 17 participants.

5. Conclusion

Blockchain in education is quite popular recently. Blockchain in education can be used to validate the data records and asset for students such as diploma certificate and academic transcript. This paper simulates the application prototype for recording Academic Transcript Data to prevent the forgery as many cases happen because of fake diploma dan academic transcript. Using blockchain technology will ensure the data integrity. The Focus Group Discussion gives positive results. All participants agree and approved the application. The users also think it is appliable to their university, but another improvement needs to be made regarding data standardization and infrastructure. Based on the simulation, Blockchain (Multichain) is possible to be implemented in University for Academic Transcript record.

The limitation of this research is because this is still in very initial stage of development, this prototype simulation is using Multichain with no modification and only implemented with one node so there is no backup if any error or crash happened. Next project will improve this research.

Conflict of Interest

The authors declare no conflict of interest.

Fault Diagnosis and Noise Robustness Comparison of Rotating Machinery using CWT and CNN

Byeongwoo Kim[*], Jongkyu Lee

Department of Electrical, Electronic and Computer Engineering University of Ulsan, Ulsan, KS016, South Korea

A B S T R A C T

For systems using rotating machinery, diagnosing the faults of the rotating machinery is critical for system maintenance. Recently, a machine learning algorithm has been employed as one of the methods for diagnosing the faults of rotating machinery. This algorithm has an advantage of automatically classifying faults without an expert knowledge. However, despite a good training performance of the deep learning model, there remains a challenge of performance degradation arising from noise when the model is applied in a real environment. In this study, to solve this problem, we identified the faults of a rotating machinery after applying the continuous wavelet transform (CWT) and then we extracted the images for detecting the faults of rotating machinery and apply y them to the convolution neural network (CNN). Subsequently, we compared it with a commonly used artificial neural network technique according to load and noise. When we added the white noise from 1dB to 20dB to vibration signal, the proposed method converged to 100% accuracy from 8dB at no load, at 10dB at presence of load. we verified that the proposed method improved the performance in diagnosing the faults of rotating machinery.

1. Introduction

With the development of industry and technology, various industrial rotating machines have become capable of handling high speeds and heavy loads, which cause massive mechanical and thermal loads, resulting in their breakdown [1]. When a rotating machine fails, fault diagnosis is very important as time and economic loss can occur. Therefore, a countermeasure is required to check the condition of rotating machines and to diagnose faults. According to statistical data, 45%–55% of failures in rotating machines are due to faults in the bearings [2]. Monitoring the condition of the rotating machine to detect its faults helps reduce losses [3]-[5].

Machine learning algorithm is a common method of diagnosing faults of rotating machines.

In general, the fault diagnosis method of rotating machines using a machine learning algorithm is divided into four steps: (1) data acquisition, (2) feature extraction, (3) machine learning algorithm training (neural network training), and (4) classification [6]-[9].

The data acquisition step is the process of obtaining a signal that indicates the state of a rotating machine using a sensor. A noise-measuring device, the electric current signals of the motor, and vibration signals are used to obtain signs that indicate the state of the rotating machine [10]-[12]. Among them, the commonly used method detects the fault of the rotating machine by obtaining vibration signal data that are the easiest to measure and can clearly indicate the state of the rotating machine [13].

In the feature extraction step, signs that indicate the state of the rotating machine are extracted from the vibration signals. In general, a signal measured from the rotating machine consists of a mixture of noise and a sign indicating the state of the rotating machine. If vibration signals containing noise are used as input values in the machine learning algorithm, it is difficult to accurately diagnose the state of the rotating machine due to the noise. Hence, noise should be removed from the vibration signals through feature extraction to use them as input values for the machine learning model.

The most common feature extraction methods use filters and signal decomposition [14]-[16]. The widely used methods of diagnosing faults in vibration signals include empirical mode decomposition (EMD) technique, which uses intrinsic mode function (IMF) to decompose the signals, and wavelet transform method, which uses the wavelet function to decompose the signals.

The EMD technique yields outstanding performance when detecting faults of rotating machines [17]. However, it requires to

combine sub-band signals because the sub-bands decomposed by IMF are generally not orthogonal to each other [18].

The wavelet transform method has the advantage of adjusting the cycle and amplitude to show the features more clearly in the vibration signals of rotating machine and to remove the noise included in the vibration signals [19], [20].

In the machine learning algorithm training step, the algorithm is trained by using the features extracted from the vibration signals as input values for the machine learning algorithm. Among the various machine learning algorithms, the algorithms using deep learning show better performance, and among the deep learning algorithms, convolution neural network (CNN) shows superior performance.

In the classification step, the test data, which are not used in the training step, are used to classify the state of the rotating machine, and the indicator showing the performance of the model can be derived.

Eren used CNN to diagnose faults of rotating machines but diagnosed their faults based solely on the performance of the CNN model without considering the method of removing the noises [21]. Meanwhile, Yuan used discrete wavelet transform and CNN to improve the performance of the existing rotating machine fault diagnosis model. However, there was a limitation in showing the suitable performance in a poor environment where noise can be measured substantially because the experiment was conducted without reflecting noise [22].

In this study, we used continuous wavelet transform method, to decompose vibration signals into noise, and signals indicating the state of the rotating machine to detect its faults, and extracted signals that can be used to detect the faults of the rotating machine, from the decomposed signals. The extracted features were used as input values of CNN, a deep-learning technique, to classify the faulty state of the rotating machine. Furthermore, we added white Gaussian noise to investigate the effectiveness of the corresponding algorithm through performance comparison between the model and conventional machine learning methods in a poor environment where a large amount of noise can be observed.

2. Theory

2.1. Continuous wavelet transform

The advantage of the wavelet transform method is that the wavelet function with dynamic resolution can be used to efficiently analyze the vibration signals, unlike Fourier transform, which cannot accurately display the characteristics of non-cyclic signals due to the fixed resolution [23][24]. The time series analysis using the wavelet transform is defined as follows.

$$\psi_{s,\tau}(t) = \frac{1}{\sqrt{s}}\psi(\frac{t-\tau}{s}) \tag{1}$$

In Eq. (1), the signal is decomposed by shifting the wavelet function to the time axis by τ and scaling by a. If the mother wavelet is given, then continuous wavelet transform (CWT) of the signal f(t) is defined by Eq. (2).

$$W(s,\tau) = \int_{-\infty}^{+\infty} f(t)\frac{1}{\sqrt{s}}\psi^*(\frac{t-\tau}{s})dt \tag{2}$$

The wavelet coefficient obtained in Eq. (2) indicates the similarity between f(t) and $\psi(t)$. The wavelet transform produces the decomposition of the time scale of f(t), but the time-frequency region can be obtained by the pseudo-frequencies.

The relationship between the scale and the pseudo-frequencies changes depending on the center of the wavelet function, performance of the scale, and sampling cycle and maximizes the spectrum of the wavelet function with the given scale. The relationship of these parameters is expressed by Eq. (3).

$$f_s = \frac{f_c}{s \cdot \Delta} \tag{3}$$

In Eq. (3), f_c denotes the center frequency, Δ is the sampling cycle, and f_s shows the result of the pseudo-frequency. The entire signal is synthesized by applying the inverse continuous wavelet transform (ICWT) defined in Eq. (4) as follows:

$$f(t) = \frac{1}{C_\psi}\int_{-\infty}^{+\infty}\int_{-\infty}^{+\infty} W(s,\tau)\psi_{s,\tau}(t)\frac{dsd\tau}{s^2} \tag{4}$$

here, C_ψ is the acceptance constant obtained when the mother wavelet satisfies all requirements.

2.2. Convolutional Neural Network

CNN was inspired by the principle of recognizing objects in the visual cortex of the brain and was derived from the field of deep learning. It consists of convolutional layer, pooling layer, and fully connected layer [25].

The main function of a convolutional layer is to obtain a feature map through the convolutional operation of filter for the input. The convolutional layer typically consists of learnable kernel and bias. The size of the kernel corresponds to the size of the filter, and the depth of the kernel corresponds to the number of channels in the feature map. The input of the convolutional layer can be calculated by the weight and the inner product of cognitive region, as expressed by Eq. (5).

$$y_{l,j}^{conv} = \sum_{i=1}^{k} w_{i,j}^l * y_{l-1}^{pool} + b_j^l \tag{5}$$

In Eq. (5), $y_{l,j}^{conv}$ refers to the convolutional value of ith channel in the convolutional layer l, y_{l-1}^{pool} refers to the ith output of the pooling layer l-1, $w_{i,j}^l$ refers to the kernel of the convolutional layer l, b_j^l refers to the bias of the jth channel in the convolutional layer l, and * refers to the convolutional operation.

After the convolutional operation is completed, the value of convolutional layer is calculated according to the activation function. The role of the activation function is to perform the nonlinear projection for the input of the neuron. Rectified linear unit (ReLU), one of activation functions, is used for pattern recognition. The ReLU function shows excellent performance in accelerating convergence and solving vanishing gradient problems. Therefore, the ReLU is used as the activation function of a convolutional layer, and the output of convolutional layer 1 can be expressed by Eq. (6).

$$y_{l,j}^{ReLU} = f(y_{l,j}^{conv}) = \max[0, y_{l,j}^{conv}] \tag{6}$$

Here, $y_{l,j}^{ReLU}$ represents the output of the jth channel in the convolutional layer l, and $f(\cdot)$ refers to the activation function.

After the convolutional layer operation, the pooling layer is used to extract additional features. It plays a role of reducing the dimensions of the output of the previous layer. Therefore, the key purpose of this layer is to reduce the volume of data to reduce the computation time on the computer. Types of pooling layer include max pooling, average pooling, logarithmic pooling, and weight pooling.

Max pooling is used to classify operation because it can speed up the convergence and improve the generalization. Max pooling function can be expressed by Eq. (7).

$$y_{l,j}^{pool} = \max\left(w(s_1, s_2) \cap y_{l-1,j}^{ReLU}\right) \qquad (7)$$

$w(s_1, s_2)$ represents the window of the pooling layer that can shift to a certain step, and s_1 and s_2 correspond to the dimensions of the pooling layer. Further, $y_{l-1,j}^{ReLU}$ refers to the output of jth channel in the convolutional layer, and $\cap$ refers to the overlap between the pooling layer and the channel's output.

In general, the CNN model contains multiple convolutional and pooling layers and extracts feature maps sequentially. The extracted feature map is transformed into a vector, which is used as an input of a fully connected layer. The main function of the fully connected layer is to extract additional features and connect the output step to the softmax classifier. A fully connected layer usually consists of 2 or 3 hidden layers, and all neurons of a hidden layer can be shown by Eq. (8).

$$y = \sigma\left(\left(w_f\right)^T s_m + b_f\right) \qquad (8)$$

w_f refers to the weight matrix of the fully connected layer, b_f represents the bias, and $\sigma(\cdot)$ represents the activation function of the fully connected function.

2.3. Batch normalization

In general, as the depth of the neural network structure increases, the distribution of features changes, and the overall distribution gradually approaches both ends of the nonlinear function value interval. This phenomenon is called gradient diffusion, which causes a problem with the convergence of the model. To resolve this problem, the Google DeepMind team proposed batch normalization technique in 2014 [26].

The key purpose of the batch normalization technique is to revert the distribution of all neurons to the standard normal distribution through a specific normalization method. Batch normalization can re-parameterize almost all neural networks and, thus, can be used for any hidden layer. Batch normalization, which optimizes neural networks, can improve the performance of neural networks, such as faster convergence, faster learning time, ability to allow higher learning rate, and easier initialization of weights.

First, normalization can make each scalar feature with the mean 0 and the unit variance, as expressed in Eq. (9).

$$\hat{x} = (x_i - E[x_i])/\sqrt{Var[x_i]} \qquad (9)$$

However, if Eq. (9) is used to directly normalize the features of a certain layer, the learned features can be affected, thereby reducing the performance of the neural network. To overcome this problem, each normalized x_i is modified based on two adjustment parameters, γ_i and β_i, aiming at scaling and shifting the normalized values. This process can be expressed by Eq. (10).

$$f_i = \gamma_i \hat{x} + \beta_i \qquad (10)$$

here, γ_i and β_i are parameters that can be used to learn the method of recovering the characteristic distribution of the existing neural network. By setting $\gamma_i = \sqrt{Var[x_i]}$ and $\beta_i = E[x_i]$, the existing activation can be restored. In this case, the activation values are stably distributed during learning.

Second, because the mini-batch technique is used in training process, the specific activation x_i that possesses the B value in the mini-batch is $\varphi = \{x_{1\dots B}\}$, and the corresponding transformation is $y_{1\dots B}$. Therefore, the batch normalization transform $BN_{\gamma,\beta}: X_{1\dots B} \rightarrow y_{1\dots B}$ can be represented by Eqs. (11), (12), (13), and (14).

$$E[X_\varphi] = \frac{1}{B}\sum_{p=1}^{B} x_p \qquad (11)$$

$$Var[x_\varphi] = \frac{1}{B}\sum_{p=1}^{B}(x_p - E[x_\varphi])^2 \qquad (12)$$

$$\widehat{x_p} = (x_p - E[x_\varphi])/\sqrt{Var[x_\varphi] + \varepsilon} \qquad (13)$$

$$\widehat{y_p} = \gamma\widehat{x_p} + \beta \qquad (14)$$

here, ε is a constant and is used to avoid undefined gradient values.

3. Experiment setup

This study required constructing a variety of dataset to enhance the accuracy of the fault detection of the rotating machine. Thus, we utilized the Case Western Reserve University Bearing Fault Database, which is widely used for fault detection of conventional rotating machines [27]. Because various researchers have conducted experiments using this database, there are several advantages: the data are reliable, and the performance comparison can be conducted with other learning algorithms. As shown in Figure 2, the test bench consists of a motor on the left, a torque transducer/encoder on the center, and a dynamometer on the right.

The vibration signals were measured in a total of four types: normal, ball fault, inner race fault, and outer race fault. The levels of crack consisted of 0.007, 0.014, and 0.021 inch, and the levels of load consisted of 0 HP, 1 HP, 2 HP, and 3 HP.

Figure 1 shows the fault detection process of rotating machine using vibration signals. Data having cracks of 0.007 inch were used, and the dataset was classified into Case 1 (0 HP), Case 2 (1 HP), Case 3 (2 HP), and Case 4 (3 HP), depending on the level of load. Each case consisted of 4,368 data: 1,092 for normal data, 1,092 for ball faults, 1,092 for inner race faults, and 1,092 for outer race faults. In addition, white Gaussian noise was increased in the vibration signals having cracks of 0.007 inch to verify the robustness to noise by CWT. As shown in Figure 3, the sample

data were constructed to train the CNN model by performing the segmentation with 4,392 signals where white Gaussian noise was added in the actual vibration signals. For each sample data, continuous wavelet functions, such as morse, morlet, and bump wavelet, were applied, and CWT was used. The conversion to images with the size of 224 × 224 was performed to use them as inputs of CNN after signal preprocessing, as shown in Figure 2.
Figure 1: Experiment setup

The CNN was constructed with 8 3 × 3 filters for the first layer of the CNN model, 16 3 × 3 filters for the second layer, and 32 3 × 3 filters for the third layer. Additional features were extracted through the fully connected layer, and the faults of rotating machine were classified using the softmax classifier. After the convolutional operation was completed in each layer, batch normalization and max pooling, a type of pooling layer, were applied.

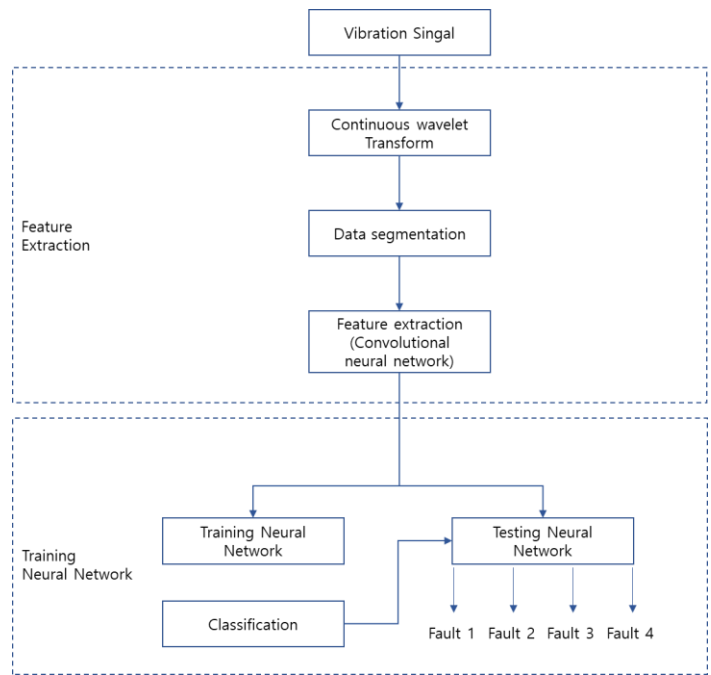
To conduct the training of the constructed CNN model, 70% of 4,368 data in the entire dataset were used for the training process of the CNN model, and the rest were used to validate the trained CNN model. To validate the performance of the trained model, comparative analysis was performed with the DNN technique, a conventional vibration signal analysis method using artificial neural network (ANN).


Figure 2: Representation of proposed fault diagnosis structure

4. Simulation

As shown in Fig 3, CWT was performed through the continuous wavelet functions—namely, morse, morlet, and bump wavelet—using the white Gaussian noise-added vibration signals, and the results were used as input values of the CNN model.

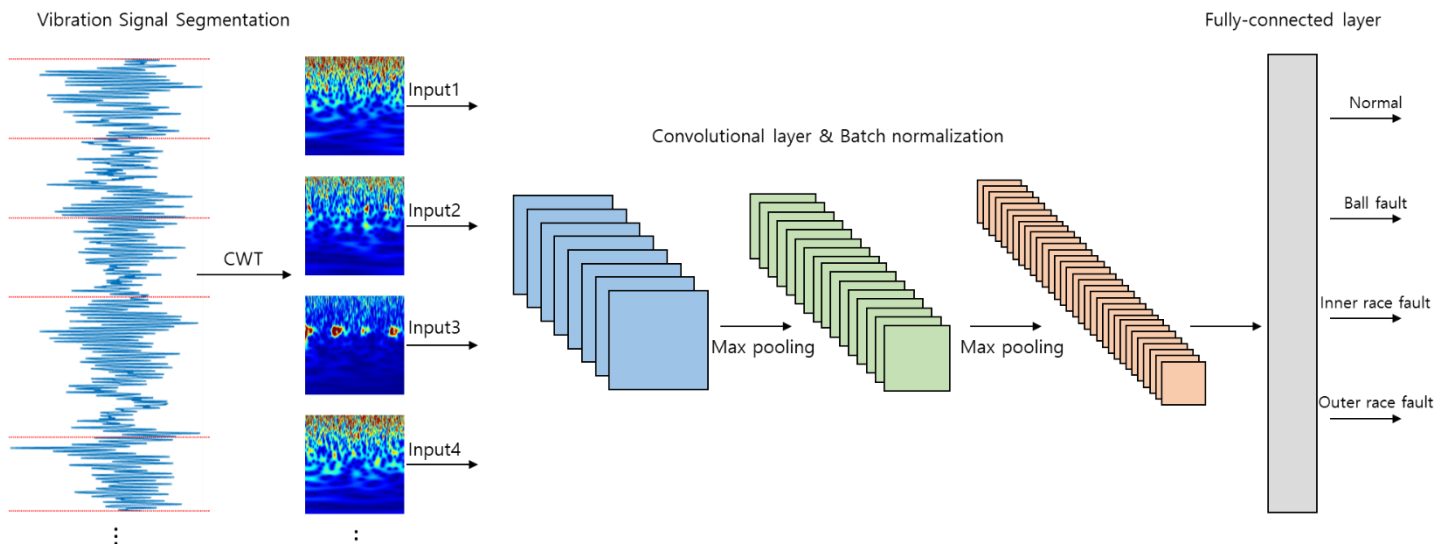
To compare the performance of the generated CNN model, comparative analysis was performed using the ANN model by extracting statistical parameters, such as peak, entropy, skewness, kurtosis, variance, and rms, and using them as the input values of the ANN, as shown in Figure 4.


Figure 3: The process of fault diagnosis in vibration signal using CWT & CNN.
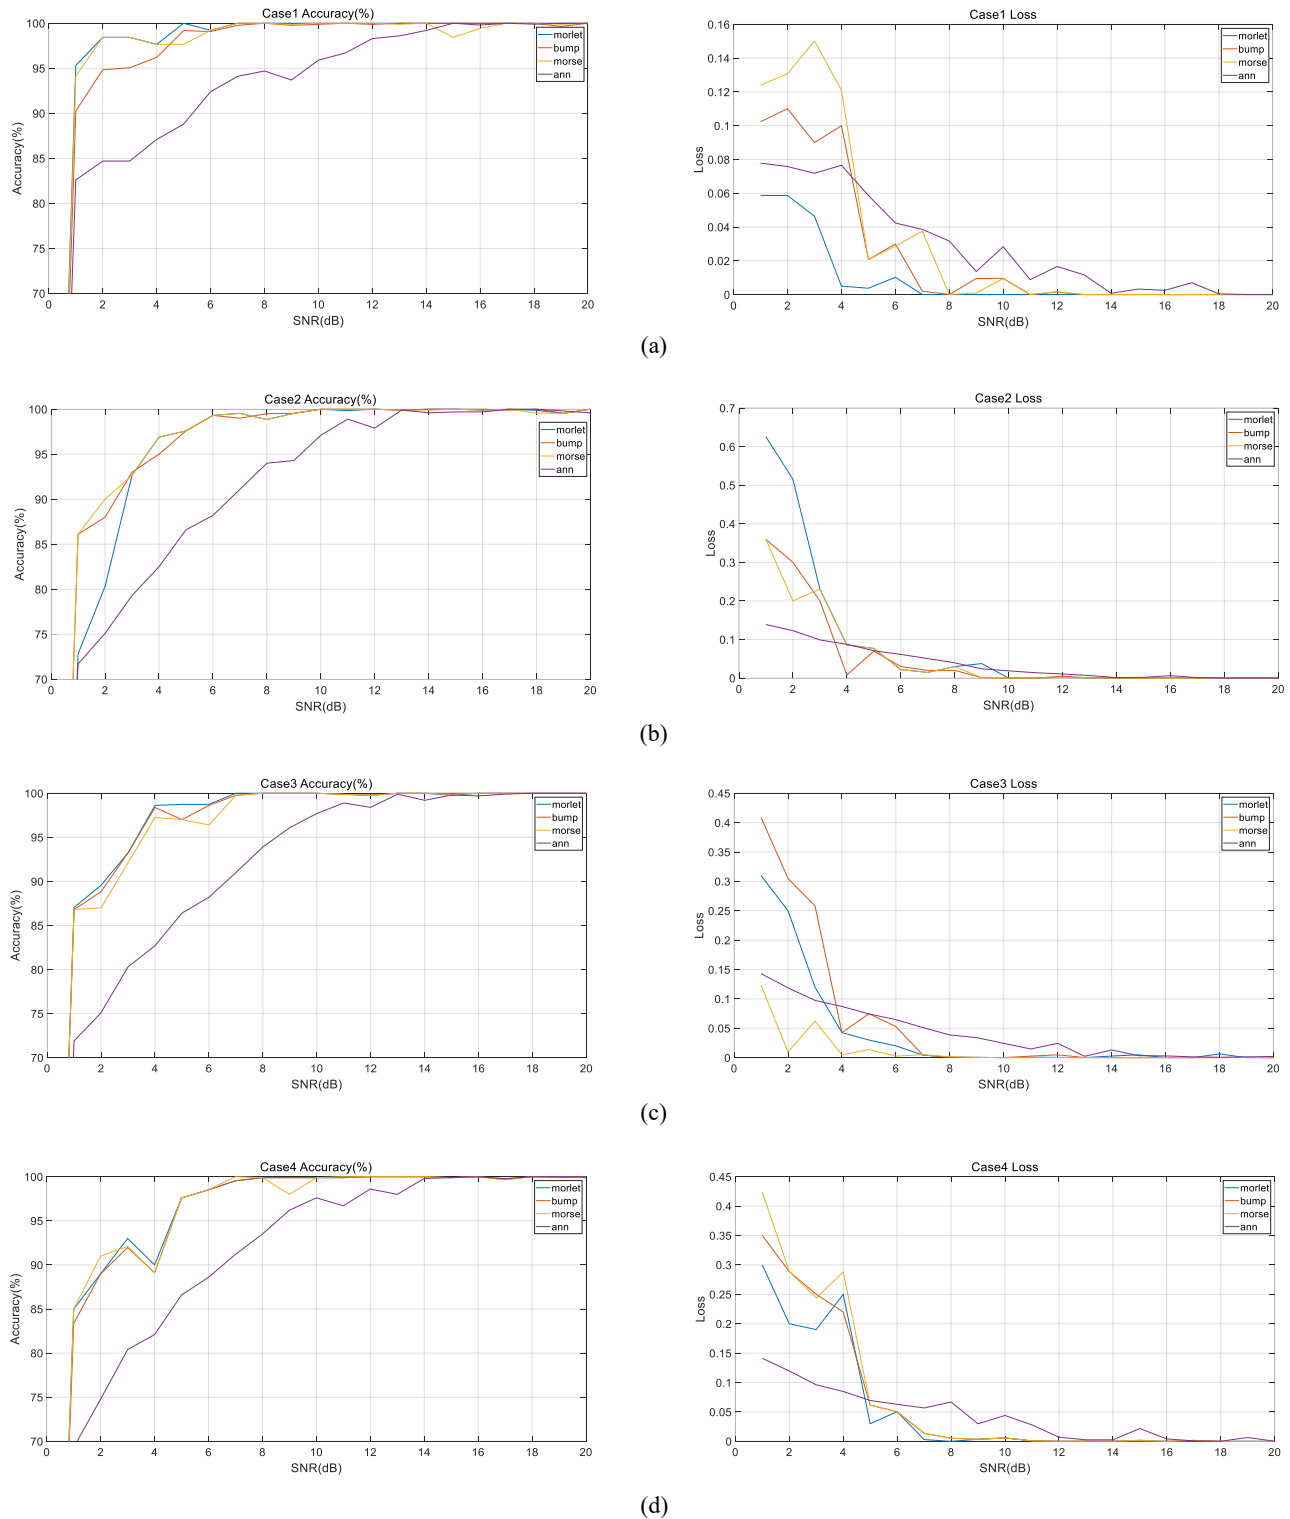

Figure 4: Result of fault diagnosis (accuracy & loss) – (a) Case1(=0HP), (b) Case2(=1HP), (c) Case3(=2HP), (d) Case4(=3HP)

To compare the performance of the CNN model and the CWT for noise removal, we compared the accuracy and loss for each signal-to-noise ratio (SNR) level with those of the existing method, in which the parameters are extracted from the vibration signals and then used as inputs of the ANN, as shown in Figure 4.

When the SNR was 1 dB in the Case 1 (0 HP) dataset, the accuracy of the CNN model using morlet wavelet was 95.31% with a loss of 0.05869, that of the CNN model using bump wavelet was 90.25% with a loss of 0.11, and that of CNN model using morse wavelet was 90.13% with a loss of 0.124. Therefore, the performance was excellent compared to that of the ANN model.

Furthermore, when the SNR level was reduced step by step, the CNN model using CWT showed that the accuracy converged to 100% at the SNR level of 8 dB, whereas the ANN model showed that the accuracy converged to 100% when the SNR level was 15 because of performance degradation in the denoising function.

In terms of loss, the CNN model using CWT showed the convergence close to 0 when the SNR level was 11 dB. However, the model using the ANN showed the convergence to 0 when the SNR level was 18 dB, indicating that the performance was lower than that of the CNN model.

When SNR was 1 dB in the Case2 (1 HP) dataset, the accuracy of the CNN model using morlet wavelet was 72.82% with a loss of 0.6254, that of the CNN model using bump wavelet was 86.12% with a loss of 0.3602, and that of the CNN model using morse wavelet was 86.09% with a loss of 0.3597. The differences were not large compared to those of the ANN model (accuracy: 71.7% and loss: 0.1388). When the SNR level was reduced, the accuracy converged to 100% at the SNR level of 10 dB in the CNN model using CWT. Conversely, the accuracy converged to 100% when the SNR level became 14 dB in the ANN model. Furthermore, in terms of loss, the CNN model using CWT showed the convergence to 0 when the SNR level was 10 dB, whereas the ANN model showed the convergence to 0 when the SNR level was 14 dB.

When the SNR level was 1 dB in the Case 3 (2 HP) dataset, the accuracy of the CNN model using morlet wavelet was 87.04% with a loss of 0.31, that of the CNN model using bump wavelet was 86.72% with a loss of 0.409, and that of the CNN model using morse wavelet 86.61% with a loss of 0.1232. Therefore, the performance was excellent compared to that of the ANN model (accuracy: 71.9% and loss: 0.1432).

When the SNR level was 1 dB in the Case 4 (3 HP) dataset, the accuracy of the CNN model using morlet wavelet was 85.13% with a loss of 0.2947, that of the CNN model using bump wavelet was 83.37% with a loss of 0.34924, and that of the CNN model using morse wavelet was 85.03% with a loss of 0.4238. Meanwhile, the accuracy and loss of the ANN model were 69.3% and 0.1431, respectively. As the noise signal decreased, the CNN model using CWT showed that the accuracy and the loss converged to 100% and 0, respectively, when the SNR level was 10 dB. However, the ANN model showed that the accuracy converged to 100% when the SNR level was 14 dB, and the loss converged to 0 when the SNR level was 16 dB. Based on these results of the vibration signal analysis, we have confirmed that the CNN model using CWT is more robust to noise than the existing method. Furthermore, we used the pooling layer and batch normalization to reduce the training time of the CNN model and improve the performance, thereby confirming the effectiveness and stability of the method, in comparison with the conventional signal analysis method.

5. Conclusion

In this study, vibration signal analysis was conducted to diagnose faults of rotating machines. Furthermore, to investigate the performance in actual work site environment, we conducted vibration signal analysis. Hence, we added white Gaussian noise in the vibration signals step by step and applied CWT. Subsequently, we extracted the images to use them as input values of the CNN. When we added the white noise from 1dB to 20dB

to vibration signal, the proposed method converged to 100% accuracy from 8dB at no load, at 10dB at presence of load. The analysis results confirmed that CWT-applied CNN model showed superior performance compared to the existing signal analysis method.

Recently, numerous scholars have suggested fuzzy time series (FTS) models to forecast many different fields. One of the vital issues for high accurate forecasting in FTS model is method of partitioning in Universe of discourse (UoD). In this research, we propose a novel FTS model, which is established by using hedge algebra (HA) and particle swarm optimization (PSO) for forecasting the different problems. In this model, HA is considered an algebraic structure for partitioning the UoD into unequal - size intervals based on optimal parameters which is determined by PSO. After making the intervals with unequal - length, the data values of times series on each interval are symbolized by fuzzy sets and then, these fuzzy sets are utilized to make fuzzy relation groups. Lastly, we keep using the PSO to adjust the size of each interval with view to reaching the better accurate prediction rate. The effectiveness of the proposed method is demonstrated on two datasets which are often applied in many studies in literature as enrolments data of the University of Alabama and Car road accident data in Belgium. The obtained results show that the proposed model produces higher accuracy forecasting when compared with the some of the recent FTS prediction models for all orders of model.

1. Introduction

The time series forecasting problem is an attractive and vital research issue. This forecasting problem has been often handled by using a variety of methods like mathematical statistics, artificial neural networks, etc. The downsides of the traditional time series forecasting models are that they extensively dependent on historical data or require having the linearity assumption and cannot solve prediction problems in which the values of time series are linguistic terms. To overcome these difficulties, the authors in [1, 2] first produced the concepts of FTS, which have the ability to deal with vague and incomplete data sets by utilizing the fuzzy set theory [3]. They have proposed the two FTS forecasting models to implement on university enrolments of Alabama with a forecasting schema consisting of main five steps: (1) defining UoD, (2) Partitioning of the UoD into intervals, (3) determining the fuzzy sets and fuzzifying the time series, (4) Establishing fuzzy logical relationship, and (5) forecasting and defuzzifying the forecasting values.

However, their approaches take a lot of time to build forecasting model because of using the complex max– min operations in fuzzy relationship matrix and lack of persuasiveness in partitioning the UoD. These limitations led research [3] to develop a new FTS forecasting model using simple arithmetic operations to replace the complex matrix operations [1, 2] in the determination of fuzzy relationship matrix and defuzzification output values. In addition, research works [5, 6] found out the importance of assigning weights to deal with the issue of recurrent fuzzy relationship and to reflect the difference in their importance. Expansion of the framework [3] into a high-order FTS schema [7], and the influence of the length of intervals in article [8] come with the development from the one-factor FTS models into two-factor FTS model [9]. These forecasted approaches are the basis for the strong development of many FTS models in the next time periods. Recently, many authors have applied different advanced data mining techniques in each stage of FTS model with view to enhancing forecasting accuracy. Study in article [10] used the automatic clustering technique for partitioning the UoD into unequal - size intervals at the fuzzification stage in their forecasting model. Some other researches apply soft computing

techniques(especially evolutionary computing, clustering techniques) for adjusting and selecting intervals with unequal-size, can be found as genetic algorithm [11, 12], simulated annealing [13], PSO [14-22], K-mean [23, 24], fuzzy C-means [25, 26]. Just recently, a completely different way from fuzzy approach, several works with regards to HA have been published. In [27], the authors have presented a forecasting method based on the theory of hedge algebra [28] for forecasting university enrolments, to be a typical option. In which, the hedge algebra was used to construct linguistic domains and variables instead of performing data fuzzification and defuzzification in the fuzzy approach. In addition, researches in [29, 30] proposed the HA-based forecasting models to obtain unequal – length intervals in the UoD by mapping the semantics of linguistic variables into fuzziness intervals. However, two these research works only focus on building the first-order forecasting model to apply the number of students annually at the University of Alabama. In addition, their forecasting models have not yet applied the optimal techniques, so the obtained forecasting results are not really good enough.

Based on analyzing of the aforementioned research works showed that determining of the length of interval and the order of fuzzy relationships affect strongly forecasting performance of the model. To avoid the above - mentioned limitations and promote the advantage of combination with methods of partitioning in the UoD. The purpose of this study is to suggest a new partition method which uses PSO algorithm to optimize parameters of HA in the FTS prediction model. Therefore, we develop a novel hybrid prediction model using method of fuzzy relation group [17], integrating with HA and PSO algorithm in the identification of optimal intervals with view to enhancing the forecasting performance of the proposed model. For making it become reality, HA has been used to divide the UoD into intervals with unequal – size based on the parameters optimized by PSO. After obtaining the intervals, the time series data is put into the intervals by fuzzy sets and used them to create the FLRs, group of FLRs. Later, all information in FLR groups are utilized to produce the final prediction results based on the our defuzzification principle [31]. Finally, to enhance the accuracy of the model, we continue applying PSO algorithm to readjust the initial interval lengths which are obtained by fuzzy parameters of HA into intervals with the more proper length. Our forecasting model is examined on two following real-world datasets: 1) the historical enrolment dataset of University of Alabama [3], 2) the dataset of car road accident [32]. The examined results point out that our forecasting model outperforms the some of the recent FTS models in terms of prediction accuracy rate.

The next content of this paper introduces brief fundamental theories related to FTS model such as, fuzzy time series, Hedge Algebras and PSO algorithm. A method using PSO technique which has never been applied before in the selecting optimal parameters of HA and optimal length of intervals simultaneously, is presented in Section 3. Section 4 discusses the forecasting performance by comparing the obtained results of the proposed model with ones of the previous models. The last section gives conclusions and directions for future work.

2. The Fundamental Theories and Algorithms

In this section, we briefly introduce general knowledge related to FTS which is proposed in [1, 2] and improved by study [3]. In addition to, the hedge algebras [28] and PSO algorithm [33] is also reviewed.

2.1. Fuzzy time series

The concepts of FTS were proposed in [1, 2], in which the historical time series data are given in the form of fuzzy sets [3].

Assume that $Y(t)$ $(t = . . , 0, 1, 2 . .)$ a real subset R $(Y(t) \subseteq R)$, regarded as the UoD on which the fuzzy sets $f_i(t)$ $(i = 1,2 ...)$ are defined. If $F(t)$ including the collection of $f_1(t), f_2(t), ...$, then $F(t)$ is namely a FTS which is defined on $Y(t)$ [1, 2]

If there exists fuzzy logical relationship (FLR) between $F(t-1)$ and $F(t)$, namely R(t-1, t), such that they can be expressed as $F(t) = F(t-1) * R(t-1, t)$ or $F(t-1) \rightarrow F(t)$; Where R(t-1, t) is the first-order fuzzy relationship between $F(t)$ and $F(t-1)$ and "$*$" represents the max–min composition operator. Here $F(t)$ and $F(t-1)$ are fuzzy sets. If, let $A_i = F(t)$ and $A_j = F(t-1)$, the relationship between $F(t)$ and $F(t-1)$ is replaced by $A_i \rightarrow A_j$, where A_i and A_j are called the current state and the next state of fuzzy relationship, respectively [1, 2, 4]

Let $F(t)$ be a fuzzy time series. If $F(t)$ is derived by more fuzzy sets $F(t-1)$, $F(t-2)$,…, $F(t-\beta+1)$, $F(t-\beta)$, then fuzzy relationship between them can be represented as $F(t-\beta)$, …, $F(t-2)$, $F(t-1) \rightarrow F(t)$. This relationship is called the β - order FTS model [1, 2, 7]

Suppose that $F(t)$ is derived from $F(t-1)$, then the relationship can be denoted as $F(t-1) \rightarrow F(t)$. If, let $A_i(t) = F(t)$ and $A_j(t - 1) = F(t-1)$. The FLR of them can be replaced as $A_j(t - 1) \rightarrow A_i(t)$. In addition, at the time t, there are also exists fuzzy relationships as $A_j(t1 - 1) \rightarrow A_{i1}(t1), . ., A_j(tn - 1) \rightarrow A_{in}(tn)$ with $t1, t2, . ., tn \le t$. It is noted that $A_i(t1), A_i(t2), …,$ and $A_i(tn)$ having the same fuzzy set A_i, but look at different times $t1, t2, …,$ and tn, respectively. If these FLRs appear before $A_j(t - 1) \rightarrow A_i(t)$, they can be grouped into a fuzzy relationship group as follows: $A_j(t - 1) \rightarrow A_{i1}(t1), A_{i2}(t2), … , A_{in}(tn), A_i(t)$, and it is called TV-FRG [17].

2.2. Some basis concepts of Hedge Algebras

Hedge Algebras are introduced by N.C. Ho in 1990. It is considered as a new approach to solve forecasting problems in which it is used to quantify the linguistic variables. Each of linguistic variable $\mathcal{X}$ is represented by an algebraic structure, which is built on the inherent semantic order of the linguistic terms [28] and defined as follows:

Definition 1: The linguistic variable $\mathcal{X}$ is a set including 5 components $\mathcal{AX} = (X, G, C, H, \le)$ and called HA;

In which, X is the basic set in $\mathcal{AX}$; " $\le$ " is a natural semantically ordering relation on X; $G = \{c^-, c^+\}$, $c^- \le c^+$ is the set of generating elements (eg., Low $\le$ High) ; $C = \{\mathbf{0}, \mathbf{w}, \mathbf{1}\}$ is a set of constants, with $(\mathbf{0} \le c^- \le \mathbf{W} \le c^+ \le \mathbf{1})$; $H = H^- \cup H^+$, with $H^- = \{ h_i : -q \ge i \ge -1\}$ denotes the set of all negative hedges of X, and $H^+ = \{h_i : 1 \le i \le p\}$ denotes the set of all positive hedges;

Definition 2. Let $\mathcal{AX} = (X, G, C, H, \le)$ be a HA. The function $fm: X \rightarrow [0, 1]$ is named to be a fuzziness measure of elements in X, if:

1) $fm(c^-) + fm(c^+) = 1$ and $\sum_{h \in H} fm(hx) = fm(x)$ with $\forall x \in X$;

2) $f(x) = 0$ with $\forall x \epsilon X$ so that $fm(0) = fm(W) = fm(1) = 0$

3) For $\forall x, y \in X, \forall h \in H, \frac{fm(hx)}{fm(x)} = \frac{fm(hy)}{fm(y)}$, this equation does not depend on x; y and it is called fuzziness measure of the hedge h and namely by $\mu(h)$. The properties of $fm(x)$ and $\mu(h)$ are given as below:

Proposition 1. The fm denotes the fuzziness measurement on X, the following statements hold.

With $\in X, x = h_n h_{n-1} \dots h_1 c, h_j \in H, c \in G$

1) $fm(hx) = \mu(h)fm(x), \forall x \in X$

2) $\sum_{-q < i < p, i \neq 0} fm(h_i c) = fm(c)$

3) $\sum_{-q < i < p, i \neq 0} fm(h_i x) = fm(x)$

4) $fm(x) = fm(h_n h_{n-1} \dots h_1 c) = \mu(h_n)\mu(h_{n-1})\dots\mu(h_1)fm(c)$

5) $\sum_{i=-1}^{-q} \mu(h_i) = \alpha$ and $\sum_{i=1}^{p} \mu(h_i) = \beta$, with $\alpha, \beta > 0$ and $\alpha + \beta = 1$

$fm(h_p c^-)\ fm(h_1 c^-)\ fm(h_{-1} c^-\ fm(h_{-q} c^-)\ fm(h_{-q} c^+\ fm(h_{-1} c^+\ fm(h_1 c^+\ fm(h_p c^+)$
Figure 1: The order of fuzziness measure of elements $x \in X, h_j \in H, c \in G$.

2.3. Particle swarm optimization

PSO is an evolutionary computation algorithm which is introduced by article [33] for searching the global optimum solution. It is developed by work [14] for applying in the forecasting field. Each particle in the swarm represents a potential solution to the global optimization problem. When particles move from this position to other position in q-dimensional space, all particles (i.e, N particles) have fitness values which are estimated according to fitness function. In the moving process of particles. The position of the best particle among all particles found so far is saved and each particle maintains its individual best position which has passed previously. Each individual particle kd ($1 \leq kd \leq N$) is composed of three components: its position $P_{kd} = [p_{kd,1}, p_{kd,2}, \dots, p_{kd,q}]$, the velocity vector $V_{kd} = [v_{kd,1}, v_{kd,2}, \dots, v_{kd,q}]$ and the best position that it has individually found so far $\mathcal{P}_{best,kd} = [\mathcal{P}_{kd,1}, \mathcal{P}_{kd,2}, \dots, \mathcal{P}_{kd,q}]$. Then the best position global $G_{best} = \min(\mathcal{P}_{best,kd}^t)$ found by the overall best out of all the particles in the swarm. The briefly summarizes steps of the standard PSO algorithm in Algorithm 1 as follows:

Algorithm 1: The PSO algorithm

Initialize: learning factors $C_1 = C_2$; ω_{max}, ω_{min}; random positions $P_{kd,i}$; random velocities $V_{kd,i}$ in q-dimensional space (i= 1,2,…,q);
▪ Positions of each kd^{th} (kd = 1,2, …, N) particle's positions are randomly determined:
$$P_{kd} = [p_{kd,1}, p_{kd,2}, \dots, p_{kd,q}]$$

---

where; $p_{kd,i}$ denotes i^{th} position of kd^{th} particle; N is the number of particles in a swarm
▪ Velocities are randomly determined:
$$V_{kd} = [v_{kd,1}, v_{kd,2}, \dots, v_{kd,q}]$$
▪ Let $\mathcal{P}_{best,kd} = P_{kd}$
while *(t ≤ iter)* **do** // iter is maximal iteration number
  for each particle kd in swarm **do**
  ▪ **Calculate** the fitness value of particle kd: $f(x_{kd})$
  ▪ **Update** the personal best position of particle kd
$$\mathcal{P}_{best,kd}^{t+1} = \begin{cases} \mathcal{P}_{best,kd}^{t+1}; & \text{if } f(P_{kd}^{t+1}) > \mathcal{P}_{best,kd}^t \\ f(P_{kd}^{t+1}); & \text{if } f(P_{kd}^{t+1}) \leq \mathcal{P}_{best,kd}^t \end{cases}$$
  End for
  ▪ **Update** the global best position G_{best} according to the fitness value.
  for each particle kd in swarm **do**
  ▪ **Update** the velocity: $V_{kd,i}^{t+1} = \omega^t * V_{kd,i}^t + c_1 * R1() * (\mathcal{P}_{best,kd} - P_{kd,i}^t) + c_2 * R2() * (G_{best} - P_{kd,i}^t)$ (1)
  ▪ **Update** the position: $P_{kd,i}^{t+1} = P_{kd,i}^t + V_{kd,i}^{t+1}$ (2)
  End for
  Update inertia weight ω : $\omega^t = \omega_{max} - \frac{t*(\omega_{max} - \omega_{min})}{iter}$ (3)
End while

3. The FTS Proposed Model Using HA and PSO

The aim of this section is to present a new FTS forecasting model based on the advantage of using PSO to get optimal parameters of HA and optimal intervals in the UoD simultaneously. Firstly, PSO is selected in the proposed model to optimize parameters of HA like fuzziness measure of the hedges and fuzziness measure of primary generator for attaining initial intervals in the UoD. Then, we continue to apply PSO algorithm to readjust the initial interval lengths in fuzzy time series obtained by HA into optimal intervals with view to obtaining the better forecasting accuracy rate. Finally, from these optimal obtained intervals, we produce the forecasting results of model by defining fuzzy sets, fuzzy historical data on each divided interval, determinizing the FLRs, establishing fuzzy relationship groups and calculating the forecasting values from the defuzzification method [31]. The step-by-step of the our model is given as follows.

Step 1: Define UoD of historical time series

Assume that $U = [d_{min} - n_1, d_{max} + n_2]$ is UoD. For defining U, the minimal value d_{min} and the maximal value d_{max} in the time series data is determined; n_1 and n_2 are two proper positive numbers, respectively to let the U cover the noise of the testing data. Then, partition UoD into several adjoining intervals based on optimal parameters of HA obtained by PSO algorithm.

Step 2: Call the proposed algorithm "**Optimizing parameters of HA based on PSO algorithm**" to obtain the initial partition of the intervals. This algorithm is introduced in the next part:

This study uses HA with structure which is presented in Definitions 1 and 2 as $\mathcal{AX} = (X, G, C, H, \leq)$, in which G = $\{c^-, c^+\}$ ={**Low, High**} with **Low** (Lw) ≤ **High** (Hi); C = {**0, w, 1**} a set of constants, with $(0 \leq c^- \leq W \leq c^+ \leq 1)$ and H = {**Little, Very** }. Here, HA is applied as basis to partition data of time series into initial intervals with unequal-size [29] and PSO is used for optimizing the parameters of HA with elements fm(Low)

and μ(little), in which fm(Low) + fm(High) =1 and μ(little) + μ(very) =1. From the optimal parameters obtained, q initial adjoining intervals with different lengths which are defined $u_1 = [d_{min} - n_1, x_1]$, $u_2 = [p_1, p_2]$,…, $u_k = [p_{q-1}, d_{max} + n_2]$, respectively.

Step 3: From on the intervals obtained in Step 2, Call the algorithm "**PSO-based optimal lengths of intervals finding algorithm**" to achieve the unequal intervals with optimal length.

This step applies PSO to adjust the initial intervals which are obtained from HA.

Step 4: From the optimal intervals achieved in Step 3, define the fuzzy sets A_i as follows:

From q intervals, there are q fuzzy sets to represent various intervals on U. Determine the fuzzy sets A_i ($1 \le i \le$ q) as follows:

$$A_1 = \frac{a_{11}}{u_1} + \frac{a_{12}}{u_2} + \cdots + \frac{a_{1q}}{u_q}$$
$$A_1 = \frac{a_{21}}{u_1} + \frac{a_{22}}{u_2} + \cdots + \frac{a_{2q}}{u_q}$$
$$\cdots\cdots\cdots\cdots\cdots\cdots\cdots\cdots$$
$$A_q = \frac{a_{q1}}{u_1} + \frac{a_{q2}}{u_2} + \cdots + \frac{a_{qq}}{u_q}$$

Where, $a_{ij} \in [0,1]$ ($1 \le i \le$ q, $1 \le j \le$ q), u_j is the jth interval of the UoD. The value of a_{ij} denotes the degree of membership of u_j in the fuzzy set A_i which are defined by the triangular membership function with three values 0, 0.5 and 1.

Step 5: Fuzzy the historical time series data into fuzzy sets A_i

Fuzzy time series is generated by converting each historical data into a fuzzy set. If a time series datum depends on interval u_j and the maximal membership value of fuzzy set A_i occurs at u_j, then the historical datum is considered as fuzzy set A_i. In this way, all historical data of time series is fuzzified into A_i.

Step 6: Define all β – order fuzzy logical relations ($\beta \ge 1$).

The fuzzy logical relationship can be construct by two or several consecutive fuzzified values, respectively. To create an β- order FLR, we need to explore any relationship - type as F(t − β), F(t − β + 1),…, F(t − 1) → F(t) , in which F(t − β), F(t − β + 1),…, F(t − 1) and F(t) are called the "current state" and the "next state" of the fuzzy logical relationship, respectively. Then, it has been obtained by replacing the corresponding fuzzy sets A_i.

Step 7: Establish all β - order fuzzy relationship groups (FRGs)

We use fuzzy relationship group [17] to form FRGs in this study. To clarify this, we consider three first - order FLRs at three different times t-2, t-1 and t as follows: $A_i \rightarrow A_j$; $A_i \rightarrow A_k$ and $A_i \rightarrow A_j$, respectively. Suppose that we want to forecast the value of time series data of time t-1, the appearance of the fuzzy sets on the right-hand side of FLRs having the same left - hand side is considered to form into together G1 as $A_i \rightarrow A_j, A_k$. The same way, if forecasting time t, the FLRs which have the same right-hand side are grouped into a group G2 as $A_i \rightarrow A_j, A_k, A_j$.

Step 8: Calculate and defuzzify the forecasted output values

To defuzzify the fuzzified time series data which are based on the established FRGs, we apply two rules which are introduced in papers [31, 14] to calculate the forecasting output values at time t as follows:

Rule 1: Applying for computing output values in the training stage

Our defuzzified principle in article [31] is employed to calculate value based on information of each group. For each group in the training stage, we divide each corresponding interval with regards to the fuzzy sets in the next state of the TV- FRGs into three sub-intervals with equal- length as calculated in (4)

$$\text{Forecasted\_output} = \frac{1}{2*n} \sum_{i=1}^{n} (subm_{ik} + Value\_lu_{ik}) \quad (4)$$

where, n denotes the total number of fuzzy sets on the left-hand side of TV-FRG.

✓ $subm_{ik}$ denotes the medium value of one of three sub-intervals ($1 \le k \le 3$) with regards to i-th fuzzy set in the next state of FRG that the real data at forecasting time falls into this sub-interval.

✓ $Value\_lu_{ik}$ denotes the one of two values belongs to lower or upper bound of one of three sub-intervals which has the real data at forecasting time ranges from L_{ik} to U_{ik} of sub-interval. **If** the real data value at forecasting time minor the mid-point value of sub-interval u_{ik}, then $Value\_lu_{ik}$ is allocated as the lower bound of sub-interval u_{ik} ; **else** $Value\_lu_{ik}$ is allocated as the upper bound of sub-interval u_{ik}

Rule 2: Applying for calculating output value in the testing stage

In the testing stage, prediction value of each group which has the unknown linguistic value on the next state is estimated by the master vote scheme [14]. Assume there a β - order FRG which has type as $A_{t-\beta}$, $A_{t-(\beta+1)}$, $A_{t1} \rightarrow$ #, the prediction value is estimated according to (5) as follows:

$$Forecated\_output = \frac{(M_{t-1}*w_h) + M_{t-2} + \cdots + M_{t-\beta}}{w_h + (\beta - 1)} \quad (5)$$

Where , the symbol w_h is the highest votes predefined by user; is the order of the FLRs; the symbols $M_{t-1}, M_{t-2} \ldots$ and $M_{t-\beta}$ are the medium values corresponding to intervals in accordance to the latest fuzzy set and other fuzzy sets on the current state of FRG having the maximal membership values of $A_{t-1}, A_{t-2}, \ldots,$ and $A_{t-\beta}$ occur at intervals $u_{t1}, u_{t2}, \ldots,$ and $u_{t-\beta}$, respectively.

Step 9: Evaluate the performance of the proposed model

The forecasting performance of the proposed model estimated by two following criterions as: Mean Square Error (MSE) and Mean Absolute Percentage Error (RMSE).

$$\text{MSE} = \frac{1}{n} \sum_{k=\beta}^{n} (F_k - R_k)^2 \quad (6)$$

$$\text{RMSE} = \sqrt{\frac{1}{n} \sum_{k=\beta}^{n} (F_k - R_k)^2} \quad (7)$$

Here, R_k and F_k are the actual and forecasted value at time k, respectively, n is number of observations to be forecasted, β is the order of fuzzy relationship.

In the following, we propose a new approach for optimizing parameters of Hedge Algebras, called "Optimizing parameters of HA based on PSO". This approach is utilized in Step 2 of the proposed model to get the optimal parameters of HA. Details of this approach are shown in Algorithm 2.

Algorithm 2: Optimizing parameters of HA based on PSO algorithm

Step 1: Initialize; Generate P particles in two - dimensional space

- ✓ Assume that the fuzziness interval of "Low" term denotes the first dimension and fuzziness intervals of "Little" hedge denotes the second dimension in the construct HA.
- ✓ Let kd be a particle including two elements $l_{kd,1}$ and $l_{kd,2}$, represented by the position vector $L_{kd} = [l_{kd,1}, l_{kd,2}]$; where $l_{kd,i} \in [0, 1], 0 \leq i \leq 1$ and $l_{kd,1} + l_{kd,2} = 1$. These two elements act as the fuzziness intervals of fm(Low) and μ(Little) of HA, as given in Figure 2(a). The velocity of each particle kd is denoted by the velocity vector $V_{kd} = [v_{kd,1}, v_{kd,2}]$ including two elements $v_{kd,1}$ and $v_{kd,2}$ as shown in Figure 2(b).
- ✓ In th PSO, the initial position vector L_{kd} and the initial velocity V_{kd} of each particle kd are generated randomly in range [0, 1], the personal best position vector $P_{best,kd} = [p_{kd,1}, p_{kd,2}]$ of each particle kd denoting the best position which has the minimum objective value found so far. Initially, the personal best position vector $P_{best,kd}$ of each particle kd like its initial position vector L_{kd}.

$l_{kd,1}$	$l_{kd,2}$

a) Position vector of particle *kd*

$v_{kd,1}$	$v_{kd,2}$

b) Velocity vector of particle *kd*
Figure 2: The graphical representation of particle kd

Step 2:   while *(t ≤ iter)* **do** // *iter is a predefined number of iterations*

For each particle *kd* **do** the following steps:

Step 2.1: Calculate the objective value MSE_{kd} of each particle kd, as given by following sub-steps:

Step 2.1.1: Generate q linguistic terms corresponding to q intervals From the position vector $L_{kd} = [l_{kd,1}, l_{kd,2}]$ or two parameters fm(Low) and μ(Little) of HA, divide the U into q intervals as $u_1 = [d_{min} - n_1, p_1]$, $u_2 = [p_1, p_2]$,..., $u_k = [p_{q-1}, d_{max} + n_2]$, respectively.

Step 2.1.2: Based on the obtained intervals, define q fuzzy sets as $A_1, A_2, ..., A_{q-1}$ and A_q

Step 2.1.3: Fuzzy the historical time series data into fuzzy sets A_i

Step 2.1.4: Establish fuzzy relationships based on the fuzzy sets A_i defined and fuzzified data

Step 2.1.5: Establish all TV-FRGs based on FLRs defined

Step 2.1.6: Defuzzify and calculate the forecasting output values

Step 2.1.7: Compute the objective value MSE_{kd} of each particle based on formula (6)

Step 2.2: Update the private best position vector $\mathcal{P}_{best,kd}$ of each particle kd, if $MSE^t(kd) \leq MSE^{t-1}(kd)$; $p_{kd,1} = l_{kd,1}$ and $p_{kd,2} = l_{kd,2}$

Step 2.3: Choose the best particle *Gbest* among all *P* particles, (which has the minimum MSE value), set $P_{Gbest} = [l_{Gbest,1}, l_{Gbest,2}]$ be the position vector of the Gbest

Step 2.4: Update the velocity V_{kd} and the position L_{kd} of each particle k*d* according to (1) and (2), respectively; update ω in (3).

end for
Step 3: **Check the stopping criterion**

If (t < iter), then let **t = t+1** and go to ***Step 2.1 else***, print the results (the position vector $P_{Gbest} = [l_{Gbest,1}, l_{Gbest,2}]$ be the optimal parameters of HA by letting Fm(Low) = $l_{Gbest,1}$ and μ(Little) = $l_{Gbest,2}$)).

end while

To sum up, the flowchart of the proposed algorithm "**Optimizing parameters of HA based on PSO**", which is shown in Figure 3.

Next, we present algorithm **"Finding optimal intervals using PSO"** which has been called in Step 3 of the proposed model to find the best length of each interval with view to getting the better accurate forecasting.

Finding optimal intervals using PSO

In this algorithm, PSO is used to adjust the initial interval lengths which are determined by Algorithm 2. The briefly explanations of this algorithm are given as below: Each particle of PSO in q-dimensional space is used to represent the partitioning of time series data, where q is the number of intervals in the *UoD*. Assume that the lower bound and upper bound of UoD be $p_0 = (d_{min} - n_1)$ and $p_q = (d_{max} + n_2)$, respectively. Each particle represents a vector including q-1 elements as $p_{kd,1}, p_{kd,2}, ..., p_{kd,q-2}$ and $p_{kd,q-1}$, where $(1 \leq i \leq q - 1)$ and $p_{kd,i} \leq p_{kd,i+1}$. From q-1 elements, attain the q adjoining intervals as $u_1 = [p_0, p_{kd,1}], u_2 = [p_{kd,1}, p_{kd,2}], ..., u_q = [p_{kd,q-1}, p_{kd,q}]$, respectively. If particles in a swarm move to from current position to another, the elements of the new vector with regards to position of particles that need to be adjusted in an ascending order $(p_{kd,1} \leq p_{kd,2} \leq \cdots \leq p_{kd,q-1})$. In the training phase, position of each particle is changed by using (1) and (2), and repeated the steps until the repeated value (t) equal to the predefined number of iterations (iter). If (t = iter), then all the FRGs obtained by the (Gbest) among all personal best positions $(\mathcal{P}_{best\_kd})$ of all particles which used to forecast the new data in testing phase and presented in Algorithm 4. Here, the MSE function in (6) is used to represent the forecasting accuracy of each particle in the training stage. The steps of the algorithm **"Finding optimal intervals using PSO"** are shown in **Algorithm 3** as follows:

Algorithm 3: Finding optimal intervals using PSO

Input: Historical time series data
Output: Optimal intervals and the MSE value

Initialize:

- ✓ P particles in q-dimensional space, the maximum iteration (iter)
- ✓ The initial position P_{kd} and the velocity V_{kd} of all particles, respectively. Where, the intervals in position vector is created by the particle 1 be the same as the one which are created from HA as $u_1 = [p_0, p_{1,1}]$, $u_2 = [p_{1,1}, p_{1,2}], ..., $ and $u_q = [p_{1,q-1}, p_{1,q}]$,
- ✓ The initial personal best position vectors of the kd^{th} particle is the same as its initial position vector at the beginning: let $\mathcal{P}_{best,kd} = P_{kd}$

while *(t ≤ iter)* **do** // *iter is maximum iteration number*

    for each particle kd $(1 \leq kd \leq P)$ **do**

- **Calculate** the objective value MSE_{kd}, of each particle kd by performing the steps from Step 4 to Step 8 above, such as: defining fuzzy sets, fuzzify time series data, determining all $\beta -$ order fuzzy relations, establishing all $\beta -$ order TV- FRGs, computing forecasted values
- **Update** $P_{best,kd}$ value of particle kd by the MSE values

$$\mathcal{P}^{t+1}_{best,kd} = \begin{cases} \mathcal{P}^{t+1}_{best,kd}\ ; & \text{if } MSE\left(P^{t+1}_{kd}\right) > \mathcal{P}^{t}_{best,kd} \\ MSE\left(P^{t+1}_{kd}\right)\ ; & \text{if } MSE\left(P^{t+1}_{kd}\right) \le \mathcal{P}^{t}_{best,kd} \end{cases}$$

End for

- **Update** the global best position G_{best} by the MSE value.

for each particle kd $(1 \le kd \le P)$ **do**

- **Update** the velocity: $V^{t+1}_{kd,i} = \omega^t * V^t_{kd,i} + c_1 * R1() * \left(\mathcal{P}_{best,kd} - P^t_{kd,i}\right) + c_2 * R2() * \left(G_{best} - P^t_{kd.i}\right)$
- **Update** the position: $P^{t+1}_{kd.i} = P^t_{kd,i} + V^{t+1}_{kd,i}$

End for

- **Update** inertia weight ω : $\omega^t = \omega_{max} - \frac{t*(\omega_{max}-\omega_{min})}{iter}$

End while

Instance: Explanation of the optimization process of the proposed model using Algorithm 3 on the enrolments data [4] is given as follows: the number of intervals and particles corresponding be (q = 7 and P=4, respectively. From the historical enrolments data, we define the UoD as U = [13000, 20000], where lower bound p_0 =

13000 and upper bound p_7= 20000, respectively. For finding the optimal solution, the parameters in PSO is defined as: the values of $p_{kd,i}$ fall within the range of (13000, 20000], the values of $v_{kd,i}$ fall within the range of [-100, 100], $(1 \le i \le 7, 1 \le kd \le 4)$, the values of C_1 and C_2 be 2, and the ω value ranges from 0.9 to 0.4 and maximum number of iterations be 2, respectively. The positions and velocities of all particles are initialized randomly and listed in Tables 1 and 2, respectively.

Algorithm 4: The forecasting algorithm in the testing stage

The optimal lengths of intervals and order of FLRs obtained in Algorithm 3 that are used to estimate untrained data in the testing stage based on the Principle 2 in the forecasting model.

In Table 1, we have given the 7 intervals for 4 particles which are $u_1 = [p_0, p_1]$, $u_2 = [p_1, p_2]$,..., and $u_7 = [p_6, p_7]$, respectively. Where, the initial position of particle 1 act as the intervals are created as the same the one which are obtained from HA in Algorithm 2 and listed as u_1= [13000, 14470.47), u_2= [14470.47, 15149.8) , u_3= [15149.8, 15829.15), u_4=[15829.15, 16143), u_5= [16143, 16528.14), u_6 = [16528.14, 17361.8), u_7= [17361.8, 20000]. The MSE value of particles is considered according to equation (6). From the corresponding MSE values, every particle records its own personal best positions ($\mathcal{P}_{best}$) so far.

4	16098.76	17518.15	18332.49	18779.17	18995.24	19826.96	558449.1

Firstly, the $\mathcal{P}_{best}$ values are initialized to the same as the initial position of all particles. Table 3 presents the $\mathcal{P}_{best}$ values of all particles so far and the global best position Gbest = min ($\mathcal{P}_{best}$) which is particle 1. After the first iteration, all particles change its positions based on (1) and (2). The second positions and the corresponding new MSE values of all particles are presented in Table 4.

Comparing the MSE values in Table 3 with the MSE values in Table 4, it can be seen that particle 2 and particle 3 in Table 4 attained a better position than their own $\mathcal{P}_{best}$ values so far. Thus, the two particles are updated in Table 5. The new Gbest is obtained by particle 2, because of the its smallest MSE value. The proposed model is accomplished by repeating the steps in Algorithm 3 until the maximal number of iterations is reached. Finally, the proper lengths of intervals are achieved corresponding to Gbest value that the particle 2 gets so far. These obtained intervals are employed to forecast the final output results.

4. Experiments and analysis

In this paper, our forecasting model has been implemented on two datasets as enrolments data of University of Alabama [3] and number of deaths in car road accidents in Belgium [32]. These two datasets have been applied for forecasting with the huge amount of research works in the literature. Before implementing the proposed forecasting model, two time series datasets are briefly described. Then, the simulated results and analyses related to these datasets are given, respectively. Description of time series data and evaluation of the proposed model are discussed as follows.

4.1. Prepare data for experiments

4.1.1. Time series description

This study, we focus on two time series datasets which are often used to demonstrate validity and performance of the FTS forecasting model. The statistical characteristics of two these time series are expressed as follows.

(a) The enrolments dataset of university of Alabama

This time series data consists of 22 values between 1971 and 1992, see Figure 4(a). This dataset has utilized to examined with the huge amount of reseach works which are presented in the articles [1, 2, 4, 6 - 7, 10 -12, 14, 15, 17, 21 - 24, 29 - 31]. The obtained results among these works are choosed for comparing with our proposed model. Some of results among these studies are considered for comparing with that of the proposed model in this paper. The UoD of enrolments time series is determined as U = [$d_{min} - n_1$, $d_{max} + n_2$] = [13000, 20000].

(a) Real data of enrolments time series

(b) Real data of car road accidents time series
Figure 4: Plots of the amplitude of time series used in experiments

In which, the minimal value and the maximal are $d_{min}=13055$ and $d_{max}=19337$, respectively, and two proper positive values n_1 and n_2 are set as 55 and 663, respectively

(b) The dataset of car road accidents in Belgium

There are 31 observations about the car road accidents ranges from 1974 to 2004 that taken from National Institute of Statistics, Belgium. Figure 4(b) depicts the yearly deaths in car road accidents in Belgium. This time series data is investigated in the research works [6, 32, 40 - 42]. The obtained results from these works have been also selected to compare with our proposed model. In this time series, the minimal value and the maximal are $d_{min}= 953$ and $d_{max}=1644$, and two proper positive values n_1 and n_2 are set as 3 and 6, respectively. Therefore, the UoD can be defined as $U = [d_{min} - n_1, \ d_{max} + n_2] = [950, 1650]$.

Table 6: The parameters of PSO are applied to the enrolments data and car road accidents data

The parameters in PSO	Enrolments	Car road accidents
The number of particles N	50	50
The max number of iterations *iter*	150	150
The inertial weight ω is decreased by	ω_{max}= 0.9 to ω_{min} = 0.4	ω_{max}= 0.9 to ω_{min} = 0.4
The coefficient C1 = C2	2	2
The positions P in search space	[13000, 20000]	[950, 1650]
The velocities V in search space	[-100, 100]	[-100, 100]
Number of intervals q	Defined by HA	Defined by HA
The number of particles N	50	50

4.1.2. Setup parameters for experiments

For implementing the experiments, we use C# programming tool on an Intel Core i7 PC with 8GB RAM. From parameters of each time series data in Table 6, our forecasting model is tested 30 independent runs on each of dataset with various number of orders and intervals to make forecasting results. Then, the best result of among testing runs is recorded to compare with most well-known models in the same dataset with regards to MSE (6) and RMSE (7) functions. The selected parameters of the PSO are used in

experiments for receiving optimal intervals and final forecasting results are placed in Table 6.

4.2. Application of forecasting and comparing results

In this section, we give out results of two experiments with regards to real-world time series datasets which are described in Section 4.1. Then, comparison of results between the proposed model and well-known FTS models in the literature are also presented.

4.2.1. Applying for Experiment 1

Case (1): Forecasted results obtained by the first – order FTS

The forecasting results obtained from this experiment are compared with the ones of the current models [34-37, 27, 29] under the same number of intervals equal to 7. A comparison with regards to RMSE value between the proposed model and the different forecasting models are given in Table 7. Considering the Table 7, the results show that the proposed model has the smallest forecasting errors with regards to RMSE value equal to 188.8 among all its counterparts. There are significant differences between the proposed model and the compared models above. It is the way which determining of the fuzzy relationship group and method of partitioning the UoD are applied in the forecasting model. Three models in works [34-36] are constructed according to the framework [3] to forecast different problems and apply information granules for partitioning, respectively, whereas the proposed model uses hedge algebras for determining unequal-sized interval lengths. Comparing with two models in articles [27, 29]. These models apply the fuzzy relation groups [3] to structure the forecasting model, in which the proposed model uses the fuzzy relation groups that we have proposed in article [17] to build the forecasting model. Comparing the model [37], the proposed model employs the HA combining with PSO to select the optimal intervals, whereas the model [37] applies the maximum spanning tree based fuzzy clustering for dividing intervals with different lengths in the intuitionistic FTS model. In addition, the proposed model is also given to compare with other models which are presented in [6, 11, 14, 15, 17, 36, 38] under the number of intervals of 14. The forecasting results and MSE values between our model and other models are given in Table 8. Table 8 shows that our model has capable of more accurate forecasting and obtains the MSE value 5938.8 which is the smallest among all the existing models.

Table 7: Comparative results of proposed model with the current models based on first – order FTS under seven intervals

Year	Real data	[34]	[35]	[36]	[27]	[37]	[29]	Proposed model

1992	18876	19500	19059	19014	19014	19031	18820	18718	19043.13
MSE		297788	31684	35324	22965	8224	7475	14534	5938. 8

Case (2): *Forecasting results obtained by the high – order FTS*

In this case, all historical enrolments dataset [4] covering a period from year 1971 to 1992 are separated into two parts. The first part including 19 observations between 1971 and 1989 is used for training and the second part consists of 3 observations is utilized for testing. The forecasting performance of our model and the compared models are evaluated using the MSE and RMSE function.

a) The obtained results in the training stage

To authenticate the superiority of our prediction model based on the different high - order FLRs, the research works [7, 12, 14, 15, 17] are cited for comparing. The comparative results for all forecasting models under the number of intervals equal to 7 are shown in Table 9. From Table 9 shows that the proposed model outperforms in term of forecasting accuracy the other existing models under different high-order fuzzy relationships at all. In particularly, our model has the smallest average MSE value of 1608.26 among all of compared models. Among all fuzzy relationships is done in the model, the proposed model obtains the lowest MSE value equal to 111.6 by 6th- order fuzzy relationships. The major difference between our model and the compared models is approach of forming FRGs and optimization method they used. In optimization method, the model [12] performs genetic algorithm but the models in articles [14, 15, 17] and the proposed model proceed the PSO algorithm to achieve the best intervals, respectively. Also using PSO to find suitable intervals, our model incorporates HA to partition the different initial intervals of the UoD instead of equal length intervals. In the determining of FRGs, our model is constructed from model [17], the remaining models in articles [7, 12, 14, 15] are created from structure [3]. From the above analysis, it is clearly seen that our model provides more convincing forecasted results when compared to five models considered above.

In addition, our proposed model has been also applied to compare with other existing models based on the different high–order FTS under number of intervals equal to 14. These compared models which are presented in papers [7, 39,12, 14, 15]. The comparative results of the proposed model with its counterparts are placed in Table 10. Comparing model [39] with the proposed model, the proposed model provides the better MSE value. In addition, comparing the forecasting model in article [7] and the proposed model, both of them use the 5th-order fuzzy relationship but our model is much more superior in term of forecasting accuracy. When compared with remaining forecasting models in articles [12, 14, 15]. Although these modes use the fuzzy logical relationship with number of orders is larger, but the results obtained from our model are also better than the existing competing models. In particular, from Table 10, our model obtains the forecasting error MSE of **16.9** which is the lowest among five compared models above. This can conclude that the proposed model not only provides superior forecasting results but also shows the best stability based on the various high-order FLRs, for all cases. To be clearly imagined, Figure 5 describes the trend in term of forecasting accuracy between our model and the previous models for different orders. Viewing these curves, it is clearly seen that forecasting accuracy of our model is more accurate than those of compared models under dissimilar high-order FLRs at all. To sum up, the comparisons above is enough to demonstrate the effectiveness of our model which outpace the previous models based on high - order model with unlike number of intervals in the forecasting the enrolments of University of Alabama.

b) *The obtained results in the testing stage*

From enrolments time series from 1971 to 1992, to forecast the new enrolments for the next year with one head - step. Can be explained through the examples as below: the historical data of enrolments from year 1971 to 1989, is utilized to forecast the new enrolment of year 1990. In the same way, the enrolments data between 1971 and 1990 are used to forecast data of year 1991. Thereafter the enrolments data have been well trained by our model, the future enrolments values could be accomplished to compare to the future ones of the forecasting models proposed in articles [4, 11, 14, 39]. A comparative forecasting results produced by the 3rd - order FTS with different number of intervals and the highest vote W_h=15 [14] which are shown in Table 11 and 12. From these Tables show that our model obtains the smallest RMSEs value equal to 99.2 and 60.28 among five competing models, respectively.

4.2.2. Applying for Experiment 2

In this section, our proposed model have been implemented for forecasting the car road accidents in Belgium [32] ranges period from 1974 to 2004. We also test 30 times and take the best forecasting result to compare with the results from the other five forecasting models in articles [40 - 42, 32, 6]. The comparative results based on the different number of intervals and the various orders of FTS are shown in Table 13. Comparing between models [40, 6] and our proposed model, our model achieves the far better MSE value of 29.4 in two compared models based on the first - order FTS with different number of intervals. Also, from Table 13, we can be seen that, comparing model [41] and model [32], our proposed model produces the far smaller MSE value of 0.85 in two considered competing models using the 3rd - order FTS with different number of intervals. To summarize, the our model provides better forecasting results and higher accuracy than the models in [40 – 42, 32, 6] corresponding to the number of orders of FTS and number of intervals equal to 14 as shown in Table 13.

5. Conclusions and upcoming work

In this paper, a novel model for predicting enrolments and car road accident is developed. To remedy the downside of the conventional FTS model, the FTS proposed model combines hedge algebras and PSO is developed to resolve two issues which are considered to be important and greatly affect the forecasting accuracy is that the length of intervals and fuzzy relationship group. By utilizing the concept of time variant fuzzy relationship group, the proposed model has handled the more persuasive historical data and has been demonstrated to be more appropriate for real-world applications. In addition to that the parameters of HA are modified by PSO algorithm to get the initial intervals partitioning of the UoD. In data mining and finding of optimal solution, PSO is considered to accomplish better compared to other heuristic techniques with regards to success rate and solution quality. Furthermore, the forecasting efficiency of the proposed model is significantly improved in adjusting the lengths of intervals. The forecasting performance of the proposed model is demonstrated by forecasting the enrolments at University of Alabama and the car road accidents in Belgium. Details of the comparison in Tables 7-13 indicate that the proposed model achieves the lowest forecasting errors when compared with other forecasting models., for many cases. Also, from Figure 5, it can be observed that the amount of error rate in terms of MSE obtained by our high - order FTS model are smaller than all other models considered in this research. Even though our model shows that the greater forecasting capability when compared with some of recent ones based on the high-order FLRs. Determining of the high-order FLR spends a lot of computational time than first-order FLR. Therefore, development of new approaches that can automatically select out the optimal degree of the high-order FLRs is a worthy idea in FTS forecasting model. Those will be the work closely related to this research in the coming time.

	Higher efficiency and lower losses are widely considered as the best metrics to optimize, in a high-power converter performance context. To provide a solution to the ever-increase of high switching frequencies challenges, we must explore soft-switching technologies to resolve interface issues and reduce the switching losses. This manuscript describes a comparative analysis between the fixed-bandwidth (FBW) and the variable-bandwidth (VBW) of the hysteresis modulation (HM) based on the conventional sliding mode (CSM) strategy. The two adopted techniques are applied to a bidirectional multichannel DC-DC asynchronous Buck converter. The cells are parallel-connected and operating in continuous conduction mode (CCM). The objective is to have a system that is more stable, more efficient and able to cope with variations in input voltage, load and desired output voltage. That requires, first, to attenuate the non-linearity phenomenon of the conventional sliding mode by placing a hysteresis modulation. Then, after applying this technique, we confronted the dilemma of the variable switching frequency. Our hypothesis was to incorporate a variable bandwidth of the hysteresis modulation. The results obtained under parametric variation clearly show the areas where significant differences have been found between the two approaches. Likewise, they both share several key features. Simulation studies in the MATLAB® / Simulink™ environment are performed to analyze system performance and assess its robustness and stability.

1. Introduction

DC-DC converters, with many different topologies, represent a hotspot in modern technology and have revolutionized switching control. Although the characteristics of power electronics, in terms of nominal voltage and current values, continue to improve, the range of applications continues to expand in several areas including energy storage, automation, transport, high power industrial drives and transmission / distribution of electrical energy [1], [2]. Whereas the needs for higher efficiency, reliability, modularity in high electronics power, multicellular converters are on the rise. Studies [3–6] based on a parallel multiphase topology have shown that the latter provides better performance, lower losses, reduced cost, and fast dynamic responses. Parallel-connected multi-cell DC-DC converters have an important role in

several applications such as inverters, powertrain systems and equipment of the power factor correction and they have countless advantages, the major one is to enhance performances such as energy efficiency and high capacity [7–11]. One approach dedicated to small converters is to run them at a higher switching frequency, this will reduce the size of reactive components (inductors and capacitors) and it contributes to the improvement of the output voltage's quality of the converter. High losses in the IGBT switches remains the major limitation of the high frequencies, which reduces efficiency. Significant information and in-depth investigations in the same framework can be found in these studies [12–18].

Higher efficiency and more stringent control features of power electronics become very attractive. Nonlinear Sliding mode controllers applied to parallel multi-cell converters combine control concepts with multiple sliding surfaces and integral

*Corresponding Author Rihab Hamdi, Email: rihab.hamdi2012@gmail.com

variable structure. They are easy to design, robust and shows good transient and stable performances. Furthermore, they restrict the switching frequency variation, mitigate the undesired transient response and achieve a good compromise between transient and stationary performances. Hence, there are two ways of control involved for multicellular converters. The first consists in controlling the multi-commutations with phase shifting from one another, one therefore speaks of interleaving. The second is to apply the same control signal simultaneously to the multi-switchings, it is therefore synchronicity. The controllers developed for paralleled multiphase converters take into consideration most of the characteristics mentioned above [19]. To date, several researchers have reported that these control schemes have many desirable features: easy-designed because each sliding surface is independently controlled, smooth transient responses tested under parametric variations, eliminate the problem of chattering, the impact of high switching frequencies is managed by the integrators. All these promising results have been experimentally proven on a closed loop system. Previous studies proposed to use the extended linearization method for the design of the sliding mode controller, and then improving robustness using the combined controllers. Thus, they developed a procedure to choose the high-pass filter parameters of the sliding mode-controlled converters. In addition, they presented derivatives of sliding mode control, including the direct /indirect sliding mode, the integral sliding mode, the proportional sliding mode and the high order sliding mode [20–28]. As far, sliding mode control has been widely studied and has proven to be a future solution for generations of power converters, yet, it suffers from the problem of high frequency oscillation (chattering) due to the practical limitations of system components and the problem of switching frequency variation by applying the traditional sliding mode.

This leads us to propose an implementation of the sliding mode controller by hysteresis function. The implementation is easy to reproduce and does not require additional auxiliary circuits or complex calculations. The introduction of a hysteresis band as the limit conditions of the sliding mode, delays the period of states exchange and gives a sign to control the switching frequency of the system, and therefore, the trajectory of the system variates in close proximity to the excesses of the band. So, the practical problem of chattering will be solved. Particularly, boundary layer-based control schemes allow multicell converters to operate with a fixed switching frequency [29–35]. This strategy will be fully covered in the rest of our work. The remainder of the paper is organized as demonstrated: In Section II, the adopted system is described and modeled. Section III reviews the control mechanism based on the sliding mode controller. Section IV is devoted to analyze the simulation results and to discuss the effectiveness of the control strategies. The conclusion is reported in Section V.

2. Paralleled Non-Isolated Multi-Cell Converter

The studied three-cell DC-DC buck converter is shown in Figure 1. It consists of a constant DC input voltage source V_{in} connected to three similar modules sharing a resistive load R and a filter capacitor C. Each module is based on an implemented controllable power MOSFETs S, the antiparallel diode D that authorizes the embedded switch to exhibit a bidirectional current conduction property and a filter inductor L. Note that the parallel

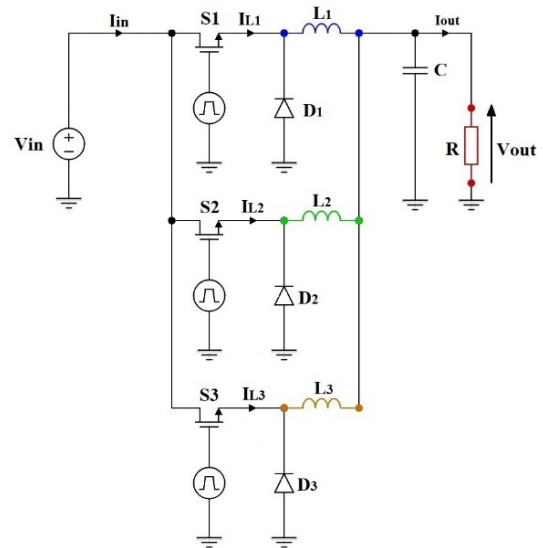
switching buck converter operates in continuous conduction mode (CCM). The three cells are identical, in other words, $L_1=L_2=L_3$.


Figure 1: Three-channel Buck converter parallel-associated

The converter can be represented by a system of equations based on a model with mean values, then the system dynamics of the studied converter can be expressed as:

$$L\frac{dI_{Lj}}{dt} = V_{in}D - V_{out} \tag{1}$$

$$C\frac{dv_{out}}{dt} = I_L + \frac{V_{out}}{R} \tag{2}$$

Where I_{Lj} is the current flowing through inductance $j = 1,2,3$, I_L the current at the output of the converter, V_{in} is the input voltage and V_{out} is the output voltage of our converter and V_{ref} is the desired output voltage. The state of space can be expressed as:

$$
\begin{aligned}
x_1 &= V_{ref} - V_{out} \\
x_2 &= \dot{x}_1 = -\frac{dV_{out}}{dt} = \frac{1}{C}\left(\frac{V_{out}}{R} - \int \frac{uV_{in} - V_{out}}{L}dt\right)
\end{aligned}
\tag{3}
$$

This model can be used directly to simulate the converter, in MATLAB / Simulink type environment.

3. Hysteresis Modulation-Based Sliding Mode Controller

We propose two different control schemes, developed in the continuous domain, to stabilize parallel multi-phase standalone converter and compare them. The proposed sliding mode control (SMC) strategy based on hysteresis modulation (HM) automatically compensates for the parametric variations of the converter and the variation of the line impedance, such that it allows the three-cell paralleled converter to share the load and does not require the modules to be interconnected. We illustrate the fixed-bandwidth of the hysteresis modulation technique-based sliding mode control; however, this approach has accentuated the problem of variable switching frequencies that requires a high-bandwidth current sensor. At this point in our work, we are interested in an adaptive and feedforward current control solution to overcome this problem and adapt a variable-bandwidth of the

hysteresis modulation to mitigate the nonlinearity phenomenon in conventional sliding mode control to fix the switching frequency.

Describing the mathematical model of the system in question, operating in CCM, and especially its states of space necessary for the design of the sliding mode voltage control (SMV), the reformed expression of the state of space is:

$$\begin{bmatrix} \dot{x}_1 \\ \dot{x}_2 \end{bmatrix} = \begin{bmatrix} 0 & 1 \\ -\dfrac{1}{LC} & -\dfrac{1}{RC} \end{bmatrix} \begin{bmatrix} x_1 \\ x_2 \end{bmatrix} + \begin{bmatrix} 0 \\ -\dfrac{V_{in}}{LC} \end{bmatrix} u + \begin{bmatrix} 0 \\ \dfrac{V_{ref}}{LC} \end{bmatrix} \quad (4)$$

Employing the sliding mode voltage control (SMVC) and taking into account the state trajectory that includes the control parameters x_1 and x_2, we can determine the switching function u.

$$S = \alpha x_1 + x_2 = Jx \quad (5)$$

$$\begin{cases} J = [\alpha, 1] \\ x = [x_1, x_2]^T \end{cases} \quad (6)$$

That forms the control law:

$$u = \begin{cases} 1 = \text{'ON'} & When\ S > k \\ 0 = \text{'OFF'} & When\ S < k \end{cases} \quad (7)$$

The convergence conditions are the criteria that allow the dynamic errors of the system to converge towards the sliding surface. They are ensured by a judicious choice of the function of LYAPUNOV, which guarantees the attraction of variables to regulate to their references, to build the discontinuous control size and meet the stability criterion:

$$\lim_{S \to 0} S.\dot{S} < 0 \quad (8)$$

Thus, the existence condition for the adopted control strategy is:

$$\dot{S} = \begin{cases} J\dot{x} < 0 & for\ 0 < S < \xi \\ J\dot{x} > 0 & for\ -\xi < S < 0 \end{cases} \quad (9)$$

where ξ is a positive quantity, infinitely small and arbitrarily chosen.

Substituting (3) and (5), we find:

$$S = \frac{1}{R}(V_{ref} - V_{out}) - i_C \quad (10)$$

The sliding coefficient is set as (11) and thus the above equation is valid:

$$\alpha = \frac{1}{RC} \quad (11)$$

We can therefore deduce the conditions of existence:

$$\lambda_1 = (\alpha C - \frac{1}{R})x_2 - \frac{1}{L}x_1 + \frac{V_{ref} - V_i}{L} < 0 \quad (12)$$

$$\lambda_2 = (\alpha C - \frac{1}{R})x_2 - \frac{1}{L}x_1 + \frac{V_{ref}}{L} > 0$$

The bandwidth of the FBW regulator based sliding mode controller has been selected according to the following equation:

$$B_{Fixed-Width} = \frac{(V_{in0} - V_{out})}{2.L.fw} \cdot \left(\frac{V_{out}}{V_{in0}} \right) \quad (13)$$

$$V_{in0} = \frac{3 \cdot V_{in} \cdot \sqrt{6}}{\pi} \quad (14)$$

Hence, we focus on the adaptive feedforward current control technique in continuous conduction mode (CCM). So that, the expression of the current variation ΔI_L, as a function of the input voltage V_{in}, the output voltage V_{out}, the switching frequency fw, and the value of the inductance L, can be shown as:

$$\Delta I_L = \frac{(V_{in} - V_{out})}{L.fw} \cdot \left(\frac{V_{out}}{V_{in}} \right) \quad (15)$$

Still with the aim of ensuring the operation at fixed frequency of the proposed hysteresis modulator, a requirement is imposed, and that the hysteresis bandwidth must satisfy it, is:

$$B_{Variable-Width} = \frac{\Delta I_L}{2} = \frac{(V_{in} - V_{out})}{2.L.fw} \cdot \left(\frac{V_{out}}{V_{in}} \right) \quad (16)$$

The dynamic performance of the two schemes needs to be demonstrated under conditions when some changes are imposed and a feedforward transient occurs. Simulations are performed for various cases of the circuit parameter variations: load changes, input voltage changes and reference voltage changes.

4. Simulation Results and Robustness Assessment

In this part, and to properly study the behavior and performance evaluation of the closed-loop converter and the various control techniques synthesized in the previous section, particularly when modifying the operating conditions, we will simulate the behavior of a 3-cell chopper connected to an R load. A robustness test was carried out to analyze the sensitivity of the strategies and the correctors implemented with regard to possible variations in the parameters of the model. For the parameter's identification of the studied converter, we determine the nominal values of the inductance L and the capacitance C using the conditions below:

➢ The current through the inductance, must be within a reasonable interval, for all the conditions of charge, because our converter is operating in continuous conduction mode.

➢ The maximum ripple of the output voltage should not exceed a small percentage, usually 5% of the output voltage V_{out}.

Taking these conditions into account, the LC filter must obey the conditions of the relationships below, where fw corresponds to the switching frequency and β is the duty cycle.

$$L \geq \frac{V_{in}}{\Delta I_{out,\max} \cdot f_w} \beta (1 - \beta) \quad (17)$$

$$C \geq \frac{(1-\beta)}{8L.f_w^{\,2}}\left(\frac{V_{out}}{\Delta V_{out}}\right) \qquad (18)$$

Table 1 shows the specifications that we adopted of the studied buck converter simulated in the MATLAB® environment.

Table 1: Specifications of The Paralleled Three-Channel Buck Converter

Description	Parameters	Nominal Value
Input voltage	V_{in}	*24 V*
Capacitance	*C*	*60 µF*
Inductance	*L*	*50 mH*
Resistance	*R*	*12 Ω*
Switching frequency	*fw*	*400 kHz*
Desired output voltage	V_{ref}	*12 V*

Figure 2 duplicates the variation of the average switching frequency as a function of the input voltage variation. The VBW HM-based SMC adaptive feedforward control reduces switching frequency variation compared to the FBW HM-based SMC control. This result highlights the major contribution of our work, thanks to the developed strategy, we achieve a significant reduction in the variation of the switching frequency.

Figure 3 and Figure 4 show the output voltage response for the two control strategies used. it seems clear that the system operating with VBW HM-based SMC achieves the best compromise passing from the transient regime to the stationary regime. Thus, its transition response is smoother, more stable, without overshoot and with less chatter, on the other hand, the response of our system under the control of the FBW HM-based SMC is faster but it represents more variation in amplitude of the oscillations, with an overshoot.

It appears clearly from Figure 5 and Figure 6, during an increase/decrease in resistance (50% variation) every 0.2s, that the closed-loop output voltage response reacting with the FBW HM-based SM exhibit an undesired transient drop that lasts a few seconds and disturbs the smoothness of the output voltage followed abruptly by a steady-state. While, in the other case, the system compensates for a transient drop in a soft way. Through the output current simulation results, we can observe that the VBW

HM-based SM goes perfectly with the load changes to even almost assure that there is no transient regime. Figure 7 and Figure 8 point-out the output voltage response and the output load current response for the two controllers when the system undergoes a change in the input supply (V_{in} varied from 24V to 50V) at 0.2s. For the two cases, the chattering increase, however, the output voltage and the output load current vary around the reference values. The zoom in clearly shows an increase in the amplitude of the oscillations accompanied by an upward shift of the output voltage in steady-state regime when the input voltage increases, it comes down to the variation of the switching frequency.

Figure 9, Figure 10, Figure 11 and Figure 12 present the output voltage response and the output load current response for the two controllers when the system undergoes a change in the output reference (V_{ref} varied from 12V to 20V). Switching from one value to another is almost similar, there is no big difference except that the VBW HM-based SM is more precise. The carried-out simulations show extremely encouraging outcomes as far as reference tracking effectiveness and robustness, a quick estimation of the control law permits a quicker dismissal of the unsure load impact. They demonstrate the propriety of sliding mode control for such sort of framework.

The results in terms of stability assessment and performance analysis under system parameters variation are recapitulated in Table 2.
Figure 2: The variation of the average switching frequency as a function of the input voltage variation.

5. Conclusion

The variable-bandwidth hysteresis modulation is favored because it ensures the chattering suppression caused by the switching of the MOSFETs and provides high efficiency since it offers a greatly desired output voltage tracking. The VBW HM-based SMC is faster to the point that the response time at 5% is mostly short. His appropriate dynamic accuracy is characterized by zero overshoot during the transient regime for the output voltage response, contrariwise to the FBW HM-based SMC that represents 2.5% overshoot. The output voltage regulation is improved from 2% (V_{in}=24V) to 0.15% (V_{in}=24V) through the VBW HM-based SMC. Add to that, the frequency variation is reduced from 30% to 15% with the developed strategy. The various control techniques provide similar performances, they have improved the dynamic conduct and they can adapt to include

voltage and load varieties. The use of variable bandwidth hysteresis modulation and fixing of the switching frequency leads to large scale dynamics.

A B S T R A C T

Solar ultraviolet radiation (UVR) is considered a relevant health risk for the workers of the maritime and port sectors, but scant data are available on actual exposure measured using personal dosimeters. Moreover, in outdoor workers sun protection habits are usually poor, while some promising data suggest that sun-safety campaigns can be effective in increasing self-protection at work. Accordingly, our aim was to conduct an assessment of solar UVR exposure in dockworkers and fishermen using personal dosimeters, and to evaluate the use of sun protection measures at work after a sun-safety training. We performed two different UVR measurements campaigns in spring-summer 2018, investigating 7 fishermen and 14 dockworkers. Electronic dosimeters have been placed on the workers for at least a half work-day. Only at the port it was also possible to register the environmental UVR exposure with a specrto-radiometer, while for fishermen we estimated the corresponding environmental exposure using an algorithm. Our results demonstrate a high erythemal UVR dose received by the workers, with an individual exposure up to 542 J/m2 for fishermen in spring and up to 1975 J/m2 for dockworkers in summer. This data indicates an excessive occupational risk, needing more effective prevention. Accordingly, we offered a sun-safety training to the workers. Before the training, protective behaviour of the workers was rather poor: about the 50% never used the hat, the 40% never wore sunglasses and none of the workers referred to apply sunscreens at work. After the training, fishermen reported a relevant improvement in the use of individual UV protections, as hat (+9.6%), sunglasses (+28.5%) and clothes (+5%), even if the use of sunscreens at work was not increased.

1. Introduction

Solar ultraviolet radiation (UVR) exposure represents an important occupational risk in the maritime and port sectors: this paper is an extension of work originally presented in the 2020 IEEE International Conference on Environment and Electrical Engineering and 2020 IEEE Industrial and Commercial Power Systems Europe (EEEIC / I&CPS Europe) [1], integrated with data we published elsewhere [2], further elaborated and with additional inclusion of new results.

The possible adverse health effects occurring in workers exposed to solar UVR include both acute and long-term ones and mainly involve the skin and the eyes. The consequences may be severe, as in the case of cancers: solar UVR is considered the most frequent occupational carcinogenic exposure [3], for its ability to

induce in particular non-melanoma skin cancers (NMSC) [4], but also some forms of melanoma skin cancers may be related to occupational UV exposure [5], as well as rare forms of eye tumors, as the squamous cell carcinomas of the cornea and conjunctiva and ocular melanomas [6]. Considering the skin, other frequent adverse health conditions associated with cumulative solar UV exposure, and representing precancerous lesions, are photo-aging and actinic keratosis [7]. Regarding the eyes, it should be noted that usually this organ is much more protected from UV rays compared to the skin, for anatomical reasons and for the actions of various involuntary reflexes (pupillary reflex, squinting, winking) [8]. Nevertheless, UV eye exposure may be relevant in particular conditions, as in the case of UV rays reflected from surfaces like polished metal, water, snow, white sand and marbles, etc [8]. Fishermen and dockworkers, often close to the water, may be at particular risk for relevant UV eye exposure. In addition to the eye tumors, there are various ocular diseases recognizing solar UVR as a risk factor: among all, cataract [6], currently the leading cause of visual impairment worldwide [9]; pterygium, a hyperplasia of the bulbar conjunctiva highly correlated with increased levels of UV radiation [6]; and possibly also age-related macular degeneration [6], a chronic degenerative retinal disease, the second leading cause of blindness in the world [9]. For all these three eye pathologies, positive significant associations with solar radiation exposure and increased risks for outdoor workers of being diagnosed with the diseases have been well documented [10–12].

Despite the recognized health risk, there are scant studies investigating solar UVR exposure levels in the maritime and port sector [2,13–15]. Fishermen spend most of their working time outdoor on the boats, close to the water surface, reflecting a relevant amount of UVR [8]; but also dockworkers, in particular those working at the quay, are almost always outside and quite often close to reflecting surfaces, such as water, but also lucid metallic surfaces on the quay/ships. According to these considerations, it is certainly of interest a detailed assessment of solar UVR exposure of these groups of workers. Furthermore, the extant scientific literature shows a relevant under-estimation of the risk by outdoor workers, with indications of poor protective habits and behaviors with respect to a relevant occupational risk, which is solar UVR exposure [16–22].There is also a growing evidence that sun-safety interventions are effective in increasing outdoor workers' sun-protection habits [21]; nevertheless, there is still a scarcity of these interventions focused on outdoor workers, and in particular on those of the maritime and port sectors.

Our objective is to report the results of two different solar UVR measurements campaigns, respectively performed in a group of Italian dockworkers and fishermen, and a subjective evaluation of sun-exposure in a sub-group of the workers. Moreover, we wanted to test the possible improvement of the use of sun protections one year after our measurement's campaigns, including specific sun-safety trainings.

2. Materials and Methods

2.1. The solar UV radiation measurements campaigns

We registered personal exposure to solar UVR with electronic dosimeters during two different campaigns involving two groups of outdoor workers: fishermen (FM) and dockworkers (DW). Both the groups were voluntary recruited respectively from a fishing and a port company active in the area of the north-east of Italy, on the Adriatic sea (coordinates: 43° 9' N, 12°7' E for FM; 45° 4' N, 13° 5' E for DW). Considering the unstable whether conditions and the job activities mainly in the morning, we monitored FM for two consecutive spring days (15–16 May 2018), while for DW we registered personal solar UVR exposure during a summer day, with almost sunny wheather (4 July 2018). The personal electronic dosimeter used were 10 devices of the Gigahertz-Optik X2000 and X2012 series, while for a reference of the environmental erythemal UV dose in the monitored days we consulted the free online database of the Troposphperic Emission Monitoring Internet Service (TEMIS) of the European Space Agency, as described in detail in our previous works [1,2]. Briefly, the TEMIS website provides daily erythemal UV dose data for various places of the world; the data provided are derived by means of radiative transfer calculation codes from satellite measurements, considering local meteorological variables; such data were used to calculate the local environmental radiant exposure referred to the horizontal surface plane. The closest location to the dosimetry campaigns for which effective irradiance data have been made available is Venice, in Italy, that was selected as a proxy, being less than 200 km north-east compared to the workplace of the fishermen, and approximately 160 km south-west considering the port of the dockworkers. Erythemal UVR dose in Venice was 2.6 kJ/m^2 on 15th May, 3.6 kJ/m^2 on 16th May and 4.7 kJ/m^2 on 4th July. For dockworkers, we used this data only as comparison, as we registered the local erythemal radiant exposure on the horizontal surface with a Gigahertz-Optik BTS2048-UV-S spectro-radiometer placed at the quay. For fishermen it was not possible to use the spectro-radiometer on the boats, and we applied a formula [2] to reconstruct the percentage of ambient UVR received by the workers. For all the workers, the dosimeters were mainly placed on the upper back, that was the position we found most comfortable in order to not interfere with the job activities. In some cases we were able to put the devices on the chest of the workers, and only for a fisherman we had the possibility to attach the meter on the back side of his cap to simulate nape exposure (Fig. 1).

Figure 1: Placement of the UV electronic dosimeters at the workplace, on the fishermen (FM) and dockworkers (DW). From left to right, top to bottom: (1) a FM with a dosimeter on the back and one on the cap to simulatenape exposure; (2) a FM with a back dosimeter working in a covered area of the boat;(3) two FM with back dosimeters working in an uncovered area of the boat; (4) a DW working as port coordinator with a chest dosimeter; (5) a DW working as longshoreman with a

dosimeter on the upper back; (6)spectroradiometer for ambient solar UV dose measurements placed at the quay of the port.

The measurements were organized within a preventive campaign for the evaluation of the occupational risks in various occupational activities according to the Italian national occupational health and safety legislation, and were also aimed to the development of more adequate information and training of the workers. All the ethic principles considered in the Helsinki declaration were followed.

2.2. The sun exposure habits and protective behaviors investigation and the sun safety intervention

Only for the fishermen, between the two consecutive days of the measurements campaign we were able to collect a self-administered questionnaire, investigating personal solar UVR exposure habits and protecting behaviors during work and leisure activities, previously described [18]. Briefly, the 22 items questionnaire has two sections, one for work and one for leisure exposure; questions investigate the type of outdoor activity and the protections adopted to reduce solar UVR exposure. With the purposes of evaluating possible improvements of sun protection habits and behaviours at work after a sun safety training, we analyzed the results related to four items investigating the frequency of adoption of individual protections at work: use of UV protective hat, sunglasses with UV filtering lenses, UV protective clothes and sunscreens protections. Workers were asked to answer mainly on a 5 point Likert scale (from 0, meaning "never adopted the exposure habit/protective behavior", to 5 "always adopted the exposure habit/protective behavior"). The questionnaire was collected before a four-hours sun-safety training, explaining to the workers the characteristics of the solar UVR risk, the methods to evaluate the risk, the possible adverse health effects associated to solar UVR exposure and the importance of prevention during outdoor work practices, including the use of individual protections. The training was performed by the same experts involved in the measurements campaigns, for both DW and FM, but, as previously mentioned, the questionnaire was collected only for FM. The group of FM who participated in the training was larger compared to the workers we individually investigated with our dosimeters during the measurements campaigns. We decided to administer the questionnaire before the training, i.e. before the workers received any information on solar UVR risk that could be able to influence their answers. Then, one year after the measurements campaigns and the sun-safety training (May 2019), we contacted via phone the fishermen who participated in the sun-safety training and we administered the same questionnaire, in order to evaluate a possible improvement of the protective habits and behaviors of the workers, to be possibly attributed to the intervention we performed.

3. Results

3.1. Results of the solar UV radiation measurements campaigns

We measured individual solar UVR exposure of 7 fishermen and 14 dockworkers, all males (Table 1). FM worked on three fishing boats with different characteristics with respect to the availability of protections against solar radiation: one medium size boat (B1), only partially covered, but with various tasks of the work activity (mussel fishing) performed in shielded areas, one small boat (B2), with almost no coverage from UVR, for activities (sea snails and cuttlefish fishing) performed in direct sunlight and

another medium size boat (B3), partially covered, with only parts of the activities (trawling fishing) in direct sun. Considering DW, 10 of them worked as longshoremen (LSM) almost always close to the quay and to the water, while 4 subjects worked as coordinators of the port traffic (traffic coordinator, TC), with some activities performed inside a small office (Table 1).

Table 1: Results of individual measurements of occupational solar UVR exposure for 7 fishermen and 14 dockworkers from the North-East of Italy.

Work place / job task		Placement of the dosimeter	Working period / length of the period measured (minutes)*	Personal UV erythemal dose (J/m²)*	Ambient UV effective radiant exposure (H_eff) (J/m²)* ±	Personal erythemal vs. ambient UVR exposure (%)* ±
B1	FM1	Back	morning / 397	213	1710	12.5
	FM2	Back		79		4.6
	FM3	Back		71		8.8
B2	FM4	Back (& Nape)	morning / 180	542 (380)	830	65.3 (45.8)
	FM5	Back		288		34.7
B3	FM6	Back	morning / 300	151	1560	9.7
	FM7	Back (& chest)		129 (98)		8.3 (7.8)
Quay	DW1-LSM	Back	full-day / 432	1975	3339	59
	DW2-LSM	Back	full-day / 417	1067	3276	32
	DW3-LSM	Back	morning / 144	288	857	33
	DW4-LSM	Back	morning / 191	402	1322	30
	DW5-LSM	Chest	morning / 243	257	1596	16
	DW6-LSM	Back	morning / 251	854	1965	43
	DW7-LSM	Back	morning & early afternoon / 260	551	2675	20
	DW8-LSM	Back	afternoon / 246	622	2191	28
	DW9-LSM	Back	afternoon / 226	458	2001	22
	DW10-LSM	Back	afternoon / 225	413	1981	20
Center of the port (partially indoor)	DW11-TC	Chest	morning / 177	48	1550	3
	DW12-TC	Chest	Morning / 193	139	1759	7
	DW13-TC	Chest	Afternoon / 210	89	1876	4
	DW14-TC	Chest	Afternoon / 248	44	2045	2

Legend: B1= boat 1, middle-size, partially covered; B2= boat 2, small size, no coverage; B3= boat 3, partially covered; FM= fisherman; DW= dockworker; LSM= longshoreman; TC= traffic coordinator. *= for fishermen the worst exposure scenario occurred in one of the two days with measurements is reported in the Table; ± = for fishermen, ambient exposure was estimated according to a specific formula [2]

Regarding the length of the individual measurements period, unfortunately for almost all the workers it was not possible to monitor an usual full working day, as FM started their work-shifts few hours before sunrise, so that measuring UVR in that period was meaningless, and they finished between 1:00-2:00 p.m.; considering DW, for the large majority of them the activities were organized on separate morning and afternoon work-shifts, and only two DW worked both in the morning and in the afternoon the day we performed our measurements.

Considering the worst exposure scenario for the seven fishermen during the two days monitored, we found personal UVR exposure at the back ranging between 71 J/m^2 registered for FM3 working on the B1 and 542 for FM4 on the B2. The estimated proportion of environmental erythemal UVR dose received on the back of the FM resulted between a minimum of 4.6% for FM2 on the B1 and a maximum of 65.3% for FM4 on the B2 (Table 1).

Considering DW, we collected personal solar UVR exposure data at the back for LSM while at the chest for the TC, as they had quite often to sit inside a small office in the middle of the port area. The results of the measurements show a higher exposure in LSM compared to TC: the highest exposure of 1975 J/m^2 was collected, not surprisingly, for one of the two LSM (DW1) who worked for a full day (approximately 7 hours and a half). The individual exposure of the other LSM ranged between 257 J/m^2 collected at the chest of DW5 (i.e. the oly LSM with a chest dosimeter, who was monitored for more than four hous in the morning) and 1067 J/m^2 for the other LSM who was monitored for approximately seven hours (DW2). For the other LSM with dosimeters on the back and monitored only in the morning or afternoon, exposures resulted between 288 J/m^2 measured in the morning in about two hours and a half (DW3) and 854 J/m^2 registered again in the morning but in more than four hours (DW6). Percentages of ambient exposure received by the LSM varied between the 16 and the 59%. Considering TC, their individual solar UVR exposures at the chest varied between 44 J/m^2 measured in about four hours in the afternoon (DW14) and 139 J/m^2 registered in approximately three hours in the morning (DW12), with percentages of individual versus ambient exposure between the 2 and the 7% (Table1).

3.2. Results of the investigation of sun exposure habits and protective behaviors among fishermen

Twenty-one fishermen, all males, participated in the sun-safety training we proposed to the fishing company where we performed the individual solar UVR measurements campaign. We administered our questionnaire investigating sun exposure habits and behaviours before the starting of the training, and all of them filled-in the questionnaire. The 47.7% of the FM reported to never use an UVR protective hat at work. The 38.1% of them never used UV filtering sunglasses on the boats. None of the workers reported to use. always, often or even sometimes, sunscreens at work. Only for the clothes we collected some positive responses: the 40% of the sample wore often protective clothes (Table 2). After one year from the sun safety training we contacted all the 21 fishermen via phone, asking them the same questions related to the frequency of adoption of solar UVR individual protections at work.

Table 2: Results of the subjective investigation on the frequency of adoption of solar UVR individual protections at work among 21 fishermen

Individual protecions against solar UVR				
Frequency of adoption on a 5-point Likert scale	**Fishermen adopting the individual protection: % (n)**			
	Protective hat	UV filtering sunglasses	Protective clothes*	Sunscreens
ALWAYS	14.3 (3)	14.3 (3)	15 (3)	0
OFTEN	19 (4)	9.5 (2)	40 (8)	0
SOMETIMES	19 (4)	14.3 (3)	25 (5)	0
SELDOM	0	23.8 (5)	15 (3)	19 (4)
NEVER	47.7 (10)	38.1 (8)	5 (1)	81 (17)

1 answer was missing

In order to better appreciate the differences between the answers given before and after the training, we grouped together as positive responses the answers "always", "often" and "sometimes" and we analyzed the percentage of FM who reported to adopt UV protections at the baseline and one year after the sun-safety campaign (Fig. 2). After the sun-safety interventions there was an improvement of the 9.6% for the use of UV protective hat at work, of the 28.5% for the use of UV filtering sunglasses (with a significant difference at the non-parametric McNemar statistical test for paired nominal data, p=0.031) and of the 5% for the wearing of UV protective clothes. No improvements have been found for the use of sunscreens at work by the fishermen (Fig. 2).
Figure 2: Use of individual solar UVR protections at work before and one-year after the sun-safety training in a group of 21 fishermen.

4. Discussion

Our results on personal solar UVR exposure measured in a group of dockworkers and fishermen of North-East Italy show remarkable high UV exposure levels. For FM we collected measures in late spring, while for DW in summer: not surprisingly, the exposure levels we detected resulted higher in the case of DW. Nevertheless, even if the two days of the measurements campaign for the FM were partially clouded spring days, we registered, in less than five hours on average, an exposure above the equivalent of a Standard Erythemal Dose (SED, i.e. an UVR personal

exposure able to induce an erythema in an individual, adjusted for skin pigmentation, and corresponding approximately to 100 J/m^2) in all but two FM, with a maximum exposure of more than 5 SEDs/day. This indicates a very high risk of acute skin burns, and, considering the photochemical accumulation of UV-induced damages, may also represent an increased risk for long-term adverse health effects, in case of exposures prolonged over years. Considering the specific work tasks, the FM were involved in three different types of fishing performed on three different boats. We collected the highest exposure levels on the smallest boat, with almost no coverage from the solar UV rays, dedicated to an activity (sea snails and cuttlefish fishing) performed almost always in direct sunlight.

Considering now the DW, also in this case we measured different solar UVR exposure levels depending on the specific type of work activity performed. We registered higher solar UVR individual levels for longshoremen compared to traffic coordinators. The personal UV doses collected for LSM, in the 90% of the cases with dosimeters placed on their upper back, varied between 2.6 SED/half-day and 20 SED/day. Also, for the LSM investigated with a chest dosimeter we registered a quite high exposure of 5.5 SED/half-day. Considering dockworkers employed as TC, we had to place the dosimeters on their chests, as they frequently had to be seated at a desk inside a small cabin office, therefore performing also partially indoor activities. For TC we measured exposures between 0.4 and 1.4 SED/half-day.

Discussing now the relations between individual and environmental solar UVR skin exposure, we found quite high variability both in the results related to FM and in those collected for DW. This variability is not surprising and reported also in other studies of personal solar UVR eposure measurements in outdoor workers [14,23–28]. It can be related to the different working postures adopted by the workers and to other factors, as the sun-angle on the horizon, the distance from reflecting surfaces (e.g. water) and the presence of shading structures: accordingly, the exposure of different body districts can change during the day in relation to the ways the activity is performed and to the environment. Percentages of individual vs. environemtal UVR exposure varied between the 4.6 and the 65.3% for FM, 20.6% on average including only data retrieved for dosimeters placed on the backs. For longshormen, the average percentage of ambient exposure received at the workers' backs was of 31.9%, with a maximum of 59 and a minimum of the 20%, dropping to the 16% considering the LSM with a chest dosimeter. It should be noted a lower variability of the results related to the solar radiation exposure of dockworkers employed as port traffic coordinators compared to fishermen and longshoremen. A possible reason is that the activity of the TC is less dynamic compared to that of the other groups: for these workers we found a percentage of personal vs. ambient exposure between the 2 and the 7%, almost stable and quite low, considering that the dosimeters in these cases were placed on the chest and that some working tasks of the workers were performed in an indoor area.

As regards to the results of the investigation on solar UVR individual exposure habits and behaviours before and after a specific sun-safety training, first of all it should be noted that, to the best of our knowledge, this is the first reporting of a sun safety initiative specifically addressing fishermen. As reported also by similar studies performed in other groups of outdoor workers [16–20], our results indicate poor protective habits and behaviors of fishermen, in particular before the sun-safety training. After our intervention, we observed a slight improvement related to the adoption of three specific individual protections: the UV protective hats, sunglasses and clothes, with an increased percentage of fishermen who reported to use, at least sometimes, these protections at work. This is still far from an adequate perception of the risk, as even after our sun-safety campaign approximately the 35-40% of the workers never or only seldom reported to use hats and sunglasses at work, while more adequate habits have been reported for protective clothes. Unfortunately, our intervention apparently failed in raising the awareness of the group of fishermen on the importance of applying sunscreens at work: this is a relevant point, and we should reflect on what can be the issues in achieving the goal of a more widespread use of sunscreens at work. Some possible problems may be related to the quite high costs of the sunscreens, in particular considering that they have to be abundantly applied and re-applied during the work-day, and to the fact that, at least in Italy, these costs are usually not covered by the companies. Nevertheless, it should also be noted that sunscreens can't be considered personal protective equipment as UV protective hats, sunglasses and clothes, but they are an additional protective measure to be adopted in case the other personal protections can't be considered sufficient to limit the exposure.

Our study also has some limitations: first of all, the sample size, in particular in the case of the fishermen, where we collected solar UVR exposure data of only seven workers: nevertheless, having followed the workers for two days, and in some cases with two dosimeters per worker, we retrieved a total number of nineteen point measurements, i.e. even more measurements compared to the campaign performed at the port, where we investigated fourteen dockworkers in only one day. Also, for the subjective investigation of solar UVR exposure habits and behaviours the sample of twenty-one subjects can be considered of a quite small size: in this case, a relevant point, possibly reducing the limitation, is that we were able to re-contact all the investigated workers after one year, and accordingly our analysis of the changes in protective behaviours after our sun-safety training resulted more valid.

A further limitation is related to the estimate of the environmental UVR doses for the measurement campaign in the fishing company. Unfortunately, we performed ambient measurements with an UVR spectro-radiometer only at the harbour, where it was possible to safely place the instrumentation in a stable site. This was not possible on the small boats of the fishermen, so that we had to retrieve environmental data from an online database, and estimate the corresponding dose in the period worked by the fishermen. Moreover, in the database we selected there was no availability of ambient data referred to the place where we actually performed the measurements (43° 9' N, 12°7' E), so that we considered available data for the city of Venice (about 200 km in the northern-east direction, at a slightly higher latitude and similar altitude).

Finally, we want to mention also some possible limitations related to the placement of the dosimeters on the workers. Unfortunately, we were not able to "a priori" select the most appropriate body districts where to fix the dosimeters according to the specific working tasks of the workers with respect to solar UVR

exposure. On the contrary, as this was an on-field measurements campaign during real working situations, we had to place the dosimeters in positions selected as the best compromise between an appropriate evaluation of the personal exposure and the need of not interfering with the usual job activities of the workers. Accordingly, we decided to place the dosimeters mainly at the upper back for fishermen and dockworkers employed as longshoremen, while at the chest for the dockworkers performing as traffic coordinators of the port area. In the few cases we had for the same workers both the data from the back dosimeter and the data from other body districts (chest, and in one case also the nape), the upper back resulted the district with the highest exposure levels.

5. Conclusions

In conclusion, our data are, to the best of our knowledge, the first Italian data demonstrating with on field measurements an intense solar UVR dose received by fishermen and dockworkers in the spring and summer seasons. According to the photo-chemical effect of the UV rays absorbed in the skin, these data indicate an excessive occupational risk, possibly resulting after years of work in an increased occurrence of skin pre-cancerous and cancerous lesions. Therefore, there is an urgent need of sun-safety campaigns for outdoor workers, in particular for those of the maritime and port sectors, as we found no previous reporting of such campaigns for these workers in scientific literature. We offered a sun-safety training to the workers we investigated with dosimeters for their personal solar UVR exposure. Before the training, workers reported very poor sun exposure habits and behaviours. After our training, fishermen reported an improvement in the use of individual UV protections, as hat, sunglasses and clothes. Unfortunately, no positive improvements have been found with respect to the use of sunscreens at work in these workers.

Conflict of Interest

The authors declare no conflict of interest.

A B S T R A C T

European counties continue to receive an increasing number of migrants and refugees from an also increasing number of both European and non-European countries. This results in a huge societal challenge which is societal inclusion of people speaking different languages and of diverse backgrounds. Key for their inclusion is job finding which comes with hurdles like the language, the difficulty in assessing and certifying their skills and many more. In this paper, we present the architecture of a novel platform that aspires to provide migrants with a) assistance in discovering and assessing their hard and soft skills by employing Artificial Intelligence technologies, b) recommendations of appropriate job sectors and positions based on their profile, c) recommendations about training that would allow them to find jobs in the country/region they are located and d) practical information regarding the integration process. Furthermore, the proposed platform aims at assisting host authorities, non-governmental organizations and companies in detecting the needs of the target populations (migrants and refugees) through data analytics and supports them in reaching them. Apart from the technical architecture, we provide the results from the initial testing of the platform in real-life pilots in two countries.

1. Introduction

The current trend of migration for economic reasons combined with large flows of refugees ("people fleeing their countries due to armed conflicts or persecution") challenges our societies. A key to societal inclusion of migrants and societal coherence is their integration in the labour market. Nevertheless, the elaborate human resource recruitment processes established in our economies make it difficult and complicated not only for the migrants but also for host organisations, according to the claims gathered through interviews with field experts. The main barriers (also discussed in [1]) are multiple: a) lack of professional qualifications and certified skills and competences; b) language skills are impeding fluent communication and this is even more intense for refugees; c) the scale of the phenomenon which is large and increasing: over a million refugees in Europe since 2015, 70% of them with ages between 18 and 64, i.e. in working age and low-skilled people percentages greater than the average of the hosting countries' [2]. Refugees and migrants are a heterogeneous group

as far as education and other issues are concerned and thus, special vulnerabilities have also an impact on individuals' labour market integration chances.

In the host societies, there are organisations (public, private or Non-Governmental Organisations) that try to assist migrants and refugees in finding their way to the labour market. However, two factors limit the positive impact of these efforts to a certain extent: a) the multiplicity of entities operate usually with no coordination among them and b) the fact that the potential employers have to follow stricter regulations when hiring migrants and also have to afford the cost for screening their skills and profiles at the absence of any certificate and/or proof. At the same time, tailored training is considered of paramount importance to increase the probability of employment of refugees and migrants according to the Committee for Labour Migration [3]. Soft skills are also important and should not be overlooked. The new recommendation on Key Competences for Lifelong Learning [4] has enhanced the importance of key competences and soft skills, which are considered as equally important to hard skills when looking for a job. The evaluation of the soft skills is also difficult to be

*Corresponding Author: Helen Leligou, Email: leligou@gmail.com

performed imposing further barriers in the integration of migrants in the labour market.

The exploitation of Information and Communication Technologies (ICT) is considered an appropriate mean to communicate with the migrants and refugees as they usually have access to the internet usually through mobile devices. ICT technologies could also contribute to personalization of the information presented to the users. However, up to now, ICT has been used mainly for information provisioning which is valuable but yet not enough. As a result, the integration of migrants and refugees is still a challenge for all involved actors i.e. migrants, refugees, host authorities, NGOs, private and public organisations and society alike.

In this article, we present a novel digital platform that aspires to support not only migrants and refugees but also the host authorities and organisations towards the integration of the first group in the labour market. The proposed platform employs state-of-the-art technologies like artificial intelligence and data analytics to lower the cost of skills evaluation, facilitate the operation of organisations and significantly shorten the path of migrants to the labour market. In its design, we have combined Artificial Intelligence, data analytics, native mobile applications and web technologies with social science expertise and skill assessment techniques to offer a novel holistic platform to the migrants. The proposed platform is not a "bundling" of functionalities like the ones offered by multiple other platforms; instead, it offers novel functionalities like the skill assessment functionality based on machine learning algorithms trained on data from migrants' populations. The proposed platform has been prototyped and used by migrants/refugees in real life.

The rest of this article is organized as follows: in section 2, we present existing digital platforms tackling the migrants' integration challenge and discuss their strengths and weaknesses. In section 3 we describe the proposed platform, and its technical architecture is presented in section 4. Section 5 presents the results from the evaluation in real life and section 6 concludes the article. A preliminary version of the presented approach was initially published in [1] without technical details and any evaluation results.

2. Existing Platforms

Up to now, few tens of platforms primarily targeting the needs of the migrants/refugees have been deployed exploiting the fact that the majority of them has access to the internet through their mobile phones. The following table is based on the table that appears in [1] and reflects the current situation. The fact that such platforms proliferate, show that they cover actual needs and thus the involved actors try to satisfy them. The table includes the information considered necessary for their comparison.

Examining the table, it is evident that there is no platform adopting a holistic approach. Most of these platforms present to the user information but the supported functionalities of search and the limited languages reduce their actual value. Just one of these platforms supports skill assessment and this targets a limited set of job sectors. This is mainly due to the language barrier which is difficult to overcome with any textual-based assessment. As explained in [5], there are methodologies to assess skills and competencies, but they are mainly twined with the education processes which is not a representative case for the migrants arriving in a new country. The use of neural networks has been proposed in [6] in the context of assessing skill of surgical doctors. With respect to digital tools, they usually evaluate performance in a normative way after the user has completed an exercise. In many cases, this is not possible without the subjective scoring of an external evaluator.

To sum up, guidance through the path from arrival to labour market integration is provided in a rather segmented way by existing platforms. Having a unique platform offering all these services through a single point and having a digital companion guiding the user through it would be of high value.

Table 1: Online platforms for migrants

3. The Proposed Solution

We have designed a novel platform which has multiple target groups: a) refugees which are seeking for asylum, b) migrants who are seeking a better life, c) vulnerable migrants (e.g. suffering diseases), d) host authorities which are trying to improve their offerings and facilitate the integration of migrants and refugees, e) non-governmental organisations and f) organisations that consider migrants as receivers or target groups of their services.

For the users falling under the first three aforementioned categories, we aspire to assist them in preparing effective job applications and in finding appropriate positions to apply. For local people, finding a job consists primarily of three steps: as shown in Figure 1 below: 1) inspect available job positions which is usually done through a web-based job position portal or a professional social network or (more rarely) through a Human Recruitment agent; 2) filter the jobs and select those of interest to apply. Language is not a barrier for locals and the creation of a CV or an application is usually not an issue. 3) go through (one or more) interviews or follow the recruitment process of the specific organization where again, in principle,communication and specific aid is not required, although ways to maximise the potential of getting the job exist and are gaining momentum, as shown in Figure 1. For migrants and refugees, each of these steps represents a challenge: accessing the job announcement, understanding them (due to language barrier) and selecting some of them are of great difficulty. Often the CV format is not familiar to them, and usually their qualifications are not certified since they are gained via informal and nonformal experiences.

Figure 1 shows the process of labour integration without the proposed platform on the left (marked as a) and with the functionalities offered by the proposed platform on the right. As shown in the right (figure 1b), the 1st step is completely changed and automated by the proposed platform:

1. to prompt the selection of job position and relieve the migrants from searching in relevant portals which they may not be aware of, the platform prompts them to fill in their skills and profile.

2. Additionally, the platform prompts them to answer dedicated questionnaires which enable the evaluation of soft and hard skills. Artificial intelligence technology is used to evaluate the skills through these questionnaires as it will be elaborated in the next section.

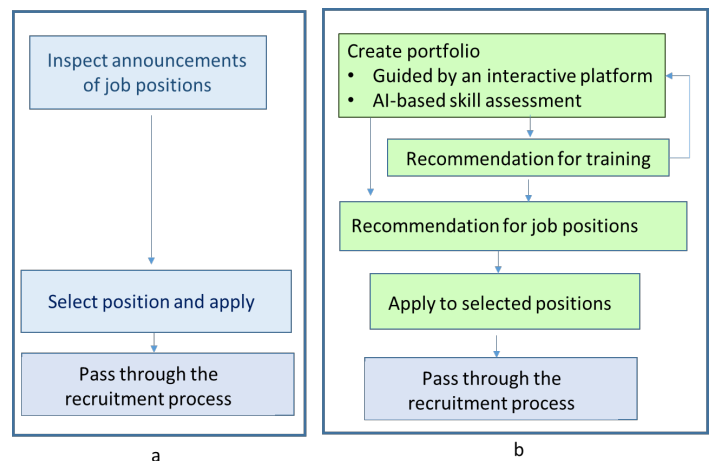
3. As many refugees and migrants do not possess certification of their qualifications, the platform supports them in entering other types of proofs (e.g. images or videos). The proposed platform offers to them guidance through a wizard (step-by-step approach) and also provide videos to help them create their portfolio.


Figure 1: The path to the labour market now (shown in (a)) and with the proposed intervention (shown in (b), on the right)

Once the profile and skills are registered, the user is provided with

- Personalized recommendations about the job categories he/she is appropriate for, based on the definition of skills relevant to each occupation or more specifically to the ESCO code, i.e. to the code of the occupation category in the multilingual classification of European Skills, Competences, Qualifications and Occupations [7].

- Recommendation of additional training modules which would significantly improve their potential for getting a job. For example, assuming a user has a set of certain skills and according to these skills he matches job category A. If a skill is also needed for this job category, then a training that leads to the improvement of this skill is suggested to the migrant. This way, the migrant/refugee becomes aware of opportunities to maximise their potential for being hired.

- Once this is done, the migrant/refugee is ready to get from the proposed platform a list of job positions related with the job categories he is appropriate and then (if the wishes) to apply (e.g. send his CV created in the previous step).

To facilitate the migrants/refugees life easier, a conversational interface (a chatbot) is integrated in the platform. The proposed chatbot and the whole platform support multiple languages as it is crucial for the migrants and refugees to easily find the information they are looking for in their native language and understand the results of their activities.

Turning out attention to the rest target user groups mentioned at the beginning of this section and to offer them valuable assistance, we have designed the platform so as to represent a single-point-of-entry for them with regards to information about refugees/migrants flows, demographics of the migrants' population per country, statistics about their needs and skills as well as the means they find more useful for finding a job. For these groups, once they have set a concrete goal, (e.g. assist vulnerable migrants in finding jobs), they need as accurate information as possible and as fast as possible because the resources that can be devoted are scarce. The proposed platform essentially aggregates information and presents it to the users (indicating of course the source of the information) in an easy to understand way by employing data analytics.

Table 2: The offerings of the platform for the two target groups

Offerings targeting migrants
1. multilingual environment (English, Greek, French, Arabic, Spanish and Farsi)
2. Information about employment
3. Information about social integration
4. Skill assessment using a) Questionnaires and b) Serious games
5. Online training including a) Text, b)Videos and c) Self assessment questionnaires
6. Relocation recommendations based on the migrant's social needs
7. Recommendation of appropriate job categories (using ESCO classification)
8. Recommendation of appropriate job vacancies
9. Recommendation of trainings
10. Chatbot that is trained on the employment/social information and provides answers to migrants questions in many languages
Mobile app for foreign language learning and assessment
Tools for Host authorities, Companies and NGOs
1. Graphs and statistics about the skills of the migrants
2. Recommendations for the host authorities
Statistics regarding migration and employment in Europe

Additionally, to facilitate the task of organizations working with the migrants, the platform supports the organization of users (migrants) in groups. This way, if an organization wants to summarize the skills of a group they are managing/handling, the organization can ask the migrants to use the group identifier and fill in the skill assessment questionnaires. Then the organization can observe the statistics of the skills of this specific group and look for appropriate job positions and relevant trainings. This was considered a very valuable tool during the interviews we organized with such organisations.

To sum up, the major difference between the proposed method and the other in the literature is that no other platform adopts a holistic approach. The offerings of the proposed platform are summarised in the Table 2.

4. Technical Architecture

The technical architecture of the proposed platform is shown in Figure 2, where the distinction between the front-end components, the backend components and the repositories is clearly shown. The platform runs in a cloud environment. The front end is organized in two sets of components: a) those serving the migrants/refugees (shown on the left in green) and b) those serving Host authorities, Companies and NGOs (HCN) (shown on the right in orange). Both sets include a) a home page which is the landing page of the platform and is different per user groups once the user is logged in, b) an account page- here the user creates his/her profile inserting different information depending on the user type they belong and c) the "about" page where information for the platform, the services it provides and the way it handles the collected data is provided. In the account page, the host authorities, companies and NGOs insert their name, the services they offer and the geographical area where they operate (for example, health services in Athens). In the same page, if the user has entered as a migrant, the information collected includes personal information.

The interface for the migrants/refugees further includes: a) the "e-portfolio" component which guides step-by-step the migrant to fill in his/her skills and competences in a very user friendly way; b) the "chatbot" which responds to questions relevant to legal, social and health – it supports relevant questions in six different languages; c) the skill-assessment (SA) questionnaires which include multiple choice questions and questions requiring the association of elements (visual or textual); d) the recommender User Interface (UI) that offers recommendations for trainings and job vacancies and e) the social/career interface which offers general information about relevant issues.

The interface for the HCN group includes (apart from the three components already presented) a) the data analytics component through which the HCN finds information about the migrants' flows and needs as already described above, b) the group analytics, which presents to the HCN statistics about the group they manage and they have the rights to access (e.g. on the results from the skill assessment or their needs) and c) the social/career interface where they can upload pieces of information they consider of value to the migrants/refugees.

The back-end part is where intelligence resides. First of all, the component "neural network algorithms for skills assessment" implements artificial intelligence to evaluate a mix of thirty five hard and soft skills (like numeracy and communication) based on the serious games the migrants played. This component uses a model which has been trained with data that come from the local society. To improve the accuracy of the evaluation, we are using the platform to collect data from migrants and train the model with them to provide more accurate evaluation results.

The chatbot backend component is responsible for the processing of the information available to it (the migrants' question) by providing the appropriate answer. The proposed chatbot [8] is a Question-Answer oriented agent, capable of replying to migrant administrative service-related queries and it incorporates two different systems, a daily conversation agent
Figure 2: The technical architecture of the presented platform

based on the model released by Huggingface and an answer retrieval module. The latter initially searches for valid in regard to the user query documents, splits them into semantic paragraphs and then applies a BERT [9] fine-tuned model to finally reply to the user.

The methodology of initially splitting the document into paragraphs depending on the structure of the text, rather than directly forwarding the whole document to the model has shown improved results. Towards extending the chatbot's capabilities, aim is to further take advantage of paragraph embeddings during answer prediction, incorporating them online into the models. A challenge faced by this specific chatbot application is the support of multiple languages and more specifically the support of non-European languages like Arabic and Farsi which are spoken by significant percentages of the migrants and refugees arriving in European countries. As presented in [10] the most common countries of origin to Europe (Mediterranean) for 2019 is Afghanistan, Syria, Morocco and Algeria hence Farsi, Arabic as well as European languages (France Spanish and English) cover the vast majority of the migrant spoken languages.

The Data Analytics algorithms is the component that retrieves data from the repositories so as to present to the HCN information about migrants' flows and needs, as well as information about the performance and characteristics of each group they manage. Thus, it is connected to the data analytics and group analytics component of the front-end. More specifically, this module can display not only the skills of individuals but also the average skills of the entire group. As a result, each HCN is able to identify in an easy and user-friendly way the strengths and weaknesses of each group of migrants in order to offer to them tailored trainings based on their skills and competences.

Finally, the recommender system is responsible for the following functions:

a) it retrieves information about the migrants' social needs (which are declared by himself) and suggests relocation options. In order to identify the most suitable city for relocation, the recommender uses Quality of Life tables of European cities and correlates them with the user needs.

b) it retrieves information regarding the skills of the migrant/refugee and recommends appropriate ESCO job categories and job vacancies. More specifically, the recommender system includes 40 occupation categories, that are matched to all the second level of ESCO-classification, ensuring representativeness of all job categories that exist in the labour market. For every job category we set up thresholds that specific skills must pass in order to assign this job category to the specific user. For every job category the algorithm checks if the skill vector of the user (35 skills) passes the thresholds and if the result is positive then it returns the respective job category.

Additionally, the proposed platform suggests specific job vacancies to the users based on their recommended ESCO categories and location (city). The job vacancies are retrieved from job vacancies web sites and then each job title is assigned to one or more ESCO codes using the ESCO Web Services. The vacancy is considered suitable for the user if it is assigned to ESCO categories that have been recommended to the user. The recommender system allows the user to search for vacancies from a long list of European cities. However, the platform offers a personalized list of cities based the social needs matching (the top cities are the most suitable) in order to assist further to his relocation.

c) it recommends to the migrant trainings that would significantly improve his/her potential of being hired. The platform is equipped with training sessions designed for each of the 35 skills. Each session includes training material (text, video presentations) as well as testing and self-assessment activities.

d) it presents to host authorities evaluations of eight indicators (social, health and other defined by European initiatives) for different European cities. This way a mayor of city A could easily compare city A with other cities with respect of the eight considered aspects, check in which aspect(s) city A is lagging behind the rest of the cities and decide to proceed to implementing

measures to improve city A. For example, if city A has low evaluations in health services, the mayor may trigger appropriate actions and measures to improve health services in city A. With respect to the relocation options, it is worth providing an example: the platform prompts the migrant to declare their priorities with respect to their needs and takes them into consideration when the platform suggests to the migrant to relocate. This implies, that if a migrant has declared that health services are of premium importance, the platform will not suggest him to relocate to a city with low evaluations in health services.

To support this rich functionality, we have deployed a relational database which stores the data relevant to migrants and refugees (in one part) and relevant to HCN in the other as shown in Figure 2. To enable the communication between the repository and the frontend and backend components, a set of Application Programming Interfaces (API) has been developed.

Apart from the platform which runs through any browser and can also run as a web-based mobile app, we have considered the case where a native mobile application can be integrated with the platform. We assume a mobile application that allows the user to assess its reading and speaking competence in English or other EU languages. Having a native mobile application in place allows the evaluation of pronunciation apart from understanding. Although this application could include all the front-end interfaces of the platform, we have opted not to do so and we have kept it as different app to showcase that any relevant mobile app developed by a 3rd party, could be integrated with our platform and use the open API we have developed to include the results in the portfolio (upon specific minor modifications). Once the user interacts with the application and completes the assessment, the score (the level A1/A2, or other according to European qualification levels) is

stored as a hard skill in the repository. It is stressed that the platform supports the evaluation and storage of a set of hard skills, i.e. skills that are easy to quantify like proficiency in a language and a set of soft skills like communication and leadership which are often also called interpersonal skills. This information is directly integrated in the user's portfolio (and CV) and is considered when they seek for job recommendations. Similarly, if the recommender provides to the user a recommendation to improve his English-speaking competence, a mobile app developed for this purpose will be proposed. This app can be the one described above or any other app providing foreign speaking competence. Any training opportunity can be registered in the platform and suggested to migrants, if it fits their needs. The result from the training can be integrated in the e-portfolio and can be used during job recommendations.

In the following Figure 3, indicative screenshots of the platform are shown. In Figure 3a, the page where the user selects his type (migrant/refugee or HCN) so that the platform provides relevant information. In Figure 3b, the landing page of the migrants is shown while in Figure 3c the web page where the portfolio is created is depicted. Finally, in Figure 3d, the landing page of the HCN user is shown.

5. Evaluation in Real Life

The presented platform has been used in real life by migrants and refugees in two European countries receiving large flows: Spain and Greece. The piloting was organized in the framework of H2020-NADINE project. For the evaluation purposes, three different sub-groups of the first user group was considered: a) asylum seekers, b) recognized refugees and c) vulnerable migrants.

a)

b)

c)

d)

Figure 3: Screenshots from the platform: a) selection of type of user, b) the screen offered to the migrant, c) the page where the migrant creates their portfolio, d) the web page offered to the HCN type of user

They were invited in the premises of NGOs in these countries in small groups. They first watched a demonstration of the platform by a NADINE person which showed the different functionalities and then they were asked to use the platform and evaluate it through online questionnaires to have an objective and harmonized evaluation. The users spent two days in the premises of the NGOs. They also had the option to comment on the platform and the different pages and results they were presented with. The assessment targeted each functionality of the platform separately. The collected results and comments from the two-days tests and the 96 users were used to improve the platform. Further details on the evaluation activities, demographics of the users and details about the evaluation of each functionality can be found in [11].

The results from the real-life evaluation per functionality are shown in Figure 4. The users were asked to rate the functionalities in a 5-level Likert scale. The results showed that for e-portfolio and registration page, the "excellent" and "good" levels were scored by the majority of users. This is considered satisfactory as the proposed platform was used in Farsi and Arabic in the pilot tests. For the rest three functionalities, the results are slightly lower which comes as no surprise because any artificial intelligence-based component requires training. Up to now the AI-based components of the platform have been further trained based on limited datasets. We anticipate that as the platform is more and more used, we will use the data we collect to further train the AI-based components so that these provide more valuable results to the migrants and thus enhance their satisfaction. Namely, for the chat bot, 68% of users evaluated this as "average" and above. It is worth stressing that the migrants "talk" to the chatbot in Farsi and Arabic. Actually, for all functionalities (apart from the registration page), more than 66% of the users evaluate it as average and above. This shows that the platform, although it is currently in a prototype form, succeeds in satisfying the users. We anticipate that this first real time piloting results will help us improve the platform so as to beeter satisfy their needs. This also contributes to the sustainability of the platform. The "language assessment" functionality was tested through a mobile app which injected the results in the presented platform. This way the potential of integrating 3rd party applications was confirmed.
Figure 4: Statistics of the assessment results per component

For each functionality included in the figure, a set of 10 indices were evaluated including: "easy to use", "enjoyable activity", "meet my expectations", "comprehensive/clear", "time spending", "cover my personal needs", "easy to navigate", "overall aesthetics" along with some additional ones which are linked to the

specifics of each functionality. These results together with the comments received through free text questions are now used to improve the platform. A common observation was that higher levels of satisfaction were indicated by vulnerable migrants compared to the rest two categories of recognized migrants and asylum seekers. In the language assessment, the percentages of results do not sum up to 100% as a percentage of the pilot users did not test and thus did not rate the language mobile app.

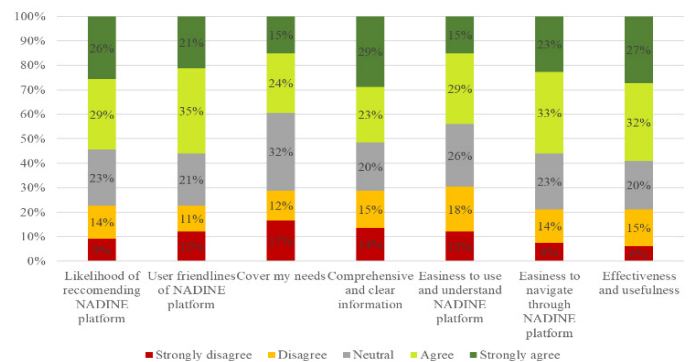
Moreover, and in order to evaluate the participants' overall experience from the platform, more specific aspects were also examined: Likelihood of recommending NADINE platform, User friendliness of NADINE platform, on which level the platform covers the participants' personal needs / requirements, How comprehensive and clear it is, Easiness to use and understand NADINE platform, Easiness to navigate through NADINE platform, Effectiveness and usefulness. All results regarding the evaluation of the participants' overall experience from NADINE platform are thoroughly demonstrated in the Figure 5. The result is very satisfactory, as the strong majority reports good experience for the platform which is currently in prototype level. Further details of the evaluation can be found in [11].


Figure 5: Statistics of the assessment results per component

Turning our attention to the host authorities, NGOs and private organisations, in this phase, ten (10) interviews were conducted. The main outcomes of the interviews were: a) finding information in a single point saves a lot of time for them as they have a clear picture of the situation in significantly shorter time; b) for NGOs working with migrants, the data analytics presented by the platform regarding the information relevant to the groups of migrants they work with was considered an extremely valuable tool; c) for host authorities, the most valuable functionality was the ability to see the sector (social, health, other) that they lack behind and also the ability to communicate with the migrants; for organizations working towards job finding for migrants, having in place a component that evaluates the skills in an accurate way for migrants and refugees is very valuable. They all consider the platform a valuable tool for their everyday job which creates the expectation that the number of migrants and of HCN users engaged with the platform will continuously increase. HCN actors considered that the deployment of a platform like the presented one requires funding from host authorities (regional or national) or EU-wide initiatives.

6. Conclusions

The societal inclusion of migrants and refugees passes through their integration in the labour market. A platform that supports all

their way to the labour market has been proposed in this paper. Its novelty lies not only in the fact that it does support them along the whole path but also on the fact that it exploits mature ICT technologies like artificial intelligence and data analytics to offer unprecedented experience to the users. Utilising artificial intelligence, a set of soft and hard skill are assessed through the platform. Through an appropriately designed user interface, the users are guided to create their e-portfolio. Based on this information, appropriate job sectors and concrete job positions are suggested to the users. The host organizations in turn enjoy mainly data analytics which offer them appropriate information facilitating their decision making. The offerings of the proposed platform prototype have been positively evaluated in real life in two countries receiving large numbers of refugees and migrants.

Quantium Medical, Research and Development Department, 08302 Mataró, Spain

A R T I C L E   I N F O

A B S T R A C T

The objective of this research is to study the behaviour of the anaesthesia monitor Conox during natural sleep to open the gate for this devices to assess subjects during this stage. The values of qCON and qNOX indices and EEG frequency bands are analysed during night sleep of 10 volunteers when they lose consciousness, in order to determine if they can be used for monitoring sleep. The possibility of using these indexes to differentiate between NREM/REM cycles of night sleep is studied. A reduction in the hypnotic index was observed while the nociception index stayed significantly higher. Statistical differences where found for qCON between sleep cycles, allowing this index to detect REM intervals and possibly opening the gate to use depth of anaesthesia devices to monitor sleep.

1   Introduction

This paper is an extension of work originally reported in 11th Conference of the ESGCO [1].

Sleep disorders such as insomnia, abnormal movements or behavior during night, and inability to control the sleep hours, can cause severe health problems such as depression or attention deficit hyperactivity disorder. Hence, sleep is widely studied in order to develop methods to detect these disorders by its monitoring. Some relevant laboratory tests for studying sleep disorders consists of an overnight polysomnography, measuring how fast the patients fall asleep and their attention for being awake as well as actigraphy [2]. Nowadays, there are commercial medical devices designed to monitor the level of consciousness during general anesthesia, allowing the anesthesiologists to individually tailor the administration of anesthetics. These devices monitor and process the electroencephalography (EEG) that is recorded by non-invasively locating electrodes on the forehead of the patient. The frequency and the amplitude of the EEG evolve because of changes in cerebral activity between wakefulness and sleep stages, and these variations can also be used to differentiate between the rapid eye movement (REM) and non-rapid eye movement (NREM) states of sleep. The energy of the EEG frequency bands Delta, Theta, Alpha, Beta and Gamma (from lower to higher frequencies) also varies between natural sleep stages according to literature [3], being the REM stage characterized by a decrease in the energy of low frequencies such as Delta band, and an increase in high frequencies as Beta and Gamma

bands. Previous studies [4, 5] have proposed to use EEG monitoring devices to measure also the natural sleep further than using them only for anesthesia assessment. In this work we analyzed the behavior of the anesthesia monitor Conox (Fresenius Kabi, Bad Homburg, Germany), during natural sleep. Sleep disorders such as insomnia, abnormal movements or behavior during night, and inability to control the sleep hours, can cause severe health problems such as depression or attention deficit hyperactivity disorder. Hence, sleep is widely studied in order to develop methods to detect these disorders by its monitoring. Some relevant laboratory tests for studying sleep disorders consists of an overnight polysomnography, measuring how fast the patients fall asleep and their attention for being awake as well as actigraphy [2].

Nowadays, there are commercial medical devices designed to monitor the level of consciousness during general anesthesia, allowing the anesthesiologists to individually tailor the administration of anesthetics. These devices monitor and process the electroencephalography (EEG) that is recorded by non-invasively locating electrodes on the forehead of the patient. The frequency and the amplitude of the EEG evolve because of changes in cerebral activity between wakefulness and sleep stages, and these variations can also be used to differentiate between the rapid eye movement (REM) and non-rapid eye movement (NREM) states of sleep. The energy of the EEG frequency bands Delta, Theta, Alpha, Beta and Gamma (from lower to higher frequencies) also varies between natural sleep stages according to literature [3], being the REM stage characterized by a decrease in the energy of low frequencies such as Delta

Figure 1: Mean qCON and qNOX for all volunteers from 15 minutes before loss of consciousness (qCON=60) until 4 hours after.

band, and an increase in high frequencies as Beta and Gamma bands. Previous studies [4, 5] have proposed to use EEG monitoring devices to measure also the natural sleep further than using them only for anesthesia assessment. In this work we analyzed the behavior of the anesthesia monitor Conox (Fresenius Kabi, Bad Homburg, Germany), during natural sleep.

2 Methods

In order to obtain the evolution of both anesthesia indexes during natural sleep, 10 volunteers were accepted for this study and agreed to be connected to a Conox device during one night sleep. Signal registration started a few moments before the subject falling asleep and lasted for at least six hours. As an indicator for unconsciousness, the same threshold as in clinical practice during a surgery was used, being a qCON value of 60. A Mann-Whitney U test and also a paired Wilcoxon test were performed in order to analyze if there was significant difference between the two indices. Instants of both indices falling below different thresholds (90, 80, 70 and 60) were also computed in order to know the time decay of each index when the subjects are losing consciousness.

From the EEG signal recorded we analyzed the spectrum in five frequency bands: Delta (0.5 - 4 Hz), Theta (4.5 - 8 Hz), Alpha (8.5 – 13.5 Hz), Beta 1 (14 - 20 Hz) and Beta 2 (20.5 - 30 Hz). Beta energy has been divided in two separate ranges for a better differentiation of the behavior of each frequency since the whole Beta range is very wide. The energy was calculated applying the Fast Fourier Transform (FFT) on 2-seconds EEG windows with overlap of 1 second. The FFT was normalized by the energy contained between the 0.5 and 30 Hz range. A 60 samples moving average smoothing filter was applied for a better visualization of the results, and the mean value of each frequency band was calculated during awake and asleep stages. It was considered that patients were awake when the qCON value was above 60, and asleep otherwise. To determine if there were significant differences between the values of the frequency bands between sleep and awake stages, a Wilcoxon signed rank test was used, at significance level of 0.05.

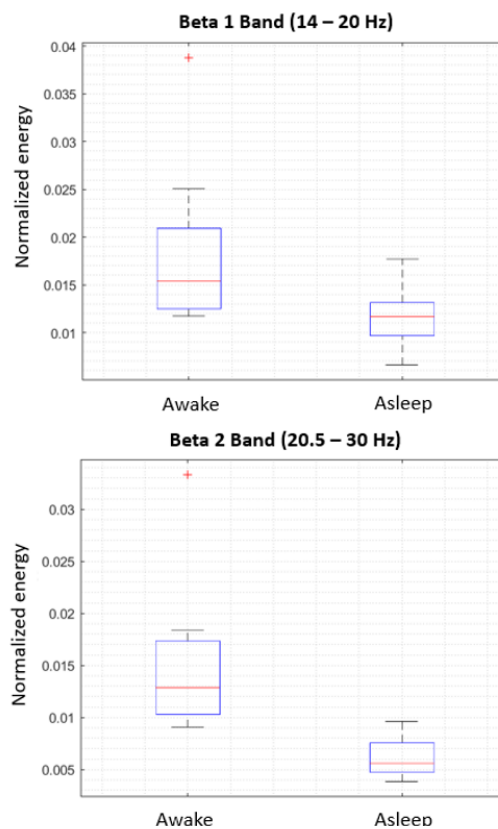
Taking into consideration the variation of energy in high and low frequencies, to distinguish between REM and NREM stages, we proposed an adaptive threshold for Delta and Beta 2 energy based on a preliminary data analysis which indicated that these frequency bands are the most affected by the transition between sleep stages. Delta threshold is calculated as the 80 % of the difference between maximum and mean energy values during the last 3600 seconds of recording. Beta 2 threshold is calculated as the 80 % of the difference between mean and minimum energy values during the last 3600 seconds of recording. We considered that a REM interval was detected when Delta energy was below the threshold and Beta 2 energy was above it, short intervals being less than 5 minutes were not considered.


Figure 2: Boxplots of Beta 1 (above) and Beta 2 (below) bands during awake (qCON $\geq$ 60) and asleep (qCON < 60) stages. On each box, the central mark is the median, the edges of the box are the 25th and 75th percentiles. The outliers are marked with a +.

We studied the values of qCON and qNOX during the REM and NREM stages previously identified, and we performed a Wilcoxon signed rank test, at significance level of 0.05, for comparison of the indices.

Table 1: Column 1 shows the mean value ± standard deviation of the qCON for each volunteer when below 60 and column 2 shows the corresponding mean value of qNOX when qCON is below 60. The last column shows the difference between the mean values of qCON and qNOX. The last row indicates the mean and the standard deviation for all volunteers, where qNOX has significantly higher values as compared with qCON. (*p-value = 0.002)

ID	Mean value qCON<60	Mean value qNOX (when qCON<60)	qNOX-qCON
1	45.46 ± 6.11	62.36 ± 10.07	16.90 ± 11.78
2	50.02 ± 5.71	61.72 ± 7.34	11.69 ± 9.30
3	50.73 ± 5.87	61.93 ± 10.71	11.20 ± 12.22

9	N.A.	5.60	4.83	N.A.
10	14.85	11.15	8.72	N.A.
Mean all volunteers	7.14 ± 5.01	7.65 ± 4.46	6.43 ± 3.29	3.67 ± 2.24

3 Results

In Figure 1, average indices values across volunteers are shown and it can be observed that nociception (qNOX index) stays higher than consciousness (qCON index) during sleep. The differences between the two indices were statistically significant (p-value < 0.05, Mann-Whitney U test). In Table 1 mean values of both indexes

are compared when qCON is below 60 for every subject. Results confirm that qNOX was higher for all patients than qCON (p-value < 0.05, Wilcoxon paired test). Table 2 includes the differences of time decay between indexes, showing that qNOX takes more time to fall under all thresholds set than qCON, and in some case never decreases under those values.

The spectrum analysis of the EEG showed that the energy in the low frequency bands Delta, Theta and Alpha present no significant differences between awake and asleep stages (p-values > 0.05, Wilcoxon signed rank test). On the contrary, the energy from Beta 1 and Beta 2 did have significant differences and showed on average higher values while the volunteers were awake (Table 3). The difference in energy value of these bands for both stages can also be observed in Figure 2.

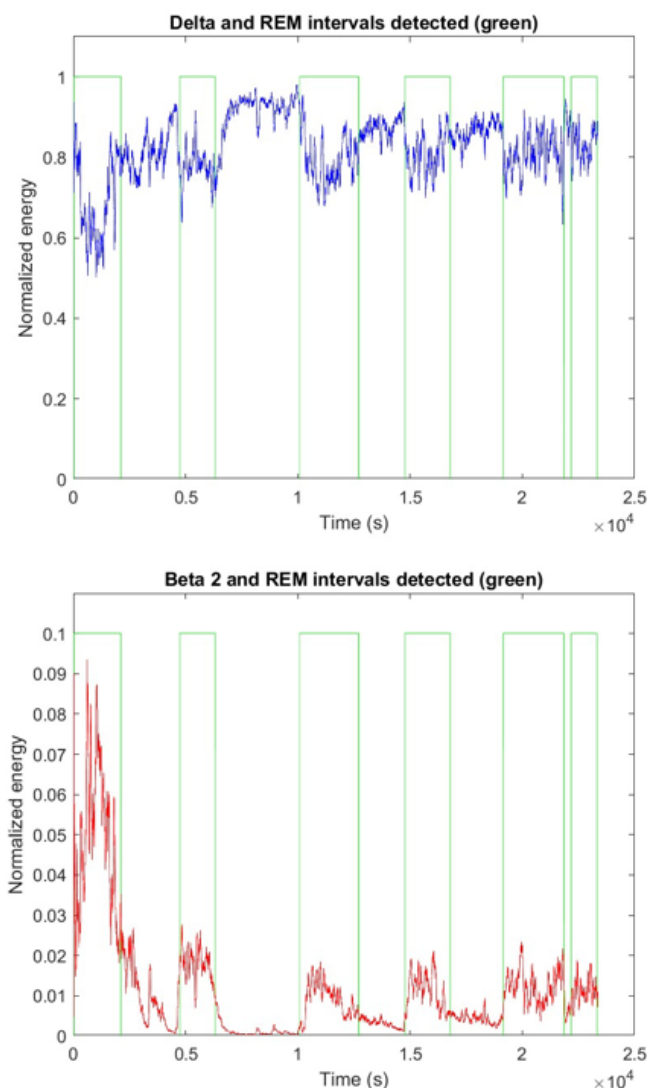
In Figure 3 we can observe the transition between NREM and REM intervals after applying the adaptive thresholds designed. It can be observed that these transitions occurred with certain periodicity during all recording.


Figure 3: Delta (above) and Beta 2 (below) energy from one subject. The transition between REM and NREM, which corresponds with the moment where the value of Delta and Beta 2 pass their respective thresholds, is represented with the green line.

Table 3: Mean ± standard deviation values of the five selected EEG frequency bands for the periods where the subjects are awake and when they are asleep. P-value is obtained from a Wilcoxon signed rank test, at significance level of 0.05.

	Mean value Awake (qCon ≥ 60)	Mean value Asleep (qCon < 60)	p-value
Delta (0.5 - 4 Hz)	0.856 ± 0.137	0.866 ± 0.122	0.625
Theta (4.5 - 8 Hz)	0.068 ± 0.071	0.069 ± 0.064	0.920
Alfa (8.5 - 13.5 Hz)	0.042 ± 0.054	0.047 ± 0.065	0.695
Beta 1 (14 – 20 Hz)	0.019 ± 0.023	0.012 ± 0.016	0.019
Beta 2 (20.5 – 30 Hz)	0.015 ± 0.020	0.006 ± 0.008	0.002

Table 4: Mean values of qCON during REM and NREM stages for each volunteer and Wilcoxon signed rank test between both sleep stages revealing statistically significant differences (p < 0.05).

qCON

9	72.23 ± 12.20	69.33 ± 8.64	
10	58.44 ± 6.95	68.08 ± 8.40	
Mean all volunteers	57.82 ± 11.24	64.81 ± 12.09	0.049

Table 5: Mean values of qNOX during REM and NREM stages for each volunteer and Wilcoxon signed rank test, no significant differences were obtained (p > 0.05).

qNOX			
ID	**Mean value NREM**	**Mean value REM**	**p-value**
1	65.94 ± 13.97	81.59 ± 13.49	
2	66.66 ± 10.77	77.21 ± 13.56	
3	75.08 ± 14.86	64.23 ± 14.50	
4	81.99 ± 19.66	71.14 ± 18.54	
5	70.77 ± 9.99	72.61 ± 11.74	
6	72.21 ± 11.26	77.65 ± 12.64	
7	64.13 ± 10.63	60.57 ± 12.77	
8	76.34 ± 8.30	79.67 ± 13.16	
9	88.38 ± 9.50	82.16 ± 10.70	
10	81.35 ± 6.72	84.28 ± 9.65	
Mean all volunteers	74.29 ± 11.57	75.11 ± 13.07	1.00

The results regarding the qCON and the qNOX values during the REM and NREM stages, previously delimited with the thresholds,

showed significant differences in qCON values between stages (p-value < 0.05, Wilcoxon signed rank test), which was not observed in qNOX values, as shown in Table 4 and Table 5 respectively. In the boxplot of Figure 4 there is a representation of the differences in the qCON values for REM and NREM.
Figure 4: Boxplot containing the values of the qCON index during the sections of NREM and REM of night sleep. On each box, the central mark is the median, the edges of the box are the 25th and 75th percentiles. The outliers are marked with a +.
Figure 5: Mean qCON and qNOX for all volunteers during NREM interval. The indices have been aligned at the beginning of NREM interval of each subject.

The trends of the mean qCON and qNOX values for NREM and REM are shown in Figure 5 and Figure 6 respectively. The data of the volunteers has been aligned at the beginning of the REM interval that was around 5000 seconds for all cases. It can be noted from Figure 5 that in NREM sleep qCON and qNOX decrease until the minimum in the first part of the recording and then slightly increase

in the last part, showing more variability. During REM sleep (Figure 6) qCON and qNOX time evolution decreases in the first part of the recording to a stable value that is maintained until the last part, where the index values are lower.
Figure 6: Mean qCON and qNOX for all volunteers during REM interval. The indices have been aligned at the beginning of REM interval of each subject.

4   Discussion

In this study it was found that qCON and qNOX indices behave differently during general anesthesia than compared to natural sleep. During anesthesia, anesthetic and analgesic agents are administrated to reduce both consciousness and nociception levels [6], whereas during night sleep, loss of consciousness is not accompanied by a similar nociception reduction.

Literature suggests that an increase in the energy of Beta is correlated with arousal during sleep [7], as higher values in this band are associated with an awake state. The increases in Beta during sleep found in this study could be related with sympathetic overactivity, which is associated with fragmented sleep [7].

Different NREM and REM sleep stages during natural sleep are characterized by changes in energy distribution in the frequency domain of EEG such as slow (Delta) and fast (Beta 2) oscillation patterns and also other physiological parameters. Indeed, in medical practice, polysomnography is considered the gold standard in sleep analysis because it takes into account several physiological signals such as electrooculogram (EOG) to identify rapid eye movements and electromyogram (EMG) to detect lack of muscular tone, which are characteristic physiological parameters of REM sleep [8]. Conox monitor performance is based on the processing of the EEG, hence it does not take into consideration as many parameters as a polysomnography. Despite that, from the results obtained in this study, qCON index has been able to correctly identify REM intervals

Other studies have been performed about depth of anesthesia monitors being used to monitor sleep since they provide real time EEG data that may be of some value for assessing sleep. A study performed with Sedline monitor (Masimo, Irvine CA) showed higher values during awake and the first parts of the sleep recording, as entering into deeper sleep stages the index of the monitor decreased considerably [5]. From the results obtained with the Conox it has been observed this same tendency, higher qCON values when awake and a decrease as the subject falls asleep. Nevertheless, qCON showed an increase during REM intervals, whereas the Sedline index continued at low values. Another sleep study performed with Bis Vista (Covidien, CO, USA) showed similar results than qCON during REM stage, with a mean (SD) BIS value of 75 (10) [9]. The mean (SD) value of qCON during REM interval was 64.81 (12.09), it is possible to differentiate this interval from an awake state where qCON values are higher.

In regard with nociception, qNOX index showed higher values during sleep than those observed in general anesthesia. Since qNOX index decreases with the administration of analgesic drugs, it could be expected to obtain higher values during sleep than in surgical procedures, where no analgesics are involved.

5   Conclusions

Analysis presented here allows to conclude that natural sleep is characterized by a reduction in consciousness which can fit into ranges similar to general anesthesia, especially during NREM sleep (qCON below 60), but that nociception (qNOX index) tends to remain higher, revealing that an asleep person can still respond to external painful stimuli. It has also been observed that when the subject is losing consciousness, the nociception index decreases slower than the consciousness index.

When studying the energy of the different EEG frequency bands, no significant differences were encountered in the low frequencies between the awake and asleep periods. Nevertheless, higher frequencies did show an increase in their energy when the subjects are awake.

By analyzing time series of energy contained in Delta and Beta 2 bands, one can identify cycles during night sleep. After studying qCON and qNOX indices evolution during these cycles, it can be concluded that qCON has greater values in REM intervals, whereas qNOX does not show significant differences between sleep stages. The significant differences of qCON values between NREM and REM cycles suggest that this index can also be used to differentiate these two stages of night sleep. The Conox monitor does not consider as many sleep parameters as the gold standard, polysomnography. Nevertheless, the present investigation is a preliminary study that might open the gate to use depth of anesthesia devices as Conox to monitor sleep, since it has proven to be able to detect the different sleep cycles by processing the energy of the EEG bands.

For future studies it would be interesting to consider a wider sample of patients, including some subjects with sleep disorders to observe differences in the results against healthy patients.

A B S T R A C T

Software evolution is one of the software process activities that occupies a major percentage of software development cost. Since requirements change continually and new technologies emerge, software should be adapted to satisfy these new changes to continue to survive. Despite software evolution being performed after software validation and deployment, software developers should predict at earlier stages how software would evolve in the future to avoid surprises. Although many works focus on how to enhance the program structure to facilitate maintenance tasks, only few works treat software evolution in earlier phases of software development process. In this direction, we propose an UML profile that permits to tackle software maintenance issues at the early phases of software development process. The proposed approach helps software developers to predict in design phase the kind of maintenance tasks that could occur in the future.

1   Introduction

According to [1], software evolves and changes continually in order to support new emerging technologies and satisfy customers and business needs. Some studies estimate that software evolution could reach more that 60% of software development total cost [2]. This issue pushes software engineering community to focus on how optimizing software evolution cost.

In fact, software maintenance cost varies depend on the kind of maintenance tasks that will be performed. For example, if the source code to be maintained is crosscutting among software modules, maintenance tasks performed on that source code are as well, the thing that could generate an extra cost. But, if the source code to be maintained is encapsulated in a single module, software maintenance applied to that source code is modular (less time and less cost).

Duality among crosscutting maintenance and modular maintenance motivates the community to provide solutions to keep software maintenance being modular. For example, some design patterns [3] and some program structuring/decomposition [4]–[8] facilitate software reuse and maintenance. But, even though some solutions could assure modular software maintenance, the challenge still existing since software maintenance could be modular for the same program with respect to a given architecture/structure but not

with respect to another. A such problem is known as tyranny of decomposition or expression problem [9] (see Sect. 3 for more details). To resolve this problem, many works ([10]–[14]) tried to attenuate the effect of tyranny of decomposition on software maintenance but results still relative and they treat this issue only in source code level.

In this paper, we illustrate how software developers could tackle software maintenance issues at the design phase of software development process. The early treatment and analysis of software maintenance tasks that could occur later permits to get a clear overview about how the program will evolve in the future. The main goal is to specify from the beginning the program structure that is more adaptable for future maintenance tasks. This could be realized by: first, identifying what kind of maintenance tasks is more probable to occur and then recommending the program architecture that is more adaptable to this kind of maintenance tasks. To concertize our approach, we define an UML profile that helps software developers to analyze and predict the kind of future software maintenance tasks that could occur.

The rest of this paper is organized as follows: first, we explore some related works (Sect. 2). Then, we give some explanations about tyranny of program decomposition problem. We show also how this problem affects modular maintenance (Sect. 3). Next, we present how we have defined *SEA* UML profile (Sect. 4). After that,

*Corresponding Author: Akram Ajouli, Department of Computer Science, College of Computer and Information sciences, Jouf University, Sakaka 2014, KSA , Contact No: +966547205946 & Email: asajouni@ju.edu.sa

we show how we validated *SEA* by applying some stereotypes in a real case study (Sect. 5). Finally, we resume our contributions and we propose some future works (Sect. 6).

2 Related work

In fact, this paper is an extension of the paper [15] (presented in the International Conference on Computer and Information Sciences (ICCIS) in 2019). In [15], the approach consists of proposing an UML profile called *MODEM* used to model maintenance tasks in design phase. This profile provides some UML stereotypes that permits to software developers to model and analyse maintenance tasks before occurring. The extension we propose in this work consists of adding more details and semantics to the previous work. We have modified some stereotypes, added new stereotypes and added tagged values in order to better analyse and predict in design phase future maintenance tasks that could occur. Further more, comparing to the previous work, we validate the extended UML profile by apply it to a real case study.

In [16], the author proposed a process of eight steps helping to supervise maintenance tasks that could occur later. Their approach simulates communications between stakeholders in order to design maintenance tasks, apply them and test software again before delivering the final version. In [17], the author proposed also an approach that aims to treat maintenance tasks in early phases of software development. They propose a software maintenance life cycle model that relies on a process of four steps. During this process, stakeholders interact between each other to study and analyze maintenance tasks to do in order to guarantee a consistent planning for performing maintenance tasks. The process is incremental and iterative and it stops when maintenance tasks analysis proves that software maintenance requests percentage becomes under a given threshold.

Although these works show a relevant contribution in planning maintenance tasks at earlier stages of software development, both of them involve different stakeholders to express needed maintenance tasks which could disturb software development process. In addition, maintenance issue is not expressed explicitly in models as we propose in our approach.

In [18], the author proposed an UML profile that permits to support requirements evolution. Their method is tool supported and consists of extending requirements engineering process by making it supporting requirements evolution. Although this approach facilitates requirements changes management, it still limited to specification phase. In our work, we focus more on design phase because we treat a problem which is related to software architecture rather than software requirements.

Some other works like [19]–[22] focus on analyzing and expressing design patterns explicitly at early phases of software development by defining the appropriate UML profiles. These works aim to enhance design patterns implementation comprehension for programmers since design pattern does not appear explicitly on source code. These works focus more on improving software comprehension rather than treating software evolution issue.

Some other works such as [13] and [23] treat maintenance issues in implementation phase by providing reversible transformations

among dual design patterns (composite and visitor) in order to keep maintenance tasks modular. In [24], the author proposed also a relevant approach that treats software maintenance issue in source code level. Their approach consists first of exploring the best machine learning techniques used for predicting software maintenance and then improving their performance. Although these works show important contributions in treating software maintenance issues, they still limited to implementation phase while we focus more on tackling this issue in earlier software process activities.

3 Background

We present in this section an overview about potential challenges that software evolution could face. One of the issues that could affect software evolution is tyranny of decomposition or expression problem [9]. In fact, although software modularity enhances program structure and facilitates software maintenance, a modular program structure could be biased to one kind of modular maintenance and not to another. A maintenance task is called modular when changes are mostly encapsulated in one module. Contrary to this, if changes touches many modules at the same time, the maintenance task is called crosscutting.

For example, Figure 1 illustrates a program composed of two classes *Circle* and *Rectangle* that extend an abstract class *Shape*. The program contains also two methods *print()* and *show()* which represent the business code of the program. The structure of the program is a base form of Composite design pattern in which each data type is encapsulated in a module. A such program structure decomposes the program with respect to data-types axis.

The decomposition of the program (Figure 1) permits to perform modular maintenance with respect to data-types. For instance, if we add a new shape (a Triangle for example) to the hierarchy of shapes shown in Figure 1, we first create a new class, then, we redefine the code of methods *print()* and *show()* only in this new class. In this case, the maintenance task is modular (low cost). But, if we add a new feature to the program (for example a method *color()*), we have to implement it in all classes which causes a crosscutting maintenance (extra cost). We deduce that the architecture of the program shown in Figure 1 allows a modular maintenance with respect to data-types and not with respect to functions (methods). Hence, the program structure is dominated by the data-types decomposition axis (a tyranny of decomposition according to data-types).

Another axis of decomposition of the program described above is illustrated in Figure 2. This program represents the Visitor design pattern implementation of the program shown in Figure 1. The Visitor pattern encapsulates each business code in a single module: the business code *print* is encapsulated in module/class *Print* and the business code *show* is encapsulated in module/class *Show*. This program structure decomposes the program with respect to functions which permits to add a new function without touching other modules: for example if we add a feature *color* to the program, we add a new class in which we implement this new feature for all shapes. Thus, Visitor design pattern permits to perform modular maintenance with respect to functions since it provides a functions decomposition axis.
Figure 1: Decomposition axis of a simple variety of Composite design pattern.

But, if we add a new shape to the program shown in Figure 2, many modules would be changed since the new shape should be visited by both *print* and *show* business codes. In this case, the program maintenance is crosscutting. We say that the program structure is dominated by functions decomposition axis (a tyranny of decomposition according to functions).

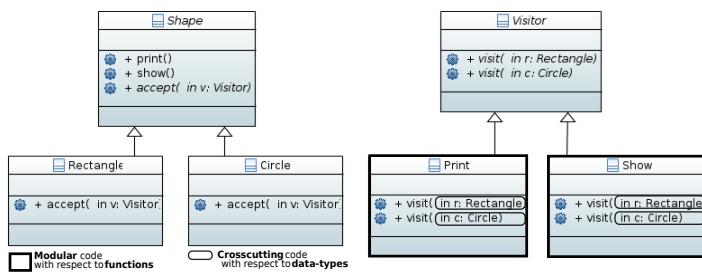
The above two examples explain well the problem of tyranny of decomposition. A such issue still always a main problem that affects software evolution. In this work, we aim to contribute in attenuating tyranny of program decomposition effect on software maintenance. Our target is to help software developers in analyzing and predicting in earlier phases of software development the kind of maintenance tasks that could occur later and in recommending the right architecture (decomposition axis) of the program that could keep maintenance being modular.


Figure 2: Visitor structure corresponding to the program shown in Figure1.

4 SEA specification

4.1 Overview

Many works have treated software evolution issue at the implementation phase. In this work, we tackle this issue in design phase of software development process. Since UML (Unified Modeling Language) [25] does not provide customized semantic constructs related to software maintenance, we propose an UML profile [26] that supports analyzing / predicting maintenance tasks that could occur in the future.

The UML profile we propose is called *SEA* (in short *SEA* for

*S*oftware *E*volution *A*nalysis) (see Fig. 3) . *SEA* is defined in Papyrus [27] EMF-based editor and it provides the following features:

- tracing software evolution history by adding some information to each software version. This feature could help to get an overview about maintenance tasks characteristics, the thing that could provide some recommendations about choosing the right program structure.

- studying and deciding which parts of a given software are more stable than others. This feature could help to predict at earlier phases the program structure evolution.

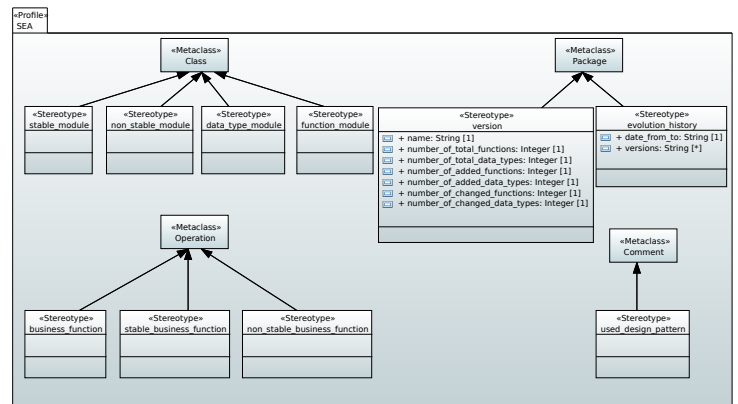
- expressing explicitly some semantic terms related to software maintenance in class diagrams such as data-type module, function module, composite design pattern...etc. This feature enhances software comprehension and helps to identify the decomposition axis of a given software.


Figure 3: *SEA*: an UML profile for analyzing software evolution.

4.2 Stereotypes for analyzing software modularity

Marking modular and crosscutting software parts. Modularity in software architecture helps to optimize software maintenance cost. It permits also to encapsulate concerns and minimize crosscutting concerns effect. Thus, expressing modularity concepts explicitly in models and diagrams helps software developers to explore at early stages of software development the decomposition axis that is dominant. This helps to recommend the right kind of future maintenance tasks that are modular and to avoid those which are crosscutting. In this direction, *SEA* permits to mark explicitly in class diagram which elements represent modular concerns and which elements represent crosscutting concerns.

Until now, *SEA* supports two concerns (or two decomposition axes): data-types concern and functions concern. In this context, we propose the following stereotypes:

- *<<data_type_module>>*: it extends the meta class *Class* and it is used to precise classes that belong to data-types concern when software architecture is built according to Composite design pattern.

- *<<function_module>>*: it extends the meta class *Class* and it is used to precise classes that belong to functions concern

and that encapsulate program business code when software architecture is built according to Visitor design pattern.

- <<*business_function*>>: it extends the meta class *Operation* and it is used to mark methods that contain program business code. It could be used especially in Composite pattern structure to show that business code is crosscutting among different modules. This feature helps software developers to be aware of the cost of maintenance tasks performed with respect to functions.

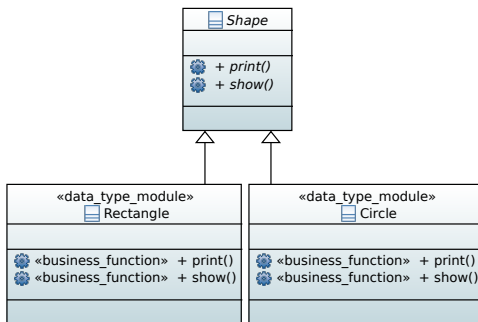
Fig 4 shows an example of how to precise explicitly modules/classes that belong to the concern data-types by applying <<data_type_module>> to class diagram. In the example, we see explicitly that classes *Rectangle* and *Circle* are marked as data-type modules. In the same example, methods *print()* and *show()* are marked explicitly as business code. This shows visually that business code is crosscutting among program modules which gives an indication that maintenance tasks performed with respect to functions are costly.


Figure 4: Use of *SEA* in marking modular data-types concern.
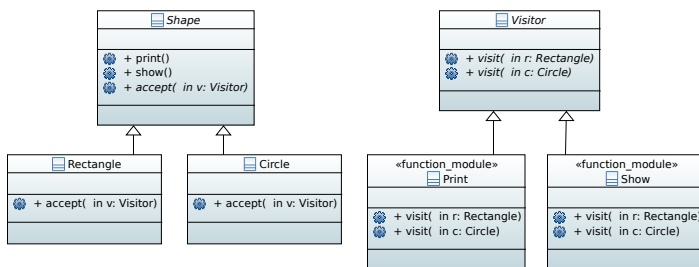

Figure 5: Use of *SEA* in marking modular functions concern.

Fig 5 shows how to use <<function_module>> stereotype to indicate that business code is encapsulated. This is used when the program is structured with respect to Visitor design pattern. We remark that classes *Show* and *Print* encapsulate respectively *show* and *print* business codes. The fact that these two classes are marked explicitly as functions indicates that software maintenance performed with respect to functions is not costly.

Precising modular program decomposition visually on diagrams helps to guide software developers to perform the right kind of maintenance that respects the existing concern. If they have to perform a crosscutting maintenance, they could be at least ready early to apply some tools or techniques that transform automatically the actual

architecture to another one that supports modular maintenance (for example using reversible transformations among Composite and Visitor [13]).

Marking stable and changeable software parts. In order to predict future software evolution at early stages, one should predict which software parts tend to change sharply. For this purpose, we propose the following stereotypes:

- **stable_business_function vs non_stable_business_function**: these two stereotypes extend the meta class *Operation*. The former is used to mark functions/methods that would not be sharply changed. The latter marks probable functions that could change drastically in the future.

- **stable_module vs non_stable_module**: these two stereotypes extend the meta class *Class*. The former is used to mark classes/modules that would not be sharply changed, or will have small changes that do not influence the software architecture. The latter marks classes/modules that could radically change.

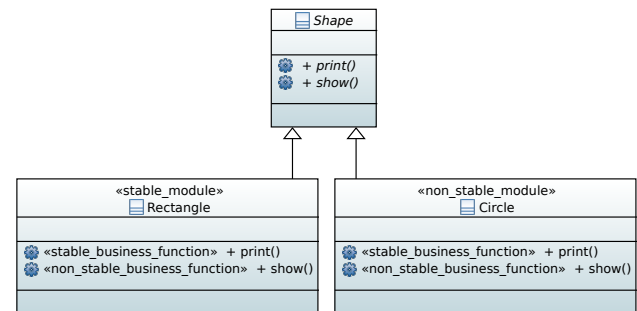
Fig. 6 shows how to apply stereotypes mentioned above to a class diagram. For example, after marking software parts as stable or non stable, one could identify which parts seems to be more stable than others. In case of finding that stable data-types modules number is greater than stable functions number, then, the decision could be biased to choose Visitor pattern as a future software architecture (since business code tend to change more than data-types).


Figure 6: Use of *SEA* in marking changeable and stable software parts.

4.3 Stereotypes for software evolution history tracing

With time, software evolution could cause software architecture degeneration [28]. So, having a backup for each version is necessary and helps to get back to the non degenerated version. This is already existing by saving old versions. In our approach, we propose the stereotype <<evolution_history>> (extends meta-class *Package*) which permits to precise explicitly on a package including all software versions that this package contains software evolution history. The proposed stereotype provides two tagged values: <<date_from_to>> and <<versions>>. The former is used to indicate visually the period of time during which versions included in a package stereotyped <<evolution_history>> are built. The latter is used to list all versions that are built in the period of time indicated by <<date_from_to>>. These tagged values permit to add valuable

visual data that could be used to assess the stability of software during a period of time.

Fig. 7 shows how to apply <<evolution_history>> stereotype: the package *software_X* (stereotyped <<evolution_history>>) includes three sub-packages that include respectively three versions of *software_X*.
Figure 7: Tracing software evolution with <<evolution_history>> stereotype.

The second stereotype that is related to software evolution history is the stereotype <<version>> which extends meta-class *Package*. It provides information about each version of a given software. It contains seven tagged values:

- *name*: version name

- *number_of_total_data_types*: total number of classes of current version

- *number_of_total_functions*: total number of methods of current version

- *number_of_added_data_types*: number of classes that have been added to the previous version to get the current version

- *number_of_added_functions*: number of methods that have been added to the previous version to get the current version

- *number_of_changed_data_types*: number of classes that have been changed to get the current version

- *number_of_changed_functions*: number of methods that have been changed to get the current version

Tagged values mentioned above permit to provide visual information about the behavior of software evolution. Getting a visual access to added classes and methods number during switching among software versions helps to get an overview about the recommended software architecture that could optimize maintenance cost. For example, if the percentage of *number_of_added_data_types* comparing to *number_of_total_data_types* is always greater than the percentage of *number_of_added_functions* comparing to *number_of_total_functions* and the current architecture is implemented with respect to Visitor pattern, then it will be better to switch the program structure into Composite pattern in order to keep maintenance modular with respect to data-types (see more details in Sect. 5).

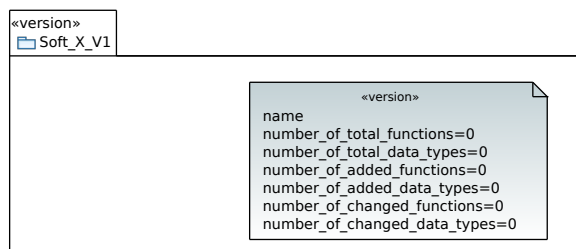
Fig. 8 shows how to apply <<version>> stereotype: the package *soft_X_V1* (stereotyped <<version>>) shows the seven defined tagged values that permits to note helpful information about software evolution behavior related to *soft_X_V1*.


Figure 8: Adding helpful information to a software version by applying <<version>> stereotype.

4.4 Visualizing design patterns

Many programmers face some difficulties when implementing design patterns. Thus, visualizing in design phase some information about the design pattern that will be implemented later orients programmers early to cover any lack of knowledge about the indicated design pattern. In addition, marking design patterns explicitly on diagrams enhances software comprehension.

Marking information about chosen design patterns on diagrams could also assist used techniques in design pattern detection [29] and provide relevant data for data analysis and classification.

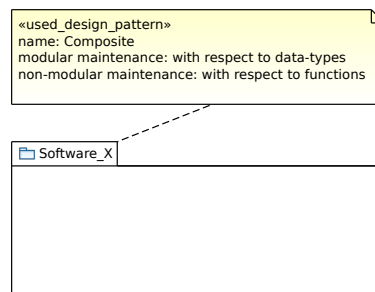
To reify this idea, we propose the stereotype <<used_design_pattern>> that extends the meta-class *Comment*. It could be associated to the package that includes the hole software project and indicates information about the chosen design patterns to implement. Provided information includes pattern name, pattern uses, modular maintenance tasks permitted, crosscutting maintenance tasks...etc. Fig. 9 shows how to apply <<used_design_pattern>> on comments.


Figure 9: Use of *SEA* in visualizing information about chosen design patterns.

5 Application of *SEA* on a real software

5.1 An overview about JHotDraw evolutions

We study the utility of *SEA* in analyzing *JHotDraw* [30] evolutions. *JHotDraw* is a framework for two-dimensional graphics used for structured drawing editors. It is implemented in Java and it is based on Erich Gamma's *JHotDraw*, which is copyright 1996, 1997 by IFA Informatik and Erich Gamma [31].

We define the following metrics to use them in the rest of this section:

- V_i: a version i of *JHotDraw* where $1 <= i <= 13$ (we study here 13 versions of *JHotDraw*)

- CNV_i: classes number in version V_i

- MNV_i: methods number in version Vi

- ACV_1: added classes number to version $V1$ to obtain version V_i

  $ACV_1 = CNV_i - CNV_1$

- AMV_1: added methods number to version $V1$ to obtain version V_i

  $AMV_1 = MNV_i - MNV_1$

- ACV_{i-1}: added classes number to version $Vi - 1$ to obtain version V_i

  $ACV_{i-1} = CNV_i - CNV_{i-1}$

- AMV_{i-1}: added methods number to version $Vi - 1$ to obtain version V_i

  $AMV_{i-1} = MNVi - MNV_{i-1}$

- $RACV_1$: rate of added classes number to version $V1$ to obtain version V_i

  $RACV_1 = \frac{ACV_1}{CNV_1}$

- $RAMV_1$: rate of added methods number to version $V1$ to obtain version V_i

  $RAMV_1 = \frac{AMV_1}{MNV_1}$

- $RACV_{i-1}$: rate of added classes number to version $Vi - 1$ to obtain version V_i

  $RACV_{i-1} = \frac{ACV_{i-1}}{CNV_{i-1}}$

- $RAMV_{i-1}$: rate of added methods number to version $Vi - 1$ to obtain version V_i

  $RAMV_{i-1} = \frac{AMV_{i-1}}{MNV_{i-1}}$

V_i	CNV_i	MNV_i
V_1	148	1229
V_2	208	1896
V_3	296	2723
V_4	301	2809
V_5	301	2809
V_6	343	2809
V_7	487	4234
V_8	463	4285
V_9	621	5486
V_{10}	638	5627
V_{11}	639	5582
V_{12}	669	5845
V_{13}	672	5885

(a) Classes number and Methods number of each version (data extracted from [32]).
(b) Evolution of *JHotDraw* classes number (CNV_i) during 11 years.
(c) Evolution of *JHotDraw* methods number (MNV_i) during 11 years.

Figure 10: Variations of classes number and method numbers during *JHotDraw* evolution.

The table shown in Fig. 10(a) illustrates *JHotDraw* evolution during 11 years. During this period of time, there were 13 versions of *JHotDraw* (5.2, 5.3, 5.4 b1, 5.4 b2, 6.0 b1, 7.0.8, 7.0.9, 7.1, 7.2, 7.3.1, 7.4.1, 7.5.1 and 7.6). We call here each version by V_i where $1 <= i <= 13$. The first column of the table mentions the version name (V_1, V_2,...,V_{13}), the second column mentions classes number in V_i (CNV_i) and the third column mentions methods number in V_i (MNV_i).

Like any software, *JHotDraw* is influenced by Lehman law [1] as shown by the shape of both curves of CNV_i progress (Fig. 10(b)) and MNV_i progress (Fig. 10(c)). We remark that classes number, which was 148 in V_1, increases to reach 672 in V_{13}, and methods number jumps from 1229 in V_1 to 5885 in V_{13}. Considering these evolutions, we apply some stereotypes of *SEA* profile to show its utility in analyzing software evolution during earlier stages of software process.

5.2 Using SEA to trace JHotDraw evolutions

To make *JHotDraw* evolutions easy to analyze in the design activity of software process, we apply stereotypes <<evolution_history>> and <<version>>. The former is applied to a package that includes all versions of JHotDRaw during 11 years and the latter is applied to each package that includes a version V_i of *JHotDraw*.

Application of <<evolution_history>> stereotype The target of applying <<evolution_history>> stereotype is to add information about the period of time in which *JHotDraw* versions are built and also about number and names of versions. This information is represented by defined tagged values that characterize the mentioned

stereotype.

Fig. 11 shows how <<evolution_history>> stereotype and its tagged values are applied. By using this stereotype, software developers could create a package that includes all versions of *JHotDraw* and marks this package as a special package to trace *JHotDraw* evolutions history. In addition, they could note information such as "date_from_to=2000_to_2011" and list different versions that has been elaborated during this period.

«evolution_history»
{date_from_to=2000_To_2011 , versions=[V1, V2, V3, V4, V5, V6, V7, V8, V9, V10, V11, V12, V13] }
JHotDraw_versions
Figure 11: Application of <<evolution_history>> stereotype to JHotDRaw.

In fact, the expressiveness provided by the stereotype <<evolution_history>> permits to assess the stability of *JHotDraw*. The stereotype <<evolution_history>> provides information about the rate of versions number of *JHotDraw* by a given period of time (here 13 versions by 11 years) which could evaluate the impact of *JHotDraw* evolution on total development cost. It motivates also software developers to focus on studying the switch from V_i to V_{i+1} and deduce lessons for future evolutions.

Application of <<**version**>> **stereotype**   As detailed in Sect. 4, the stereotype <<version>> has 7 tagged values. We consider here only *name*, *number_of_total_functions*, *number_of_total_data_types*, *number_of_added_functions* and *number_of_added_data_types*. For each version V_i of *JHotDraw*, software developers could apply the stereotype <<version>> to the package that contains V_i and they could assign a value to each tagged value. For example, Fig. 12 shows the main package that is stereotyped as <<evolution_history>> and inside of it the set of packages stereotyped as <<version>> that represent the 13 versions of *JHotDraw*.

«evolution_history»
{date_from_to=2000_To_2011 , versions=[V1, V2, V3, V4, V5, V6, V7, V8, V9, V10, V11, V12, V13] }
JHotDraw_versions

«version»
{name=5.2 , number_of_total_functions=1229 , number_of_total_data_types=148 , number_of_added_functions=0 , number_of_added_data_types=0 }
V1

| «versio..» V2 | «versio..» V3 | «version» V4 | «version» V5 | «version» V6 | «version» V7 | «version» V8 | «version» V9 | «version» V10 | «version» V11 | «version» V12 |

«version»
{name=7.6 , number_of_total_functions=5885 , number_of_total_data_types=672 , number_of_added_functions=4656 , number_of_added_data_types=524 }
V13

Figure 12: Application of <<version>> stereotype to JHotDRaw.

For each version V_i, we assume that software developers mark:

- name of the version (example: for version V_1, name is *5.2*)
- *number_of_total_data_types* (example: for version V_{13}, *number_of_total_data_types*= 672)

- *number_of_total_functions* (example: for version V_{13}, *number_of_total_functions*= 5885)
- *number_of_added_data_types* (example: for version V_{13}, *number_of_added_data_types*= 524)
- *number_of_added_functions* (example: for version V_{13}, *number_of_added_functions*= 4656)

5.3   *Utility of* SEA *in* JHotDraw *evolutions analysis*

As shown in the two last paragraphs, the application of stereotypes <<evolution_history>> and <<version>> adds explicit information about each version of *JHotDraw* (the thing that UML does not provide). This information makes packages that includes different versions being more expressive and informative about how *JHotDraw* (or any other software) evolves. This helps software developers to analyze easily the growth of *JHotDraw* at design phase and to take the right design decisions.

Let's assume a scenario in which a software developer analyzes information marked explicitly on packages that represents *JHotDraw* versions (each package is stereotyped as <<version>>):

***JHotDraw* evolution analysis scenario based on *SEA* application**   We associate to each tagged value a metric from those presented above:

- *number_of_total_data_types* is represented by CNV_i
- *number_of_total_functions* is respresented by MNV_i
- *number_of_added_data_types* is represented by ACV_1
- *number_of_added_functions* is respresented by AMV_1

The table shown in Fig. 13(a) resumes values that are calculated basing on data collected from packages stereotyped as <<version>>. It shows variations of $RACV_1$ and $RAMV_1$ for each version V_i. The curve shown in Fig. 13(b) visualizes the progress of $RACV_1$ and $RAMV_1$ during 11 years. We remark that in all versions $RAMV_1$ is greater than $RACV_1$ which means that the percentage of added methods in each version comparing to initial number of methods in V_1 is greater than the percentage of added classes comparing to initial number of classes in V_1.

The fact that $RAMV_1$ is always greater than $RACV_1$ during 11 years of *JHotDraw* evolution indicates that maintenance tasks are applied more on methods. We could deduce in this case that software developers should recommend to use Visitor design pattern if it is not already used in *JHotDraw*.

V_i	$RACV_1$	$RAMV_1$
V_2	0.4	0.54
V_3	1	1.21
V_4	1.03	1.28
V_5	1.03	1.28
V_6	1.31	1.64
V_7	2.29	2.44
V_8	2.12	2.48
V_9	3.19	3.46
V_{10}	3.31	3.57
V_{11}	3.31	3.54
V_{12}	3.52	3.75
V_{13}	3.54	3.78

(a) Rates of added classes and methods number in a version Vi comparing to first version of JHoDraw $V1$.
(b) Rates evolution of added classes and methods number in a version V_i comparing to first version of JHoDraw V_1.

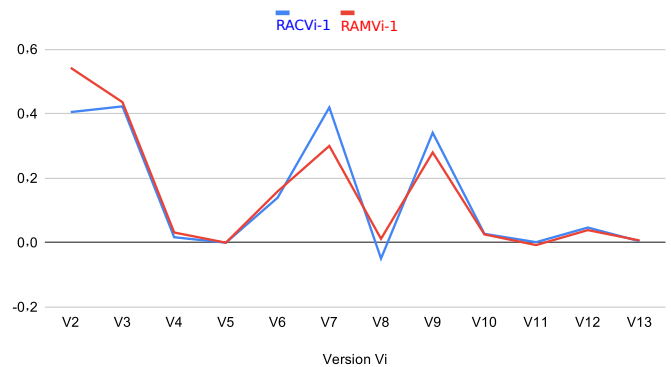
Figure 13: Study of Rates evolution of added classes and methods number in a version Vi comparing to first version of JHoDraw $V1$.

Let's now interpret evolutions from one version to its successor version. The table illustrated in Fig. 14(a) shows variations of $RACV_{i-1}$ and $RAMV_{i-1}$. We remark that $RACV$ of version V_2 is 0.4 and its $RAMV$ is about 0.54 which means that version V_2 of *JHotDraw* grows by 40% of V_1 classes number and 54% of V_1 methods number. Hence, maintenance tasks that switches V_1 to V_2 are applied more on methods (functions decomposition axis). This case occurs 5 times against 7 times in which maintenance tasks are applied more on classes (data-types decomposition axis). So, the switch from version to version shows that maintenance tasks change their behavior: they are applied 5 times with respect to functions decomposition axis against 7 times with respect to data-types decomposition axis. In this case, Composite design pattern seems to be the best choice for the future versions.

Lessons By analyzing *JHotDraw* evolutions as done above, we deduce that long-term evolution shows that Visitor design pattern is the best choice to optimize maintenance cost. But, variation in targeted decomposition axis due to the switch from version to version indicates that *JHotDraw* should change its architecture in order to keep maintenance being modular (software developers could use

automatic reversible transformations among Composite and Visitor each time they remark that maintenance tasks would change behavior when switching from version to version).

V_i	$RACV_{i-1}$	$RAMV_{i-1}$
V_2	0.4	0.54
V_3	0.42	0.436
V_4	0.017	0.031
V_5	0.0	0.0
V_6	0.14	0.15
V_7	0.42	0.3
V_8	-0.049	0.012
V_9	0.34	0.28
V_{10}	0.027	0.025
V_{11}	0.002	-0.007
V_{12}	0.047	0.039
V_{13}	0.004	0.006

(a) Rates of added classes and methods number in a version V_i comparing to version V_{i-1}.


(b) Rates evolution of added classes and methods number in a version Vi comparing to version V_{i-1}.

Figure 14: Study of Rates evolution of added classes and methods number in a version Vi comparing to version V_{i-1}.

6 Conclusion and future work

We have defined an UML profile called *SEA* which could help software developers to analyze and predict maintenance tasks in early activities of software process. To reify our approach we defined some stereotypes that support treating maintenance issue in design phase of software development. *SEA* treats three main issues related to software evolution:

- Analyzing and predicting maintenance tasks by defining stereotypes that allow to trace software evolution history. They permit also to precise software parts that are more probable to change in the future and those which could stay stable. This feature helps to recommend the right software architecture that supports changes without extra cost.

- Marking explicitly on class diagrams software parts that are

encapsulated in modules and those that are crosscutting. For example, in Composite pattern, components classes represent data-types modules and methods/functions represent crosscutting concern. This feature permits to precise visually and easily modular concerns and crosscutting concerns, the thing that permits to identify quickly which kind of maintenance tasks is preferred.

- Visualizing in design phase design patterns that will be implemented later. This feature enhances software comprehension and helps to assimilate the chosen design pattern use and properties before implement it (sometimes programmers face difficulties to understand some design patterns). This could also give an overview about maintenance tasks that could be modular with respect to a given design pattern and those which could not. In the last case, software developers could use appropriate tools to switch program structure into another design pattern that is more convenient (such as automatic reversible transformation among Composite and Visitor [13]).

SEA is partially validated by apply it on *JHotDraw* evolution. This partial validation shows that it is possible to analyze software evolution history and predict the kind of maintenance tasks that could occur in the future. Our approach validation still partial until applying all *SEA* stereotypes to *JHotDraw* and also to other case studies. As a future work, we look for developing an algorithm based on supervised data analysis and classification to exploit data provided by *SEA* in models and diagrams to predict automatically future maintenance tasks kind.

Conflict of Interest   The authors declare no conflict of interest.

Event Modeller Data Analytic for Harmonic Failures

Futra Zamsyah Md Fadzil[*], Alireza Mousavi, Morad Danishvar

System Engineering Research Group, CEDPS, Brunel University London, UB8 3PH, UK

A R T I C L E   I N F O

A B S T R A C T

The optimum performance of power plants has major technical and economic benefits. A case study in one of the Malaysian power plants reveals an escalating harmonic failure trend in their Continuous Ship Unloader (CSU) machines. This has led to a harmonic filter failure causing performance loss leading to costly interventions and safety concerns. Analysis of the harmonic parameter using Power Quality Assessment indicates that the power quality is stable as per IEEE standards; however, repetitive harmonic failures are still occurring in practice. This motivates the authors to explore whether other unforeseen events could cause harmonic failure. Usually, post-failure plant engineers try to backtrack and diagnose the cause of power disturbance, which in turn causes delay and disruption to power generation. This is a costly and time-consuming practice. A novel event-based predictive modelling technique, namely, Event Modeller Data Analytic (EMDA), designed to inclusive the harmonic data in line with other technical data such as environment and machine operation in the cheap computational effort is proposed. The real-time Event Tracker and Event Clustering extended by the proposed EMDA widens the sensitivity analysis spectrum by adding new information from harmonic machines' performance. The added information includes machine availability, utilization, technical data, machine state, and ambient data. The combined signals provide a wider spectrum for revealing the status of the machine in real-time. To address this, a software-In-the-Loop application was developed using the National Instrument LabVIEW. The application was tested using two different data; simulation data and industrial data. The simulation study results reveal that the proposed EMDA technique is robust and could withstand the rapid changing of real-time data when events are detected and linked to the harmonic inducing faults. A hardware-in-the-Loop test was implemented at the plant to test and validate the sensitivity analysis results. The results reveal that in a single second, a total of 2,304 input-output relationships were captured. Through the sensitivity analysis, the fault causing parameters were reduced to 10 input-output relationships (dimensionality reduction). Two new failure causing event/parameter were detected, humidity and feeder current. As two predictable and controllable parameters, humidity and feeder velocity can be regulated to reduce the probability of harmonic fluctuation.

1   Introduction

This paper is an extension of work originally presented in the conference Proceedings of the 2019 IEEE/SICE International Symposium on System Integration (SII) [1]. Power Quality (PQ) monitoring has been the focus of research and development for many years. Recently, [2], [3] addressing the PQ issues in various industry and proposing different methods in tackling this issues.The main focus is to protect the equipment and minimize the losses while increasing the levels of operational safety. However, systems are becoming more complex as they are being further developed for improvement. Huge numbers of control drive and other non-linear loads have been

installed to satisfy the demands of modern lifestyles. It has led to instability of the power system, creating high noise levels in the system grids and decaying the electrical distribution system. Even worse, climate change has an impact on the environment that the system operates in. In some cases, particularly for hot countries, the electrical distribution system requires air conditioning to protect the electrical equipment in the substation. In normal circumstances, if the air conditioning fails, it may surpass the permitted set point and may not protect the equipment. When the global temperature rises, the potential rate of failure also increases. Research has shown that the long-term average global temperature is increasing, which has a significant negative impact on the performance of the machines [4].

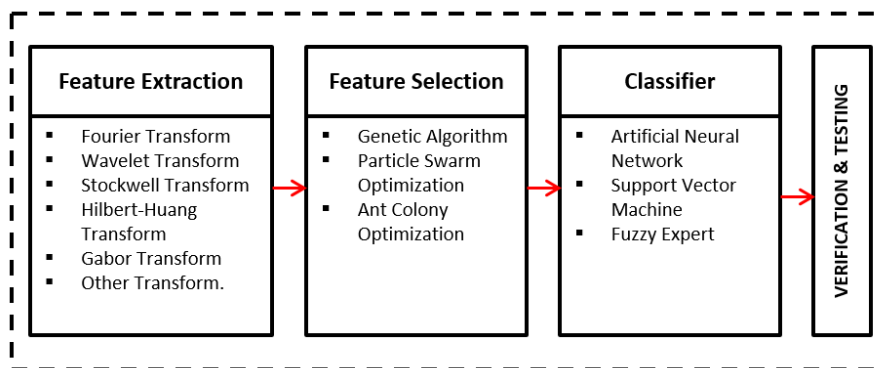

Figure 1: Various techniques of Power Quality Classification

The arrangement of the three principal stages in PQ Classification: (1) Feature extraction - a key transformation of the fundamental signals into time-frequency based information. A broad selection of Fourier Transform, Wavelet Transform, Stockwell Transform, Hilbert-Huang Transform, Gabor Transform and others. (2) Feature Selection - a key method in selecting the most suitable features from the feature extraction stage while discarding the redundant features. Few main optimizers include Genetic Algorithm, Particle Swarm Optimization and Ant Colony Optimization. (3) Classifier – a selection of artificial intelligence tools in classifying PQ disturbances such as artificial neural network, support vector machines, and fuzzy expert.

Earlier, conventional methods use manual configurations and visual inspection to monitor the quality of the power supply in the system. This method was too difficult to interpret and time-consuming. Later, an automated classification system, which uses the signal processing technique was developed and currently advancing with various Machine Learning and Deep Learning approach. Various combinations of features extraction and classifiers have proven to locate PQ disturbances accurately while using synthetic data. However, this is not the case with real industry data. Real industry data are complex and much more complicated when there are external or environmental factors that could potentially influence the state of the system. This creates a gap in existing techniques, which motivates authors to investigate the relevance of the environmental parameter to the issue of PQ disturbances. In addition, with the current emergence of big industrial data, system engineer must ensure that the system is robust and capable of performing ML/DL techniques in real-time applications. Disturbance data exists in the order of microseconds, which greatly enhances the record data [5].In consequence, it will burden learning classifiers to run unimportant parameters that result in high computation. The authors, therefore, suggest a method that could minimize the dimensional by selecting the most relevant data to be trained automatically, while incorporating a new unknown parameter that was previously considered irrelevant in the system state.

The aim of this paper is to introduce event-based analysis as a technique for detecting harmonic failure in real time. The technique is capable of grouping together high correlation system parameters, forming an input-output relationship that is not limited to internal parameters only. As such, the homogenized correlation system will indicate the possible root cause of harmonic failures, while eliminating non-important parameters in real-time [6]. This paper presents a real-time simulation of CSU machines, which shows the changes in the output parameters of the input activity. The data will be used to measure the suitability and applicability of event modelling techniques in the power system environment. It is then extended to the actual plant data, exploring the integration of this dynamic platform with the Key Performance Indicator (KPI) in order to recognize the

system operating pattern. This data analytics technique expects to predict the homogenized system parameter that could present the current state of the system in real time.

1.1 Power Quality Disturbance

A number of PQ disturbance types are implicated: voltage sag, voltage swell, transients, harmonics, fluctuations, flickering, voltage imbalance, interruption, DC offset and notches. A high level of engineering expertise [7] is needed to effectively diagnose these PQ disturbances. Preventing PQ disturbances is critical to minimize power interruptions between the power utility and the end user. With modern technology, a substantial amount of research has been devoted to alleviating these problems using signal processing technique. This technique has three principal stages which incorporate feature extraction, feature selection and classification.

Feature extraction is a key transformation of the fundamental signals into time-frequency based information. It can be extracted directly from the original measurement either from a transformed domain or from the signal model parameters [8]. Several approaches include short-time Fourier transform [9], wavelet transform [10], wavelet packet transform [11], Hilbert Huang transform [12], Stockwell transform [13], Gabor-Wigner transform [14], and other hybrid transform-based [15].

Feature selection is a key method in selecting the most suitable features from the feature extraction stage while discarding the redundant features. Based on the extraction data, optimization techniques such as Ant Colony Optimisation [16], Genetic Algorithm [17], and Particle Swarm Optimisation [18] are the common algorithm used in locating PQ disturbances.

Classification is the process of predicting the class of data points. It uses an algorithm to implement classification by approximating the mapping function from the input variable to the output variable. One of the most popular and influential types of machine learning algorithms is the Artificial Neural Network. Other machine learning includes Support Vector Machine [19] and fuzzy expert system [20]. Figure 1 illustrates the three main phases of the PQ classification.

[21]–[22] provide a detailed review of these techniques.

1.2 Power Quality Standards

Harmonic assessments of utility systems require procedures in place to ensure that the efficiency of the voltage supplied to all consumers is adequate [23]. However, most of the harmonic issues arise at the end of the consumer. Their devices contain non-linear loads resulting in resonance conditions [23]. These non-linear loads are the current harmonic sources. The system voltage appears stiff to individual loads, and the loads draw distorted current waveforms. It is therefore important to maintain the PQ International standard, to provide the guidelines and limits for the acceptable levels of compatibility, between consumer equipment and the system utilities.

The International Standard IEEE 519-1992 sets the limit for both harmonic voltages and currents at the Point of Common Coupling (PCC) between the end-user and the utility supplier. It limits Voltage Total Harmonic Distortion (THD), defined as the ratio of the RMS value of the harmonic voltage to the RMS value of the fundamental (50Hz) voltage, to a maximum of 5%. Individual voltage harmonic magnitudes are limited to 3% of the fundamental voltage value [24]. The International Standard IEC 61000-3-4 sets the limits for the emission of harmonic currents in low-voltage power supply systems for the requirement with rated current greater than 16A [25].

1.3 Environmental Parameters

Compliance with the International PQ Standards is the policy for both utilities and customers. In order to maintain a good PQ system, an enormous amount of research and PQ analysis has been undertaken to ensure it complies with the standards. However, in some cases, the machine still fails, although it complies with the standard. It is important to note that most of these research focuses on the fundamental of the electrical system and leave behind the external parameters that may have a substantial effect on the problem. In [26], the authors suggest that there could be further environmental and operational factors that could also affect the performance of power systems.

1.4 Problem Statement

In this article, we intend to investigate what possible factors that could link a well-maintained machines with a proper operation to a frequent harmonic failure incidents. While PQ parameters are eliminated by its healthy measurement, an alternative technique to solve this harmonic failure mystery is required to evaluate if there is an existence of a different parameter that could lead to this failure. Therefore, the authors are proposing the Event Modeller techniques which could link the internal and external parameters together, to create a cause-effect relationship, while updating the system status in near real-time before the machine fails. The implementation of the event modeller technique recently has shown positive practical findings in various area and application such as high-speed causal prediction modelling [27, 28], real-time Remaining Useful Life (RUL) estimation [29], and as a middleware to highly coupled input variable in zero-defect manufacturing [30], and predicting N_2O Emission [31].

1.5 Contribution & Advantages

The first contribution of this paper is to proposed a robust system engineering tools that be able to formulate a piece of new knowledge information in the diagnosis of PQ disturbances in real-time. This tool is found robust, workable with the dynamic and autonomous environment while being able to withstand real industry data which is non-linear and highly influenced with various factors. The second contribution of this paper is that the proposed technique could visualize the group of highly correlated variables in the form of occurrence matrices in real-time, proposing a mathematics equation that represents the current state of the system. This is optimum to system operators who can make a quick decision before the system fails.

1.6 Challenges

However, implementing this technique in solving PQ problems has its challenges. The harmonic readings (THD) is taken from the Multi-Function meter, which is installed at the electrical switchgear. The reading will not be as accurate as of the conventional method, but the measurement is sufficient to prove that the PQ parameters can be eliminated. Another challenge is to determine the threshold setting. In general, a scenario of events in the actual system varies according to the system characteristic and its system deterministic. An event could happen instantaneously, or it may have some delay before it reached to the target output. For example, the scenario of a room temperature does not change immediately when the heater or air conditioner was switched on. In comparison, a dark room will be immediately bright when the switch was turned on. Both of the scenarios have made changes to the system state at a different pace. In order to detect this, a data benchmarking is required which were decided based on historical data and system expert point of view.

2 Event Modeller Technique

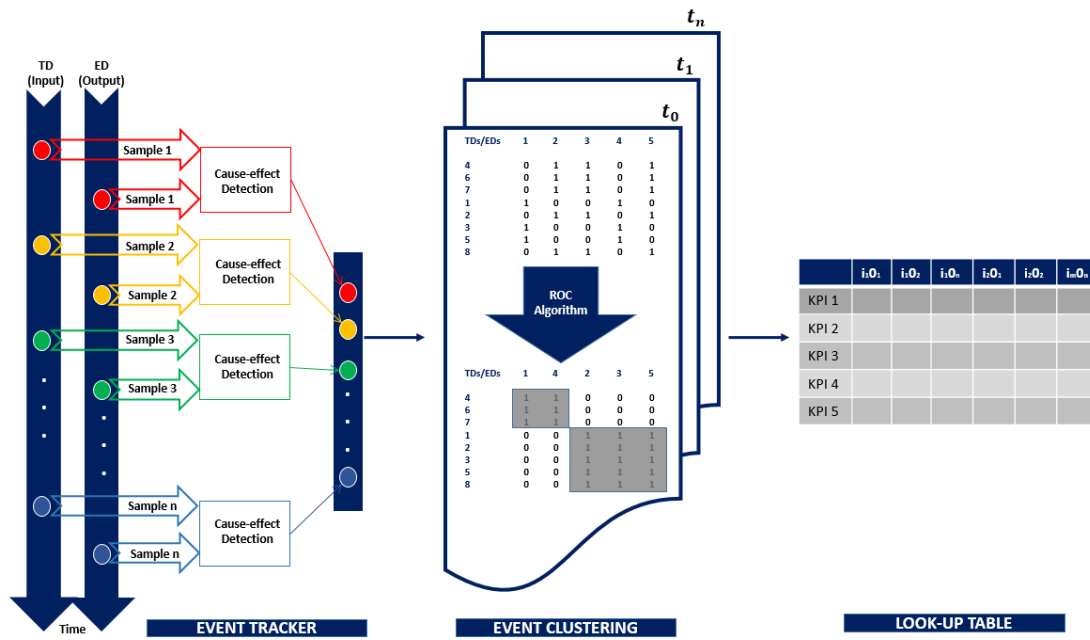
The event modeller technique is designed to investigate the association between the observable events (Output Data) with the causal events (Input Data) through a data mapping concept [30]. It clusters the system parameters with the highest correlation in the form of matrices and places them into mutually exclusive blocks. This creates an input-output relationship, which considers both internal and external factors. One significant difference between the proposed event modeller and other traditional data modelling techniques is how the input data assumes its output data. The traditional method assumes the input-output relationship as a true representation of a known data series, while the event modeller technique makes no assumption about it (unbiased) [32]. This fundamentally makes the approach non-unbiased vis-à-vis input-output relationship. The proposed Event Modeller Data Analytic (EMDA) is designed to find any interceptions between the known influential parameters (reported in previous literature) and new operational and environmental data by expanding the spectrum and reassessing the relationship between influential parameters on harmonic behaviour. It is a proven, computationally effective method of analyzing harmonic behaviour without bias. Borrowing from the Event Tracker [33] and Event Clustering [34] method, the proposed EMDA extends


Figure 2: Event Modeller Techniques

The arrangement of the three principal stages in Event Modeller: (1) Event Tracker – A collection of input-output cause-effect detection of a system state with highly sensitivity index in real-time. (2) Event Clustering – A rank order grouping technique based on the interpretation of the changes of input-output data in the previous stage. (3) Look-up Table - A population table that links the Key Performance Indicator with the Sensitivity Indexes.

the previous authors' correlation map by adding the information from the machine performance metrics. Information such as machine availability, utilization and performance are combined with other technical data, to group the highly correlated individual data together, revealing the machine's status in real-time. Figure 2 illustrates the event modeller techniques, including Event Tracker, Event Clustering and a Look-up table. Details of each stage will be briefly discussed in the following subsection.

2.1 EventTracker Algorithm

EventTracker algorithm was introduced [35] to construct a discrete event framework for online sensitivity analysis (SA). This algorithm was designed to be applied to highly volatile environments with real-time scalar data acquisition capabilities (e.g. Internet of Things (IoT). It uses a cause-effect detection algorithm to dynamically track events' triggers and their interrelationship with one another in a given system. It generates a sensitivity index that measures the relationship between the triggered data and the event data pairs. High sensitivity index score will be indicated while the lesser impact relationship will be eliminated. This will reduce the computational effort while achieving dimensional reduction. The Event Tracker is a computationally efficient technique that focuses on the state changes of the involved system components. It merely takes a snapshot of the system states, which helps engineers observe system performance [6]. Further details on the description and four Event-Tracker functional parameters (Search Slot, Analysis Span, Event Threshold and Trigger Threshold) can found in [35].

2.2 Event Clustering Algorithm

Event Clustering Algorithm (EventiC) [34] is designed to improve the real-time sensitivity analysis, by automatically re-arranging the input-output relationship in rank order of its importance and relevance. The algorithm applied the Rank Order Clustering (ROC) technique, which was initially introduced in [36]. This technique interprets the changes in input-output data's value at the given level, detecting the coincidence and finally groups it as a related event. The process of calculating the number of coincidence occurs at a specified scan rate time interval, to ensure a relationship weight is established for modelling and control purposes [32]. Despite filtering the unimportant relationship between the input-output relationship, event clustering can identify new influencing parameters that were previously thought irrelevant, making it unique and interesting to improve the data quality. One key advantage of EventiC compared to EventTracker is that EventiC can assess multiple input/ output relationship in every single scan, whilst EventTracker considers multiple input single output relations. A detailed explanation of EventiC algorithm and the basic concept is discussed in [34]. Algorithm 1 shows the main procedure of Event Modeller.

2.3 Look-up Table

A look-up table is an array of data to map input values to output values. It is used to transform the input data into a more desirable output format. The look-up table allows replacing run-time computation or logic circuitry with a simpler array indexing operation [37]. Retrieving a value from a look-up table is faster rather than examining it from the whole database. With the advantage of the

logical separation of data, it makes it relevant to prepare the data for machine learning purposes. This EMDA technique's novelty can be found in this look-up table, thus a rapid response to changes in the system's stability (i.e. the KPIs).

Algorithm 1: Event Modeller

Set Event Modeller Limit (EML);
Set Threshold Setting (Th);
Populate ULTh and LLTh;
Populate All Input Data (TD1, TD2...TDn);
if *Triggered Data = Dynamic TD* **then**
    Compute TDx = TDn - TDn-1;
    Compare TDx with ULTh and LLTh;
    if *(LLTh<TDx<ULTh)* **then**
        TDx = 0;
    else
        TDx = 1;
    end
else
    Triggered Data = Static TD;
    TDx = TD1,TD2...TDn.;
end
repeat
    repeat
        Populate All Output Data (ED1,ED2...EDn);
        Compute EDx = EDn - EDn-1;
        Compare EDx with ULTh and LLTh;
        if *LLTh<EDx<ULTh* **then**
            Set EDx = 0;
        else
            Set EDx = 1;
        end
        Populate the models input-output event coincidence matrix with binary weighting values of exclusive NOR function;
        Average each input-output event coincidence;
        Sort rows of the resultant binary matrix into decreasing order of their decimal weights;
    until *for every column*;
until *position of each element in each row and column does not change*;
Calculate the weight for each row i and column j (in a m by n matrix) using Equation 1 and Equation 2.

$$Row : W_i = \sum_{j=1}^{m} a_{ij} 2^{m-j} \tag{1}$$

$$Column : W_j = \sum_{i=1}^{m} a_{ij} 2^{n-i}. \tag{2}$$

2.4 Key Performance Indicator

The use of existing shop-floor in modern manufacturing to measure and monitor industrial KPIs has been a trend. In [38], the author used Object Linking and Embedding (OLE) which integrates with Discrete Event Simulation (DES) modelling capabilities to measure

the KPIs for brewery industry. In [39] the author used data-driven scheme of KPIs prediction and diagnosis for hot strip mill industry. In [40], the author proposes an analytics solution for calculating statistical KPIs in the Human Machine Interface (HMI) layer. There is a need to translate a suitable KPI that suit the type of operation. Basic KPIs are calculated directly from the output operation data, and they serve as the foundation for Overall performance KPIs [41].

Time-based KPIs are data related to time duration, defining activities associated with production and maintenance. The calculation of KPI has to consider all these factors to reflect accurate metrics. Hence it is important to understand the KPI interrelationship. A hierarchical structure for KPI categorization is proposed by [41]. The time-based KPIs studied in this paper are Availability, Instantaneous Utilization, Schedule Utilization and Performance.

To complement the Time-Based KPIs, it is useful to look at the energy consumption and emission contribution that could potentially harm the environment. In general, energy consumption can be calculated by multiplying the motor rating (kW) with the duration it operates. There are three states of motor known as run, idle and stop. During running state, the motor is capable of operating at its 100% loading while in idle state, the motor operates at 25% of its loading. Obviously, there is no loading when it stops. Having the total energy consumption, it is easier to calculate the carbon footprint; Carbon Dioxide Emissions ($kgCO_2$, $kgCO_2e$), Methane ($kgCH_4$) and Nitrous Oxide ($kgNO_2$) using the formula in [42].

3 A Case Study

A Continuous Ship Unloader (CSU) is one of the leading bulk material handling machine. In a coal-fired power plant, this machine is used to transport coal from the vessel to the pulverized boiler through a series of belt conveyors. It has been reported that the CSU machine in one of the power plants in Malaysia has a frequent harmonic failure. The repetitive incidents lead to catastrophic failure, which harms the electrical devices. Besides having a vast replacement cost for the faulty parts, it is also affecting the plant availability, which concerned the management team. Even worse, it could pose a potential hazard, to the personnel working in the area if it is happening again in the future. A thorough Power Quality (PQ) assessment within the electrical distribution system has been assessed, but the results have not given any indication of internal disturbance or fault. Table 1 shows the assessment result for the CSU machine. To mitigate the problem, an effort to analyze both internal and environment parameter that has a significant impact on the system is highly desirable. The authors are keen to embrace the event modeller techniques, to evaluate the significant correlation between the output and input, which could cause harmonic failures in the system. A real-time simulation which incorporates the CSU machine parameters and the event modeller algorithm was developed using National Instruments LabVIEW.

3.1 Experiment 1: CSU Real-time Data Simulation

The purpose of a real-time simulation is to measure the suitability and applicability of the event modeller technique in the power system environment. To ensure the system incorporates the industrial

Table 1: Assessment Results for CSU Machine

Parameters	Units	Min	Max	Avg
Voltage	V_{ab}	385.9 V	424.0 V	411.2 V

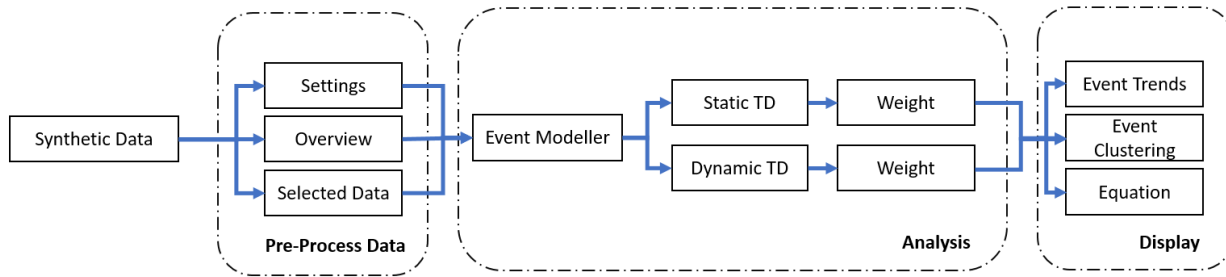

Figure 3: Experiment Strategy for Event Modeller Simulation

The arrangement of the three principal stages in the Experiment Strategy for Event Modeller Simulation: Pre-process Data, Analysis and Display.

case study, the requirement specification has been set based on the following:

1. 8 Event Data (ED's). This synthetic event data is simulated using Normal Distribution which represents the CSU Machine Output Data which includes Voltage, Humidity, Harmonics, Slewing Movement, Luffing Movement, Travel Movement, Temperature and Wind Speed;

2. 8 Triggered Data (TD's). This synthetic TD's is simulated using Normal Distribution which represents the CSU Machine Input data which includes Busy Slew, Busy Luff, Busy Travel, Busy Bucket Elevator, Slewing Motor Run Bit, Hydraulic Motor Run Bit, Travel Motor Run Bit and Bucket Motor Run Bit;

3. Threshold Setting. For the purpose of examining the Trigger Threshold, an arbitrary 5% threshold setting was set, that could later be adjusted;

4. Event Modeller Limit. This setting reduces the complexity

of an input-output relationship by its correlation confidence level. An arbitrary 80% was set, that could later be adjusted;

3.1.1 Experiment Strategy

Sixteen input/output system parameters of a CSU Machine were sampled from the Allen Bradley PLC-SCADA system using the FactoryTalk view. Once it is proven to be suitable, it will be extended to 120 parameters, which will be discussed further in Section 3.2. Data collection was conducted over a single day shift of a machine operation period, collecting approximately 43,200 lines of 12-hour data samples.

The sampling frequency follows [43] by applying the right bandwidth, time constant and settling time. Having this data in hand, synthetic data was constructed to have the same nature and properties as the real CSU machine. The overview of the experimental methodology is shown in Figure 3. Details of the dataset arrangement will be discussed in the following section.

Table 2: CSU Real-time Data Simulation Results (Weight) Based on Disturbance

Description	Voltage		Humidity		Harmonic		Temperature		Wind Speed	
	Static	Dynamic	Static	Dynamic	Static	Dynamic	Static	Dynamic	Static	Dynamic
Overall Maximum	0.8387	0.9996	0.8364	0.9996	0.8370	0.9997	0.8360	1.0000	0.8340	1.0000
Overall Minimum	0.5000	0.6288	0.5000	0.6371	0.5000	0.6360	0.5000	0.6312	0.5000	0.6325
k-Disturbance (Pre)	0.8345	0.9890	0.8287	0.9790	0.8181	0.9791	0.8306	1.0000	0.8424	1.0000
k-Disturbance (Dur)	0.7615	0.8065	0.7781	0.8304	0.7637	0.8137	0.7977	0.8976	0.7848	0.8103
k-Disturbance (Post)	0.7813	0.8667	0.8011	0.8789	0.7897	0.8650	0.8087	0.9310	0.8035	0.8654

3.1.2 Dataset Arrangement

ED is defined as a series of data that represent the state of the system at a given time [35]. In this simulation, the ED consists of simulated voltage, humidity, harmonics, machine positioning (slewing, luffing and travelling), temperature and wind speed. The simulation data is based on the actual operation and environment data of the CSU machine events by considering the assessment result in Table 1 and the location of the power plant located in Malaysia. The plant is located near to the seaside, which is hot and humid throughout the year and may tend to have strong winds. On the other hand, the machine movements are simulated based on the 3-axis movement, which includes slew (x-axis), luffing (y-axis) and travel (z-axis).

In Discrete Event System, any input variable whose value transition register as an event is defined as a TD [35]. In this simulation, the TD consists of machine status (slewing, luffing, travel and bucket) and motor run feedback (slewing, hydraulic, travel and bucket). For comparison purposes, two types of TD are presented here known as Static TD and Dynamic TD. Static TD registered the original TD signal from the source while Dynamic TD multiply the changes of TD with a threshold setting defined by the system engineer. Both types of TDs were used in this experiment to investigate which source of data to be selected. This will ensure the event modeller algorithm provides an accurate sensitivity index or weight output.

Meanwhile, the threshold level could be adjusted based on the expert point of view. In this simulation, the threshold level is set at 5% (0.05); thus, the Upper Limit and Lower Limit will automatically set to 1.05 and 0.95 consecutively. The limits will be multiplied to the individual data computationally, to calculate the changes of the current data to the previous data and reflects the algorithm for weight score using X-NOR logic. The event modeller limit is the desired weight limits which also could be adjusted based on the expert point of view. In this simulation, the event modeller limit is set at (0.8). The weights who score above the Event Modeller Limit is shaded in the ROC Output table, indicates a significant correlation between the ED and the TD.

The sequence of TD's and ED's is updated every second and are re-arrangeable according to the weighted score. The weighted score can take a value of 0.5 and 1. The value is 1 when both or none of the input/output are triggered. Otherwise, it is 0.5. The weighted score is then averaged based on the number of iteration. Having the weight score in real-time, system engineers could easily notify the management team if there is any disturbance occurs in the system state by looking at the sequence and the weights. For trending purposes, a waveform chart is presented to improve the visibility of the data.

3.1.3 Disturbance Signal

The purpose of this simulation is to test the applicability of the Event Modeller algorithm in the handling of real-time data, thus observing the reaction of the system to the abnormal events. To ensure the system is sensitive to this abnormality, a k-Disturbance signal is introduced to the system. In this simulation, the data is simulated in 3 stages known as pre-disturbance, k-disturbance and post-disturbance. The pre-disturbance refers to the warm-up stage, which represents the machine normal steady state. The k-disturbance refers to the fluctuation of the k-event data, in such generating disturbance to the system. The post-disturbance refers to the reaction of the abnormal system back to normal steady state. A 5 minutes time interval is selected for each stage, which accumulates to 15 minutes of sampling time.

In this simulation, 5 ED's signal, which represents the internal and environment parameter, has been chosen to be disturbed. This includes voltage, humidity, harmonic, temperature and wind speed. The signal data are simulated based on random fluctuation with 5% disturbance limit from normal operation data capability.

3.1.4 Simulation Results

Table 2 compares the results obtained from the simulation of the CSU machine against the k-disturbance signal. To present the findings, the performance is measured from the score of the sensitivity index from two main perspectives, which includes the overall maximum and minimum weight, and the average score for each stage. What stands out in the table is that the value of the weight has changed drastically between the pre-disturbance and during disturbance for all case. For e.g., when the k-disturbance is applied to the machine voltage using Static TD, the weight value drops from 0.83450 to 0.76154. However, when the k-disturbance is removed, the weight value rose to 0.78132. These indicate that the system parameters are sensitive to the disturbance signal introduced in the system.

It is interesting to note that all ten cases of this study have a common finding. The transition of average sensitivity index (weight) from Pre-Disturbance to k-Disturbance have the same reduction trend with an average of 8.2% reduction for Static TD and 15.94% reduction for Dynamic TD. Alternatively, when the k-Disturbance recovers, there is also a trend of increased weight with an average of 3.218% increment for Static TD and 6.023% increment for Dynamic TD. This finding confirms the interrelation between the triggered data and the k-disturbance event data, where different TD types have different performance. The Dynamic TD has a higher percentage of changes compared to Static TD.
Figure 4: Tabulation of CSU Machine Failure vs REGEN Failure

The bar chart reveals that the highest number of REGEN faults was reported in October 2018, followedby August 2018, September 2018 and January 2019 consecutively.

On the other hand, it has been observed that the minimum weight for Static TD is fixed at 0.5000 while Dynamic TD has different minimum weight scores for each experiment. A possible explanation for this might be that the Dynamic TD captured the changes of input sensitivity rather than a direct Boolean signal from the input itself.

3.2 Experiment 2: CSU Real-time Machine Failure Analysis with KPIs

Harmonic filter failure can be influenced by various factors, such as faulty device, operator handling, and environmental factors in which the machine operates. It has also occasionally been affected by the combination of these factors. Based on the CSU machine expert point of view, the harmonic problem is associated with the occurrence of Regenerative Drive (REGEN) fault. In order to access the REGEN fault events, the abnormal dataset was selected. The frequency of the REGEN failure was compared with other types of fault, as presented in Figure 4. The bar chart reveals that the highest number of REGEN faults was reported in October 2018, followed by August 2018, September 2018 and January 2019. Although the highest number of REGEN failures was recorded in October 2018, no report indicated that the REGEN drives had been replaced. However, the January 2019 reports indicated that the maintenance team had replaced the REGEN during this month due to a fault. The January dataset was therefore chosen to further explain the relationship of the variables using the proposed technique.

3.2.1 Experiment Strategy

Building a solution capable of translating engineering data automatically into high-level management information is the principal motivation for this experiment. The KPIs shall be calculated based on the operation of the machine during the selected period. The method used in [1] is borrowed to run a fault dataset with a time interval of 5 minutes. The first 5 minutes are the events before the fault occurs, followed by the fault, and end with the last 5 minutes that accumulate up to 15 minutes of sampling time. The reason why this method was adopted is to prove that the event modeller could instantly solve a complex system without having to run the system for a longer period. It is easy to sample data in a simulation environment, as the user can decide when the fault may occur, but this is not the case with industrial data. The dataset was therefore analyzed to determine which data was almost equivalent to the setting. The experiment strategy is summarised in Figure 5. The results are presented in two phases. First, the event modeller was used as a tool to reduce the dimensionality of the data being observed. Second, the relationship between the observed data and the KPIs has been compared. The results will be explained as follows.

3.2.2 Dataset Arrangement

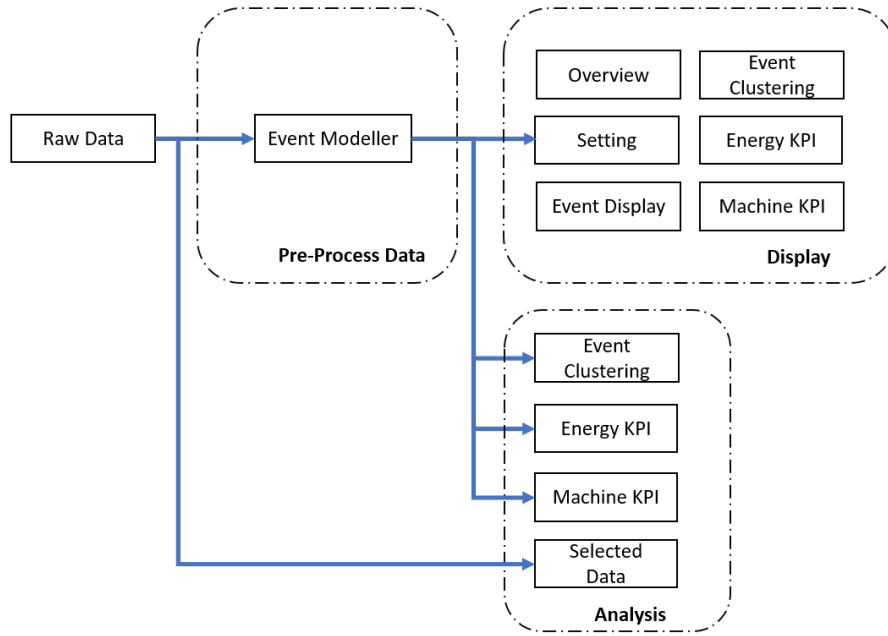
In this example, a homogenous dataset representing REGEN failure of the predictive model population was sampled for 16 minutes. The dataset of 30th January 2019 was sampled between 12:47 pm and 13:03 pm. The dataset arrangement indicated that there were 96 TDs to be grouped against 24 EDs in the form of matrices to show


Figure 5: Experiment Strategy for KPIs Analysis

The arrangement of the three principal stages in the Experiment Strategy for KPI Analysis: Pre-process Data, Analysis and Display.

which system parameters were highly correlated. It is noteworthy that the 96 X 24 matrices are too complex for a correlation analysis; therefore, the 96 TD was divided into 4 clusters. For each TD cluster, 24 X 24 matrices were analyzed using the event modelling technique.

The sensitivity index of each input-output relationship has been measured and updated every second. The ROC pattern was observed in real-time and captured every minute. As a result, four-quadrant windows representing four key states were presented: Initial, Pre-Fault, Fault and Post Fault for each TD cluster. This analysis intends to examine how TDs influence the pattern of the ROC. It is necessary to clarify what happens during this 16-minute time stamp before presenting the chart. Based on the report, the machine is running at its optimum level before it is fully phased out after 10 minutes. The reason why machine trips are unknown, which left the proposed method to be concluded further.

3.2.3 Dimensionality Reduction using Event Modeller

One advantage of using Event Modeller is to reduce the dimensionality of a complex system. As the main objective is to identify the root cause of the failure, this technique is capable of highlighting the ROC pattern based on its correlation analysis. One important finding was that the first four EDs were the same for all clusters. They comprised of E-House Humidity (ED24), Portal Conveyor Current (ED18), Wind Speed (ED 12) and Portal Speed Drive (ED14). This indicates that one of these EDs would have been the cause of failure. However, it has been noted that Cluster 2 and Cluster 3 consistently remain the same pattern with or without fault happened.

Therefore, we have eliminated Cluster 2 and Cluster 3 from the analysis. Moving to the ROC patterns for Cluster 1 and Cluster 4, major changes were observed after the fault in this quadrant. From this observation, it is suggested that the TDs could have originated from these clusters. Equation 3 indicates the possible root cause of Cluster 1. If we overlap both relationships, the new equation for Cluster 1 is expressed in Equation 4.

$$
\begin{aligned}
\rho_{0.95} = (ED18) &\times (TD6, TD7, TD11, TD8, TD9, TD10)+ \\
(ED24) &\times (TD8, TD9, TD10, TD24, TD21, TD2, \quad (3) \\
&TD22, TD23, TD20, TD13, TD12)
\end{aligned}
$$

$$
\rho_{0.95} = (ED18 + ED24) \times (TD8, TD9, TD10) \quad (4)
$$

On the other hand, the following equation 5 indicates the possible root cause of Cluster 4. If we overlap both relationships, the new equation for Cluster 4 is expressed in Equation 6.

$$
\begin{aligned}
\rho_{0.95} = (ED18) &\times (TD15, TD18, TD16, TD17, TD20)+ \\
(ED24) &\times (TD16, TD17, TD14, TD13, TD19, \quad (5) \\
&TD12)
\end{aligned}
$$

$$
\rho_{0.95} = (ED18 + ED24) \times (TD16, TD17) \quad (6)
$$

Combining Equation 4 with Equation 6, the sensitivity index is expressed in Table 3. With that, Event Modeller has reduced the dimensional to a smaller scale that will help the system engineer

Table 3: Summary of Sensitivity Index

Description	TD8	TD9	TD10	TD16	TD17
ED18	0.97919	0.97138	0.96878	0.98337	0.96881
ED24	0.95838	0.96982	0.996982	0.95842	0.97089

decide which relationship is liable to this fault. The following section will be discussed on the relationship between the observed data and the KPIs to validate the findings of the Event Modeller. Figure 6 and Figure 7 represent the pattern of the ROC system state for Cluster 1 and Cluster 4, respectively.

3.2.4 Relationship between the observed data against Key Performance Indicators

The KPIs are the translated index of the machine operation. It provides operational information for the decision-making of both the machine and the system operator. Four main KPIs have been adapted in this experiment known as Availability (A), Instantaneous Utilization (IU), Schedule Utilization (SU) and Performance (P). Having these four KPIs in line with CSU machine data, the possible root cause of frequent harmonic failure could be determined.

The following steps have been taken to analyze the data: (1) Select fault dataset from the Predictive Model Dataset. (2) Identify the fault observed data location. (3) Distinguish observed data according to Environment Variables, Electrical Variables and Motor Variables. (4) Plot Environment Variables data against KPIs. (5) Plot Electrical Variables data against KPIs. (6) Plot Motor Variables

data against KPIs.

The easiest way to identify fault events is by exploring the main incomer trip data. Theoretically, the entire electrical system will be tripped when there is a REGEN fault. Although it may conflict with other events in which the operator may trip the main incomer on purpose, the system could automatically distinguish between the actual fault and the simulated fault using the translated KPIs data.

For example, when a fault occurred during the operation, the data of the KPIs will hold the value in percentage. This verifies that the fault that occurred is genuine. If the machine is stopped or not operated, the value is either zero or hold to a specific value. In this example, the same dataset used in the previous experiment was chosen. This is to compare the relationship between the data observed using both techniques. The dataset dated 30th January 2019 was therefore sampled between 12:47 pm and 13:03 pm. The target data was then divided into three and plotted against the KPIs as follows:

Figure 8 shows the observed electrical data against the KPIs when electrical faults occurred. This graph is quite revealing in several ways. First, the main fault has been observed. The chart reveals that the main fault occurred at 09:50. This is the turning point of all events. Next, the four KPIs are observed. The perfor-

Figure 7: Rank Order Clustering - Cluster 4

ROC Pattern on four quadrant: Initial, Pre-Fault, Fault and Post-Fault for Cluster 4. The blue shaded region with red boxes represent the cluster of a high correlation value between 0.95 to 1.00.

Table 4: Summary of Electrical Variables

Description	ED1	ED2	ED4
Min	427.33 V	9.66 A	1.84 %
Max	427.47 V	242.93 A	2.19 %
Average	427.44 V	73.13 A	2.00 %

mance was initiated at 100% and remained for 1 minute. It was then exponentially reduced to 16% when the main fault occurred. This indicates that the unloading of coal has stopped immediately after 1 minute.

On the other hand, both Instantaneous Utilization and Schedule Utilization started at 58% and gradually decreased to 35% at 04:24. At this point, Schedule Utilization bounces back to 39%, but Instantaneous Utilization remains reduced to 30% until the main fault event occurs. The availability started at 95% and remained until 04:24 before it gradually decreased when the main fault occurred. These trends have shown that there is a relationship between the main fault and the KPIs. Table 5 summarised the KPI results.

Moving to electrical variables, the main input voltage (ED1) remains at 427V for the entire time. Although the fault occurred, the main input voltage does not respond to this. This validates that the fault is not caused by power disturbances from the supply, such as transient, interruption, under-voltage or over-voltage. The Main Incomer Current (ED2) pattern was then observed. Before the fault, ED2 shows the current drawing of the electrical distribution. The pattern is based on loads of the motor during machine operation.

However, when the fault occurred, trends show that ED2 is re-sponding to the event. An instantaneous drop was discovered during this period. ED2 does not fall to zero because the energy was still drawn from the maintenance feeder for essential loads. The main incoming THD (ED4) has also been observed. ED4 has been generated assuming that there will be no harmonic distortion during these events. The ED4 pattern remains at an average of 2.0% throughout the sampling time, indicating that the THD remains at IEEE 519 Standards. Table 4 summarised the electrical variables.

Meanwhile, to further explain the relationship between the motor variables and the KPIs, Figure 9 shows the current drawing of five main processes in the CSU machine. These include Bucket Elevator Current (ED17), Portal Conveyor Current (ED18), Travel Current (ED19), Boom Conveyor Current (ED20) and Hydraulic Power Pack (ED21). In order to validate the ED2 from the previous graph, this chart reveals that ED2 has a linear relationship with all motor variables within this graph. For example, when ED17 was drawn at the beginning of the sampling and all other motor loads were added during that period the ED2 measurement reached its peak value. Some attention is given to the small circle in the chart. It is clear that there was some instability happening at 01:48, which could be linked to the fault.
Figure 8: Electrical Variables vs KPIs

This figure illustrates the relationship between the Machine KPIs (Availability, Instantaneous Utilization, Schedule Utilization, and Performance) against the observed electrical data (Voltage, Current, Harmonic, Incomer and Regen) when the same event of electrical faults occurred at Time: 09:50.

Table 5: Summary of KPIs

Description	A	IU	SU	P
Min	64.37 %	25.01 %	34.82 %	11.52 %
Max	91.67 %	58.33 %	58.33 %	100.00%
Average	76.43 %	32.48 %	39.59 %	26.72 %

ED18 had an impulsive signal and remained zero after that event. On the other hand, ED19 has also revealed some dramatic changes. Just after ED18 had an impulsive signal, ED19 experienced some negative distortion for 12 seconds, followed by an interruption for 48 seconds and a further positive distortion for 60 seconds completely before it stopped. Another attention has to be made at ED17. In the beginning, ED17 had drawn some fluctuation current and had spiked for a few seconds before stopping at 00:40. The trend shows that ED17 is struggling to recover, but ends up stopping when the main fault has occurred. Otherwise, all other motor variables are operating in their normal state. Table 6 summarised the motor variables.

Figure 10 displays the environment data observed against the KPIs when the same electrical faults have occurred. Five environmental data were reported, including Panel Humidity (ED3), Panel Temperature (ED5), E-House Temperature (ED6), Wind Speed (ED12) and E-House Humidity (ED24). Attention must be given to the humidity and temperature of the electrical room where the electrical distribution panel is located. The pattern has shown an instant increase of ED24 at 02:36. The humidity builds up and reaches its highest peak at 58% and slowly decreased with two spikes before the fault occurred. On the other hand, ED3 has also been increased

but not as much as ED24. ED5 has an average temperature of 33.13 degrees Celsius, while ED5 has an average temperature of 17.82 degrees Celsius. Eventually, ED12 fluctuates within the normal range. Table 7 summarised the environment variables.

3.2.5 Discussion

The main outcome of the experiment is to show how the proposed technique can be used as a tool to reduce the dimensions of a highly complex system. In this case study, 96 TDs were analyzed against 24 EDs in real-time to help system engineers visualize any changes to the system state. The EMDA implementation will group high correlation system parameters in the form of matrices and place them in mutually exclusive blocks. Having a huge matrix, however, will make things difficult. The matrix needs to be presented as a square for clear visibility. Thus, the 96 TDs were divided into 4 clusters, where each cluster has a relationship with 24 EDs. The example accessed a 16-minute dataset that belongs to a fault population. The result for each cluster was shown in a four-quadrant to show the pattern change. In this example, there is a significant change in the pattern observed in Cluster 1 and Cluster 4. Further analysis of the two clusters suggested a new formula representing
Figure 9: Motor Variables vs KPIs

This figure illustrates the relationship between the Machine KPIs (Availability, Instantaneous Utilization, Schedule Utilization, and Performance) against the Five Main Electrical Motors (Bucket Elevator Current, Portal Conveyor Current, Travel Current, Boom Conveyor Current and Hydraulic Power Pack) when the same event of electrical faults occurred at Time: 09:50.

Table 6: Summary of Motor Variables

Description	ED17	ED18	ED19	ED20	ED21
Min	0.00 A	-2.96 A	-133.97 A	0.00 A	0.05 A
Max	119.31 A	25.67 A	97.87 A	54.41 A	52.05 A
Average	5.41 A	0.69 A	2.49 A	5.03 A	30.60 A

the state of the system. After the fault event, the new formula for Cluster 1 and Cluster 4 is expressed in Equation 4 and Equation 6, respectively. As a result of these equations, the main culprit of the fault was identified. The ED variables were reduced from 24 EDs to 2 EDs (a decrease of 91.76%) while the TDs variable was reduced from 96TDs to 5TDs (a decrease of 94.79%). As listed in Table 3, the possible root causes of the fault are the combination of:

1. Portal Conveyor Current (ED18) with Rotary Feeding Table Motors (TD8), Bucket Elevator Motors (TD9), Bucket Elevator Brake Motors (TD10), Busy Rotary Table (TD16) and Busy Bucket Elevator (TD17) or

2. E-House Humidity (ED24) with Rotary Feeding Table Motors (TD8), Bucket Elevator Motors (TD9), Bucket Elevator Brake Motors (TD10), Busy Rotary Table (TD16) and Busy Bucket Elevator (TD17)

Further analysis with the KPIs will validate the existence of unknown events that could be linked to a harmonic problem. In normal circumstances, electrical variables such as voltage, current and THD should have a linear relationship with the KPIs. As the KPIs

responded to the fault, the electrical variables should also respond. However, the voltage and the harmonic measurement remain constant after the fault has occurred. Although current measurements have responded to this fault, trends show that the current value is not zero. It indicates that there was still a current drawing for the essential loads. Therefore, this eliminates the possibility of machine failure due to electrical variables.

Moving to the motor variables, as explained in the result, ED17, ED18 and ED19 showed some undiscovered events that could lead to fault. When comparing the performance trend to ED17, the performance measurement falls in line with the activity of the bucket elevator. Although the trends for ED17 fluctuate before it stops, this could be explained from the perspective of uneven coal inside the bucket. On the other hand, ED18 has experienced an impulsive signal that leads to an immediate stop. However, looking at the timing of this event, it took about 9 minutes for the fault to happen. The same goes for ED19, which experienced negative and positive distortions right after ED18. This can be claimed as a result of an event. However, when it comes to the type of operation, ED19 is a travel motor that operates in two directions. Although some distorted measurements were made, this could be explained by the
Figure 10: Environment Variables vs KPIs

This figure illustrates the relationship between the Machine KPIs (Availability, Instantaneous Utilization, Schedule Utilization, and Performance) against the Environment Variables (Panel Humidity, Panel Temperature, E-House Temperature, Wind Speed and E-House Humidity) when the same event of electrical faults occurred at Time: 09:50.

number of motors that were operating. There were ten motors in service working at different efficiency levels. Having said that, the motor variables are also excluded from being the root cause of the fault.

Turning to environment variables, the trends in Figure 10 have shown some indications that the humidity could be related to the fault. The rise in humidity up to 58.06% shows that the state of the system has been compromised. Although high humidity patterns started 7 minutes before the fault, the measurement continuously retained above 40 % after the fault. This type of phenomena takes a fixed amount of time to reach the fault level. To explain this phenomenon, we take an example of preheating an oven. When a person decides to bake a cake, the oven needs to be heated to the right temperature before putting the cake inside the oven. Although it takes a few seconds to turn the oven on, it may take a few minutes to get the right temperature. This phenomenon is referred to as a fixed time delay deterministic event. However, if the person warms up the oven, without shutting the oven door, it may take longer to get to the right temperature. This phenomenon is referred to as a deterministic sequence of different input events. The heat produced

in the oven was cooled by the amount of cold air present in the surroundings, which would delay the oven pre-heating process.

When we relate this to our case study, the power electronic component such as choke, rectifier, REGEN and control drives produce an excessive amount of heat during operation. To ensure that the heat is kept at certain limits, two units of air conditioners were designed to combat this heat. However, after considering the amount of heat generated in the room along with the hot and humid climate of Malaysia throughout the year, experts have reviewed and decided to install two additional air conditioners to cater for this amount of heat. As a result, when CSU machine is fully operational, the four-unit air conditioners are sufficient to cool down the electrical room. However, when the machine stops at intervals, the air conditioners are found oversized to the power electronic component. As a consequence, the humidity increases; the component becomes wet, resulting in machine failure. The humidity in the electrical switchgear room must be maintained at an elevated temperature relative to the ambient inside the room. Condensation is usually considered a problem only if the humidity in the switchgear room is 65% or greater [44]. Although the humidity in this example does

Table 7: Summary of Environment Variables

Description	ED3	ED5	ED6	ED12	ED24
Min	10.35 %	31.41 degC	17.12 degC	2.22 m/s	30.64 %
Max	18.52 %	35.54 degC	18.16 degC	9.19 m/s	58.06 %
Average	14.95 %	33.13 degC	17.82 degC	6.74 m/s	39.21 %

not reach 65%, considering the machine has been running for a decade, the efficiency of the machine may decrease as the humidity may be the contributing factor. This finding suggests that there is a relationship between the humidity and the fault.

As mentioned earlier, this paper's main outcome is to show how the EMDA can be used as a tool to reduce the dimensions of a highly complex system. 96 Triggered Data were scanned against 24 Event Data, which then formulated an equation representing the system state in a single second. This sort of like a "scanner" that will keep converting a complex relationship into a simple equation (a huge reduction of dimensionality) in a low computational effort. The results in Table 3 shows that the complex relationship has been reduced to 2 EDs against 5 TDs. Further analysis with the KPIs has validated the existence of unknown events that linked to the frequent harmonic failure. The rise in humidity level shown in Figure 10 has proven that the system state has been compromised. In comparison, other variables such as electrical variables, motors and other environment do not show any evidence that compromises the system state. Besides, the relationship between the observed data and the KPIs appears to be consistent. The suggested finding was tested at site, and the operators confirmed the importance of humidity factor (environmental factor) in the machine's performance. A humidity regulator has been suggested to be installed at the site. The control of the regulator was linked to the plant automatic control system.

4 Conclusions

Managing repetitive harmonic failures in an industrial application is a recursive, costly and time-consuming exercise. Industrial data are multidimensional and random in nature. The problem with analyzing this data is that many events do not necessarily repeat often enough to have statistical significance. Still, they cause minor or major faults and need to be captured and understood. Identical machines perform differently in different environments and conditions. In most cases, PQ engineers focus on the fundamental problem, transforming the power system signal into various signal processing methods to locate the fault. An Event Modeller technique, which is low in the computational effort, has been considered to solve this problem. This technique, which is extremely computational effective, managed to reduce system state definitions' complexity into a simpler formulation. Also, the performance metrics translated from the machine operation are now automated and require minimum operator intervention. It reduces wrong interpretations and possible mistakes in decision making. However, one of the method's weaknesses is its reliance on technical expert judgement on adjusting the threshold settings. One of the ongoing research endeavours of the authors is to automate the trigger detection phenomena.

In this present work, authors focused on reducing dimensionality while collectively including the modelling equation's performance

metrics parameter to verify the system state. Two approaches were taken to validate and verify the propose EMDA algorithm. First was the simulation process (SiL). It considered the voltage, humidity, harmonic, slewing movement, luffing movement, travelling movement, temperature, and wind speed as system output variables. Two types of triggering data, i.e. Static TD and Dynamic TD were considered. K-disturbance signal was generated for the five (excluding movements) output variables. The results show that, as the disturbance is induced, the sensitivity indices were reduced by an average of 8.2% for Static TD and 15.94% for Dynamic TD. However, when the disturbance was removed, the sensitivity indices regained by an average of 3.218% and 6.023% for Static TD and Dynamic TD consecutively. As a result, the Dynamic TD was chosen for the field experiments. In the field experiment (HiL), 914 data series in real-time were acquired from the SCADA. Each dataset is containing 96 Input vs 24 Output parameters. The results show that two new parameters were detected to significantly impact Harmonic Filters; humidity and portal conveyor current (velocity of the conveyor). The tests proved that humidity as an environmental factor is linked to the frequent harmonic problems. This revelation was also verified by looking up the historical evidence of humidity data against the frequency of failures and the variation in the feeder's speed (conveyor). In the future, the proposed EMDA will be integrated as a vehicle for training supervised machine learning models to predict the remaining useful life of the filter as a predictive

ARTICLE INFO	ABSTRACT
	Real-time embedded systems are widely adopted in applications such as automotive, avionics, and medical care. As some of these systems have to provide a guaranteed worst-case execution time to satisfy the time constraints, understanding the timing behaviour of such systems is of the utmost importance regarding the reliability and the safety of these systems. In the past years, various timing analysis techniques have been developed. Probabilistic timing analysis has recently emerged as a viable alternative to state-of-the-art deterministic timing analysis techniques. Since a certain degree of deadline miss is still tolerable for some systems, instead of deriving an estimated worst-case execution time that is presented as a deterministic value, probabilistic timing analysis considers execution times as random variables and associates each possible execution time with a probability of occurrence. However, in order to apply probabilistic timing analysis, the measured execution times must be independent and identically distributed. In the particular case of hybrid timing analysis, since the input and the initial processor state of one software component are influenced by the preceding components, it is difficult to meet such prerequisite. In this article, we propose a hybrid probabilistic timing analysis method that is able to (i) reduce the dependence in the measured execution times to facilitate the application of extreme value theory and (ii) reduce the dependence between software components to make it possible to use convolution to calculate the probabilistic WCET of the overall system.

1 Introduction

Due to the demand for better performance and the increased number of functionalities in embedded systems, acceleration features, such as multi-cores and caches, are added to the modern processors [1]. However, because of these acceleration features, timing analysis has become more complicated and time-consuming.

Over the past years, various researches have been carried out to develop timing analysis techniques that can derive a sound and safe result within a reasonable cost. With "sound", it is meant that a timing analysis result is accurate and not overly optimistic concerning its timing behaviour. The word "cost" describes the time and effort spent on deriving a timing analysis result. In the plethora of techniques, probabilistic timing analysis (PTA) has recently emerged as a viable alternative to state-of-the-art deterministic timing analysis techniques.

In real-time systems, failing to meet the deadline does not necessarily imply a failure of the system. For instance, in video conferences, an occasional deadline miss of the arrival of one frame can degrade the service but is not a failure of the system. Therefore, the timing requirement does not always have to be strictly guaranteed, and a certain degree of deadline misses is still tolerable. Therefore, Instead of deriving an estimated worst-case execution time (WCET) that is presented as a deterministic value, PTA considers execution times as random variables and associates each possible execution time with a probability of occurrence.

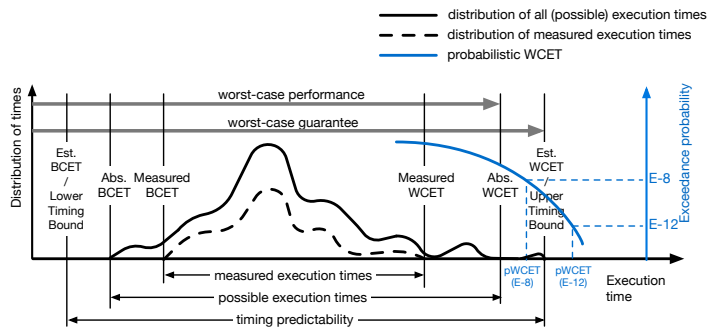
Figure 1 is the examples of the probabilistic WCET (pWCET) and the deterministic WCET, as well as the terminologies we use through this paper. The authors suggested that since the upper timing bound derived using the probabilistic worst-case execution time (pWCET) can be adjusted according to the safety requirement of the system, probabilistic timing analysis (PTA) is supposed to be more flexible and potentially less pessimistic compared with the classical deterministic approaches [2]. Therefore, we developed our approach based on the work in [3, 4] with measurement-based probabilistic timing analysis (MBPTA).


Figure 1: Examples of pWCET analysis and deterministic WCET timing analysis (based on [5]).

One prerequisite of applying MBPTA is that the measured execution times must be independent and identically distributed (i.i.d.). However, in hybrid timing analysis, the input and the initial processor state of one code block/component are influenced by the preceding code/component. Therefore, it is very challenging to collect execution times following the independent and identical distribution.

In this article, we present a hybrid probabilistic timing analysis (HPTA) approach that can facilitate in conducting MBPTA on software blocks/components and safely construct the overall execution of the complete program by reducing the dependence in the measured execution times and the dependence between the components. The goal of this approach is to provide more flexibility in the timing analysis results, which can be used by experienced engineers as references when designing non safety-critical systems that can tolerate a certain degree of deadline misses.

The rest of this paper is organised as follows. Section 2 gives the background of PTA. Section 3 explains the details of the extreme value theory (EVT) and how to apply it in MBPTA and HPTA. The proposed HPTA method is presented in Section 4. Section 5 demonstrates the experiment setup and the case studies, followed by the results and discussion in Section 6.

2 Background

The acceleration features of the hardware, the different input values, and the paths taken through the software introduce a certain degree of variability to the execution time of a system [6]. Because of such variability, PTA considers each observed execution time as an event with a probability of occurrence. Thus the worst-case execution time (WCET) can be viewed as an event that is more extreme than any previously observed event [7].

PTA derives a cumulative distribution function (CDF) using the observed execution times in the measurement. Since PTA aims to provide the probability that one execution time is going to exceed a given time bound, the result is usually presented as a complementary cumulative distribution function (CCDF) [8, 9, 10].

Figure 2 is an example of the results in measurement-based probabilistic timing analysis (MBPTA). The EVT takes the measured execution times to generate the CCDF. This CCDF-function then represents the probability that an event will have an execution time larger than a given pWCET value. This way, every pWCET

is associated with such an exceedance probability. For example, in the given figure, the pWCET shows that for every execution of the program, the probability of the execution time exceeding 9.6ms is 1E-16.
Figure 2: Example of the analysis result of one MBPTA shown as CCDF [11].

For instance, to calculate the pWCET of a task with the probability that the execution time will be 1 time unit is 0.15, the probability that the execution time will be 2 is 0.4, the probability that the execution time will be 4 is 0.4 and the probability that the execution time will be 8 is 0.05. The discrete probability distribution function of execution times of this task can be expressed in the form of a probability mass function (PMF), which is also known as execution time profile (ETP) in the context of PTA:

$$X = \begin{pmatrix} 1 & 2 & 4 & 8 \\ 0.15 & 0.4 & 0.4 & 0.05 \end{pmatrix} \quad (1)$$

The CDF, which indicates the probability that one execution time is less than x, is:

$$CDF_X(x) = F_X(x) = \mathrm{P}(X \le x) = \begin{cases} 0 & if \quad x \in [0,1) \\ 0.15 & if \quad x \in [1,2) \\ 0.55 & if \quad x \in [2,4) \\ 0.95 & if \quad x \in [4,8) \\ 1 & otherwise \end{cases} \quad (2)$$

Eventually, the CCDF is generated to represent the analysis results because pWCET analysis rather focuses on the probability that an execution time exceeds a particular level:

$$CCDF_X(x) = \bar{F}_X(x) = \mathrm{P}(X > x)$$

$$= 1 - F_X(x) = \begin{cases} 1 & if \quad x \in [0,1) \\ 0.85 & if \quad x \in [1,2) \\ 0.45 & if \quad x \in [2,4) \\ 0.05 & if \quad x \in [4,8) \\ 0 & otherwise \end{cases} \quad (3)$$

3 Extreme Value Theory

EVT is a branch of statistics that is used to assess the probability of the occurrence of rare events based on previous observations

[8]. It has been widely applied in many disciplines such as finance, earth sciences, traffic prediction, and geological engineering. In MBPTA, EVT is used to analyse the tail behaviour of the execution time distribution based on the execution times observed during the measurement.

3.1 Independent and identical distribution

The prerequisite of EVT requires the observations to be independent and identically. *Independent* means that the occurrence of one event does not impact the occurrence of the other event. *Identical* indicates that each measured execution time is random and has the same probability distribution as the others.

In the context of timing analysis, i.i.d. implies that the measured execution time is not affected by the past events of the same task. For example, task *A* is executed twice consecutively on a processor with a first-in-first-out (FIFO) cache. The measured execution time is *x* for the first time and *y* for the second time. Because the cache is loaded with data and instructions needed after the first time the task is executed, *y* is expected to be much smaller compared with *x*. In this case, the execution time *x* and *y* are said to be dependent, which does not meet the i.i.d. requirement.

Previous research has proposed the adoption of randomised architectures for measurement-based probabilistic timing analysis[12, 13]. If the processor of the target system has a deterministic architecture, randomisation needs to be applied to randomise the measurement samples to satisfy the i.i.d. precondition [9, 14, 15].

If two events are independent, the joint probability is equal to the product of their individual probabilities:

$$P(A \cap B) = P(A)P(B) \tag{4}$$

For example, given a a task *A* with probabilistic execution time:

$$\begin{pmatrix} 5 & 10 \\ 0.1 & 0.9 \end{pmatrix} \tag{5}$$

and task *B* with probabilistic execution time:

$$\begin{pmatrix} 1 & 2 \\ 0.4 & 0.6 \end{pmatrix} \tag{6}$$

the probabilistic execution time of the both tasks is:

$$\begin{pmatrix} 5 & 10 \\ 0.1 & 0.9 \end{pmatrix} \times \begin{pmatrix} 1 & 2 \\ 0.4 & 0.6 \end{pmatrix} = \begin{pmatrix} 6 & 7 & 11 & 12 \\ 0.04 & 0.06 & 0.36 & 0.54 \end{pmatrix} \tag{7}$$

The CCDF is therefore:

$$\bar{F}_{A \cap B}(x) = \begin{cases} 1 & if \quad x \in [0, 6) \\ 0.96 & if \quad x \in [6, 7) \\ 0.90 & if \quad x \in [7, 11) \\ 0.54 & if \quad x \in [11, 12) \\ 0 & otherwise \end{cases} \tag{8}$$

3.2 Applying extreme value theory in measurement-based probabilistic timing analysis

Algorithm 1 demonstrates how to apply EVT in MBPTA, which includes three main steps: (1) extreme value selection; (2) fitting the distribution; (3) compare and convergence.

Algorithm 1: How to apply EVT in MBPTA
Result: pWCET
select extreme values;
fit the first distribution;
estimate the first CDF;
while *first round or not converged* **do**
collect more extreme values;
fit a new distribution;
estimate the new CDF;
compare;
end

3.2.1 Extreme value selection

EVT makes assumptions on the tail of the data distribution based on the extreme observations obtained from the measured data. Therefore, the measured execution times of the program must be converted into a set of extremes before applying the EVT. Two approaches can be used to collect the observed extreme execution times: block maxima (BM) and peak over threshold (POT).

The BM approach divides the collected execution times into subgroups/blocks. The longest execution time in every subgroup is one sample of extremes. The POT approach defines a threshold. All the execution times longer than the threshold are used as the extremes to estimate the pWCET.

The selection of a suitable size of the subgroups in the BM or a suitable threshold value in the POT plays a crucial role. Studies have been carried out to determine the impact of these decisions on the estimated results [2, 16, 17]. Neither an optimal size of the subgroups nor the best threshold value exists. Generally speaking, a smaller subgroup size or a lower threshold value can decrease the pessimism in the results. However the risk of obtaining an overly optimistic pWCET that is not safe to use increases.

3.2.2 Fitting the distribution

In this step, a model distribution that best fits the extremes is estimated. If BM was used in the previous step, the distribution must be Gumbel, Fréchet, or Weibull distribution. These three distributions are combined into a family of continuous probability distributions known as the generalised extreme value (GEV) distribution.

The GEV is characterised by three parameters: the location parameter $\mu \in \mathbb{R}$, the scale parameter $\sigma > 0$, and the shape parameter $\xi \in \mathbb{R}$. The value of the shape parameter ξ decides the tail behaviour of the distribution and to which sub-family the distribution belongs: Gumbel ($\xi = 0$), Fréchet ($\xi > 0$) or Weibull ($\xi < 0$). The CDFs of these three distributions are given below.

- Gumbel or type I extreme value distribution ($\xi = 0$):

$$F_{(\mu,\sigma,0)}(x) = e^{-e^{-(x-\mu)/\sigma}}$$

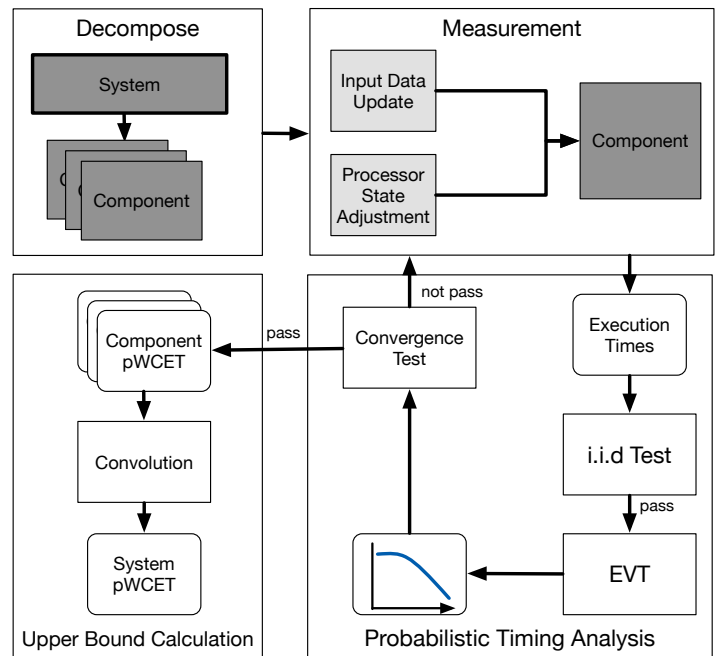
- Fréchet or type II extreme value distribution ($\xi > 0$):

$$F_{(\mu,\sigma,\xi)}(x) = \begin{cases} e^{-y^{-\alpha}} & y > 0 \\ 0 & y \le 0 \end{cases}, (\xi = \alpha^{-1} \text{ and } y = 1 + \xi(x - \mu)/\sigma)$$

- Reversed Weibull or type III extreme value distribution ($\xi < 0$):

$$F_{(\mu,\sigma,\xi)}(x) = \begin{cases} e^{-(-y)^{\alpha}} & y < 0 \\ 1 & y \ge 0 \end{cases}, (\xi = -\alpha^{-1} \text{ and } y = -(1 + \xi(x - \mu)/\sigma)).$$

If POT was used in the previous step, the distribution needs to fit the generalised Pareto distribution (GPD), which is a family of continuous probability distributions. The GPD is specified by the same three parameters as GEV: location parameter μ, scale parameter σ, and shape parameter ξ. The CDF of the GPD is:

$$F_{(\mu,\sigma,\xi)}(x) = \begin{cases} 1 - \left(1 + \frac{\xi(x - \mu)}{\sigma}\right)^{-1/\xi} & \text{for } \xi \ne 0 \\ 1 - \exp\left(-\frac{x - \mu}{\sigma}\right) & \text{for } \xi = 0 \end{cases}, (x \ge \mu \text{ when }$$
$$\xi \ge 0, \text{ and } \mu \le x \le \mu - \sigma/\xi \text{ when } \xi < 0).$$


3.2.3 Compare and convergence

Once the first data set of extremities is collected, the EVT uses the data to estimate the first CDF of the pWCET. In every subsequent round of the estimation, more extremities are collected and added to the data set to derive a new CDF. The CDF in the current round is compared with the CDF of the previous round using metrics such as the continuous ranked probability score (CRPS) [18]. In our case, we use the following convergence criteria to compare the respective accuracy of the two CDFs:

$$Score = \sum_{x=0}^{+\infty}[F_{current}(x) - F_{previous}(x)]^2 \tag{9}$$

Where F is the cumulative distribution. The score indicates the level of difference between the two cumulative distributions. The lower the score is, the closer the CDF is going to reach the point of convergence. Once the score reaches the desired value (such as 0.1), the pWCET can be derived using the converged CDF.

4 The proposed hybrid probabilistic timing analysis

Figure 3 is the illustration of the proposed HPTA approach. In our research, a system can be divided at different decomposition levels according to the requirement of the user. Because of the block isolation technique described in [3, 4], the software components can be executed independently from the rest of the program, and the processor state can be adjusted before every execution. This allows us to overcome two major challenges in applying the HPTA approach: (1) the i.i.d. data requirement of the EVT; (2) the calculation of the upper bound of the overall system.

In the section, we will describe the concept of decomposition level, and explain the challenges and how we solved these challenges using the proposed HPTA.

Figure 3: The proposed HPTA approach.

(a) A system with three decomposition levels.

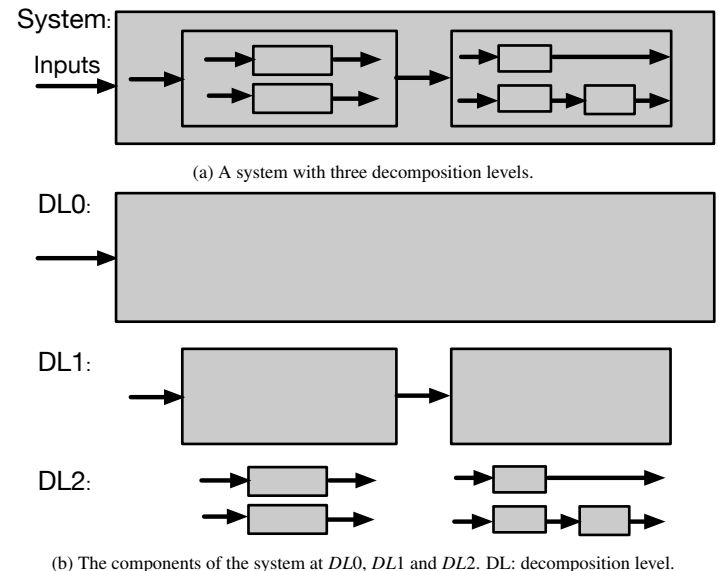
(b) The components of the system at *DL*0, *DL*1 and *DL*2. DL: decomposition level.


Figure 4: A system and the decomposition of the system at three decomposition levels.

4.1 Decomposition level

Figure 4a shows a system with components at three decomposition levels. The decomposition of the system is demonstrated in Figure 4b. Every grey rectangle represents one component, and the solid black arrows represent the data flow of the components. By our definition, *DL*0 is the lowest degree of decomposition because the complete system is measured at this level. The complete system is considered as one abstract component from which no details of the subsystems can be retrieved. At *DL*1, the mask of the system at *DL*0 is opened. Measurement can be conducted on the subsystems that are revealed at this level. As the decomposition level increases,

the system is decomposed in further detail, more components are revealed. The decomposition level can increase until the last sub-system is opened. The granularity of the timing analysis increases with the decomposition level.

4.2   Challenges

4.2.1   Independent and identical data requirement

Although EVT requires the samples to be identically distributed, the adoption of GEV opened up the applicability of MBPTA to more cases because it can tolerate up to a certain degree of dependence in the measured execution times[10]. The disadvantage is that such dependence can corrupt the reliability of the derived pWCET [19]. In some domains, techniques such as re-sampling and de-clustering can be applied to create independence between measurements [20]. Nevertheless, forcing independence into dependent execution time measurements can result in overly optimistic pWCET that is not safe anymore [2].

For instance, the calculation in the example given in Section 3.1 is only valid when task A and B are independent, otherwise the result might be overly optimistic. Suppose dependence exists between the two events such that the execution time of task B is always 2 when the execution time of task A is 10. The probabilistic execution time when A and B are both executed would be:

$$\begin{pmatrix} 6 & 7 & 12 \\ 0.04 & 0.06 & 0.9 \end{pmatrix} \tag{10}$$

The probabilistic execution time of the both tasks in this case is:

$$\bar{F}_{A \cap B}(x) = \begin{cases} 1 & if & x \in [0, 6) \\ 0.96 & if & x \in [6, 7) \\ 0.90 & if & x \in [7, 12) \\ 0 & otherwise \end{cases} \tag{11}$$

Given a deadline of 11, the probability of missing the deadline is 0.54 when A and B are independent (8), and 0.90 when A and B are dependent (11). In this case, overlooking the dependence between the tasks resulted in overly optimistic probabilities of a deadline miss.

4.2.2   Upper bound calculation

In deterministic hybrid timing analysis, the results are presented in absolute values. Therefore, the WCET of the complete system can be calculated simply by adding up the WCETs of every individual component. In statistics, convolution may be usually used to calculate the joint probability of two random variables. Unfortunately, this is not applicable in this context. The reason is that the probability distribution of the sum of two or more random variables is equal to the convolution of their distributions only when the variables are independent.

Since hybrid timing analysis is conducted on the components that construct the complete system, the execution time of one component often impacts the execution time of another component. This dependence makes the calculation of the overall pWCET much more complicated.

4.3   Solutions

Based on the information provided in the previous text, one can conclude that in order to overcome the challenges, we need to find a solution to the dependence in the measured execution times and the dependence between individual components.

4.3.1   Dependence in the observed execution times

In MBPTA and HPTA, dependence exists in the data samples if two or more of the observed execution times interfere with each other. Generally speaking, such dependence can come from:

1. *Software dependence*: The dependence between inputs and the paths taken by the program. For example, if input/path A is always followed by input/path B, A and B are dependent.

2. *Hardware dependence*: The hardware state left by the previous execution, which becomes the initial hardware state of the current execution.

To reduce the software dependence, we choose the *per-path* approach to collect the execution times for EVT. The other approach is know as the *per-program* approach [7]:

1. *Per-program*: After the measurement, the EVT uses all the measured execution times as one sample group. EVT is applied to the sample group to estimate the pWCET for the complete program.

2. *Per-path*: After the measurement, all the measured execution times are divided into sample groups. One group includes all the execution times measured from one program path. EVT is applied to each sample group to estimate the pWCET of the program path the sample group represents. The pWCET of the complete program is then calculated by taking the upper bound of the pWCETs of all the paths.

For instance, a system has two paths with the execution times at 10/15 (10 or 15 time units) and 60/65. The probabilities of the paths taken by one randomly chosen single execution are 0.3 and 0.7 respectively. Suppose the different execution times observed in the same path are due to a hardware component, which may generate 0 extra time units with a probability of 0.4 or 5 extra time units with a probability of 0.6. The probability execution time profile (ETP) of the system is:

$$\begin{pmatrix} 10 & 15 & 60 & 65 \\ 0.12 & 0.18 & 0.28 & 0.42 \end{pmatrix} \tag{12}$$

The pWCET derived using the per-program approach is:

$$pWCET_{per-program} = \begin{cases} 1 & if & x \in [0, 10) \\ 0.88 & if & x \in [10, 15) \\ 0.7 & if & x \in [15, 60) \\ 0.42 & if & x \in [60, 65) \\ 0 & otherwise \end{cases} \tag{13}$$

$$= \begin{bmatrix} 0 & 10 & 15 & 60 & 65 \\ 1 & 0.88 & 0.7 & 0.42 & 0 \end{bmatrix}$$

The pWCET derived using the per-path program is:

$$pWCET_{per-path} = \begin{bmatrix} 0 & 60 & 65 \\ 1 & 0.6 & 0 \end{bmatrix} \quad (14)$$

As can be seen, compared with the per-path approach, the per-program approach was able to produce a tighter result. The pWCET derived using the per-program approach is valid to upper bound randomly chosen single executions of the target program. However, it is not applicable to be used in convolution when calculating the overall pWCET of multiple executions of the target program. The reason is that the probability distribution of the sum of two or more random variables is equal to the convolution of their distributions only when the variables are independent. For example, if path 60/65 is forced to be taken when path 10/15 is observed in the previous execution, the pWCET of two consecutive executions of the program is:

$$\begin{bmatrix} 0 & 70 & 75 & 80 & 120 & 125 & 130 \\ 1 & 0.952 & 0.808 & 0.7 & 0.588 & 0.252 & 0 \end{bmatrix} \quad (15)$$

The pWCET calculated using the probability derived from $pWCET_{per-program}$ is:

$$\begin{bmatrix} 0 & 70 & 75 & 80 & 120 & 125 & 130 \\ 1 & 0.9424 & 0.8428 & 0.6412 & 0.4116 & 0.1764 & 0 \end{bmatrix} \quad (16)$$

Under the dependence introduced by the execution condition, the probability that the two consecutive executions exceed 125 time units is 0.252. However, the pWCET using the convolution on the probability derived from $pWCET_{per-program}$ gives a probability of 0.1764, which is too optimistic.

In the per-path approach, the measured execution times are grouped according to the program paths. Therefore, the influence of the input data is eliminated within every group. The variations in the execution time within the same group are purely due to the hardware. By taking the upper bound of the pWCETs of all the paths, the pWCET generated by the per-path approach can be used safely in convolution for estimating any overall pWCET in which the execution of this task is executed consecutively. In the above example, the pWCET calculated by applying convolution to the probability derived from $pWCET_{per-path}$ is:

$$\begin{bmatrix} 0 & 120 & 125 & 130 \\ 1 & 0.84 & 0.36 & 0 \end{bmatrix} \quad (17)$$

Therefore, using the per-path approach, the proposed HPTA method can upper bound the $pWCET$ under the dependence introduced by the execution condition.

To reduce the hardware dependence, we try to push the hardware to the worst-case state at the beginning of every execution so that every execution can start with nearly the same initial state. For example, the pipeline is flushed, and "trash code" is executed to fill the caches with irrelevant data and instructions before every execution.

4.3.2 Dependence between components

In order to calculate the pWCET of the overall system using convolution, the independence between the pWCETs of the software components must be guaranteed. Such kind of dependence can be found in:

1. *Software dependence*: The output of the precedent components, which is the input of the current component.

2. *Hardware dependence*: The hardware state left by the previous component, which becomes the initial hardware state of the current component.

The software dependence can be removed together with the dependence in the observed execution times by the per-path approach. This is because the path-approach automatically selects the input(s) leading to the longest execution paths that upper bound all the other inputs. The hardware dependence no longer exists because the components execute in isolation from the rest of the program in the proposed method. Hence there are no precedent components.

5 Case study and experiment setup

5.1 Case Study

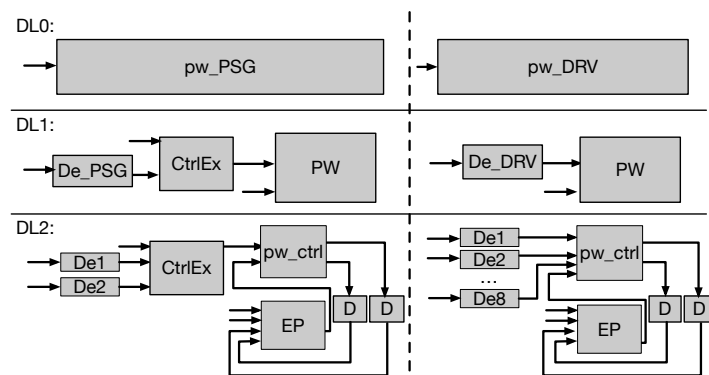
For the case study, we adopted a Simulink power window model. Figure 5 is the power window model [21, 22] at *DL*0, *DL*1 and *DL*2. A power window is an automatic window in a car that can be raised and lowered by pressing a button or a switch instead of a hand-turned crank handle. The complete application of a power window normally consists of four windows that can be operated individually. The three passenger-side windows can be operated by the driver with higher priority. In this paper, we only use the front passenger-side window and the driver-side window.


Figure 5: Power window passenger (left) and power window driver (right) at decomposition level 0, 1 and 2. DL: decomposition level; pw_PSG: powerwindow passenger, De_PSG: debounce passenger, CtrlEx: control exclusion, PW: powerwindow main component, De_DRV: debounce driver, De: debounce, pw_ctrl: powerwindow control, EP: end of range and pinch detection, D: delay.

The C code of the power window was generated using Embedded Coder® [23] targeting an ARM Cortex microprocessor with a discrete fixed-step solver at a fixed-step size of 5 ms. The BM approach with a block size of 20 was used in the extreme value selection process to collect the extremities for the EVT. The exceeding probability of 1E-10 was used for the pWCET.

The Kolmogorov-Smirnov (KS) test was used to verify the identical distribution requirement, and the runs-test was used to verify

Table 1: The p-values for the independent and identical distribution tests. NoN: number of nop instructions; pw_DRV: powerwindow driver; pw_PSG: powerwindow passenger; R: runs test; KS: Kolmogorov-Smirnov test.

7	2714	2797	1670	1689	15	2568	2569	1632	1658

the requirement for independence. $p > 0.05$ indicates the data follows the desired distribution.

The case study is designed to test the following assumptions:

1. Can the proposed HPTA method reduce the dependence in the measured execution times and facilitate the collection of i.i.d. execution times?

2. Can the proposed HPTA method reduce pessimism at a higher decomposition level?

5.2 Experiment Setup

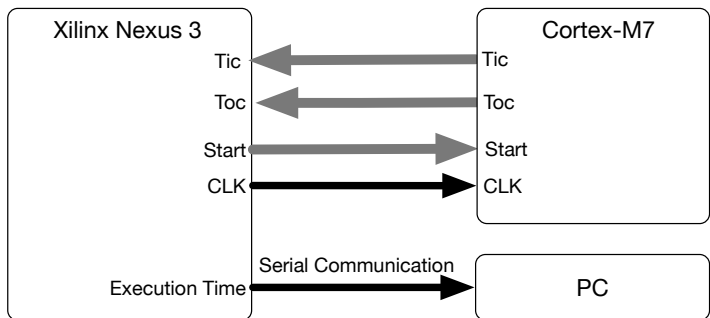
The experiment setup is shown in Figure 6. The processor is an ARM Cortex-M7 processor that contains a four-way set-associative data cache and a two-way set-associative instruction cache. Both caches use the random replacement policy. The Xilinx Nexus 3 FPGA is used to measure the execution time of the code on the ARM-processor. It is driven by the *CLK* signal sent from the processor to synchronise the clocks. The measurement process starts by sending the *Start* signal from the FPGA to the processor. Two GPIO pins of the processor are used to set the *Tic* and *Toc* flags. Before the code starts to execute, the *Tic* pin is toggled to start counting the number of clock cycles that have passed. After the code is executed, the *Toc* pin is set to stop the timer. Eventually, the value in the timer (*Execution Time*) is collected through a serial port.


Figure 6: Experiment setup.

6 Results and discussion

6.1 Reducing dependence in the measured execution times

Table 1 shows the results of KS and runs test. As can be seen, all the *p*-values are significantly higher than 0.05, which means that the i.i.d. requirement is fulfilled and the collected data can be applied in EVT to estimate the pWCET. The NoN indicates the number of the *nop* instructions added to emulate different memory alignments [3]. These *p*-values confirm our assumption that the proposed HPTA can reduce the dependence in the executions to facilitate the collection of i.i.d. data required by the EVT.

Table 3: The estimated pWCET calculated using sum and convolution at different decomposition levels. DL: decomposition level; pw_DRV: powerwindow driver; pw_PSG: powerwindow passenger; cc: clock cycles; dWCET: measured deterministic WCET; $pWCET_{Sum}$: estimated probabilistic WCET calculated by adding the pWCETs of the components up; $pWCET_{Conv}$: estimated probabilistic WCET derived from the convolution of the pWCETs of the components.

	pw_DRV (cc)			pw_PSG (cc)		
	dWCET	$pWCET_{Sum}$	$pWCET_{Conv}$	dWCET	$pWCET_{Sum}$	$pWCET_{Conv}$
DL0	2764	2849		1678	1953	
DL1	2652	3852	3465	1838	2949	2690
DL2	4820	6025	5167	2596	3778	3484

Table 2 shows the WCETs of the complete powerwindow-driver benchmark and the complete powerwindow-passenger benchmark with 16 different alignments. The longest measured deterministic WCET was 2764 reached by NoN = 3 in the driver-side window

Across all the alignments, the estimated pWCET is more pessimistic at the selected exceeding probability compared with the deterministic WCET. However, in some cases, such as NoN = 15 in pw_DRV, the difference between the two WCETs is relatively small. The reason could be that the execution time contributed by independent random elements in the hardware is reduced by imposing a worst-case execution scenario on the longest path. Since random events in the hardware rarely happen, the measured execution times can be very close to the estimated pWCET.

The pWCET calculated using convolution ($pWCET_{Conv}$) is in general lower compared with the $pWCET_{Sum}$. Nevertheless, $pWCET_{Conv}$ still leaves a reasonable margin with the deterministic WCET. This observation confirms our assumption that simply adding up pWCETs in HPTA will lead to overly pessimistic results. Using convolution can help to reduce such pessimism and produce a reasonably sound result.

7 Conclusion

In this article, we proposed a HPTA method that is able to (i) collect the i.i.d. data required by EVT by reducing the dependence between the measured execution times and (ii) reduce the dependence between blocks to make it possible to use convolution to calculate the pWCET of the overall system. We are aware that forcing independence into dependent execution time measurements can make the data no longer representative of the dependent system behaviour. Therefore, several approaches, such as using the per-path approach to upper bound the pWCETs of all the paths, were taken to ensure the derived pWCET is not overly optimistic. However, this might have introduced too much pessimism into the estimated pWCET.

Another novelty of the proposed HPTA method is that it can be applied at different granularities by adjusting the decomposition level. Performing the analysis at a higher decomposition level can help to reduce pessimism. On the other hand, with the increased decomposition level, the cost to derive the pWCET also increases.

Compared with the deterministic HTA approach proposed in [3], this HPTA approach is more pessimistic with the exceedance probability of 1E-10. On the other hand, instead of giving a de-

and 1678 reached by NoN = 8 in the passenger-side window. The estimated pWCET in the driver-side window was 2849 reached by NoN = 3 and 1953 reached by NoN = 8.

6.2 Reducing pessimism in high decomposition levels

Table 3 shows the estimated pWCETs of the benchmarks calculated using sum and convolution at three decomposition levels. The highest pWCET of the 16 different alignments were used as the pWCET of every block. As can be seen, the WCETs increase with the decomposition levels. The highest WCET was reached by $pWCET_{Sum}$ at $DL2$ with 6025 clock cycles for the driver and 3778 clock cycles for the passenger. The difference between the deterministic WCET and pWCETs also became more prominent with the decomposition level, which means a higher decomposition level is associated with larger pessimism.

terministic value, this approach gives an exceedance probability to each possible execution time. We hope the results of this HPTA approach can be used as a reference to avoid unnecessary waste on the hardware cost in the hand of experienced engineers when designing a non safety-critical system that can tolerate a certain degree of deadline misses.

In a content-based image retrieval system(CBIR) feature classification,identification, and extraction play an important role. The retrieval of images using a single feature is a challenging task in CBIR systems. The high retrieval rates are reported based on combining multiple features, multiple algorithms and preprocessing steps, feature classification, and segmentation because the image retrieval are mainly based on the content in an image. This paper presents a texture feature extraction for the image retrieval system from semivariogram and robust semivariogram technique. A semivariogram is a statistical approach that provides the textural information based on the lag distance 'h'.The proposed method is tested on various standard image databases such as Corel-1k, Corel-10k, and Coil-100 database. The semivariogram and robust semivariogram methods are tested for the Corel 1k database using four distance metrics i.e. Euclidean, Manhatten, Canberra, and Chord distance to check which distance measure is appropriate for the CBIR system.The proposed method is also tested on three types of databases to investigate the performance of the CBIR system. The Matlab simulation results show that the effective performance of the system with Euclidean distance.

1   Introduction

The capturing of an image is started back in the past one and half a century, and the collection of images is rapidly growing from the past thirty years of growing digital technology and internet usage. The collection of images is also increasing leading to a extremely large database. In many applications, the extraction of equivalent images from the large database is essential and useful. There are two trends currently using the image search from the image collection data set namely text-based and content-based. The text-based search uses meta-data like keywords, description of the image to get back the similar images. It is the main disadvantage of this system. In contrast content based uses existing property (color, texture, and shape) to find the equivalent images from the large database. This paper is an extension of work originally presented in conference [1].

Many researchers have come up with the idea of combining basic image features to get the most comparable images as required by the query image. The color and texture feature is taken together to get the image information by applying wavelet [2]. The wavelet transform decomposes the images into orthogonal components for the better localization of the spatial information in an image. The method applied to extract color and texture information is a color histogram and wavelets respectively. .

It is noticeable that based on these work the retrieval rates are improved by combining multiple features, multiple algorithms and preprocessing steps, classification, segmentation, etc. In this work, a good CBIR system is designed by using the texture feature. In an image retrieval system all the three features color, texture, and shape play an important role [3]. Texture identification is an important part of the research in image retrieval and pattern recognition. It is categorized into two classes i.e. regular and irregular, directional, and non-directional based on the observations of real life. In general, the texture is characterized as two main approaches: Statistical and Structural.

1)Structural approach: the texture analysis is done based on the arrangement of preserving texture pixel in some pattern or repetitive pixel. 2) Statistical approach: The texture feature can be analyzed by studying numerical data of the image. It provides the relative estimation of the arrangements of the intensities in an image region [4]. The most commonly used and widely accepted statistical approach for texture, classification is the GLCM method [5]. The recently developed method for the texture classification and analysis includes block truncation coding [6], Markov random fields [7] to construct the image patches using neighboring pixel, local energy histogram [8], hidden Markov model [9], shearlets and linear regression [10]. Many of the texture algorithms and methods have been applied to the Brodatz database.

In this paper, geostatistical parameter called semivariogram and robust semivariogram are applied to the image to get the texture information to the image databases. The semivariogram method is basically applied to remote sensing images to characterize the texture property. It is a distance metric that calculates the absolute differences between the semivariogram of the two images to determine the class of test images. The various distance measures are used to verify the effective retrieval of images.

1.1 Motivation

The main idea of the designing image retrieval system is to provide the desired images as of user interest. This leads to finding the solution to set up a good image retrieval system that will be able to find similar images from the huge image data set. The image search is basically with the use of content in the image.

In this study, a new CBIR system is proposed based on semivariogram. In general the semivariogram is applied for the remote sensing images in the area of geo-statistics.These images are captured by satellites that will be having high spatial resolution.To analyse the characteristics of this data semivariogram is one of the best method.Like remote sensing image CBIR system works with large image database. These databases contain many categories of images that will have a non-uniform distribution of the pixel intensities and dissimilar backgrounds.Since semivariogram is a statistical approach, it really works well for the image to characterise the texture intensities.This is the case the idea of adapting semivariogram method for the CBIR system.The main focus of the work is to use the minimal feature from the image and reduce the computational time required for the entire image database.

1.2 Organisation of the paper

The remainder of this article is organized as follows. Section 2 discusses the related work and section 3 gives the mathematical model of the proposed system. In section 4 feature extraction is discussed with an example. Section 5 briefly explains the experimental design and results. Section 6 gives the distance metrics for similarity measurements. Section 7 discusses the experimental design and Section 8 gives performance evaluation and conclusion followed by section 8.

2 Related Work

From the discrete wiener-Levy process in [11], it is proved that a semivariogram gives a spatial correlation of the pixels than the covariance method. The random process called the Levy process is a Brownian motion mathematical representation. The covariance fails to extract spatial information with distortion whereas the semivariogram strongly characterizes the spatial features. In geostatistics, the features analysis has to be done by fitting the experimental semivariogram to a theoretical semivariogram. The model examines the structure and continuity of the spatial relationship in a random field.

The experimental semivariogram model can be fit into the theoretical semivariogram model. There are two methods have been used in [12]. One is by manual fitting and the second is by automatic model fitting. The automatic model fitting uses methods

like maximum likelihood or least squares [13].In manual fitting, the model was chosen based on picture perception of the experimental semivariogram. For a given waveband information reproduction of the pattern will be clear and strong explanation of the pattern in an image can be provided by the semivariogram.

In general remote sensing images for the land, consolidation is having a high spatial resolution. This is a limitation for the pixel-based analysis and land cover classification in remote sensing images concerning its spectral behaviour. To overcome this problem texture extraction is done using fixed window size and varying window size depending on semivariogram result. Texture classification in microwave images [14] is executed using the semivariogram method. The statistical parameters are determined and considered as image features. They are first and second-order element difference, first and second-order element inverse difference, entropy and, uniformity.

The accurate object-oriented classification is presented in [15] for Quick Bird images by applying a method called the set of semivariogram texture feature(STF) based on the mean square root pair difference(SRPD). The parameter like direction, lag distance, and moving window size are considered for semivariance analysis to classify the texture feature.

A new set of 2-D RCWF(Rotated complex wavelet filter) is designed to improve the retrieval accuracy using complex wavelet filter coefficients. It produces strong texture information of the oriented images in six different directions. This is non-separable and oriented relatively improves the classification of oriented textures. Also, they have used the combination of dual-tree RCWF and DFWCT to extract the texture features in 12 different directions [16].

The new algorithm based on Gabor filter and EHD(Edge Histogram Descriptor) has been proposed for the texture feature extraction. These two are fused to get the good performance of the system. The Gabor and EHD are applied to every 40 images and then six bins are considered from each of the images. This improves the efficiency of the EHD. As a result, the dimension of the character is reduced to 40X6 as mentioned in [17].

Perceptual texture features are considered for the representations and retrieval of images. These features contain contrast, directionality, and coarseness and dryness. Where busyness has given less importance compared to the other three features. They have used these four perceptual features for the experiment. The experiment result shows appreciable scores for the broadtz image database retrieval [18].

The image retrieval system uses a combination of color and texture features. As a color feature color autocorrelation of the HSV color model is used and for texture feature BDIP(Block difference of inverse probabilities) and BVLC(Block variation of the local correlation coefficient)are used. These two texture features effectively measure the texture smoothness. The image is divided into 2X2 blocks and these moments are computed in the wavelet transform domain. This gives better accuracy when compared with conventional texture extraction methods [19].

Palm print retrieval is proposed in [20] using texture features. Texture energy is presented to identify the global and local texture features of the palm print. The four masks which are defined in the work are used to extract the line segment in horizontal and verti-

cal directions and is referred to as local feature. The local feature provides detailed information and global feature provides overall properties of the palm print. The steps involved in global feature calculations are image alignment, energy computation, boundary tracing, a center of gravity calculation, and mapping the key points.

The content-based image retrieval system is an active research area for the past two decades. Many researchers have come up with different ideas to enhance the performance of the system by extracting texture features. The most used texture extraction methods are GLCM, covariance method and co-occurrence matrix, and so on. In this work, the semivariogram method is applied for texture extraction. The semivariogram is widely used to analyse the pattern of the remote sensing images. The content-based image retrieval databases will have distinct images with different types of patterns. The function of the semivariogram is to find the spatial distance between each pattern in the image. The semivariogram approach and spectral distortion measures are applied to image texture retrieval in [21]. The experiment is conducted using the Broadtz texture database. The spectral distortion methods are combined with a semivariogram to retrieve similar images. The effectiveness of the work is tested on Illinois at Urbana-Champaign texture database. The semivariogram method does not need the knowledge of the mean value of the function for the estimation of the spatial relationship. The probability of the random function is not required for the semivariogram methodology as in the GLCM method and co-occurrence method.

A hierarchical retrieval system is proposed in [22] using the visual contents(color,shape and texture).The fusion of histogram gradients, adaptive tetrolet transform and auto color correlogram methods are applied to extract the image features and to make the image retrieval more effective.

The proposed method estimates the pattern similarity by finding the distance between the pixels as it plays an important role in recognition of the similar images from the large database.

3 Mathematical Model for Semivariogram and Robust semivariogram

Variance is a measure of data spread between numbers in a data set. It measures the data on how far each number in the set is from the mean and also its variability from the average mean. A small variance shows how close the data to the mean and high variance indicates the data points are how far from the mean.The variogram is a statistical measure can be represented graphically in a manner which characterizes the spatial continuity i.e. roughness of a dataset.

Semivariogram is one of the standard geo-statistical parameters is used to find spatial relationships between two values in that location as a function of the distance. The lag distance h is taken for paired location in an image.

Let X, z, and h be a random function, a spatial location, and a lag distance in the sampling space, respectively. The variogram of the random function is defined as:

$$2\gamma(h) = Var[Z(x) - Z(x + h)] \tag{1}$$

where $\gamma(h)$ is called the semivariogram of the random function. Let $Z(x_i)$ be the pixel value at the location , i = 1, 2, . . ., n, where n is

the sampling size. The variable z is the intensity value at location of the image. The experimental semivariogram, of the random function is expressed as in [26]

$$\gamma(\hat{h}) = \frac{1}{2N(h)} \sum_{i=1}^{N(h)} [Z(x_i) - Z(x_i + h)]^2 \tag{2}$$

The reason for introducing the robust semivariogram is because the semivariogram is not robust with respect to skewness and distorted information.The robust semivariogram denoted as $\gamma_R(h)$ is defined as in [23] ,[24]

$$\gamma_R(h) = \delta[\frac{1}{N(h)} \sum_{i=1}^{N(h)} | Z(x_i) - Z(x_i + h) |^{1/2}]^4 \tag{3}$$

where

$$\delta = \frac{1}{2(0.457 + \frac{0.494}{N(h)})} \tag{4}$$

4 Extraction of Texture Feature of an Image

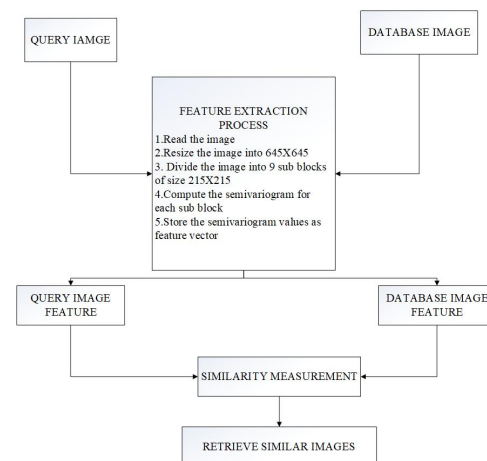
The texture feature can be extracted using the semivariogram.The block diagram of the proposed method is as shown in fig 1.Let us consider an image as shown in fig 2. To extract texture information the image is resized into 640X640 pixels. Then the image is divided into 9 sub-images of size 215X215. The lag distance 'h' value is taken as 20. The variogram is calculated for each sub-image and its results in a feature vector size 20X9. The pictorial representation of the semivariogram features and robust semivariogram features is as shown in fig 3 and fig 4.The variogram shape near the origin is linked to the smoothness of the phenomenon. If the shape is continuous and differentiable it shows smoothness of the image, if it is not differentiable it shows roughness of the image. This process is applied to all the images in the query database and search database and these features are stored to find the similarity distance.


Figure 1: Block diagram of the proposed method

Figure 2: Bus Image
Figure 3: Experimental Semivariogram for the Bus image
Figure 4: Robust Semivariogram for the Bus image

5   Distance Metrics for similarity measurements

Euclidean distance: If S (x1, y1) and T (x2, y2) are the two feature points of the image then the Euclidean distance between the two points is given by,

$$EUD(S, T) = \sqrt{(x_1 - x_2)^2 + (y_1 - y_2)^2} \qquad (5)$$

label1.4

Canberra distance: The Canberra distance is a numerical measure of the distance between pairs of points in a vector space. The Canberra distance (CBD) between two vectors is given by ,

$$CBD(S_i, T_i) = \sum_{i=1}^{N} \frac{\mid x_i - y_i \mid}{\mid x_i \mid + \mid y_i \mid} \qquad (6)$$

Manhattan distance: If S (x1, y1) and T (x2, y2) are two points then the Manhattan distance between two points S and T is given by,

$$MHD(S, T) = \mid x_1 - x_2 \mid + \mid y_1 - y_2 \mid \qquad (7)$$

Chord distance: It is used to find the correlation between the two images.If a and b are referred as a array of the two images then the chord distance is given by.

$$C = 1 - abs[\frac{a(i) * b(j)}{norm(a(i)) * norm(b(j))}] \qquad (8)$$

6   Experimental Design and Discussion

6.1   Experiment with three databases using Euclidean distance

The image retrieval experiment is conducted using the natural and object-based image database namely Corel 1K, Corel 10K, and Coil 100. The images in these databases are taken to investigate the performance of the proposed method. The Corel 1K database contains 10 categories and each category has 100 images such as people, beach, bus, dinosaur, roses, and so on. Each image of size 256X384 and 384X256.This is divided into query database of 300 images i.e 30 images from each category and search a database of 700 images i.e. 70 images from each category.

The proposed method is examined using the Corel 10K database [6]. This database contains 10000 natural image collection of 100 categories. Each image of size 126X187 and 187X126. The images in this database are having a dissimilar and unstructured pattern. Some categories of images are dolls, doors, sunset, mountains, etc. Each category has 100 images which are divided into 3000 images of query database i.e 30 images from each class and 7000 images of search database i.e. 70 images from each category.

The COIL 100 dataset is used to investigate the performance of the proposed image retrieval system. This database contains 100 categories of 7100 images. Each image is of size 128X128. This database is having object-based images like a hammer, car, toy, fruits, etc with uniform background and these images are most similar in pattern. This database is divided into a query database of 1000 images 10 images from each class and a search database of 6100 images 61 images from each class.

The system is designed to show the top ten retrievals of similar images for each query image. The similarity matching is based on the shortest distance score measured using Euclidean distance metrics between the query image and the database image. If the system retrieves similar images according to query, then we say the system is retrieved the target images else the system fails to retrieves the target images. The performance of the system is examined using average precision and average recall.Table 1 shows the three databases' precision and recall values using semivariogram method and lag distance is set to 20.

Table 1: Prescision and recall values using Experimental semivariogram on Image Databases.

sl No	Name of the Database	Precision	Recall
1	Corel 1K	0.77	0.109
2	Corel 10K	0.323	0.045
3	Coil 100	0.858	0.126

6.2 Experiment with Corel-1k database using four distance measures

The retrieval rates are computed using the complete Corel 1k dataset using four distance metrics. The retrieval test is done using the semivariogram and robust semivariogram method by setting the lag distance value h is equal to 20.

The distance measures compared using semivariogram and robust semivariogram methods. Table 2 and Table 3 show the average precision and average recall values for four distance measures. The examples for retrieval of these measure is as shown in fig 12, fig 13, fig 14 and fig 15. The fig 11 shows the query images.

Table 2: The average Precision values for Four distance metric

sl No	Distance metric	Semivariogram	Robust Semivariogram
1	Euclidean	0.77	0.78
2	Manhatten	0.52	0.51
3	Canberra	0.58	0.72
4	Chord	0.38	0.54

Table 3: The average recall values for four distance metric

sl No	Distance metric	Semivariogram	Robust Semivariogram
1	Euclidean	0.109	0.109
2	Manhatten	0.061	0.072
3	Canberra	0.071	0.102
4	Chord	0.176	0.057

6.3 Experiment with lag distance 'h' for the Corel-1k database using Euclidean distance

The semivariogram is a function of variable lag distance h. The semivariogram increases the dissimilarity with the lag distance h. If the distance is more it fails to identify the patterns of the image. The semivariogram is calculated based on the lag distance. In this experiment, the distance chosen is 20 and 30. As the distance increases the textural information is lost. if the distance is less than strong textural information can be extracted. The table 4 shows the time taken for the calculation of semivariogram and robust semivariogram for a single image. Table 5 shows the precision and recall values for the retrievals of corel 1k database with lag distance 20 and 30. From the table 5 we can notice that for the lower lag distance the performance of the system is effective.

Table 4: The computation time for different lag distance

sl No	Lag distance(h)	Semivariogram	Robust Semivariogram
1	30	1.070 sec	2.88 sec
2	50	1.483 sec	4.25 sec
3	100	2.136 sec	6.59 sec
4	150	2.448 sec	7.566 sec
5	200	2.479 sec	7.91 sec

Table 5: The computation of Image retrievals for the lag distance h=20 and h=30 using semivariogram

sl No	Lag distance(h)	Precision	Recall
1	20	0.77	0.109
2	30	0.74	0.06

From the Table 4, we can see that as distance increases computation time increases, and the amount of information decreases. As the distance taken is small the rate of information increases and results in more retrieval of similar images i.e. lower the distance higher the continuity. For the lag distance h the proposed method results in an effective retrieval of similar images.

Figure 5: Query Images from COIL 100 dataset
Figure 6: Retrieved images for the queries show in figure 5.

6.4 Retrieval results

The feature vectors are stored and are tested for four distance metrics. The result shows that Euclidean distance is best suited for the retrieval of similar images from the image database. The robust semivariogram shows still good performance comparing with the semivariogram method. This is because the semivariogram is not robust against the distribution and distortion of the pixel values. The Euclidean distance measure results in good retrieval of similar images when compared to the other three distance measures. Results

are tabulated for the first top ten retrieved images. For the Dinosaurs, Rose, and Horse class Ten images of the same class are retrieved at the top ten images. The results by using the semivariogram method for the image databases are tabulated in Table 1.

Figure 7: Query image from COREL-1K database

Figure 8: Retrival using Euclidean distance for the COREL-1K database

Figure 9: Query image from COREL-10K database

Figure 10: Retrival uisng Euclidean distance for the COREL-10K database

The top ten retrieved images for the Coil-100, Corel 1K, and Corel 10K database are shown in fig 6, fig 8, and fig 10 respectively. The Query samples for these retrievals are shown in fig 5, fig 7, and fig 9. For the COIL 100 database, the proposed technique is effective in retrieving similar images from the database for all the categories present in the database. The semivariogram method

works well for the Corel 1k and Corel 10k database in which these databases are having the most dissimilar pattern of images.

7 Performance Evaluation and comparison

In content-based image retrieval, most of the researchers use precision and recall as the evaluation metrics. Precision is the proportion of relevant images retrieved over the total number of images retrieved and recall is the relevant images retrieved over a total number of relevant images are there in the database. The precision and recall are defined,

Precision = $\frac{R}{R1}$

Recall = $\frac{R}{R2}$.

where, R: Number of relevant images retrieved.
R1: Total number of images retrieved.
R2: Total number of relevant images in the database.

The proposed method gives 77% of efficiency for the corel 1k database,32.3% for corel 10k and 85.8% efficiency for the coil-100 database as shown in the Table 1.

The experiment is conducted to investigate which distance measure is best suited to find the query image's closeness with the database image.We have compared the performance of the CBIR systems in terms of precision and recall values using Euclidean distance, Canberra distance, Manhattan distance, and Chord distance. The performance results are as tabulated in the table shows that Euclidean distance is best suited for retrieving images from the large database for the proposed approach. Whereas Chord distance shows very low performance compared to Euclidean distance,Canberra distance and Manhattan distance.

7.1 Comparison with existing methods

The experiment is compared with some of the existing methods under the Corel 1k database. It can be seen that the proposed method performs better in comparison with the existing CBIR methods as in [12]–[25]. The proposed methods yield the average precision value 0.77 and 0.78 concerning semivariogram and robust semivariogram.Table 6 shows the comparison of Corel-1K database with existing methods.

For Corel 10000 database, the experiments were conducted as similar to Corel 1000 database. In this work, 100 categories are used to check the system performance. The work carried in [26] uses the 20 image categories to test the system performance. As similar to the experimental set-up in [27], [28]the number of retrieved images is set to 10.Table 7 exhibits the proposed method's comparisons over the existing methods for Corel 1k and Corel 10k database.

The COIL-100 database is compared with existing methods as shown in Table 8. The former schemes show good results by considering only a few categories of the COIL-100 database. In our work, the results are tabulated for the entire categories present in the COIL-100 database.

The Table 7 and 8 shows the average precision values for the best retrievals of image categories. The authors from [29], [30]

presents the system performance which gives best results for some categories of the image database.The number categories does not play any role for the system performance ,it mainly depends on right choice of the feature and the similarity measurement. The proposed work is tested for all the categories of the image database and it is capable of retrieving most similar images for all the categories except for the Corel 10k database.

Sr. No	Method	Average precision
1	[39](10 categories)	0.86
2	[40](15 categories)	0.88
3	[41](15 categories)	0.78
4	[42](10 categories)	0.86
5	[43](10 categories)	0.93
6	**Proposed method**(100 categories)	**0.858**

8 Conclusion

The semivariogram and robust semivariogram techniques are applied to the color images for the feature extraction and retrieval processes from the large database.These techniques gives promising texture feature for the images.Both methods are analysed and compared with different distance metrics. The experiment tested using three databases having images of natural scenes, color, texture, and objects. The results are computed in terms of precision and recall. The precision rate achieved for the Coil-100 database is 85% and the Corel-1K database is 76%. The improved performance is observed with Euclidean distance measure over three distance measures. The experiment results show that the semivariogram is more effective for the content-based image retrieval system but not limited to remote sensing images.

ABSTRACT

Computer Vision is a domain which deals with the challenge of enabling technology with vision capabilities. This goal is accomplished with the use of Convolutional Neural Networks. They are the backbone of implementing vision applications on embedded systems. They are complex but highly efficient in extracting features, thus, enabling embedded systems to perform computer vision applications. After AlexNet won the ImageNet Large Scale Visual Recognition Challenge in 2012, there was a drastic increase in research on Convolutional Neural Networks. The convolutional neural networks were made deeper and wider, in order to make them more efficient. They were able to extract features efficiently, but the computational complexity and the computational cost of those networks also increased. It became very challenging to deploy such networks on embedded hardware. Since embedded systems have limited resources like power, speed and computational capabilities, researchers got more inclined towards the goal of making convolutional neural networks more compact, with efficiency of extracting features similar to that of the novel architectures. This research has a similar goal of proposing a convolutional neural network with enhanced efficiency and further using it for a vision application like Image Classification on NXP Bluebox 2.0, an autonomous driving platform by NXP Semiconductors. This paper gives an insight on the Design Space Exploration technique used to propose A-MnasNet (Augmented MnasNet) architecture, with enhanced capabilities, from MnasNet architecture. Furthermore, it explains the implementation of A-MnasNet on Bluebox 2.0 for Image Classification.

1 Introduction

Computer Vision is becoming an essential application in this modern world. With advances in technology autonomous cars, drones and UAVs, robots etc have been enabled with vision capabilities. These technologies use Convolutional Neural Networks (CNNs) to process the images or video input. They are used for applications like Image Classification, Object Detection and Semantic Segmentation etc. CNNs are a part of Deep Learning, which is a subset of Machine Learning (ML). Due to the advances in AI, ML capabilities increased and this enabled a whole new field of Deep Learning. This field deals with creating, optimizing and implementing algorithms which enables technology to become self-reliant and gain human level precision. The prime goal is automation of these technologies in a way that they are able to operate perfectly without any human intervention.

Convolutional Neural Networks are used in developing healthcare technologies, which have almost human level precision and are used to save lives in hospitals. Medical imaging devices which, de-

tect even minute particles, are used for diagnosis of various diseases. Autonomous cars which will make roads safer and will reduce fatal life-threatening accidents, Autonomous Drones which will revolutionize the logistics and will deliver packages more efficiently, UAVs which will aid militaries with surveillance and help prevent wars, smart cameras which will be able to recognize people and track their activities to reduce crimes. Smart imaging of atmosphere for weather prediction and warnings for natural calamities like tsunami, tornadoes etc. These are a few examples of how CNNs are making a major impact in our lives.

These technologies require computational power, speed, accuracy and precision. In order to make them efficient, the algorithms have to be fast having low latency, working efficiently on low power, being more accurate and consuming less memory. CNNs have so many layers so as the architectures become deeper and wider, giving more accuracy, their computational cost increases. These CNN models have to be more compact and should work as efficiently as the novel architectures. With new research and advent of new algorithms, now it is possible to make CNNs more efficient having

*Corresponding Author: Prasham Shah, Email: pashah@purdue.edu

competitive size and accuracy. This research aims to contribute towards this same goal, making CNNs compact in terms of model size and increasing its accuracy so that they can be used for such applications[1].

A-MnasNet [2] is derived by Design Space Exploration of Mnas-Net. New algorithms were implemented for more efficiency with competitive size and accuracy. Furthermore, it is deployed on NXP Bluebox 2.0 for Image Classification [3]. RTMaps Studio is used to deploy the model on the hardware by establishing a TCP/IP connection.

In this paper, section 2 discusses MnasNet architecture. Section 3 introduces A-MnasNet [2] and discusses the new algorithms implemented to achieve better results. Section 4 demonstrates deployment of A-MnasNet [2] on NXP Bluebox 2.0 for Image classification [3]. Section 5 states the hardware and software requirements to conduct this research. Section 6 illuminates the results that demonstrate the model comparison, model size and accuracy trade-offs and deployment results. Section 7 is conclusion which gives the gist of this research.

2 Prior Work

This section gives an insight on MnasNet [4] architecture. It explains the features of this architecture and what can be improved in order to make it more efficient.

2.1 MnasNet Architecture

MnasNet [4] was introduced in 2019 by Google Brain Team with a goal of proposing an approach of neural architecture search which would optimize the overall accuracy of the architecture and reduce the latency of the model on mobile devices. MnasNet outperformed all existing novel architectures on ImageNet dataset with enhanced accuracy. This architecture extracts features by using depthwise separable convolutional layers with 3*3 and 5*5 filter dimensions and mobile inverted bottleneck layers. It has ReLU [5] activation layers which introduces non-linearity to the network. It uses Batch normalization to adjust and scale the output of activation layers. Dropout regularization is used to reduce the overfitting in the network.

Figure 1 shows MnasNet architecture and illuminates its convolutional layers. This architecture was designed for ImageNet dataset so the input dimensions were set to 224*224*3. It had a validation accuracy of 75.2% and outperformed all other existing state-of-the-art architectures. For this research, MnasNet was used with CIFAR-10 [6] dataset so the input dimensions were modified to 32*32*3. Table 1 shows various layers of the architecture.

An important aspect to observe about MnasNet is that it only explores the channel dimensions of the feature maps throughout its architecture. The convolutional layers fail to explore the spatial feature scale in the network. The activation layers used in the architecture have become outdated and today there are better algorithms which work more efficiently then the used activations.

3   A-MnasNet Architecture

This section gives an insight on the A-MnasNet [2] CNN architecture and its features.

3.1   Convolution Layers

Harmonious Bottleneck Layers [7] were introduced in the architecture. This special convolutional layers extract features across the spatial and channel dimensions. They are more efficient then the depthwise separable convolutional layers. Harmonious layers consist of spatial contraction-expansion keeping the number of channels constant and channel expansion-contraction keeping the spatial dimensions constant. This down-scaling reduces the number of parameters of the model. Hence, the model size is reduced. Since it extracts features more efficiently, the overall model accuracy is enhanced.
Figure 2: Comparison of Depthwise Separable Convolution Layer and Harmonious Bottleneck Layer.[7]

A comparison between Harmonious bottleneck layers [7] and depthwise separable layers is demonstrated in Figure 2. Here, Input size and output size is represented by H and W respectively. C1 and C2 denote the input and output feature channels where K is the size of the filter and s is the stride value.

The total cost of depthwise separable convolution is

$$(H \times W \times C1 \times K \times K) + (H \times W \times C1 \times C2) \quad (1)$$

The total cost of harmonious bottleneck layer is

$$B/s^2 + (H/s \times W/s \times C1 + H \times W \times C2) \times K^2 \quad (2)$$

where, B is the computational cost of the blocks inserted between the spatial contraction and expansion operations.

Dowmsampling the channel dimensions and extracting features from the spatial dimensions results in reduced spatial size of wide feature maps. The parameters of the model are reduced by a factor of the stride value. As a result the model size reduces and the accuracy of the model increases.

Hence, these layers were added to enhance the performance of the model. Table 2 shows various layers of A-MnasNet [2].

Table 2: A-MnasNet Architecture

A-MnasNet Architecture					
Layers	Convolutions	t	c	n	s
$32^2 \times 3$	Conv2d 3×3	-	32	1	1
$112^2 \times 32$	SepConv 3×3	1	16	1	2
$112^2 \times 16$	MBConv3 3×3	3	24	3	2

$7^2 \times 320$	FC,Pooling			10	

t: expansion factor, c: number of output channels, n: number of blocks and s: stride

3.2   Learning Rate Annealing or Scheduling

This parameter defines the rate at which the network learns the parameters. It sets the speed of learning features. It a large value is set then the speed of training would increase but with that, the accuracy would decrease as the efficiency of learning more features would reduce. This parameter is tuned throughout the training process in a descending manner. The learning rates are scheduled so that the step size in each iteration gives out the best output for efficient training. There are various methods to set learning rates. Some them have been demonstrated in Figure 3.
Figure 3: Comparision of different LR scheduling methods.

3.3   Optimization

Optimization is an essential aspect of enhancing the efficiency of the CNN models. Basically, it is a method of correcting the calculated error. It might sound simple but it just as complicated. There are various optimizers which are used to do this optimization. There are constant learning rate algorithms and adaptive learning rate algorithms. For this research, Stochastic Gradient Descent optimizer

[8] was used because of its enhanced performance on optimizing A-MnasNet [2]. It was used with varying values of learning rates during training with a momentum set to 0.9.

3.4 Data Augmentation

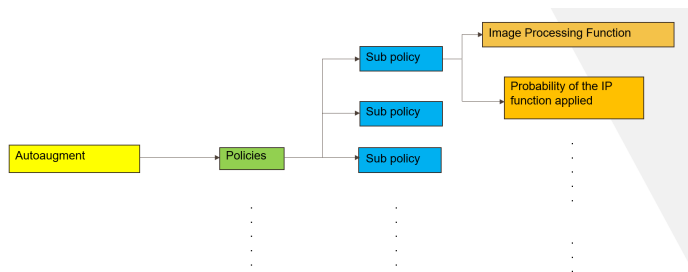
This step is used to preprocess the dataset. Various transformations are applied on the images. The purpose of data augmentation is the enhance the accuracy of the model. In other words, it enables the CNN model to learn features more efficiently. AutoAugment [9] is implemented to preprocess the dataset. It uses reinforcement learning to automatically select the transformations that are most efficient for the CNN model. It defines two parameters for the process. First is the transformation and the other is the magnitude of applying it. These two together are defined as a Policy. A Policy consists of sub-policies which have those two parameters. Different sub-policies are selected by the controller which best suit the training. This process is demonstrated in Figure 4. It was evident that by using AutoAugment [9] the accuracy of A-MnasNet increased to 96.89% from 92.97%.


Figure 4: AutoAugment

4 Image Classification on NXP Bluebox 2.0

A-MnasNet [2] was deployed on NXP Bluebox 2.0 for Image Classification [3]. BlueBox 2.0 by NXP is a real-time embedded system which serves with the required performance, functional safety and automotive reliability to develop the self-driving cars. It is a ASIL-B and ASIL-D compliant hardware system which provides a platform to create autonomous applications such as ADAS systems, driver assistance systems.

There are three processing units in Bluebox 2.0. There is a vision processor, S32V234, a radar processor, S32R274, and a compute processor, LS2048A. This enables to develop autonomous applications. The vision processor and the compute processors are used to perform Image Classification [3] using A-MnasNet [2]. Figure 5 shows the methodology to deploy A-MnasNet [2] on Bluebox 2.0 for Image Classification.

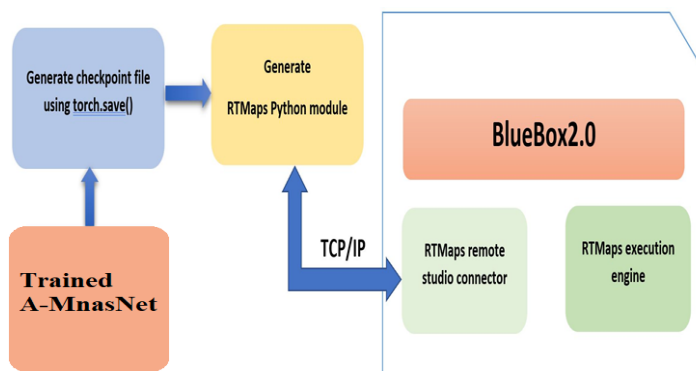
After training A-MnasNet [2], the model is imported in the RTMaps Studio using its python component. A TCP/IP connection is used for data transmission between RTMaps Design Studio and NXP Bluebox 2.0. The model was successfully implemented on the hardware and was able to predict the object in the input images accurately.


Figure 5: Deployment of A-MnasNet on NXP BlueBox 2.0

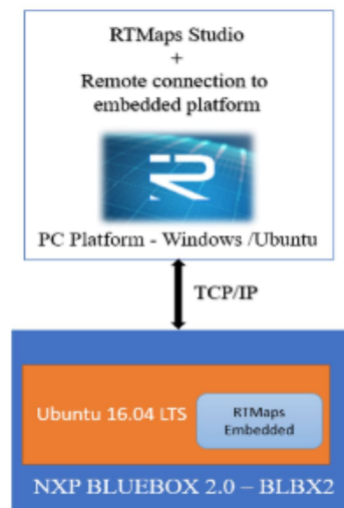
RTMaps Studio was used for real-time implementation of A-MnasNet[2] on NXP Bluebox 2.0. It is an asynchronous high performance platform which has an advantage of an efficient and easy-to-use framework for fast and robust developments. It provides a modular toolkit for multimodal applications like ADAS, Autonomous vehicles, Robotics, UGVs, UAVs, etc. It provides a platform to develop, test, validate, benchmark and execute applications.


Figure 6: RTMaps connection with Bluebox 2.0

Figure 6 shows the role of RTMaps in the implementation. It provides an interface between the hardware and the embedded platform. It uses a TCP/IP connection by assigning a static IP address to enable data transfer between them.

5 Hardware and Software used

- NXP Bluebox 2.0
- Aorus Geforce RTX 2080Ti GPU
- Python version 3.6.7.
- Pytorch version 1.0.

- Spyder version 3.6.

- RTMaps Studio

- Tera Term

- Livelossplot

6 Results

MnasNet [4] achieved 80.8% accuracy with CIFAR-10 [6] dataset achieving 12.7 MB model size without data augmentation. New convolutional blocks resulted in an increase of accuracy to 92.97%. Furthermore, AutoAugment [9] was implemented for enhancing overall accuracy which increased from 92.97% to 96.89%. The final model is of 11.6 MB and a validation accuracy of 96.89%.

Implementation of new algorithms resulted in enhanced accuracy. It is demonstrated in Table 3. The overall accuracy increases by 16.09% with a slight decrease in model size.

Table 3: Comparison with baseline architecture

Comparison of models		
Architecture	Model Accuracy	Model size (in MB)
MnasNet	80.8%	12.7
A-MnasNet	96.89%	11.6
Figure 7: MnasNet (Baseline Architecture)
Figure 8: A-MnasNet (Proposed Architecture)

Figure 7 and figure 8 demonstrate the training curves. It is evident that by implementing new algorithms resulted in reduced overfitting and better accuracy.

For resource constrained hardware, desired model size and accuracy can be obtained by tuning width multiplier. Table 4 demonstrates the idea of having multiple size and accuracy by scaling width multiplier.

Table 4: varying model size by width multiplier

Scaling A-MnasNet with width multiplier		
Width Multiplier	Model Accuracy	Model size (in MB)
1.4	97.16%	22
1.0	96.89%	11.6
0.75	96.64%	6.8
0.5	95.74%	3.3
0.35	93.36%	1.8

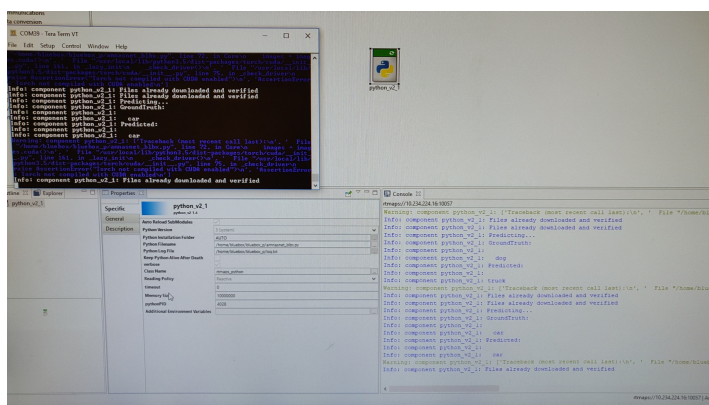
Figure 9 shows the console output for Image Classification on NXP Bluebox 2.0. The model predicts that the object in the input image is a car. The window in the left corner shows the console output in Tera Term.


Figure 9: Image Classification using A-MnasNet

7 Conclusion

Design Space Exploration of MnasNet [4] architecture resulted in enhanced accuracy and a decrease in model size. The proposed architecture, A-MnasNet [2], has an accuracy of 96.89% and a size of 11.6 MB. It surpasses MnasNet [4] in terms of model size and accuracy. New convolutional layers were added to make A-MnasNet [2] more efficient in extracting features. AutoAugment[9] was used to preprocess the dataset. The model was scaled with width multiplier to get various trade-offs between model size and accuracy. The architectures were trained and tested on Cifar-10 [6] dataset. Furthermore, they were implemented on NXP Bluebox 2.0 for Image Classification. Results show that the new architecture successfully detects the object and successfully performs Image Classification.

Conflict of Interest   The authors declare no conflict of interest.

BrcLightning - Risk Analysis and Scaling for Protection against Atmospheric Discharge - Extender

Biagione Rangel De Araújo*

BRC – Biagione Rangel Consulting, Natal, 59064-490, Brazil

A R T I C L E I N F O	A B S T R A C T
	This manuscript intending to publicize the improvements incorporated in the BrcLightning application, including the Risk Analysis module with the help of a pop-up, which provides the result and assists in the identification of mitigating measures by the professional, which must be defined to reduce the calculated risks. Other points addressed in this extension are the improvements added to the database to meet the corporate demands of companies, referring to the Risk Analysis module. It also incorporates flexibilities to perform the sizing separately, in the design, evaluation and scaling modules of the LPS – Lightning Protection System that using rolling sphere method and Angle Method, incorporating, in some of the modules, the issue of opinions or alerts. These modules use the mathematical approach methodology. In addition to these improvements, this review included the reporting module of facilities in the filter system, which allows the use of the database more selectively for the emission of these documents. This filter has a structure for issuing corporate demands of reports. The results can be obtained quickly and easily, on-screen or printing several reports. The reliability and safety of the results can be assessed through the check with the examples of the standards that define the criteria and methodology, that must be followed to carry out for cases of Risk Analysis or through graphic drawings on AutoCad platform or similar for the sizing modules. Other improvements in this extension are the addition of topics for new modules for which we already have the equations modeled in Excel, although we have not yet coded in the programming language.

1. Introduction

This article is an extension of the work originally presented at the Symposium SIPDA XV [1]. In the event, representatives of a large company attended our explanation and reported that the great difficulty they faced was to have the control and traceability of the various Risk Analyses that are performed for each building or structures of the various units of the company. So, considering that our system is structured in the form of a database, we evaluated that, by introducing structural changes in this database, it will be possible to meet this demand.

Concomitantly with this observation, we also identified that other improvements would be required, even to use the various modules of the system in isolation (before having to register a project), either in the database or through an app which may be via mobile phones. These improvements aim to meet specific demands, such as those to evaluate the effectiveness of the volume of protection of a given SPDA concerning the various structures or equipment and facilities that, in principle, are or would be under protection against direct impacts of atmospheric discharges. In this case, the data is not embedded in the database but can be consolidated into a report, with options to be printed or archived.

Regarding the Reporting Module, this extension was less extensive, as it was composed by the improvements of the filters defined to facilitate the selective issuance of Database Reports, with limited coverage of the specificity of each module that make up the current system. However, because it is a database, we intended (in a new version) to provide tools in this module, to enable the data export specifically to the Excel environment, to allow better tools for analyzing historical data.

2. Definitions

- Coverage radius (rc): The distance between the point of the cover margin, of a determined envelopment of an LPS. This distance determines the size of the horizontal projection of the fictitious plane, given by equation (1):

$$rc = [h_1(2R - h_1)]^{1/2} - [h_2(2R - h_2)]^{1/2} \qquad (1)$$

*Corresponding Author: BRC – Biagione Rangel Consulting,
contato.brc@biagione.com.br, +55-84-98723-8753

where:

rc		horizontal protected distance
h1		height of the higher mast
R		rolling sphere radius
h2		height of the lower mast:

- *Cover margin height (hc):* The dimensions of the height of the nearest point on the envelope over the structure under the protection of the LPS;

- *Distance from the critical point (d1):* The distance between the critical point and one metallic element such as rods or wire air-terminations

- *Envelopment:* Geometric shape that limits the protected volume according to the rolling sphere method;

- *Coverage margin (cm):* The shortest distance between a point of the structure under the protection of the LPS and the envelopment of the protective volume. The dimension of the margin corresponds to the perpendicular tangent measurement of the envelopment to the nearest point of the structure under protection. The graphical representations of "cm" are as shown in Figure 1a, Figure 1b, and Figure 1c (all contained in Figure 1):
Figure 1: Examples of coverage margins

- *Fictitious plane (Fp):* Assumed horizontal plane that provides coverage of protection at a given height;

- *Hazardous areas:* Area surrounding storage facilities or transfer station of flammable liquids or gases, due to the possibility of containing flammable or explosive mixtures. They are defined in: Zone 0 (when the explosive/inflammable mixture is still there or will be for long periods); Zone 1 (likely to occur in normal operating conditions) and Zone 2 (it's unlikely – an abnormal condition of operation);

- *Sizing module marks*: The marks indicated in the graphs of the sizing and limit variation modules correspond to the extreme points of the structure that should be protected or evaluated on the effectiveness of the coverage by the SPDA protection wrap, as shown in figures 2 and 3 below:
Figure 2: Hazardous areas limiting point figure (see Figure 1b)
Figure 3: Structure limiting point figure (see Figure 1a)

3. Software Development

The application is developed in Access, in VBA language, to allow it to run on Windows and on the Internet. We had a project to carry out the migration to an Internet language; however, due to the Covid 19 pandemic, we had to cancel it. Nevertheless, we hope that, considering the problems due to the current situation, we can resume the project in the year 2021.

In this version, the system continues with the same configuration of modules and sections of the previous publication, from which this paper is an extension of (SIPDA XV [1]). Thus, we will focus on detailing the improvements that have been introduced, as described in sequence (items 4 to 7).

4. Risk Analysis Module

Risk Analysis consists of 5 sections: 1. Registration Module; 2. Zone Registration Module; 3. The configuration data of the connected lines and Zone.; 4. Risk Analysis Factors Module (typical loss value) and 5. Results Module.

4.1. Registration Section

In this section, there are specific data related to design registration that can be common to all modules and all sections, but also, there are important data specific to the Risk Analysis Module. Due to this, we have identified that it will be more effective for these data input to be dismembered in two modules: one for general project registration and another for registration and

configuration of the Risk Analysis Module. However, this should only be performed in a new version.

The improvements that we introduced in this section included the fields of input to meet the demand to perform the registration of organizational structures, containing up to 5 levels: Level 1 - Hold Company; Level 2 – The Business Unit, which may or may not cover several other Operating Units; Level 3 - The Operational Unit; Level 4 - The Operational Sector and Level 5 - The

installation subject to risk analysis or the one containing Air Terminal. This improvement is only incorporated into the Registration Form of this Section. Therefore, in this version, it has not yet been possible to integrate this organizational structure registration with the other modules, including the Risk Analysis Module itself, regarding the reports. This requires numerous changes in the reports already formatted. The reported modifications are highlighted in green as shown in Figure: 4.

Figure 4: Main screen of data input

Figure 5: Screen for customizing structure and zones)

4.2. Zone registration module

The System was engineered to cover up to 5 Zones (NBR-5419-2 [2] and IEC 62305-2 [3] do not establish limits, but provide examples of up to 5 Zones), as we observe that this is a practice used and that already surpasses the examples provided by the standards cited. The number of Zones is selected as shown in Figure 4 (Zone in Study).

The System already makes several types of structures available, which were understood as necessary and sufficient to meet the range of facilities and buildings that must be studied and related to each of them, the different types of Zones. However, the Designer can insert new structures and new zones, but he or she must proceed to register them. To do so, it will be necessary to customize them and make the association with the loss factors, as shown in Figure 5.

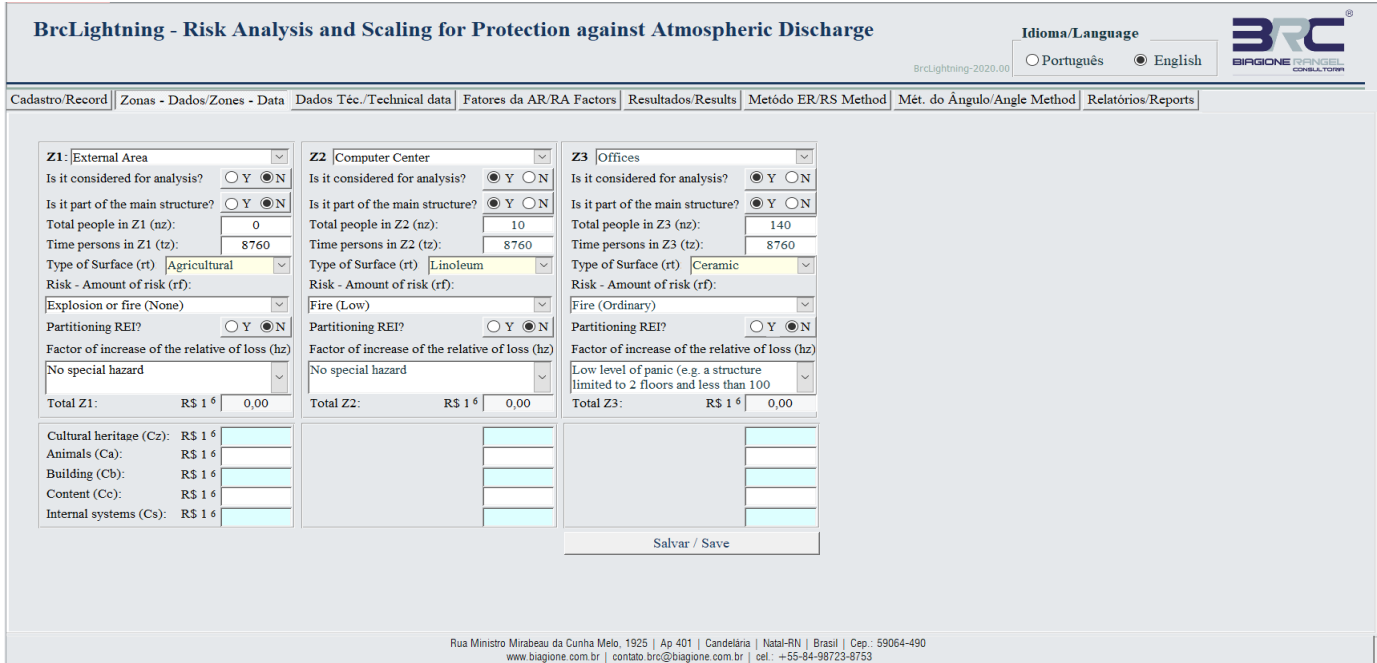
In this Section, the designer inserts the data for each zone that is defined for Risk Analysis, according to Section One of the Register, as shown in Figure 4. In this section, no improvement has been introduced, as show in Figure 6. For more details see SIPDA XV [1].


Figure 6: Screen of the setting module of the Zones (structure with all 3 Zones)
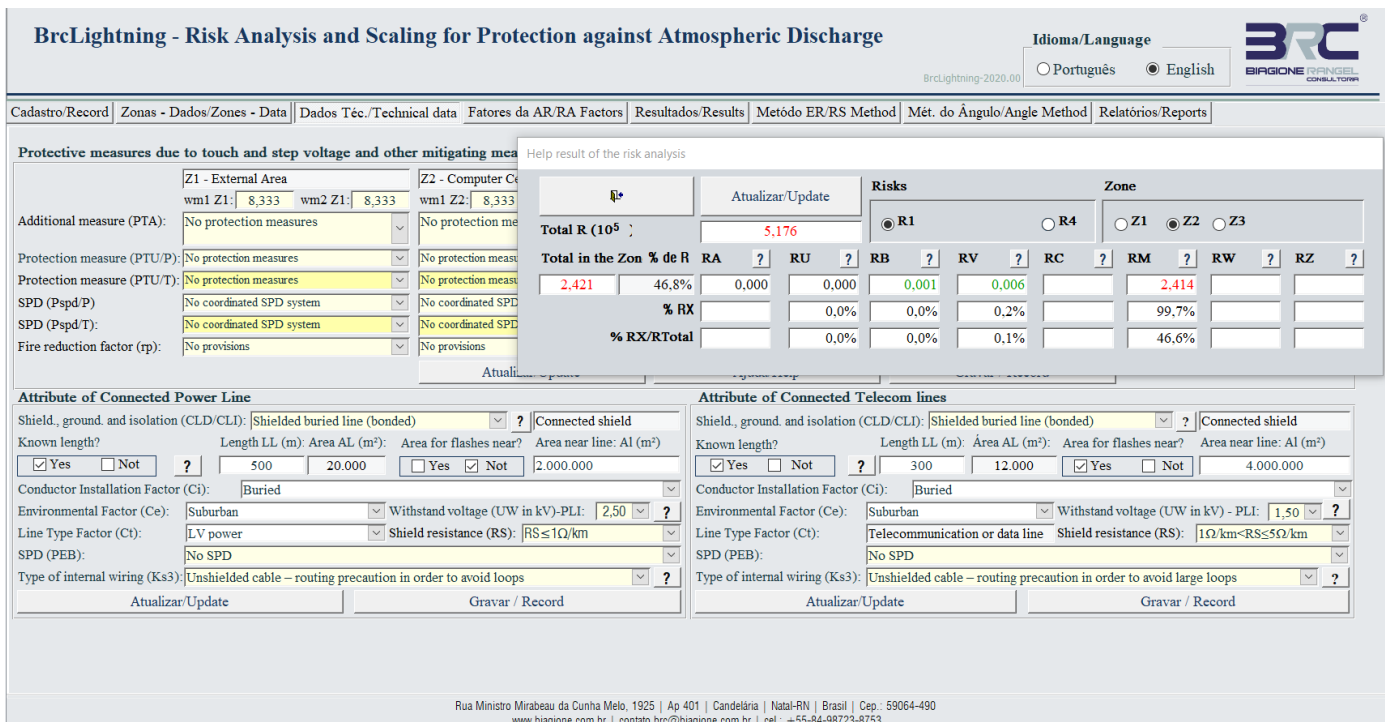

Figure 7: Setting screen of the connected lines and other zone data

4.3. The setting data of the connected lines and Zone

This Section provides the space to enter information about power lines and telecommunications lines: how they connect to the site (building; installations; etc.). The designer can also enter protective measures due to touch and step voltage and other risk-mitigating measures, individually for each defined Zone. In this section, it was introduced improvements to the Help pop-up form with the result of the risk analysis, as shown in Figure 7. Thus, the designer can monitor the effectiveness of each mitigating measures

in real-time. This pop-up, once visible, can be viewed in all sections of the risk analysis module.

Also, there is a pop-up to help define line parameters and other alert parameters as shown in Figure 8.

4.4. Risk Analysis Factors Module

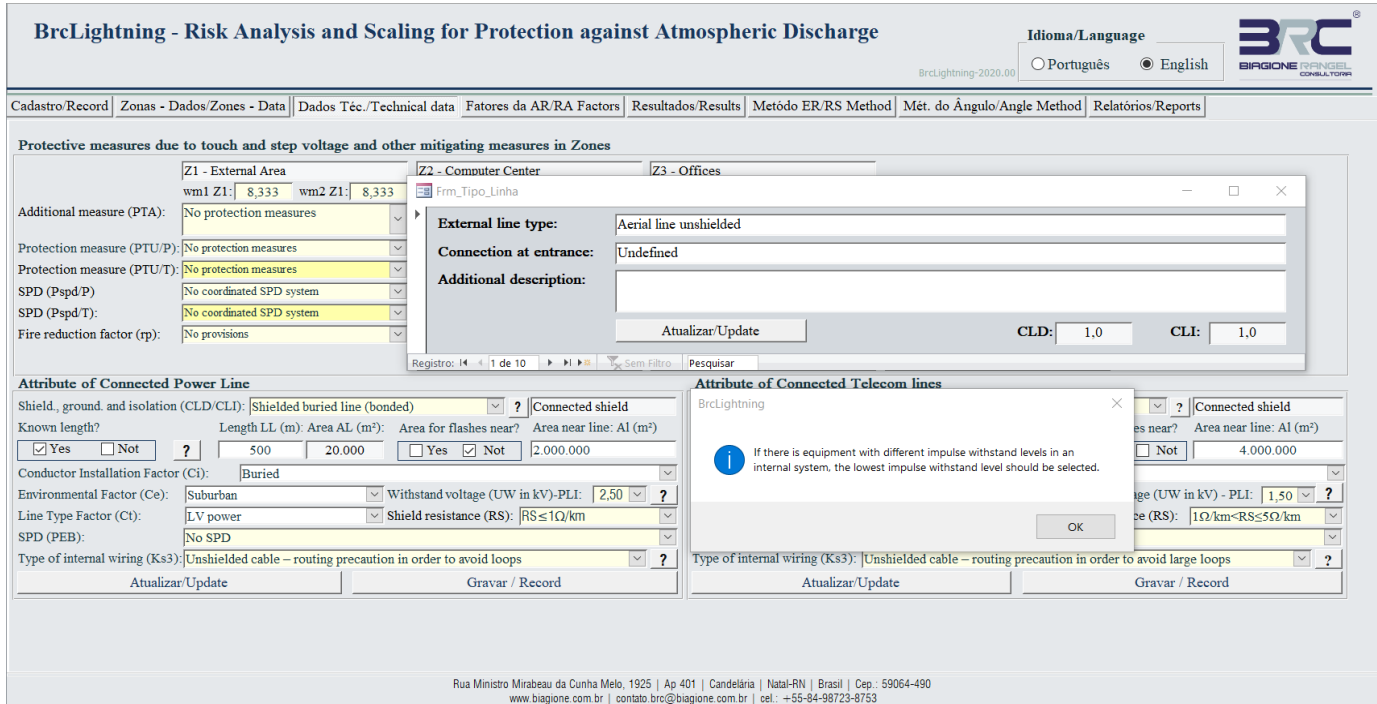
This section presents the typical loss values for each zone (as shown in Figure 9), based on the definitions established in section one (as shown in Figure 4) and two (as shown in Figure 5).


Figure 8: The pop-up helps with line parameters and other information
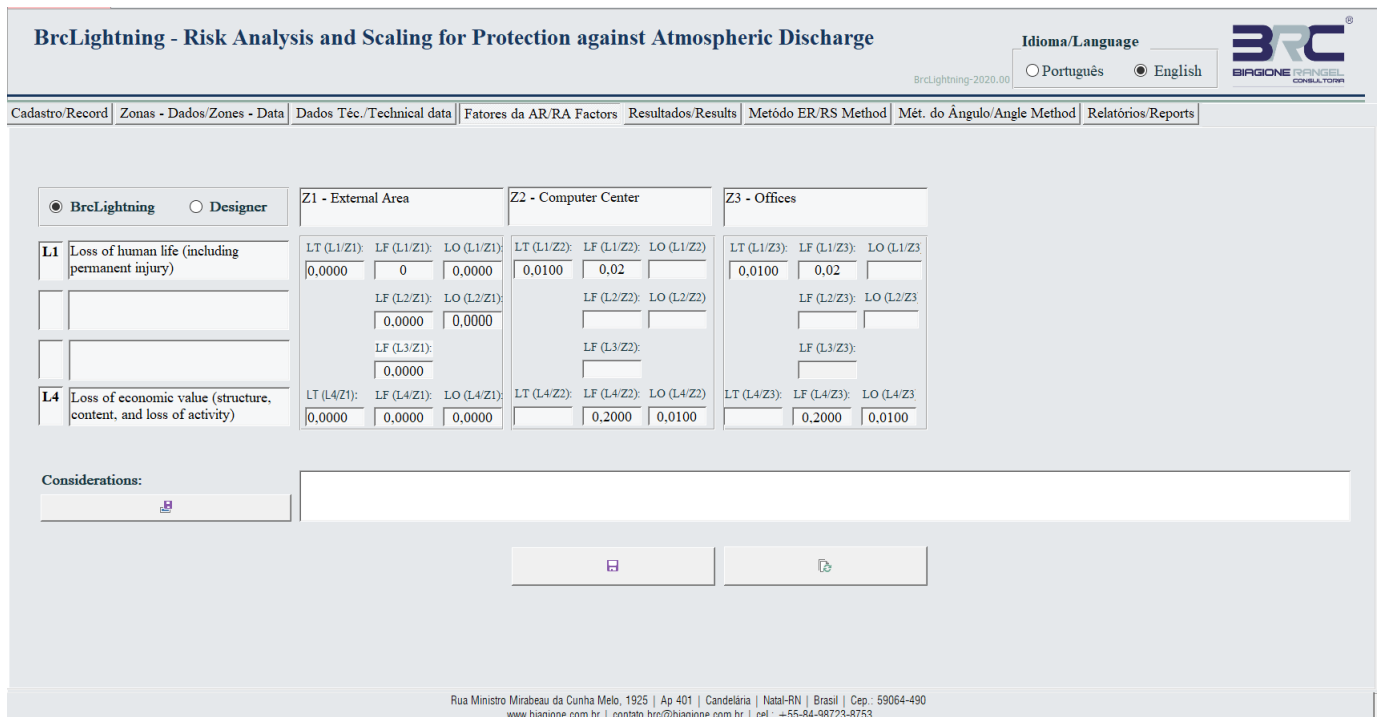

Figure 9: Loss Type Factors Module Screen

In the version presented in SIPDA XV [1], it was already possible for designers to change the typical loss value, if they had another interpretation regarding the one previously defined in the system (these factors defined in the system were based on the definitions established in NBR 5419 -2 [2] and IEC 62305-2 [3] for typical loss values). In this case, in the previous version, the designers had to standardize their basic values for each type of installation in advance. The improvement introduced allows that, in case they don't have a database parameterized with the values according to their interpretation criteria, they can do so by simply selecting the designer parameters (in the input field) and applying a double click on each factor that they want to parameterize. This way, a pop-up (as shown in Figure 10) form will appear for each factor and they will define it at their discretion. The new defined typical loss value, after being updated, will be highlighted in green

(as shown in Figure 10), but there are security restrictions and other requirements (see item 9.4).

4.5. Results Module

In this section, the final result is as shown in Figure 11. Mitigating measures can also be inserted (the description of these measures), if the results indicate that this is necessary. Mitigation measures, as needed, can be included (these should be inserted descriptively). A technical note with the analysis design also can and should be inserted. Another improvement is the possibility of issuing, in a summarized format, the risk analysis report, as shown in Figures: 12 (a) and (b). This report contains the basic information of the risk analysis study and the result.

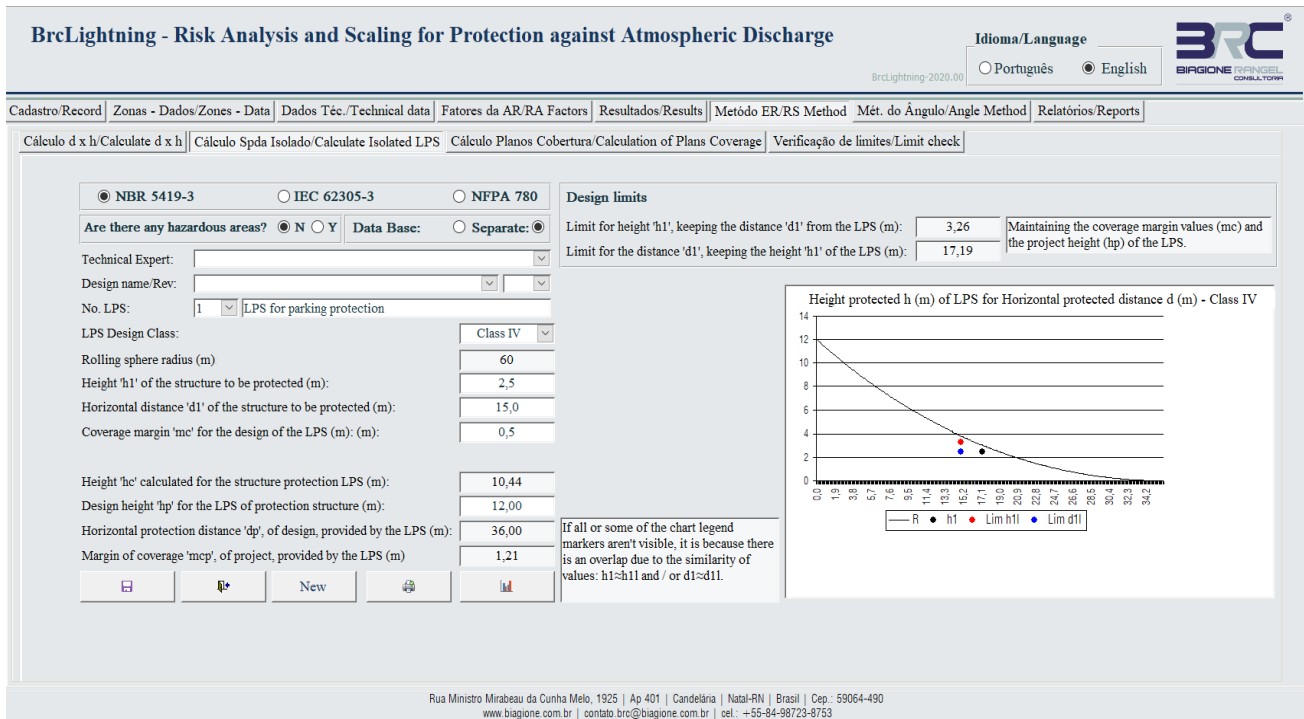
Figure 13: Example of calculation of h x d for Class IV


Figure 14: Sizing of the Isolated LPS, without hazardous area
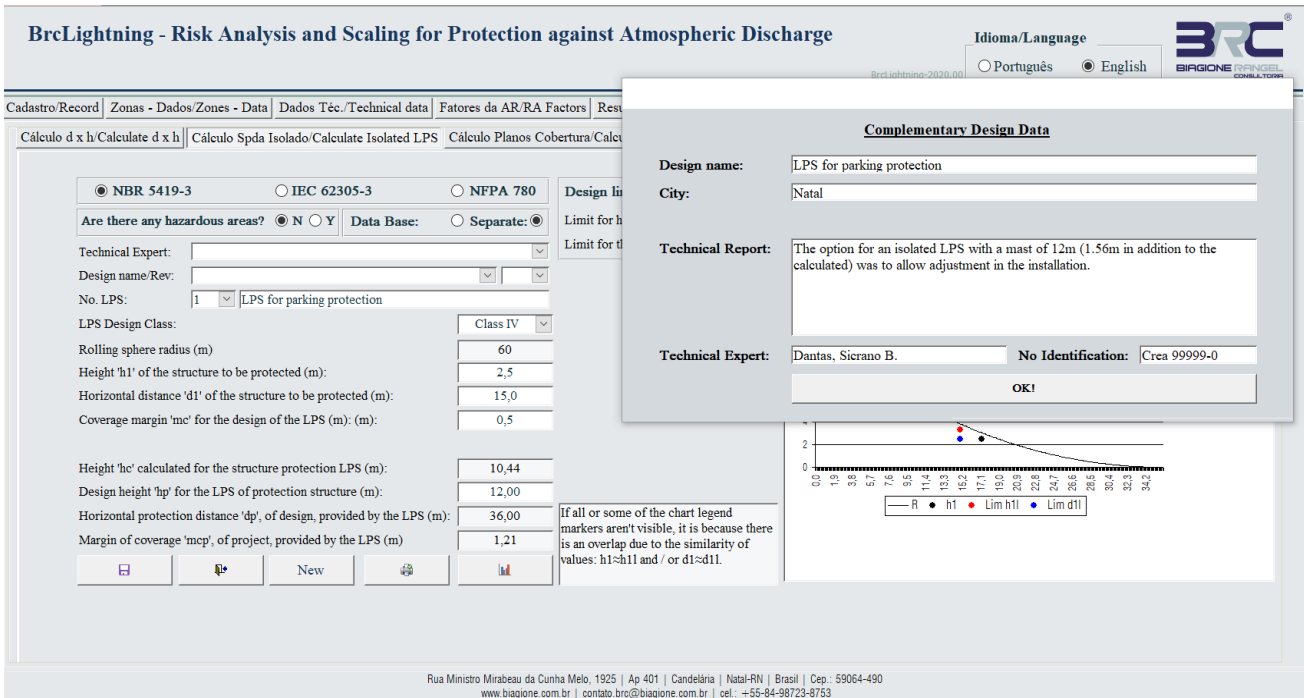

Figure 15: Pop-up for supplementary data

5. Rolling sphere module

This Module maintains the 4 Sections of the original version presented in SIPDA XV [1] and is in accordance with NBR 5419-3 [4]; IEC 62035-3 [5] and NFPA 780 [6]. However, the possibility of performing the sizing separately and the printing of the report of this dimensioning was introduced in all four sections. This can be seen in the sequence. Other improvements have been introduced and are detailed in each of the sections.

5.1. Section for sizing 'h' or 'd'

In the version presented in SIPDA XV [1], the system included one graph related to the calculation of the protected horizontal distance at ground level or on a reference surface when the height of the LPS is known and another for the calculation of the height, required to provide protection of a horizontal distance at ground level or a reference surface. Now, these graphs have been integrated into one (as shown in Figure 13). When calculating the height, it is a non-standard commercial value, this version provided

an input field to adjust the calculated height. In addition, it was added the option for issuing the report of this dimensioning.

In this section, the height of the insulated LPS is scaled (mast or air termination system of the insulated (only one) overhead wire to protect a specific structure) based on the required LPS Class and the determined coverage margin, including the characterization of a structure with or without hazardous area, as shown in Figure 14. Improvements were also incorporated to print the report of the sizing (the button with the printer icon) and the option to scale the LPS of a database design or a separate design for the issuance of

the report, it is necessary to provide additional data, as shown in Figure 15 (in the case of a separate project). The pop-up appears when the print button is pressed. The issued report is shown in Figure 16. Separated projects are not saved in the database.

When the design definitions of the structure to be protected ('h1' and 'd1', besides 'mc') do not allow the sizing of the LPS to the defined protection Class, the System issues an alert of the impossibility of sizing and indicates the limit of the maximum distance and height the structure can be protected by LPS, as shown in Figure 17.

Figure 16: Example report of sizing the isolated LPS

Figure 17: Alert for impossibility of isolated LPS sizing

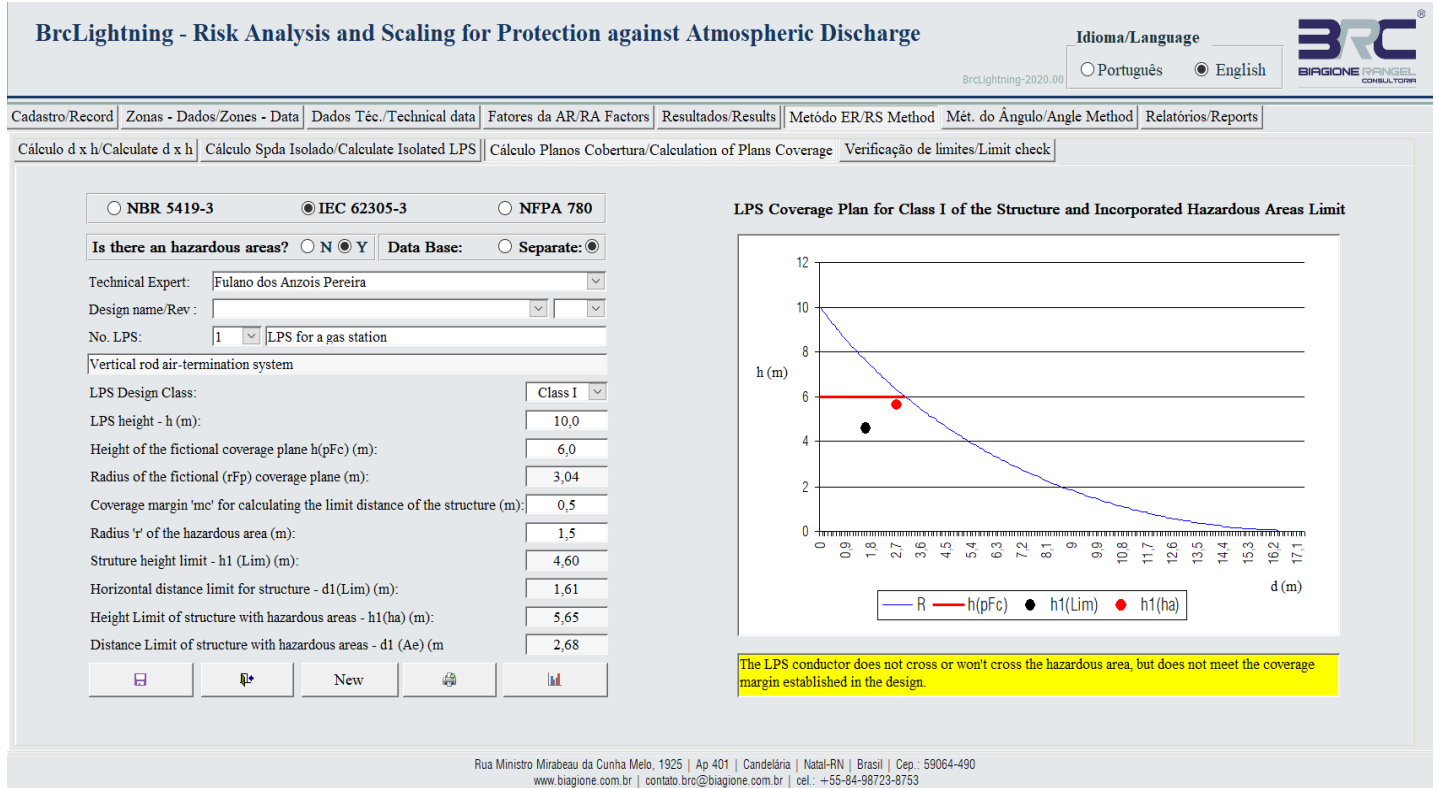
Figure 18: Screen with pop-up to define the LPS type


Figure 19: Calculation of the Fictional Coverage Plan with alert

5.2. Evaluation section of the limits of an installed LPS

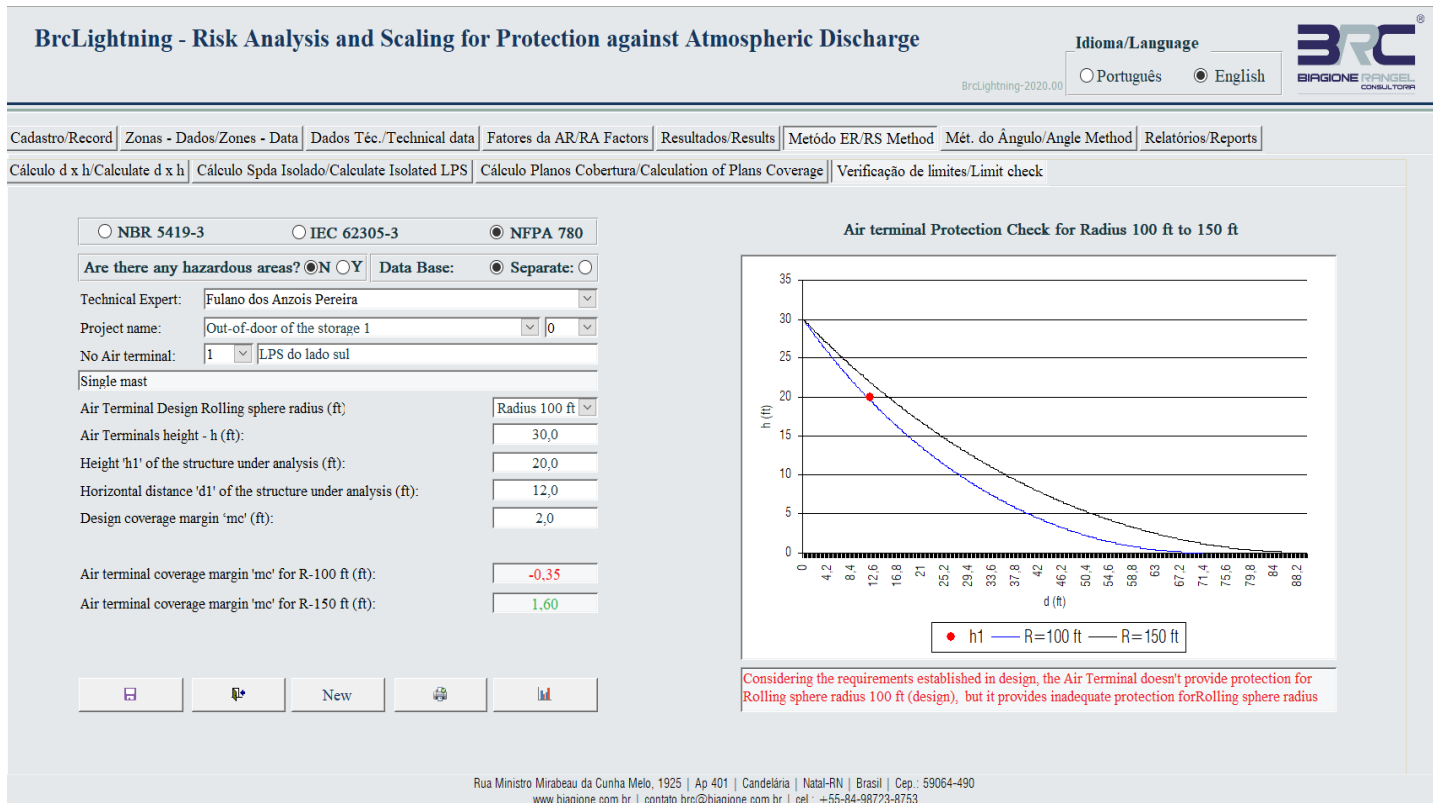
This last section of the Rolling Sphere Module is intended to assess the protection that a specific LPS can provide, considering all the Classes of Protection established by NBR-5419-3 [4]; IEC 62305-3 [5] and NFPA 780 [6]. Improvements have been made to the definition of the LPS type and alert with a technical note, as shown in Figure 20.


Figure 20: Limits evaluation module screen

6. Angle Method Module

This module maintains the three Sections of the original version presented in SIPDA XV [1] and in accordance with NBR 5419-3 [4]; IEC 62035-3 [5]. However, it was introduced in all of them the possibility to carry out the sizing separately and printing the report of this. Considering that this method is not widely used, only an improvement was introduced, in addition to those reported above, in Section 1, as detailed below.

6.1. Height or Distance Sizing (Angle Method)

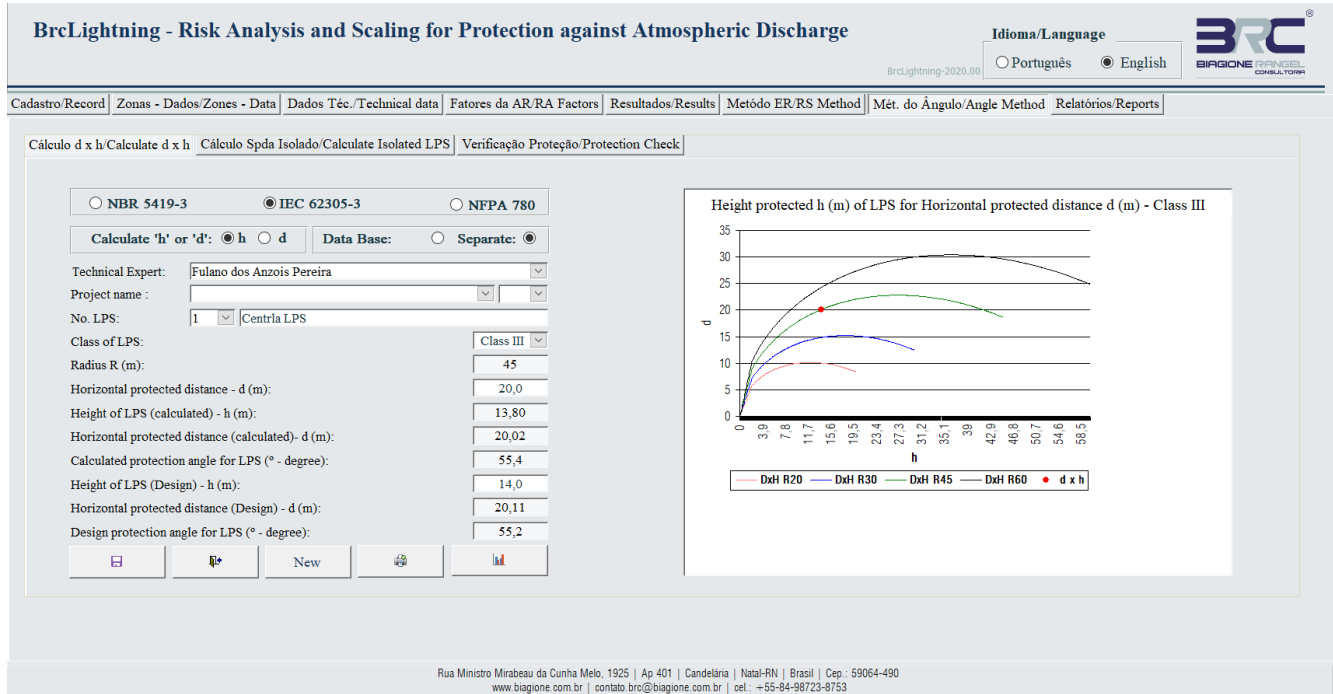
This Section calculates the horizontal distance protected at ground level or from a reference surface when the height of the LPS is known. It also allows you to calculate the height required for an LPS when you know the horizontal distance that needs to be protected, as shown in Figure 21.


Figure 21: Calculation of the height x distance
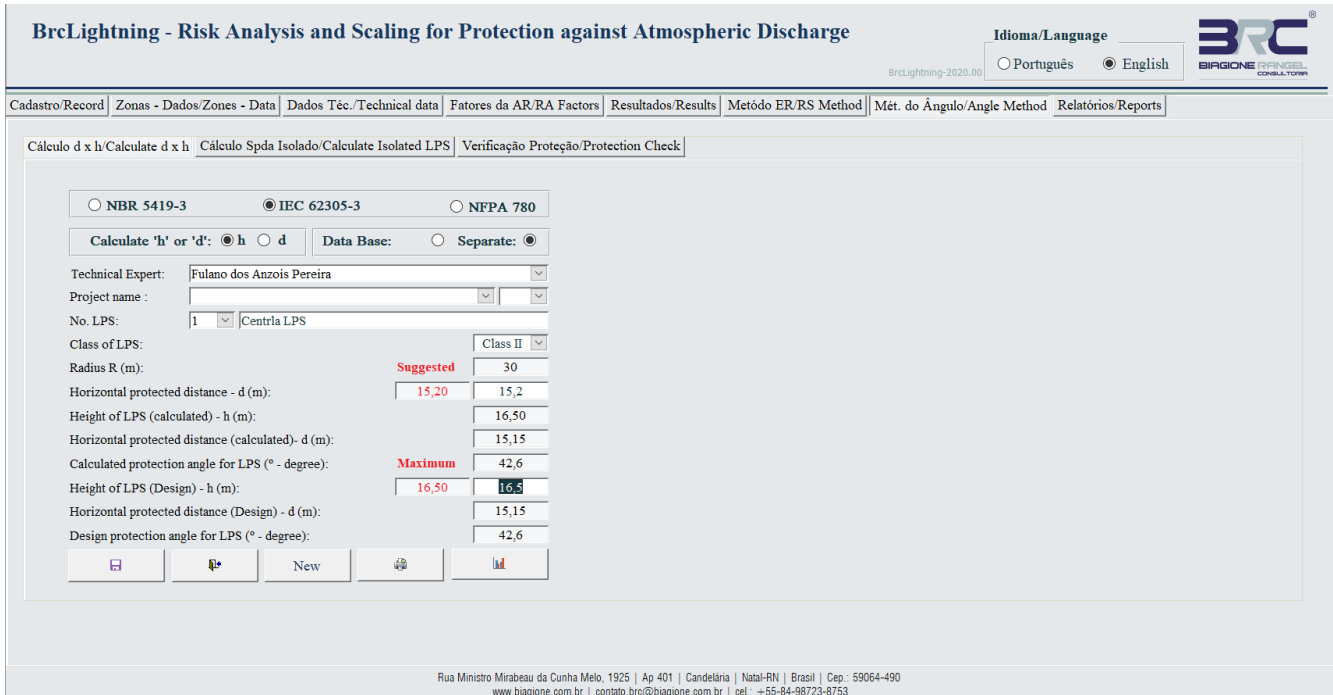

Figure 22: Calculation of the height x distance - Alert
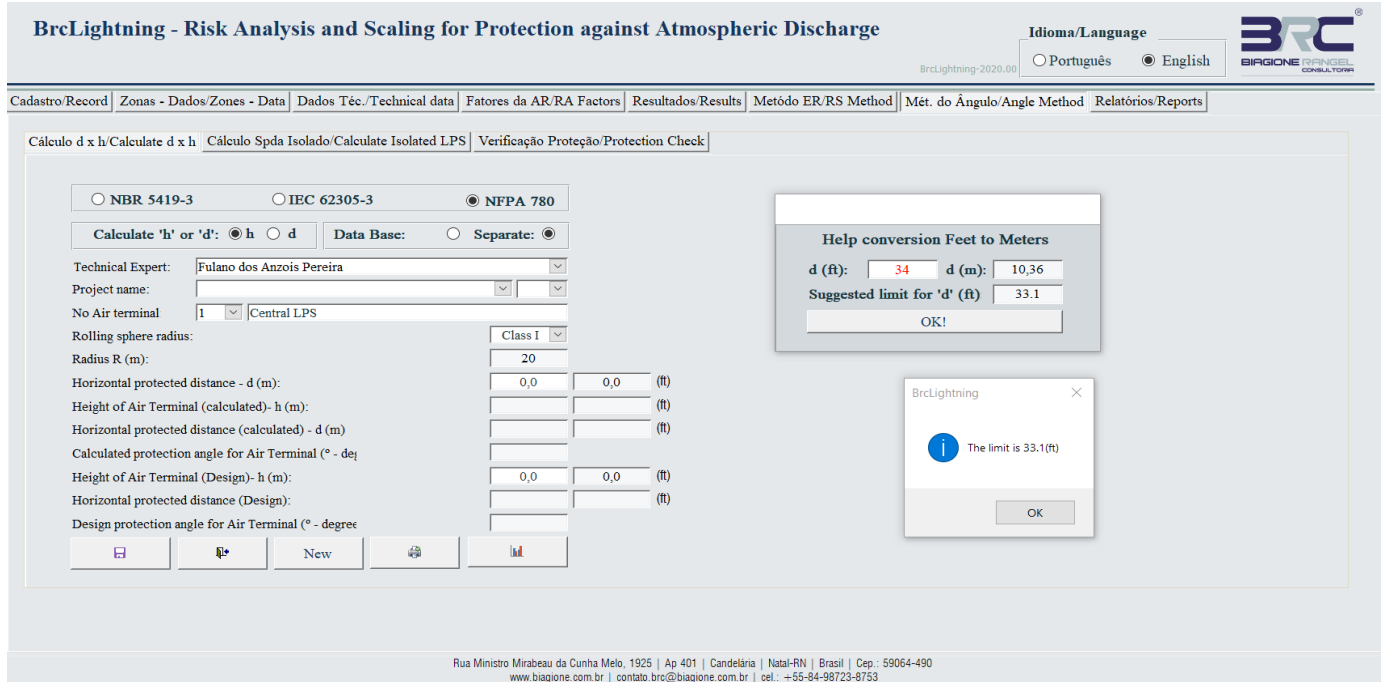

Figure 23: Calculation of the height x distance with alert

In order to comply with NFPA 780 [6], the improvement for converting units of measure in meters was introduced, as shown in Figure 23.

The system for this calculation only allows input in meters, thus, with this improvement, it becomes possible to insert the values in feet unit. To do so, two clicks are applied in the input field and one pop-up appears (as shown in Figure 23), providing an input field with the unit in feet. After this, when the pop-up is closed, the unit of measurement in meters. In case of exceeding the suggested limit, an alert will be issued.

7. Report Module

This Module includes options for the various preformat of reports that the system, currently, can provide: Risk Analysis Report; LPS project report by Rolling Sphere Method; Module Report using angle method, etc. The system screen where these options are available is shown in Figure 24 and several report templates are shown in Figure 25a Figure 25b. The improvements introduced in this module were composed by the increase in filter options to allow for more appropriate selectivity and the inclusion of the project revision number, as shown in Figure 24.

8. Improvements already identified for future insertion

8.1. Module for sizing the surge protective device

Considering that one of the most important mitigating measures identified in the Risk Analysis is the installation of Surge Protective Devices - DPS, it was understood that the inclusion of a module to meet this need is extremely important and, as the methodology and formulas already exist and are supported by NBR-5419-4 [7] and IEC 62305-4 [8], the insertion of a module with this function was included in the planning of future improvements.
Figure 26: Efforts in wire air termination with supports of the same height
Figure 27: Efforts in wire air termination with supports of different heights

8.2. Module for sizing wire air-termination support structures

Considering that many of the SPDA systems are composed of wire air-termination, it was identified that it is convenient to have a tool to scale the efforts requested from supports of this kind of captor, especially when there is variation in room temperature. Considering, also, that the guarantee of the volume of protection derives from a projection of the height of a captor element and that the control of this lowest point is critical. So, equations were

developed to calculate these efforts from the catenary arrow that is required for the wire air-termination. Therefore, it was reversed the practice of calculating this type of sizing, where the effort is calculated and after that, the arrow of a catenary of the cable is calculated. The developed equations include both for supports for the same height and different heights, as shown in Figure 26 and Figure 27. However, these equations are not yet coded in a programming language.

The mathematical approach to dimension the efforts in the wire air-termination was developed in a spreadsheet and the results are in tables such as the Table 1. Other temperature ranges are possible. This is for information only.

8.3. Module to consolidate the list of materials of a project

The insertion of the LPS type in the sizing sections already allows to insert in the database the list of materials. Thus, it will be possible from commercially standardized systems to associate the spare parts list required for that dimensioning, when applicable. This module should have a restricted section to address the material list of grounding systems. There is no prediction to perform the calculation of grounding systems because several software are already dedicated to this purpose. Hence, the module includes only the integration of materials to the LPS design.

8.4. Module for sizing parallel wire air-termination system

We already have several mathematical models responsible for sizing this kind of LPS by parallel wire air-termination in several configurations for this type of systems, as shown in Figure 28 and Figure 29 (other details can be found in the XIII SIPDA [9]). However, we do not yet have the conversion of equations into

programming codes, but this is not the biggest problem for insertion. The understanding is that the greatest difficulty is to develop the graphic formulation because it is more complex and I still do not have training in this area, and the addition of this qualification will require planning.

Figure 28: Representation for different levels of parallel wire air termination

Figure 29: Representation for equal levels of parallel wire air termination

The mathematical approach to determine the limits of a parallel wire air-termination design, considering a possible unevenness of the terrain – at the time of the project implementation or spacing between the wire air-termination or both – produces a table as the one presented in Table 2. This is only an example.

Table 1: Calculated forces for the wire air-termination

Span: 20,30 (m)			Arrow of a catenary: 0,20 (m)		Length: 20,30 (m)		Reference temperature: 26ºC
Item	Temp.: (ºC)	Length: A (m)	f (m)	To (kgf)	T (kgf)	p$_s$ (kgf)	Transverse force (kgf)
01	16	20,303	0,153	137,63	137,63	4,151	2,85
02	20	20,304	0,175	120,55	120,55	4,151	2,85
03	26	20,305	0,203	103,78	103,79	4,151	2,85
04	30	20,306	0,220	95,84	95,85	4,151	2,85
05	36	20,308	0,243	86,75	86,75	4,151	2,85
06	40	20,309	0,257	81,95	81,95	4,151	2,85
07	45	20,310	0,274	76,94	76,95	4,151	2,85
08	22	20,304	0,185	138,38	138,38	4,151	2,85
09	36/16	20,301	0,075	280,12	280,12	4,151	2,85
10	36/22	20,302	0,128	200,00	200,01	4,151	2,85

Note: Reference temperature: 26ºC

Table 2: Calculations of the LPS Limits for Figure 28

Designation		Distance between LPS)					
		30.0 (m)		30.5 (m)		31.0 (m)	
Reduce level	Height of the lower LPS	a	hpc	a	hpc	a	hpc
-	16.00	13.23	10.50	13.55	10.21	13.87	9.92

0.50	15.50	13.03	10.18	13.35	9.89	13.68	9.60
1.00	15.00	12.83	9.85	13.16	9.56	13.49	9.27
1.50	14.50	12.63	9.51				

8.5. Development of tools to integrate with software graph

Another important tool is the integration with design software, such as Autocad. Therefore, the future idea is to develop tools to migrate the sizing data of the various Modules and Sections to enable the plotting of drawings with the horizontal coverage planes for the various Covering projection for the various classes of protection of 15 meters high LPS over structures with a height of 3.5 m. These tools should incorporate the generation of 3D plants, which the resources necessary to rotate and promote cuts of the protected volume.

9. Software security requirements

This software is intended to be a tool used by professionals who design systems to protect against atmospheric discharges – either by direct or nearby impacts – and these might cause harmful effects with high probability of causing losses either by L_1 - losses of human life (including permanent injury); L_2 - losses of services to the public; L_3 - losses of cultural heritage and L_4 - losses of economic value. Thus, it is necessary for these professionals to carry out a very detailed and safe risk analysis. Therefore, safety requirements were established, with the goal of blocking errors or deviations from the requirements established by the standards on which this application was based. These requirements are as follows:

9.1. Controle na determinação das Zonas

The System alerts and blocks Zones from being repeated in the Risk Analysis, as shown in Figure 31.
Figure 30: Horizontal projection screen of an LPS project (only for guidance)

9.2. Control of the total number of people in the Zones

When the number of people distributed in all Zones is inserted, the System verifies consistency. So, in case of divergence with the total number reported in the Registry (Figure 4), it issues an alert and blocks for further correction, either for more (Figure 32) or for less (Figure 33):

Figure 31: Zone alert already selected

Figure 32: Alert of more people in the Zones than the registered total

Figure 33: Alert of fewer people in the Zones than the total registered

9.3. Consistencies of line parameters

The System filters the options of values of the probability PLD depending on the resistance RS of the cable screen and the impulse withstand voltage UW of the equipment, based on the line type, routing, shielding, and bonding conditions, as can be seen in Figure 34. Power line is not bonded to the same bonding bar as equipment and telecom is bonded to the same bonding bar as equipment.

Figure 34: Filters for line parameters

9.4. Restrictions for changing typical loss values

When it comes to loss of human life (L1), the typical LT loss values (loss due to injuries from electric shock) cannot be changed (the system freezes). The same applies to the typical LF loss value (loss in a structure due to physical damage) when it is indicated that there is a risk of explosion in the Zone or when it is indicated that the place is a hospital, hotel, school or civic building.

In addition, changes in typical LO loss values (loss in a structure due to failure of internal systems) are blocked when it comes to areas that are part of the hospital or life support structure. When dealing with L2 and L3 losses, the values of LF and LO are also blocked for changes. For losses of type L4, permissions similar to L1 losses are applied. Blocking alerts are via a pop-up message, as shown in Figure 35.

Figure 35: Blocking alert screen for changing typical loss value

9.5. Permission to modify data and customize

It is important to emphasize that to perform any customization and or modify parameters predefined in the System, there is a need for the professional to make, in advance, his or her registration in the system and, after that, he or she will have to define on the initial screen (Figure 4) the designer responsible for the project. This way, the system will save the modifications in an associated way with the person responsible for performing them.

10. Acknowledgment

This is a work that I have been developing alone, from the need I had to carry out the evaluation of projects of Protection Against Atmospheric Discrimination. Therefore, to be certain about my work, I developed the methodology and then the migration to the programming codes of this system, having paid every expense with my own resources, including all the development so far and the costs regarding my participation in all the previous symposia and the development of the papers.

11. Conclusion

This paper is in line with the conclusion of the work originally presented at the SIPDA XV symposium [1], as it incorporates new resources to provide LPS designers with more efficient and safe tools and means for project development, in accordance with Brazilian, International and American standards.

In this context, the BrcLightning application continues, also, with the objective of consolidating itself as an integrated software, having as a support, for some of its modules, the dimensioning of LPS based on the mathematical approach, which was developed and presented at the SIPDA XIII [9] and SIPDA XIV [10] symposia. Thereby, we hope to be contributing to a better understanding of the standards and to the development of safer and more effective projects for protection against lightning strikes.

Also, its modulated design and the format of a database allows the development of applications to be used on the internet, online, and by app systems used on cell phones or other mobile devices.

Exposure to Optical Radiation and Electromagnetic Fields at the Workplace: Criteria for Occupational Health Surveillance According to Current European Legislation

Alberto Modenese, Fabriziomaria Gobba[*]

Department of Biomedical, Metabolic and Neural Sciences, University of Modena and Reggio Emilia, Modena, 41125, Italy

A B S T R A C T

A very large number of workers is occupationally exposed to Optical Radiation (OR) worldwide, while indeed nowadays an exposure to Electromagnetic fields (EMF) can occur in almost all workplaces. OR origin can be natural, including the most relevant source, i.e. the sun, or artificial, that can be further classified in incoherent and coherent, i.e. the LASERs. Solar radiation (SR) exposure, and in particular its most harmful component, the ultraviolet radiation (UVR), is a significant occupational risk in "outdoor workers", including e.g. farmers and construction workers. UVR is mainly absorbed in the eye and the skin, there inducing various short-term and chronic adverse health effects, as burns, cataract and skin cancers. At least in Europe, for SR exposed workers no specific obligations currently exist regarding the Health Surveillance (HS), that is instead required for occupational exposures to artificial OR according to the legislation of the European Union (EU, Directive 2006/25/EC). Considering now EMF, the EU Directive 2013/35/EU provides an obligation for the HS of exposed workers, aimed at the prevention of the possible direct short-term effects, as involuntary contractions or temperature increase of tissues, and indirect effects, as shocks and interference. Conversely, long-term effects are not considered in the Directive as data on causal relationship, including reliable mechanisms, are considered inadequate. Direct short-term and indirect effects can appear solely in case of high exposures, usually occuring only accidentally, but a specific group of workers, defined "at particular risk", exists, and it includes e.g. persons with implanted active medical devices, as cardioverter defibrillators or pacemakers. In these workers, adverse effects can be induced at lower EMF levels. The identification and an adequate protection of the workers at particular risk is one of the main goals of the HS of occupational EMF exposure.
The main HS criteria applicable for workers with exposure to OR and EMF are discussed in this article.

1. Introduction

Exposure to Optical Radiation (OR) and Electromagnetic Fields (EMF), i.e. Non-Ionizing Radiation (NIR), at work represents a relevant occupational risk for many work activities: this paper is an extension of work originally presented in the 2020 IEEE International Conference on Environment and Electrical Engineering and 2020 IEEE Industrial and Commercial Power Systems Europe (EEEIC / I&CPS Europe) [1].

Occupational risks can be classified in chemical, biological, physical risks and others (including ergonomic, psichosocial and safety risks) [2]. NIR exposure is included among physical risks together with e.g. noise and vibrations. As it happens for all the other occupational risks, adequate prevention should be emplaced in the companies in order to warrant appropriate occupational health and safety (OHS) conditions for the exposed workers. This involves a specific evaluation of the risk related to the working activity with NIR exposure, aimed at identifying the most appropriate preventive measures. An important part of the prevention process to ensure OHS is the health surveillance (HS) of the workers exposed to occupational risks that may affect their health, usually performed by trained occupational physicians. HS is defined, according to the International Labour Office (ILO), as a group of "procedures and investigations to assess workers' health,

[*]Corresponding Author: Fabriziomaria Gobba, v. G. Campi 287 – 41125 Modena (Italy), +390592055463, fabriziomaria.gobba@unimore.it

in order to identify any abnormality possibly associated to a recognized work-related risk in exposed workers", involving "the review of the health records and any other opportune medical examinations needed" [3]. Considering possible implications for workers' health of NIR exposure, it should be noted that NIR are included in the part of the electromagnetic spectrum with lower energy compared to ionizing radiation, meaning that both OR and EMF have not enough energy to cause ionization, i.e. to remove electrons from atoms and molecules. Accordingly, the interaction mechanisms with the biological tissues, and the penetration ability of NIR are very different from ionizing radiation. Nevertheless, also within the various regions and sub-regions of the NIR spectrum significant differences exist, and therefore the possible health effects and the criteria for the health surveillance of the workers exposed to non-ionizing radiation should be discussed separately. In the following parts of this article these criteria are introduced and discussed.

2. Optical radiation: occupational exposure and health effects

2.1. Occupational exposure to optical radiation

OR includes wavelengths (λ) between 100 nanometers (nm) and 1 millimeter (mm), distributed in three different regions: ultraviolet radiation (UVR), further classified in the subregions UV-A, UV-B and UV-C, visible radiation and infrared radiation (IR), with other three sub-regions: IR-A, IR-B and IR-C [4].

Occupational OR exposure can be possible both in case of artificial OR and solar radiation (SR) exposure.

Artificial sources can emit incoherent radiation or coherent bands of amplificated radiations (i.e. LASERs). Considering UVR, among the main applications relevant for occupational exposure there is the use of UV as sterilizing agents for both surfaces and products, the idustrial processes applying UV rays in the machineries for photo-lithography and printing, the medical applications as e.g. the photo-therapy for the neonatal jaundice, the UV emissions during welding processes, and many others. Also visible light is emitted during welding, and of course it is used for illumination purposes: kind of intense exposures can be possible in the entertainment sector, e.g. in theatres or in television studios, in shopping centers, and in general where it is required to be close to sources emitting intense lights (indicators, signals, LED, projectors, etc). Also visible light is used for industrial, e.g. printing processes, and medical applications, e.g. for photopolymerization of the materials used in dental clinics. Finally, infrared radiation is also emitted during welding activities, and moreover it is emitted as a result of industrial processes generating very high thermal energies during the treatment of metals, glass and other materials. Furthermore, IR-based technologies are widely applied e.g. in communication and surveillance systems [4]. LASER technologies can use all the optical radiations. Gas LASERs, as those using argon or krypton, mainly amplify UV or short wavelength visible light, while solid state LASERs, as neodymium YAG LASERs, and semi-conductor LASERs, as those using gallium, mainly amplify infrared or long wavelength visible light [4].

Even if the number of artificial sources emitting OR at the workplaces is huge, the effective number of workers exposed to

levels potentially determining relevant health risks is relatively limited, as frequently the sources are appropriately shielded [4–7]. A possible exception is represented by welding activities: welders should be appropriately protected, with adequate clothing and face masks with eye filters for the specific bands of ORs emitted during the welding process [4–6, 8]. For the other sources of artificial OR the major problems may occur in case of malfunctions of the machineries with failures of the protection mechanisms, and/or of workers with inadequate protections, determining work-related accidents possibly causing severe damages [9, 10]. The eye is one of the most frequently involved organ, in particular in these cases [11, 12].

On the other hand, the most important source of occupational exposure to OR, in terms of both the numbers of exposed workers and relevancy of possible adverse effects, is certainly the Sun. Millions of workers have an exposure to solar radiation (SR) worldwide: among the main job categories involved there are farmers [13, 14], construction workers [15–17], fishermen [18], lifeguards [19, 20], gardeners [21, 22], ski instructors/mountain guides [23, 24] and others [25, 26]. These workers, spending a significant part of the working day outside, are collectively identified with the term of "outdoor workers". Fortunately, SR at the Earth' surface does not include all the components of OR spectrum, and in particular all UVC rays and the large majority of the UVB are blocked in the stratosphere [5, 26]. As UV radiation is a carcinogenic agent, also SR is considered a carcinogenic exposure [27]: it is estimated that SR represents the occupational carcinogenic exposure with the highest amount of workers exposed [28].

2.2. Interaction mechanisms with biological tissues and main effects of optical radiation exposure

OR have a quite low ability of penetrating the biological tissues, and therefore the main targets are the eyes and the skin [5, 26]. Two main mechanisms of interaction with the biological tissues can be identified for OR bands:

- Thermal mechanisms: these effects are typical of IR and of long wavelength visible light, and they are related to the conduction of heat in the tissues, usually requiring intense exposures. In case of insufficiently intense exposure no appreciable effects can be determined, as the heat is dissipated through the surrounding tissues [29]. Accordingly, usually only acute effects, resulting in eye injuries or skin thermal burns can be associated to infrared or visible light exposure with thermal mechanisms [29], even if, mainly in the past, some chronic skin alterations [30] as well as thermal cataract have been reported [31, 32].

- Photo-chemical effects are possible in case of exposure to UVR and to short wavelength visible light [5, 26]. Photons are absorbed by specific targeted molecules (i.e. chromophores) in the biological tissues, releasing energy and inducing chemical reactions, with consequent damages and alterations (e.g. inflammation) [5, 26]. Photochemical effects are possible both in case of short-term intense exposures but also as a consequence of long-term less intense exposures [33].

The most hazardous component of OR is UVR: UV rays have higher energy compared to infrared and visible radiation and they act with photochemical mechanisms, causing both acute and chronic effects in humans [5, 26]. After intense short-term exposures, acute skin effects as skin erythema and photodermatoses, in case of presence of a photo-toxic substance (e.g. a topic drug or a cosmetic) on the skin, can occur (it should be noted that photodermatoses may be also associated with some wavelenghts of visible radiations) [5, 26]. Also photochemical burns of the unprotected eyes are possible, especially in case of intense direct exposures or indirect exposures from surfaces with high reflectance (e.g. snow, polished metals): UV rays can be highly absorbed in the ocular surface, causing an acute inflammation of the cornea and of the conjunctiva called photokeratitis/photoconjunctivities, determining photophobia, redness, pain, burning, tearing and foreign body perception [5, 12, 26].

Considering long-term exposure, UVR is able to induce various skin and eye effects, many of them very severe. UVR is mutagenic for the DNA and cumulative damages over time can induce pre-cancerous and cancerous alterations [5, 26, 27]. In the skin chronic UVR exposure is able to induce photoaging, i.e. a progressive process including functional and aesthetic skin changes with loss of elasticity, cell depletion, pigment accumulation and substitution of normal tissue with fibrous tissue. considered to be a precancerous alteration [5, 26, 34, 35]. Other pre-cancerous lesions, sometimes identified also as *in situ* carcinomas, induced by chronic UVR exposure of the skin are actinic keratoses (AK). AK are disorders of the keratinocytes resulting in thickening of the skin with formation of scaly and/or crusty lesions. Untreated lesions have up to a 20% risk of progression to squamous cell carcinoma (SCC) [5, 26, 27, 35, 36]. In addition to pre-cancerous lesions, UVR is able to induce skin cancers. The most common are the basal cell carcinoma (BCC) and the SCC of the skin, also called as keratinocytes cancers [26, 27, 37]. These tumours are the most frequent malignancies in subjects with fair skin, and accordingly they are the most frequent type of cancer in Europe, Canada, US and Australia. Fortunately these tumors have mainly a local malignancy, resulting only seldom in methastatization processes: accordingly, the prognosis is quite good compared to other tumors, and, if treated in time, the mortality is low, but they can result in quite impressive mutilations, especially considering that they usually appear in solar UV exposed skin areas, as the face [38, 39]. Both BCC and SCC are somehow related to cumulative UVR exposure and there is evidence that outdoor workers have a relevantly increased risk of getting these tumors [40], while only few reports of associations with artificial UVR exposure at work are available [41]. Another skin tumor related to excessive UVR exposure is the malignant melanoma (MM), a cancer originating from the skin melanocytes. MM are less frequent compared to BCC and SCC, but they often methastatize if not diagnosed in time, determining an important burden not only in terms of disability adjusted life years (DALYs) but also in term of mortality [27, 42]. Considering occupational exposure, the relation with SR exposure in outdoor workers is controversial, as some studies reported a possible protective effect of cumulative UVR exposure, while the increased risk of MM is associated with intense exposure in the childhood with repeated sunburns [27, 43]. Some studies reporting a possible increased melanoma risk for welders have also been published [27, 41].

Considering now possible long-term effects in the eyes, UVR can induce chronic alterations of the ocular surface, being absorbed mainly in the cornea and in the conjunctiva, determining a chronic inflammatory stimolous and pathological alterations with abnormal growths of the corneal and conjunctival cells [5, 26, 44]. This may result in various diseases, some of them representing mainly aesthetic alterations with no clinical relevancy, as pinguecula, other more severe with potential affection of the visual function if not treated, as the pterygium, an abnormal growth of the conjunctiva from the nasal angle of the eye to the center, finally covering the cornea [44, 45]. Corneal and conjunctival squamous cell carcinomas (i.e. the same types of cancers occurring in the skin) are also possible: fortunately they are very rare, but with demonstrations of associations with UV exposure [44]. Moreover, also another eye tumor, the melanoma of the eye, more frequent compared to corneal and conjunctival carcinomas, even if still quite rare, has been reported as possibly associated with UV exposure, in particular in welders [44, 46].

Furthermore, a relevant quote of UVR is able to penetrate the ocular surface being absorbed in the lens [5]. There, with photo-oxidation damages contributing to the age-related process of the denaturation of the lens proteins, UVR can accelerate and increase the opacification of the lens [47]: it is estimated that more than the 20% of the cataracts can be attribued to excessive UVR exposure [48], and it should be noted that cataract is still the main cause of blindness worldwide [49]. Not only solar radiation, but also artificial UVR is associated to an increased risk of cataract development [47, 50].

Finally, another possible chronic adverse eye effect that can be associated in particular to long-term SR exposure is macular degeneration, a very frequent multi-factorial degenerative disease of the central part of the retina, currently the third among the major causes of blindness worldwide [49]. Scientific demonstrations of the relation between this eye pathology and SR exposure are mainly epidemiological, rather then experimental, but some hypothesis have been proposed [51]. In this case, the role of UVR is limited to that of a small portion of UV-A radiation, able to reach the retina especially in younger subjects when the lens is more transparent [5]. But also violet/blue visible light can contribute to a chronic photochemical retinal damage through photo-oxidations [52, 53].

3. Prevention of the health risk related to occupational optical radiation exposure

3.1. Occupational optical radiation exposure risk in the workplaces and workers belonging to particularly sensitive risk groups

Currently in Europe there are no specific obligations for the HS of workers exposed to solar radiation, even if, considering the relevancy of the risk and of the adverse health effects to be expected, in many countries an increasing attention to the protection of outdoor workers against UVR and to the occurrence of solar UV-induced occupational diseases has been raised in recent years [5, 26, 38, 54–59]. One of the issues still to be solved is the lack of a recognized occupational limit for solar UVR

exposure at work in Europe: the recognition of such a limit would be helpful to implement risk evaluation processes in the workplaces, defining the specific protections needed. On the other hand, since 2006 a specific European Directive "2006/25/EC" for the prevention of the occupational risk related to artificial optical radiation exposure has been emplaced [4]. In this case, specific occupational exposure limits to be respected are available, and moreover the Directive requires mandatory risk evaluation, definition of technical and organizational preventive measures, specific training of the workers, the forniture of adequate personal protective equipment and, if needed, an appropriate health surveillance.

For all the previously mentioned steps of the process for an adequate prevention of OR risk at the workplaces, the Directive indicates that a special attention has to be deserved to the workers "*belonging to particularly sensitive risk groups*" [4]. No specific indications are included in the EU Directive helping in identifying these workers. We report here below a non-exhaustive list of possible conditions determining a particular susceptibility to OR exposure, increasing the risk of adverse effects, mainly for the eye and the skin, and requiring a special attention [4, 5, 26].

- Conditions related to a possible increased risk of adverse skin effects (mainly related to the UVR component of OR): e.g. albino subjects and all the workers with fair skin photo-types (i.e. at least Fitzpatrick skin photo-type 1 or 2 [60]), who are at an increased risks for developing all the UV-related acute and long-term skin effects; workers affected by skin diseases that can be photo-induced or photo-aggravated, as psoriasis or xeroderma pigmentosum; workers being diagnosed with precancerous or cancerous skin lesions; workers being treated with photosensitizing drugs or in contact with photosensitizing substances as psoralenes.

- Conditions related to a possible increased risk of adverse eye effects: workers with alterations of the eyes structure possibly affecting the quantity of OR absorbed in specific eye regions, as e.g. iris alterations (as coloboma, aniridia), pupil alterations (as tonically dilated pupil, mydriasis), lens alterations (aphakia, artificial intraocular lens); workers being diagnosed with eye diseases possibly being worsened by excessive OR exposure, as e.g. initial lesions of the lens (as presence of small lens opacities or cataract at an initial stage) or of the retina (as the presence of drusen in the macula); subjects with only a monocular vision, as the possible occurrence of OR-related adverse effects in the eye may result in blindness.

- Other conditions: pregnant workers are usually considered among the workers belonging to particularly sensitive risk groups, mainly considering (but not limited to) the possible thermal effects of the infrared component, increasing the body temperature in the abdominal region; underage workers can be also potentiually included, especially considering that the lens is more transparent to UVR, possibly enabling a higher amount of radiation reaching the retina.

3.2. Health surveillance of workers exposed to optical radiations

According to the current European legislation, there are two possible scenarios for the HS of OR exposed workers. The HS is an obligation in case a relevant risk is evaluated in the workplace according to the EU Directive 2006/25/EC for artificial OR exposure, both in case of incoherent sources and of LASER use. On the other hand, considering SR exposure risk of outdoor workers, currently in Europe HS is not mandatory [5, 26], even if, in the light of the numbers of outdoor workers, the high levels of occupational UVR exposure detected in several studies [13–26] and of the documented increased risk for these workers of developing UVR-induced eye and skin effects [25, 26, 40, 44–48, 50, 51, 54, 55, 27, 28, 34–39] an appropriate HS seems absolutely necessary.

The objective of the HS of OR-exposed workers is the prevention and the early diagnosis of adverse effects, mainly of the eyes and of the skin. During HS activities, specific attentions have to be deserved to the workers affected by conditions inducing a particular susceptibility to the risk, as the ones mentioned here in the previous section 3.1. HS programs usually include both pre-employment and periodic medical examinations from trained occupational physicians, who may require, on individual basis, supplementary health controls possibly encompassing other specialists involved in the specific problem detected (e.g. ophthalmologists, dermatologists, etc) [26, 38, 59]. As stated above, the most alarming health risk to be considered during HS is the one related to the UVR component that can induce relevant adverse health effects as skin cancers, currently the most frequent tumors among Caucasian subjects. These cancers, together with other OR-induced eye and skin pathologies, are recognized occupational diseases in many European countries, but not in all [38, 59]. Nevertheless, these cancers are largely underreported: an extension of the HS also to outdoor workers should help in increasing the reporting of OR-induced occupational diseases, allowing workers to receive an adequate medical care and compensation for the diseases, and letting institutional authorities and governments acknowledged of the true magnitude of the phenomenon, and consequently of the need of preventive measures [38, 55, 59].

4. Electromagnetic fields: occupational exposure and health effects

4.1. Occupational exposure to electromagnetic fields

Nowadays, a certain level of EMF exposure is present in almost all the working environments, and there is an extremely large, and increasing, variety of occupational EMF sources. Accordingly, some exposure to EMF is present for almost all workers. But, on the other hand, numerous sources are present also in the general environment. Accordingly, it can seem inappropriate to consider every single worker as an "*exposed worker*". A detailed discussion on this topic is beyond the scopes of this article but, in general, it can be considered appropriate to evaluate as "*exposed*" workers, those with an expected EMF exposure above the levels usually detectable for the general population at home and in public places [61–64]. A peculiar aspect in this context is that in some workers with a particular susceptibility (*"workers at particular risk"* - WPR), also EMF levels permittable for the general public may determine a non-irrelevant residual health risk. This is specifically the case of workers with active implanted medical devices (AIMD), who may be at risk for interference problems when in proximity of an EMF source [65–67]: these aspects will be discussed in detail in the next paragraphs.

When dealing with the problem of occupational exposure to EMF, as it happens also for OR, it is important to identify the specific types of EMFs emitted by the considered sources, as different regions of the EMF spectrum have different biological interaction mechanisms and, consequently, different effects, depending on the frequency bands. For the objectives of this article, we adopt a simplified EMF classification, discussing here the main issues related to the exposure in particular to static magnetic fields (SMF, frequency= 0 Hertz), extremely-low frequency magnetic fields (ELF-MF, frequency= 1 - <300 Hertz), intermediate frequency EMF (IF-EMF, frequency= 300 Hertz - <100 kilohertz) and high frequency EMF (HF-EMF, frequency> 100 kilohertz, including radiofrequency - RF -, microwaves, millimeter and terahertz waves) [61–64, 68]. Considering now specific working situations and occupational sources with potentially relevant emissions of EMF, a useful guide for the prevention of EMF risk at work is the so-called "*non-binding guide*" for the application of the European Directive 2013/35/EU [68]: we present here an extract of the document with a list of work activities and EMF-sources determining occupational exposures (Table 1).

Table 1: Non-exhaustive list of work activities/occupational sources inducing a potentially relevant exposure to electromagnetic fields extracted from the "non-binding guide" for the application of the European Directive 2013/35/EU

Type of equipment or workplace
Construction: various equipment and machineries (e.g. concrete mixers, cranes, vibrators, welding machines, etc)
Electrical supply: electrical installations, generators, inverters
Infrastructure (buildings): base station antennas
Infrastructure (grounds): garden appliances
Heavy industry: industrial electrolysis, furnaces, arc melting, welding machines
Light industry: arc welding processes, dielectric heating and welding, industrial magnetizer/ demagnetizers
Medical: magnetic Resonance Imaging (MRI), other medical equipment using EMF for diagnosis and treatment (for example, short wave diathermy, transcranial magnetic stimulation)
Office: audio-visual equipment containing RF-transmitters, office equipment (e.g. photocopiers, electric staplers, paper shredders)
Transport: motor vehicles and plants, radars (air traffic control, military use, weather monitoring, long range radars), electrically driven trains and trams
Wireless communications Cordless phones (including base stations for cordless phones), mobile phones, wi-fi routers

It should be noted that for the sources and the occupational activities with potentially relevant occupational EMF exposures presented in the Table 1 no specific frequencies ranges of EMF emissions are reported. This is because in many cases the exposure can include various EMF bands, as e.g. in welding activities, where ELF, IF-EMF and RF can be represented in the specific emission spectra depending also on the type of welding procedure, or in MRI activities, where operators are exposed to the action of the SMF as well as to time-varying EMF when they move within the SMF, while the patients are also exposed to RF when the scanner is in function. In other cases, the EMF exposure can be referred to specific EMF bands, as e.g. for electrical installations, generators and inverters, emitting mainly in the ELF range, or for wireless communication systems, with emissions mainly in the RF band [61–64, 68–70]. Another relevant note for an appropriate interpretation of the Table 1 is that not all the potential exposures listed represent, in normal conditions, a relevant risk for the workers; e.g., again in the case of wireless communication systems or in the case of office equipment, the listed sources may determine an occupational risk only for workers with an increased susceptibility to the EMF risk, as subjects with AIMD who have to work close to the sources [61–68], as previously introduced. On the other hand, other sources can be able to usually induce high exposure levels, potentially representing an occupational risk in case of inadequate working conditions, e.g. in the case of close proximity of operators to a MRI scanner, in industrial electrolysis plants, or in working activities involving induction heating systems, soldering devices, or broadcasting systems and devices, etc. [61–64, 68].

4.2. Interaction mechanisms with biological tissues and main effects of electromagnetic fields exposure

According to the above mentioned European Directive 2013/35/EU, currently in Europe for the prevention of the occupational risks related to EMF exposure only effects based on recognized interaction mechanisms with the biological tissues are considered [68]. The EU Directive indicates specifically the short term direct biophysical effects and the indirect effects related to EMF exposure [68]. A necessary punctualization here, considering the quite large number of studies dealing with suggested long-term effects related to EMF (among the main examples there are the suggested associations between leukemia and ELF-MF exposure, and brain cancers with RF exposure), is that, for these effects, the current European legislation does not consider sufficient the available scientific evidence, in particular considering that no adequate pathogenetic mechanisms in humans have been demonstrated [61–64, 68]. The position of the EU Commission is coherent with the opinions of various recognized national and international organizations and institutions [61–64, 71-85].

According to the above mentioned EU approach, we discuss here only: a) direct biophysical effects caused in the human body by its presence within an EMF; and b) indirect effects, induced by the presence of an object in the EMF (object that can also be placed inside the body, as in the case of implanted medical devices) [68].

According to the frequency band of the EMF, different mechanisms are involved for the occurrence of direct effects: non-thermal mechanisms for static and low-frequency fields, and thermal mechanisms for high frequency fields. For the intermediate frequencies both the mechanisms are possible [61–64, 68]. Among non-thermal effects, based on cuurents induction in the biological tissues, there are the following: limb currents,

stimulation of muscles, nerves or sensory organs with induction of temporary annoyance or with a possible detrimental effect on cognition or on other brain or muscle functions, with possible risks for the safety of the workers [68]. Considering thermal mechanisms, the direct effects, related to HF-EMF exposure, and possibly to IF-EMF, are related to an increase of the temperature in the body, that can be usually more relevant at the surface, and accordingly in targets as the eyes, where very intense HF-EMF can theoretically induce a thermal damage of the lens with opacification (cataract), and the skin, where thermal burns can be possible, also in this case after very high exposures levels [64, 68]. A further classification of direct effects according to the 2013/35/EU Directive is the one concerning *"sensory"* and *"health effects"* [68]. Sensory effects are usually rapidly reversible and transient. They can be considered non-pathological effects, usually with no consequences for the individuals, even if they can be associated with an increased risk of work accidents. Sensory effects are mainly related to relevant SMF and ELF-EMF exposures, representing the consequence of an induction of currents, stimulating the nervous systems and/or sensory organs. Examples of sensory effects are vertigo, nausea, perception of a metallic taste in mouth after SMF exposure, magnetophosphenes (i.e. eye lamps perception) and minor reversible changes of some brain functions (e.g. attention, congnitive function) in case of ELF-EMF exposure [61–63, 68]. On the other hand, EMF-related *"health effects"* represent severe alterations, that usually appear only in case of overexposure to EMF, significantly above the occupational limits established e.g. in Europe by the 2013/35/EU Directive. A non-exhaustive list of these health effects, based on non-thermal mechanisms for SMF and ELF-MF (an example can be an alteration of the cardiac rythm) and on thermal mechanisms in case of very intense HF-EMF exposure (e.g. skin burns), is presented in the Table 2. As stated above, for IF-EMF exposure sensory and health effects typical of both low and high frequencies can be possible [61–64, 68].

Table 2: Non-exhaustive list of health effects caused by overexposure to electro-magnetic fields, based on the European Directive 2013/35/EU

EMF type	
Static magnetic field	Alterations of the blood flow in the limbs; alterations of the brain functions; alterations of the cardiac rhythm and of the cardiovascular fuction
Low frequency fields	Pain and/or tingling sensations due to an involuntary contractions of the muscles or to the stimulation of the nervous system; alterations of the cardiac rhythm
Intermediate frequency fields	The effects of both high and low frequencies can be possible
High frequency fields	Excessive increase in temperature and/or thermal burns over the whole body or in specific areas; thermal damage of the eyes (possibility of thermal cataracts), skin, testicles

Considering now indirect effects, these effects can occur, as stated above, when there is an object inside the EMF, together with the human body. All the EMF frequencies can be involved, and, as in the case of medical devices, it should be noted that the object can be also implanted in the human body [68]. Some of these indirect effects mainly represent a risk of work-related injuries: EMF can initiate electro-explosive devices causing fires and explosions. Other indirect effects possibly associated to severe injuries are contact currents, that can be induced in the body by the contact with charged objects within an EMF [68]. The most relevant indirect effects that can happen also in case of usual exposures, and not as a consequence of a malfunction/wrong procedure, are interference problems of EMF with implanted or body worn devices, usually for medical purposes. The major problems can be experienced in case of active devices, as pacemakers or implantable cardioverter defibrillators (ICD): their functions can be altered by the EMF, determining a risk for the workers' health [61–68]. Also, passive devices, as e.g. metal splinters or graft, can be affected by EMF: in particular, SMF may dislocate the devices made of ferromagnetic materials, causing inflammation or other problems in the surrounding tissue. Moreover, IF-EMF and HF-EMF can determine a heating of the metallic parts of the devices, also in this case with a potential damage to the biological tissue [65–68].

5. Prevention of the health risk related to electromagnetic fields exposure

5.1. Occupational electromagnetic fields exposure risk in the workplaces and workers at particular risk

In Europe, the prevention of the occupational risk related to EMF is regulated according to the Directive 2013/35/EU. As it happened also for OR, a specific *"non binding guide"* was then produced by the European Commission, to give practical indications for the application of the Directive [68]. The Directive requires mandatory EMF risk evaluation in the workplaces, defining the technical and organizational preventive measures to be applied, including a specific training of the exposed workers, the adoption of adequate personal protective equipment and, if needed, an appropriate health surveillance. Specific occupational exposure limits are available for the different EMF frequencies, mainly based on the guidelines of the International Commission on Non-Ionizing Radiation Protection (ICNIRP) [61–63]. Different limit values are available not only according to the EMF frequency, but also based on the different effects to be prevented: separate limits for the prevention of the above-mentioned *sensory* and *health effects* are defined in the EU Directive [68]. As previously introduced, the possibility to reach exposure levels able to induce *health effects* is very rare, happening only in case of overexposure, e.g. in case of accidents. Moreover, it is not sufficient to simply exceed the limit value to induce the appearance of a *health effect*, as usually exposures highly above the limits are needed. Furthermore, also the exceeding of the limits for *sensory effects*, much lower compared to the limits for *health effects*, is not usual, and in principle it has to be avoided in normal conditions [86, 87].

Considering this, one of the main problems for the prevention of the occupational EMF risk is the possible presence at the workplace of WPR, as defined by the Directive 2013/35/EU, for whom the occupational limits set might be not fully protective [68]. Currently, a non-exhaustive list of WPR for EMF exposure includes:

- Workers with active implanted medical devices (AIMD): e.g. pacemakers, implanted cardioverter defibrillators, ear implants, neurostimulators, implanted drug infusion pumps, etc [65–68, 88, 89].

- Workers with passive implanted medical devices containing metals: e.g. artificial joints, plates, surgical clips, stents, heart valve prostheses, intra-uterine devices, etc [68, 88–91].

- Workers with body-worn devices: e.g. drugs infusion pumps, hearing aids, continuous glucose monitoring systems, etc [68, 88, 89].

- Other WPR categories included in the EU Directive: pregnant workers [68, 88, 89].

5.2. Health surveillance of workers exposed to electromagnetic fields

According to the Directive 2013/35/EU, HS of EMF exposed workers is mandatory, when a relevant risk for the workers is evaluated. Moreover, for the HS, as well as for the risk assessment, the problem of the WPR has to be specifically taken into account [68, 89]. As defined in the Introduction, HS is aimed at identifying any abnormality possibly associated to a recognized work related risk in exposed workers [3]. All the investigations chosen for HS have to be proved with an appropriate level of scientific evidence: the contents of the HS can include biological tests and other investigations, when they are chosen for their validity and relevance with respect to the occupational risks, avoiding investigations that don't fulfill these criteria [92]. Considering the specific case of EMF exposure, a reliable application of these criteria may involve some possible issues. In fact, according to the EU Directive the scopes of the HS are the prevention and early detection of the previously defined direct biophysical effects, including the sensory ones (as e.g. the presence of vertigo or of nausea associated to EMF exposure, etc.), based on non-thermal and thermal mechanisms [68]. In general, these effects do not appear for occupational exposure levels below the limit values, as they can be induced only as a consequence of excessive exposures to quite high levels of EMF [86, 87]. It has also to be highlighted here that sensory effects, that are fully reversible and transient, cannot be considered an actual health risk for the workers [93–95], even if some data suggest a possible association with an increased risk of work-related injuries for the exposed subjects [96, 97]. The other main purpose of the health surveillance related to the occupational EMF risk is the prevention of indirect effects, and this specifically involves the identification of the WPR. Among the conditions of particular susceptibility, probably the main issues are related to possible electromagnetic interference (EMI) problems with AIMD. EMI can appear also as a consequence of kind of low exposure levels if a susceptible subject with an AIMD is close to an EMF-source, and the interference can impair the fundamental functions of the devices [61–68].

Considering this, the health surveillance criteria to be considered should mainly address the identification of possible medical signs and symptoms of sensory effects and of the conditions of particular susceptibility to the EMF-risk, typical of the WPR. For these purposes, particular lab tests or other specific clinical investigations are not required on a routine basis, while their opportunity can be judged by the occupational physician on

an individual basis after a medical examination. Useful instruments to be periodically administered to the workers are the questionnaires evaluating symptoms and conditions of particular susceptibility [93–95]. When administering questionnaires, important prerequisites are a validation process [98] and a preparation of the tool based on scientific results: unfortunately, to the best of our knowledge, to date there are no examples of questionnaires specifically designed for an application during HS examinations of EMF-exposed workers. A further note to the problem of the EMF-related HS is that, in general, medical examinations for workers in good health conditions, with no conditions of particular susceptibility and working in environnments where the EMF levels are supposed to be low or very low (e.g. offices) have not to be considered as activities to be periodically repeated. In these cases, only a single medical investigation performed before the starting of the job, with an effective information on all the conditions possibly determining a particular susceptibility to the EMF risk (NB: the information has to be periodically repeated in these cases, while the medical examination doesn't), seems advisable for an adequate prevention [68, 89].

Finally, a peculiar situation explicitly mentioned in the EU Directive is the case of an *"extraordinary"* HS of the EMF exposed workers, needed when *"any undesired or unexpected health effect is reported by a worker"* or *"in any event where exposure above the ELVs* (i.e. exposure limit values) *is detected".* In these situations, an appropriate *"medical examination"* needs to be provided to the workers [68]. Also, in this case, no guidelines or evidence-based indications are available to define valid contents for these medical examinations. Furthermore, as previously noted, situations with exposure levels exceeding the limits do not necessarily result in the occurrence of adverse health effects [86, 87]. Also, in this case, the main problems should be expected for the WPR. Accordingly, both for extraordinary and routine HS the contents of the examinations include an appropriate in-depth medical examination of the workers by an occupational physician with an adequate competence in the field, administrating specific questionnaires to collect information on suspected EMF-related symptoms and possible conditions of particular susceptibility to the risk, eventually integrated by specific medical consultations and/or laboratory tests and/or diagnostic exams to be decided on an individual basis, considering the types of EMF frequency involved, the exposure level, the susceptibility of the workers and the expected effects to be evaluated [68, 89].

6. Conclusions

Occupational NIR exposure, including EMF and OR, is almost ubiquitous: in principle, an evaluation of the occupational health risk should be appropriate in all workplaces. Based on the health risk assessment, HS programs for the exposed workers have to be established, with the objective of preventing or, at least, identifying at an early stage the possible health effects associated with the exposure. Both risk evaluation and HS activities have to specifically consider the possible presence in the workplace of "workers at particular risk", who deserve a specific attention, as they have an increased susceptibility to the risk. The HS needs to be performed by occupational physicians with adequate and updated skills in the prevention of NIR risk, and accordingly with an appropriate specific training in this field. Here below we present

a conclusive summary of the main relevant points to be considered for the health surveillance of NIR exposed workers:

Optical radiation:

i.   Occupational physicians have to consider that the exposure can be associated to both artificial and natural sources. In particular, solar radiation is certainly the main occupational exposure source, even if sometimes under-recognized as a specific occupational risk.

ii. The main target organs of optical radiation exposure are the eyes and the skin.

iii. For the prevention and early diagnosis purposes, the possible occurrence of both short-term and long-term eye and skin effects, respectively related to acute and cumulative exposures, has to be adequately considered as a fundamental criterion of HS.

iv. The most harmful component of optical radiation is UVR, able to induce both acute and long-term effects with photochemical mechanisms; among the most severe adverse effects related to chronic UV exposures there are skin cancers, i.e. the most frequent forms of neoplasms in Caucasian subjects. Other diseases identified in UVR exposed workers are: skin erythema, photoaging and actinic keratosis for the skin, photokeratoconjunctivitis, pterygium, lens opacities and possibly macular degeneration for the eyes.

v.   During HS activities, specific conditions of particular susceptibility for the exposed workers have to be considered: e.g. a fair skin phototype, eye alterations as aphakia, and others.

vi. Optical radiation related adverse effects are recognized "occupational diseases", even if frequently underreported: physicians have to notify the occurrence of these diseases in exposed workers to the specific workers' compensation Authorities in their Country.

Electromagnetic fields:

i.   According to the European legislation, the recognized effects related to EMF exposure to be considered for the health surveillance of the workers are short-term direct biophysical effects and indirect effects.

ii. Direct effects can be related to both non-thermal and thermal mechanisms, and they are usually induced only by high exposures.

iii. Indirect effects, as the electromagnetic interference with AIMD, can occur also as a consequence of lower exposure levels.

iv. To date, there are no agreed and shared criteria for the health surveillance of EMF-exposed workers, and in particular there are no evidence-based indications on the appropriate contents and procedures for the medical examinations to be performed for the monitoring of the health status of the exposed subjects.

v.   The trained occupational physicians have to evaluate all the possible symptoms related to the sensory and health effects of EMF exposure, considering specifically the type of frequency, the exposure level and the mechanisms involved.

vi. One of the most important activities during health surveillance is the screening of all the conditions that can induce a particular risk for the exposed workers, as e.g. AIMD: a check for the presence of these conditions needs to be done before the employment by the physician, and an extensive information on these conditions has to be provided to the workers, and periodically repeated.

vii. In case of overexposure situations or in case of workers reporting symptoms associated to the EMF exposure, an appropriate medical examination has to be provided to the workers, with specific contents to be evaluated on an individual basis, again based on the type of EMF-frequency, on the exposure level detected and, on the mechanisms, involved.

Conflict of Interest

A sensor fusion concept integrating the optical and microfabricated eddy-current sensor for the non-destructive testing of the grinding burn is reported. For evaluation, reference grinding burn with varying degrees are fabricated on 42CrMo4 tool steel cylinder. The complementary sensing nature of the proposed sensors for the non-destructive testing of the grinding burn is successfully achieved, wherein both the superficial and an in-depth quantitative profile information of the grinding zone is recorded. The electrical output (voltage) of the optical sensor, which is sensitive to the optical surface quality, dropped only by 20 % for moderate degree of grinding burn and by ca. 50 % for stronger degree of grinding burn (i.e., by exclusively considering the superficial surface morphology of the grinding burn). Moreover, a direct correlation among the average surface roughness of the grinding burn, the degree of grinding burn and the optical sensor's output voltage was observed. The superficial and in-depth information of the grinding burn was recorded using a microfabricated eddy-current sensor (planar microcoil with circular spiral geometry with 20 turns) by measuring the impedance change as function of the driving frequency. The depth of penetration of induced eddy-current in the used 42CrMo4 workpiece (with a sensor to workpiece distance of 700 μm) varied from 223 μm to 7 μm on increasing the frequency of the driving current from 1 kHz to 10 MHz, respectively. A very interesting nature of the grinding burn was observed with two distinct zones within the grinding zone, namely, the superficial zone (starting from the workpiece surface to 15 μm in grinding zone) and a submerged zone (>15 μm within the grinding zone). The impedance of the microcoils changed by ca. 8 % and 4 % for the superficial and submerged zone for regions with stronger degree of grinding burn at a frequency of 10 MHz and 2.5MHz, respectively. Furthermore, a correlation between the microhardness of the grinding burn and the impedance change is also observed.

1. Introduction

Grinding technology is considered as the strategic process in the manufacturing technology with its application spanning from the manufacturing of parts for aerospace, defense industry to the production of surfaces with optical quality for the electronics and telecommunications devices, with technology moving towards processing of also the hard ceramic materials [1]. The mechanics involved during the grinding process include the interaction between the grinding wheel with abrasive grains and the

*Corresponding Author: Ulrich Mescheder, Furtwangen University, Robert-Gerwig-Platz 1, 78120, Furtwangen, Germany

workpiece's surface, wherein the material from the workpiece (WP) is removed in a complex manner governed by the interplay among the rubbing, cutting and ploughing stages of material abrasion. However, in case of grinding processes with high material removal rates involving hard steel workpieces, the operating temperatures during the grinding process might easily go beyond the tempering temperature of the WP when the grinding operating conditions are sub-optimal, and might result in an irreversible thermal damage on and within the grinding zone (i.e., the region of interaction between the grinding wheel and WP surface), which is usually referred to as the so-called grinding burn (GB) [1–4]. Among the several defects such as microcracks, pores etc., occurring within the grinding zone (GZ) due to sub-optimal grinding conditions, the occurrence of GB is the most complex defect to detect. The reason behind the complexity in the detection of GB is attributed to the nature of complex microstructural modifications that occur not only on the surface of GZ, but also a few hundred micrometers deep within the GZ [4–6]. As described in [1] and [7], the thermal damage caused by sub-optimal grinding conditions results in tensile residual stresses within the GZ. Moreover, it can lead to grain growth, precipitation, softening, phase transformations resulting in re-hardening, thermal expansion/contraction creating microcracks, and chemical reactions leading to discoloration, i.e., severe oxidation GB; all of which are not only detrimental to the quality of the WP (limiting the performance of the WP), but also lay an enormous financial burden on rejection of ground workpieces having GB [8].

In a recent review paper [2], the authors comprehensively summarized the different methods for detection of GB pre- and post-grinding process, out of which, they are broadly classified under destructive- and non-destructive testing (NDT) methods. Under destructive methods, the method of Nital etching revealing the microstructure of the GZ, and microhardness testing revealing the microstructural change as a function of the hardness profile of the GZ can be used. Furthermore, the optical inspection (with sophisticated CCD cameras and visual inspection), residual stress inspection using x-ray diffractometer (XRD), spectroscopic measurement of elemental study in the GZ, electromagnetic methods involving conventional eddy-current sensors, magnetoelastic methods involving the Barkhausen noise analysis and acoustic emission sensors can be used to detect the occurrence of GB on the ground WP post grinding process [2]. Few of the reported methods like XRD and spectroscopy cannot be integrated in the grinding machine, while the others such as electromagnetic and acoustic emission sensors still rely on the conventional sensor systems; wherein, on one side the system is quite bulky (which hinders its integration within the grinding machine), and on the other side the detection resolution is limited due to the size of the conventional probes used.

Furthermore, since the past two decades there have been a constant quest to realize realistic intelligent grinding manufacturing processes, which has further gained momentum in terms of research and development, owing to the emergence of industry 4.0 and big data with the concept of smart interconnected

real-time condition monitored manufacturing processes [8–14]. However, among other challenges associated with the implementation of the intelligent grinding process, the availability of sophisticated approaches for the integrated process monitoring (i.e., the sensor systems), considering the difficulty to model process dynamics of grinding processes, is a fundamental requirement for the development of intelligent grinding. In order to fulfill this requirement, a sensor fusion system comprising of more than one sensing principle would enormously increase the detection capability, the sensitivity of the parameters of interest, and also the reliability of the test results. The authors in [15] reported a sensor fusion concept with integration of accelerometers and power-cell sensors for the detection of the roughness of the WP, however, the reported system is not capable of detecting GB. Therefore, in this paper, which is an extended version of a previous research [16], we report the detailed analysis of the sensor fusion concept with the integration of an optical sensor (OS) and a microfabricated eddy-current sensor (μEC) working complementary to each other for NDT of GB using a 42CrMo4 cylinder with varying degrees of reference GB. The proof-of-concept for the NDT of GB using the OS and μEC sensors has been already reported along with the individual development and characterization in [17–19], therefore, this paper deals with the experimental analysis of the complementary sensor functionality of combined OS and μEC sensors for NDT of GB.

2. Sensor fusion concept for non-destructive testing of grinding burn

The occurrence of the GB results in hard to model modifications on and within the GZ of the ground WP. Depending on the severity of the GB, it can get explicitly visible by discoloration (i.e., so-called severe oxidizing GB) on the surface of the GZ (as shown in the schematic in Figure 1 with orange coloration of the ground WP surface), or during the concluding spark-out period of grinding process, however, the discolored oxidized layer might be removed. In this case, the irreversible microstructural changes withing the GZ, which can propagate up to a few hundred micrometers within the GZ, still exist (depicted as hidden GB in Figure 1). Furthermore, the microstructural changes can result in either softening of the GZ or might result in a re-hardened layer (due to quenching effect) on top of the softened layer [4–6]. Therefore, the proposed sensor fusion system in this paper combines two sensor principles, namely the OS and μEC sensors (as shown in schematic in Figure 1) capable of detecting the surface morphological changes and the in-depth microstructural changes (as function of varying driving frequency which influences the depth of penetration of the induced eddy-currents within the WP), respectively. An interesting effect of the surface morphological changes on the GZ surface was shown in our previous paper [17], wherein it was found that the reference GB with varying degrees showed a direct correlation to the average surface roughness values (R_a) of the ground WP surface. The average surface roughness increased with increasing degree of GB. The proposed OS works on the principle of illuminating
Figure 1: Schematic showing the sensor fusion concept integrating the optical sensor and the microfabricated eddy-current sensor for the NDT of GB. The optical sensor detects the superficial surface modifications for e.g., the change in R_a as function of GB, and the microfabricated eddy-current sensors records the in-depth profile information within the GZ (i.e. by varying the driving frequency). Therefore, making it possible to even detect the so-called hidden and severe degree of GB resulting in significant microstructural changes in the GB.

the WP surface and recording the reflected light, which is transduced into sensor output voltage (detailed explanation of the sensor electronics can be found in [17]). The voltage drop (ΔV) increased with an increase in R_a, which in turn increased with the degree of GB [17].

Among several applications exploiting the use of eddy-currents such as contact-less breaks in this work, µEC sensors are used for the NDT of microstructural modification within the GZ (i.e., an in-depth profile information of GZ). The microfabrication steps are described in [16, 18]and the characterization of the µEC sensors for NDT of GB is shown in [18, 19]. The µEC sensors exploit the fact of the predominant change in the relative permeability (μ_r) within the GZ in case of WP out of hardened ferromagnetic steels, which are inevitably reliant on the grinding technology for many precision applications [3]. As shown in Figure 1, swirling eddy-currents are induced on and within the conductive WP, when it is in the vicinity of the µEC sensors, whose depth of penetration (δ) as shown in the Equation 1 depends on frequency (f) of the driving current, the conductivity (σ) and μ_r.

$$\delta = \frac{1}{\sqrt{\pi \sigma \mu_r f}} \tag{1}$$

Furthermore, in case of occurrence of GB, the microstructural changes within GZ affects the nature of the induced eddy-current in WP [20], which is then recorded either as the impedance change (ΔZ) in case of single µEC sensor (absolute sensor) or the voltage

change in case of sender-receiver µEC sensor combination. The main advantage of the use of µEC sensors is the possibility of varying δ of the induced eddy-current by varying f, wherein δ is inversely proportional to f. Therefore, by varying f of the µEC sensors, the depth profile within the GZ can be quantitively recorded and compared with the reference material profile. Thereby, making the µEC sensor suitable for the NDT of not only superficial GB, but also the so-called hidden GB within the GZ. Hence, with this proposed approach of sensor fusion concept, the NDT of GB can be enhanced for the quality testing of ground workpieces. Furthermore, the proposed fused sensor system can be integrated within the grinding machine to facilitate the in-process detection of GB and to increase the material removal efficiency.

3. Results and discussion

For the experimental characterization of the sensor fusion concept, reference GB with varying degrees were fabricated on 42CrMo4 steel cylinder as shown in Figure 2(a) (the grinding parameters and conditions are described in [16]). Each region named as S2-S8 in Figure 2(a) belongs to a different degree of GB, except region S3, which is considered as the reference ground region without GB as a calibration for the sensor measurements. Figure 2(b) shows the micrographs recorded using an optical microscope, wherein the discoloration i.e., the oxidative GB along with the undulation pattern corresponding to the abrasive grains in the grinding wheel can be seen. Furthermore, the surface morphology was further characterized using a white light
Figure 2: (a) 42CrMo4 cylindrical workpiece ground with reference grinding burn with varying degrees from S2, S4-S8, wherein region S3 is the reference ground region without GB (Region S1 is original unground state of the workpiece), (b) micrographs recorded using an optical microscope for each individual region S2-S8 showing the undulating pattern corresponding to the abrasive grains of the grinding wheel along with the dark discoloration corresponding to the oxidative grinding burn.

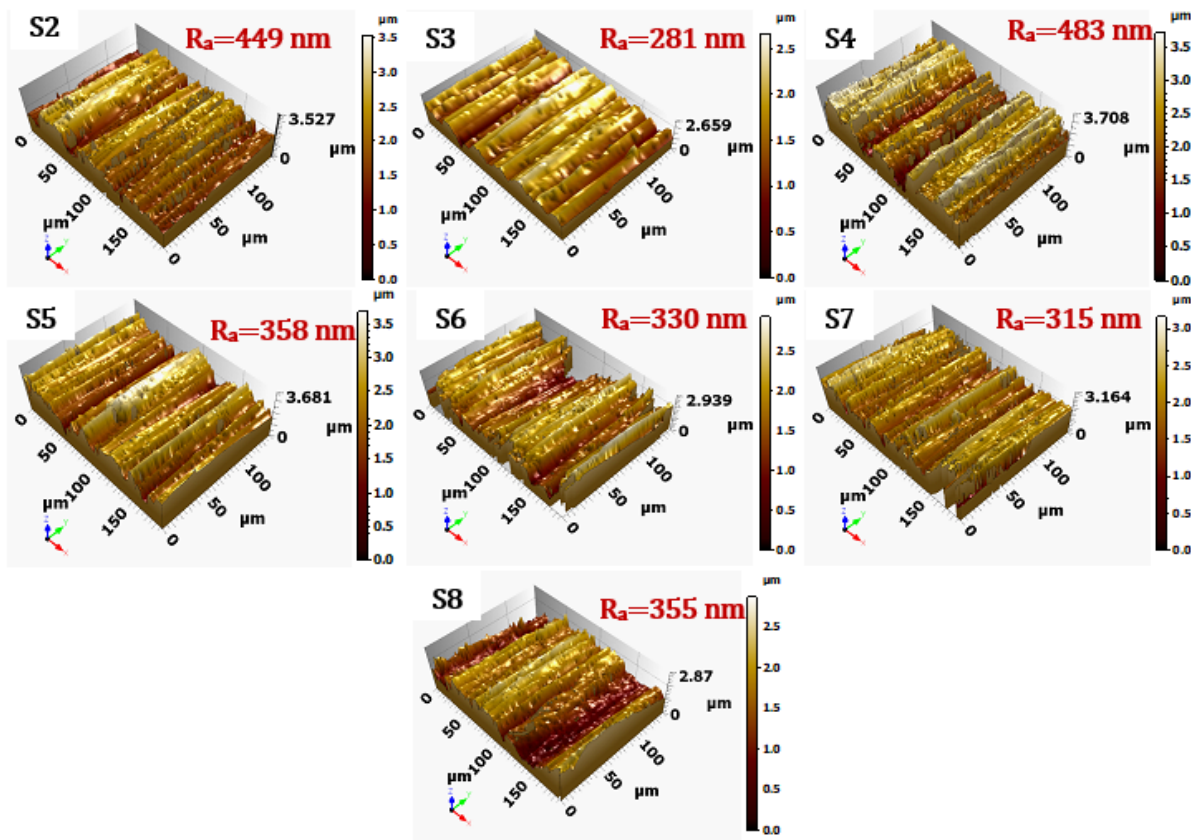

Figure 3: Surface morphology micrographs recorded using a white light interferometer (Zygo Newview) with 50x magnification resulting in a scan area of 188 µm x 140 µm. The average surface roughness values are shown in the top right corner of each micrograph.
Figure 4: Measured Vickers microhardness on regions S2-S8 on the reference workpiece 42CrMo4 with varying degrees of GB. Each measurement is mean of 5 indentations on each region.
interferometer (Zygo Newview) in order to quantitatively compute the average surface roughness (R_a) values. Figure 3 shows the recorded surface topology micrographs using 50x objective within a scan area of 188 µm x 140 µm for the regions S2-S8 along with the computed R_a values (mean of 10 measurements). The R_a values varied from 281 nm to 483 nm for the reference region S3 and the strongest GB region S4, respectively. This observation can be attributed to the surface morphological modifications occurring on the surface of GZ with the occurrence of GB, which appear not only in the form of discoloration i.e., oxidation GB, but also results in the modification of the surface topology.

Moreover, considering the microstructural modifications as a consequence of GB, which might either soften or re-harden the

Figure 5: Normalized optical sensor output voltage experimentally measured as a function of varying degrees of GB on regions S2-S8, with a sensor to workpiece distance of 700 µm under quasi-static conditions.

Figure 6: Normalized impedance of 20 turns circular spiral geometry µcoil experimentally measured as a function of varying degree of GB on regions S2, S4-S8, with a µcoil to workpiece distance of 700 µm under quasi-static measurements (the measurements from region S3 are considered as reference).

GZ, the microhardness of each region S2-S8 was measured using Vickers Microhardness device from Innovatest Falcon 501 device with a 20 g load. Furthermore, the indentation depth with the used 20 g load was 1 µm to 2 µm, for the measured microhardness range, and hence the measured microhardness values are more superficial in nature. Figure 4 shows the computed microhardness values (mean of 5 measurements) for the regions S2-S8. The microhardness increased from 333 HV0.02 for region S7 to 685 HV0.02 for region S4. This effect can be attributed to complex microstructural changes, which result in either softening, re-hardening and combination of re-hardened and softened profile within the GZ [6]. From Figure 4, it can be seen that ground region S7 shows the presence of softened layer with reduced microhardness compared to reference region S3, while all other regions showed a re-hardened layer with S8 and S4 showing an almost twofold increment in the microhardness compared to the reference region S3.

The experimental measurements using OS and the µEC sensor were done on a lathe machine to emulate the conditions within a grinding machine. The details of the experimental setup along with the information related to the optical sensor can be found in [17], and the microfabrication steps of µEC sensor with circular spiral geometry (20 turns µcoil used in this work) is reported in [18]. The distance between the sensors and WP was kept constant at 700 µm for all the measurements and the WP was rotated per hand for each new measurement; thereby, resulting in a quasi-static measurement. Figure 5 shows the normalized output voltage of the optical sensor as a function of varying degree of GB on the WP, by taking the voltage recorded from region S3 as reference value. The optical sensor takes into account the surface morphological changes, i.e., either the discoloration as a result of oxidation GB or the modified surface roughness profile on the GZ,

Figure 7: Theoretical computed depth of penetration of induced eddy-current within the 42CrMo4 workpiece at a µEC sensor to workpiece distance of 700 µm and considering the material properties as reported in [21].
both of which would adversely affect the intensity of the reflected light (i.e., in response to the incident light form the optical sensor), which is transduced into voltage by the OS. Therefore, the presence of the GB is detected as the function of voltage change ($\Delta V_{OS} = (V_{ref} - V_{wp})/V_{ref}$) with respect to the reference voltage (V_{ref}) from the reference region S3 and the voltage recorded from ground surface with GB (V_{wp}). As seen in Figure 5, the OS is capable for the NDT of GB, wherein the output voltage changes as a function of the different degree of GB on regions S2 and S4-S8. Furthermore, the recorded ΔV_{OS} values are directly proportional to the R_a values, i.e., the higher the surface roughness, the larger are the ΔV_{OS} values as shown in [17]. As seen in Figure 5, the ΔV_{OS} values dropped by ca. 20 % and 50 % for the regions S5-S8 and regions S2 and S4, respectively. Thereby, depending on the intensity of drop in ΔV_{OS} values, the GB can be roughly classified under moderate (i.e., for ΔV_{OS}=20 %) and strong (i.e., for ΔV_{OS}=50 %) degree of GB. Complementary to the OS measurements, the µEC measurements on the same WP were carried out under the similar working conditions as described above for OS measurements. However, in case of µEC sensors, the impedance response (Z_{wp}) of the µEC sensor as function of the different regions S2-S8 was recorded. Similar to the OS measurements, Z_{wp} for the region S3 was considered as the reference and the normalized impedance change ($\Delta Z = (Z_{ref} - Z_{wp})/Z_{ref}$) for the regions S2, S4-S8 as a function of f is computed and shown in Figure 6. Primary, the ability of the µEC sensors for the NDT of GB is observed for all the ground regions with varying degree of GB, and secondary, on contrary to the OS measurements, where only the surface morphological information was revealed, in case of the µEC sensors, an in-depth profile information is revealed as function of varying f as seen in Figure 6. A very interesting trend of variation in ΔZ as function of f is observed, wherein ΔZ initially increased on increasing f from 1 kHz to 1.2 MHz and decreased further with increase f; however, it increased again from 4 MHz to 10 MHz (the f limit of the used LCR meter was 10 MHz). This effect can be attributed to the
(a)
(b)

Figure 8: Comparison of sensor fusion concept using the OS and µEC sensors as function of the measured Vickers microhardness values (i.e. destructive approach) (a) normalized impedance of µEC sensor as function of measured Vickers microhardness for the reference GB regions on 42 CrMo4 for 4 MHz (δ = 11 µm) and 10 MHz (δ = 7.5 µm), and (b) normalized optical sensor voltage as function of measured Vickers microhardness values.

microstructural changes occurring within the GZ few hundred micrometers deep in case of the occurrence of GB. At this point it comes to the complementary sensing nature and measurement capability of µEC sensors compared to the OS, where it can quantitatively record the microstructural variation in ΔZ as seen in Figure 6. This effect is because of the variation in δ for the induced eddy-currents as function of f as shown in Equation 1. For e.g., Figure 7 shows the theoretical δ for the induced eddy-currents within the used WP (i.e., 42CrMo4, taking the material properties from [21]), wherein the induced eddy-current tends to be more superficial with increasing driving frequency, i.e., it decreased from 230 µm to ca. 7 µm on increasing the frequency from 0.01 MHz to 10 MHz. Therefore, from Figure 6 it is evident that the microstructural changes within the GZ consist of two zones, namely submerged (>15 µm within GZ) zone and superficial zone (i.e., near to the surface within <15 µm). Furthermore, the ΔZ values increased at higher f, showing that

GB caused severe microstructural changes in the superficial zone in case of ground regions S2, S4, S5 and S8. Additionally, the order of arrangement of the WP ground regions in Figure 6 is with respect to descending order in the ΔZ values (i.e., at higher f), is comparable with the measured microhardness as shown in Figure4. For e.g., the ground region S4 followed by the region S8 showed the maximum microhardness values and hence, a larger ΔZ variation was observed i.e., 8.7 % and 7.8 % at 10 MHz for S4 and S8, respectively, which is evident from Figure 6. Meanwhile, the region S7 showed minimum microhardness and hence, it also showed minimum variation in ΔZ values as seen in Figure 6. Another interesting observation can be noticed for region S6, wherein the ΔZ is larger in the submerged region as compared to the superficial region and an opposite trend is then recorded for region S7. Thereby, showing the complex in-depth nature of the occurrence of the GB. However, in respect to the very similar impedance dependence on frequency of regions S4 and S8, the OS provides a significant signal difference between these surfaces. Moreover, apart from the complementary information related to superficial and in-depth profile obtained using the combination of OS and μEC sensors, the comparison of both sensors merits for the superficial measurement as function of destructive approach i.e., the Vickers microhardness (Figure 4) is shown in Figure 8(a-b). Here, the measured microhardness HV is plotted on the x-axis considering HV as reference for microstructural changes by grinding related GB which is correlated to the μEC (Figure 8a) and OC (Figure 8b) measurements. For the used load of 20 gf an indentation depth of $1 \, \mu m - 2 \, \mu m$ is obtained for Vickers microhardness measurements. The normalized impedance ΔZ in Figure 8a is evaluated for 4 MHz ($\delta = 11 \, \mu m$) at a frequency where a pronounced minimum in the normalized impedance is found (Figure 6) and for 10 MHz ($\delta = 7.5 \, \mu m$) to reveal more the superficial information. It is found that ΔZ for $f = 10$ MHz initially increased as function of microhardness, however it decreased steeply within the microhardness range of 375 HV0.02 – 450 HV0.02, and subsequently increased as function of microhardness values. At 4 MHz, the minimum of ΔZ occurs at around 450 HV0.02 and the changes of ΔZ towards lower and higher microhardness values are less pronounced. The observed trend can be attributed to the complex microstructural changes occurring within the GZ. ΔV_{OS} showed a different dependence on microhardness and therefore, can provide complementary information about GB compared to μEC especially in the range of 400 HV0.02 - 450 HV0.02. At higher microhardness values, ΔV_{OS} showed a gradual decreasing trend as function of the microhardness values.

Therefore, the sensor fusion by integrating the OS and μEC sensors makes it possible the NDT of GB, by not only considering the surface morphological information on the GZ, but also by revealing the in-depth profile information up to few hundred micrometers within the GZ on occurrence of GB. The presented sensor fusion concept is preliminary approach towards the proof-of-concept for the complementary sensing nature for the NDT of GB. However, there is enough room for the further development and optimization to successfully integrate the developed sensor fusion unit in the grinding machine to realize and fulfill the quest towards the intelligent grinding process.

4. Conclusion

The sensor fusion concept integrating an optical sensor and a microfabricated eddy-current sensor is reported for the non-destructive testing of the grinding burn. The complementary sensing nature of the reported sensor combination results in not only the superficial non-destructive testing of grinding burn, but also an in-depth profile within the grinding zone. The optical sensor voltage dropped as function of varying degree of grinding burn, which was observed to be directly correlated to the average surface roughness of the grinding burn. The voltage dropped by 20 % for moderate degree of grinding burn, and by 50 % for strong degree of grinding burn. The in-depth quantitative profile of the microstructural changes within the grinding zone is recorded with the use of the microfabricated eddy-current sensors (circular spiral μcoils with 20 turns) as a function of the varying driving frequency. A very interesting nature of the grinding burn was observed as function of the impedance variation of the microcoils with two distinct zones, i.e., the sub-merged zone (>15 μm within grinding zone) and superficial zone (from WP surface to 15 μm within grinding zone). Impedance changes of ca. 8 % and 4 % were obtained for stronger degree of grinding burn (i.e., regions S4 and S8) for the superficial and sub-merged grinding burn at 10 MHz and 2.5 MHz, respectively. Utilizing the impedance information of the grinding zone as function of varying driving frequency, it could also be possible to build qualitatively the profile of the microstructural changes for quality testing, and hence ease the observation for the severity of the grinding burn. The reported sensor fusion concept can be further optimized to increase the detection sensitivity and robust packaging immune to the harsh environmental conditions occurring within the grinding machine to realize intelligent grinding processes and in-process monitoring capabilities corresponding to the requirements of industry 4.0. Furthermore, to model the surface morphology of grinding burn, an in-depth surface roughness analysis can be done (considering the parameters beyond root mean squared and average surface roughness values) to unveil the surface modifications at the atomistic level.

A B S T R A C T

This is a report describing the impact of calcination on the morphological and optical properties of nanoparticles Iron doped-nickel oxide. By synthetic precipitation, the technique makes use of it. Three samples have been calcined in different temperatures and were characterized by X-ray diffraction (XRD), Fourier transforms infrared spectroscopy (FTIR), UV spectroscopy, and scanning electron microscopy (SEM), energy dispersive X-Ray (EDX). The study showed that the increase in the temperature enhances the structural and optical properties of the samples, and makes the samples take a more crystalline structure. It is also shown that there has been an expansion of the volume of the samples, making the samples having a small bandgap. UV-Visible absorption spectra of Iron doped-nickel oxide nitrate shows a peak of absorption between 350 to 400 nm. The bandgap value is calculated to be 1.86 eV at a calcination temperature of 350°C. The required structural and optical properties of Iron doped-nickel oxide nanoparticles make it a promising material for optoelectronic applications.

1. Introduction

There have been extensive studies about nanomaterials from the very beginning of the invention of it, due to their unique physical properties and bulk counterpart. Many methods are used to synthesize Nano-scale materials [1]. Oxidized metals are commonly used in numerous areas, such as photoelectric, sensors, recording materials, and catalysts, etc [2]. These applications can be enhanced and well-controlled by fabricating them into nano-sized materials. Nano-materials properties are peculiar and fascinating therefore scientists have been studying them intensely for the past few years. Among various nanomaterials, metal oxide as NiO has attracted technological and industrial interest for its optical-electronic, magnetic, thermal, and mechanical properties this metal is a good P-type semiconductor because of its wide bandgap [3]. Also, the high activity in the degradation of phenol and phenolic derivatives. There are several ways to synthesize it, such as sol-gel [4-7] co-precipitation [8] hydrothermal [9] solvothermal [10], and chemical precipitation [11, 12]. In this study, we prepared iron-doped NiO NPs using the chemical precipitation method. Previous studies showed the advantages of it, such as the simplicity and condition of the process, condition, crystal structure, and particle size can be more controllable. NiO is a transition metal oxide with a density of 6.67gm/cm3 and a melting point reaching 1955°C along with a self-ignition temperature of 400°C [13], nanoscale NiO particles are between 10 -30 nanometers and the surface area of NiO is about 130-150.

The XRD pattern of NiO NPs exhibits a face-centered cubic (FCC) crystalline structure [10]. The UV-IR spectrum of biosynthesized NiO Nanoparticles showed optical properties well-defined at 321 nm and its exhibited optical band gap is (3.83-3.18eV) [13- 16]. Furthermore, in previous studies, nanoparticles of NiO with different concentrations and calcination temperatures of Iron have been investigated, and it's found that the properties of NiO NPs enhance with the addition of Fe and give excellent optical, structural, and magnetic properties. Therefore, this material can be a promising material when used in different applications such as optoelectronics, sensors, and batteries due its desired structural, optical, and magnetic properties. [8, 17, 18, 19, 20, 21, 22].

2. Experimental

2.1. Materials

The materials used in this research are: Nickel Nitride Ni $(NO_3)_2$, Iron nitride (Fe_2N), Citric Acid ($C_6H_8O_7$), and Ammonia hydrate (H_6NO).Deionized water was used in all the experimental procedures.

2.2. Preparation of Iron doped NiO nanoparticles

In this research, NPs of Iron doped NiO samples have been prepared by dissolving 13.81 g of Nickel Nitrate Ni $(NO_3)_2$ and 1.01 g Iron nitrate Fe $(NO_3)_3$ into an aqueous solution of 50 ml distilled water under medium stirring speed and temperature of 50

1422

C°. After 15 min, 1g of citric acid was added to the solution and kept stirring for another 15 minutes. Hereafter, Ammonium Hydrate (Liquid Ammonia) was added drop by drop, and precipitate started to appear until the mixture turned into a thick gel. Eventually, the temperature was raised to obtain a completely dry sample, which resulted in 5% Fe doped NiO nanoparticles. The dried samples were ground into a powder. In the end, the samples were placed in a muffle furnace at different temperatures ranging at (300,350,420) °C for 2 hours.

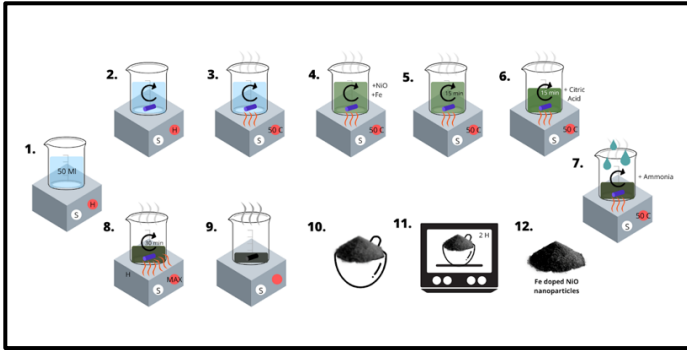

Figure 1: Iron-NiO Nanoparticles preparation method

2.3. Measurements of microstructure and performance

This work aims to study the impact of calcination temperatures at 300, 350, and 420 °C on the structural and optical properties of Iron doped NiO samples. The structural properties of purity and crystalline Fe doped NiO were characterized by XRD measurements using Philips diffractometer with an accelerating voltage of (λ=1.54°A) with CuKα radiation. The morphological studies done by using a scanning electron microscope (SEM) have been carried out. equipped with EDAX to record the composition analysis (JEOL Model with an accelerating voltage of 30kV). The optical properties of the samples were calculated with the SHIMADZU double beam UV-visible spectrophotometer. Finally, Thermal analysis was carried out by Perkin-Elmer Fourier transform-infrared spectroscopy (FTIR) over the range of 590-4000cm^{-1}.

3. Result

3.1. XRD Analysis

The structures of Iron-doped NiO nanoparticles calcined at 300, 350, 420 °C were analyzed using XRD and are represented in Fig.2. peaks of diffraction have been found near to 37.3°, 43.1°, 62.90°, 75.2°, and 79.3° in nanoparticles. However, both rhombohedral and cubic structural nanoparticles have been reported in reference [10, 17, 23]. Well-defined diffraction peaks for (111), (200), (311), and (222) cubic Iron-doped NiO NPs [10,17,22] were observed, which correspond to the standard spectrum (JCPDS, No.73-1519). At higher calcification temperatures, formed crystals get larger, which can be ascribed to thermally improved growth of crystals. The sizes of Iron doped NiO nanoparticles obtained from the diffraction ridges using the Scherrer equation are 5.6 nm and 9.6 nm and 11.6 nm for the sample calcined at 300°C, 350°C, and 420°C respectively, the sizes of nanoparticles increase with an increase in calcification temperatures and, the crystalline volume increases as the calcification temperature increases. W-H analysis was performed

to calculate the volume and fine diffraction contributions for the XRD line expansion. The very small diffraction values of all samples result in a close agreement between the estimated crystalline sizes from Scherrer's equation and the W-H analysis. The occurrence of vacancies and defects in composition Iron doped NiO nanoparticles can lead to subtle diffraction that leads to the widening of XRD peaks. From the Debye-Scherer equation, the average diameter of spherical particles can be easily calculated from

$$D = \frac{k\,\lambda}{\beta\,coscos\,\theta} \qquad (1)$$

where D represents the crystallite size, and K= 0.89 is the Scherrer constant and its associated with spherical particles and index (hkl) of the crystals. λ=1.54°A wavelength of source, β means the full width at half maximum (FWHM) of the peaks in radians. The average crystalline size increases from 4.83 nm to 14.5 nm as the calcination temperature increases and that is near previous studies [22,24].
Figure 2: XRD structures of Iron doped NiO NPs samples at different calcination Temperatures

3.2. SEM Analysis and EDX

The particle size, shape, and morphology are identified using SEM micrographs. SEM images of the obtained Iron doped NiO NPs for the samples are shown in Fig.3. The SEM images show the morphology of the Iron doped NiO nanoparticles. It is observed that the shape of the particles is nearly spherical and Oval with non-homogeneous distribution, and they are in the range of 10 nm to 30 nm and that is close to the previous studies [15, 16, 24,4]. Particle size came out to be 4.6, 8.3, and 12.2 nm which means that particle size increases with the increase of the temperature. The particle size calculated from the SEM analysis seems to be quite similar to that measured from the XRD analysis of crystallite size. The EDX spectrum of Iron doped NiO nanoparticles is shown in Fig4. revealed the presence of Nickel, Oxygen, Carbon, and Iron is the only elementary species in samples.

3.3. FTIR Analysis

Figure 5 shows the FTIR spectra of Iron doped NiO particles samples calcined at 300, 350, and 420 °C. To determine the chemical structure of the samples the spectra were observed over

the frequency range of 590-4000 cm^{-1}. The broad absorption band centered at 3450 cm^{-1} is assigned to O–H stretching vibrations and the band at 1630 cm^{-1} is attributable to H–O–H bending vibration of water absorbed from the atmosphere when samples were prepared in the open air. Also, the absorption band in the region of 462–560 cm^{-1} is assigned to Fe–O stretching vibration mode and the second broad absorption band in the region 410 – 474 cm^{-1} is assigned to Ni–O stretching vibration mode. The broadness of the absorption band indicates that the NiO powders are nanocrystals and well crystallized. The intensity of Ni – O and F – O stretching bands seen in Fig.5 are increasing as the calcination.
Figure 3: SEM images of Iron doped NiO NPs Calcined at (a)300, (b) 350, and (c) 420 °C.

3.4. UV-Visible studies

Figure 6 shows spectra for UV-visible absorption and $(\alpha h\nu)^2$ versus energy plot for Iron doped NiO nanoparticles samples. UV studies of absorption showed that a rise in calcination temperature results in a redshift in the absorption spectrum and a decrease in bandgap as a result of an increase in particle size. The peaks range in the ultraviolet spectrum showed between (300-400 nm) and that is close to the previous studies [10, 15]. In general, the data show that the sample calcined at 300°C has a value of 307 nm, and the value of 347 nm for the sample calcined at 350°C, lastly the value

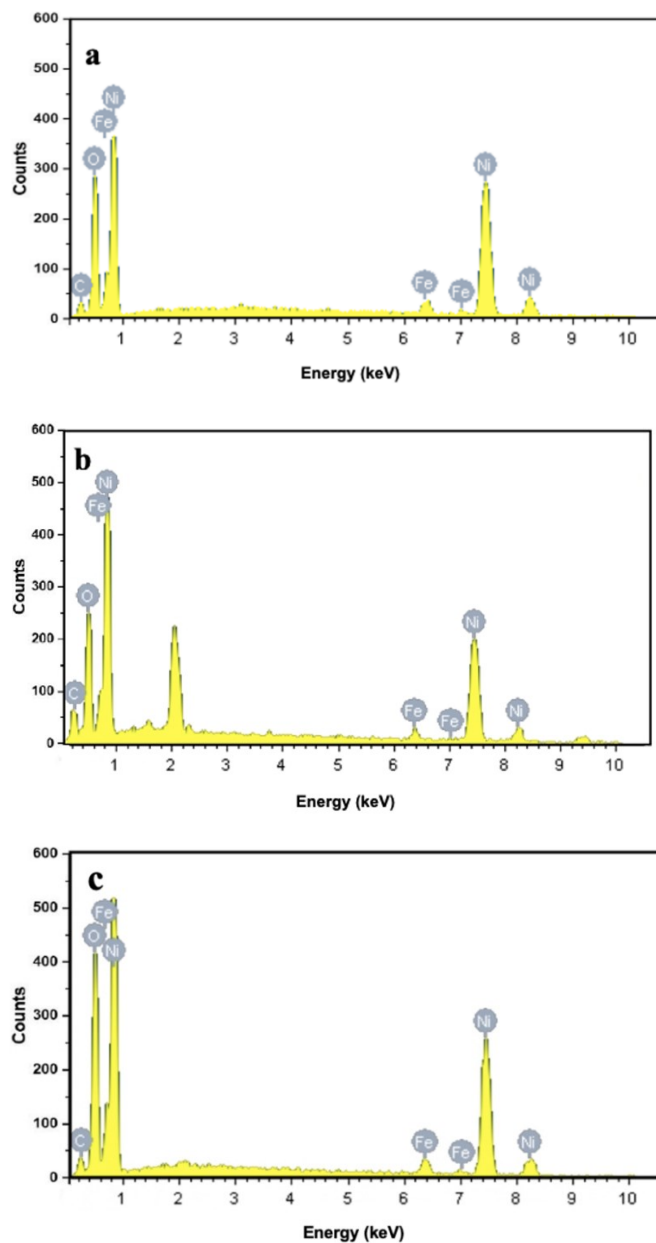
436 nm for the sample calcined at 420°C, the peaks mean the matter absorption of the spectrum and also work to stimulate the electrons. The best result of the Three samples is the sample calcined at 350°C with a bandgap value of 1.86 eV and high absorption value which makes the bandgap a small value. At calcination temperatures, the properties of the material are enhanced.


Figure 4: EDX spectra of Iron doped NiO NPs calcined at (a)300°C (b) 350°C, and (c) 420°C.

4. Conclusions

Nanostructured Iron doped NiO particles were prepared successfully utilizing nickel nitrate hexahydrate and ammonium carbonate via the chemical precipitation method. The results obtained from XRD is that the crystalline structure of nanoparticles has been improved due to the addition of Fe and calcined samples at different temperatures to be FCC, this

observation is consistent with the previous studies. Furthermore, UV-visible absorption results have shown that a rise in the temperature of calcination causes a redshift in the absorption spectrum and a decrease in the bandgap due to an increase in the size of the particles. We can say calcination samples at high temperatures with a constant concentration of Fe are the main parameters of the appearance of a redshift in our results. Also, the particle size decreases with an increase in the dopant concentration of Fe. Based on these systematic observations, it is concluded that calcined NiO doped with 5% Fe nanoparticles may have been an outstanding option for optoelectronic applications because of its desired structural and optical properties.

A B S T R A C T

In this paper, a new polynomial shear deformation theory for the static flexural analysis of anisotropic rectangular thick plate was developed. The plate which carries a uniformly distributed load is clamped on the three edges, and free of support on the other edge (CCFC), is analyzed to determine the in-plane displacement, vertical displacement, bending moment, and shear force, bending and transverse shear stress. The General variation approach was used to obtain the general governing equation and its associated boundary conditions, thereafter the coefficient of deflection and shear deformation along the direction of x and y coordinate was determined by minimizing the energy equation obtained using the new established theory. The study revealed that: (i) as the displacement and stress decrease, the plate's span-thickness ratio increases (ii) as the length to breadth ratio of the plate increases, the value of displacement and stresses increase. To validate the theory, the numerical results are obtained and compared with an available solution in the literature. The result showed good agreement with those in the literature.

1. Introduction

Plates, generally well-known structural element have been extensively used in different fields like engineering, and other industries due to their high strength, lightweight, load resistance characteristic and their cost benefits, as recorded in [1]. Plates are widely used in structural engineering, aerospace engineering, mechanical engineering, etc., for the construction of buildings, retaining walls, ships, bridges, railways, etc., [2 - 3].

Plates have been classified based on thickness as: thick, moderately thick, and thin plates [4], based on material composition as: isotropic and anisotropic plates, based on shape as: circular, rectangular, triangular, elliptical, and skew plates, [5]. The edges of plates can be of different kinds of supports such as: simply supported support, point and fixed supports, etc. as seen in [6].

The analysis or solutions of plates help to determine the stability of plates, and it entails the determination of

displacements, stresses, moments, etc., at a different portion of the plate, [7]. Also, the analysis of plates can be due to bending, buckling, and vibration caused forces. It is generally known that the bending of plates relates to the deflection of the plate at a right angle (90°) to the plate plane due to the influence of forces and moments [8].

It is the depth of plates that mainly affects their bending characteristics compared to other surface dimensions like: length and breadth [9].

There have been different theorems: the classical plate theory (CPT) and refined plate theory (RPT) developed and applied in the analysis of the different categories of plates by many researchers. The classical plate theory (CPT), which was developed by [10 - 11], is based on the assumption that the line which is normal to the mid-surface remains so, before and after deformation. The classical plate theory (CPT) is mainly used in the analysis of thin plates and has also been used by [12 - 14] in the analysis of solutions involving plates and shells, respectively. But it has been found to be inadequate by [15] for the analysis of thick plates as its neglects the effect of shear deformation – a gap that led to the development of refined plate theory by researchers.

The Refined Plate Theory (RPT) is used for the analysis of thick plates [16], and it addresses the gap in classical plate theory (CPT).

The RPT comprises First-Order Shear Deformation Theory (FSDT – which has a correction factor as a limitation, and Higher-Order Shear Deformation Theories (HSDT), etc., taking into account the effect of shear deformation and has been applied by different researchers in analyzing thick plates. Authors in [17 - 18] revealed that the limitations in CPT and FSDTs led to the formulation of higher-order shear deformation theory (HSDT). There have been various studies on the bending analysis of thick rectangular plates with different boundary conditions using refined plated theory with different methods and techniques.

This present paper is aimed at bridging the gap in the literature by applying the polynomial shear deformation theory in obtaining the displacements, bending moment, and stresses of the thick rectangular plate. This theory, which is based on a traditional fourth-order shear deformation plate, is presented and applied in a bending analysis of thick rectangular plates using the Energy-variational approach. The investigation has conducted on the plate that has three edges clamped and the other opposite edge free of support (CCFC). Furthermore, derivation of general governing equations for the plate and numerical solutions for deformation, moment, and stress distributions of different points of the plate with a uniformly distributed transverse load is presented.

The physical interpretation of CCFC plate is that, the three clamped edges are supported by a beam and continuous over the span of the plate while the remaining one is free of support i.e. hang without support (Eg. Cantilever). This makes the study very significant because such BC exist depending on the type of beam/column support in the plate structure i.e. it contains different support case of the plate structure than other BCs. So, whenever such case (CCFC) as explained occurs in the structure, analyzing the plate as if is any other BC like SSSS, CCCC etc.(22, 27, 28 and 29) will not account for all the forces (stresses) acting on it. This is because, forces are generated due to the applied load on the structure thereby will introduce significant errors in the analysis and not predict an accurate or reliable result for the design if they are not considered. Thus, for a safe structural design of plate (slab) in a building or any type of structure with CCFC BCs, plate analysis with CCFC BCs like this is required.

The aim of this study is to determine the bending analysis of an isotropic rectangular plate for the effects of aspect ratio and displacement on the moment, shear force, stresses, and stress resultant of a thick rectangular plate. The study sought to achieve the aim through the following objectives:

- To generate the potential energy of a thick plate in line with the work of authors in [5].

- To formulate the general governing equations of the plate and obtain equations for the coefficients of deflection and shear deformation slope for x and y coordinates.

- To determine the expressions for the in-plane and out of plane displacement, bending moment, shear force and stresses of the thick rectangular plate.

2. Previous Works

The authors in [19] used Fourier trigonometric series to analyze the bending of rectangular plates on elastic foundations. They developed the deflection equation, which was in the form of trigonometric series using the Navier solution to the plate. The constraint of the trigonometric series is that it is tedious and rigorous for the formulation of shape functions for the analysis of rectangular plates. The authors in [20] stated that the constraint of the trigonometric series is that it is very strenuous for the formulation of shape functions relating to plates with unsymmetrical boundary conditions.

The authors in [21] used Mindlin's plate higher-order shear deformation theory to generate governing equations for the bending analysis of thick rectangular plates with clamped supports at all its edges (CCCC). Their developed theory involved the decoupling method and improvement on Navier's solutions with partial differential equations, which reduced the complexity involved in obtaining coefficients of plates. In as much as their results showed great accuracy when compared with past results of other studies, their study did not address plate with the CCFC edge condition and didn't make use of the direct variation energy method, which is less rigorous.

In [16], the authors used polynomial shape function for the analysis of rectangular isotropic thick plates. They used the direct variation energy method to obtain displacement coefficients without the need for correction factor for plates with CCCS and SSFS edge conditions, respectively. Their results (displacements and stresses), which they found to be adequate after comparing with results from previous works but did not include the CCFC plate's edge condition as it was not included in their study.

In [17], the authors used exponential function in shear deformation to determine the bending solution of the thick isotropic square and rectangular plates with simply supported supports. They applied the refined shear deformation theory and exponential functions in the form of thickness coordinate to obtain transverse shear deformation and rotary inertia without the need for a correction factor. They found their results: displacements, stresses, and frequencies to be satisfactory after comparing with other refined and exact theories. They only considered the boundary condition (SSSS) using the exponential function and not the polynomial displacement function in an energy method, which is less cumbersome.

The authors in [22] worked on the bending solutions of a thick rectangular plate with CCCC edge conditions. They used refined plate theory (RPT) - polynomial shear deformation theory (PSDT) with the Ritz energy method in their analysis without considering correction factor, and they obtained the coefficients for displacement by putting the total static energy equations to direct variation. They found out that their results (displacements and stresses) were accurate after comparing with results from other previous studies. The authors in [23] used the same boundary condition to study the bending behavior of the elastic rectangular thick plate using the Bergan-Wang approach. They found out that their approach can be used to determine the deflection of plates and analysis of thin, moderately thin, and thick plates, respectively. The authors in [22] used an assumed shape

function, which is not a close-form solution, while the authors in [23] didn't use the Energy method, which is more simplified. Both authors did not consider the plate with the CCFC edge condition in their analysis.

In [24], the authors did a study on bending solutions of the thick plate using a numerical method - based on the 3-D theory of elasticity. They used the method: spline collocation in two coordinate directions for their analysis. They concluded their approach to be useful in determining the distribution of displacements and stresses in thick rectangular plates, with hinged or clamped edge conditions. Their study did not cover the plate with the CCFC edge condition, and also they made use of a numerical method which, unlike the analytical approach, cannot determine the value of deflection at any given point in the plate.

The author in [25] used HSDT with stretching effect to determine bending characteristics of exponentially graded material plates. In his study, he made the assumption that the modulus of elasticity varies exponentially through the plate thickness direction. He found that his theory satisfied the shear stress-free condition at the top and bottom surface of the plates without considering the correction factor. He found out from his study that his theory was satisfactory after compared with previous studies and then concluded that the theory is suitable for predicting bending behavior of exponentially graded material plates. It can be seen from his study that he used shear strain shape function – a new higher-order shear deformation theory and not a polynomial displacement function in the energy method.

The authors in [26] have used PSDT for the analysis of rectangular plates. They obtained the expression for the critical lateral load that induces deflection and shear as a solution to the bending problem of rectangular plates with all four edges clamped (CCCC) and plate with free of support at the third edge and the other edges clamped (CCFC) using third-order shear deformation theory for thick rectangular plate respectively. They did not analyze the effect of displacement, moment, and stresses in predicting responses of the applied load on the plate structure.

Apart from the distinctiveness of the present study with respective individual previous works, there exists an aspect of the distinctiveness of the present study over the previous works put together. This lies in the type of shape functions, and plates support boundary conditions. Unlike the previous works that assumed the displacement function, the present work obtains the exact formulation of the total potential energy from a principle of static elastic theory to get a close form solution of the polynomial displacement function. Except for the author in [26], none of the researchers could determine the analytical solution of bending moment and stresses used in predicting the bending behavior of an elastic thick rectangular CCFC plate. These aspects cannot be overlooked.

3. Methodology

3.1. Assumptions

Considering the following assumptions, the total potential energy of a thick rectangular plate will be formulated. They include:

- ➢ The material of the plate is elastic and homogeneous in nature.
- ➢ The vertical line that is initially normal to the middle surface of the plate before bending is neither straight nor normal to the middle surface after bending.
- ➢ The effect of the strain and stress normal to the x-y plane on the gross response of the plate is small and can be neglected. Thus, the in-plane displacements, u and v, are differentiable in x, y, and z coordinates, while the deflection, w, is only differentiable in x and y coordinates.

3.2. Displacement, Strain and Stress Relationships

Figure 1 shown the two in-plane displacements: in-plane displacement in the direction of x coordinates (u) and in-plane displacement in the direction of y coordinates (v) are represented in Equations (1) and (2) (see the author in [1]):
Figure 1: Deformation of a section of a thick Plate

$$u = \frac{zd \cup}{dx} + S(z).\cap_x \qquad (1)$$

$$v = \frac{zd \cup}{dy} + S(z).\cap_y \qquad (2)$$

The shear deformation profile of plate section $S(z)$ is given (see the author in [5]) as:

$$S(z) = \frac{5z}{3}\left(z^3 - \frac{2z}{t^3}\right) \qquad (3)$$

where;

$\cap_x$ and $\cap_y$ is the shear deformation slope in x and y axis respectively.

It is assume from this work that the out-of-plane displacement ($\cup$) is only differentiable in x and y coordinates.ie. ($\cup = \cup(x, y)$).

The normal stress along x-axes (ε_x) becomes:

$$\varepsilon_x = \frac{du}{dx} \qquad (4)$$

The normal stress along y-axes (ε_y) gives:

$$\varepsilon_y = \frac{du}{dy} \qquad (5)$$

The shear strain along (x-y), (x-z) and (y-z) respectively are given in the Equation (6), (7) and (8) respectively as:

$$\gamma_{xy} = \frac{du}{dy} + \frac{dv}{dx} \qquad (6)$$

$$\gamma_{xz} = \frac{du}{dz} + \frac{d \cup}{dx} \qquad (7)$$

$$\gamma_{yz} = \frac{dv}{dz} + \frac{d \cup}{dx} \qquad (8)$$

Similarly, the stress normal to x-axes is defined as:

$$\sigma_x = \frac{E(\varepsilon_x + \mu\varepsilon_y)}{1 - \mu^2} \tag{9}$$

the stress normal to y-axes is defined as:

$$\sigma_y = \frac{E(\varepsilon_y + \mu\varepsilon_x)}{1 - \mu^2} \tag{10}$$

Considering the relationship between the strain and stress in the plate, the shear strain in x-y plane is given as:

$$\tau_{xy} = \frac{E}{2(1+\mu)} \cdot \frac{du}{dy} + \frac{dv}{dx} \tag{11}$$

the shear strain in y-z plane is given as:

$$\tau_{xz} = \frac{E}{2(1+\mu)} \cdot \frac{du}{dz} + \frac{d\cup}{dx} \tag{12}$$

the shear strain in y-z plane is given as:

$$\tau_{yz} = \frac{E}{2(1+\mu)} \cdot \frac{dv}{dz} + \frac{d\cup}{dx} \tag{13}$$

Substituting Equation (1), (2), (4) and (5) into Equation (9), we have:

$$\sigma_x = \frac{E}{1-\mu^2}\left[\left(-\frac{zd^2\cup}{dx^2} + \frac{S(z)d\cap_x}{dx}\right) - \mu\left(\frac{zd^2\cup}{dy^2} + \frac{S(z)d\cap_y}{dy}\right)\right] \tag{14}$$

Substituting Equation (1), (2), (4) and (5) into Equation (10), we have:

$$\sigma_y = \frac{E}{1-\mu^2}\left[\left(-\frac{zd^2\cup}{dy^2} + \frac{S(z)d\cap_x}{dx}\right) - \mu\left(\frac{zd^2\cup}{dx^2} + \frac{S(z)d\cap_y}{dy}\right)\right] \tag{15}$$

Substituting Equation (1), (2) and (6) into Equation (11), we have:

$$\tau_{xy} = \frac{E(1-\mu)}{(1-\mu^2)}\left[-\frac{z\partial^2\cup}{\partial x\partial y} + S(z)\left(\frac{d\cap_x}{dy} + \frac{d\cap_y}{dx}\right)\right] \tag{16}$$

Substituting Equation (1), (2) and (7) into Equation (12), we have:

$$\tau_{xz} = \frac{E(1-\mu)}{(1-\mu^2)}\left[\frac{z\partial^2\cup}{\partial x\partial z} + S(z)\left(\frac{d\cap_x}{dz} + \frac{d\cap_z}{dx}\right)\right] \tag{17}$$

Substituting Equation (1), (2) and (8) into Equation (13), we have:

$$\tau_{yz} = \frac{E(1-\mu)}{(1-\mu^2)}\left[\frac{z\partial^2\cup}{\partial y\partial z} + S(z)\left(\frac{d\cap_y}{dz} + \frac{d\cap_z}{dy}\right)\right] \tag{18}$$

where:
the symbol $\cup$ denotes out-of-plane displacement
the symbol $F(z)$ denotes Shear deformation profile
the symbol $\cap_x$ denotes shear deformation rotation along x axis
the symbol $\cap_y$ denotes shear deformation rotation along y axis
the symbol μ denotes poison ratio
the symbol E denotes modulus of elasticity of the plate
the symbol σ_x denotes stress normal to x axis
the symbol σ_y denotes stress normal to y axis
the symbol τ_{xy} denotes shear stress along x-y axis
the symbol τ_{xz} denotes shear stress along x-z axis
the symbol τ_{yz} denotes shear stress along y-z axis
the symbol ε_x denotes normal strain along x axis
the symbol ε_y denotes normal strain along y axis
the symbol γ_{xy} denotes shear strain along x-y axis
the symbol γ_{xz} denotes shear strain along x-z axis

the symbol γ_{yz} denotes shear strain along y-z axis

3.3. Total Potential Energy Equation

The total potential energy expression ($\not{\exists}$), was formulated in accordance to the kinematics and constitutive relation in the previous section (see [27]).

$$\not{\exists} = \Delta + \nabla \tag{19}$$

Where;

$$\nabla = -\int_0^a \int_0^b w \cup (x,y)\partial x\partial y \tag{20}$$

Where w is the uniformly distributed load.

$$\Delta = \frac{1}{2}\iiint_{-\frac{t}{2}}^{\frac{t}{2}} (\sigma_x\varepsilon_x + \sigma_y\varepsilon_y + \tau_{xy}\gamma_{xy} + \tau_{xz}\gamma_{xz} + \tau_{yz}\gamma_{yz})dxdydz \tag{21}$$

Thus:

$$\begin{aligned}
\not{\exists} = D\int_0^a \int_0^b \Bigg[&\left|\frac{g_1}{2}\left(\frac{\partial^2\cup}{\partial x^2}\right)^2 - g_2\left(\frac{\partial^2\cup}{\partial x^2}\cdot\frac{\partial\cap_x}{\partial x}\right) + \frac{g_3}{2}\left(\frac{\partial\cap_x}{\partial x}\right)^2\right| \\
&+ \left|g_1\left(\frac{\partial^2\cup}{\partial x\partial y}\right)^2 - g_2\left(\frac{\partial^2\cup}{\partial x\partial y}\cdot\frac{\partial\cap_x}{\partial y}\right)\right. \\
&\left. - g_2\left(\frac{\partial^2 w}{\partial x\partial y}\cdot\frac{\partial\cap_y}{\partial x}\right)\right| \\
&+ \left|(1+\mu)\frac{g_3}{2}\left(\frac{\partial\cap_x}{\partial y}\right)\left(\frac{\partial\cap_y}{\partial x}\right)\right| \\
&+ \frac{(1-\mu)}{4}\left|g_3\left(\frac{\partial\cap_x}{\partial y}\right)^2 + g_3\left(\frac{\partial\cap_y}{\partial x}\right)^2\right| \\
&+ \left|\frac{g_1}{2}\left(\frac{\partial^2\cup}{\partial y^2}\right)^2 - g_2\left(\frac{\partial^2\cup}{\partial y^2}\cdot\frac{\partial\cap_y}{\partial y}\right)\right. \\
&\left. + \frac{g_3}{2}\left(\frac{\partial\cap_y}{\partial y}\right)^2\right| \\
&+ \left|\frac{(1-\mu)}{4}g_4(\cap_x)^2\right. \\
&\left. + \frac{(1-\mu)}{4}g_4(\cap_y)^2\right|\Bigg]\partial x\partial y \\
&- \int_0^a \int_0^b \frac{w}{2}\cup(x,y)\partial x\partial y \tag{22}
\end{aligned}$$

The non-dimensional values of quantities along the x and y-axis respectively is presented below.

$$z = ts; \quad x = a\ni \text{ and } y = b\in \tag{23}$$

where;

a, b and t are the length, breath and thickness of the plate while $\ni$, $\in$ and s are the non-dimensional value of length, breath and thickness of the plate.

Let the length to breadth aspect ratio, $\alpha = \frac{b}{a}$ (24)

Span to thickness ratio, $\beta = \frac{a}{t}$ (25)

Deflection ($\cup$), is the product of shape function of the plate and deflection coefficient:

$$\cup = \complement.n \tag{26}$$

Similarly;

The shear deformation rotation along x-axis becomes:

$$\cap_x = \left[\frac{dn}{d \ni}\right][C_x] \tag{27}$$

Similarly, the shear deformation rotation along y-axis becomes:

$$\cap_y = \left[\frac{dn}{d \in}\right][C_y] \tag{28}$$

where,

n is the shape function of the plate

C is the coefficient of deflection

C_x is the coefficient of shear deformation along x axis

C_y is the coefficient of shear deformation along y axis

By substituting Equation 23, 24, 25, 26, 27 and 28 into 22, gives:

$$
\begin{aligned}
\daleth = \frac{D}{2a^4} \int_0^1 \int_0^1 & \Bigg[\Bigg| g_1 C^2 \left(\frac{\partial^2 n}{\partial \ni^2}\right)^2 - 2g_2 CC_x \left(\frac{\partial^2 n}{\partial \ni^2}\right)^2 \\
& + g_3 C_x^2 \left(\frac{\partial^2 n}{\partial \ni^2}\right)^2 \Bigg| \\
& + \Bigg| 2g_1 \frac{C^2}{\propto^2}\left(\frac{\partial^2 n}{\partial \ni \, \partial \in}\right)^2 \\
& - 2g_2 \frac{CC_x}{\propto^2}\left(\frac{\partial^2 n}{\partial \ni \, \partial \in}\right)^2 \\
& - 2g_2 \frac{CC_y}{\propto^2}\left(\frac{\partial^2 n}{\partial \ni \, \partial \in}\right)^2 \Bigg| \\
& + \Bigg| (1+\mu)g_3 \frac{C_x C_y}{\propto^2}\left(\frac{\partial^2 h}{\partial \ni \, \partial \in}\right)^2 \Bigg| \\
& + \frac{(1-\mu)}{2}\Bigg| g_3 \frac{C_x^2}{\propto^2}\left(\frac{\partial^2 n}{\partial \ni \, \partial \in}\right)^2 \\
& + g_3 \frac{C_y^2}{\propto^2}\left(\frac{\partial^2 n}{\partial \ni \, \partial \in}\right)^2 \Bigg| \\
& + \Bigg| g_1 \frac{C^2}{\propto^4}\left(\frac{\partial^2 n}{\partial \in^2}\right)^2 - 2g_2 \frac{CC_y}{\propto^4}\left(\frac{\partial^2 h}{\partial \in^2}\right)^2 \\
& + g_3 \frac{C_y^2}{\propto^4}\left(\frac{\partial^2 h}{\partial \in^2}\right)^2 \Bigg| \\
& + \Bigg| \frac{(1-\mu)}{2}\beta^2 g_4 C_x^2 \left(\frac{\partial n}{\partial \ni}\right)^2 \\
& + \frac{(1-\mu)}{2}\cdot\frac{\beta^2 g_4 C_y^2}{\propto^2}\left(\frac{\partial n}{\partial \in}\right)^2 \Bigg| \Bigg] ab\partial R\partial Q \\
& - \int_0^1 \int_0^1 wCn \, ab\partial \ni \, \partial \in
\end{aligned}
\tag{29}
$$

Given that D is the rigidity; let:

$$D = \frac{Et^3}{12(1-\mu^2)} \tag{30}$$

3.4. Governing Energy Equation

The elastic plate presented plate in figures 1 and 2 under bending subjected to uniformly distributed load was used to obtain the displacement – strain relationships in terms of curvatures.

3.4.1. General Governing Equation

The total potential energy shall be minimized with respect to the deflection w, shear deformation along the x axis, $\cap_x$ and shear deformation along y axis$\cap_y$. Minimizing or differentiating total potential energy equation with respect to $\cup$, $\cap_x$, and $\cap_y$ is said to be the direct variation.

$$\frac{\partial \Pi}{\partial \cup} = \frac{\partial \Pi}{\partial \cap_x} = \frac{\partial \Pi}{\partial \cap_y} = 0 \tag{31}$$

By solving the resulting three simultaneous governing equation the actual deflection $\cup$, shear deformation along the x axis, $\cap_x$ and shear deformation along the y axis, $\cap_y$ was gotten as:

$$
\begin{aligned}
\cup = & \left(a_0 + a_1 \ni + \frac{a_2 \ni^2}{2} + \frac{a_3 \ni^3}{6} + \frac{wa^4}{D}\left(\frac{n_1}{\cup_3}\right)\cdot\frac{\ni^4}{24}\right) \\
& \times \Bigg(b_0 + b_1 \\
& \in + \frac{b_2 \in^2}{2} + \frac{b_3 \in^3}{6} + \frac{wa^4}{D}\left(\frac{n_1}{\cup_3}\right)\cdot\frac{\in^4}{24} \\
& + \frac{b_5 \in^5}{120}\Bigg)
\end{aligned}
\tag{32}
$$

The general polynomial shear deformation function (Rotation equation for the y-axis) of a rectangular plate as was obtained and presented:

$$
\begin{aligned}
\cap_x = & \left(a_4 + a_5 \ni + \frac{a_6 \ni^2}{2} + \frac{wa^3}{D}\left(\frac{n_4}{g_2 \cap_3}\right)\cdot\frac{\ni^3}{6}\right) \\
& \times \Bigg(b_7 + b_8 \\
& \in + \frac{b_9 \in^2}{2} + \frac{b_{10} \in^3}{6} + \frac{b_{11} \in^4}{24}\Bigg)
\end{aligned}
\tag{33}
$$

The general polynomial shear deformation function (Rotation equation for the y-axis) of a rectangular plate as was obtained and presented:

$$
\begin{aligned}
\cap_y = & \left(a_7 + a_8 \ni + \frac{a_9 \ni^2}{2} + \frac{a_{10} \ni^3}{6} + \frac{a_{11} \ni^4}{24}\right) \\
& \times \Bigg(b_4 + b_5 \\
& \in + \frac{b_6 \in^2}{2} + \frac{wa^3}{D}\left(\frac{\propto^3 n_5}{g_2 \cap_1}\right)\cdot\frac{\in^3}{6}\Bigg)
\end{aligned}
\tag{34}
$$

The support conditions of the plate consideration is presented in the Figure 2.

Figure 2: CCFC Rectangular Plate

3.4.2. Direct Governing Equation

The direct variation method was used to obtain the direct governing differential equation by differentiating the total potential energy with respect to the coefficient of deflection (C), coefficient of shear deformation with respect to x-axis (C_x) and coefficient of shear deformation with respect to y-axis (C_y). Minimizing the Energy expression ($\exists$) with respect to the coefficient of deflection (C), coefficient of shear deformation with respect to x-axis (C_x) and coefficient of shear deformation with respect to y-axis (C_y):

$$\frac{\partial \exists}{\partial C} = \frac{\partial \exists}{\partial C_x} = \frac{\partial \exists}{\partial C_y} = 0 \tag{35}$$

The solution of Equation (35) yields the three Equations of equilibrium which is presented as:

$$t_{11}C - t_{12}C_x - t_{13}C_y = \frac{wa^4}{D}s_q \tag{36}$$

$$-t_{21}C + t_{22}C_x + t_{23}C_y = 0 \tag{37}$$

$$-t_{31}C + t_{32}C_x + t_{33}C_y = 0 \tag{38}$$

Where;

$$t_{11} = g_1\left(s_1 + \frac{2}{\alpha^2}s_2 + \frac{1}{\alpha^4}s_3\right) \tag{39}$$

$$t_{12} = -g_2\left(s_1 + \frac{1}{\alpha^2}s_2\right) \tag{40}$$

$$t_{13} = -g_2\left(\frac{1}{\alpha^2}s_2 + \frac{1}{\alpha^4}s_3\right) \tag{41}$$

$$t_{21} = -g_2\left(s_1 + \frac{1}{\alpha^2}s_2\right) \tag{42}$$

$$t_{22} = \left(g_3s_1 + \frac{(1-\mu)}{2\,\alpha^2}g_3s_2 + \frac{(1-\mu)}{2}\beta^2 g_4s_4\right) \tag{43}$$

$$t_{23} = g_3\frac{(1+\mu)}{2\,\alpha^2}s_2 \tag{44}$$

$$t_{31} = -g_2\left(\frac{1}{\alpha^2}s_2 + \frac{1}{\alpha^4}s_3\right) \tag{45}$$

$$t_{32} = g_3\frac{(1+\mu)}{2\,\alpha^2}s_2 \tag{46}$$

$$t_{33} = \left(g_3\frac{(1-\mu)}{2}\left(\frac{1}{\alpha^2}s_2 + \frac{1}{\alpha^4}s_3\right) + g_4\frac{(1-\mu)}{2\,\alpha^2}\beta^2 s_5\right) \tag{47}$$

Given that s_1, s_2, s_3, s_4, s_5 and s_q are the stiffness coefficients, let:

$$s_1 = \int_0^1\int_0^1\left(\frac{d^2n}{d\,\ni^2}\right)^2 d\ni\,d\in \tag{48}$$

$$s_2 = \int_0^1\int_0^1\left(\frac{d^2n}{d\ni\,d\in}\right)^2 d\ni\,d\in \tag{49}$$

$$s_3 = \int_0^1\int_0^1\left(\frac{d^2n}{d\in^2}\right)^2 d\ni\,d\in \tag{50}$$

$$s_4 = \int_0^1\int_0^1\left(\frac{dn}{d\ni}\right)^2 d\ni\,d\in \tag{51}$$

$$s_5 = \int_0^1\int_0^1\left(\frac{dn}{d\in}\right)^2 d\ni\,d\in \tag{52}$$

$$s_q = \int_0^1\int_0^1 n.\,d\ni\,d\in \tag{53}$$

Solving Equation (36), (37) and (38) simultaneously, gives Equation (54), (55) and (56):

$$C = \frac{wa^4}{D}(k) \tag{54}$$

$$C_x = CM_2 \tag{55}$$

$$C_y = CM_3 \tag{56}$$

Where;

$$M_2 = \frac{t_{21}.t_{33} - t_{23}.t_{31}}{t_{22}.t_{33} - t_{23}.t_{32}} \tag{57}$$

$$M_3 = \frac{t_{21}.t_{32} - t_{22}.t_{31}}{t_{23}.t_{32} - t_{22}.t_{33}} \tag{58}$$

$$k = \frac{s_6}{t_{11}M_1 - t_{12}M_2 - t_{13}M_3} \tag{59}$$

3.5. Displacement, Stresses, Bending moment and Shear force Equations

The equations for the moment (M_x and M_y), shear force (Q_x and Q_y), in-plane displacement (u and v), deflection ($\cup$) and the stress of isotropic rectangular thick plate was derived according to [28] by substituting the Equation (54), (55) and (56) where appropriate.

Substituting Equation (54) into (26), gave:

$$\cup = \bar{C}n\left(\frac{wa^4}{D}\right) \tag{60}$$

Let:

$$\bar{C} = k$$

The bending moment along x-axes:

$$M_x = \left(-\frac{D_1}{D}wa^2\bar{C}\left[\frac{d^2n}{d\,\ni^2} + \mu\frac{d^2n}{d\in^2}\right]\right.$$
$$\left. + g_2\left[\bar{C_x}\frac{d^2n}{d\,\ni^2} + \mu\bar{C_y}\frac{d^2n}{d\in^2}\right]\right) \tag{61}$$

That is:

$$M_x = \overline{M_x}wa^2 \tag{62}$$

Given that $D_1 = g_1D$; and $D_2 = g_2D$; let: $g_1 = 1$ and $g_2 = 1.2$

$$\overline{M_x} = -g_1\bar{C}\left[\frac{d^2n}{d\,\ni^2} + \mu\frac{d^2n}{d\in^2}\right]$$
$$+ g_2\left[\bar{C_x}\frac{d^2n}{d\,\ni^2} + \mu\bar{C_y}\frac{d^2n}{d\in^2}\right] \tag{63}$$

Where;

$$\bar{C_x} = M_2\bar{C} \tag{64}$$

$$\bar{C_y} = M_3\bar{C} \tag{65}$$

The bending moment along y-axes:

$$M_y = \left(-\frac{D_1}{D}wa^2C\left[\frac{d^2n}{d\in^2} + \mu\frac{d^2n}{d\,\ni^2}\right]\right.$$
$$\left. + g_2\left[\bar{C_y}\frac{d^2n}{d\in^2} + \mu\bar{C_x}\frac{d^2n}{d\,\ni^2}\right]\right)wa^2 \tag{66}$$

That is:

$$M_y = \overline{M_y}wa^2 \tag{67}$$

where;

$$\overline{M_y} = -g_1C\left[\frac{d^2n}{d\in^2} + \mu\frac{d^2n}{d\,\ni^2}\right]$$
$$+ g_2\left[\bar{C_y}\frac{d^2n}{d\in^2} + \mu\bar{C_x}\frac{d^2n}{d\,\ni^2}\right] \tag{68}$$

Shear force $Q_x = \dfrac{dM_x}{dx}$ and $Q_y = \dfrac{dM_y}{dy}$ (69)

Thus, the shear force along x-axes:

$$Q_x = \left(-\bar{C}\left[\frac{\partial^3 n}{\partial \ni^3} + \mu\frac{\partial^3 n}{\partial \in^3}\right]\right.$$
$$\left. + \left[\overline{C_x}\frac{\partial^3 n}{\partial \ni^3} + \mu\overline{C_y}\frac{\partial^3 n}{\partial \in^3}\right]\right)wa \quad (70)$$

That is:

$$Q_x = \overline{Q_x}wa \quad (71)$$

Where;

$$\overline{Q_x} = -\frac{D_1}{a^3}\bar{C}\left[\frac{\partial^3 n}{\partial \ni^3} + \mu\frac{\partial^3 n}{\partial \in^3}\right]$$
$$+ \left[\overline{C_x}\frac{\partial^3 n}{\partial \ni^3} + \mu\overline{C_y}\frac{\partial^3 n}{\partial \in^3}\right] \quad (72)$$

The shear force along y-axes:

$$Q_y = \left(-\bar{C}\left[\frac{\partial^3 n}{\partial \ni^3} + \mu\frac{\partial^3 n}{\partial \in^3}\right]\right.$$
$$\left. + \left[\overline{C_x}\frac{\partial^3 n}{\partial \ni^3} + \mu\overline{C_y}\frac{\partial^3 n}{\partial \in^3}\right]\right)wa \quad (73)$$

That is:

$$Q_y = \overline{Q_y}wa \quad (74)$$

where;

$$\overline{Q_y} = -\frac{D_1}{a^3}\bar{C}\left[\frac{\partial^3 n}{\partial \ni^3} + \mu\frac{\partial^3 n}{\partial \in^3}\right] + \left[\overline{C_x}\frac{\partial^3 n}{\partial \ni^3} + \mu\overline{C_y}\frac{\partial^3 n}{\partial \in^3}\right] \quad (75)$$

The in-plane displacement along x-axes:

$$u = [-\bar{C}s + \overline{C_x}S(s)]\frac{dn}{d\ni}\left(\frac{wa^4}{\beta D}\right) \quad (76)$$

The in-plane displacement along y-axes:

$$v = \frac{1}{\propto}[-\bar{C}s + \overline{C_y}S(s)]\frac{dn}{d\in}\left(\frac{twa^3}{D}\right) \quad (77)$$

The normal stress along x-axes:

$$\sigma_x = 12\left[[-\bar{C}s + \overline{C_x}S(s)]\frac{d^2 n}{d\ni^2}\right.$$
$$\left. + \frac{\mu}{\propto^2}[-\bar{C}s + \overline{C_y}S(s)]\frac{d^2 n}{d\in^2}\right](w\beta^2) \quad (78)$$

The normal stress along y-axes:

$$\sigma_y = w\beta^2\left[12\left[\mu[-\overline{C}s + C_x S(s)]\frac{d^2 n}{d\ni^2}\right.\right.$$
$$\left.\left. + \frac{\mu}{\propto^2}[-\bar{C}s + \overline{C_y}S(s)]\frac{d^2 n}{d\in^2}\right]\right] \quad (79)$$

The shear stress along x-y axes:

$$\tau_{xy} = 6\frac{(1-\mu)}{\propto}\left[-2\bar{C}s + \overline{C_x}S(s)\right.$$
$$\left. + \overline{C_y}S(s).\frac{1}{\propto}\right]\frac{d^2 n}{\partial \ni \partial \in}(w\beta^2) \quad (80)$$

The shear stress along x-z axes:

$$\tau_{xz} = 6(1-\mu)\overline{C_x}\frac{dS(z)}{dz}\frac{dn}{d\ni}(w\beta^2) \quad (81)$$

The shear stress along y-z axes:

$$\tau_{yz} = \frac{6(1-\mu)}{\propto}\overline{C_y}\frac{dS(z)}{dz}\frac{dn}{d\in}(w\beta^2) \quad (82)$$

q_d = Self weight of the plate

4. Results and Discussions

The numerical analysis of a CCFC rectangular plate of various span-thickness ratios is presented in Table 2 to 6. A third-

order polynomial displacement function for the analysis CCFC as was derived in Equation (32) in line with the work of [29] is presented in Equation 83 to 94:

$$U_{(\ni,\in)} = \left(a_0 + a_1\ni + \frac{a_2\ni^2}{2} + \frac{a_3\ni^3}{6} + \frac{\ni^4}{24}Sa_4\right).\left(b_0 + b_1\right.$$
$$\left. \in + \frac{b_2\in^2}{2} + \frac{b_3\in^3}{6} + \frac{\in^4}{24}b_4 + \frac{b_5\in^5}{120}\right) \quad (83)$$

where;

$$S = \frac{wa^4}{D}\left(\frac{n_1}{U_3}\right)$$

At $\ni = \in = 0; U = 0$ \quad (84)

At $\ni = \in = 0; Slope\left(ie.\frac{dU}{d\ni} = \frac{dU}{d\in} = 0\right)$ \quad (85)

At $\ni = \in = 1; U_x = 0$ and $M_y\left(ie.\frac{d^2 U}{d\in^2} = 0\right)$ \quad (86)

At $\ni = 1, slope\left(ie.\frac{dU}{d\ni} = 0\right); at \in = 1, slope\left(ie.\frac{dU}{d\in} = \frac{2}{3b_5}\right)$ \quad (87)

At $\in = 1;$ shear force $Q_y\left(ie.\frac{d^3 w}{d\in^3} = 0\right)$ \quad (88)

Substituting Equations (84 to 88) into Equation (83) and solving gives the following constants:

$$a_0 = 0; \; a_1 = 0; \; a_2 = \frac{Sa_4}{12}; \; a_3 = \frac{-Sa_4}{2} \; and \; b_0 = 0; \; b_1 = 0; \; b_2 = 2.8b_5; \; b_3 = -5.2b_5; S_{b4} = 3.8b_5 \quad (89)$$

Substituting the constants of Equation (89) into Equation (83) gives;

$$U = \frac{S_{a4}}{24}(\ni^2 - 2\ni^3 + \ni^4)$$
$$\times \frac{b_5}{360}(2.8\in^2 - 5.2\in^3 + 3.8\in^4 - \in^5) \quad (90)$$

That is:

$$U = \frac{S_{a4} \times b_5}{8640}(\ni^2 - 2\ni^3 + \ni^4)$$
$$\times (2.8\in^2 - 5.2\in^3 + 3.8\in^4 - \in^5) \quad (91)$$

Recall from Equation 26, that;

$$U = n.C$$

Let the amplitude:

$$C = \frac{1}{8640}(S_{a4} \times b_5) \quad (92)$$

and;

$$n = (\ni^2 - 2\ni^3 + \ni^4) \times (2.8\in^2 - 5.2\in^3 + 3.8\in^4 - \in^5) \quad (93)$$

Therefore:

$$U = \frac{S_{a4}.b_5}{8640}(1.5\ni^2 - 2.5\ni^3 + \ni^4)$$
$$\times (2.8\in^2 - 5.2\in^3 + 3.8\in^4 - \in^5) \quad (94)$$

The values stiffness coefficient obtained from the above expression is presented in Table 1. Table 2 contains the result of bending moment, shear force, and their resultants of a square CCFC rectangular plate at different span to thickness aspect ratio. These numerical values of the design factors of these quantities ($\overline{U}$, $\overline{M}$ and $\overline{Q}$) for a square thick plate is obtained using Equation (60) to (75) as obtained from this study. Table 3 contains the result of the values of displacement (u, v and U) and the stresses characteristics ($\sigma_x, \sigma_y, \tau_{xy}, \tau_{xz}$ and τ_{yz}) of a square CCFC

rectangular plate at different span to thickness aspect ratio using Equation (60), (70) and (77). These numerical values were obtained from the Equation (60), (78) to (82). Table 4 contains the result of the value of displacement (u, v and ∪) and the stresses characteristics $(\sigma_x, \sigma_y, \tau_{xy}, \tau_{xz}$ and $\tau_{yz})$ for length to breadth ratio of 1.5 for CCFC rectangular plate at different span to thickness aspect ratio. These numerical values were obtained from the Equation (60), (78) to (82). Table 5 contains the result of the values of displacement (u, v and ∪) and the stresses characteristics $(\sigma_x, \sigma_y, \tau_{xy}, \tau_{xz}$ and $\tau_{yz})$ for length to breadth ratio of 2.0 for CCFC rectangular plate at different span to thickness aspect ratio. These numerical values were obtained from the Equation (60), (78) to (82). A comparative analysis of results obtained from this work is presented in Table 6 and Figure 3. This is determined the correctness of the results from the present studies, comparison was made between values from the present study and those of past scholars. Table 2 presents the result of the comparison done with the work of [30] for CCFC rectangular thick plate of 2.0 lengths to breadth ratio of various aspect ratios and the corresponding percentage difference between the values of centroidal deflection. Figure 3 contains a graph of the deflection versus span to the thickness aspect ratio of CCFC thick plate of length to breadth ratio of 2.0. This shows the comparison between the present work and that of the author in [30].

4.1. Discussion

The numerical results of stiffness coefficient of the plate is obtained from Equation (31) to (36).

It is seen from Table 2 that as the deflection (∪), bending moment (M_x and M_y) and (Q_x and Q_y) decreases, the span to thickness ratio increases. These continue until failure occurs in the plate structure. This means that, the load that causes the plate to deflect also causes the plate material to bend simultaneously. It is observed that the value of deflection varies less as the span to thickness increase, this equal to the value of the CPT at span to thickness ratio of 100 and above. Table 2 reveals that the values of deflection at both the x and y axis decrease as the span-thickness ratio increases with a constant value of 0.0092 at the span-thickness ratio of 30.

From the results of SCFS plate presented in Figure 12 to 20, it shows that the values of critical lateral imposed load q_{iw} decrease as the length-width ratio increases, this continues until failure occurs. This means that an increase in plate length increases the chance of failure in a plate structure. Meanwhile the values of critical lateral imposed load q_{ip} increase as the length-width ratio increases, this continues until safety is ensured.

From a critical look at Table 3, it is shown that the value of displacement (u, v and ∪) characteristics decreases with increases in the value of the span-thickness ratio. It is also observed in the Tables that the displacement (u, v and ∪) and stresses characteristics increases as the value of the length to breadth ratio increases. This means that, the in-plane displacement is functions of x, y and z as it varies with the plate thickness while the deflection is only a function of x and y and did not vary linearly with the thickness of the plate thickness. Also, it was deduced that the normal stress (σ_x and σ_y) and shear stress characteristics (τ_{xy}, τ_{xz} and τ_{yz}) also decreases as the span-thickness ratio increases. It is also observed in the Table 3 that the stresses characteristics ($\sigma_x, \sigma_y, \tau_{xy}, \tau_{xz}$ and τ_{yz}) increases as the value of the length to breadth ratio increases.

It can be seen that, at span to thickness ratio between 4 and 15, the value of transverse shear stress along y and z axes (τ_{yz}) varies between 0.022904 and 0.001370. These values of transverse shear stress (τ_{yz}) decrease between 0.000765 and 0.000100 at the span to thickness between 20 and 55 respectively. Hence, the value of transverse shear stress (τ_{yz}) is about 0.000084 and 0.00003, at the span to thickness between 60 and 100. The value becomes almost constant or equal to the value from CPT. This value becomes negligible as the value span to thickness increases. The values of transverse stress for span-thickness ratios of 100 and above are equal to the value from CPT.

In summary, there are three categories of rectangular plates. The plates whose vertical shear stress do not vary well from zero will be classified as thin plates because its value is almost equal to the value of the CPT. In between the thin and thick plate is the classified as moderate thick plate. Since the plate whose

transverse shear stress varies very much from zero is categorized as thick plates. Therefore, the span-to-depth ratio for these categories of rectangular plates are: Thick plate: $a/t \leq 15$; moderately thick plate: $20 \leq a/t \leq 55$; thin plate: $a/t \geq 60$. This confirmation can be used to show the boundary between thin and thick plate. Thus, it can be deduced from this research work that thick plate is the one whose span-depth ratio value is 4 up to 15.

CPT	0.0103	-0.0032	0.2048	-0.0337	0.0000

From a critical look at Table 4, it is shown that the non-dimensional displacement (u, v and ∪) characteristics decrease with increases in the value of the span-thickness ratio. It is also observed in the Tables that the displacement (u, v and ∪) and stresses characteristics increase as the value of the length to breadth ratio increases. This means that, the in-plane

displacement are functions of x, y and z as it vary with the plate thickness while the deflection is only a function of x and y and did not varies linearly with the thickness of the plate thickness. Also, it was deduced that the normal stress (σ_x and σ_y) and shear stress characteristics (τ_{xy}, τ_{xz} and τ_{yz}) also decrease as the span-thickness ratio increases. It is also observed in the Table 4 that the stresses characteristics ($\sigma_x, \sigma_y, \tau_{xy}, \tau_{xz}$ and τ_{yz}) increase as the value of the length to breadth ratio increases.

It can be seen that, at span to thickness ratio between 4 and 10, the value of transverse shear stress along y and z axes (τ_{yz}) varies between 0.012564 and 0.001667. These values of transverse shear stress (τ_{yz}) decrease between 0.000724 and 0.000100 at the span to thickness between 15 and 40. Hence, the value of transverse shear stress (τ_{yz}) is about 0.000079 and 0.000016, at the span to thickness between 45 and 100. The value becomes almost constant or equal to the value from CPT. This value becomes negligible as the value span to thickness increases. The values of non-dimensional value of transverse stress for span-thickness ratios of 100 and above are equal to the value from CPT.

In summary, there are three categories of rectangular plates. The plates whose vertical shear stress does not very well from zero will be classified as thin plates because its value are almost equal to the value of the CPT. In between the thin and thick plate is the classified as moderate thick plate. Since the plate whose transverse shear stress varies very much from zero is categorized as thick plates. Therefore, the span-to-depth ratio for these categories of rectangular plates are: Thick plate: $a/t \leq 10$; moderately thick plate: $15 \leq a/t \leq 40$; thin plate: $a/t \geq 45$. This confirmation can be used to show the boundary between thin and thick plate. Thus, it can be deduced from this research work that a thick plate is the one whose span-depth ratio value is 4 up to 10.

CPT	0.0107	-0.0033	0.2087	-0.0262	0.0000

From a critical look at Table 5, it is shown that the non-dimensional displacement (u, v and ∪) characteristics decrease with increases in the value of the span-thickness ratio. It is also observed in the Tables that the displacement (u, v and ∪) and stresses characteristics increase as the value of the length to breadth ratio increases. This means that, the in-plane displacement are functions of x, y and z as it vary with the plate thickness while the deflection is only a function of x and y and did not varies linearly with the thickness of the plate thickness. Also, it was deduced that the normal stress (σ_x and σ_y) and shear stress characteristics (τ_{xy}, τ_{xz} and τ_{yz}) also decrease as the span-thickness ratio increases. It is also observed in the Table 4 that the stresses characteristics ($\sigma_x, \sigma_y, \tau_{xy}, \tau_{xz}$ and τ_{yz}) increase as the value of the length to breadth ratio increases.

It can be seen that, at span to thickness ratio between 4 and 10, the value of transverse shear stress along y and z axes (τ_{yz}) varies between 0.008325 and 0.001101. These values of transverse shear stress (τ_{yz}) decrease between 0.000478 and 0.000118 at the span to thickness between 15 and 30 respectively. Hence, the value of transverse shear stress (τ_{yz}) is about 0.000087 and 0.000011, at the span to thickness 35 and 100. The value becomes almost constant or equal to the value from CPT. This value becomes negligible as the value span to thickness increases. The values of non-dimensional value of transverse stress for span-thickness ratios of 100 and above are equal to the value from CPT.

In summary, there are three categories of rectangular plates. The plates whose vertical shear stress do not vary well from zero will be classified as thin plates because its value are almost equal to the value of the CPT. In between the thin and thick plate is the classified as moderate thick plate. Since the plate whose transverse shear stress varies very much from zero is categorized as thick plates. Therefore, the span-to-depth ratio for these categories of rectangular plates are: Thick plate: $a/t \leq 10$; moderately thick plate: $10 \leq a/t \leq 30$; thin plate: $a/t \geq 35$. This confirmation can be used to show the boundary between thin and thick plate. Thus, it can be deduced from this research work

that thick plate is the one whose span-depth ratio value is 4 up to 10.

In the classical plate theory (CPT), it is assumed that the plane cross sections initially normal to the plate's mid-surface before deformation remain plane and normal to the mid-surface after deformation , and the length of such elements is not altered [31]. This is the result of neglecting the transverse shear strains, therefore value of vertical shear stress from CPT analysis is zero. Any plate whose span-to-thickness ratio is such that the value of transverse shear stress from thick plate analysis is approximately zero can be idealized as thin plate. Analyzing such plate with classical plate theory will not introduce significant errors.

Thus, these plates can be classified as moderately thick plate. Hence, analyzing them with classical plate theory will introduce significant errors. When the span-to-thickness ratio is less than 15, the value of vertical shear stress is significant even when corrected to 4 decimal places. This range of span-to-thickness ratio produces plate classified as thick plate. It is also, showed that at span-thickness ratio above 100, the values obtained from the models used herein coincide exactly with values from CPT. This is quite expected since we assumed in CPT analyses that at span-thickness ratios from 100 and above, a plate can be taking as being thin.

Table 6: Comparative analysis of results from the present work and literature for 2.0 aspect ratio (α)

β	Present work $u(m)$	[30] $u(m)$	Percentage difference (%)
4	-0.0044	-0.0037	20.772
10	-0.0034	-0.0033	3.3903
50	-0.0033	-0.0033	0.2749
100	-0.0033	-0.0033	0.0306
1000	-0.0033	-0.0033	0.0306
CPT	-0.0033	-0.0033	0
Average total % difference	4.9		

From Table 6, it is shown that the present study predicts slightly higher values of in-plane displacement along the direction of x coordinate with highest percentage difference of 20.8% which occur at length to breadth aspect ratio of 4. This proves the safety of the present model. The present study converges with the work as value of span to thickness ratio increases and becomes the same or equal to CPT value at span to thickness ratio of 100. The rate of convergence can be seen in Figure 3. The total average percentage difference between the present study and the author in [30] is 4.9%. This means that at about 95 % confidence level, the values from the present study are the same with those of [30]. This higher confidence level proved that the polynomial shear deformation theory can be used with confidence for stress and bending analysis of thick rectangular plate clamped on three edges, and free at the other remaining edge.

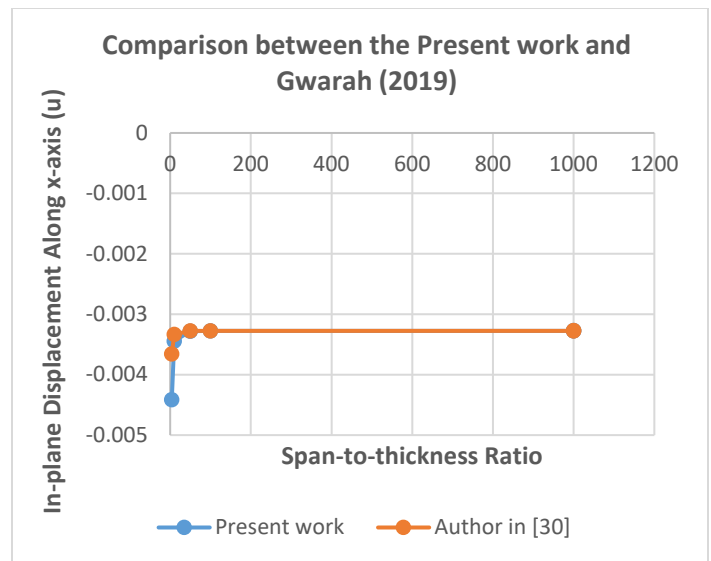

Figure 3: Graph of in-plane displacement versus span-to-thickness ratio

5. Conclusion

Stress analysis of thick rectangular plate using higher order polynomial shear deformation theory has been investigated. From the study this conclusion has been drawn:

i. It is concluded that the values of transverse shear stress obtained by this theory achieve accepted vertical shear stress to the thickness of plate variation and satisfied the transverse flexibility of condition at the top and bottom faces of the plate while predicting the flexural characteristics for an isotropic rectangular CCFC plate.

ii. The result moment and stresses obtained by present work using polynomial shear deformation theory agreed well with those of refined plate theory, but varied more with value of CPT. This validates the efficacy of the present theory in the thick plate analysis.

iii. The governing differential equations and associated boundary conditions obtained are variationally consistent and can be used with confidence in the analysis of rectangular thick plate.

6. Recommendation of Future Scope of Studies

This lies in the establishment shear deformation/displacement function for free vibration and buckling analysis of rectangular or circular thick plate. Then determining the displacement and stress parameters for the plate using virtual work principles.

Quality Function Deployment: Comprehensive Framework for Patient Satisfaction in Private Hospitals

Mohammad Kanan[*], Siraj Essemmar

Industrial Engineering Department, College of Engineering, University of Business and Technology, Jeddah, 21448, Kingdom of Saudi Arabia

A R T I C L E   I N F O

A B S T R A C T

This paper addresses the quality of private healthcare services in the western region of the Kingdom of Saudi Arabia (KSA) and provides a comprehensive analysis of the customer requirement to improve the quality of these services. The study begins by reviewing literature on the subject of quality in general and then in terms of the service and healthcare sectors. To assess the healthcare system, the paper then presents the literature on accreditation, which is a tool for healthcare quality assessment. Past studies in healthcare are also reviewed. The voice of the customer (VOC) is an essential factor in this study, so the quality function deployment (QFD) tool was implemented to satisfy the customer requirements and achieve the purpose of the study. A customer focus group was used to determine the VOC, and a survey of 300 samples was conducted to assess the importance of each requirement. The study implemented four houses, which represent the four phases of a comprehensive QFD. According to QFD analysis the results show that there are two main factors that affect the private healthcare system in the (KSA). The first factor deals with management issues, while the second one relates to the recording and flow of information. The study suggests several ways to improve the management and information issues of the healthcare system in (KSA).

1. Introduction

Due to globalization and the rapid changes in various industries, improvement in the quality of the healthcare sector has been relatively slow. As such, the governments need to give serious attention to this sector, which delivers one of society's basic needs. The population of the Kingdom of Saudi Arabia (KSA) is approximately 34 million, with an annual population growth rate of 2.52% (General Authority of Statistics). According to United Nations projections, by 2025 the population of KSA will be approximately 39.8 million [1]. Hence, KSA's 2030 vision includes several initiatives to improve its healthcare services. Currently, there are three medical sectors in KSA: the government agencies sector, the public healthcare sector, and the private healthcare sector. The government agencies sector makes up 17.7% of total healthcare services, and provides healthcare services to specific government employees and families through specialist hospitals and research centers, National Guard health affairs, security forces medical services, Royal Commission health services, army medical services, and the Ministry of Education hospital [2]. The public healthcare sector makes up 60.2% of total healthcare services, which are provided by the Ministry of Health (MOH). The private sector makes up 22.1% of total healthcare services [2]. The MOH plans to transfer 295

hospitals and 2,259 health centers to the private sector by 2030 [1]. It also revealed that, out of 2,390 healthcare centers in KSA, only 55 have attained the standards of the Saudi Central Board for Accreditation of Healthcare Institute (CBAHI) (CBAHI, 2013). The governments needs to establish a new system, method, and measurement of quality that will enhance performance, reduce costs, and eliminate waste. This study aims to improve the quality of private healthcare services in the western region of KSA. The study focuses on patients as a major stakeholder in these services. Although the suggestions are related to the structure and process of healthcare systems, they also affect the outcomes in the healthcare service framework. To achieve this aim, it is essential to evaluate current services and the performance of competitors, for which the quality function deployment (QFD) tool will be used.

2. Literature review

The quality definitions is highly debated in the associated literature. However, a challenge arises due to the difference in perspectives of different types of products, which range from goods and services to software [3].

2.1. Quality review

In terms of goods, there are multiple definitions of quality. In 1984, Garvin dealt with quality by categorizing past definitions

*Corresponding Author: Mohammad Kanan. Email: m.kanan@ubt.edu.sa

into five approaches—value based, product based, user based, transcendent, and manufacturing based—and separating the basic elements of product quality into eight dimensions [4]. Also, Garvin studied the relationship between quality and other terms such as marketing, price, and cost. He discussed four types of costs which are: appraisal cost, external and internal failures, and prevention cost [4]. Feigenbaum coined the term cost of quality in a 1956 which include the four types of cost [5]. Juran defined quality as "fitness for use" and argued that an analogy can be made between financial management and quality management, establishing a tripartite approach of quality planning, quality control, and quality improvement [3]. Japanese philosophy defines quality as having no defects, being done right the first time. Reinforcing the latter definition, Crosby defined quality as "conformance to requirements or specifications" [6]. Deming's definition of quality is slightly more expansive: "Quality is a predictable degree of uniformity and dependability, at low cost and suited to the market". Deming also identified 14 areas of quality management that support and improve an organization's performance [7].

Quality of service, however, differs from the quality of tangible goods. Parasuraman and Grönroos defined quality of service as the perceptions of consumers that are associated with their expectations of the service and the received service [8]. Parasuraman and Grönroos's definition established quality as the gap between customers and managers. They identified five types of gap—knowledge, standards, delivery, communications, and expected service/perceived service—and ten dimensions of service quality, which they called SERVQUAL. Although SERVQUAL is one of the most common models used in the literature for services similar to healthcare, such as tourism, hospitality, marketing, and banking, it needs to be modified to fit the context [9]. Cronin and Taylor rejected this method of gaps/score measurement, instead measuring service quality using a tool called SERVPERF, which depends only on performance [9].

Many recently developed products are software based, and software has become a significant factor in quality of life. Both goods and services depend on software. As such, the need to understand, control, and design high-quality software has become important [10]. Managers generally focus on improvement, so researchers have designed tools and instruments to measure and improve quality in any field. In the United States manufacturing industry during the 1980s, quality was transformed from small-q to big-Q. This change, established by Juran, highlighted the difference between focusing on reworking existing conditions in a limited capacity (small q), which often neglected other factors like resources and management, and managing quality in all aspects of business (big Q). This concept later became known as total quality management (TQM) [11]. TQM is an organized approach to achieving customer satisfaction using several techniques, tools, and systems through continuous improvement of a process [12]. In 1987, the Malcolm Baldrige National Quality Award was established and the Lean Six Sigma was revealed by Motorola. The Lean Six Sigma is a model that focuses on the variations of products to reduce the chance of defects to less than 3.4 per million. Its methodology follows five stages: definition, measurement, analysis, improvement, and control (DMAIC) [13].

2.2. Quality in the service industry

Literature has identified three main economic sectors: the primary sector, the secondary sector, and the tertiary sector. The primary sector deals with the extraction of natural resources through farming and mining, while the secondary sector transforms these raw materials into tangible goods. The tertiary sector focuses on the production of services rather than goods, and has a significant effect on gross domestic product (GDP). It also greatly impacts everyday life in areas such as education, healthcare, and transportation.

According to the Oxford English Dictionary, a service is "a system supplying a public need such as transport, communications, or utilities (electricity and water)". The Business Dictionary defines service as "a valuable action, deed, or effort performed to satisfy a need or to fulfill a demand". Service involves all aspects of modern life—it is the several processes that deliver benefits to customers. The nature of service is more complex than that of tangible goods, and the problems of the service sector are related to the characteristics of different services, which can be classified into three main categories: intangibility—a service is performed, rather than being an object, so it cannot be measured in advance to assure the quality − heterogeneity − a service depends on the performance of staff, so it differs from one provider to another—and inseparability—the delivery of a service depends on the interaction between a customer, a provider, and their environment [6]. One of the limitations of a service is that a customer cannot evaluate its quality until they have experienced it, a limitation that Phillip Nelson highlighted when he distinguished between "search" and "experience". In search, quality can be determined before purchase, but in experience it can only be known after purchase and use [4]. The limited knowledge of the customer in the healthcare process makes it harder to judge the quality of healthcare service.

2.3. The definition of healthcare quality

Healthcare is a complex service system; according to Donabadian's framework, the healthcare system consists of three main categories: structures, processes, and outcomes. While structures relate to facilities, equipment, layout, and physicians, a process is any interaction between the customer and the healthcare structure. Outcomes are the consequences of the healthcare service [14]. Overall, the healthcare system provides benefits to several stakeholders, including patients, attendants (relatives, friends), physicians, nurses, insurance companies, and the government.

Scholars and researchers have provided different definitions of high-quality healthcare. Ovretveint defined it as "fully meeting the needs of those who need the services most, at the lowest cost to the organization, within the limits and directive set by higher authorities and purchases" [2]. Campbell, Roland, and Buetow (2000) categorized high-quality healthcare into two types: individual patient care and population care. Individual patient care is defined as "whether individuals can access the health structures and processes of care which they need and whether the care received is effective". Population care is "the ability to access effective care on an efficient and equitable basis for the optimization of health benefit/well-being for the whole population". Deepti Singh and Kavaldeep Dixit argued that the satisfaction of the patient will be achieved by improving the delivery of health care service, considering patients' needs, and reacting with their annotation [15]. So, the involvement of patients and shear their experience with healthcare professionals is a critical factor that will impact the quality improvement process [16].

2.4. Healthcare quality standards

An effective factor in assessing and improving quality is accreditation—a framework to help and improve the quality of healthcare by fulfilling the standards of an external independent accreditation body [17]. Standards are a measure of excellence that indicate key functions, processes, structures, and activities. In healthcare facilities, it is a requirement to assure the provision of safe and high-quality care [18] . Although standards are the tools and requirements of accreditation, they also help an organization improve the quality of its services [19] . Araujo, C. A., Siqueira, M. M., & Malik, A. M reviewed 37 studies about the impact of accreditation on the healthcare quality and they concluded that the accreditation effects on healthcare quality indicators are mostly positive [20].

2.5. The Saudi Central Board for Accreditation of Healthcare Institutions (CBAHI)

The CBAHI is a non-profit governmental organization authorized to give accreditation to healthcare centers in KSA. It aims to continually improve healthcare services in terms of quality and safety, and seeks to achieve this by supporting healthcare facilities in following the established standards. The organization was itself accredited by the International Society for Quality in Healthcare (ISQua), making it one of the few healthcare accreditation organizations around the globe. In the CBAHI's third edition standards manual, there are 23 chapters explaining the functions and key services that must be provided to obtain accreditation, such as leadership, nursing care, quality management, patient safety, operating rooms, facility management, safety, and emergency care [18].

2.6. Healthcare quality studies

Several relevant case studies have been conducted in healthcare literature. Due to the difficulties associated with measuring quality in healthcare sectors, different models were employed based on the tools or methods used. One of the most popular models used in the healthcare sector is SERVQUAL, and although some researchers were committed to Parasuraman's dimensions, a modified SERVQUAL model was needed in some case studies. For example, authors studied the relationship between patient satisfaction, service quality, and word of mouth (WOM), concluding that the main dimension of service quality that affects WOM is empathy, and that some dimensions, such as assurance, responsiveness, and tangibility, have an indirect effect on patient satisfaction [8]. Later, authors applied a new scale to measure SERVQUAL gaps in Malaysian private healthcare services [21]. Padma, Rajendran, and Sai (2009) found that the dimensions of SERVQUAL are not sufficient to reflect actual quality level, so they adapted dimensions from the Malcolm Baldrige National Quality Award (MBNQA, 2007) and Joint Commission International framework (JCI, 2007) and modified dimensions in [9].

Some researchers have used another model, the plan–do–study–act (PDSA) model, which is a tool for quality improvement developed by Shewhart and Deming. The model consists of four stages: the planning stage, which identifies the improvement of the process; the doing stage, which deals with testing the improvement; the studying stage, which examines the success of the improvement; and the acting stage, in which a new cycle is initiated by the identification of further possible adaptations [22]. Authors reviewed 73 articles related to healthcare and found that more than 60% of the articles fulfilled

PDSA criteria and information. Based on their findings, the benefits of the PDSA can be maximized by starting the cycle on a small scale and following an iterative approach [22].

Other researchers have expanded the concept of healthcare quality through the use of TQM. Dilber, Bayyurt, Zaim, and Tarim (2005), for example, identified the critical factors of TQM in the healthcare sector—process management, the role of top management, employee relations, and data reporting—and measured the impact of these critical factors on business performance in Turkish hospitals [7]. Some authors also integrated TQM with business process re-engineering (BPR), which is a fundamental and radical redesign and rethinking of business processes to create significant improvements in performance [3].

2.7. Quality function deployment (QFD)

One of the main critical factors in TQM is the voice of the customer (VOC). There are several ways to study the VOC, one of the most popular tools is the quality function deployment (QFD).

In 1972, authors published a paper about quality deployment. This, along with Nishimura's paper, was the route of the new concept of QFD to the west. Authors then established a way to convey customer requirements from the design stage to the operation stage, called quality function deployment (hinshitsu kino tenkai). Finally, in 1978, a book titled Deployment of the Quality Function, which discussed the Japanese experience of QFD [23].

QFD is a tool for transforming customer requirements into design with a satisfying level of quality assurance, and can create novel solutions [23]. It can, however, be difficult to apply, as it is loosely defined and can therefore be more of an art than a science [23].

The primary fields into which QFD was introduced were quality management systems, customer needs, product development, and analysis. It was later extended to other fields, such as construction, costing, education, decision making, software, and services. QFD can be used in any field, without boundaries [23, 24].

House of quality (HOQ) is the basic design tool of QFD. It started in 1972 in Mitsubishi's Kobe shipyard, and was then implemented by Toyota in different ways. HOQ is a conceptual map that provides the means for inter-functional planning and communication. The main principle of HOQ is to satisfy customer needs by learning from customer experiences [25]. QFD uses several iterations of HOQ to translate customer needs into detailed functional characteristics, and these iterations (houses) require a high level of cooperation between cross-functional teams [26]. Jaiswal (2012) defined these iterations as product planning, product design, process planning, and process control [27]. The authors explained that implementations in QFD often need several HOQ repetitions to obtain a satisfactory result, but organizations usually only get through the first house of QFD [27].

Generally, there are two main phases in each house or iteration; the first phase deals with the quality plan, answering the "What" questions, while the second phase is related to quality design, answering the "How" questions [28]. "What" questions appear in the HOQ conceptual map (see Figure 1) as room (1), containing customer requirements or preferences. Beside it, the priorities being assigned based on customer

preferences. The engineering characteristics are generated and entered in room (3). The biggest room, constructed between the "How" and "What" questions, is room (4), the relationship matrix, which indicates how much the "How" and "What" relate to or affect each other. Rooms (5) and (6), respectively, represent the benchmark for customer satisfaction and engineering characteristics correlating to benchmarks. Room (7) is located at the bottom of the house and includes the targets for a new product or service. The final part of the house is a coupling matrix, which appears as room (8), the roof. This is used to show the relationship between one engineering characteristic and another [29].

Figure 1: House of quality model [33]

3. Study Execution

This study aims to provide appropriate suggestions for improving service quality and satisfying customer needs in the private healthcare sector in KSA. As the VOC is the core of this paper, the QFD was used.

3.1. Methodology

To determine customer requirements (the VOC), a focus group session was held with customers then the survey was conducted to measure the importance of customer requirements. The results were analyzed and based on the analysis, the HOQ was established to generate the engineering characteristics. A scale of 0, 1, 3, and 5 points was used in the relationship matrix, as put forward in [30]. To achieve comprehensive analysis, benchmarking was performed in each phase and the public and other government agencies were seen as competitors.

3.2. Gathering the VOC

Customers were gathered in Jeddah from different ages and perspectives to determine the most important needs based on their experience with different private hospitals. The sessions discussed Cooperation of medical staff, Waiting time, Ease of procedures, And Cost of medical care among others. As shown in table 1. The sessions took more than 30 hours spanning five days. Doctors and experts were also consulted.

Table 1: Importance of customer requirements

n	Customer requirement	Weight	Percentage	Customer importance
1	Waiting time	2643	11.26%	9
2	Availability of appointments	2776	11.82%	9
3	Cooperation of medical staff	2893	12.32%	10
4	Cooperation of administrative staff	1973	8.40%	7
5	Quality of facilities	2256	9.61%	8
6	Reputation of the hospital	2296	9.78%	8
7	After-service communication	1112	4.74%	4
8	Ease of procedures	2032	8.65%	7
9	Software application	1108	4.72%	4
10	Calling method in the waiting room	1068	4.55%	4
11	Access to medical records	1165	4.96%	4
12	Cost of medical care	2156	9.18%	7

Table 2: Engineering characteristics for product planning

n	Engineering characteristic	Explanation
1	Scheduling	Scheduling of appointments/employees
2	Training and consultation	Periodic training in communication and empathy
3	Ergonomics	Making workplaces suitable for people
4	Facility layout	Arrangement and state of the facility
5	Optimizing the number of patients and resources	Eliminating waste and regulating the number of patients for each doctor
6	Motivating employees	Encouraging doctors and other staff to be kind and inspiring them to perfection
7	Accreditation	Achieving the specifications and standards of the CBAHI
8	Information systems	Information flow within the hospital and other healthcare centers
9	Communicating with patients	Any process of communication with patients
10	Encouraging patients to take out insurance	Convincing and influencing patients to take out insurance
11	Making the app easy to use	Simplifying the app and making it user friendly

The results from the focus group and consultation sessions revealed that there are 12 requirements to be considered. The 300-sample size survey was conducted to know the priority of each requirement. Using the ranks obtained in the survey questions, the highest customer preference was multiplied by 12, the second highest by 11, the third highest by 10, and so on, to balance the weight of importance for each customer requirement. To modify the scale of customer requirements to between 1 and 10, the weight percentage was multiplied by 80. The outcomes are shown in Table I.

3.3. Product planning

The first house was built based on the survey analysis. After looking at the VOC in the first two rooms, the third room was constructed by listening to the voice of the engineers on how to satisfy the customer requirements, So the engineers studied all requirements and suggested the solution (characteristic) that will affect them. Table 2 shows out the engineering characteristic - representing the suggested solution - and a brief description of each one.

Figure 2: Engineering characteristics details

Figure 3: Product design

The relationship between customer requirements and engineering characteristics was then determined in the correlation matrix. Negative and positive signs were also used to determine the correlation between each engineering characteristic. Finally, the relative weight for each customer requirement and engineering characteristic was calculated. The results of the first phase identified 11 engineering characteristics and the details were represented in Figure 2.

The highest value represents the "optimizing number of patients and resources". So, focusing on the "optimizing the number of patients and resources" will satisfied customer requirements by 19%. Focusing on a hospital's internal environment is one of the most valued outcomes, appearing with a high value in both the ergonomics and facility layout characteristics. In relation to encouraging patients to take out insurance, Saudi labor law requires private companies to pay the health coverage costs (insurance) for all employees [31], but other employees should be encouraged to take out their own insurance. As such, encouraging patients to take out insurance is an engineering characteristic that can help minimize the cost of medical care.

3.4. Product design

The engineering characteristics of the previous phase were added as the requirements in this phase, and a new set of engineering characteristics was generated, as shown in Table 3. To satisfy the requirements, controlling scheduling factors should be prioritized, as it has the highest impact on the requirements (see Figure 3). Fixing the number of patients for each doctor is shown to be important, as it reduces physician burnout, which would otherwise affect the healthcare system [32].

Table 3. Engineering characteristics for product design

| n	Engineering characteristic	Explanation
1	Controlling scheduling factors	Identifying and limiting the factors that can affect scheduling, such as breaks, number of physicians, and appointment duration
2	Using the app	Involving the app in the communication and information recording process
3	Conditional scheduling plans	Backup plans for scheduling
4	Courses (communication, empathy)	Guidelines and seminars on communication and empathy
5	Periodic consultation sessions	Regular therapy consultations to deal with stress and burnout
6	Workshops and conferences	Lectures and motivational events
7	Comfortable work environment	Making workplace conditions more comfortable
8	Cleanliness	The state of the facility
9	Time and motion studies	Studying the time of each process and the movement effort required
10	Fixing the number of patients for each doctor	Regulating the number of patients each physician treats in a day
11	Combining a procedure in one place	Gathering the process for ease
12	Eliminating resource waste	Reducing wasted time, effort and equipment
13	Inspiring statements	Statements aimed to motivate employees
14	Talks	Inviting motivational speakers
15	Intrinsic rewards	Non-material incentives for employees
16	Expertise	Hiring a specialist physician
17	Fulfilling the national standards (CBAHI)	Achieving the CBAHI standards
18	Evaluation forms for visitors	Assessment from patients receiving services
19	Observing patient treatments	Observing the state of patients after discharge
20	Using a number calling method	Using a numbered queuing technique
21	Ease of information flow	Ensuring information travels between departments easily
22	Linked system between hospitals	Integrating a database between all hospitals
23	Big-data recording	Using big-data principles to record all information
24	Training stakeholders to use the app	Training patients and staff to use the app properly and effectively
25	Redesigning the app	Redesigning the interface and functionality of the app

Figure 4: Relative weight of engineering characteristics for product design

3.5. Process planning

According to authors, only the most important characteristics from each phase should be moved to the next phase. Therefore, the Pareto method was used to focus on the characteristics that were found to have the greatest impact on the requirements. The impact of each characteristic was detailed on table 4. From that table and following Pareto principal, 28% of these characteristics were moved to the next phase as requirements. (see Figure 4)

Table 4: Engineering characteristics: Contribution to product design

Engineering characteristics	Relative weight	Cumulative	Relative weight after rounding
Controlling scheduling factors	8.22%	8.2%	8%
Using the app	7.27%	15.5%	7%
Fixing the number of patients for each doctor	7.11%	22.6%	7%
Eliminating resource waste	6.48%	29.1%	6%

Conditional scheduling plans	**5.93%**	**35.0%**	**6%**
Big-data recording	**5.85%**	**40.9%**	**6%**
Ease of information flow	**5.69%**	**46.6%**	**6%**
Cleanliness	5.45%	52.0%	5%
Combining a procedure in one place	4.98%	57.0%	5%
Comfortable work environment	4.58%	61.6%	5%
Periodic consultation sessions	3.87%	65.5%	4%
Workshops and conferences	3.87%	69.3%	4%
Courses (communication, empathy)	3.72%	73.0%	4%
Linked systems between hospital	3.72%	76.8%	4%
Time and motion	3.64%	80.4%	4%
Fulfilling the national standards (CBAHI)	3.32%	83.7%	3%
Evaluation forms for visitors	2.53%	86.2%	3%
Observing patient treatments	2.53%	88.8%	3%
Redesigning the app	2.29%	91.1%	2%
Talks	2.13%	93.2%	2%
Using a number calling method	1.66%	94.9%	2%
Inspiring statements	1.50%	96.4%	2%
Intrinsic rewards	1.50%	97.9%	2%
Training the stakeholders to use the app	1.19%	99.1%	1%
Expertise	0.95%	100.0%	1%

Table 5: Engineering characteristics for process planning

n	Engineering characteristics	Explanation
1	Forecasting the number of patients	Predicting the daily demand of patients
2	Deposit fees for appointments	Fees paid to confirm the appointment and deducted from medical costs
3	Periodic breaks	Giving breaks to staff during working hours
4	Providing an internet connection	Availability of an internet connection within hospital facilities
5	Self-service machines	Machines for patients to facilitate procedures
6	Research on human subjects	Conducting studies in anthropological fields
7	Lean Six Sigma tools	Using Six Sigma principles and tools
8	Establishing a big-data department	Forming a new department for big-data collection and analysis
9	Standard platforms	Unified platforms containing medical records and other information
10	Computerized communication between departments	Eliminating all paperwork and replacing it with electronic communication
11	Replacement people for every job	Assigning employees to cover the absences of others

From the requirements, 11 engineering characteristics were considered as solutions. The descriptions of each characteristic are summarized in Table 5.

Resource waste caused by the transfer of information between departments has an impact on several factors (See Figure 5).

Computerized communication between departments uses fewer resources, such as paper and time. Moreover, its application enhances patient service and helps in the improvement of scheduling, data recording, and the flow of information. One of the other conclusions of this phase is that the impact of forecasting the number of patients will help reduce the chance of physician burnout, hence improving the quality of patient care [32].

3.6. Process control

The final technical solutions were conducted in this phase. The engineering characteristics of this phase (see Table 6) can be considered the main factors in achieving the customer requirements in the first house.

This phase proved that information could affect quality in healthcare and showed that information has the highest rating in the engineering characteristics of gathering information and contracting IT companies (See Figure 6). The contracted IT company has the responsibility of analyzing and recording information, while leadership faces a challenge in collecting the correct information from various departments. Efficient record keeping and documentation can be difficult [17].

The involvement of IT companies would require time and money, but would help improve information systems by contracting expertise or hiring a specialized employee. The assignment of surveying responsibility to a quality department would also improve quality. This department should be given an extensive training program before its staff are considered qualified to conduct surveys [17].

4. Result and discussion

To summarize the analysis of the QFD and satisfy the customer requirements, two main factors should be taken into consideration. The first factor is management, which was revealed in the first phase to consist of optimizing the number of patients, scheduling, and accreditation. This was expanded in the second phase to controlling scheduling factors, conditional scheduling plans, fixing the number of patients, and fulfilling standards.
Figure 5: Process planning

Figure 6. Process control

This consideration has some contributions to third and fourth phases, such as forecasting the number of patients and contracting a consulting center. The second factor is information, which begins in the first phase with an information system and develops into ease of information flow, big-data recording, and linked systems between hospitals in the second phase. It becomes the main focus in the third phase through computerized communication between departments, establishing big-data self-service machines, and standardized platforms. In the final phase, it expands to gathering information, hiring experts in data science, and contracting IT companies.

Table 6: Engineering characteristics for process control

n	Engineering characteristics	Explanation
1	Gathering information	Collecting data and information in an appropriate way
2	Contracting consulting centers	Contracting specialist centers in data science, supply-chain management and anthropology
3	Facilitating payment methods	Making payment methods easier
4	Short breaks	Short breaks for physicians and other staff
5	Suitable areas for high-speed connection	Preparing a high-speed connection area for patients and staff
6	Contracting IT companies	Contracting a professional IT company
7	Instructions for using self-service machines	Placing instructions near self-service machines to help the users
8	Training quality department employees	Training employees in principles of quality and survey methods
9	Hiring experts in data sciences	Finding experts to analyze data
10	Government initiatives	Governmental initiatives, especially on standardized platforms
11	Incentives	Rewards to motivate and encourage employees

5. Conclusion

KSA's vision is to privatize public hospitals as part of its aim to improve the Saudi economy and make KSA one of the most competitive countries in the world [31]. This implies an increase in the demand for private healthcare services. Thus, tools for the assessment and development of quality need to be implemented. As shown in this study, QFD can be an effective and realistic tool because it considers the VOC. Utilizing QFD, it was found that information recording and flow have the greatest impact on improving service quality in healthcare. Scheduling also plays an important role in improving customer satisfaction, as it was given the greatest weight of all the engineering characteristics that have a strong correlation with customer requirements.

6. Future research

To develop a comprehensive QFD, all departments and expertise from different fields should be integrated, which would improve research in the field of healthcare service. Moreover, including the third factor of Donabadian's model (outcomes) and considering it as a customer requirement may improve the implementation of the QFD in healthcare. Future research should focus on other stakeholders, such as nurses and physicians. Communication has a potential for further studies, which should concentrate on all aspects of communication, such as electronic communication and face-to-face interaction. Such studies would need to examine, evaluate, and enhance communication to achieve the standard requirements.
