Offers Medium (CO2 fixation, waste water treatment) but releases GM organisms	[45]
Produces less biomass for commercialization	[40]
Leaking of GMO to environment pausing ecological risks	[46-48]
Large carbon and nitrogen required. (However, Solar energy is daytime). Requires Nutrients recycling in the process	[49]
Harvesting of microalgae is expensive, and complicated	[50]
No regulation for marine cultivation but strict regulation is required with GM algae	[40, 51]
Initial cost for large scale cultivation is expensive	[40]
Cultivation in harsh environmental condition possible (such as high pH, salinity high light intensities)	[52, 67]

Fourth generation biofuels are oils therefore produced from genetically modified feedstocks able to consume more CO_2 from the atmosphere than what they will produce during the

combustion phase as fuels [80]. Therefore fourth generation fuel utilizes the existing platform technologies such as pyrolysis, gasification, solar to fuel and genetic manipulation of organism's genetic order. The fourth-generation family is referred to as smart fuels based on the conversion of vegoil and biodiesel to biogasoline using advanced technology.

Despite large-scale production and efforts to try to commercialize this family progress has not been sufficient. This has been due to lack of sufficient biomass, increased production costs and set-up, environment and human health concerns as fewer feasibility studies have been completed [40]. Table 7 is showing health and environmental effects of fourth generation biofuels. While Figure 4 is showing main steps of algal biomass technologies in carbon fixation.

Table 7: The health- and environment-related risk of GM algae Human health [81, 82]

Topic Risk contribution	Risk contribution	Effect	References
Allergies	Human health	Dermal, ingestive, respiratory exposure	[82-86]
Antibiotic resistance	Human health	Reducing the effectiveness of medical treatments	[84-86]
Carcinogens	Human health	Carcinogenic residues	[82]
Pathogenicity or toxicity	Environment	Pathogenicity of some strain to human; toxic blooms; chemical transfer; toxic residues	[82, 87, 88]
Change or depletion of the environment	Environment	Removal of nutrients from ecosystem; reducing biodiversity of the flora and fauna	[89, 90]
Competition with native species	Environment	Outcompete native organisms; changing aquatic ecosystems	[91, 92]
Horizontal gene transfer	Environment	Transfer of genetic organisms	[93, 94]
Pathogenicity or toxicity	Environment	Pathogenicity of some strain to human; algal blooms; generating genetic–related toxins	[95]
Figure 4: Carbon dioxide fixation and main steps of algal biomass technologies adapted [80]

GM crops have been with us since 1996 as sources of 3rd and 4th generation biofuels and have increased in their global acreage. For example soybeans, maize and rapeseed occupy 73.3×10^{13}, 46.8×10^{13}, and 7×10^3 respectively of all global land mass area under cultivation [96, 97]. Nevertheless, in order to increase fourth generation biomass production of biofuels algae is heavily GM sourced. Which is achieved by improving areas of the micro-organism using genetic material engineering manipulation. For example, the following areas are mentioned in literature to engineer increased microalgal biofuel production. (i) Improvement of photosynthetic efficiency, (ii) Increasing light penetration by using the truncated chlorophyl antenna and (iii) Reduction of photo-inhibition.

Literature is averse with these developments in the literature reviewed and presented here such as [98-101]. The development in fourth generation biofuels also aims at providing new economic development opportunities in remote and suburban areas of developing countries. These opportunities include reduction of emission to zero for both air pollutants and GHG [102, 103].

Microalgae form a large group of eukaryotes and cyanobacteria and have a wide range of compositional characteristics which include; [104] Food reservation, Photosynthetic pigments, Cell wall chemistry and reproduction. However out of the many species of microalgae only Bacillanophyceae (diatoms), Eustigmatophyte, Chlorophyceae and Chrysophyceae are potential sources of biofuel production [105]. Microalgae have high adaptability in extreme environmental conditions such as high salinity, drought, photo oxidation, osmotic pressure, temperature, anaerobiosis and ultraviolet (UV) radiation [106]. Their main nutrients are nitrogen

and phosphorous which accounts for 10% to 20% of its biomass [107, 108].

3. Biodiesel Feedstock Sources, Production, and Processing Techniques

3.1. Introduction to Edible Vegetable Oil and traditional Feedstocks

The production of biofuels such as biodiesel is becoming convenient as alternative energy. The use of biofuel such as biodiesel reduces GHG and provides opportunities for local and regional development in remote areas. This is made feasible considering the number of feedstocks sources. Biodiesel feedstock types differ from country to country depending on the geographical locations and their development [109, 110]. Globally more than 350 oil bearing crops have been identified [111] as possible biofuel feedstocks. However, there are many relevant candidates for biofuel production feedstocks adding to the list but are non-plant based. Figure 5 is showing the growth in vegetable oil production in China from 2003 to 2015.
Figure 5: China's biofuel production over the past decade [112]

The advance in experimental biodiesel production from theses feedstocks has led to a waste to energy revolution. Biodiesel production from readily available feedstock considered waste candidates for dumping and landfill [113]. This has encouraged value addition and co-product markets while contributing to diversification of the biofuel industry [114]. Nevertheless, since each feedstock is different from the other the conversion and processing techniques vary but the basic process of production remains the same. The wide range of feedstocks availability plays a significant role in promoting the biofuel industry.

The availability of feedstocks is influenced by regional climate, geographical location, local soil characteristics and general agricultural practices of a region or country [115]. In sources of biofuel development production and processing, only sunflower, cottonseed, safflower, rapeseed and peanuts are considered compared to two, corn and sugarcane for bioethanol used in gasoline engines;. However, it is important to mention here that non-edible oil plants such as Karanja, rubber seed, tallow oil and microalgae, Jatropa and neem seeds are also gaining

acceptance as alternative sources of biofuel. In the last decade, non-edible feedstocks have been extensively studied in literature surveyed such as [77, 116-118].

Among plant-based feedstocks palm oil, soybean and rapeseed account for almost 80 % of global feedstock for biofuel production as shown in Table 8. To qualify as a feedstock for biodiesel production the oil percentage and yield are important factors for consideration [119-122]. Nevertheless quality, availability, physicochemical properties, composition and production costs are some of other critical factors of feedstock determination and acceptability [119]. Feedstock prices account for more than 80% of the cost hence selecting and quality feedstock is vital to ensure low production costs [120, 123]. Since feedstocks are impacted by oil percentage yield, these factors are critical and need consideration. Figure 6 is showing total global vegetable oil production and production contribution of each source from 2013 to 2018. While Table 8 shows major vegetable oil producers and their main sources of feedstock respectively. On the other hand, Figure 7 is showing, international vegetable oil prices from 2000 to 2014.
Figure 6: Global vegetable oil production and consumption [124]

3.2. Soybean Biodiesel Feedstocks

Soybean comes from the Glycinemax L. as a legume with an annual cycle from the Fabaceae family [130]. United states of America, Brazil and Argentina are the leading producers
accounting for 80% of all global production [131]. However, china is increasing production and catching up, hence expanding its role in the near future considerably. It is important also to note that china imports almost 1/3 of the world's production of soybean. This accounts for 62% of all global soybean trade [132]. Soybean as a grain contains 14% to 17% oil, 33% to 40% protein [133]. In the period of 2013 to 2015 soybean was responsible for over 65% of the global supply of protein supplements and feeds [134]. Soybean meal is the extraction obtained from the oil extraction process and one of the most important source of human and animal protein [135-138].

Table 8: Shows major vegetable oil producers and their main source of feedstock [12, 125-129]

Country	Production (1000t)	Main feedstock
USA	4.150	Soybean (53%)
Brazil	3.000	Soybean (77%)
Germany	3.000	Rapeseed (>50%)
Indonesia	2.750	Palm oil (100%)
Argentina	2.550	Soybean (100%)
France	1.850	Rapeseed (>50%)
Thailand	1.050	Palm oil (77%)
Total Europe	10.200	-
Total world	26.150	-

In addition soybean extracts are used in the textile and plastic industry as molds, glue or adhesives for laminated paper and wood [139]. Soybean is also the main raw material in the vegetable oil industry, whose production by 2012 exceeded 40 million tonnes representing 25% of global production of vegetable oils [140]. Environmentally soybean compared to fossil energy consumption over the biofuel life ranges from 2 MJ/MJ^{-1} to 8.5 MJ/MJ^{-1} [141-143]. On the other hand, comparatively its GHG life cycle varies from 8 gCO$_2$e MJ^{-1} to 42 gCO$_2$e MJ^{-1} of biodiesel [143]. However, in the literature surveyed only one researcher reported higher values of 50 gCO$_2$e MJ^{-1} [142]. This was attributed to the assumption adopted during life cycle analysis hence the difference in the values of the findings [114].

Figure 7: International prices of vegetable oils from 2000 to 2014

3.3. Rapeseed Feedstocks for Biodiesel Production

Known scientifically as Brassica hapus L., rapeseed is also known as colza and one of the most cultivated crops globally only beaten in acreage by soybean [140]. Its main geographical origin is the Mediterranean area and northern Europe. Among the leading global producers of rapeseed include China, Germany Canada, India and France accounting for 65% of global production [140]. Table 9 shows Oil yield for major non-edible and edible oil sources and feedstocks.

In Europe rapeseed is the main plant biofuel source accounting for 55% of the total European production of biofuel feedstocks and 68% of global feedstock production in 2016. However, its market share has been slowly decreasing as more recycled oil and alternative feedstocks eat away its market share since 2016 [144]. Other usefulness of rapeseed is in the protein range and food supplements, rapeseed can be used as an animal feed for pigs, cattle, sheep and poultry [145, 146].

Table 9: Oil yield for major non-edible and edible oil sources

Type of oil source (feedstock	(kg oil/ha)	Oil yield (Wt %)	Prices (USD/ton)	Literature references
Jatropha	1590	Seed:35–40 kernel:50–60	370	[5,6]
Rubber seed	80–120	40–50	1250	[7][147]
Castor	1188	53	1600	[5,9][148]
Pongamia pinnata	225–2250	30–40	286	[8],[149], [150]
Sea mango	N/A	54	N/A	[9]
Edible oil Soybean	375	20	684	[5,11]
Palm	5000	20	600	[5,12
Rapeseed	1000	37–50	683	[5,13

Rapeseed meal is known to contain 34% to 38% protein with an oil range of 34% to 40% [151]. However rapeseed has an unpleasant flavor due to glucosinolates which sometimes lead to toxicity in combination with the enicic acid [152]. This is one of the major drawbacks especially on cost reduction in related industries even though utilization can be undertaken by processing [153]. As a source of feedstock rapeseed has low levels of saturated fats coupled to high levels of monosaturated fats with omega 3 and 6 making it a healthy source for human consumption [96]. As a plant feedstock rapeseed ensures a steady acreage yield at stable production over a range of time [154] while allowing intercropping. Compared to soybean, and palm oil, rapeseed performs well in emission studies for example it reduces smoke, PM, and UHC [155]. Environmentally, life cycle studies report a wide range of mixed results. Nevertheless it reduces GHG emissions from 85% to 40% and fossil energy use from 83% to 43% compared to petroleum fuels [156].

3.4. Palm Oil Feed Stocks

Palm originate in West Africa and is used as the main feedstock for palm oil production. Palm oil plant has a life cycle of 26 years [157]. Palm plant as a feedstock generates co-products of 20% to 21% oil, 17% kernel oil, 3.5% palm kernel cake, 22% to 23% empty fruit bunches, 12% to 15% fiber, 5% to 7% shells and 50% liquid POME [158]. Palm oil plants are natural in Central America, north and south. Palm oil is rarely planted commercially due to its low oil content. As such attempts have been made to breed Elaeis OLEIFERA and Elaeis guineensis species to improve disease resistance, palm tree height and increase unsaturated fatty acid [159].

Palm oil as a biofuel feedstock is one of the leading vegetable oils with over 50 million metric tonnes accounting for 30% of global palm oil production in 2013 alone. However, by 2017 the production of palm oil rose to 37.6% (70.3 million metric tonnes) [124]. Nevertheless, as a feedstock only 10% of its global production goes to bioenergy and biofuels [160]. The leading producers of palm oil are Indonesia and Malaysia which control 85% of global production [130]. Palm oil in south east Asia was introduced in Malaysia in 1870 from Singapore [161]. As a feedstock, palm oil has a number of uses considering its byproducts. For example palm oil is used in the food industry as butter, solid fats, cooking oil, industrial oil, baking oil or as a substitute for trans-fat [159, 162].

Additionally, palm oil is applicable in the cleaning, cosmetic, and soap and detergent production. In the chemical industry palm oil is used as a lubricant and in oil production [162]. In waste to energy reform, palm oil shells and fiber can be used in chain production of steam for electricity in co-generation systems. For example, in literature surveyed it was reported that for a palm tree bunch the energy is 300 kWh and 600kg of steam [163, 164]. In literature-surveyed palm oil as a biofuel feedstock has limitations which include; (i) Low supply of seeds, hence poor production [165], (ii) Lack of research in co-product industries and comprehensive economic data due to logistical issues [166], (iii)The long cycle of the palm tree growth [130].

3.5. Cotton Seed Feedstocks

Cotton which is known scientifically as Gosypium hirsutum L., comes from the family of Malvaceae and is grown globally for the production of fiber used in the textile industry [167]. Cotton comprises of 65% seed and 35% fiber [168], oleic acid 15% to 20%, stearic acid 2% to 5% [167], with major fatty acid being palmitic acid at 27.76% while linoleic acid stands at 42.84% [169]. Nevertheless cotton as a feedstock for biofuels has a low oil content at 16% to 23% but with breeding and selection researchers have observed an improvement of 5% in crop oil yield [170].

However, what is of great interest is the cotton meal, which is heavily rich in protein second only to soybean after oil, has been extracted. The cotton meal is mainly used as an animal feed although it has other vital uses such as being a fertilizer, food flour or as a dye in the textile industry and as a biodiesel feedstock [171-174]. Globally cotton is the ninth highest oil producing plant [175]. Despite its low oil content cotton is advanced as a biofuel feedstock due to lower smoke and particulate emissions compared to other feedstocks such as palm oil discussed in earlier subsection

[155]. Nevertheless it has limitation which include poor quality oil requiring pre-treatment hence increased cost of biodiesel production when used as a feedstock [114]. Figure 8 is showing a cottonseed oil sample after extraction from cotton seed.

Figure 8: A sample of cottonseed biodiesel layer of cottonseed oil [167]

3.6. Sunflower

Known as Helianthus annuus L and a dicotyledon, Its oil content varies from 38% to 50% based on the species of variety employed [176, 177]. Russia is the world leading producer of the sunflower crop with a 21% of the total global landmass, others include Ukraine at 12.97%, Argentina at 11.83%, China at 7.17%, Romania at 6.56%, France at 5.56% India at 4.77%, USA at 4.14% and Spain at 3.09% [178]. Globally sunflower covers an area of 23.7 million hectares with an annual production of 1322 kg/ha on an expected production of 2.3 tonnes to 2.5 tonnes/ha [179].

Beside its potential for oil, sunflower grain produces 250 kgs to 350 kgs of meal shell and 45% to 50% crude protein per tonne of grain [180]. The co-products of sunflower can be utilized for other uses such as in packaging materials, animal feeds, forage silage or as green manure or as a biofuel feedstock [181, 182]. Sunflower in the last decade has gained prominence as a feedstock, for example in Brazil 62000 tonnes were realized in the 2015 to 2016 season. However this was a decrease compared to the previous seasons due to a drop in the acreage under cultivation [183]. The introduction of new crops such as corn saw farmers shift to corn due to low cost of production of inputs and processing [184].

Sunflower is a good feedstock for biofuel due to its drought resistance to cold and heat conditions besides being less likely to be influenced by latitude, longitude or photoperiods [185]. As a feedstock sunflower can be grown in rotation with other plants (intercropping), which offers higher returns to farmers and producers [186]. The main limitations of sunflower as biofuel feedstock include High international market prices [134], besides a cloudy nature as temperatures drop due to its high wax content [187]. Additionally Sunflower contains linoleic, oleic and linoleic acids, which account for almost 70% hindering oxidative

properties, which offer stability, hence rapid lipid oxidation of its oil [188-190].

3.7. Jatropa Curcas

This is a plant cultivated almost globally for the production of biofuel although it is a non-edible plant. Jatropa seeds are composed of 37 % shell, and 63% kernel (dry matter) with a protein content of 35% and a 15% of oil [191]. Jatropa has been on the radar of biofuel developers and producers due to a number of factors. These include low production cost, Water stress tolerance, High oil content and yield, Resistance to pests and diseases; Resistance to drought, Good adaptability to semi-arid wastelands, hence reduces competition with food crops for arable land [36, 192].

Other uses of Jatropa as a feedstock include as a cooking fuel, insecticide, soap making, and for medicinal purposes [191]). Additionally Jatropa can be used as an organic fertilizer, livestock feed and a biogas feedstock [193, 194]. On the other hand, the limitations of Jatropa arises: From uncertainties around its seed yield range which is 2 to 12 Mg/ha leading to poor economies of scale for a feedstock [36]. Secondly, even when it seems adaptable to drought during flowering studies have shown it needs watering otherwise the yield drops significantly.

In other words, Jatropa capabilities are not exploitable and applicable simultaneously. This is evidenced by the moisture and nutrients influence on yield [195]. The third limitation is due to its vulnerability to viral infection [36, 196, 197]. The fourth limitation is due to lack of scientific validation regarding the basic ecological and agronomical properties. For example, yield, potential production and costs, and breeding programs have not been identified in the literature reviewed.

4. Introduction to Non-Edible Vegetable Oil and Emerging Feedstocks

The use of non-edible feedstocks for biodiesel production is an answer to the challenges of edible oil as biofuel feedstocks. Non-edible feedstocks are gaining attention, as they are easily available globally in wastelands in unsuited for food crops. This eliminates competition for food, reduction in deforestation rate and co-products. Although there is no direct competition for food versus fuel, Nevertheless, there is indirect competition for land. Among the non-edible plants used for biofuel production include; Cotton (Gosypium hirsutum), Castor (Ricinus curcas), Jatropa (Jatropa curcas), Rubber (Hevea brasiciensis), Mahua (Madhuka indica), Ethiopian mustard (Brassica carinata), Castannola (Terminalia catappa) [198-202]. Figure 9 is showing Waste cooking oil production based on country and global contribution.

In India, there are two major species of the genus, Madhuka longifolia and Madhuka indica, on the other hand rubber seed tree is mainly in Indonesia, Malaysia, Liberia, India, Sri-lanka, Sarawak and Thailand. Rubber as feedstock contains seed kernels of 40 % to 50% brown oil [203]. Another non-edible oil biofuel source is neem (Azadirachta Indica) a natural plant of the Indian subcontinent and commercially grown in India, Bharma, and

surrounding regions. Jojoba oil is another non-edible oil a shrub in southern Arizona. Therefore, in Literature reviewed non-edible oil studies as alternative biofuel feedstocks fill many researcher reports such as [44, 201, 204-207].
Figure 9: Waste cooking oil production based on country [10, 14-15]

4.1. Waste Cooking Oil Feedstocks

Waste cooking oil is also known as yellow grease due to the fact that most waste cooking oil FFA content is 8% to 12% wt. Waste cooking oil offers a high potential as a feedstock to biofuel production due to low cost. As modernization grows and more people shift to urban lifestyles the total quantity of waste cooking oil has been growing since 2008. Waste cooking oil can be collected from households and hotels and restaurants, fast food outlets with heavy use of frying activities [208]. The disposal oil from these activities is problematic as it contaminates ground water. However, their cooking oil sources differ greatly since their base material are plant lipids like corn, margarine, coconut oil, palm oil, olive oil, soybean oil, grape seed oil and canola oil. The most commonly used material for vegetable oil is palm oil [209].

The use of WCO as a biofuel feedstock does not come at the expense food versus energy or land resources. Instead it's a sustainable use of resources which reduces adverse effects of water pollution and blockage of water and drainage sewage system [210]. Presently WCO has been heavily utilized in soap manufacturing, although the soap produced is of poor quality hence its utilization has been low [211]. The main objective of using WCO is to transform it by reducing its viscosity to values close to diesel oil. Globally over 15 million tonnes of waste cooking oil are produced annually and if converted it can meet and satisfy the world demand of a biofuel feedstock [212]. Production of WCO oil as a biodiesel can contribute to a saving 21% in crude and a 96% energy saving [213].

Non-edible vegetable have potential to substitute a global fraction of petroleum diesel [214]. Plant oil feedstock when processed to biodiesel reduce particulate and sulfur emission and aromatic compounds [215] compared to petroleum diesel [216]. In 2009, the production of FAME waste oil was 11 tonnes with a

demand increase of 3.5 metric tonnes/year. However, the production of waste oil in Europe, north America and in selected Asian countries such as China combined had a production of 16.6 metric tonnes [217, 218].

For example in 2014, China alone had a total WCO production of 1.8Mtonnes [112], pushing China to 3.4 Mtoe hence accounting for 2.9 % of global biofuel production, distributed in 50 plants. In other words, currently, the main leading feedstock of biofuel production in China is waste oil. However its main limitation is waste oil increased prices due to rapid development of the biofuel industry in the last decade [219].

The use of waste cooking oil has a number of challenges due to FFA and presence of high moisture, which make it hard for transesterification. Although chemical and physical properties of waste cooking oil are similar to fresh edible oil they differ from source to source [217]. For example, the water content and FFA in WCO compared to fresh edible is higher due to the frying process. During frying edible oil undergoes higher heating temperatures of 160 °C to 200°C for a long and a sustained period.

As a result, increased viscosity specific, specific heat, surface tension, colour and fat formation occur. Hence reactions of thermolytic oxidative and hydrolytic nature are observed [220]. Nevertheless, current research centres in operation and management of waste to energy with the focus on the following two key areas. (i) The supply chain incentive, and (ii) regulation policies for WCO to energy.

There is a growing importance on the use of subsidies as a measure of addressing issues of waste to energy based on the model dynamics [221-229]. Regulation policies of waste cooking oil to energy report illegal transaction in waste cooking oil utilized as barriers to expanding WCO utilization. This need increases a requirement of standard inspection and regulations with dedicated infrastructure to help in recycling [223, 230, 231]. For example, in America in south California and north western Mexico [232].

4.2. Animal Fats Feedstocks

Tallow is the most common commercially available feedstock from animals for the production of biofuels [233]. The production of meat in the last decade increased significantly to 237.7 million tonnes in 2010 represented by 42.7%, 33.4% and 23.9% for pork, poultry and beef. Nevertheless, the projected growth of these resources increased steadily and now stand at 266909000 million tonnes annually [124]. This corresponds to a representation of 39.76%, 37.3% and 22.97% for pork, chicken and beef. However lard and chicken fat [234] are also commonly used in addition to insects and all other high fat containing animals.

The main reason for use of animal fats as feedstock source is due to their cheap and low prices, hence providing an economical option for biodiesel production [201, 233]. For example, since 2013 the prices of animals based fats has been $ 0.4 to $ 0.5/litre compared to vegetable oil at $0.6 to $0.8 [201]. In the world today 90% of feedstocks for biodiesel production originate from animal

fats and greases compared to the USA at 8% to 10% [235]. In other words from this report there is an observed dynamic animal protein and being expressive especially in the poultry production which shows an annual growth of 4% to 5% in the last decade [236].

Animal fats are characterized by a high content of saturated fatty acids and as biological lipid materials they are composed of TAGs and less of di (DAGs), and mono-acylglycerols (MAGs). Animal fats and greases tend to be solid at room temperature compared to liquid oil of plant origin. This is due to their high content of SFAs [233]. Tallow is a waste final product generated in slaughterhouses and meat processing facilities, whose major composition is myristic, palmitic and stearic acids with tallow and pork lard composition of 40% SFA.

However in the literature surveyed the composition figure is higher for tallow at 45.6%, mutton tallow at 61.1%, lard at 39.3% and chicken fat at 32% [207]. Saturated fatty acids present increased demerits on the physical and chemical properties of biofuels. For example fatty acids cause poor cold properties while unsaturated animal fat content offers advantages of high cetane number, oxidation stability and high calorific value [234]. Thus considering the composition of animals fats as a source of biofuel requires synthesis at elevated temperatures compared to processing vegetable oil [237]. Animal fat greases are classified into two types as reported in literature. This classification is based on the level of FFAs,[207] such as Yellow greases with FFAs of ≤15% w/w and Brown greases with FFAs >15%w/w.

In theory animal fats are thought to contribute to oxidative stability for biodiesel, due to the lack of polysaturated fatty acids such as linoleic and linolenic commonly found in vegetable oil [238]. However comparatively in real-life, animal fats are unstable due to lack of anti-oxidants in their structure. Hence use of animal fats and greases eliminates the need for disposal and result in utilization to the supply of biofuels [239]. Like all feedstock, animal fats have limitations, for example, animal fats contain phospholipid or gums, which are insoluble in water.

These precipitates can plug fuel filters and render them ineffective. Secondly animal fats oil biodiesel deactivates exhaust pre-treatment devices in diesel vehicles [238]. Thirdly is the problem of the presence of high sulfur content mainly from sulfur containing amino acids traced from animal feeds [240]. Since animal fats are highly viscous and solid at ambient temperatures due to unsaturated fatty acids. This leads to poor atomization properties, hence incomplete combustion, while increases emissions of pollutants and particulate matter [241]

4.3. Algae Oil Feedstocks

The microalgae family contains more than 100000 species which can be utilized for biodiesel production [242]. However the most one with the highest probability of development in literature surveyed are green algae, diatoms and cyanobacteria (blue algae)

[243]. Microalgae content is projected to hit 70% of dry matter and a yield of 90 tonnes/ha of cultivation [244].

Algae grow rapidly in different environmental conditions, while utilizing efficient use of water CO_2 and nutrients on the water surface [245, 246]. This requires if planted in a pond stirring becomes a necessity to ensure accessibility to CO_2 [247]. In addition to their faster growth and high yield content per acre, microalgae oil contains properties identical to petroleum fossil fuel. This is especially true for viscosity, density, flash point and the hydrogen carbon ratio [248].

Use of microalgae as an alternative fuel is being advanced as the fourth-generation biofuel as technology for producing and processing biofuels increases. This will enable its production as a biofuel to be cost effective for large-scale production in the near future. Microalgae compared to land-based plant feedstocks have efficient photosynthetic process in converting and utilizing solar energy into biomass [249]. The main algae, which can be utilized for the production of biofuel, are cyanobacteria as micro or macro algae.

Their sizes determine and influence the production process techniques. For example microalgae produce high oil content but their harvesting is costly due to low efficiency, cell size and low biomass concentration [250, 251]. On the other hand compared to cyanobacteria which are macroalgae the conversion rate into biomass is good but with a complex membrane rapture [252].

In the literature surveyed to produce algae it requires cell growing, separation, and lipid extraction [246]. The main microalgae growing technologies available vary but open pond and closed photobioreactors are commonly utilized [253]. In harvesting microalgae to extract oil physical chemical and enzymatic techniques are employed [254]. Processing of microalgae oil for biofuel production commonly takes the same route of processing and technologies used in vegetable oil and animal fats. It is important to note that fourth generation technologies for production of algal biofuels are still under research and development.

A number of questions remain unanswered. For example, in literature surveyed on algal feedstocks advantages and disadvantages of growing microalgae in fresh and salty water is not available in literature for all types of algae marked for biofuel production. Another factor noticed from literature surveyed is lack of feasibility studies whose data for biofuel microalgae is unavailable. For example, the cost of production for algae is projected at $0.9/kg to $2.55/kg in open pond systems compared to $1.5/kg to $5.5/kg using photobioreactors.

This is despite development in more realistic and appropriate technologies used for algae on commercial scale [243]. The methods utilized in the farming, harvesting and oil extraction for biofuel production still face surmountable difficulties. Nevertheless, microalgal diseases such as contamination are still not clear, although biofuel especially in chain and value addition offer high returns compared to other feedstocks [255]. If

technologies are developed for value addition such as on pharmaceutical, nutraceuticals, biodiesel commercialization etc. could increase economic viability of algal feedstocks for production [256].

4.4. Waste Biomass Feedstocks

A number of waste resources arise in line with the diverse human economic and social activities. However, utilization of natural resources such as water, air, soil etc. are being threatened. This solid biomass wastes take many forms either as solids. Although classified as waste they can be reused and turned into energy resources for industrial and domestic purposes [257]. In the current world energy scenario, a number of waste to energy, technologies have emerged. These technologies convert waste biomass into various forms of fuel before utilization as biodiesel [258].

Bio-waste feedstocks differ greatly from primary sources such as coal, in both energy content and physical properties. However compared to coal bio-waste comprise low carbon, high oxygen content, high silica and potassium, less aluminium and iron, low heating values, high moisture, low density per unit of mass and friability [259]. Figure 10 shows the Main waste to energy (WTE) technologies available currently for the utilization of biomass waste.
Figure 10: Main waste to energy (WTE) technologies adapted from [259].

However, utilization of natural resources such as water, air soil etc. is being threatened and takes many forms either as solids and can be utilized and reused to become energy resources for industrial and domestic use [260]. In the current world energy scenario, a number of wastes to energy technologies have emerged. These technologies convert waste biomass into various forms of fuel before utilization as a biofuel or biodiesel [259]. Depending on the use of the technology so is, the name derived.

For example in the literature surveyed technologies for fuel production are referred as waste to energy technologies (WFT) [259].The waste technologies include the following categories of utilization; Physical methods, Thermal methods and Biological

methods. Globally these technologies have grown to nearly 750 facilities with a capacity to process 140 million tonnes of waste annually [261]. Energy from waste can be treated and compressed to solid fuel or converted into biogas, syngas, or combusted to produce heating for steam production in power generation. The gases produced in such cases include methane, CO_2, hydrogen, and H_3CO or liquid fuels such as ethanol and biodiesel [262].

Biomass to energy has potential feedstocks, which form its main potential line. These include wood, short rotation wood, crop waste, agricultural wastes, short rotation herbaceous crops and animal waste [263]. It is important to note that biomass accounts for 35 % of all energy consumption in developing countries [264, 265]. Nevertheless, biomass utilization carries a huge untapped potential for environmental and energy production, especially agricultural based plants absorbs CO_2 during growth and emit it during combustion.

This helps in the recycling of CO_2 in the atmosphere hence climate change mitigation [266]. Since biomass feedstocks contain lignocellulosic materials, they inherently produce high content of polymers such as cellulose $(C_6H_{10}O_5)x$, hemicellulose (xylas) $(C_5H_8O_4)m$, lignin $(C_9H_{1[267]0}O_3(OCH_3)_{0.9-1.7]n}$ and sometimes protein. This contributes to renewable energy sources, which are natural, sustainable, inexpensive and eco-friendly feedstocks [260]. Wood biomass thus forms the bulk of waste biomass accounting for 64%, municipal solid waste 24%, agricultural waste 5 % and landfill gases accounting for 5% [268, 269].

4.5. Bioethanol Feedstocks

Bioethanol is one of the leading clean and renewable energy sources in the transportation industry today. Globally bioethanol has seen a growth from 4.8 billion gallons in 2000 to 16 billion gallons in 2007 [270], representing a 30 % increase within the mentioned period. However, current statistic trends paint encouraging prospects, indicating for example that since 2007 with global production of 60 billion litres of bioethanol, by 2017 the figures stood at 143 billion litres annually [271].

Bioethanol has many advantages compared to fossil fuels such as high octane, which prevents knocking in internal combustion engines and high oxygen content, which helps to produce less greenhouse gas effects [272-274]. This advantages Allows direct use of ethanol in the automotive industry for internal combustion SI engines without modification and bioethanol works with other oils as a blending agent.

Currently the USA and Brazil are the leading global bioethanol producers with the two countries combined contributing 75 % to 80 % of the total global production [270, 273]. Using corn grain the USA has 187 bioethanol plants spread across different states to produce ethanol [275]. On the other hand, Brazil produces bioethanol from sugar cane based feedstocks only, compared to the European Union who use wheat and sugar beets. In 2013, Brazil produced 37 billion litres compared to European

Union production of 5.785 billion litres of bioethanol and is expected to double its production in the near future.

Due to the reservation on plant-based feedstocks, in future renewable and sustainable feedstocks will dominate energy sources, hence replacing fossil fuels. Bioethanol has been a dominant feature of biofuels, nevertheless technology is moving to microalgae carbohydrates as potential feedstock [276-278]. Microalgae biomass feedstocks contain high contents of carbohydrates, (glycogen, starch, and cellulose) that through fermentation can be converted to sugars for production bioethanol [279, 280].

5. Factors Affecting Biodiesel Production

5.1. Biodiesel Quality

The quality of biodiesel of the feedstock used to produce a biodiesel determines the type of catalyst and process applied to produce FFA for the biodiesel production. Nevertheless, the biodiesel feedstock selection and determination are an important factor, inconsistence in the selection of feedstocks can lead to problems of quality and over-budget production. Suffice to mention that biodiesel fuels have standards recommended for their production such as ASTM D675 and EN14214. For example, feedstocks with more than FFA>3wt% cannot use homogeneous catalysts like NaOH, KOH or methoxide due to unwanted side reaction.

In order to produce biodiesel commercially the commonly used basic catalysts such as NaOH, KOH, or Methoxide are utilized. In addition, as a general rule acid catalyst are more appropriate for high FFA content feedstocks. On the other hand, homogeneous catalysts require less alcohol; have a shorter reaction time even though they result into complex products. This leads to required product purification compared to heterogeneous catalysed transesterification process. Development in catalysts has ensured use of a wide range of catalysts for biodiesel production such as heterogeneous and homogeneous acids, bases, sugars, lipases ion exchanges resins, zeolites etc. A number of researchers in the literature reviewed mention biodiesel quality as a factor influencing production include [135, 281-286].

5.2. Cost of Biodiesel Feedstocks, Investment and Material

Another factor that influences biodiesel fuel production is the higher cost of production arising from erratic feedstock prices as biodiesels gain widespread application. This is increased by the chemical composition due to their relatively low energy content increased NOx emissions compared to fossil fuels such petroleum diesel [287]. Price determination is an important factor of biodiesel production system and processing.

In every production system of biodiesel, a 50% feedstock price should be the guiding principle of all cost of production. Another factor to consider and is proposed in literature reviewed is price fluctuation especially when promoted through government policy shifts in relation to subsidies and tax incentives [8, 288, 289]. In other words when alternative sources

are promoted there is diversification and stock piling to create demand and stabilize stabilization [287].

A number of researchers have reviewed and reported on this concept and can be read in some references provided here such as [239, 290-295]. In all the literature surveyed there is agreement that the higher cost of biofuel production is a major barrier for acceptability and use of biodiesel as an alternative fuel [296, 297].

In literature surveyed, a number of suggestions thus come forward to address this issue. For example, use of cheaper alternatives catalysts Coupled to conversion technologies with lower energy input and faster transesterification reaction [201, 296, 298-301]. Another commonly suggested solution in literature surveyed is the diversification of feedstock by increasingly moving to material materials, not formerly considered as feedstock [302-304]. Figure 11 shows the effect of government policy and promotion to create demand and stabilize prices on palm compared to petroleum diesel.
Figure 11: Effect of government promotion on price of feedstock price fluctuation 1997-2012 [305]

5.3. Effect of Tax Policy Subsidy and Regulation

In order to empower biofuels and bring them into mainstream economy as usable fuels there is need to implement laws and regulation. These laws should include taxes, policies and subsidies from government as incentives to develop this sector. Particularly in the area of enforcement which mostly needs guidance in order to improve the basic economics of biodiesel.

In the literature surveyed for example, European Union has proposed a renewable energy policy for transport fuels to ensure a viable expansion of the biofuel industry in the near future. As a result, the European Union introduced a blending target in their range of biofuels, which involved hitting a target of 5.75% to 10 % by 2020. Additionally, an amendment to the fuel quality service brought into service a mandatory 6% reduction of GHG by 2020 for transport fuels and non-road and transport engines [306].

Between 2000-2013 biofuels such as ethanol and biodiesel grew exponentially in terms of output from 64 million to 23 billion litters and 0.8 to 14.7 billion litres respectively [307]. For example the USA also crafted a renewable fuel standard program to increase the share of biofuels by 10 % by 2017 and beyond

since 2005 [308]. This increment in biofuel production is purely driven by government policy interventions. This is particularly so in the USA where financial incentives are almost guaranteed for producers [309].

Due to policy shift and incentives, a larger share of global biofuel market has been taken from ethanol to biodiesel in the market [310]. In other words, appropriate policies, tax, mandates and incentives can successfully drive growth of biodiesel. However, it is important to note that biodiesel incentives are distortionary in nature as biofuel use uniquely food crops and multiple feedstocks [311].

In other words, in 2006 for example 20 % of all USA corn production went to biofuels compared to ethanol. Although indicating a positive development in the growth of biofuel, this led to increased producer prices between 2003 to 2008 [312-315]. On the issue of regulation and GHG emission studies in literature reviewed, indicate a negative impact in reduction for specific types of crop feedstocks and their processing techniques. For example, this is revealed in studies conducted by researchers such as [316-318].

5.4. Competition with the Food Industry Chain

The increased biofuels production supported by the government policies interferes with food industry chain such as the oleo chemical industry. These industries use the same feedstocks as biofuels hence the rapid growth in the biofuel, which threatens their growth in the future. This is true considering the level of increased feedstock prices yearly. In other words, resource availability will be constrained hence causing a negative impact on the economic value of the food chain [288, 319, 320]. As the Competition for feedstock resources increases with greater incentives to encourage producers meet the demand. This leads to increased demand for resources and with it increased prices for land resources and prices for food [321].

In order to implement a sustainable biodiesel production strategy. The focus should not only be on reduction of GHG emissions but rather a complete package of policies, which support economic and environmental sustainability. However, one notes that the increased biofuel production from land resources and plant feedstocks is the leading cause of deforestation.

In recent trends governments defend their guidelines on implementation of sustainable policies on deforestation as is the case in brazil though it is not sustainable [288]. The second issue on sustainability is related to animal habitat destruction when deforestation is carried in large scale with some of these animals facing extinction [322]. This is due to replacement of virgin forests with plantations of plants such as palm oil. This can led to global warming especially in lower latitude areas while causing overcooling in high latitudes [323]. Use of biofuel in the transport industry when fully running is hoped to stabilize the global carbon cycle although deforestation will negate it. A practical example is in Malaysia where as a consequence GHG emissions increased to about 40 million tonnes of CO_2 up from 5 years earlier at 20 million tonnes of CO_2 [324, 325].

Another area that is often ignored in literature surveyed is change in land use, even with sustainable programs and policies. This problem is acute and severe in America, Mexico, and brazil where abuse of power forces farmers to sell land and move out leading to large population displacement and demographic changes [320]. However the European union seems to contain the problem by putting requirements for types of land to be used for biofuel production plantations as pointed in a number of literature surveyed such as [326, 327].

5.5. Biomass composition

In biomass composition, the most influencing factor is the carbon to hydrogen ratio. In other words, due to the differences in decomposition temperature for each of the constituents of biomass. These constituents thus undergo decomposition hence varying product yield. For example, in literature surveyed the following are the temperatures of the three main ligno-cellulosic biomasses [328-330]. This include Hemicellulose with a range of 150℃ to 350℃, Cellulose with a range of 275℃ to 350℃ and Lignin with a range of 250℃ to 500℃.

5.6. Particle Size

The particle size and composition, the physical structure and shape have a greater influence on the pyrolysis process products when exposed to heating [331]. For example, fine particles offer less resistance to escaping non-condensate gases and vice versa. This behaviour affects product yield [332]. In other words, size reduction of biomass before product extraction offers greater surface area for mass transfer. This enhances diffusion of the active components within the feedstock [333]. In literature surveyed, most scholars report these factors as variables in optimizing bio-oil production. Among the scholars who take this position, include the following researchers [334-337].

5.7. Effects of Temperature on Pyrolytic Process

Temperature is an essential factor of influence on pyrolytic product yield. Pyrolytic temperature defines the rate of increase from ambient to maximum until the completion of the process. Pyrolysis temperature thus influence composition and product yield and release rate of the constituent gases. Besides these components, the char produced depends on the pyrolysis temperature [336, 338, 339].

In other words, as the temperature of the reactor increases, the carbon content of the pyrolytic char products increases. This is due to the increase in surface area of the char. However beyond 1173k the temperature decreases slightly due to structural ordering and micropore coalescence with increasing temperature for char above 1073k [340, 341]. Increased heating rate results into a decrease in the carbon content while increasing hydrogen and oxygen content of the char [342].

In literature, surveyed pyrolysis takes many forms of processing but four forms of the criteria are critical namely: Slow

pyrolysis, which is a carbonization pyrolytic process with a primary goal of producing charcoal and char. This is the oldest form of pyrolysis operating at below <400°C over an extended period. Fast pyrolysis is tailored for liquid or bio-oils where biomass is subjected to rapid high temperature heating before decomposition begins. The rate of temperature increase can range from 1000°C/s to 10000°C/s. Nevertheless, the peak temperature is maintained between 650°C to 1000°C. The main features of fast pyrolysis are high heating rate, reaction temperatures of 425°C to 600°C, short residence time (<3s) and rapid cooling of the gas product.

Flash pyrolysis where rapid heating of biomass occurs in the absence of oxygen at moderate temperatures of 450°C to 600°C. In other words, the products of both condensable and non-condensable gas leave the reactor unit faster (short residence time) of 30ms to 1500ms [331]. Ultra-rapid pyrolysis, which borders on the extreme fast mixing of biomass with heating and a carrier solid leading into high transfer of heat and rate of heating. Ultra-rapid pyrolysis utilizes temperatures of 1000°C for gas components compared to 650°C for liquids in order to minimize product yield [343, 344]

5.8. Effect of Heating Rate Change

It is important to note that the heating rate of biomass particles from rapid to moderate 400°C to 600°C leads to high volatile yields by producing more char [345]. Owing to fast volatile material release which causes internal pressure and coalescence of smaller pores leading to increased surface area [346]. A number of scholars have studied this phenomenon and reported on it widely such as [347-349]. Nevertheless in literature surveyed it is widely reported that high heating rates of 900°C, a lower surface area is produced and vice versa [350]. In other words higher heating rates cause high char yield interior temperatures, partial graphitization and curtails development of large surface areas [351].

5.9. Effects of Residence Time

Residence time Space is inversely proportional to space velocity of the reactants in a pyrolytic reactor [352]. In other words, residence time has a greater impact on conversion and product yield in the pyrolysis process. Studies conducted on biomass gasification from kinetic models report positively on this influence of residence time. For example, the following researchers report how conversion increases in the first 20s and their after the chemical reaction slows down as reflected in a number of studies such as [353-356].

6. Biodiesel Production and Processing Techniques

6.1. Introduction to Production and Processing Techniques

Biofuels have increased in demand as the global energy demand grows significantly, although with a requirement for clean fuels [297]. Biofuels are degradable and promising fuels compatible with environment preservation and biodegradable [297]. Although biodiesel is advantageous as a biofuel, its major

hindrances are high cost of production, processing and raw materials (feedstock). These costs account for 80% of the total cost of production, making biodiesel more expensive than fossil fuels which it is intended to replace [357]. However, one of the most glaring advantage of biodiesel is its use without modification for diesel-powered engines. Biodiesel use reduces emissions of PM, sulfur, UHC, and carbon monoxide due to a high oxygen content and carbon to hydrogen ratio [358, 359].

In literature surveyed a number of researchers have used many production and processing techniques. However, it is clear from the studies that feedstocks dictate and influence these techniques of production and processing. For example, thermal cracking (pyrolysis), catalytic cracking, Nano-catalytic processing, catalytic hydrocracking, micro-emulsion using solvents and surfactants, transesterification, bio-catalysis processing supercritical production processing.

The following literature references shows extensive work that has been done and reported in modern production techniques as knowledge and skills increase in biofuels; [205, 222, 360-365]. Nevertheless, the number of production methods has been increasing as the material science and biochemical-engineering sections grow. This has brought new and novel concepts as will be seen in the preceding sections of this review.

6.2. Biodiesel Thermal Cracking (pyrolysis)

Thermal cracking's main role is to decompose, rearrange and combine hydrocarbon molecules through application of heat. In other words, thermal cracking decomposes high molecules-weight hydrocarbon components into lower molecules weight. This makes the products more valuable hydrocarbon derivatives with lower boiling point species [366], such as gas liquids and char. Pyrolysis as a thermochemical decomposition process has similarities or overlaps with other processes such as carbonization, dry distillation, devolatilization, destructive distillation and thermolysis.

Nevertheless thermal cracking (pyrolysis) is similar and identical to gasification process [332]. Gasification is more external with chemical reactions compared to pyrolysis, carried out in low temperature settings of 300°C to 650°C or higher temperatures of 800°C to 1000°C. The main factors, which influence the process of thermal cracking, include feedstock type, residence time, operating temperatures and pressure. Many of this factors in literature reviewed are discussed and their influence on thermal cracking processes. However, these factors are discussed here briefly but further reading can be done from the references provided here in this section. The process of cracking alternative oils mainly vegetable or animal oils takes two main forms as mentioned in the following references [367-369].

Primary cracking where decomposition of triglycerides molecules occurs, forming acid species by breaking C-O bonds of the glycerides and triacyglycerides chain. Secondary cracking which involves degradation of the produced acids in the primary stage while forming hydrocarbons with properties identical or

similar to petroleum derivatives. The initial products of pyrolysis are condensable gases and solid char. However, further classification of the gases brings a non-condensable class such as CO, CO_2, H_2 and CH_4, liquid and char. In other words, this processes go through gas phase homogeneous reactions, partly gas solid phases heterogeneous reactions [332].

6.3. Chemical Catalysis Production Technologies

Chemical catalysis is the science of materials, which accelerate chemical reactions without affecting the equilibrium position of the thermodynamic reaction. Under this method which mostly describes use of catalysts both alkali and acid in the transesterification process. Transesterification has become a more popular method due to its versatility and ease of use [370]. This scheme utilizes triglycerides by reacting them with alcohol in the presence of a catalysts to produce biodiesel (FAME) which is a type of biofuel [371]. Once transesterification process is completed it produces glycerol by products of the process [372].

Transesterification process comprises of sequent reversible reactions. The first step is the conversion of triglycerides to form diglycerides. Followed by the conversion of the diglycerides to monocerides and glycerol and producing one methyl, ester molecule. It is important to note that the transesterification process is heavily dependent on external catalysts to perform reactions. For activation catalysts in transesterification takes two main forms either biological or chemical.

The chemical catalysts comprise of both alkali and acid catalysts as homogeneous agents [373, 374]. Namely, Heterogeneous agents' solid acid or solid alkali, Heterogeneous Nano-catalysts, Supercritical fluids (catalysts). On the other hand, biological catalysts come up through genetic engineering and are mostly preferred. This type of transesterification packs an environmental advantage over all other methods as reported by researchers such as [375-377]. However since it is still under research and development, the cost is prohibitive for commercialization and laboratory use [378].

6.4. Transesterification Biodiesel Production Techniques

Transesterification is a process in which none edible oil chemically react with alcohol. It is an imperative process for the production of biodiesel as it reduces biodiesel viscosity of feedstock oil closer to petroleum diesel viscosity [379]. The catalysts used during transesterification are either acidic (sulphuric acid, hydrochloric acid or phosphoric acid) or could be base catalysts such as NaOH, KOH, carbonates and Alkoxides [380]. Base catalysts (alkaline bases) are suitable for oils with FFAs below 3-wt % [381, 382].

Due to their less damage to equipment and efficiency in production, alkaline catalysts are preferred to acidic catalysts in transesterification [383]. During processing in transesterification, it is assumed that 100kg of glycerol will form a cubic meter of biodiesel [166]. This means a large portion of the by-products of the production of biodiesel causes concern to environmentalists. Hence, a number of studies in literature surveyed have studied on how to utilize glycerol, which is a major by-product of this process. For example, a number of researchers have proposed use of glycerol in the hydrogen reaction reforming processes as aqueous or vapour [384-386].

Utilization of glycerol is hailed as a breakthrough in lowering production costs which make biodiesel fuels expensive [387]. In the production of biodiesel 10 %, w/w is glycerol, which translates to every gallon of biodiesel, produces approximately 1.05 pounds of glycerol. For example in a 30 million gallon production plant per year, glycerol is 11500 tonnes. Therefore presenting an opportunity for new application and value addition processes in the commercial and chemical industry. Nevertheless, this area in research is aging behind in terms of data and experimental work, with few researchers having published reviews. Other uses of glycerol identified in literature surveyed include: Glycerol can be used in the production of animal feeds [388]. Glycerol feedstocks are good for chemicals production for example poly-hydroxyalkanoates (PHA), and docosahexaenoic acid (DHA) [389-391]. Glycerol can be used in the production of lipids for sustainable biodiesel feedstock production [392, 393], and in the manufacture of citric acid through biosynthesis [394, 395].

The commonly used alcohols in transesterification reactions include methanol and ethanol due to their low cost and availability. This reaction of alcoholysis reduces viscosity of nonedible oil converting it into triglycerides esters [396]. In other words, transesterification converts the carboxylic acid esters into carboxylic esters. The critical lipid in transesterification include non-polar lipids, triacylglycerols (TAGs) and free fatty acids (FFAs) [397]. There are two main forms of executing transesterification, either through catalytic transesterification or through non-catalytic transesterification [204, 398].

Nevertheless there are two main challenges in literature surveyed related with these two techniques. For example it takes longer time to process biodiesel and there arises a need for separation of the oil alcohol catalyst and the impurities from saponification in the mixture [399]. Therefore, a number of factors, which affect the transesterification process according to literature, surveyed. This factors include such as Reaction temperature, Ratio of alcohol to vegetable reaction, Catalyst used, the mixing speed (intensity of mixing) and Purity of reactants.

6.5. Emulsion and Microemulsion Biodiesel Production Techniques

Emulsion or micro-emulsion processes upgrade commodity fossil fuels by forming emulsion and micro-emulsion fuels. Micro emulsion also upgrades oil from other sources or feedstocks such as bio-oil without the help of a surfactant [400, 401]. Emulsion also helps in reducing problems associated with stand-alone bio-oils, hence reduced pollutants in emissions [402]. Emulsion as an upgrading of fuel method ensures that all the components of emulsion are utilized as fuel resources compared to other techniques discussed in other sections in this review.

Emulsion is among the key techniques that solves the problem of performance and emissions prevalent in internal

combustion engines especially diesel propelled ones. This technique is a solution that relies heavily on modification of fuel so that it reduces or eliminates engine modification and redesign. Globally many countries have fuel mandates specifying quantity and type of biofuel to use although the percentages may vary from country to country [403, 404]. For example water emulsion in diesel fuel is regarded as the most economical and effective method to reduce PM and NO$_X$ emissions [405]. Emulsion in diesel fuel extends the combustible limit compared to using non-emulsified diesel fuel. This is due to the reduction of combustion temperature as the water in the mixture has a higher specific heat capacity resulting into secondary atomization as the water droplets explode in the combustion chamber [406-408]. Table 12 showing the properties, droplet size, stability, visual appearance, composition components of emulsion and micro-emulsion.

6.6. Blending and Hybridization

Blending in biodiesel production refers to mixing or combining two or more feedstocks into a final product with superior quality and desired characteristics. The blending process has a significant influence on the product homogeneity, as the biodiesel product is denser than petro-diesel besides their differences in cold flow properties. Blending of fuels depends

largely on ambient temperature because in cold weather blending may present with challenges or fail in its objectives. There are two basic methods of blending (i) splash blending (either in a tank or in a truck), (ii) in-line blending which includes sequential blending, ratio blending, hybrid blending or side stream blending [409, 410].

Biodiesel hybridization is a new concept that has come up in the study of biofuels. Hybridization is a chemical process of two or more different feedstocks comingled in varying proportions in the production of a new hybrid fuel possessing different physico-chemical properties. Since fuel properties and the physico-chemical configuration of each feedstock vary from source to source, hybridization improves and enhances these properties.

Therefore, the combination of different feedstocks' (hybridization) enhances and improves properties of the initial parent stock, by adapting to improved and high attributes. It is important to mention here that both blending and hybridization cab be *ex-situ* or *in-situ* (the former means after production while the later means before production of biodiesel). Secondly both hybridization and blending produce fuel blends with intermediate properties able to improve combustion and emission characteristics when applied in internal combustion engines [411].

Table 12: Comparisons between emulsion and Microemulsion

Properties	Droplet size	Stability	Visual appearance	Composition	Production	Interfacial tension	Energy input	Chemical reagent Cost
Emulsion	1 µm - 10µm	Kinetically stable, thermodynamically unstable	Translucent, anisotropic	Water, oil, small amount of surfactant , no co-surfactant	Mechanical agitation, ultrasound	Low	High	Low
Microemulsion	1nm - 100nm	Thermodynamically stable	Transparent, isotropic	Water, oil, large amount of surfactant, and sometimes co-surfactant	Produced spontaneously without extra energy	Ultralow	Low	High

Table 13: Potential biodiesel yield from triglyceride feedstocks

Source	Annual yield, gallons/Acre	Reference
Corn	18-20	[416, 417]
Cotton	35-45	[152, 418-421]
Soybean	40-55	[152, 415, 418, 420, 422]
Mustard	60-140	[415, 423]
Camelina	60-65	[423-425]
Safflower	80-85	[420, 426, 427]
Sunflower	75-105	[428-430]
Canola	110-145	[431-433]
Rapeseed	110-130	[235, 434, 435]
Jatropa	140-200	[436-439].
Coconut	250-300	[434, 440, 441]
Palm oil	400-650	[294, 442-444]
Algae	>5000[a]	[445-447]

7. Biodiesel Composition and Physicochemical Properties

7.1. Introduction

There is a renewed and continuous increase in the use of biodiesel globally. The composition of biodiesel plays a critical role in dictating physical and chemical profiles of biodiesel FAME materials. A number of researchers such as [215, 412] have investigated this phenomenon. Greenhouse gases, (GHG), have accelerated this global warming, which has caused climate change. The other factor is due to a growing demand and desire to go green by using sustainable energy sources (renewable).

Another important factor fueling biodiesel research and development is energy security domestically as the demand for liquid fuels and supply grows in a fast-changing landscape. In the last decade, a number of countries have embarked on legislative and regulatory pathways to encourage production and use of biodiesel fuels. For example, in the USA using both prescriptive volumetric requirements and incentives.

The energy independence and security Act (EISA of 2007) required 0.5 million gallons/year for biomass-based biofuels to be increased to 1 billion gallons/year by 2012 a target, which has been surpassed [413]. Although biodiesel fuels have a wide variety of feedstocks depending on the geographical location, however the dominant feedstocks are soybean in the USA, rapeseed in Europe and palm oil in South East Asia [414, 415].

Nevertheless, the list of feedstocks is growing to include non-traditional feedstocks such animal fats and lard, used cooking oil, used engine oil, microalgae, municipal solid biomass, canola, coconut, Jatropa, sunflower, safflower, camelina. Table 13 showing Potential biodiesel yield in gallons per acre from triglyceride feedstocks and their references.

In literature, surveyed biodiesel fuel produced contains different varieties of individual FAME species. Nevertheless, a particular feedstock in the literature surveyed could dominate within a FAME species. FAME and FA are classified according to two categories; the first naming uses the number of carbon atoms in the FA chain. The second naming uses the number of carbon double bonds in the chain [414]. Among the 13 commonly found species in literature surveyed, there are 5 species which are dominant and are majorly derived from vegetable and animal fats and include the following; Palmitic acid (16:0), Stearic acid (18:0), Oleic acid (18:1), Linoleic acid (18:2), Linolenic acid (18:3). Table14 is showing the most commonly found fatty acids in the literature surveyed, their common names, formal names, molecular formula and molecular weight.

In biodiesel, composition FAME produced through transesterification is composed of exclusively of even numbered FA chains. It is important to mention here that FAME composition is not limited to vegetable and animal oil feedstocks but includes also algal derived lipids [448]. However, using the hydro-processing on biodiesel alters the FA chain irrespective of feedstock source to odd numbered FA chains. This is due to the removal of one carbon molecule during production of the biodiesel and has been reported in literature significantly by researchers such as [414, 449].

Table 14: Typical fatty acid (FA) groups in biodiesel

Common name	Formal name	Abbreviation	Molecular formula	Molecular weight
Lauric acid	Dodecanoic acid	12:0	$C_{12}H_{24}O_2$	200.32
Myristic acid	Tetradecanoic acid	14:0	$C_{14}H_{28}O_2$	228.38
Myristoleic acid	cis-9-tetradecenoic acid	14:1	$C_{14}H_{26}O_2$	226.26
Palmitic acid	Hexadecanoic acid	16:0	$C_{16}H_{32}O_2$	256.43
Palmitoleic acid	cis-9-hexadecanoic acid	16:1	$C_{16}H_{30}O_2$	254.42
Stearic acid	Octadecanoic acid	18:0	$C_{18}H_{36}O_2$	284.48
Oleic acid	cis-9-octadecenoic acid	18:1	$C_{18}H_{34}O_2$	282.47
Linoleic acid	cis-9,12-octadecadienoic acid	18:2	$C_{18}H_{32}O_2$	280.46
Linolenic acid	cis-9,12,15-octadecatrienoic	18:3	$C_{18}H_{30}O_2$	278.44
Arachidic acid	Eicosanoic acid	20:0	$C_{20}H_{40}O_2$	312.54
Gondoic acid	cis-11-eicosanoic	20:1	$C_{20}H_{38}O_2$	310.53
Behenic acid	Docosanoic acid	22:0	$C_{22}H_{44}O_2$	340.60
Erucic acid	cis-13-docosenoic acid	22:1	$C_{22}H_{42}O_2$	338.58

Among the commonly found FAME majority are dominated by C18 compounds although a few have lighter compounds C12 such as coconut and palm oil with C16. Feedstocks dominated by C18 have their relative saturation at 18:0, mono-saturated at 18:1 and di-saturated at 18:2. Plant based feedstocks such as rapeseed and canola contain 18:1. Corn and safflower, soybean and sunflower 18:2, Jatropa and yellow grease have similar values 18:1 and 18:2. However, Camelina in literature surveyed contains the highest level at (18:3) while Jatropa has lignocenic acid level of (24:0).

The physicochemical properties of biodiesel are determined by the compositional profile. The physicochemical properties of biodiesel vary substantially as with feedstock source [450, 451]. Due to higher oxygen, content (11% or more) biodiesel fuels have a low carbon to hydrogen content compared to fossil diesel. This gives biodiesel a 10% lower mass to energy content, but due to high density the biodiesel volumetric energy content drops about 5-6% compared to fossil diesel.

In other words, biodiesel has increased molecular weight compared to fossil diesel, reflected in the high distinction temperature (T90). Another important property exhibited by biodiesel fuel is good and excellent cetane number due to the straight chain esters compared to NO_2 fossil diesel octane 93. Biodiesel fuels also especially renewable contain paraffinic hydrocarbons, dominated by odd carbon numbers [452-454]. Lastly comparing biodiesel viscosities with fossil diesel show higher values by a factor of 2 when compared to fossil diesel [455].

7.2. Kinematic Viscosity

Viscosity of a biodiesel fuel is a critical property. Viscosity plays a key role in the spray quality, mixture formation and ultimately influences the entire combustion process. In other words high kinematic viscosity interferes with the entire injection process thus leading to insufficient fuel atomization hence poor engine combustion and performance. The mean diameter of the atomized fuel droplets sprayed by the injector and their penetration increases as viscosity increases [456, 457]. Additionally high viscosity leads to rapid pressure rise in injection pumping system thus leading to advanced injection timing [458-462].

Among the leading problems associated with viscosity of fuel, include: Inefficient mixing of fuel which results into incomplete combustion [463]. Early injection due to the high line of pressure thus moving the start of combustion (SOC) closer to the top dead centre (TDC). This increases the maximum mean effective pressure leading to combustion chamber elevated temperature hence increased NO_X emissions in biodiesel blends and fuels [464, 465]. As a property of fuel, viscosity is directly linked to the chemical structure of the fuel composition.

For example viscosity has been reported to increase as the carbon length increases and decreases with increased saturation (number of double bonds) of the biodiesel [214, 466]. Another important fuel property linked to the chemical structure via viscosity is the heat content (also known as the calorific value of a fuel) for both the feedstock and the biodiesel. For both the feedstock and biodiesel, the values increase together, in other words the heat content and viscosity increase or decrease together [214, 467].

Viscosity also is connected to the type of feedstock, for example, the viscosity of fats and greases is higher compared to vegetable oil sources. This is due to different saturation levels of the feedstock, which has been reported by a number of researchers such as [235, 468, 469]. Viscosity values for vegetable oil based feedstocks vary from between 27.2 mm^2/s to 53.6 mm^2/s compared to vegetable oil methyl esters at 3.6 mm^2/s to 4.6 mm^2/s. This phenomenon is due to the process of transesterification [470]. Nevertheless, despite this variation in viscosity due to feedstocks, biodiesel fuels have values relatively within specifications of prescribed standards.

7.3. Biodiesel Density

Density is described as the unit of mass per unit area. The density of a biodiesel causes the break-up of fuel injected into the engine cylinder. In other words, as the density of a fuel sample increases the mass of fuel-injected increases. However, regardless of the feedstock used to produce biodiesel oil all biodiesel are high in density compared to fossil diesel [215, 471-473]. The density of a fuel and its compressibility hold a very high influence in diesel engine fuel injection systems. Density thus influences the injected mass injection timing and the injection spray pattern.

These are critical parameters in biodiesel fuel and engine combustion behaviour [464, 474]. In other words, increasing the density increases the diameter of the droplets injected and considering the high inertia of heavier fuel droplets, this increases their penetration as denser fuel requires a shorter injection duration [456]. The speed at which the injected fuel spray penetrates across the combustion chamber determines air utilization and fuel /air ratio mixing rate [475].

Low-density fuel paired with low viscosity fuel when injected provides better and improved atomization and diffusion of the spray, which is an important factor in emission reduction and control. Atomization of the injected liquid fuel mass in the combustion chamber is important. Its importance is in the number of droplets, which are necessary for creating a large surface are for the liquid fuel to evaporate. This is governed by injection parameters and the air/fuel properties [475]. Density is also linked to the calorific value (heating content) of a fuel [214]. For example in literature reviewed density is shown to correlate to PM and NO_X emissions and reported by many researchers in different experimental works such as [476-478].

The carbon chain and the level of saturation affect the density of fuel. In other words, these two factors can increase or lower density considerably depending on their interplaying factors. For example, biodiesel produced from fats and greases tend to be more saturated compared to vegetable oil. An increase in density for example from 860 kg/m^3 for vegetable oil methyl ester (biodiesel) increases the viscosity from 3.59 mm^2/s to 4.63 mm^2/s [470] Hence, fats and greases produce high-density oil compared to vegetable based feedstocks. Nevertheless as alluded earlier this increase in density due to the difference in feedstock falls within acceptable standards a factor that has been reported in literature reviewed for example [479, 480].

7.4. Cetane Number

A cetane number in any given fuel is a primer indicator of the fuel ignition quality, which is the same as octane rating in SI fuel. The cetane number measures the knock tendency of a diesel fuel of biodiesel as a function of ignition delay. Although the cetane number is dimensionless, it is generally understood that ignition in compression ignition engines depends on self-ignition of the fuel.

Cetane number has been included as a fuel quality in biodiesel standard and placed at 47 as the minimum for neat biodiesel using ASTM standard. The cetane number also measures the readiness of a particular fuel to auto ignite when introduced into the combustion chamber for combustion. Hence the cetane number is a parameter that is directly proportional to ignition delay in IC engines [481].

Another general assumption made with cetane number is the conceptual generality of the octane scale for gasoline with petrodiesel cetane scale. For example high iso-octane as a primary reference fuel (PRF) has an octane rating of 100 compared to n-heptane at 0 [482]. On the other hand, the cetane scale the long

straight chain hydrocarbon hexadecane ($C_{16}H_{34}$) is used as a PRF with an assigned CN of 100 compared to the highly branched hepta-methylnonane ($C_{16}H_{34}$) at 15. This confirms that branching and length of the carbon chain influence the CN [481]. In other words, increasing branching decreases the chain length hence the CN number also decreases or becomes smaller.

Ignition delay is a period between SOI and SOC. Ignition delay is heavily influenced by engine design parameters such as compression ratio, injection rate, injection time, inlet air temperature and fuel composition and fuel properties. As the cetane number increases, it directly decreases the ignition delay while increasing the phase combustion in diffusion-controlled combustion. Higher cetane numbers result into shorter ignition time. In other words, high cetane numbers reduce injection time, SOC and rapid pressure rise in diesel engine combustion ignition quality varies depending on the density, thus causing trouble during cold start and low load engine operating conditions. Other effects include long ignition delay, leading to increased and rapid pressure rise and high maximum combustion pressure factors, which are not desirable leading to rough engine operation.

In diesel engines, ignition knock is not desirable as it causes engine knock. Among influential effects of cetane number, cold flow and cold starting properties is the increase in smoke and engine noise emissions if found to be low. On the other hand, high cetane number causes SOC close to the injector nozzles hence overheating and nozzle premature failure. Secondly, it increases heat, and traps solid coated particles hence plugging the injector nozzles [472]. Because of this behaviour, a number of literature surveyed, limit the cetane number to below 65 [475]. Additionally a number of studies in literature surveyed on the effect of high cetane number report a correlation with reduced emissions [483-485]. For example smoke, UHC, NO_X emissions reduce, with high CN. This has led to increased efforts to improve biodiesel fuel cetane numbers using additives or cetane improvers [463].

7.5. The Bulk Modulus of Compressibility

The bulk modulus of compressibility of a biodiesel explains and provides critical information on the number of spaces in biodiesel fuel molecules. The bulk modulus of compressibility also measures how much the biodiesel oil molecules can be compressed [486]. Although its measurement is difficult in liquids such as biodiesel, the measurement is obtained from the speed of sound and density of a biodiesel using the Newton-Laplace equation. This model utilizes estimates from a number of carbon and double bond of FAME in their chemical structures [487-489]. This is represented in Gibbs free energy (as shown in equations 10 and 11.

$$lnk_s = lnA' + \frac{\Delta Gk_s}{RT} \qquad (10)$$

where

$$k_s = \frac{1}{v}\left(\frac{\partial v}{\partial p}\right) s \text{ or } u^2 = \frac{1}{k_s\rho} \qquad (11)$$

In other words, the bulk modulus of a biodiesel fuel is the reciprocal of its compressibility. This is the fractional change in volume per unit change in pressure P.

where

K_s is the isentropic compressibility (Pa^{-1})

u is the speed of sound ($m.s^{-1}$)

P is the density in $kg.m^{-3}$

The bulk modulus of compressibility is a critical property in hydraulics such as biodiesel as it affects the hydraulic behaviour of fuels during injection hence its dilation [490]. The bulk modulus of compressibility is associated with the increase in NO_X emissions in diesel and biodiesel variants. High NOx emissions produced by neat and blended biodiesel are linked to low Ks compared to fossil diesel. This has been reported in a number of literature surveyed such as [491-495]. In Studies by [496], the authors established a linear relationship between isentropic compressibility of blends of biodiesel and NOx emission characteristics.

Therefore, the bulk modulus variation within the fuel composition and molecular structure is critical especially in biofuels, which are alternatives to fossil diesel. For example in literature surveyed, a number of experimental studies have been conducted in bulk modulus on biodiesel as alternative fuels and ULSD (Fisher Tropsch) [458, 497, 498]. This studies report advances in injection timing with use of biodiesel and ULSD fuels mainly due to the bulk modulus of compressibility and increased speed of sound. This leads to an earlier needle lift for in-line pump delivery systems [460, 499-502]. It is important to note that advanced injection timing in biodiesel and retarded timing in ULSD increases NO_X as the blend ratio increases with the blend sample and vice versa [503, 504].

In the literature surveyed on the bulk modulus of compressibility there are a number of models used by different authors to estimate the speed of sound in biodiesel. Nevertheless, only two models are commonly used an Example of these authors who have conducted experimental work include [505-509].

7.6. The Calorific Value

The calorific value otherwise known as the energy content is energy per unit mass or the volume consumed during the process off combustion to give maximum energy output. The calorific value is also known as the heat of combustion and is numerically equal to the enthalpy of reaction [510]. The calorific value is measured using a bomb calorimeter under ASTM 2015. It is interesting to note that high-density fuels have greater energy content compared to low density fuels. Nevertheless they pack high energy content per unit mass in comparison [295]. In other words, when different fuels with different energy balances are used for performance testing and evaluation the same engine experiences different power outputs.

Biodiesel fuels as hydrocarbon compounds comprise n-saturated, unsaturated, branched cyclics. Vegetable oil, which form a bulk of biodiesel, contain three fatty acids called triglycerides. These fatty acids have a carbon chain length formed in a number of double bonds [511]. Most biodiesel oil contain 74.5 wt % to 78.4 wt%, hydrogen content of 10.6 wt% to 12.4 wt% and an oxygen content of 10.8 wt% to 12 wt % [463].

In other words, the elemental composition of fatty acids is important because it defines the energy content, through provision of weight percentage of carbon, hydrogen and oxygen components within a given sample of biodiesel. For example, the heating values of vegetable oil range from 24.29 MJ/kg to 41.20 MJ/kg. Vegetable source feedstocks have greater differences in heating values, but in surveyed literature, camelina has the highest HHV at 45.2MJ/kg in one study[414]. Others include corn and safflower with 43.1MJ/kg and 42.2MJ/kg respectively. It is also important to note in literature surveyed and data reported in literature there is confusion between this two terms LHV and HHV, which is confirmed in a number of studies such as [414, 448, 449].

Another observation found in the literature surveyed for commonly used biodiesel heating values indicates that they are few. Nevertheless, few researchers have managed to research and put some values for heating values together such as [512-514]. Hence, experimental determination of HHV of biodiesel fuels and other pure fatty acids is not exhaustive. Nevertheless a variety of correlations for predicting different HHV of fatty acids exist such as in (12 and 13 [513].

$$HHV = 49.43 - 0.015 IV - 0.041 SV \qquad (12)$$

$$HHV = 30.84 Exp(0.0013 MW) \qquad (13)$$

where

HHV, IV, SV and MW are high heating value, iodine value, saponification value and molecular weight of the fatty acids

Due to the high oxygen content biodiesel fuels have lower mass to energy, ratio values compared to fossil diesel fuels. Hence, it is generally accepted that biodiesel has 10% less mass energy content MJ/kg [462, 515]. The reduction in calorific value is mainly due to the presence of high oxygen content in the molecular structure of biodiesel fuels. These findings corroborate to a number of studies such as [463, 516, 517].

There are mainly two properties of biodiesel, which influence the calorific value, namely the saponification number and iodine values[518]. In other words, the decrease in saponification value reduces its molecular weight, which is similar to the effect of increased carbon and oxygen percentages in an oil sample. It is also important to note that in a given oil sample the calorific value is greatly affected by the iodine value [470]. The iodine value measures fuel properties of unsaturation.

The ASTM65751 nevertheless excludes it while the EN14214 specifies 120 mgI$_2$/100g. On the other hand, the saponification value of biodiesel sample refers to a hydration reaction to break ester bonds using free hydroxide between fatty acid and glycerol of the triglycerides. The result forms free fatty acids and glycerol components soluble in aqueous solutions in (14.

$$HHV = 0.0303(C) + 1.423(H) \qquad (14)$$

As observed from (12 the HHV can be determined using C, H, and O contents of the chemical structure as a function of percentage of these three components. However, (14 is a combination, of oxidative heat, values of C and H and the reduction heat of O with an assumption that the oxygen content effect on the fatty acid fuel has negative HHV. The determined values obtained by equations 12 and 13 and show the hydrogen content as the most decisive factor for unsaturated fatty acids [514]. Nevertheless, (13 shows HHV to be a functional component of the carbon percentage.

7.7. Oxidative Stability of Biodiesel

Biodiesel fuels degrade after storage for a long time due to oxidation. Hence, biodiesel stability refers to the ability of the biodiesel to resist degradation to form undesirable species and properties [519, 520]. This makes it possible for a biodiesel to resist physical and chemical changes caused by environmental factors. Nevertheless biodiesel fuels are none resistant to oxidation when exposed to air and moisture, this ultimately affects the biodiesel quality and storage. The existing time from initiation of oxidation to increased rate of oxidation is called induction period [521, 522]. During induction period, the concentration of ROOH is very low although this situation reverses as the reaction progresses.

In literature surveyed biodiesel fuel can degrade through a number of mechanisms [523] such as; Oxidation or autoxidation which occurs as a result of contact with ambient oxygen. The second mechanisms of oxidation is due to thermal oxidative decomposition due to exposure to excessive storage heat or direct light UV rays. The third mechanism comes from hydrolysis or accumulation of moisture or contact with water in storage tanks, fuel lines or moisture due to condensation. The fourth mechanism of biodiesel degradation is due to microbial or biodegradation contamination due to dust particles or water and moisture which contain bacteria or fungi into the storage tank or system. Metal contamination [524] and the Presence or absence of additives [525].

Besides these mechanisms biodiesel fuel itself is susceptible to oxidation and contamination through interaction with light and temperature. This is due to the presence of fatty acids, which interact with oxygen thus making biodiesel unstable. Besides nature and interaction, there are inherent chemical reactions such as alkenes, dienes and compounds of nitrogen, sulfur and oxygen, which hasten and play a dominant role on oxidation. The initial biodiesel products of oxidation are peroxides and hydro-peroxides, which when further degraded produce short chain hydrocarbons such as aldehydes, alcohols, ketones and low molecular compounds [520, 526, 527].

Among the visible physical changes to the naked eye is change in biodiesel physical colour, deposit formation that reduces biodiesel clarity and cleanliness [523, 528]. The degradation of biodiesel correlated to the process of transesterification, which either uses methanol or ethanol as each of them produces different esters. In other words during transesterification the fatty acid chain remains unchanged hence retaining the oxidation chemistry of the feedstock.

This is one of the leading explanation and cause of instability in biodiesel oil [519]. There are three types of oxidative stability identified with biodiesel fuels, which include oxidative stability [529, 530]. Storage stability which involves degradation due to interaction with light, air, metals, moisture and other storage related conditions [531, 532]. And Thermal stability which deals with oxidation at high temperature causing increased oil and fat [533, 534].

Nevertheless primary oxidation is further classified into three main reactions according to [519]. The first one is the initiation reaction where carbon free radicals are formed and produced [531, 535]. In other words, the diatomic oxygen present within the free radicals to form peroxy and further reaction leads to carbon free radical hydro-peroxide (ROOH). This is an extraction of the hydrogen atom from the carbon atom of the chain. The second reaction is the propagation reaction, which reacts the free carbon with atomic oxygen forming stable reaction products of two carbon free radicals, hence termination of the reaction. Vividly captured in equations 15 and 16 either through thermal dissociation of hydrogen peroxide.

$$RH + 1^* = R^* + 1H \qquad (15)$$

$$ROOH \rightarrow RO^* + OH^* \qquad (16)$$

Alternatively, it takes a metal catalysed decomposition of the hydrogen peroxide as in equations 17, 18, 19 and 20.

$$ROOH + M^{2+} \rightarrow RO^* + OH^* + M^{3+} \qquad (17)$$

$$ROOH + M^{3+} \rightarrow ROO^* + H^+ + M^{2+} \qquad (18)$$

$$R^* + O_2 \rightarrow ROO^* \qquad (19)$$

$$ROO^* + RH \rightarrow ROOH + R^* \qquad (20)$$
In the secondary oxidation reactions, the hydrogen-peroxide breaks down to form aldehydes of propanol, hexanals and heptanol while forming formic acid, aliphatic alcohol and formate esters. Additionally there is formation of short chain fatty acids, which lead to increased acid biodiesel value [536, 537].

7.8. Biodiesel Lubricity Properties

The lubricity of biodiesel refers to the reduction of friction between solid surfaces relative to their motion [538]. Lubricity in biodiesel takes two main mechanisms namely; Hydrodynamic lubrication where a layer of a liquid such as blended biodiesel within the injection system prevents direct contact between opposing moving sides. The second is Boundary lubrication,

which refers to compounds formulated to adhere to metallic surfaces while forming a thin protective layer that prevents wear.

These two forms of lubrication alternate with each other to provide lubrication especially boundary lubrication when hydrodynamic lubrication seizes to work or is removed from opposing surfaces. In other words, biodiesel oil should have good lubricity qualities, as this is critical in protecting moving parts in the modern injection systems. Modern day increased operational demands for injection systems is a critical factor and includes high and sustained pressure, injection rate shaping, multiple injection and engine injection cycles. Nevertheless, suffice to say that despite increased need for lubricity, natural lubricity from petroleum fuels has been decreasing with the advent of ULSD. This technology uses high level of hydrotreatment, which removes all heteroatom molecules of O, N and S which are key in improved lubricity[481, 539].

Generally, biodiesel is regarded with high and excellent lubricating properties a reason why blending with ULSD is recommended. This natural lubricity of biodiesel causes biodiesel to have no specification within ASTM and EN standards for B100. However blends B5 to B20 in ASTM7467 includes lubricity specifications[481]. Biodiesels excellent properties of lubricity traced to the esters group within its FAME molecules and other trace impure compounds. For example, free fatty acids and monoglycerides are effective in lubrication [540, 541]. In a number of studies reported in literature surveyed the authors note that the purification process by distillation decreases its lubricity as it removes impurities which are necessary to lubricity [539].

In literature surveyed, the effect of unsaturation on lubricity is inadequately covered and needs further study, as there is no comprehensive data. It is not clear from literature surveyed the role of unsaturation on lubricity and in the few available literatures, the results are mixed. For example, in a number of research work positive and negative effects of carbon-carbon double bonds is reported [215, 481, 542]. It is important to note that this impurities in biodiesel impact lubricity positively although they increase operational problems such as cold starting. Trying to reduce these impurities to improve cold flow properties of biodiesel has worsened the consequence of poor lubricity [414].

7.9. Cold Flow Biodiesel Properties (Flash Point, Pour Point and Cloud Point)

The cold flow properties of biodiesel indicate the ability of a biodiesel during cold weather and engine cold starting and is dependent on the long chain saturated factor [204]. Biodiesel fuels have similar and comparable physicochemical features as fossil diesel although their cold flow properties of the two fuels are dissimilar. All biodiesel fuels have very poor cold starting properties irrespective of the source of feedstock and blends without additives.

In biodiesel clod flow properties relate to the melting points of individual fuel components and their solubility in blends [543]. In other words, a high MP causes crystallization and precipitates

once its blend goes beyond its solubility. Due to long chain saturated fatty acids, biodiesel fuel components exhibit higher MP compared to fossil diesel. However, when unsaturated fatty acid components are present the MP decreases. Table 15 shows CP for different feedstocks.

Table 15: Selected biodiesel feedstocks cloud points [544]

Oil /Fat	Methyl ester composition (wt %)						Cloud point	
	$C_{16:0}$	$C_{18:0}$	$C_{18:1}$	$C_{18:2}$	$C_{18:3}$	Others	K	°C
Beef tallow	23.9	17.5	43.9	2.3	0.1	12.3	286	13
Palm	39.5	4.1	43.2	10.6	0.2	2.4	283	10
Sunflower	6.1	4.2	24	63.5	0.4	1.8	274	1
Soybean	10.7	3.2	25	53.3	5.4	2.5	272	-1
Linseed	6.7	3.7	21.7	15.8	52.1	0	268	-5
Olive	10.7	2.6	78.7	5.8	0.7	1.5	268	-5
Safflower	6.4	2.2	13.9	76	0.2	1.3	267	-6
Rapeseed	4.3	1.9	61.5	20.6	8.3	3.1	267	-6

Nevertheless the flash point of biodiesel differs and refers to a safety measure of biodiesel storage as it's a point at which a biodiesel fuel spontaneously becomes flammable [545]. On the other hand, the fire point of a hydrocarbon is a point at which a sample of fuel will continue to burn at its highest temperature and remains burning. The difference between the flash point and the fire point is 50 °F to 70 °F. For example, fossil diesel has a flash point of 60 °C to 140°F while the fire point is 93°C to 200 °F $(32°F − 32) × \frac{5}{9} = °C)$.

Table 16: Flash point and fire point of biodiesel and its blends

Type of fuel	Flash point (°C)	Fire point (°C)
Diesel	60	65
Mahua oil	286	295
MME	175	186
Ethanol	40	47
Kerosene	72	77
MME 20 % ethanol	50	55
MME 10 % ethanol	52	57
MME 10 % ethanol 10% diesel	54	59
MME 20 % kerosene	90	97
MME 10 % kerosene	95	101

The average flashpoint for biodiesel fuel is 150°C compared to fossil diesel at 55°C to 66°C [546]. This difference is primarily due to the difference in their physicochemical properties. For example diesel fuel has low molecular weight molecules with branched compounds hence low flash point compared to biodiesel with trace of alcohol which reduces its flash point [450]. Due to the relationship between the biodiesel flashpoint and alcohol

content, the flashpoint sets the limit of residual alcohol in a biodiesel or biofuel.

This means therefore that the flashpoint is an empirical measurement but not a fundamental physical biodiesel parameter and is inversely proportional to fuel volatility [547]. Higher ethanol blends are a fire hazard and as such should be discouraged as they reduce flashpoint and firepoints of biodiesel. Table 16 shows the Flash point and fire point of different biodiesel and their blends.

The pour point of biodiesel is defines as the lowest temperature point which a biodiesel fuel will still manage to flow before turning jelly and waxy [548]. The difference in CFPP value in biodiesel oil samples depend on the feedstock but relies more on the carbon chain length of the saturated oil fatty acids. For example palmitic acid ($C_{16:0}$) in palm oil and ($C_{12:0}$) and ($C_{14:0}$) for coconut and Babassu respectively. In other words, carbon chains produce higher CFPP values [215, 414].

7.10.   Acid Number Biodiesel Properties

The acid number of biodiesels is defined as the quantity of potassium hydroxide (KOH) which neutralizes fatty acids in a 1g sample. This is expressed in (form as follows in (21.

$$RCOOH + KOH \rightarrow RCOOK + H_2 \tag{21}$$

The acid value is an important biodiesel property as it determines the amount of free fatty acids in a sample of fat; this is elaborated further in (8 [549]:

$$Acid\ Value = \frac{(S−B)×N×56.1}{W} \tag{22}$$

where

S is the standard alkali used during titration of the sample in ml

B is the blank sample used during titration in ml

N is the normal standard alkali

W is the weight of the sample in grams

The biodiesel acid number also shows the sum total of all acid chemicals comprising the following: Phenols, Acids, Sugars, biodiesel oil extracts. Since biodiesel oil have high content of oxygen there is a high association with acidity linked to it [550]. This means the acid number measures the quantity of carboxylic acid groups in a chemical compound like fatty acid or as a mixture of compounds [551]. The acid number of biodiesel is contained in ASTM D 6751 using method ASTM D664 and EN14214 using method EN14104 [481]. Acid numbers quantify the acid values in a sample of biodiesel. Nevertheless Higher acid values cause a number of problems in injection systems by causing severe corrosion of internal component parts [551].

8.   Conclusion and Future Recommendation

- Families and family generation are defined by the length of time, likewise the biodiesel families are defined by the length of time.

- Use of non-edible feedstocks is an answer to the challenges paused by edible oil feedstocks. The use of non-edible feedstocks in the production of biodiesel eliminates competition for food, reduction in deforestation rate and co-products waste.

- Besides chemical and physical factors, which affect biodiesel production tax and policy subsidy, completion with food industry, cost of feedstock and investment affect production of biodiesel.

- Although biodiesel is advantageous in many aspects, high cost of production, processing and raw materials (feedstock) which account for 80% make it expensive as an alternative.

- Viscosity plays a key role in the spray quality, mixture formation and ultimately influences the entire combustion process. In other words high kinematic viscosity interferes with the entire injection process thus leading to insufficient fuel atomization hence poor engine combustion and performance.

- The density of fuel is a prime role in the injected mass timing and the injection spray pattern. It is also important to remember that as the density of a fuel sample increases the mass of fuel-injected increases too.

- The cetane number in any given fuel is a primer indicator of the fuel ignition quality, which is the same as octane rating in SI fuel. The cetane number measures the knock tendency of a diesel fuel of biodiesel as a function of ignition delay.

- The elemental composition of fatty acids is important because it defines the energy content within a given sample of biodiesel. Through provision of weight percentage of carbon, hydrogen and oxygen components with a given sample of biodiesel it makes easy to determine the energy content.

- Biodiesel fuel is susceptible to oxidation and contamination through interaction with light and temperature due to the presence of fatty acids, which interact with oxygen. Visible physical changes to the naked eye to show this change in biodiesel include physical colour change of oil, deposit formation that reduces biodiesel clarity and cleanliness.

- Generally biodiesel is regarded with high and excellent lubricating properties a reason why blending with ULSD is recommended.

- Due to the relationship between the biodiesel flashpoint and alcohol content, the flashpoint sets the limit of residual alcohol in a biodiesel or biofuel. In other words although flashpoint is an empirical measurement but not a fundamental physical biodiesel parameter and is inversely proportional to fuel volatility.

- The feedstock type influences difference in the CFPP value in biodiesel oil samples although it relies more on the carbon chain length of the saturated oil fatty acids.

- The acid value has a significant impact on system components life and performance. Higher acid values contribute to a number of problems in the injection systems sometimes resulting into severe corrosion of internal component parts for injection.

In this paper, one of the "problem zones" in mathematics concerned with the surface area of three-dimensional bodies is presented by computer and mathematical modeling with synergetic effects using intelligent system support. The problems of personal self-organization and technological stages of student's research activity in the process of modern achievements in science adaptation in teaching mathematics by means of computer and mathematical modeling based on intelligent system support are considered. The technology of intelligent system support to choose and investigate the complex generalized constructs in student's research activity (on the example of multifaceted surfaces of Schwartz cylinder (or "boot")) using computer and mathematical support are considered. So, the technological stages and personal quality parameters of student's research activity and content of adaptation the most important generalized constructions of surface area to the actual positions of mathematical knowledge and fractal parameters are considered with synergetic effects and extend Vygotsky' zones of immediate development as a finding. Intelligent management of student's cognitive activity on the base of expert systems during the complex knowledge development creates the zones of immediate development and self-development of students as a new methodology of cognitive student's activity. The original computer design and mathematical modeling of nonlinear dynamics of synergetic effects manifestation are developed step by step and dynamic invariants are revealed in the course of surface area mastering as a realization of student's educational trajectory. The model of hybrid intelligent system for supporting of student's research activities is constructed. Details of concretization are described on the example of Schwartz cylinder so it is fractal complex surface with problems zones of student's understanding on complex concept "surface area". Moreover, all constructs of mathematical and computer modeling with Schwartz cylinder are new and based on means of the QT Creator environment and GeoGebra. Namely, the means of the QT Creator environment are used for computer design of non-linear dynamics of functional and fractal parameters and technological constructs and students reveal the regularities and irregularities of lateral surface approximations of Schwartz cylinder. The construction of Schwartz cylinder's fractal surface as an indirect synergetic effect of student's research activities is new mathematical and computer design result. Conclusion: new methods of intelligent management of student's research activity and thinking development using neural networks support was carried out on the basis of lateral surface triangulations of the Schwartz' cylinder with regular and irregular limiting grinding by layered polyhedral complexes with computer and mathematical modeling tools and as one of the educational trajectories of student's research activity.

1. Introduction

The development of personality is impossible to imagine without the presence of situations of intellectual tension in the conditions of uncertainty and lack of future activities prediction, opportunities to overcome the problem areas that arise in an education and in real life. The presence of such problem areas and situations of overcoming is directly related to the development of complex knowledge and is an important attribute of qualitative changes in the development of personality [1]-[3]. The methodology and guide for the study of such content of education are the functional characteristics of the state and order parameters in the transitions from chaos to the equilibrium setting of systems of different types (fractal objects and processes [4], Benard's cells [5], turbulence and lasers, chemical effects of Zhabotinsky-Belousov [6], the theory of dissipative structures, nonlinear dynamics [7], etc.). It is quite significant that in this case, the transition from chaos to order (and vice versa) occur through the universal mechanisms of system complexity. In particular, this can be implemented, for example, through a cascade of doubling bifurcations period, implementing the scenario of P. F. Verhulst in the development of M. Feigenbaum tree [8], or by opening a step-by-step process of moving to the object essence by means of mathematical and computer modeling. Thus, the introduction of the processes of mastering complex knowledge into student's mathematical education creates the conditions for synergy manifestation in teaching mathematics and, thereby, contributes to the development of intellectual operations of thinking and creative independence of students [9]. Later the similar scientific facts will be called as "modern achievements in science". So, it should be characterized by applied effect, visual modeling, need for computer and mathematical modeling together the possibility of adapting the basic constructs for school mathematics with synergistic effects for personal development and research activity.

In this article we study one of the "problem areas" of mathematics, which concerns the problem of measuring and understanding the complex concept essence of surface area with intelligent system support. Although for some reason, the essence of this concept remains inaccessible to the student (as the limit of the areas of multi-faceted complexes of tangent planes fragments on the crumbling triangulations of three-dimensional surface of mathematical object). It will be one of the personal trajectories by student's choice of research activity with intelligent system support. Therefore, it is necessary to be able to stage-by-stage design of cognitive activity of students to develop the manifestations variety of surface area concept as an extension of Vygotsky' zones of immediate development [10]. Namely, functional parameters and regularities of approximation will be revealed and the areas of layered multi-faceted complexes will be investigated at the limit grinding of regular and irregular triangulations of the lateral surface of Schwartz cylinder [11, 12] by means of computer and mathematical modeling using intelligent system. So, it will be checking the personal opportunities and skills in dynamics and perspectives of student's research activity. is become the managing instrument for defining

of zones of immediate development of the person (create, check, direct, evaluate, create on new stage). Moreover, it will be constructing of Schwartz cylinder's fractal surface as an indirect synergetic effect of student's research activities as new mathematical and computer design result. Methods of fractal analysis of technological constructs of Schwartz cylinder research [4, 8, 13, 14] are used.

The development of intelligent learning systems based on artificial intelligence methods is a promising direction in solving complex problems of managing students' research activity, aimed on increasing their self-organization and self-learning levels with a continuous decrease of teacher participation degree [15]. Intelligent management of learning process in "teacher – computer – student" triad requires a hybrid approach in mathematical and computer modeling. It integrates the functions of expert systems, fuzzy logic, artificial neural networks and genetic algorithms taking into account the research interests and preferences of students [16]. The using of intelligent systems in education (neural networks, fuzzy logic, cellular automata, hybrid expert systems with fuzzy logic, etc.) is actively implemented in tools environments development and software systems for evaluating student's knowledge and competence [17]-[21]. However, the use of intelligent systems for managing students' research activities has not been considered in educational practice.

2. Methodology, Methods and Technologies

In modern psychological and pedagogical research, learning is considered as an intellectual process that al lows you to de sign and implement in dividual educational routes de pending on the le vel of subject training and individual psychological characteristics of students in a hybrid learning environment. Hybrid neural network of intelligent system support of student's research activity is defined by an expert system information support (big data, methods, instruments, etc.) on neural layers depending from student's research activity results and personal changes in scientific thinking. Thus, it becomes possible to di versify the in dividual trajectories of students' research activity depending on their interests and scientific experience. The leading role in the analyzed aspect is played by the synergetic approach in education, which determines the design of individual educational environments consisting of educational elements of different levels based on the processes of self-organization of its subjects. The synergetic approach is based on the mechanisms of interdisciplinary interaction in order to create new, more complex structures with a new quality [7, 22, 14, 23, 24]. The possibility of setting and solving the individualization problems of ma thematical education and motivation to study mathematics both at school and at university in modern Russia can be based on the actualization of leading pedagogical technologies (visual modeling and founding person's experience [10, 25], theory of multi-stages ma thematical and in formational tasks [1, 14, 23], learning complex knowledge [26]) and the adaptation processes of complex knowledge learning (including modern achievements in science) to the development of ma thematical methods

(parametrization, se arch of generalized constructs, ma thematical modeling, ets.) by the most accessible for these purposes means, methods and selection. It is necessary to design techniques and methods of re flection and research of technological parameters of generalized construct against the background of the adaptation system and obtaining new results: in our case, the generalized construct of scientific knowledge as an example of in dividual trajectories of student's realization – the concept of surface area is in directly up dated through computer and ma thematical modeling of research processes of lateral surface of Schwartz cylinder [11].

The identification of fractal structure of scientific and ma thematical knowledge, the content of education, learning element, knowledge base allows the use of fractal methodology and its principles in the phase of analysis, se lection and structuring of educational material [4, 8, 13]. Knowledge in artificial neural networks base on the detection of hierarchies and characteristics of fuzzy modeling, the choice of the primary ways his re presentation and fuzzy linguistic variables as well as in the diagnosis of training material quality [1, 10, 21]. The emergence and formation of self-similar structures in pedagogy is not accidental, as this is one of the natural ways to increase the efficiency, reliability and sustainability of modern intelligent learning systems.

3. Innovative Organization Technology of Research Activities Based on Using of Hybrid Intelligent Systems

Tasks of modern achievements research in science:

- to master the stages of generalized scientific knowledge adaptation to the processes of ma thematical activity with student's self-organization effects by means of mathematical and computer modeling techniques;
- to identify and substantiate the ma thematical results du ring the development and research of essence manifestation stages of generalized construct (build a founding spiral of the essence); build graphs of educational elements coordination with elements of generalized structures; provide visibility of modeling and high level of student's educational motivation and self-organization in the context of applications up dating and the essence specifying of generalized construct;
- to reflect and update the thesaurus of ma thematical education synergy in the course of student's research activities: fluctuations, bi furcation points, at tractors, pools of at traction, etc.;
- to develop the divergent thinking and creative in dependence of students against the background of mastering integrative constructs of ma thematical knowledge and procedures, taking in to account probable and improbable circumstances, constructing the content, stages, basic and variable characteristics of the object design;
- to develop the ability to ad apt and develop in social communication and cognitive activity based on ma thematical, in formation, natural science and humanitarian cultures dialogue.

Intelligent management in the ma thematical education of students is using of intelligent systems support functionality (including a hybrid artificial neural networks) in conditions of openness (to external in fluences and factors) and the synthesis of mathematical and computer modeling in order to identify the essence and effectiveness of ma thematical and evaluation procedures based on individualization of teaching mathematics and personalized and computerized feedback actualization of cognitive and evaluation processes. It is characterized by:

- functioning of stochastic, threshold, bifurcation and fluctuation transitions of se arch and creative procedures for the content of student's cognitive activity;
- evaluation of educational results based on implementation of expert systems with fuzzy logic and hybrid neural networks;
- multiplicity of goal setting functionality and of computer modeling content of processing and accounting of personalized databases images, texts, signals, table data based on effective feedback;
- ma thematical, informational, natural science and humanitarian cultures dialogue and final student's synergy and self-organization effects in research activities and assessment of knowledge and competencies quality;
- optimization of the of intelligent systems functioning results in the direction of their classification, clustering, segmentation, regression in accordance with the standards and models of intellectual management of cognitive activity and evaluation of ma thematical education results.

We will proceed from the fact that the set of quality parameters of scientific knowledge dynamics, personal characteristics and research activities of students consists, among other things, of three clusters of parameters: scientific thinking, scientific activity and scientific communication [10]. The ultimate attractor of students' research activities should be a database of modern achievements in science (elements of fractal geometry, information encoding and encryption theory, fuzzy sets and fuzzy logic, Schwartz cylinder, generalized functions, cellular automata, etc.), differentiated by factors reflecting the content of the coordinate parameters of the Smirnov cube [26], based, among other things, on the typology of information perception modalities [10]. Thus, we will distinguish the following parameters clusters of scientific knowledge and quality of research activity of students:

- scientific thinking: creative acts, logical acts, principles and styles;
- scientific activities: research of experience (analysis, synthesis, associations, analogies, collection, study and processing of information, etc.); variability of data, limitation of experience; improvisation, reflection of common sense, trial and error, actions in conditions of uncertainty, problem statement and search for contradictions; obtaining a new or side result, setting an experiment, hypothesizing;
- scientific communication: accuracy of practical implementation, practical significance of the project, cross-

cultural interaction, teamwork, social verification of new knowledge, etc.);

- typology of perception modalities: sign-symbolic, verbal, figurative-geometric, concrete-activity;
- experience and personal qualities: technological readiness, need and interest in research, creative independence, self-actualization, self-organization, self-realization and self-esteem.

It is necessary to diagnose the state of basic parameters (no more than 10) at the initial, current (according to the levels of research activity) and final measurements. The success of research activities is determined by the classification criteria of parameter quality (expert assessment). In addition, the level of complexity of the generalized construct (3 levels) can become a factor of differentiation of database elements of modern achievements in science. Thus, if there are 10 generalized constructs, then each of them represents at least 8 modifications designed as a problem statement. The content of the database and its formal presentation are implemented by experts, and the tool environment and software package are developed by programmers.

Example: A generalized description of the construct: Fractal geometry of the Mandelbrot and Julia sets [11]. Variations of the generalized construct:

- Historiogenesis and variability of iterative dynamics of the development of representations of Mandelbrot and Julie sets;
- Iterative processes and computational design of infill sets, Julia sets;
- Iterative processes and computer design of Mandelbrot sets;
- Topological and fractal dimensions of the Julia and Mandelbrot sets;
- Smooth Julia sets for Chebyshev polynomials [14]: mathematical and computer modeling;
- Method of visualization of Julia and Mandelbrot sets in information environments;
- Calculation of the Feigenbaum constant [8] for the Mandelbrot set [4];
- Computer design and construction of Cantor and connected Julia sets [13].

Each variation of the generalized construct is the end point of a hierarchical tree of subtasks arranged in logical chains and equipped with instructions and a bibliographic list of references. The hierarchical tree is based on the database of educational and research projects with similar equipment (the number of such projects in our specification for 10 generalized constructs can be no more than 40). Every student gets an opportunity by intelligent system to have support in a choice: generalized constructs of modern scientific knowledge in its variety, on every technological stage (neural layer) to get of future research activity (scientific examples of tasks and methods according to personal dynamics),

to observe of personal growth dynamics, to look on teacher comments, to collect of personal success and so on.

Below is a model of hybrid intellectual system for supporting and accompany of student's research activities by means of founding clusters mastering [4] and generalized constructs adapting of modern scientific knowledge (Figure 1). First a set of parameters for the quality and success of student's research activity (network input parameters) are described. So diagnostics quality status and initial database of student's research activity are defined in personal, substantive, procedural areas. Diagnostics of personal parameters and quality of student's research activity on every technological stage will define the selectivity and level of information support. Really in this stage the standards, samples, and procedures for adapting the intellectual management functionality in education, science, technology, and social processes are presented. Fuzzification, metrics and correction of weight functional characteristics are defined using methods of fuzzy logic. Second equipping neural layers with blocks from founding chains complexes of generalized construct of modern knowledge and variety of subtasks in different modalities are presented on every technological stage. It reflects the functionality, stochasticity, threshold of bifurcation and fluctuation transitions of search and creative procedures of student's research activity with intelligent system support. Third the aim of output layer of neural network is classification of success and quality levels of student's research activity. Identification of the essence and effectiveness of mathematical procedures and stages of generalized construct adaptation and student's research activity are evaluated by hybrid neural network. So basically a student's research activity with intelligent system support will be: research of experience (analysis, synthesis, associations, analogies, collection, study and processing of information, etc.); analysis of data variability, limitation of experience; improvisation, interpretation, reflection of common sense, trial and error, actions in conditions of uncertainty, problem statement and search for contradictions; obtaining a new or by-product results, setting an experiment, hypothesizing; scientific communication: accuracy of practical implementation, practical significance of the project, cross-cultural interaction, teamwork, social verification of new knowledge, etc.); technological readiness and self-organization.

As a result, it can be diagnosed the development of personal qualities and student's thinking, scientific knowledge experience, self-organization and creative self-sufficiency.

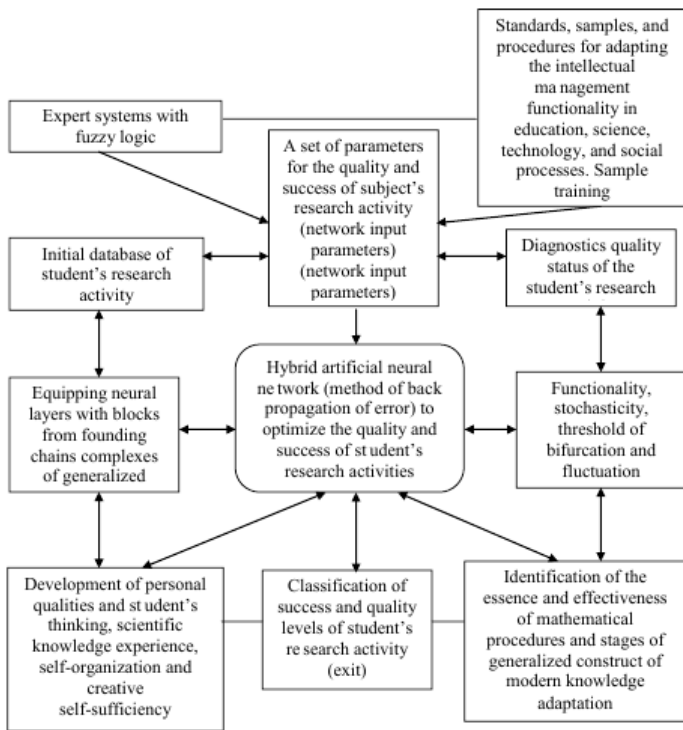
Forever the technological stages of student's research activity with intelligent system support are presented. Details of concretization are described on the example of Schwartz cylinder so it is fractal complex surface with problems zones of student's understanding on complex concept "surface area". Moreover, all constructs of mathematical and computer modeling with Schwartz cylinder are new and based on means of the QT Creator environment and GeoGebra.


Figure 1: Model of Hybrid Intelligent System for Supporting of Student's Research Activities

4. Technological Constructs of Cognitive Activity

4.1. Components, actualization and organization of intelligent system's processes to choose the content of knowledge's generalized construct

Set of parameters for the quality and success of subject's research activity (network input parameters); standards, samples, and procedures for adapting the intellectual management functionality in education, science, technology, and social processes; sample training to computer and mathematical modeling of the essence specific manifestations of generalized construct, contradictions and availability of mathematical apparatus and methods; search for stable clusters of empirical generalizations (diagnostics quality status of the student's research activity, video-clips, anticipation and samples of innovative activity, computer design and computing procedures, scientific conferences and seminars):

- *Motivational field:* Visual modeling of motivational applied situations of " new " interpretation of surface area concept (the area of multi-faceted surfaces, the inability to sweep the sphere, surface rotating, regular Schwartz cylinder (uniform division of the base into n sectors, and m - is the height of layers – Figure 2.), the surface area of the sphere, cylinder, cone, torus by the method of G. Minkowski (cf. [27], experimental mathematics [13])).
- Initial database of student's research activity; tasks for actualization of "problem zone" for small groups of students: form of realization - laboratory-calculated classroom and resource lessons [25] (4 -6 lessons).
Figure 2: Element of Layers Triangulation of Schwartz Cylinder Lateral Area

4.2. Hybrid Artificial Neural Network (Method of Back Propagation of Error) to Optimize the Quality and Success of Student's Research Activities; Multiple Goal-setting of Research Processes of Generalized Construct of Scientific Knowledge

(example: actualization of surface area concept by research methods of Schwartz cylinder "area" (content aspect)): pathological properties of the "area" of cylinder lateral surface are well studied in the so -called "regular" ca se (see for example [11,12])). In the work of E. I. Smirnov and A. D. Uvarov [26] the behavior of function and the angle between triangulation triangles with common base is studied, if $m = f^n(a_0) \cdot n^2$ and $m, n \to \infty$, where $f(a_0) = xa_0(1 - a_0)$ - logistic mapping adequate to the scenario of P. Verhulst [8]. The technology uses the research activities in small groups of students in remote environment [10] or in research activity solving of multi-stage mathematical and information tasks [14].

4.3. Classification of Success and Quality Levels of Student's Research Activity; Actualization of Synergy Attributes (Bifurcations, Attractors, Fluctuations, Attraction Pools) in Research Process

(adaptation of surface area to school mathematics when working in small groups with variations of " area " of Schwartz cylinder; equipping neural layers with blocks from founding chains complexes of generalized construct of modern knowledge; functionality, stochasticity, threshold of bifurcation and fluctuation transitions of se arch and creative procedures).

4.4. Development of personal qualities and student's thinking, scientific knowledge experience, self-organization and creative

Identification of the essence and effectiveness of mathematical procedures and stages of generalized construct of modern knowledge adaptation.

Example [26]. Let us consider the following Figure 3.
Figure 3: A Regular Hexagon is Inscribed in the Circle of Radius AT

Figure 3 shows a circle centered in point A and with radius of $g_1 = 1$. A regular hexagon is inscribed in the circle and the radius AT is drawn so that it intersects the side of the hexagon at U. Le t's assume that the point T moves along a circle. In this case, we will match the length of the segment UT to the central corner $c_1 = \alpha$ and get the function $f(\alpha)$. The introduced function $f(\alpha)$ is bounded and periodic, namely $0 \leq |f(\alpha)| \leq 1 - \dfrac{\sqrt{3}}{2}$ and $T = \dfrac{\pi}{6}$ is the period of $f(\alpha)$.

The function $f(\alpha)$ can be de fined explicitly.

$$f(\alpha) = 1 - \frac{\dfrac{\sqrt{3}}{2}}{\sin(120^0 - (\alpha - [\frac{\alpha}{60^0}] \cdot 60^0))}. \qquad (1)$$

It is not difficult to define a function $f_n(\alpha)$ when an arbitrary regular n-gon is inscribed in the circle. Indeed, denote by $\varphi = \dfrac{360^0}{n}$ the central angle of the inscribed n-gon, then $f_n(\alpha)$ takes the form:

$$f_n(\alpha) = 1 - \frac{\sin(90^0 - \dfrac{\varphi}{2})}{\sin(90^0 + \dfrac{\varphi}{2} - (\alpha - [\frac{\alpha}{\varphi}] \cdot \varphi))}. \qquad (2)$$

Define the following function $g(\alpha)$ as the sum of the function series:

$$g(\alpha) = \sum_{n=1}^{\infty} f_{k \cdot n}(\alpha), \qquad (3)$$

where the functions $f_{k \bullet n}(\alpha)$ are defined by the formula (2). Geometric meaning of the function $g(\alpha)$ is as follows: le t's write all regular $k \cdot n$ -gons in to the circle at the same time, where $k = const$, at the same time $k \geq 3$.
Figure 4: The Graph of the Function $g(\alpha)$ Has a Fractal Structure

From Figure 4 it is easy to see that the graph of the function $g(\alpha)$ has a fractal structure, similar to the graph of Van der Waerden's function [28]. Now consider the layer of Schwartz cylinder intersected by the plane of its orthogonal axis (Figure 5).
Figure 5: The layer of Schwartz cylinder intersected be the plane of its orthogonal axis

To solve this problem, we assume that the point x moves within the first layer. We introduce a one-dimensional coordinate system that coincides with the axis of the cylinder, the beginning of the system is located in the center of the upper base, and the direction from the upper base to the lower is considered positive. Considering the entered designations, we have: $x \in [0, \dfrac{1}{m}]$.

Consider a section of a layer with a plane passing through a point $x = \dfrac{1}{4m}$ (that is, through a quarter of the layer height).

Using the formula (4)

$$g(\alpha) = \sum_{n=1}^{\infty} f_{k \bullet n}(\alpha) =$$

$$\sum_{n=1}^{\infty} \frac{\sin(90^0 - \dfrac{90^0}{kn})}{\sin(90^0 + \dfrac{90^0}{kn} - \dfrac{\varepsilon}{2})} \bullet (1 -$$

$$-\frac{\sin(p(\alpha-[\frac{\alpha}{\phi}]\cdot\phi))}{\sin(180^0-s(\alpha-[\frac{\alpha}{\phi}]\cdot\phi)-p(\alpha-[\frac{\alpha}{\phi}]\cdot\phi))}) \,, \quad (4)$$

where k - some constant, $\varphi=\dfrac{360^0}{kn}$, a functions s и p are defined by formula's (5) and (6):

$$s(\alpha_1)=\begin{cases}\alpha_1, \alpha_1\le\varepsilon\\ \alpha_1-\varepsilon, \alpha_1>\varepsilon\end{cases}, \quad (5)$$

as $\varepsilon+\delta=\varphi=\dfrac{360^0}{n}$, each whole angle α uniquely define the angle $\alpha_1=\alpha-[\dfrac{\alpha}{\varphi}]\cdot\varphi$, so $\alpha_1\in\varepsilon+\delta$;

$$p(\alpha_1)=\begin{cases}\dfrac{180^0-\varepsilon}{2}, \alpha_1\le\varepsilon\\ \dfrac{180^0-\varphi+\varepsilon}{2}, \alpha_1>\varepsilon\end{cases}. \quad (6)$$

$x=0$
$x=\dfrac{3}{4m}$

Figure 6: Changes of function $g(\alpha)$ for x=0 and $x=\dfrac{3}{4m}$

You should pay attention to the nature of the function $g(\alpha)$ change when the section moves from the upper base of the layer to the lower base. For example, let the position of a point x

change from 0 to $\dfrac{1}{m}$ (i.e., within a single layer) in increments $\dfrac{1}{4m}$.

Consider the following problem. Let the section of Schwartz cylinder pass through the axis of the cylinder and any radius r based on its arbitrary layer, forming a polyline l at the intersection. Let x be a point on the axis of the layer, and r_x let be a ray perpendicular to the axis with the beginning at the point x , drawn in the direction of the radius r . Consider a function $h(x)$ that maps the distance from the point x , where the beam r_x intersects with the line l to the p int where the beam r_x intersects with the surface of the cylinder (described around Schwartz cylinder). What is the nature of the function $h(x)$ in this correspondence?

We have

$$h(x)\approx h_{k\cdot1}(\varepsilon)=$$

$$\frac{\sin(90^0-\dfrac{90^0}{n})}{\sin(90^0+\dfrac{90^0}{n}-\dfrac{\varepsilon}{2})}\bullet(1-$$

$$-\frac{\sin(p(\alpha-[\frac{\alpha}{\phi}]\cdot\phi))}{\sin(180^0-s(\alpha-[\frac{\alpha}{\phi}]\cdot\phi)-p(\alpha-[\frac{\alpha}{\phi}]\cdot\phi))}). \quad (7)$$

Now le t's introduce the function $h'(x)$:

$$h'(x)\approx\sum_{n=1}^{\infty}h_{k\bullet n}(\varepsilon)=$$

$$\sum_{n=1}^{\infty}\frac{\sin(90^0-\dfrac{90^0}{kn})}{\sin(90^0+\dfrac{90^0}{kn}-\dfrac{\varepsilon}{2})}\bullet(1-$$

$$-\frac{\sin(p(\alpha+\dfrac{\varepsilon}{2}-[\dfrac{\alpha+\dfrac{\varepsilon}{2}}{\phi}]\cdot\phi))}{\sin(180^0-s(\alpha+\dfrac{\varepsilon}{2}-[\dfrac{\alpha+\dfrac{\varepsilon}{2}}{\phi}]\cdot\phi)-p(\alpha+\dfrac{\varepsilon}{2}-[\dfrac{\alpha+\dfrac{\varepsilon}{2}}{\phi}]\cdot\phi))}). \quad (8)$$

It is easy to continue the function $h'(x)$

equal to $\dfrac{1}{m}$. If we assume that in formula (4) variables α and ε are independent, then the series defined by this formula can be viewed as a function of two variables $s(\alpha, x)$. The following Figure 7 shows part of the surface $z = s(\alpha, x)$ with $0^0 \le \alpha \le 360^0$ and $0 \le x \le \dfrac{1}{30}$. We assume that the height of one layer of Schwartz cylinder is equal to $\dfrac{1}{30}$ (f or clarity, the surface is shown in a cylindrical coordinate system).
Figure 7: The Layer Image of Schwartz Cylinder's Fractal Surface [23]

Previous experiments and computer design show that in the case where the heights of all layers of Schwartz cylinder partition tend to zero, its "area" as a function of layers number tr ends to the "area" of regular cylinder wherever it is continuous. Such studies conducted by students on resource or laboratory-calculation lessons (in the performance of multi-stage mathematical and information tasks or in the course of project activities or network interaction) develop the intellectual operations of thinking, increase educational motivation and the quality of development of mathematical actions.

5. List of Principal Symbols and Abbreviations

Schwartz cylinder - a straight cylinder with a polyhedral side surface formed by dividing the height into m layers and inscribed regular n-gons with the displacement of each layer and the connection of the vertices. It was first built by T. Schwartz at the end of the XIX century. When n, m tends to infinity, the area of the side surface can be infinite.

The layer of Schwartz cylinder (Figure 5) – the result of dividing the height of straight cylinder in to m layers. The plane is shown on Fi g.5 and orthogonal to the axis [26].

The image of the layer of Schwartz cylinder's fractal surface (Figure 6) – if to add up all n-gons on the axial cross-section of lateral surface of Schwartz cylinder so we will get the fractal

curve. On Figure 6 the results similar cross-section on the layer are presented. It will be fractal surface. It was built for the first time. It is problem to know the dimension on both curves and surfaces [26].

Founding of person's experience – theory, technology and method of understanding the essence of mathematical object, phenomenon and procedure, moving in a spiral and in stages. It was created by V. Shadrikov and E. Smirnov in 2002 [29], based on E. Husserl and M. Heidegger.

Visual modeling - theory, technology and method of the modeling using series of visual models leading to the essence.

6. Results

a) The phases and technological stages of student's research activity with intelligent system support are revealed and described. First a set of parameters for the quality and success of student's research activity (network input parameters) are described. So, diagnostics quality status and initial database of student's research activity are defined in personal, substantive, procedural areas. Diagnostics of personal parameters and quality of student's research activity on every technological stage will define the selectivity and level of information support. Really in this stage the standards, samples, and procedures for adapting the intellectual management functionality in education, science, technology, and social processes are presented. Fuzzification, metrics and correction of weight functional characteristics are defined using methods of fuzzy logic.

Second equipping neural layers with blocks from founding chains complexes of generalized construct of modern knowledge and variety of subtasks in different modalities are presented on every technological stage. It reflects the functionality, stochasticity, threshold of bifurcation and fluctuation transitions of search and creative procedures of student's research activity with intelligent system support.

Third the aim of output layer of neural network is classification of success and quality levels of student's research activity. Identification of the essence and effectiveness of mathematical procedures and stages of generalized construct adaptation and student's research activity are evaluated by hybrid neural network. As a result, it can be diagnosed the development of personal qualities and student's thinking, scientific knowledge experience, self-organization and creative self- sufficiency.

b) It was revealed a new pedagogical and technological effect and extension of Vygotsky' theory of "z ones of immediate development". Namely, content and dynamics of functional parameters, adaptation stages and regularities of generalized construct approximation investigated by means of computer and mathematical modeling using intelligent system support. So, it made to be checking the personal opportunities and skills in dynamics and perspectives of student's research activity. Intelligent system is become the managing instrument for defining of zones of immediate development

of the person (create, check, direct, evaluate, create on new stage).

c) Thus, we distinguish the following clusters of parameters of elements of scientific knowledge and quality of research activity of students:

- scientific thinking: creative acts, logical acts, principles and styles;

- scientific activities: research of experience (analysis, synthesis, associations, analogies, collection, study and processing of information, etc.); variability of data, limitation of experience; improvisation, reflection of common sense, trial and error, actions in conditions of uncertainty, problem statement and search for contradictions; obtaining a new or side result, setting an experiment, hypothesizing;

- scientific communication: accuracy of practical implementation, practical significance of the project, cross-cultural interaction, teamwork, social verification of new knowledge, etc.);

- typology of perception modalities: sign-symbolic, verbal, figurative-geometric, concrete-activity;

- experience and personal qualities: technological readiness, need and interest in research, creative in dependence, self-actualization, self-organization, self-realization and self-esteem.

d) It was revealed the synergetic effects of student's research activity (bifurcations, attractors, fluctuations, attraction pools of knowledge transformation; self-organization, self-realization, self-definition, self-development; obtaining by -product of research activity; equipping of thinking process by blocks from founding chains complexes of generalized construct of modern knowledge; functionality, stochasticity, threshold of bifurcation and fluctuation transitions of search and creative procedures).

e) It was refined the concept of intelligent management in the mathematical education of students as a method of intelligent systems functionality using (including a hybrid artificial neural networks) in conditions of openness (to external influences and factors) and the synthesis of mathematical and computer modeling in order to identify the essence and effectiveness of mathematical and evaluation procedures based on individualization of teaching mathematics and personalized and computerized feedback actualization of cognitive and evaluation processes. It is characterized by:

- functioning of stochastic, threshold, bifurcation and fluctuation transitions of search and creative procedures for the content of student's cognitive activity;

- evaluation of educational results based on implementation of expert systems with fuzzy logic and hybrid neural networks;

- multiplicity of goal setting functionality and of computer modeling content of processing and accounting of personalized databases images, texts, signals, table data based on effective feedback;

- mathematical, informational, natural science and humanitarian cultures dialogue and final student's synergy

and self-organization effects in research activities and assessment of knowledge and competencies quality;

- optimization of the intelligent systems functioning results in the direction of their classification, clustering, segmentation, regression in accordance with the standards and models of intellectual management of cognitive activity and evaluation of mathematical education results.

f) It was developed the original computer design and mathematical modeling of nonlinear dynamics of synergetic effects manifestation and dynamic invariants of Schwartz cylinder investigation with intelligent system support as a method of concept "surface area" understanding.

g) At first it was constructed by -product of Schwartz cylinder as fractal surface by transformation of Van der Waerden' function on the circle.

7. Discussion

It is very important to carefully define the technological stages and personal parameters, set of generalized constructs of modern subject knowledge as attractors of research activity. Diagnostics of personal parameters and quality of student's research activity on every technological stage will define the selectivity and level of information support. At the same time the intelligent system will create the personal's educational trajectory of student. The future enhancement of intelligent system support will be depend from the quality of multiple neural network input parameters (personal, substantive, procedural), an efficiency and effectiveness of diagnostic procedures and data base of equipping neural layers with blocks from founding chains complexes of generalized construct of modern knowledge, correction of weight functional characteristics on the base of fuzzy logic, relationships and indicators of research activity, variety of generalized constructs of modern scientific knowledge.

8. Conclusion

Thus, the generalized constructions of the content and computer design of revealing the essence of "problem zone" of school mathematics – surface area are revealed and characterized. Mathematical modeling in details of nonlinear dynamics of areas growth of multi-faceted complexes in the grinding of triangulations of Schwartz cylinder lateral surface by means of computer and mathematical modeling are presented. Bifurcation points, attraction pools, computational procedures and fluctuations of state parameters, computer design and side results of the "area" of lateral surface of regular and irregular of Schwartz cylinder are identified and characterized. Hierarchies of forms and means of research activities of students are built: resource and laboratory-calculation lessons, complexes of multi-stage mathematical and information tasks, project methods and network interaction based on the use of QT Creator – a cross-platform free IDE for development in C++. Specific fragments of cognitive activity of students can be implemented using small means of informatization as ClassPad400, WebQuest by means of Web-technologies integration with educational activities, as well as using Wiki-sites, Messenger, Skype. The quality of mathematical education of students depends from development effects of

student's manifestation in the course of rich information and educational environment implementation. This is possible in the study of "problem zones" of school mathematics with the identification of complex objects essence, processes and phenomena by means of computer and mathematical modeling with the reflection of synergy procedures attributes. At the same time, self – organization and self-development of a person reflect the complexity, openness, non-equilibrium of learning content constructs - in our case, a computer design and technology for the study of nonlinear dynamics of the "areas" of lateral surface of Schwartz cylinder are developed and implemented. Pedagogical experience shows a significant increase in educational motivation of students and development improving to quality of school mathematics and computer science using in the integration context of mathematical and information knowledge and procedures. Identification and research of modern achievements in science in teaching mathematics based on intelligent control allows you to master the generalized constructs of complex knowledge through the integration of various area of science. Thus, creating the conditions of openness of educational environment, updating of complex mathematical structures, the plurality of goal setting and the possibility of obtaining by‑products provide the basis for self-organization of personality and the effective development of intellectual operations, increase educational and professional motivation, creativity and critical thinking in learning mathematics both at school and university.

Conflict of Interest

The authors declare no conflict of interest.

ARTICLE INFO

ABSTRACT

Since its release in 2013, 4.4 billion people around the world have used Kahoot!. Various topics with multiple languages have been made so that there are at least 200 billion games. A very high number for an educational application. Why Kahoot! So interesting? This study aims to analyze the gamification elements found in Kahoot! as a benchmark to create engaging game-based learning in industrial 4.0. The method used is the Octalysis Audit, which examines eight aspects of game psychology: meaning, achievement, empowerment, ownership, social influence, scarcity, unpredictability, and avoidance. The results showed, Kahoot! A value of 441 in Octalysis was obtained. This result shows an excellent balance between positive and negative motivation. Besides, Kahoot also has a balance between Intrinsic and extrinsic motivation.

1. Introduction

Game-based learning is not a new thing in education. Educational activists compete to make learning more attractive to increase students' interest in learning a learning material. Specifically, the game is known for its ability to make players feel involved and eager to play it. The enthusiasm in the learning process is an essential factor in obtaining learning outcomes. Often, players/learners are directed to master techniques to reach higher levels. This method is intended to develop skills or to feel pleasure, all of which are intellectual characteristics of motivation in humans [1]. In learning, games are usually applied to evaluate students' understanding of the material they have learned. The evaluation model often collects questions in a quiz, puzzle, questionnaire, etcetera [2,3]. In a game, gamification plays a vital role in increasing motivation [4]. Gamification is defined as the application of game elements in a non-game context [5]. The ingredients in question include at least three things: interface design patterns (badges, levels, leaderboard), game mechanisms,

and design principles [6]. The application of gamification can be found in several forms with specific objectives, such as marketing, social media, commerce, corporate marketing, and education [7].

Call it Facebook, Tokopedia, Shopee, Gojek, Waze, etcetera. One application in the world of knowledge that also applies gamification is Kahoot. Kahoot! is game-based learning that has a mission to improve education quality by strengthening the attachment and connectedness between users while playing [8]. Kahoot was released in 2013. This application has been played in more than 200 cities worldwide, with the total number of players reaching 4.4 billion [8], incredible numbers for an application. This study aims to analyze the elements of gamification contained in the Kahoot! Application. This study's research method is the Octalysis Audit, which is a technique to assess the strengths and weaknesses of a product [9]. The assessment was carried out through 8 approaches to the game's psychological side: meaning, achievement, empowerment, ownership, social influence, scarcity, uncertainty, and avoidance. This study allows further research to identify what types of motivation are weak to improve and provide new experiences. This study's results can be applied to the

application of learning so that teachers or educators continue to innovate in their teaching methods to ensure student motivation in learning sustain, especially in industry 4.0 today, the gaming elements in learning seem relevant.

2. Literature Review

In learning, assessment plays an essential role in assessing the process, progress, and student learning outcomes [10]. Several forms of assessment can be formal, informal, written, performance, traditional, authentic, etcetera. Traditionally, written assessments are the most frequent and easy to use. Paperless assessment is starting to be widely used in the 4.0 era. This fact is evidenced by some previous studies that used Kahoot in education for various purposes. For example:

- increasing motivation to learn English [11],
- enriching the ability to think historically on historical subjects [12],
- enhancing learning activities on Islamic studies topics [13],
- facilitating science learning [14],
- studying foreign languages and improve pronunciation [15],
- improving vocabulary performance [16],
- thematic education [17],
- advanced placement Biology class [18],
- formative medical learning assessment tools [19], and
- increasing test scores [20].

The majority of the research results indicate that Kahoot can be appropriately used to assess learning. Besides, the assessment process carried out in Kahoot is simultaneous and transparent in one large group. This condition has proven to be able to increase student motivation and learning outcomes. Toth Aron discovered that Kahoot had a positive effect on students' results and perception of learning. Aron's research results show that students who took part in more Kahoot quizzes tend to reach higher exam marks.

Moreover, they marked more correct answers and less incorrect ones [21]. This research is strengthened by research that states, when combined with active learning and practice, Kahoot! able to improve student learning outcomes [22,23]. Besides learning outcomes, according to the questionnaire, 82.2% of students stated Kahoot and can also increase student learning motivation [24]. The study results are in line with research that stated that Kahoot enriched student learning quality in the classroom, with the most significant influence on motivation [25,26]. A previous study strengthens this research by saying that, based on T-test testing, Kahoot can increase students' motivation and independence by a significant number [27]. Another study found the fact that Kahoot! can have a positive effect on learning performance, classroom dynamics [25], students' and teachers' attitudes, students' anxiety [28], and student engagement [29]. The effect of applying Kahoot to learning is obtained because of gamification [30–32]. This research focuses on analyzing the gamification elements in Kahoot, using a method called Octalysis Audit.

2.1. Kahoot!

Kahoot! can be accessed on the page http://www.kahoot.com. Kahoot! provides games that can be played directly in one room,

distance learning using video conferencing applications, and learning applications. Several types of user choices are available, starting from free to paid. The difference lies in the features that can be used. In the basic version, game makers can play games personally or via video for ten players. The Basic version offers users to create different types of questions and video hosting for 20 players. The Pro version provides additional game options and allows video hosting for 50 players. Finally, the premium version can host via video for 2000 players.

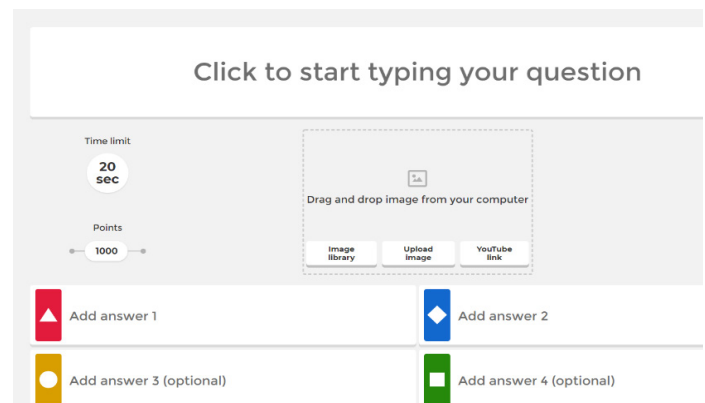
In the Kahoot! The application, the question maker, and the player have different access. Question makers can create questions independently, choose from the question banks provided, or import from Excel files if they already have them. The type of questions is multiple-choice with four choices, and True or False (Basic version). At the stage of making questions, users can also add images by selecting from the image library, uploading pictures from the device, or attaching a YouTube link. The time limit for working on the questions can be chosen from 5 seconds to 240 seconds. The choice of points in each item can also be arranged with three variants: 0, 1000, and 2000 (Figure 1). When the game maker has finished creating questions, the game can be started by pressing the Done button.


Figure 1: Question-making page on the Kahoot! website

To play the game directly, the question maker must have a tool to display the questions and answer choices on the monitor screen. After the questions are finished, the game can be started by pressing the Play button. Question makers can choose whether individuals or groups will play the game. The interface will then display the PIN that the player must input on the www.kahoot.it page on their respective devices. The player enters a PIN, then comes a nickname on the page. Players who have already joined will appear on the screen. This feature makes it easy for the instructor to monitor how many players have successfully entered. Questions and answer choices will be displayed in front of the screen, whereas on the player's device screen, there are only colors that indicate the answer choices (Figure 2).

3. Methodology

The Octalysis framework (Figure 3) was created because in [9] the author recognized the need for tools to help build strategies and analyze gamification implementation. After years of studying game mechanics, Chou concluded that eight core drives motivate someone to do certain activities. Core drives push people in different directions, and not everyone is motivated by the same drive. Visually, Octalysis has an octagonal shape in which the core

drives are represented in each corner. The drive on the right represents the creative, artistic, and social aspects, while the left's drive represents the logical and intellectual aspects. These sides are referred to as the Left Brain and Right Brain. Besides, he discussed the importance of understanding that this urge supports extrinsic or intrinsic motivation [33].
Figure 2: Illustration of Kahoot's interface! when played
Figure 3: Octalysis Framework

Core drive on the lower side of Octalysis is referred to as Black Hat Gamification, which means negative motivation. This type of encouragement relates to people who are motivated to take specific actions. For example, fear losing because of curiosity about events to come or efforts to achieve things that they cannot have. On the upper side of Octalysis is a positive motivation called White Hat Gamification. This positive core drive motivates individuals through creativity, making them feel secure because of their sense of control and the impression of more significant meaning. Octalysis emphasizes that negative encouragement can inspire motivation as much as positive motivation, but the balance between the two is essential to achieve satisfying and beneficial results.

Octalysis highlights that successful gamification requires consideration of all core drives. The eight-core drives referred to in Octalysis are as follows [34]:

1. *Epic Meaning and Calling*
    At this core, the user is motivated to do something greater than himself or feel chosen to do something. In a game, narration can make this core more pronounced. For example, in the intro of a game, it is said that the world will soon be destroyed, and somehow, the player is chosen as the only person who is qualified to save the world. This core certainly creates excitement and fosters motivation for players to carry out adventures in the game.

    Another example is people who contribute to filling content on Wikipedia pages. Someone who feels "called" will be willing to spend hours filling the content on the page, even if not paid.

2. *Development and Accomplishment*
    Development and achievement are internal drives to make progress, develop skills, and ultimately overcome challenges. In this core, various kinds of performances are designed, such as points, badges, leaderboards, rewards, and other achievements that players can get.

3. *Empowerment of Creativity and Feedback*
    At this core, users are involved in a creative process to find out different combinations repeatedly. Users not only need a way to express creativity but can also see feedback from players.

4. *Ownership and Possession*
    This core is related to the motivation of users because they feel they have something. When a player feels he has something, he will indirectly make what he has better and more.

5. *Social Influence and Relatedness*
    This core combines all the social elements that drive a person, such as guidance, acceptance, social responses, friendship, competition, and jealousy. When one player sees an extraordinary friend on a skill or has something unusual, the player will be motivated to reach the same level.

6. *Scarcity and Impatience*
    In this core, the player is a drive to want something because he cannot have it. For example: due to a time limit, then the game will restart 2 hours later. The fact that players cannot get things now motivates them to think about it all day long.

7. *Unpredictability and Curiosity*
    In general, these cores are harmless drives to find out what happens next. Uncertainty makes players curious. This core happens when someone is reading a book or watching a movie. They will finish what they started of curiosity about the end of the book or film.

8. *Loss and Avoidance*
    This core drive is based on avoiding something negative to happen. Players will feel that if they do not act immediately, they will lose the opportunity to serve forever.

Octalysis Audit is carried out by assessing each existing core. To produce an Octalysis score, researchers take how well the subject of analysis is in each core drive. Then assign a number between 0-10 based on personal judgment, data, and experience flow, then square the number to get a Core Drive score. A score of 10 indicates "How strongly this Core Drive motivates toward the Desired Action." The final Octalysis score will be obtained after adding all 8 Core Drive scores [35].

The sample in this study were 34 lecturers from 2 universities in Indonesia. Samples were selected randomly because all individuals in the population singly or together are given the same opportunity to be selected as sample members. Thus, the research results will be more objective. Lecturers, who were the research sample, had used Kahoot more than 15 times. As many as 52.9% admitted to using Kahoot for lectures, 41.2% used it for workshops, 31.4% for seminars, the rest for other purposes. Survey respondents were asked to provide an assessment both as a question maker and a player. The research instrument was in the form of 12 statements arranged according to the eight cores is Octalysis. The assessment given by respondents is subjective based on the experiences they have experienced. Each statement has a Likert scale from 0-10, according to the Octalysis Audit assessment. Table 1 below shows the instruments in this study.

Table 1: Research Instrument

No	Statement	Core No
1	Kahoot encouraged me to contribute to it	1
2	Kahoot has features such as points, badges, scoreboards, rewards, and podiums	2
3	Kahoot encouraged me to try repeatedly and make different combinations when making questions	3
4	I can see the feedback given by the players	3
5	I feel that I have to defend and increase the points I get while playing Kahoot	4
6	When I was a player, I felt proud when other players applauded when my name appeared on the Scoreboard / Podium	5
7	If my name does not appear on the Scoreboard, I have to pursue it in the next question	5
8	Often the participants asked me to repeat the game when it was finished	6
9	I was wondering how many questions I had to answer	7
10	Every 1 question is answered successfully, I always wonder whether my name is in the top 5 or not	7
11	For me, the most important thing is to answer quickly even if it is wrong	8
12	For me, the most important thing is to answer correctly even though it takes a long time	8

4. Result and Discussion

4.1. Epic Meaning and Calling

A total of 11 respondents gave a score of 8 for the statements on this core (Figure 4). Epic meaning and calling can be done when the user, for example, fills in a question bank. The question bank

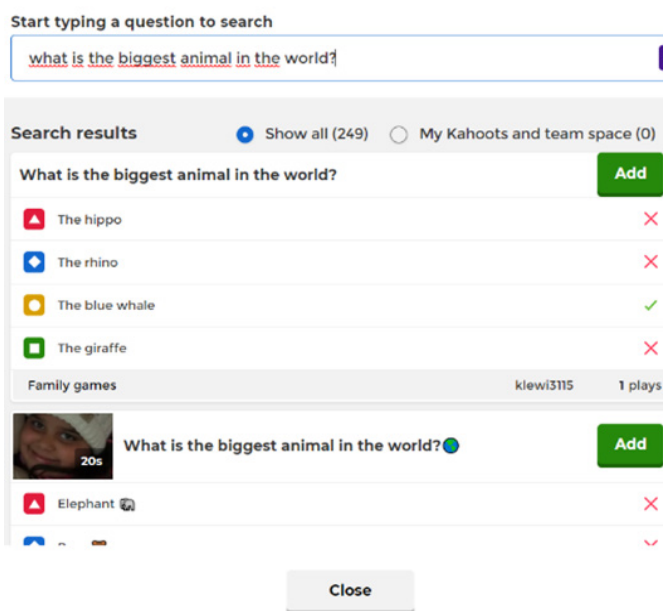
provided by Kahoot! allows users to search for problems with specific themes that have been created by other users (Figure 5). Fellow users around the world can benefit from each other. This feature is related to the core meaning in Octalysis, where users can feel motivated to make various questions for themselves and others. This calling is in line with previous studies, which stated that student motivation increased after using Kahoot! [11]. The average score for this core is 6.74.
Figure 4: Epic Meaning and Calling response result


Figure 5: The question bank on the Kahoot! Page

4.2. Accomplishment

For each question answered, Kahoot can display the correct answer, and the Scoreboard contains the five highest-ranked players and their respective points (Figure 6a). This feature certainly raises pride for players whose names are displayed on the Scoreboard. The three best players will be shown their names with a podium interface at the end of the game. The back-sound also supports it as if the player is on a real podium (Figure 6b).

At this core, 75% of respondents gave a score of 8 and 10. This result indicates that respondents have understood that Kahoot has gamification features, such as point, Scoreboard, reward, and podium. The average score obtained from the statement on this core is 8.67.

4.3. Empowerment of Creativity and feedback

An exciting game requires creativity from the creator. To not be monotonous, question makers can add questions that are not too

serious in the middle of the game. For example, by making a problem that displays a photo of one of the players, then questioning what the player is doing? This question will make the game more interesting. However, of course, creativity here is relatively dependent on the question maker. When respondents were given the statement, "Kahoot encouraged me to make different combinations when making questions." 50% gave a score of 8 and above. The survey results show a balanced answer, depending on the creativity of the question maker.
(a)
(b)

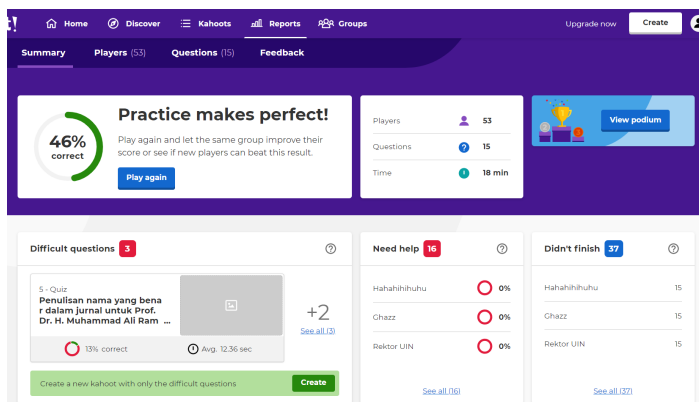
Figure 6: (a) Scoreboard Interface (b) Podium Interface


Figure 7: Summary of the Kahoot! Page

The question maker can see player feedback at the end of the game. One of the new features provided by Kahoot is the

Summary, which contains a summary of the games that have been performed. Figure 7 shows the Kahoot Summary, containing the number of players, the percentage who answered correctly, the number of questions, the time, the most difficult questions, to the player's status. This player status includes whoever needs help, players who have not finished the game to the end, and the podium. This new feature makes it very easy for question makers to review the game as a whole.

4.4. Ownership and Possession

One of the exciting gamification elements of Kahoot is the point. Points for each question in Kahoot can be varied, starting from 0, 1000, and 2000. The faster and more precise the player answers the question, the higher the score obtained. With the scoreboard feature, players can see how many points they have. If the player's name is on the Scoreboard, it will undoubtedly make them maintain a high position so that no one beats him.

The importance of the points obtained attracted 35.3% of respondents to give a value of 10 to statement number 5. This fact shows that the respondents strongly agree with this statement. Apart from getting points, more than 84% of respondents also agreed to retain their points when playing Kahoot. These survey results are in line with the core ownership and position in Octalysis, where the players try hard to defend the points they get.

4.5. Social Influence and Relatedness

One of the gamification elements that have a strong social influence is the Scoreboard and the Podium. Other players will usually congratulate or applause when a player's name appears on the Scoreboard or Podium. Events like this bring pride to these players. A total of 26 survey respondents gave a score of 8-10 concerning the statement, "I feel proud when other participants applaud when my name appears on the Scoreboard / Podium."

Conversely, this social influence also motivates players whose names do not appear on the Scoreboard. A player whose name is not on the Scoreboard will be motivated to catch up and make his points higher. A total of 29 respondents strongly agreed to pursue other participants' points when their names did not appear on the Scoreboard. This sense provides the motivation that is in line with the core of social influence and relatedness.

4.6. Scarcity and Impatience

Based on experience, some of the respondents said that often when finished playing Kahoot, the player asks the host to repeat the game. Motivation to get better grades makes players want the same game a second time. However, some respondents admitted that they did not want to repeat the game because the order of the questions displayed would be precisely the same as before. In this core statement, the average score is 7.9 (Figure 8).
Figure 8: Scoring for the Scarcity cores

4.7. Unpredictability and Curiosity

More than 60 percent of our respondents are intrigued as to how many questions they have to raise. Although, in the game-opening, a justification is given for the number of questions to be played (Figure 9). Another thing that triggers the players' curiosity is to find out whether he entered the Scoreboard or the podium at the end of the game (Figure 10). A scoreboard will appear that all participants have answered every 1 question. This core gets an average score of 8.12 points.
Figure 9: Score given by respondents regarding curiosity about the number of questions
4.8. Loss and Avoidance

The last core in Octalysis Framework is related to the speed of players in answering questions on Kahoot. Because the time to answer questions can be varied, players certainly do not want to miss answering questions because they run out of time. This feeling will harm the players because they do not get the point. Conversely, if too fast but other players can replace the wrong answer, the ranking of players.

Table 2: Average score for every core

No	Core Aspect	Average
1	Epic Meaning and Calling	6.74
2	Development and Accomplishment	8.67
3	Empowerment of Creativity and Feedback	7.5
4	Ownership and Possession	8.41
5	Social Influence and Relatedness	8.30
6	Scarcity and Impatience	8.35
7	Unpredictability and Curiosity	8.12
8	Loss and Avoidance	6.24

On this core, we ask what is most important for players. A total of 5.3 average scores was obtained for the statement to answer quickly, even though it was wrong. The statement chose the right answer, even though it took a long time to get an average value of 7. This result shows that each respondent has different priorities. Some respondents choose the time, and some are more careful even though they lose much time.

Based on the respondents' answers for each Octalysis core, we add up each point obtained, then divide by the number of respondents to obtain each statement's average value. The average value is shown in Table 2.

4.9. Octalysis Score

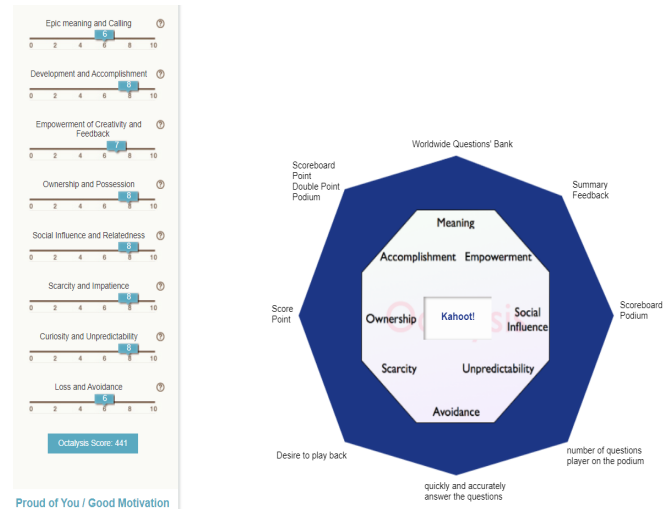
The values entered in the Octalysis tool provide only round values [36]. Therefore, we take the numbers that come before the comma. Based on the research results, the value obtained was 441. Kahoot is considered to have a balance between White Hat and Black Hat drives. This result marks Kahoot balancing the positive and negative motivations of the player. Besides, the right brain balance and the left brain is also considered quite good, which indicates Kahoot! application has a proper balance between Intrinsic and Extrinsic Motivation. An overview of Octalysis Kahoot's audit analysis present in Figure 11.


Figure 11: Kahoot! 's Octalysis audit result

Even though it is considered quite reasonable, according to the Octalysis tool, some of our respondents provide suggestions for Kahoot. The suggestions given include minus points, questions raised on players' gadgets, opportunities to correct wrong answers, open camera facilities, to custom music. These suggestions will certainly make Kahoot better and more attractive to use in learning.

5. Conclusion

Has been analyzed a game-based game application called Kahoot! by using the Octalysis Audit method. The score on the form accumulated by survey based on eight core drives on Octalysis. Based on research, a final value of 441 was obtained in the Kahoot application. This outcome is Kahoot! It is a balance in terms of motivation, both positively and negatively. The outcome also shows that Kahoot! has intrinsic and extrinsic motivation. Therefore, Kahoot! can be used as the right learning media to make similar games. Researchers have recommended some suggestions to improve Kahoot! better. Such as: providing tips to make the game more interesting, providing a random feature about the problem, and providing a minus point feature if the answer is wrong.

Conflict of Interest

The authors declare no conflict of interest.

Analysis of Pharmaceutical Company Websites using Innovation Diffusion Theory and Technology Acceptance Model

Mochammad Haldi Widianto*

Informatics Departement, School of Computer Science , Bina Nusantara University, Jakarta, Indonesia, 11480

A R T I C L E I N F O	A B S T R A C T
	The progress of information using websites is developing fast, impacting various sectors, one of which is pharmaceutical companies. Pharmaceutical companies have roles in drug manufacturing, pharmaceutical distribution, and essential services for the community—the most important and challenging activity in the IT department. The researcher is responsible for one of the Bandung pharmaceutical companies. Researchers are trading IT service managers for drug manufacturing, drug distribution, and community service units that have been conducted online. The company has an essential role in distributing drugs to pharmacists and hospitals during the pandemic at COVID-19. The use of the IDT (Innovation Diffusion Theory) and TAM (Technology Acceptance Model) models are used because, according to the agreement, TAM is a concept that researchers consider to be the best and suitable for viewing the user's use of IT systems. The study will try to convert these methods with TAM variables, such as Perception of Use, Perception of Ease of Use, Attitude Towards, and Behavior Intentions. Also, IDT variables such as Relative Advantage, Compatibility, Complexity, Trialability, Observability. This study's survey model is the SEM (Structural Equation Model) using a software application. The results showed the pharmaceutical company website could be well received at pharmacists and hospitals in Bandung. The experimental results get a hypothesis, such as finding a significant output. And with the results of this study, getting good results for the people around Bandung.

1. Introduction

Today the information system is developing rapidly along with the pandemic currently in this world (COVID-19). The development of this information system is compared with hardware technology because computers or other hardware are media that can provide convenience, especially when the pandemic is now [1]-[3].

Every company needs IT [4]–[7] to help with scheduling, purchasing, etc., so that it can be more centralized. In every company other than pharmaceuticals, procurement management must determine the existing goods, especially medicines, and manage inventory in the industry and sales [3], [8].

In its production, pharmaceutical companies in Bandung produce such products as Propepsa, Bevita Suspension, Zemindo, Amiclav, Bionemi, Calnic, D-Vit, Estin, Flamic, Fosicol, Gastrolan, Grafix, Grafed, Imox, Loxil, Mesol, Moretic, etc. , and

distributes sales results to all regions in Indonesia. Every sale of medicines to pharmacies and hospitals needs to make orders ordered from each distributor and sub-distributor [9], [10].

According to previous research sources in manufacturing Information Technology (IT) system, products in pharmaceutical companies are still traditional with direct analysis (interviews with PT) combined with the waterfall method [11], [12]. Today researchers use the waterfall method. Barriers that became obstacles were found from the results of interviews using too many typical office applications. So, now the researcher builds some websites to maximize utilization system information in the pharmaceutical company.

Researchers have carried out many web analysis theories, one of which is the Innovation Diffusion Theory (IDT) and the Technology Acceptance Model (TAM) [13], [14]. Explanation TAM is the instrument for anticipating the probability of another innovation being received inside a gathering or an association.

* Corresponding Author: Mochammad Haldi Widianto, Kecamatan Buah Batu, Bandung, Indonesia, Email: mochamad.widianto@binus.ac.id

In light of the hypothesis of contemplated activity, it has by a wide margin been the most broadly talked about among all the connected models. What's more, dictated by two convictions: saw value, which is characterized as the forthcoming client's abstract likelihood that utilizing a particular application framework will build one's work execution inside a hierarchical setting, and saw usability, which alludes to how much the planned client anticipates that the objective framework should be liberated from exertion. IDT is utilized to clarify how groundbreaking thoughts and new practices are spread inside and between associations. It is a cycle of dispersal through arranged systems to empower advancements to be received [15], [16].

With the results of the information system and the use of technology from the pharmaceutical company website in Bandung, it is necessary to measure the extent of the successful implementation. The use of the TAM [17]–[19] and IDT [15], [20], [21] model is based on the fact that so far, TAM is a concept that is considered the best and suitable in explaining user behavior towards information technology systems.

As a comparison with previous research, on [16] using a comparison application with the labor market, while on this application, researchers use pharmaceutical companies to see their effects, it is expected to be useful for the pharmaceutical company in assessing the attachment and improvising the company's IT system.

2. Theoretical Background

According to [8], [22], [23] said if the progress of the company can create healthy communities and increased life expectancy, produce and spread drugs, and ultimately lead to the commercialization of the development of drug distribution. Develop is a way to understand other thinking, useful methods, and hope for progress, where development is very rapid, with new ideas and useful. It is IT's use for recent and varied advancements as well as increasing or lower-cost nature, to meet or exceed our own goal

Innovation [24]–[26] is the essential stage of the diffusion processor so that it can trigger the process to continue rapidly. Meanwhile, good communication refers to a channel used to transfer information from one party to another so that it can start the same thoughts. The following is an illustration of diffusion theory or IDT as shown in Figure 1.
Figure 1: Innovation Diffusion Theory

Furthermore, the theory put forward [16], [27], [28] has a significant meaning and has conflicts in leadership management.

A temporary conclusion can be drawn, among other things, describing the principles that influence the rate of development deprivation, such as the progress phase, so that a leadership process is needed. Regulations affecting the deployment stage of development include the quality of the product (view progress), the type of development choice, the correspondence channel (correspondence channel), the conditions of the social framework, and the specialist work progress (change operator). The characteristics of IDT, according to [8], [9] as follow:

Rogers (1983) suggests five characteristics innovations include:

1) relative advantage,

2) compatibility,

3) complexity,

4) ability to be tested (trialability) and

5) observability.

In contrast to IDT, TAM is a new derivative that was introduced by Davis in 1986. The goals of TAM are more generalized to explain the behavior of the primary user of the computer. TAM uses the TRA derivative as a theoretical basis for deriving a causal relationship between two fundamental beliefs, such as Perceived Usefulness and Perceived Ease of Use [18], [19]. More evident than TRA because TAM is used unusually for the use of innovations in computerized techniques. This TAM model is ready to predict something and can clearly explain to experts and professionals to find out why a factor is not known and provide the potential for progress that has the right accuracy.

Using the TAM factor is to provide initial advancement of the effects of external factors on inner beliefs, frame of mind, and goals. Achieve this goal by distinguishing some of the fundamental elements put forward in the investigation following the principles that influence psychological factors and feelings of recognition in computer engineering and using TRA as a possible reason for severing the relationship of the research factor model. The stamp positions two beliefs, particularly seeing perceived convenience and benefits as essential elements of PC recognition behavior, as seen in Figure 3.
Figure 2: Technology Acceptance Model (TAM)

Based on the literature's systematic review, different works have been found that strengthen the areas of knowledge processing and representation. The branch that is responsible for the processes of knowledge representation in Artificial Intelligence, to achieve this, it is necessary to group situations that

have similar characteristics or properties instead of making individual representations.

3. System Analysis

3.1. Business Process

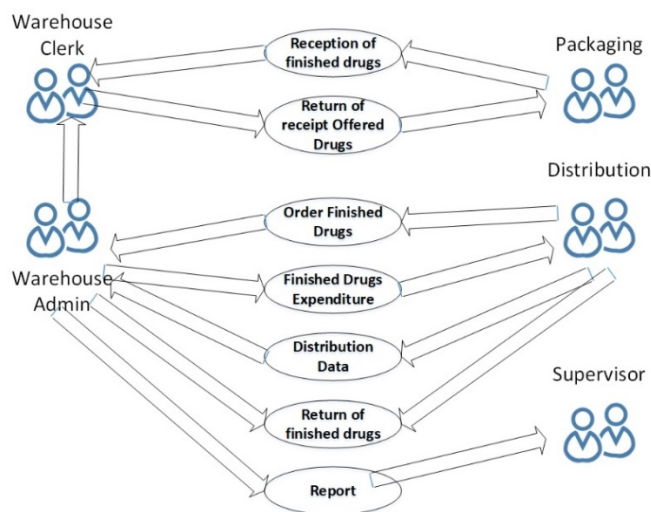
The pharmaceutical [29]–[32] business process is indeed very complicated, which can be interpreted as having a set of activities or jobs that are structured and interrelated. It is used to solve a problem or produce a new pharmaceutical product. Several sections are used to analyze employees' work procedures in IT to see the finished drug supplies at a pharmaceutical manufacturing plant in Bandung, and this business process aims to identify and problems that occur and expected needs.


Figure 3: Business Object of Drug Inventory

Table 1: Information Needs

No	Name	Goals	Frequency
1	Drug Receipt Report	Warehouse Supervisor	Monthly Period
2	Report on Drug Expenditures	Warehouse Supervisor	Monthly Period
3	Distributor Data Report	Warehouse Supervisor	Supervisor Needs
4	GOJ Inventory Report	Warehouse Supervisor	Monthly Period
6	Delivery orders	Distributor	Every Day
7	Proof of receipt of finished pharmaceutical	Warehouse Admin	Every Day
8	Reports on Receiving Medication for Finished Medicines	Warehouse Supervisor	Supervisor Needs
9	Report on Drug Expenditures Return	Warehouse Supervisor	Supervisor Needs

3.2. Identification of User Needs

The information system [33]–[35] must provide the consumer for comfort and classification incompatible with the requirements, though these system conditions are as measures:

1. The working framework will have to make the user's job easier
2. The framework produced must have data protection so that its use can be restricted
3. Employees who have been enrolled must use the program
4. The system made must be capable of displaying reports and even printing reports according to existing data input
5. All information should be available and often easy to find and obtain to help achieve the use of this system by users
6. This information system needs to be able to create its use straightforward for the warehouseman.
7. The phone designed must be able to initiate the input and distribution of pharmaceutical completes.

What needs are described in table 1:

3.3. Program Testing

The system must be free from errors before the process is implemented. To that end, the program has to be tested in advance to investigate the potential errors. This system is evaluated or reviewed using the White Box and Black Box techniques. Black Box Testing where for testing the program immediately looks at the application without knowing the program's structure. This test is carried out to see whether a program has met or not [8], [24], [36].

4. Result

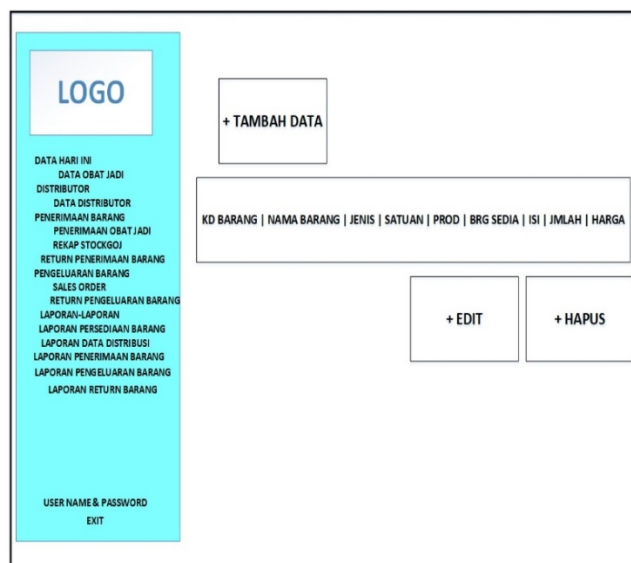
The first few contents contain the Logo etc. Next includes some vital information about the company. The most important thing is the log-in section. Employees can't enter this website.


Figure 4: Login Interface Home Admin

Furthermore, the same as before carried out several tests using the black box, with the results as in the following table:

Table 2: BlackBox Test Home Admin

Component testing	Expected results	Result
Add Data	May add data	Successful
Connect Distributor	Can Connect Distributor	Successful
Received Goods	Can Connect received goods	Successful
Report Distribution	Can Connect Report Distribution	Successful
Log Out	Can Logout	Successful

Of all the tests carried out by BlackBox and according to [37], the method of using waterfall is still efficient and effective for use in making websites for pharmaceutical companies.

4.1. Testing the Overall Research Model

This model [38], [39] shows that the model consists of 9 constructs, namely: RA (Relative Advantage), CPA (Compatibility), CPL (Complexity), TRI (Trialability), OB (Observability), PU (Perceived Usefulness), PEU (Perceived Ease of Use), AT (Attitude Towards), BI (Behavioral Intention). In this model, the relationships between constructs and the interrelationships between indicators are adjusted to the research hypothesis. The overall model test results using SPSS AMOS 22 produce the level of conformity, as shown in the table.

4.2. Hypothesis Testing with SEM

This test is done to see the relationship between the constructs that exist in the research model. The basis for decision-making was taken by looking at the regression weights for the constructs related to the test results using SPSS AMOS version 22. If p> 0.05, then H1 is rejected, and if p <0.05 or denoted by ***, then H1 is accepted as described in table 6.

Table 3: Modification Structural Model Suitability Test Results

Model Fit	Result	*Acceptable Level*	Interpretation
CMIN (*Chi Square*)	1817.325	Beetween Saturated and Independence Model	Good Conformity

Among them are the Relative Advantage hypothesis with Perceived Usefulness and Perceived Ease of Use. It is apart from the use of the pharmaceutical company, which provides opportunities for education graduates and students to apply for jobs to companies that have collaborated. The presence of this pharmaceutical company indeed feels various benefits and aspects of benefits. However, the company still determines the work that is obtained or the opportunity to receive job applicants.

Graduates and students also do not feel the influence of compatibility with the aspects of benefits and convenience. This happens as the development of information technology that makes accessing the internet through various media makes the pharmaceutical company system less suitable because it cannot reach the mobile side.

The pharmaceutical company's complexity was felt not to affect the aspect of ease, and trialability did not change the character of benefits. Because the pharmaceutical company is only intended for the academic community, the wider community can only access it. And also does not feel the effect of benefits on the intention to use, the tendency of job applicants triggers it will stop looking for another job if the person has found a job by expectations.

5. Conclusion

Based on the results of research conducted on the implementation of the pharmaceutical company using. The use of the IDT and TAM models approaches processed using the SPSS AMOS 22 application. The following conclusions can be obtained, and Relative Advantage does not affect Perceived Usefulness in the pharmaceutical company's application. Relative Advantage does not affect the Perceived Ease of Use in the application of the pharmaceutical company. Compatibility does not affect the Perceived Usefulness in the application of the pharmaceutical company

ARTICLE INFO

ABSTRACT

In this paper, hexa spacer damper is proposed and its vibration damping effect on the 765 kV power transmission network under the influence of fluctuating wind (10-60 Hz) loading is validated. This asymmetrical loadings led the bundle of Zebra ACSR conductor to be twisted and hence, cause mechanical and electrical instabilities across the span length. These issues may be addressed using the undertaken spacer damper. This paper highlights design, development and field tests of the proposed solution. The product has been validated using CATIA V5 software tools and for the field trial - 27 numbers of these dampers have been placed at various sub-spans across the line at Hydro Québec Test Station, Canada. The damping efficiency has been recorded using system integrated data acquisition set up. The proposed products are an important item of overhead line hardware and are extensively used to ensure that bundled conductors to provide mechanical and electrical performance reliability in service.

List of Symbols and Acronyms

A	Area of cross-section
$A_{m,v}$, $B_{m,v}$	Sub-span integration constants
C_m	Velocity of wave
D	Diameter of conductor
E	Conductors' Young modulus of elasticity
EI	Conductors' flexural rigidity
f_D	Forces of aerodynamic for damping
f_W	Forces of wind over sub-conductor
I	Inertia moment
l_n	Length for sub-spans
L	Span length
m	Motions' plane for sub-conductors
P	Arms of damper
Q	Quantity of damper
T_{2k-1}	Tension in $(2k-1)$th sub-conductor
T_m	Maximum value of tension
v	Interval of sub-span length
x	Location of spacer damper
Y_b	Amplitude of bending
ρ	Conductor s' material density
$\ddot{\omega}_{m,v}$, $\omega''_{m,v}$	Vibration limits at clamped support
P-P	Peak-to-peak
RIV	Radio interference voltage

1. Introduction

Today, energy has become prime necessity of growing population's livelihood and simultaneously reliability of the transmission network is vital for uninterrupted power supply service [1]. It's quite common to transmit the power at higher voltage level (like HV, EHV and UHV) for keeping the various

*Corresponding Author: Sushri Mukherjee, sushri.engg@supreme.in

losses within the permissible limits [2]. Thus, application of conductor bundling is widely adopted method to nullify the impact of voltage gradient, and hence reduction in cascading losses causes by radio interference and corona and meeting economical aspects of project deployment. The conductor bundling is get affected due to wind and ice load twisting effect, which may further led to interruption in transmission service [3-5]. For transmission line there are various parameters are considered at the time of erection and commissioning. Among all these parameters one of the most important thing is the vibration on the ACSR conductors [6, 7]. Most of the general issues are comes from this scenario even it affects communication lines too [8, 9]. The conductors are attached to the towers through rigid contacts for reducing the chances of failure, but if the wind speed is preferably higher then there might be extensive chances of vibration on the conductors. At this situation the rigid supports on the structure exerts shear force on the conductor and as a result they can fail. To get rid of this situation, we cannot apply some flexible coupling of the conductors on the tower to reduce the vibration effect. One most effective way to reduce it by application of spacer damper on the conductor, it is possible only if the conductors are very close to each other [10]. The spacer damper provides a constant space between the conductors as well as due to the damping characteristics of rubber padding on the arms it also provides an effective damping so that the chances of failure on the conductor coupling on the joint locations can be reduced.

In continuation with introduction, remaining portion of the paper is presented as: construction overview has been studied in Section II and related mathematical derivation in Section III. The proposed spacer damper has been virtually modeled in Section IV. Thereafter, in Section V, a description of field experimentation has been presented. Finally, the current study has been concluded in Section VI.

2. Constructional Overview

The spacer damper is to be required for mainly keeping a safe distance between conductors' bundle [11]. This type of damper is aluminum made rigid focal casing with numbers of arm count based on number of conductors in a bundle of particular transmission line [12]. In this study, a hexa spacer damper has been proposed for undertaken transmission line. Its shape is equilateral hexagon and the clamp body is made of aluminium (Al) alloy, which is connected with rigid frame at centre to provide effective gripping to the conductor. Major parts of the proposed damper have been presented in Table I.

Table 1: Specification of major components involved in tests.

S. No.	Particulars	Features	Quantity
1	Body of clamp	Al alloy	1
2	Arm of clamp	Al alloy	6
3	Holding sleeve	Al extrusion	6
4	Cushion for damping	Neoprene rubber	6

5	Washer	Steel HDG	6
Properties of applied conductor			
6	Diameter of applied conductor		28.6 mm
7	Strands of ACSR conductor (Zebra)		54/7
8	Applied conductors count		6
9	Mass/ length of conductor		1.621 kg/m
10	Maximum bending amplitude		265 μm
11	Nominal tension of applied conductor		35 kN
12	Rated value of tensile strength		131.9 kN

For damping sub-conductors' vibration energy at connecting point, an elastomeric bush has been used in-between clamp arms and supporting frame. And the spacer body too highly flexible in order to sustain such vibrations and damping.

3. Mathematical Modeling

In this section, mathematical modeling of the proposed solution has been carried out before initiating product development and applicable field testing. Here, Figure 1 shows the load application on the hexa-spacer damper. We have evaluated the load application and as per the design concept by the help of force component division we have applied the loads.
Figure 1: Loading application on the main structure

For the application of loads first on the manual mathematical calculation we have shown general mathematical expressions related to the vibration force and static loads due to the conductor weight. For the scenario of damping and loading three types of loadings are to be considering here these are elastic force, damping force and pounding force. The elastic force experienced by the system can be evaluated by a simple mass and spring system. The elastic forces in different directions can be taken as (1) - (3) [6, 13],

$$F_{kx} = 2kx - \frac{3}{4l^2}kx^3 \tag{1}$$

$$F_{ky} = 2ky - \frac{3}{4l^2}ky^3 \tag{2}$$

$$F_{kz} = 2kz - \frac{3}{4l^2}kz^3 \tag{3}$$

where, k represent spring constant and the l is the effective length of the spring. For our case, we can assume the length of the arm is the length of the spring or damping damper device.

The damping force is the internal force exerted by the damping device like the rubber padding on the coupling portions of the arms with the main body of the spaced damper. For mathematical evaluation some general formula can be followed, those are stated below (4) - (5) [6, 13]

$$F_{cx} = 2c\dot{x} - \frac{c\dot{x}}{l^2}x^2 \qquad (4)$$

$$F_{cx} = 2c\dot{y} - \frac{c\dot{y}}{l^2}y^2 \qquad (5)$$

$$F_{cx} = \frac{c\dot{z}}{l^2}z^2 \qquad (6)$$

here, c is the damping constant for the damping material provided on the product and $\dot{x}$, $\dot{y}$ and $\dot{z}$ are velocities of the mass block for this case we can say the mass block is the attached conductor to the spacer damper.

According to the Hertz's contact law pounding force is stated by one dimensional but for our system we have evaluated this for two dimensional points of view. In the present study, safe spacing among six bundle conductors has been kept using hexa spacer damper across the span length as shown in Figure 2. In this diagram, dampers are positioned from the left side using $x = l_n$, where, $n = 1, 2, ..., Q$. Total span length segmented into $Q+1$ sub-spans like $\Delta l_1, \Delta l_2, ..., \Delta l_{Q+1}$. Corresponding formulation for the conductor bundling has been illustrated in the succeeding section:

This sub-conductor motion (i.e., transverse) of v-th sub-span $(v = 1, 2, ..., Q+1)$ is formulated as by the transverse wave equation as presented in (6) [6, 13],

$$\rho A \ddot{\omega}_{m,v}(x,t) - T_m \omega''_{m,v}(x,t) = f_W(x,t) + f_D(\omega_{m,v}, \ddot{\omega}_{m,v}, t) \qquad (6)$$

$$\forall v = 1, 2, 3, ..., Q+1$$

$$\forall m = 1, 2, 3, ..., 2P$$

Thenafter, conductors' homogeneous motion equation while ignoring the aerodynamic forces will be simplified as (7) [6, 13],

$$\rho A \ddot{\omega}_{m,v}(x,t) - T_m \omega''_{m,v}(x,t) = 0 \qquad (7)$$

Here, considering both horizontal and vertical tension (i.e., $T_{2k-1} = T_{2k}$, where $k = 1, 2, ..., P$) to be same for the sub-conductor. Therefore, segregation of dependent factors (like time and space) from the displacement quantity may be formulated as in (8) - (9) [6, 13]

$$\omega_{m,v}(x_v, t) = \text{Re}\left[W_{m,v}(x_v) e^{st}\right] \qquad (8)$$

$$W_{m,v}(x_v) = A_{m,v} e^{\left(\frac{sx_v}{cm}\right)} + B_{m,v} e^{\left(\frac{-sx_v}{cm}\right)} \qquad (9)$$

where, among two different traveling waves of x_v-direction; its negative one pertaining towards amplitude $A_{m,v}$ while positive one $B_{m,v}$ amplitude.

Figure 2: Field test layout of the proposed damper.

4. Virtual modeling of Spacer Damper

Software simulation is one of the most effective solutions for getting the behavior of the product on loading conditions. Here, we have used CATIA V5R20 for its three-dimensional design with proper dimensions and have also performed its load simulation testing on this product. The loadings are basically compound loading on the structure and as per the loaded condition on the structure we are just showing the mechanical characteristic and its material properties has been presented in Table II. Since, we have to check the stability of the device in loaded condition therefore; we have to show the failure mode analysis. After selecting the material on the product the further step is to define the boundary conditions on the structure. Boundary conditions are the possible parameters taken as input for applying the loads on the above stated structure. If the boundary conditions are not specified properly then there will not be a meaning of actual load testing. Corresponding simulation results has been presented in Figure 3 - 6.

5. Experimentation at Site

With the increase in demand for electricity all over the world, the span and the number of bundle for transmission line are showing a trend of increase [14]. Thus, to improve reliability of 765 kV transmission line spacer dampers (27 numbers) should be deployed across the transmission line as presented in Table III. The data acquisition sequence is chosen using software developed at IREQ based on LabVIEW programming language. The hardware used for the data acquisition is from National Instruments. The data acquisition system utilizes the most recent technology including fiber optic to carry the transducer signals which has low latency hence precise time graph analysis. Vibration amplitudes are measured according to industry standards [9]. The data acquisition loop begins with the acquisition of the weather data: more precisely wind velocity; azimuth and elevation as well as air temperature at a rate of 10 points per second (pts/sec) during 300 sec.

Table 3: Spacer damper installation across the undertaken transmission line.

Span (m)	Spacer damper counts	Sub-span (m)

Wind velocity, azimuth and elevation are measured using four ultrasonic anemometers [15, 16]. On the other hand, the processing or using the discrete spectral frequencies has been adopted. Only those recordings with an apparent frequency in the range between 0.6 - 2.5 Hz were selected. In this paper, we have validated mechanical strength of the spacer damper to check sustainability of different body parts while conductors abnormality in oscillations.
Figure 7: Maximum P-P displacement in sub-span.

In the field test, as part of apparent frequency the P-P amplitude is noted in Table IV as relentless cycle behavior. Thenafter, corresponding graphical analysis of the results is presented in

Figure 7. For further study (like - vector and matrix), the conductor has been considered as located at certain height with a maximum span (*i.e.,* 450 m) and getting affected under wind exposure. This particular circumstance reflecting actual field test oscillation effect on the installed spacer damper, which has been plotted in Figure 8 to highlight wind exposition at the site. While covering this field test a wide range of velocities in various directions based on sub-span oscillations and Aeolian vibrations have been taken. Furthermore, the bending-amplitude (RMS) of the conductor will be evaluated [17], and results are graphically compiled in Figure 9.

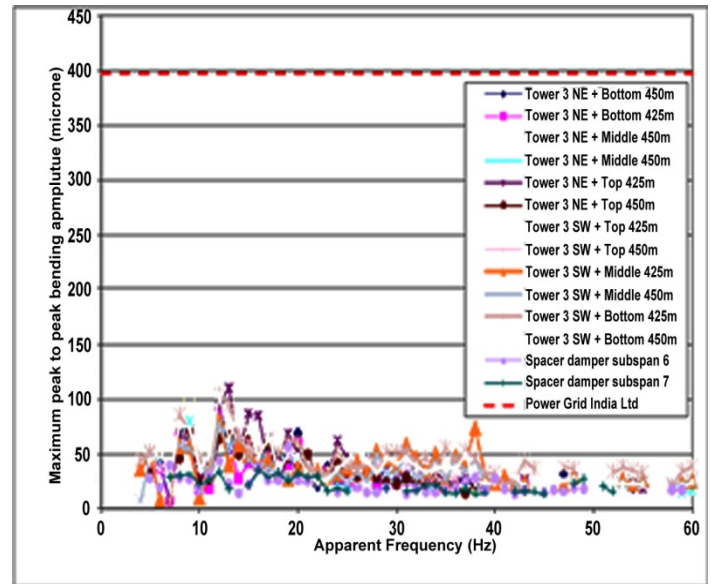
The averaged value of $f\,Y_{rms}$ which is 5 km/h at an interval of 10° is presented in Table 5. It has been found a variation of azimuth angle 270° - 280° with wind speed covering about 50- 55 km/h.


Figure 9: Bending-amplitudes' maximum (RMS) value.

Table 5: Results of $f\,Y_{rms}$ (maximum value)

Sub-spans	$f\,Y_{rms}$ (mm/s)	Wind conditions	
		Azimuth angle (°)	Velocity (in km/h)
1	4.4	270 - 280	50 - 55
2	6.3	270 - 280	50 - 55
3	6.1	270 - 280	50 - 55
4	5.7	270 - 280	50 - 55
5	6.4	270 - 280	50 - 55
6	6.5	270 - 280	50 - 55
7	5.6	280 - 290	45 - 50
8	4.4	270 - 280	50 - 55

Figure 8: Wind-expositions' polar plotting

Table 4: Peak-peak displacement (maximum).

Sub-span	P-P displacement (mm)	Maximum $f\,Y_{rms}$ (mm/s)
1	26	8.5
2	60	10
3	56	13
4	59	11
5	56	14
6	79	12
7	52	10
8	28	7.8

here, the bending-amplitude (RMS) value in sub-spans is recorded and then graphically presented in Figure 11. While, asses this particular graph, it may be seen that its variation is upto 80 mm/s value.

6. Conclusions

The product has been designed and validated using CATIA V5 software tools before initiating field trials. Since, we have applied the loads on the structure as per the weights of the conductors and according to those loading we have the output results for stress concentration and deformation therefore it is now very easy to conclude the mechanical load capacity of the proposed model. We have used a loading of 1621 kg per km of conductor, the span between two towers are 425m and according to that conductor weights will be 688.925kg. Now the usage of spacer dampers on this span is 7 so we can say each arm of the damper carrying a load of 98.417 kg in different modes like compression and tension. After application of this load we have found the maximum stress concentration on this product is $5.07 \times 10^{6}\,N/m^{2}$ which is quite preferable for the product as well as the material used as Aluminum. Along with it for the compound load application the maximum deformation on the structure is

0.0327 mm. The value of deformation is very less. Therefore, as a final conclusion we can say the product is structurally strong enough to sustain the applied load on it. The proposed solution's feasibility could be checked from Table 6.

Table 6: Summary of recorded field results.

Particulars	Standards	Findings
Clamps peak-peak bending amplitude (max)	< 398 µm	141 µm
Clamps RMS bending amplitude (max)	< 80 µm	29 µm
Peak-peak (max) displacement for sub-span oscillations	< 350 mm	79 mm
$f\,Y_{rms}$ (max) for sub-spans	< 80 mm/s	14 mm/s
$f\,Y_{rms}$ (mean) for site wind	< 70 mm/s	6.5 mm/s

ARTICLE INFO

ABSTRACT

The constant market change and the critical role of the logistics process in the supply chain need to have special attention because it is an essential piece for the global business strategy. This paper presents an assessment of the processes of handling material from Asia suppliers to North America. The data utilized for the analysis is of 12 months of 2019, valuable input to support the proposal to the company to approve the changes to get a financial gain. The proposal aims to create a complete analysis starting on how the containers are loaded currently in Asia (floor loaded) and the complexity that this strategy creates for the whole supply chain. The analysis of the overall process aims how the proposed change (pallet loaded) will reduce demurrage cost annually (USD 147,000), lead time (from 6 days to 3 days), space utilization in the facility (reduce space by 6364 sqrt/ft), reduce operational cost annually (USD 210,000), improve safety (Risk factor savings annually of USD 61,100), and on-time delivery to the customer (Increase 4%).

1. Introduction

In the current global supply chain footprint, one of the most critical parts is the transportation of goods from any place in the world to fulfill customer requirements. Companies are significant in maintaining competitive advantage from the competition, and the company needs to be prepared with flexibility and responsiveness to the dynamics of the customer demands [1].

Container loading is a pivotal function for operating supply chains efficiently, and underperformance results in unnecessary costs (e.g., cost of additional containers to be shipped) and in unsatisfactory customer service (e.g., violation of deadlines agreed to or set by clients). Thus, it is not surprising that container loading problems have been dealt with frequently in the operations research literature. It has been claimed, though, that the proposed approaches are of limited practical value since they do not pay enough attention to constraints encountered in practice [2].

Organizations must be capable of fast, radical changes, and those that aspire to be best must lead to changes [3]. Container shipping has changed the scale and scope of global freight distribution. By enabling a higher rate in freight distribution, it has opened up new global markets for export and import as a higher quantity of space could be traded with a similar, if not lower, amount of time and often at a lower cost. This rate is much more a

function of time than of speed as containerization mostly improved the function of transshipment [4].

The current customer changing needs force the supply chains to look for continuous improvement on the value-added on the different processes and create dynamic changes on how the goods are move through the chain [5].

The scope of the research is to determine the best containerization in Asia. Changing the way of containerization to create a faster supply chain reducing the safety stock needed for the waiting time in the ports to fill a floor loaded container and the overall improvement on reducing the extra cost that hits directly on the operating income of the company [6].

Part of the assessment comprised the current state of process from the point of origin Asia to the point of receipt in North America (Mexico), in that review the specific process that takes place in that part of the chain and creates a proposal for improvement that can be measured.

For the company case of study, the fast pace of customer demand is one of the essential value-added that is offered to the customer. For this reason, the supply chain needs to be fast, flexible, and dynamic to support what is being offered.

The company is focused on the wellbeing of the associates. The current container unloads process of a floor loaded container is

very demanding and with a high risk of injury due to unloading by hand over 3000 to 4000 containers daily, that in the long run, can harm the associate's health, that in the final result of the project will be to eliminate this risk of injury, the impact of this is of USD 61,100 of saving on the risk factor.

2. Literature Review

The container system is slowly reaching maturity in a market environment where freight transportation has become the most volatile and costly component of many firms' supply chain and logistics operations. Managers must deal with delays in the transport system, with rising oil prices, complex security issues, and with labor and equipment shortages and trade imbalances. Each of these problems adds risk to the supply chain, and the problems are likely to get worse before they improve. Managers in the logistics industry, including the port and maritime industry, are spending more and more of their time handling freight transport missteps and crises. As such, reliability and capacity issues have emerged as critical factors next to pure cost considerations [1].

Empty container repositioning has been an on-going issue since the beginning of containerization. However, it has become more prominent in recent decades due to the rapid growth of the container shipping business and the regional difference in economic development. The critical factors that cause empty container movements, which include the trade imbalance, dynamic operations, uncertainties, size and type of equipment, lack of visibility and collaboration within the transport chain, and transport companies' operational and strategic practices [6].

Over the past decade, there has been a growing consensus concerning the strategic importance of integrating suppliers, manufacturers, and customers convincingly argued, the once narrow subject of logistics has become a broad topic that now spans the entire value system from suppliers to customers [5].

The first in the line of warehouse processes is the receiving of goods. This process does not take as much time as picking, which is shown onwards, but it is as relevant as any. Especially if incorrect put-away occurs and causes errors in further processing. The process of receiving can begin with the notice of the arrival of the goods. It permits the warehouse to prepare to schedule inbound operations, so there are no uncoordinated events. With the arrival, unloading begins after which units are put away with accurate documenting before [7].

Container loading problems can be interpreted as geometric assignment problems, in which small three-dimensional items (called cargo) have to be assigned (packed into) to three-dimensional; rectangular (cubic) large objects (called containers) such that a given objective function is optimized and two underlying geometric feasibility conditions hold, i.e. [2]:

- All small items lie entirely within the container

- The small items do not overlap.

A formal description of a solution to an assignment problem of this kind will be called a loading pattern.

According to the typology introduced in [8], one can distinguish between container loading problems, in which enough containers are available to accommodate all small items, and such

problems, in which only a subset of the small items can be packed since the availability of the containers is limited. Problems of the first kind are of the input (value) minimization type, those of the second type represent the output (value) maximization type.

Moreover, the changes in operations and processes of warehouses should cover every activity in warehousing [9] such as:

- Receiving: the process of unloading the incoming truck, identifying, registering, and sometimes repacking.
- Put away: moving the goods from the unloading dock to the storage area.
- Storage - in bulk or pick activities at the warehouse, affect goods in storage. For instance, the number of stocks must be counted to verify inventory quantities.
- Replenish If inventory levels of the pick storage drop to specific amounts, it is replenished with stocks from the bulk storage.

Leaning on a material-handling environment encompasses two main elements; value stream mapping to define the optimal future situation and analysis of the logistics flows used to move products in order to optimize the facility layout. Both practices aim to improve the operation continuously. Traditional warehouses should become cross-dock operations. Lean cross-docking operations should integrate principles as heijunka planning, advanced routing methods, and kanban. These principles would create flow in picking, packing, and replenishing while simultaneously reducing average order cycle time in [10].

Consider shipping priority in container loading, where high priority boxes must be loaded before those with low priority. They propose a multi-round partial beam search method that explicitly considers shipping priority when evaluating the potential of partial solutions to solve this problem. Since existing benchmark data for shipping priority covers only weakly different instances, they extend the benchmark data to strongly heterogeneous instances [11].

In accordance [12], the overall duration of the transport process, as well as the balance of the elements, differ depending on different factors, such as:

- Average distance cargo transport

- Localization of distribution points and cargo transportation conditions

- The capacity of the vehicle

- Technical speed of vehicle movement

- Technical vulnerabilities of cargo transport

- The level of mechanization degree of loading mechanisms construction

- Construction of highways surface and other

3. Research methodology

The research methodology for the study is described in Figure 1. The overall process of the research is to understand what is the problem that we have encountered; moreover, after that, it is the

process that needs to be worked on to create a solution that is in line with the expectations of the company in the study.
Figure 1: Research method for the study.

4. Case study

4.1. Problem statement

The company in the study is the leader on security products, with a distribution of goods to all the world, the manufacturing plant is in Mexico for finish good and most of the main components are made in the United States of America. The supply strategy for the make to stock business is 60% of the goods purchased to Asia suppliers, and the 40% is assembled in Mexico; on the make to order business, 100% of the products are made in Mexico with most of the components from U.S. suppliers, Mexico suppliers and very small from Asia suppliers.

By doing this study, the company is looking for the overall improvement on the lead time, create a lean supply chain from Asia to Mexico. Reducing the need for safety stock inventory that is not needed and the overall reduction of cost the effect the operating income, and by making this improvement, the company will improve on the customer service level and that, in the long run, will bring incremental sales and revenue Figure 2.

The overall market dynamics are forcing supply chains to change the current footprint dynamics to accommodate every changing customer requirement better. Regarding the current stage, much investment is put into creating a better logistic

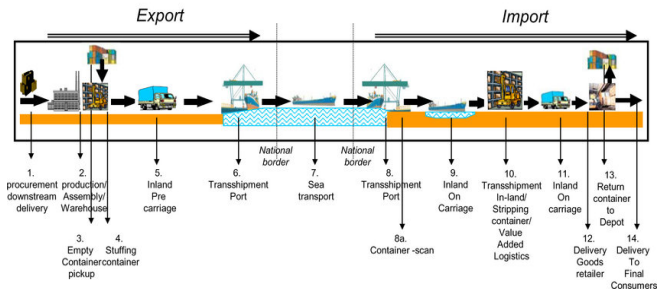
network to support this. Moreover, the company found an opportunity to create a proposal by changing the way the containers are loaded in Asia.


Figure 2: Overall ocean container flow.

In the current supply chain footprint of our Asia supplier, the company has a total of 38 suppliers that are located in mainland China, and seven are in other Asian countries (i.e., India, Vietnam, Philippines). Focusing on mainland China suppliers.

The scope of the project is to focus on the containers that are built-in mainland China that is close to the company suppliers in which the supplier ship to a consolidator in which they put cargo from different suppliers that are shipping to the same end-user. The ports utilized to ship material to the United States of America are:

- Yantian
- Hong Kong
- Shanghai
- Ningbo
- Keelung is out of Taiwan
- Shenzhen

After containers are built in China, they are moved to the freight forwarder cargo lines that will load the container to the boat to ship it out to Long Beach port to be unloaded.

The results of the demurrage cost USD 200.00 per day per container which is a delay that has been affecting the company due to the high cost per day because of not returning a container in the appropriate lead time.

The statistical data that was analyzed is from all the containers that arrived to the U.S., from Asia in 2019. Because of the COVID-19 pandemic, the data from 2020 is very different due to Asia suppliers delaying container flow. The company decided to use the 2019 data to obtain where the company was situated in the current state. Moreover, the lateness that the company has based and how long is it taking to unload the containers in the warehouse.

The total amount of containers that arrived in 2019 to the plan was 480 containers, from those, 344 are 40' size (equal to 72%) and 136 are 20' size (equal to 28%). From this data, the company needed to understand if there was a correlation between total boxes in the container and the pallets built per container. In Figure 3, a scatterplot of boxes quantity vs. pallet built for 40' container is presented and in Figure 4 is shown a scatterplot of box qty vs. pallet built for 20' container.
Figure 3: Scatterplot boxes qty vs. pallet built for 40' container.
Figure 4: Scatterplot boxes qty vs. pallet built for 20' container.

As a result of the 40'container, the high-density population is between 45 to 55 pallets built per container. Furthermore, the 20' containers' population is between 40 to 50 pallets built. The plan is to eliminate the use of 20' containers and only use 40' ones to maximize utilization of the capacity of the container that is 5 to 15 more pallets than the 20' container. It is a quick example of how a floor loaded container arrives at the facility, see Figure 5. The correlation found in the analysis was that the company could eliminate the need for shipping in the 20' container, if the process is implemented of pallet loaded and changing to use only 40' containers due to the number of pallets that can be loaded.

These are the results analyzing the data in Table 1.

Table 1: Container boxes and pallet building.

Container Length	The total quantity of boxes	Total Quantity of Pallet Built
20'	505,500	6,495
40'	1,364,734	17,214
Grand Total	1,870,234	23,709

Reviewing the results, they show the complexity of how the company has delays in unloading containers. The complexity of the process is that it is manual labor to unload the boxes from the container and then create pallets that will be received and then put-away in the warehouse. The manual process of unloading the containers has created an extra lead time of 3.06 days in the high season, and that is the issue of why the company has a high demurrage cost, affecting 240 containers every year, with those delays the company incurred in demurrage cost that affects the financial performance of the company due to an operational issue on how the container is loaded, how the container is unloaded and the receiving process of the goods.

4.2. Analyzing and creating the business model

For any continuous improvement project, it needs to define the current process map, to understand what are the areas of opportunity that are needed to focus on. This project is the actual process flow which has been focused on the receiving and put away part of the process, see Figure 6. the process map gave the company an overall perspective to analyze where it can focus resources to create a valuable proposition.

Following the current process flow, when the containers arrive from Asia, first the container arrive at Long Beach, after that it has to wait for its turn to be downloaded from the boat with a crane and be put into the inbound area, in that the transporter goes and picks up the container to bring it to the company yard, there it waits its turn to be crossed to Mexico to start the unloading process.
Figure 7: Histogram of box quantity.

In this part of the process is where we found the first issue. The complexity of how the containers are loaded in Asia (floor loaded) and the average amount of boxes per container affects the overall lead time to unload, delaying the unloading so the company occurs into demurrage.

On a yearly average, the company had 240 containers on which there was a delay of 1 day, and more to return the container to the supplier yard. This delay in the process has generated a loss of USD 147,200. By changing the process this cost can be eliminated.

In the data analysis, the average and the standard deviation per container on how many boxes and the pallet are represented in Figure 7 and Figure 8. The results obtained are that the average quantity of boxes in the container and the average pallet built from those boxes is equal to the number of complete pallets that fit inside a container, creating an opportunity in the process to change the current process of floor loaded to pallet loaded.
Figure 8: Histogram of pallet built.

The complexity of the process is outlined with the data of one year. On a yearly average per container, the company receives 3896 boxes per container and those equal to an average of 50 pallets per container. The study shifted to understand the lead time

that is taking to unload the containers from Asia, the lead time that the company has is three days to receive the container, unload, and return the container to the supplier yard, see Figure 9. In this histogram, the company is measuring the total lead time for a container to be unloaded.
There is an average of 4.2 days (this is taking the 480 containers, from which 240 were unloaded at or before the lead time of 3 days) to unload the container with a standard deviation of 2.49 days. The lead time that the company has is three days to return the container; this result creates an extra cost in the organization that is a demurrage cost in which for any extra day it takes for the company to ship the container back to the logistic cargo supplier, the cost is USD 200 per day for delay. The company needed to understand the lateness of the containers. Figure 10.
Figure 10: Histogram of days above the goal of container unload.

The result that was obtained (only 240 containers that were shipped out late back to the supplier yard) is that the days above the lead time on average is 3.06 days with a standard deviation of 2.28; with this, the company calculated an impact on the cost of USD 147,200 that affects the operating income, see in Table 2 cost due to demurrage.

Table 2: Cost due to demurrage.

Container Length	Cost due to demurrage	
20'	USD	45,600
40'	USD	101,600
Grand Total	USD	147,200

Base on the case study it's been determine that the company needs to work on improving the container loading in Asia. On the current process, the supplier can ship future P.O.s of material that are not needed yet, to fill up a container at the max on boxes and weight. This issue creates extra inventory that the company does not need; by changing the strategy, the company will eliminate the extra carryover inventory that is not needed and improving cash flow by not having inventory that is not needed due to an operation process. It will be reviewed to cut the need for those extra containers by reducing the safety stock level from 120 days of finish adequate supply to 90 days of safety stock. It will help to reduce the necessary containers between 60 to 90 that have an extra carryover of 30 extra days of safety stock. The significant impact is not having the correct inventory in the correct place to support customer demand, and the impact associated with that is customer fines because of out of stock that creates filling rate issues on the stores, on-time delivery because of shipping late, waiting for inventory to arrive and loss of sales due to cancelations.

Connecting this to the other warehouse process, in the unloading process, the company has two crews for the receiving process, each crew is of 7 associates, for a total of 14 associates, and one forklift driver that is the one that when the pallet is complete, he moves the material to a staging area for the quality team to audit each of the pallets that were made.

If the company improves the process of how the containers are loaded in Asia, there will be an immediate impact on the labor needed to unload a container, changing the how the container has been loaded in Asia from floor loaded to pallet loaded, improves the velocity in the process by eliminating the manual unloading box by box and improves the safety of the workforce by eliminating the manual labor of moving and unloading boxes.

The current labor of one crew to unload one container of 40' is between 3 to 4 hours depending on the number of boxes, the mix of SKU in the container, and the weight of each of the boxes. Each container has a different complexity inside of it. If the container is changed to a palletized container, one forklift driver can unload one container between 30 minutes to 60 minutes; in one day, one forklift driver can unload, taking the max time nine containers in one shift.

The cost of one receiving associate full loaded (salary + benefits) is around USD 15,000 per year; with this proposal, the reduction is for a total of 14 employs two unloading crews, each receiving associate earns USD 15,000 per year, with the reduction of the 14 associate the company can save on their operating cost

USD 210,000 per year when the proposed improvement is implemented.

Continue connecting the dots of the analysis, and the company encounters another area of opportunity, floor space utilization for staging the building of the pallets. Moreover, in any industry, floor space is precious because staging and storing do not add value to the product, it adds cost. If there is an opportunity to save space, the company can save money and use that space for something that can add value to a product, for example, more production lines.

The total area that can be reutilized by adding more cells in an area of 86'x74' for a total of 6364 sqrt/ft equals 10.5% of total production space, of the estimated cost of sqrt/ft, taking all of the cost into consideration for a productive area is around $48 x sqrt/ft; this gives a saving or possible revenue of USD 305,472 that can be added for the justification of the project, see Figure 11.
Figure 11: Finish good facility warehouse layout

5. Results and discussions

The purpose of this paper is to develop a proposal assessing the effectiveness of a change in the container operations loading process in Asia. As a result, the best solution found is to propose a change in the way the containers are loaded.

The improvement is changing from floor loaded container to pallet loaded container. The company has defined the pallet structure from Asia to maximize the pallets that can be loaded in the container. The proposal is to utilize only 40' containers and eliminate the use of 20' containers.

The interior dimensions of a container (in feet): 39' 6" long x 7' 9" wide x 7' 10" high, that is equal to 4,143,708 cubic/inches; with data, it can be calculated how many standard pallets the consolidator can load into the container, the standard size including the pallet will be 40"x48"x48, that will help the company load two lines of pallets double stack to have 40 pallets per container. To implement this, the engineering and the sourcing team will have to work with Asia for the supplier to have the pallet pattern and follow the new direction; that with this, the company will not have

to invest in more containers need base on the reduction due to safety stock not needed.

With this proposal, there is a potential saving in demurrage, labor, and space utilization. Another savings is the reduction of the risk factor on the unloading of the operation, due because it is a manual operation that can cause injury on the receiving operator, and because the human capital is the most crucial asset in the company, by eliminating the need of the manual force the company eliminates the risk of injury, the projected reduction of the risk factor is from 0.020597 to 0.020097 that generates to a yearly reduction on this factor of USD 61,100.

For this proposal to be implemented, it needs to have a united effort between several departments and key players to get the savings that have been identified.

For example, the packaging engineer needs to start working on standardizing the pallets and specific sizes to maximize the opportunity to double stack the container. After this activity is completed, the sourcing team will need to contact the supplier in Asia to give them the new packaging specifications, from which the supplier will need to start palletizing when they receive the new specifications. After that, the company will have a specific time frame in which it will continue to receive floor loaded containers, but when that ends, the process of unloading by pallet and auditing from quality and receive will have to change to create a more dynamic flow.

The total recurrent annual savings estimated in this project, not considering the potential inventory reduction is, with near to no investment is:

- Demurrage saving USD147,200
- Labor reduction of USD 210,000
- Space cost USD 305,472
- Risk factor reduction of USD 61,100
- Total savings USD 723,772

6. Conclusions

The case study helps the organization to identify current opportunities in the containerization process in Asia.

With the current change in the market dynamics, the company encounters an opportunity to reduce lead times. The market dynamic, based on customer needs in a faster pace to respond to demand. The pandemic of COVID-19 affected supply chains first, starting with Asia. Asia stop shipments for six weeks if it is considered that in 6 weeks there is not going to be any flow, that in a macro stage equals to 12 weeks without raw material or finish good; this pandemic created needs to improve and reduce time in the supply chain.

By focusing on creating a faster approach in the unloading of the container, there are several savings for the company. Reducing the labor or relocating labor in the area by 14 employees creates a reduction in the operating income of the company.

By changing one process, it impacts several other, for example, releasing pre-stage areas to create space for new manufacturing cells, which is a direct impact on having space utilized on value-added activities instead of staging inventory.

Overall, the proposal for the project is to change the way we have been doing the operation, by changing the process we can improve the overall efficiency of the operation.

In this time of new challenges, the companies need to think differently and have an open mind in creating a culture of change to create continuous improvement.

In this project, the approach is to work the different process that conforms the supply chain. The company is improving the warehouse activities from unloading containers, receiving material goods, and put away process by having a straighter forward operation. On the transportation side, it is improving the reduction in lead time to eliminating demurrage and having a faster return of empty containers to the supplier. In supply planning, the team needs to work with the system to have the correct supply strategy based on a dynamic and faster container supply chain, by having what we needed when we needed and overall, the company will have an improvement because it will save cost on the operating income and the customer service side, the performance on the service to the customer will improve by not delaying material to ship and to arrive at the company.

Conflict of Interest

The authors declare no conflict of interest.

A B S T R A C T

The paper a cubic spline built through a local base spline and the local interpolation bicubic spline models we offer have been selected. The construction details of the models are given, the two-dimensional local interpolation bicubic spline models considered in this study provide high accuracy in digital processing of signals, which helps experts to make the right decision as a result of digital processing of signals. As an example, the initial values of the geophysical signal were digitally processed and error results were obtained. The error results obtained by digital processing of the geophysical signal of the considered models were compared on the basis of numerical and graphical comparisons.

1. Introduction

In many geophysical surveys, scientists have sought to find predators that provide information about the location of minerals. An anomalous change in a parameter is a sudden increase or decrease in its values. That is, depending on the anomalous changes in the geophysical signal, it is possible to make a prediction. Usually, as a result of forecasting, it will be possible to predict such information as the location of the most accumulated minerals, their reserve capacity. Anomalous changes in the electromagnetic and gravitational fields of the earth, abnormal changes in the ionosphere, seismic conditions (noise), various acoustic vibrations can be used as a tree [1].

In recent years, dozens of methods for predicting minerals have been proposed by scientists around the world. One of them is the spline method. Using the spline method, scientists have the opportunity to understand the physical processes that take place underground, to observe them, to build mathematical models of the interdependence of these processes. This is mainly achieved by using two-dimensional cupcake spline functions to achieve a high level of accuracy. The two-dimensional cubic spline function we offer also has a high accuracy range.

2. Modeling of geophysical signals based on the second-order local interpolication spline-function

The application of parabolic local interpolation spline functions to build a mathematical model for the digital processing and recovery of various geophysical signals is currently relevant in solving practical problems.

The $S_n(f; x)$ function under consideration is called the local interpolation spline function when the following conditions are met:

1. $S_n(f; x) \in H_n[x_i, x_{i+1}]$,

2. $S_n(x) \in C^m[a,b]$,

3. $S_n(x_i) = f(x_i)$ i=0,n.

Based on the above conditions, we consider the construction of a local interpolation bicubic spline in the following D=[a,b]×[c,d] area. We can divide the area under consideration into N equal parts along the OX axis and M along the OY axis $\Delta = \Delta x \times \Delta y$. [1].

$$\Delta_x: \ a = x_0 < x_1 < \ldots < x_N = b, \ \Delta_y: \ c = y_0 < y_1 < \ldots < y_M = d.$$

*Corresponding Author: Muslimjon, TUIT, 100200, Uzbekistan,
muslimjon1010@gmail.com

where steps h and l are selected as follows

$$h = x_{i+1} - x_i, \ i=0,1,...,N-1; \ l = y_{j+1} - y_j,$$

$$j = 0,1,\ldots,M-1.$$

Let we look at the grid below:

$$\Delta^* = \Delta_x^* \times \Delta_y^*$$

$$\Delta_x^*: \ x_{-1} < x_0 < x_1 <...< x_N < x_{N+1}, \quad \Delta_y^*: \quad y_{-1} < y_0 < y_1 \\ <...< y_M < y_{M+1}.$$

Δ_x^* for this case we make the field look $D^* = [a - h, b + h] \times [c - l, d + l]$. Δ^*- At the node points in the grid, the values of the function are known, i.e.:

$$f(x_i, y_j) = f_{ij}, \quad i = -1,0,1,\ldots,N,N+1;$$

$$j = -1,0,1,\ldots,M,M+1.$$

Based on the above values of the $f(x,y)$ - function, we construct a local interpolation spline function for the field. To do this, we use the following 16 points.

$$(x_{i-1}, y_{j-1}), \ (x_{i-1}, y_j), \ (x_{i-1}, y_{j+1}), (x_{i-1}, y_{j+2}),$$

$$(x_i, y_{j-1}), \ (x_i, y_j), \ (x_i, y_{j+1}), \ (x_i, y_{j+2}),$$

$$(x_{i+1}, y_{j-1}), \ (x_{i+1}, y_j), \ (x_{i+1}, y_{j+1}), \ (x_{i+1}, y_{j+2}),$$

$$(x_{i+2}, y_{j-1}), \ (x_{i+2}, y_j), \ (x_{i+2}, y_{j+1}), \ (x_{i+2}, y_{j+2}).$$

Our article in Comparative Analysis Spline Methods in Digital Processing of Signals in ASTESJ magazine describes the construction of a one-dimensional local cubic spline using 4 points [2]. Here, too, $Z_j(x_i, j)$, $Z_{j+1}(x_i, j)$ parabolas are constructed using the above points. Here x is fixed, i.e. at x=x_i the local interpolation bi cubic spline-function $S_3(x_i, y)$ has the following form:

$$S_3(x_i, y) = (1 - u)Z_j(x_i, y) + uZ_{j+1}(x_i, y), \quad (1)$$

here it is

$$Z_j(x_i, y) = -\frac{1}{2}u(1 - u)f_{i,j-1} + (1 - u^2)f_{ij} + \frac{1}{2}u(1 + u)f_{i,j+1}, \quad (2)$$

$$Z_{j+1}(x_i, y) = \frac{1}{2}(1 - u)(2 - u)f_{ij} + u(2 - u)f_{i,j+1} - \frac{1}{2}u(1 - u)f_{i,j+2} \quad (3)$$

$Z_j(x_i, j)$, $Z_{j+1}(x_i, j)$ parabolas are as follows

$$(x_i, y_{j-1}), \ (x_i, y_j), \ (x_i, y_{j+1});$$

$$(x_i, y_j), \ (x_i, y_{j+1}), \ (x_i, y_{j+2}),$$

$$u = \frac{y - y_j}{l}, \ l = y_{j+1} - y_j.$$

passes through node points. Substituting (2) and (3) into (1), we obtain the following after certain reductions:

$$S_3(x_i, y) = -\frac{1}{2}u(1 - u)^2 f_{i,j-1} + \frac{1}{2}(1 - u)(2 +$$

$$2u - 3u^2)f_{ij} + +\frac{1}{2}u(1 + 4u -$$

$$3u^2)f_{i,j+1} - \frac{1}{2}u^2(1 - u)f_{i,j+2},$$

$$j = \overline{0, M-1}, \ 0 \le u \le 1.$$

Based on the above $x = x_{i-1};$ $x_{i+1};$ x_{i+2}. In fixed cases, we create the following single-variable spline functions

$$S_3(x_{i-1}, y) = (1 - u)Z_j(x_{i-1}, y) + uZ_{j+1}(x_{i-1}, y), \quad (5)$$

$$S_3(x_{i+1}, y) = (1 - u)Z_j(x_{i+1}, y) + uZ_{j+1}(x_{i+1}, y), \quad (6)$$

$$S_3(x_{i+2}, y) = (1 - u)Z_j(x_{i+2}, y) + uZ_{j+1}(x_{i+2}, y), \quad (7)$$

$S_3(x_{i-1}, y)$, $S_3(x_i, y)$, $S_3(x_{i+1}, y)$ and $S_3(x_{i+2}, y)$ Based on the one-variable cubic spline functions built above, after a certain compression, the following view of the following two-variable interpolation bicubic spline function is formed [3-7]:

$$S_{3,3}(x, y) = -\frac{1}{2}t(1 - t)^2 S_3(x_{i-1}, y) + \frac{1}{2}(1$$

$$-t)S_3(x_i, y) + \frac{1}{2}t(1 + 4t - 3t^2)S_3(x_{i+1}, y) -$$

$$\frac{1}{2}t^2(1 - t)S_3(x_{i+2}, y),$$

$$j = \overline{0, M-1}, 0 \le u \le 1, t = \frac{x-x_i}{h}, u = \frac{y-y_j}{l}, h = x_{i+1} - x_i, l = y_{j+1} - y_j.$$

$S_3(x_{i-1}, y)$, $S_3(x_i, y)$, $S_3(x_i+1, y)$ and $S_3(x_{i+2}, y)$ are generated by putting the values of the bicubic spline functions of a variable built above (8) [8-12].

$$S_{3,3}(x, y) = -\frac{1}{2}t(1 - t^2)[(1 - u)Z_j(x_{i-1}, y) + uZ_{j+1}(x_{i-1}, y)]$$

$$+\frac{1}{2}(1 - t)(2 + 2t - 3t^2)[(1 - u)Z_j(x_i, y) + uZ_{j+1}(x_i, y)]$$

$$+\frac{1}{2}t(1 + 4t - 3t^2)[(1 - u)Z_j(x_{i+1}, y) + uZ_{j+1}(x_{i+1}, y)]$$

$$-\frac{1}{2}t^2(1 - t)[(1 - u)Z_j(x_{i+2}, y) + uZ_{j+1}(x_{i+2}, y)]. \quad (8)$$

Here it is

$i = \overline{0, N-1}$, $j = \overline{0, M-1}$, $0 \le t \le 1$, $0 \le u \le 1$, $t = \frac{x - x_i}{h}$,

$u = \frac{y - y_j}{l}$, $h = x_{i+1} - x_i$, $l = y_{j+1} - y_j$.

appears after a certain contraction (9).

$$S_{3,3}(x, y) =$$

$$\varphi_1(t)[\varphi_1(u)f_{i-1,j-1} + \varphi_2(u)f_{i-1,j} + \varphi_3(u)f_{i-1,j+1} + \varphi_4(u)f_{i-1,j+2}]$$

$$+\varphi_2(t)[\varphi_1(u)f_{i,j-1} + \varphi_2(u)f_{i,j} + \varphi_3(u)f_{i,j+1} + \varphi_4(u)f_{i,j+2}]$$

$$+\varphi_3(t)[\varphi_1(u)f_{i+1,j-1} + \varphi_2(u)f_{i+1,j} + \varphi_3(u)f_{i+1,j+1} + \varphi_4(u)f_{i+1,j+2}]$$

$$+\varphi_4(t)[\varphi_1(u)f_{i+2,j-1} + \varphi_2(u)f_{i+2,j} + \varphi_3(u)f_{i+2,j+1} + \varphi_4(u)f_{i+2,j+2}] \qquad (9)$$

here it is

$$\varphi_1(t) = -\frac{1}{2}t(1-t)^2,$$

$$\varphi_2(t) = \frac{1}{2}(1-t)(2 + 2t - 3t^2),$$

$$\varphi_3(t) = \frac{1}{2}t(1 + 4t - 3t^2),$$

$$\varphi_4(t) = -\frac{1}{2}t^2(1-t)$$

$$t = \frac{x - x_i}{h}$$

$$\varphi_1(u) = -\frac{1}{2}u(1-u)^2,$$

$$\varphi_2(u) = \frac{1}{2}(1-u)(2 + 2u - 3u^2),$$

$$\varphi_3(u) = \frac{1}{2}u(1 + 4u - 3u^2),$$

$$\varphi_4(u) = -\frac{1}{2}u^2(1-u)$$

$$u = \frac{y - y_j}{l}$$

(9) can be called a local interpolation bicubic spline function.

3. Digital processing of geophysical signals based on developed algorithms

The proposed model considered the recovery of the signal obtained by aeromagnetic reconnaissance to determine the location of underground mineral resources, which is considered to be our current object (Table 1). Based on the above sequence, a local interpolation bicubic spline construction program was developed in the Matlab program environment and used in signal processing. The algorithm of this program is shown in Figure 3. We have shown the superiority of our model by comparing our developed model with the bicubic spline function S_{bsa} (10) model, which is based on the existing basic functions. Since it is not possible to cite all the known signals, we present the result in the following figures using the appearance of the signals in Table 1 (Figures 1-2). As can be seen from these pictures, it is clear from the $S_{3,3}$ and S_{bsa} spline functions that the degree of approximation of the $S_{3,3}$ we offer is high [13-16].

$$S_{\text{bsa}}(x, y) = \omega_1(p)[\omega_1(q)f_{i-1,j-1} + \omega_2(q)f_{i-1,j} + \omega_3(q)f_{i-1,j+1} + \omega(q)f_{i-1,j+2}]$$

$$+\omega_2(p)[\omega_1(q)f_{i,j-1} + \omega_2(q)f_{i,j} + \omega_3(q)f_{i,j+1} + \omega_4(q)f_{i,j+2}]$$

$$+\omega_3(p)[\omega(q)f_{i+1,j-1} + \omega_2(q)f_{i+1,j} + \omega_3(q)f_{i+1,j+1} + \omega_4(q)f_{i+1,j+2}]$$

$$+\omega_4(p)[\varphi_1(q)f_{i+2,j-1} + \omega_2(q)f_{i+2,j} + \omega_3(q)f_{i+2,j+1} + \omega_4(q)f_{i+2,j+2}]. \qquad (10)$$

here it is

$$\omega_1(p) = (1-p)(1-p)(1-p),$$

$$\omega_2(p) = (3p^3 - 6p^2 + 4),$$

$$\omega_3(p) = (1 + 3p + 3p^2 - 3p^3),$$

$$\omega_4(p) = p^3$$

$$\omega_1(q) = (1-q)(1-q)(1-q),$$

$$\omega_2(q) = (3q^3 - 6q^2 + 4),$$

$$\omega_3(q) = (1 + 3q + 3q^2 - 3q^3),$$

$$\omega_4(q) = q^3$$
Figure 1: Graphical representation of the result obtained in the S_{bsa} function of the geophysical field

We used signals as real experimental data during our research. The obtained results are used to determine the location, size and amount of reserves of mineral resources by means of aerial magnetic intelligence. Of course, signal charts here use signals in the low frequency range from 10 to 50 kHz. Also, the distances between the nodes in the area under consideration must be equal [17-19].

From the graphic images and tables it can be seen that the local interpolation bicubic spline function has a high degree of accuracy in the digital processing of signals.

4. Conclusion

The paper, a cubic spline built using a local base spline for digital signal processing and the local interpolation bicubic spline models we offer were selected. Construction details of the models are given. Two-dimensional local interpolation bicubic spline models provide high accuracy in digital processing of signals. As an example, the initial values of the geophysical signal given in Table 1 were numerically processed and the error results were obtained (Table 2). Based on the selected models, the results of geophysical signal recovery are presented graphically (Figures 1,2,3 and 4). Based on error results and graphs, it is effective to apply the two-dimensional local bicubic spline model in areas of geophysics and high accuracy.

A R T I C L E   I N F O

A B S T R A C T

No other form of technological development had negatively skewed from existing regulations as the siting of petrol filing stations. An audit of the degree to which their operators repeatedly violate the rules regulating their location and operations may encourage the legislature to pass laws that can ensure a balance between the economy and the environment. This study helps to fill this gap, by analyzing the degree to which the siting of local filling stations meets standard norms, taking Cameroon's district municipalities of Douala as an example. In order to achieve this goal, the current regulations structuring the filling station locations were carefully reviewed. Subsequently, key compliance factors were identified, operationalized, and an audit checklist was developed. Other data collection tools included a structured questionnaire designed to capture the views of neighboring communities on the possible risks to their health, land, and therefore to the environment presented by the station, and a global positioning system receiver for the collection of spatially explicit data. The nearest neighbourhood Index, (Rn) in ArcGIS10.3.1 environment was used to assess the distribution pattern of the stations. Questionnaire data was analysed using SPSS20.0. It is revealed that the distribution pattern of the 152 stations surveyed is mostly random in Douala I (Rn = 0.8573), Douala III (Rn = 0.9879), Douala IV (Rn = 0.6984), and, dispersed in Douala II (Rn = 1.7837) and Douala V (Rn = 1.5764) district municipalities. While most of them, 94 (61.84%) were within the minimum 500 m radius from one another as specified by laws, 99.34% of them didn't conform with the recommended minimum distance of 7m from the centre of a major road, and the 400m radius from residential areas. The results suggest that the siting of petrol stations in the city neglect the hazards accompanying them. The database created in this study could provide a platform to policy makers for appropriate actions.

1. Introduction

A major concern in contemporary literature remains the continuing proliferation of oil and gas stations in urban areas. In the current technological society, they are necessary, but explosions from such facilities frequently trigger loss of life and property within the surrounding communities, thereby presenting great concern to the government and people. Concerns are also raised about the ecosystem's health, protection and environmental quality resulting from these facilities [1]. Petrol vapour, for example, may ignite when exposed to sparks from sources such as lighted cigarettes or a static electrical discharge [2]. The site of petrol stations must therefore be strategically planned to mitigate their effect on both humans and their immediate surroundings [3].

Otherwise, referred to as petrol stations [4]-[5], gas station [6], filling station [7], an oil and gas station is defined as any land, building or equipment used for the sale or dispensing of petrol or oil for motor vehicles [5], Most filling stations sell petrol or diesel, some carry specialty fuels such as liquefied petroleum gas, natural gas, hydrogen, biodiesel, kerosene, or butane while others add shops to their primary business [8]. Because their products are flammable, filling stations pose a constant hazard to the staff, public, assets, and environment. They therefore, need special care in their design, construction, installations, and operations, so that, they remain safe and secure throughout their lifespans. An optimal site selection can enhance the security of the station and its environs. Conversely, a poorly selected site could cause detrimental effects on the stations, and their environs [9]. It is

therefore, important to access their locational compliance with regulatory requirements..

Historically, the inappropriate location of petrol stations has led to disasters. For example, in 2004, more than 2.3 million lives and properties worth about 4.5 billion was lost to fire outbreaks due partly to poor location and mishandling of petroleum products [4]. A similar incident occurred at a liquefied gas filling station and a nearby petrol station in the Kwame Nkrumah Circle claiming 150 lives[10]-[11]. Several other authors have evoked the underlying and proximate causes leading to hazards in filling stations including, fire hazard [12], static electricity [13], and traffic jam [14]. Leakages of pipes & underground storage tanks have been identified to result in the contamination of both surface, and underground water, and air pollution [6]. In this context, petrol stations present health, and safety concerns, especially the potential for fires owing to the toxicity and flammability of the liquid and gaseous products.

Following this, several other studies have assessed the relationship between the location of petrol stations and existing policies, e.g., [15]-[16], and their impacts on the environment [4]. Other authors like [17] and [18], have opined that exposure to diesel, petroleum fumes and fuel components such as benzene and formaldehyde contribute to cancers, acute myeloid leukemia and acute non-lymphocytic leukemia. This is not to say that the global oil industry is only known for its problems, as the industry meets humanity's energy demand. The challenge facing the global oil industry is to find a balance between the critical need for energy supply with safe and sustainable operations. Optimal site selection of these industries could minimize such challenges.

Suitability analysis for siting oil and gas filling stations have either focused on the importance of GIS-Based analysis, for example [19]-[20], or a combination of Multi-criteria Decision Analysis (MCDA) and GIS [21]-[22]. These are very useful tools for solving problems in spatial context because various decision variables can be evaluated and weighted according to their relative importance to attain the final optimal decision. The application of MCDA in siting of petrol stations has shown that accidents from filling stations have been attributed largely to oil explosions [23], spills [24], fire and leaks [25], leading to negative environmental quality, health, and safety [1], [7].

1.1. Statement of the Problem

The African continent at the beginning of the 20th century experienced very rapid urbanization. The cities of sub-Saharan Africa and Central Africa in particular, generally subscribing to this dynamic, have not been able to adapt their infrastructure and management structures to new urban realities. Because of its position as the economic capital of Cameroon and the heartbeat of Central Africa, Douala in Cameroon attracts many oil companies who find a wide demand for their goods there. The city has experienced significant demographic and spatial growth since independence.. This urban dynamic has not been accompanied by the establishment of adequate spatial management of petroleum product storage depots, which represents a major problem.

The government, in Order No. 39/MTPS/IMT of 26 November 1984 [26],lays down general measures of occupational health and safety at workplaces. Furthermore, in 1998, a government decree set out regulations for setting up petroleum product distribution stations. Article 4 states thus, "a minimum measurable distance

must be observed between service stations and establishments, administrative buildings and places, public places, strategic location. ». The distance is in particular 1000 meters for the presidency of the republic, the services of the prime minister, the national assembly, the sub-prefectures, the stations must respect a distance of 100 meters with the educational establishments, the hospitals, places of worship, sports grounds, markets, administrative buildings, etc. Land-use planning, at its simplest, should aim at separating heavily populated areas and social infrastructures from hazardous materials and their related transport routes and at minimizing hazard exposure by building buffer zones around explosive atmospheres [27]. It is of utmost importance, in the light of the dangers posed by petrol stations, that the safety measures established in local standards are fully enforced.

However, these laws are often inadequately integrated into land-use planning, especially when it comes to site selection for the construction of filling stations. Against this context, the study was performed in order to investigate the spatial distribution of filling stations and public safety in the municipality of Douala, Cameroon. The analysis was further justified by the fact that no data on this aspect of research in the region have been published to date.

1.2. Objectives

This study assesses the spatial distribution of petrol filling stations in the district municipalities of Douala, and evaluates their locational compliance with national and international norms in the city of Douala. The study aims primarily to find answers to the following questions:

1) Where are petrol stations located in the City of Douala that does not meet up with necessary regulatory requirements?
2) What is the perception of the neighbouring populations with regard to the location of such stations?
3) What policy measures can be put in place to minimize the current and potential risks posed by petrol stations?

We believe that responses to these questions may help at different scales in policy making. The research results could also assist the administrative authorities of the Municipality of Douala in the implementation of comprehensive initiatives to mitigate and respond to petrol station fires, as well as in designing public awareness campaigns for communities living near petrol stations.

2. Materials and Methods

2.1. Study Area

The Douala municipality (410 km²; ~3,600,000 inhabitants and about 13m a.s.l), is the capital of the Littoral region, located in the estuary of the Wouri River, between 4° 03' N latitude, and 9° 42' E longitude. It has six district municipalities, five of which are urban communities (Douala I-V) (Figure 1), and one (Douala VI) is a rural community.

2.2. Methodology
2.2.1. Population and sample

A two-stage sampling technic was used. First, five of the six district municipalities were selected based on whether they had petrol stations, were in the urban or rural areas. Based on these criteria, the Douala sixth district was excluded because it has no

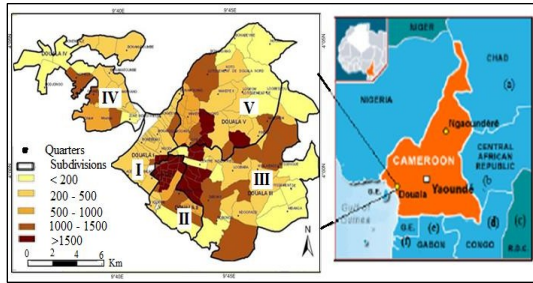
petrol filling stations. In the second stage, each of the five selected urban municipalities were exhaustively sampled.


Figure 1: Location of the study area

2.2.2. Data collection

Data collection took place between March and April of 2020. Both primary and secondary data were collected. Secondary data were obtained from a systematic review of online databases (ISI Web of Science; CAB Abstracts; and Google Scholar, etc.) from 1990 to 2018, using locational compliance of petrol stations with standard norms and related terms as keywords. The articles were screened using inclusion/exclusion criteria applied first at the title and abstract level, and then at the full article level. Articles retained after screening underwent risk of bias assessment and data was extracted. Primary data was captured through observation and a checklist/questionnaire. The design and development of this tool included literature review, and pilot testing. At each petrol station, first, the distances from the four cardinal points (North, South, East, and West) between the station and the neighbouring dwellings were measured (Figure 2), which allowed us to obtain a stratification at different levels of concentration of the population living in the vicinity of gas stations.
Figure 2: Stratification at different levels of concentration of the population living in the vicinity of gas stations

In the second stage, the locational characteristics (e.g., distance from green areas, a distance of pump station to the road, size of the filling stations, distance to neighbouring stations, and distance to any public facility (such as schools, churches, hospitals, market, etc.) were estimated. Finally, four residents/households, each from the four quadrats of the station were randomly selected, and their perceptions on the potential dangers associated with the proliferation of filling stations assessed. In total, 608 (4*152) randomly selected household heads, located within 100 m radius of the inventoried filling stations were interviewed. This technic enables us to classify the stations according to the potential risk (Rp) they pose with neighbouring social infrastructures and residents, vis-à-vis existing regulations (equation 1):

$$R_p = \begin{cases} High; if\ 75-100\%\ not\ comply \\ Moderate; if\ 50-74\%\ not\ comply \\ Low; if\ 0-49\ \%\ not\ comply \end{cases} \quad (1)$$

A section of the questionnaire contained multiple response question asked at each filling station to identify hazard contributing factors during operation and maintenance of filling stations.

The locations of the filling stations were captured using the Garmin Handheld GPS receivers (GPS, 62S). A section of the questionnaire was designed to capture the perception of local residents with regard to the potential threat posed to their health, properties, and the environment by their neighbouring filling stations.

2.2.3. Data Analysis

The software SPSS 20.0 was used to analyse the data obtained from the questionnaire. Both descriptive and inferential statistical techniques were used.. The Average Nearest Neighbour Analysis[28]-[29], using the Euclidean distance was adopted to ascertain the spatial distribution of petrol service stations in ArcGIS 10.3.1 environment, and the description of their distribution (Rn), defined as follows (equation 2):

$$R_n = \frac{2\bar{D}\sqrt{n}}{A}; 0 \le R_n \le 2.15 \quad (2)$$

where

$\bar{D}$ = mean distance between the nearest neighbours (km);
n = number of sampling points;
A = the area under study (km^2).

$$R_n: \begin{cases} 1.5 \le R_n \le 2.15, Dispersed/uniform \\ 0 \le R_n < 0.5, clustered\ pattern \\ 0.5 < R_n \le 1.5,\ Random\ pattern \end{cases}$$

The Nearest Neighbor Index (NNI) is a spatial statistic that distinguishes clustered or scattered event locations in geographical patterns. The algorithm uses the distance between adjacent petrol stations to decide on their distribution pattern (random, normal or clustered). It can provide researchers with a numerical value for the clustering of a geographical phenomenon, enabling them to contrast with other locations more accurately.

3. Results and Discussions

3.1. Spatial distribution of fuel stations in the City of Douala

A total of one hundred and fifty-two (152) filling stations are unevenly distributed all over the municipalities as at the period this research was carried out. The majority of these stations, 72(47%), are in the Douala III municipality, and the least, 11(7%) in the Douala II municipality (Figure 3).

Most of the stations are either along major roads or in thickly populated human settlement areas, or where there are markets that can be easily accessed by customers. This is dangerous to man and the environment. On the whole, 122 (80.26%) of the filling stations appear to be random in Douala I (R_n = 0.8573), Douala III (R_n = 0.9879), Douala IV (R_n = 0.6984), and, dispersed in Douala II (R_n = 1.7837) and Douala V (R_n = 1.5764) municipalities. This kind of haphazard pattern observed in Douala I, III and IV municipalities,

violates the fundamental objective of planning which is providing the right site for the right use at the right time for the right purpose to achieve spatial functionality, efficiency, and aesthetics.
Figure 3: Distribution of petrol stations in the City of Douala

A classification of the stations according to their compliance with existing regulations, and therefore, the dangers they pose to neighbouring residents and social infrastructures (Figure 4a-e) revealed that, 23 (53.49%) of those in Douala I municipality, 5(33.33%) of those in the Douala II municipality, 21 (37.5%) of those in the Douala III municipality, 7(35%) of those in the Douala IV municipality, and 7(38.89%) of those in the Douala V municipality were not in compliance with existing regulations, and therefore pose a high risk to their neighbouring population, and social infrastructures (Residents, school buildings, hotels, hospitals, markets, etc.).

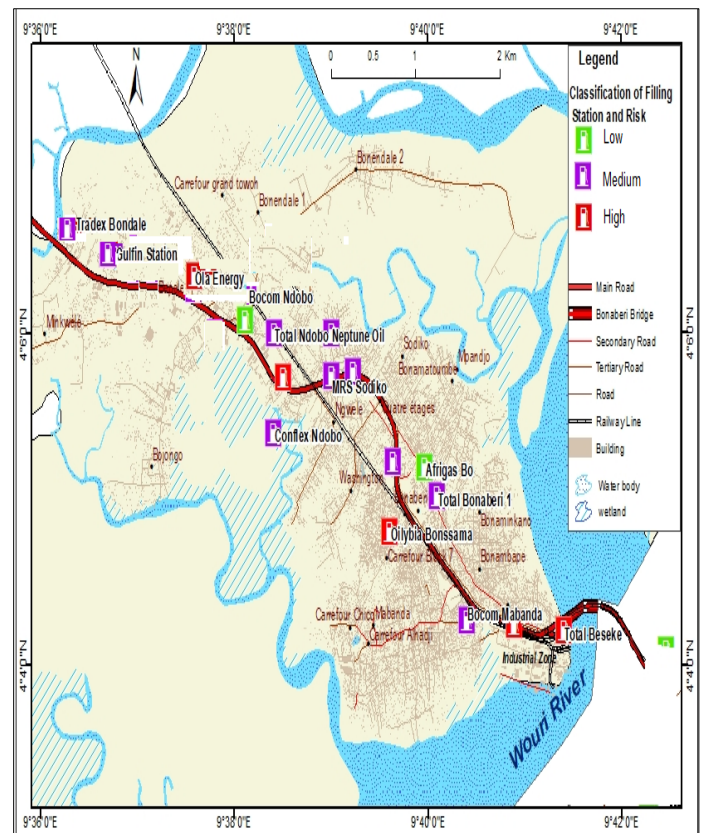

Figure 4 (c): Patterns and risk prone stations in the Douala IV
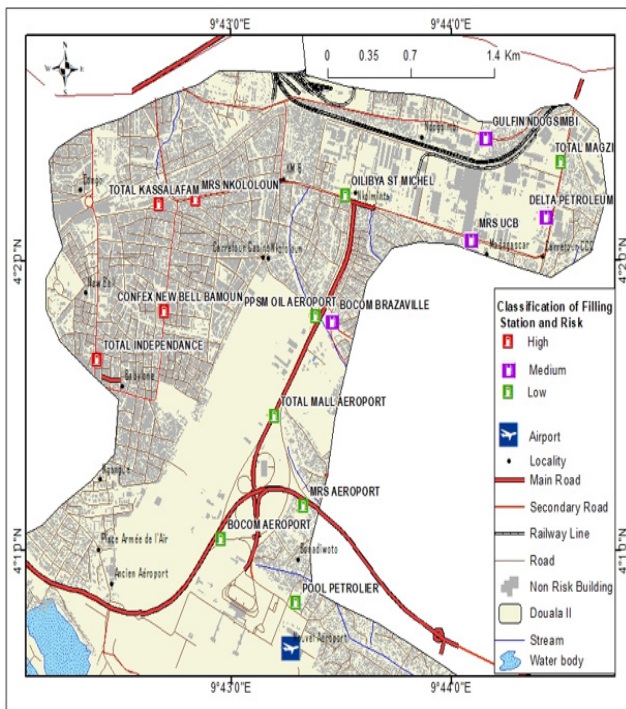

Figure 4 (d): Patterns and risk prone stations in the Douala II
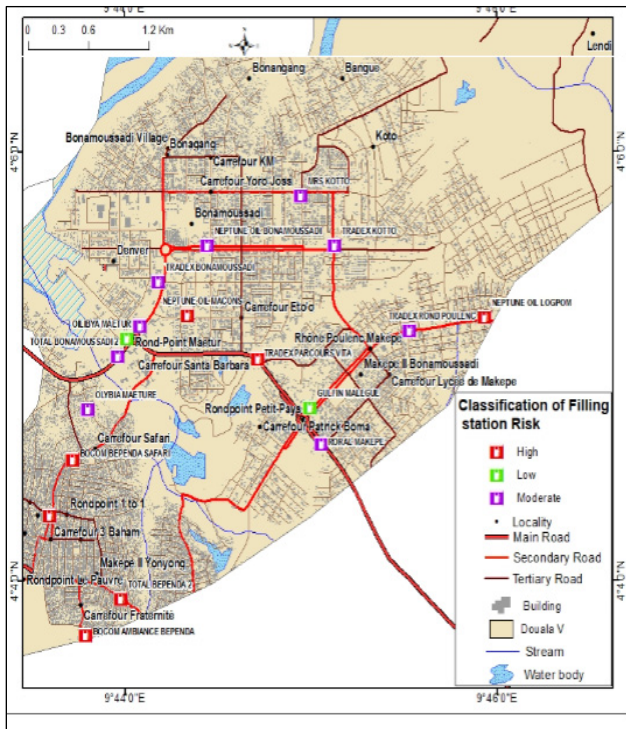

Figure 5: Petrol stations within the minimum 500 m radius in the City of Douala

3.2.2. Distances between filling stations and main road

Of the 152 stations investigated, only one (0.66 %) was within the stipulated distance of 7 m between the edges of a station, and a major road. The rest, 99.34% were between 1 and 3 m. This partly explains the rising road traffic problems such as a traffic congestion, breaches of traffic law, and road traffic accidents that have over the years disrupted the city's economic activities. It also poses questions about the threats posed to nearby communities and pedestrians by the fumes (volatile organic compounds) released from operational activities of the stations.

3.2.3. Distance of Filling Stations to Health Facilities

Of the 152 petrol stations sampled in the municipality, 126 (84%) were located within the stipulated 100 m radius ($X^2(48) = 71.442$; $p = 0.016$) as specified by law. Of these, 24 (66.78%), were from Douala I, 10 (90.9%) were from Douala II, 64 (88.9%) were from Douala III, 10(83.3%) were from Douala IV, and 18 (94.9%) were from the Douala V district. The study shows that most hospitals are conveniently situated far away from gas stations. Most of the 26 stations that did not comply with the current regulations were located in Douala I, (50%) and Douala IIII (33.33 %). It should be noted that Douala I is the Wouri Division's administrative headquarters and is the oldest municipality in Douala. On the other hand, the largest and most populous municipality is Douala III. The likely reason for these playouts may be due to the market along these areas, and the fact that regulators bend to this rule and give a waiver to the filling stations.

3.2.4. Distance between filling stations and educational establishments

Based on legal requirements, petrol stations are not allowed to operate adjacent to public institution like schools. However, should there be a need, the facility should be within 100 m radius of a school environment. Our findings showed that, overall, 119(79.3%) of the stations in the entire municipality complied. Of these, 31(86.1%) were from Douala I, 10(90.9%) were from Douala II, 56 (77.8%) were from Douala III, 8 (66.7%) were from Douala IV, and 14 (73.7%) were from Douala V. Of the 33 (21.3%) that did not comply, 17 (51.52%) were from Douala III, 5 each (15.15%) from Douala I and II, 4(12.12%) from Douala IV, and 2(6.06%) from Douala V district.

3.2.5. Distance between filling stations and the market places and human settlements

According to national guidelines, residential buildings, schools or hospitals should not be within 100 meters of gas stations unless

Figure 4 (e): Patterns and risk prone stations in the Douala V

3.2. Compliance of petrol stations with development good practices

3.2.1. Distances between filling stations

Most of the stations, 94 (61.84%) were within the minimum 500 m radius as specified by the law. Of these stations that,55 (58.51%) were found in the Douala III district, while the least number, 4(4.26%) were from Douala II district (Figure 5)

it can be clearly shown there would be no effect concerning noise, visual interference, safety considerations or smells and fumes. The analysis suggests, however, that several petrol stations have breached this law. For example, most of the stations,144 (94.74 %) in the municipality were not within a 100-m radius from markets. Likewise, most of the stations, 127 (83.55 %) were within 40 m of human settlements, which is much less than the 100 m required by law (Figure 6).
Figure 6: Distances of filling stations to human settlements

The stations therefore seem to have high potential of hazards (hydrological, geological, socio-economic, etc.) to their surroundings. The main contributors to cancers, acute myeloid leukemia, and acute non-lymphocytic leukemia have been described as exposure to diesel, petroleum fumes, and fuel components such as benzene and formaldehyde [4]. Good practice globally prohibits construction in the vicinity of gas stations, in particular hospitals, community centres, schools and old people's homes and housing [29].

These results indicate that the existing model and regulations for land use do not consider the fire threat raised by petrol stations and do not protect the public sufficiently. While there has never been a major fire at a gas station in the municipalities of Douala, a municipal explosion or fire could potentially lead to significant damage and even death and injury. Even in the moderate risk areas of the municipality, human settlement and the construction of schools and hospitals are ongoing. Given the current rate of urban sprawl and the poor implementation of government rules and regulations resulting from overall bad governance culture in the country, it is hard to estimate when the economy-ecology balance shall be taken into consideration in the city's development plan.

Nevertheless, the Douala municipalities are not unique when it comes to adhering to best practices. Similar results had been obtained elsewhere, for example, [30] and [31]. The latter pointed out that the common issue of all urban settlements today is erratic and unsound urban growth, and that the increasing continuation of this problem is unavoidable in this order, in which the balance between the economy and the environment is not taken into account and economic interests often win. While the reasons can vary, the most common ones concern the economic benefits to the local community and municipality of the petrol stations [4].

3.3. Hazard contributing factors in the operation and maintenance of filling stations in the municipalities

Several hazard contributing factors that have the potential to create unsafe conditions in the functioning of the filling stations

in the municipality were reported. In order of priority they include miscellaneous cases,152(25.63%); slips, trips & falls, 126(20.1%); carelessness 98(16.53%), transportation, 84(14.17%), electrical faults, 67(11.30%), fire risk, 49 (8.26%) and medical treatment 17(2.87%) (Figure 7).
Figure 7: Prioritized hazardous activities at petrol stations

Miscellaneous cases comprised of hazard contributing factors such as oil spillages, water leakages, robbery, law and order situation, and, maintenance issues. The numerous unsafe practices that were recorded in many of the filling stations could be attributed to inadequate safety procedures by staff, failure to clear oil spills, unsafe manual handling practices and the storage of fuel samples in unmarked containers.

Slips, trips & falls could be as a result of oil leakage. This suggests poor supervision and inadequate training. Simple prevention steps such as education and health and safety training are often ignored. Hence, occupational health services and supporting legislation need refocusing, revision and reinforcement. On the other hand, carelessness can be due to a variety of causes, including, though not limited to, the unsatisfactory use of staff protective equipment, the use of mobile phones in the tank area, and the insufficient use of signs and instructions.

3.4. Residents' perceptions of the possible hazards associated with the emergence of refueling stations

A significant 77% of the respondents perceived that the distances between some of the filling stations were inadequate. A smaller percentage, 61% percentage stated that the distances between the filling stations and the places of public assemblies were inadequate, while 58% perceived that the distances between adjacent filling stations were inadequate. (Figure 8).
Figure 8: Perception of locals of the adequacy of the siting of stations

The breaches of the appropriate distances between the filling stations, the distances between the filling stations and the nearest public assembly houses/places are strong indications of pressing concerns about the health and safety hazards presented by these petrol filling stations (PFS) and the risks to which residents are prone[7]. In the Douala municipalities, it is common to either see people acquiring lands very close to PFS to create residential homes and/or other businesses, or PFS being established at unacceptable distances from the population and social infrastructures.

A significant number of the respondents (74.25%), most of them from the Douala III district were aware of the proliferation of petrol filling stations in their communities together with the associated dangers and health hazards they pose (Figure 9). Those who were not aware of these proliferations are relatively new to the areas, while those who were aware of these proliferations have been living in the areas for more than two decades.
Figure 9: Level of awareness of locals of the potential dangers associated with fuel stations

Those who were aware of the potential health hazards of petrol fueling stations mentioned respiratory diseases as a result of chronic exposure to dust (26.37% of respondents), chronic exposure to volatile organic compounds (36.62%), and chronic exposure to vehicle exhausts (37.12%). Other findings, such as [32], have shown that petrol vapor could find its way into the basements of buildings and public drains with significant implications if the vapor comes into contact with the ignition source. Many other studies have also reported that fuel stations provide acceptable grounds for fire outbreaks and expose several physical, chemical and ergonomic threats to employees and residents [33].

While a large number of residents were aware of the possible dangers associated with fuel stations, no action was taken to resolve their concerns by the local administrative authorities. This could be viewed as a failure by local authorities and regulatory agencies to proactively resolve (in a participatory way) the problems of the haphazard proliferation of petrol stations against the context of the various possible risks and hazards associated with stations across the municipalities. Building on existing social awareness as such has been identified as a key catalyst towards the achievement of the Sustainable Development Goals [34].

3. Conclusion

In the above-mentioned discussion, the degree to which the location and operation of petrol stations in the City of Douala, Cameroon, compares with relevant current regulations and the consequences for public safety has been examined. A hybrid methodology was used that incorporated both explicit and implicit data from field investigations. The approach is comparable to other heuristic methods. In some cases, it can be considered as a real-time and reliable detection approach, and offers a strong potential for better understanding and investigating of the environment especially in regions such as sub-Saharan Africa, where existing petrol station databases are uncommon and often unreliable. The implementation of this approach has shown that the location of petrol stations in the City of Douala do not completely comply with the guidelines of good practice. Furthermore, the study shows that the haphazard emergence of municipal filling stations is laden with possible health, safety and environmental risks that could be blamed on the inability of government regulatory bodies to implement established laws and policies effectively. If a good mapping of the issue to an acceptable network architecture is identified, this method can also be used to assess hazard-contributing factors and the awareness of residents in detail. In the future, this might be a fascinating place for research. The results trigger the need for local governments to inculcate the interest of the resident population and employees of petrol stations as a core concern in projects that directly affect local ecosystems. Local administrative authorities also need to take timely action to ensure that: (a) an environmental and social audit is carried out before a petrol station is constructed to ensure that it complies with local and./or international standards, and (b) people are prohibited from purchasing land for schools, markets, etc., near filling stations or near filling stations to create residential homes, etc.

Conflict of Interest

The authors declare no conflict of interest.

ARTICLE INFO

ABSTRACT

Smart animal husbandries require the adoption of dedicated tools to assess the contribution of each animal to the production process. The IoT platform presented in this article is a real-team monitoring system for voluntary weighing of cattle. To this end, the ISO 18000-6 standard is used for animal identification through an ultra-high-frequency radio link between a reader antenna and suitable ear tags. A customized data processing algorithm has been developed and embedded in the considered system. To demonstrate the effectiveness of the solution, extensive measurements have been carried out in a real-life environment. The proposed IoT platform is useful to farmers as a control tool for selection and breeding work.

1. Introduction

Milk production plays an essential role in the global economy. Four major world exporters of dairy products (USA, EU, New Zealand, Australia) produced more than 239.2 million tons in 2019. According to the United Nations' food and agriculture organization, milk production, and the price Index for dairy products are growing annually [1]. To increase the volume of raw milk production, it is not unimportant to encourage the use of new technologies. Telemetry and monitoring systems for agricultural production are considered one of the most innovative technologies in precision animal husbandry and are automatic systems for collecting and transmitting information and data analysis and remote decision-making.

Currently, livestock farms use mainly technologies for measuring various parameters inside the farm (ventilation, power supply, heating, etc.), but unfortunately, a small proportion of them are focused directly on the animal. Modern technological tools (temperature sensors, pH sensors, identification sensors, wireless communications, Internet, and cloud storage) make it possible to monitor each animal separately.

A key indicator of the development of young cattle is their weight. In order to obtain maximum accuracy of the mass of cattle, weighing should be carried out repeatedly, using conventional industrial scales or more modern electronic devices. Weighing should be carried out regardless of the animals' location, whether it is a farm or a remote pasture. In most cases, the weighing process is carried out in manual or semi-automatic mode and takes some time. Furthermore, the weighing procedure is stressful for the entire herd. It is not uncommon to use less accurate methods of measuring the weight of animals without using scales, and the assessment is based on the size of body parts. This method is not very effective and requires highly qualified personnel.

2. Review of alternative developments

2.1. RFID-based systems

The introduction of radio-frequency identification tags has had a massive impact on the technological development of animal husbandry. The use of RFID systems has contributed to the

development of the concept of precision animal husbandry. Intensive research on automatic cattle weighing systems using RFID has led to new developments.

The Australian company TRU-TEST develops systems for measuring cattle's weight when an individual passes through a dedicated gate. The TRU-TEST data collection system assumes direct control and the operator's close presence when measuring the weight of a cow [2]. Autonomy is limited by the need for a smartphone to collect data and transmit it to the server. Human resources and the lack of an Autonomous data transmission channel limit this approach.

2.2. Systems based on LF RFID and voluntary weighing

Automatic systems that use LF RFID and stress-free weighing of animals include those supplied by GrowSafe and Intergado.

GrowSafe is a Canadian company that develops systems for automatic data collection from cattle [3], [4]. The systems are equipped with RFID antennas for reading ear tags. The watering and weighing station is integrated with electronic scales. One of the main constraints is the cost of installation. Besides, because of the inadequate cellular network coverage of rural areas and pastures, data transmission over 3G/4G networks is problematic.

Intergado is a Brazilian company that develops dedicated solutions for monitoring cattle based on RFID technology. In such solutions, the scales are integrated on load cells that regularly weigh food and water. When an animal visits the feeder, the system records its RFID tag, arrival time, departure, and duration of consumption [5], [6].

GrowSafe and Intergado systems were originally designed for indoor use, but they can also be installed in pastures. They are very effective from an application standpoint but use technologies and equipment that require large financial investments. Costs associated with the transportation of the equipment from North / South America and its installation in the final site are also, typically, significant.

3. Proposed weighing platform

This article presents a system consisting of hardware and software elements for precision animal husbandry aimed at obtaining information about the weight of the animal, the number of approaches to watering, the time and duration of drinking, with the possibility of performing insect spraying. In this context, the animal's age is assumed to be between 8 and 14 months, and weight is estimated based on the pressure made by the individual animal with the front hooves on the integrated platform. Following best practice in applied info-communication technology, a block diagram of the experimental setup used for remote monitoring of the live weight of animals has been developed and reported in Figure 1.

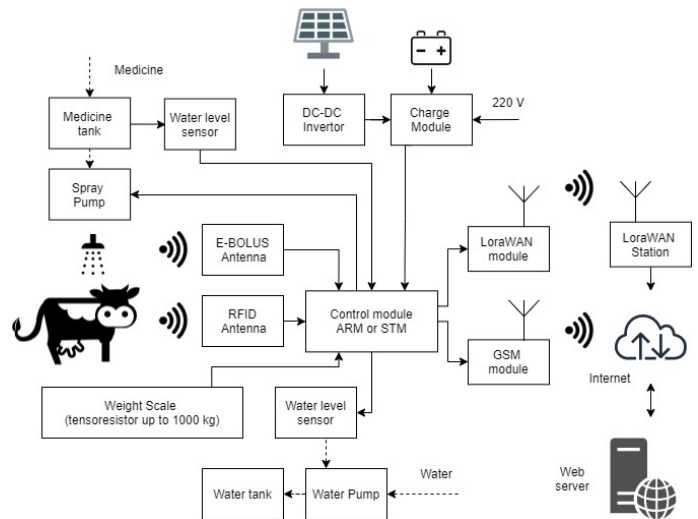
In order to organize the identification of animals, a reader with UHF RFID tags is used. Strain gauges are used for weighing. The platform's connection with the central information unit is established using multiple communication channels: via LoRaWAN, via GSM (backup), and via WiFi (for wireless configuration of the controller module). The solar power plant provides an autonomous power supply in the field.


Figure 1: Block diagram of cattle telemetry system

3.1. Design of the weighing platform

The design of the developed platform has been performed in such a way as to achieve measurable benefits against alternative solutions already available on the market. Furthermore, in order to achieve high measurement accuracy, extensive data concerning the weight and growth of young local cattle has been collected and judiciously used.
Figure 2: 3D model and implementation of the experimental sample
Figure 3: 3D model of the experimental sample pallet with pressure sensors

The main structure is designed in such a way as to resemble a "phone booth" with two side walls and a back wall with an opening for the head of the animal. The side walls have an oblique edge on the entrance side and a straight edge on the side of the drinker, for

easy integration to it. For better accessibility to the electronic components in the lower part of the platform, a novel approach to the installation of the scales has been developed. Contrary to Growsafe solution, where the entire structure is mounted on strain gauges, in our system, the scales are only pressured by the pallet on which the animal stands (see Figure 2).

The design of the fasteners for the strain gauges has been optimized so that, during assembly, easy access is given to all the bolted connections (see Figure 3).

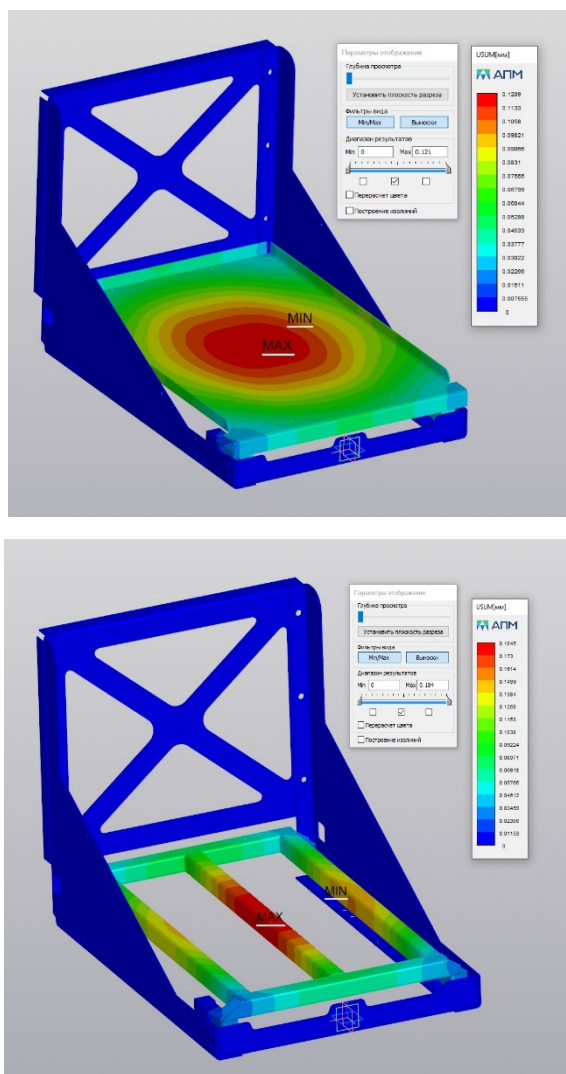
While designing the platform, the properties of the metal structures have been optimized so that the mechanical deformation under a load of 2000 N results in a maximum offset not exceeding 0.36 mm. This is important to make sure that the pressure sensors can withstand the full load from the weight of young cattle (see Figure 4).


Figure 4: Statistical analysis of the pallet for deformation

3.2. Radio-frequency identification of animals

Animal identification is regulated by ISO 18000-6 standard. According to that, the radio interface is established in the frequency range between 860 MHz and 930 MHz using long-range ultra-high-frequency (UHF) radio-frequency-identification (RFID) devices [7].

Extensive research has been devoted to antennas for RFID tags. A more in-depth analysis of passive RFID systems can be found in several publications [8], [9]. In [10], [11], the calculation methods for various antennas are presented. In [12], the principles of operation of RFID systems in the presence of backscattering are illustrated. To achieve the maximum reading range, it is necessary to properly match the complex impedances of the tag antenna and the integrated circuitry. Most often, for optimal read performance, the antenna impedance is matched to the chip impedance at the minimum chip power level.

Various modulation and encoding schemes are used to transmit data between the reader and the tag. A UHF RFID system based on reflected signal modulation in the UHF band can be produced at a reasonable price, though the system's overall efficiency can severely limit the readability. At the same time, the characteristics of the antenna can radically affect the performance of RFID systems.

In the presented study, the working frequency of 868 MHz is selected for the developed RFID system.

A Chafon CF-MU930T reader with integrated UHF RFID antenna featuring circular polarization and 9dBi gain is adopted for reading ultra-high-frequency identification tags (see Figure 5) [13].
Figure 5: UHF RFID antenna used in the proposed development
Figure 6: UHF RFID reader antenna radiation patterns

The ISO/IEC 18000-6C EPC global Class 1 Gen 2 ear tag contains an Impinj Monza® 4 chip and operates at 868 MHz (figure 6). The complex conjugate of the chip load at the specified frequency is expressed as an impedance of 13 + j151 Ω.

Figure 7: Ear tag and embedded UHF antenna used for identification

At the initial stage of development, it is necessary to identify the optimal installation site of the antenna as well as the reader's required power. A necessary condition is to ensure that the reader antenna illuminates the ear tag antenna with a minimum gain level to achieve good communication quality.

A limiting factor for applying the maximum reader power of 30 dBm is related to the possibility of performing an erroneous reading of nearby animals. An additional difficulty in selecting the proper power level is associated with the tag's location on the animal's ear at the time of reading. The antenna can be perpendicular or have an acute angle relative to the ground surface. If the reader antenna is positioned above the animal's head, the tag may be covered by the ear, thus possibly resulting in low communication quality.

Before conducting the actual experiment [14], numerical simulations of the communication channel have been performed using COMSOL Multiphysics.
Figure 8: Current distribution and radiation pattern of the RFID tag antenna

The adopted model consists of the UHF RFID reader and tag antennas, surrounded by an air region terminated with perfectly matched layers (PML). The operating frequency of both antennas is 915 MHz. In particular, the RFID tag is made out of a 0.2-mm thick polypropylene board with a thin embedded aluminum pattern that is modeled as an ideal electrical conductor (PEC). The tag antenna is an electrically small dipole (see Figure 7) whose

radiation pattern is reported in Figure 8. On the other hand, the reader integrates a directional metal stamped patch antenna (see Figure 5) characterized by an input power level of 5W. Using the developed numerical model, one can quickly evaluate the power level radiated by the reader antenna and received by the tag.

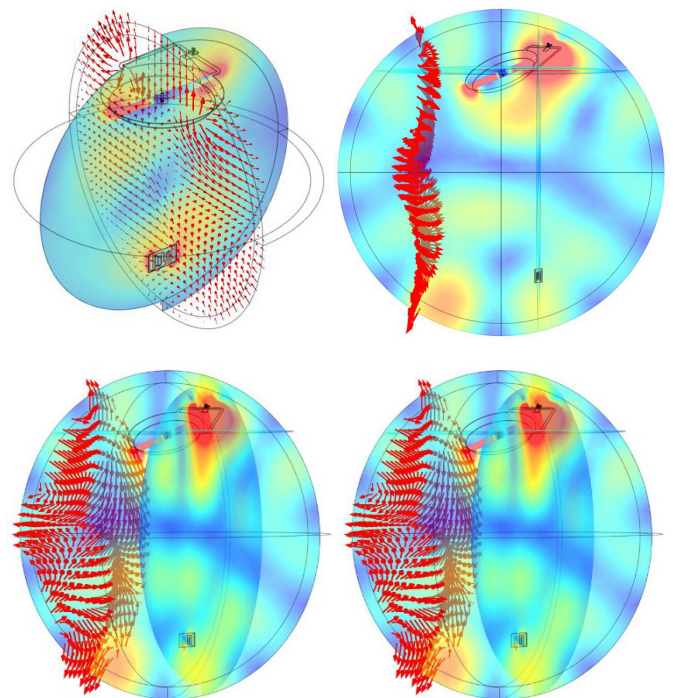
Figure 9 shows the placement of the reader antenna inside the weight platform. The distance between the antenna and the tag ranges from 30 cm to 80 cm. In real-life conditions, in the presence of an animal with total height of 190 cm inside the platform, the distance between the two antennas is typically 55 cm.
Figure 9: Model of the UHF RFID system inside the weighing platform


Figure 10: Electric field distribution excited within the UHF RFID system

Extensive analysis has been carried out as a function of the reader antenna's location relative to the platform surface and relevant sidewalls. The results relevant to the Electric Field (EMF) distribution in different system configurations are reported in Figure 10.

After the computer-aided modeling stage, experimental verifications have been conducted. Based on the data collected through numerical simulations, the reader antenna has been mounted with an optimal angle of 380 degrees relative to the platform tray and of 260 degrees relative to the side-wall of the structure, in such a way as to be in the line of sight with the animal's ear on which the tag is installed. To this end, a dedicated mechanical support for the reader antenna has been designed and integrated (see Figure 11).
Figure 11: 3D model of the upper section of the platform inclusive of reader antenna and central electronic unit

Figure 12: Layout of the electronic unit (1-UHF RFID Reader, 2-Raspberry Pi, 3-LoRa Module, 4-Spray control unit, 5-Power Adapter)

3.3. Electronic unit integrated in the weighing platform

The central electronic unit of the system is based on the modular integration of off-the-shelf components, as it can be noticed in Figure 12.

In particular, four TAL214A(350) strain gauges are connected, via the GoldShine SS-4/S equalizer, to an Arduino UNO controller. In order to process the data received from the strain gauges, a dedicated code has been implemented using the Arduino Wiring programming language. The weight information is sent to the main system controller - a Raspberry Pi - via an I2C port relying on the RS-232 standard. The UHF RFID reader is connected to the computer and receives the identification number from the ear tag. After processing the received data, the Raspberry Pi sends the information to the cloud server. The WiFi module built into the Raspberry Pi single-board computer is used to establish the communication channel. The LoRa32u4 II module supports the

remote connection, whereas a GSM/GPRS link is used as a backup channel for sending the final data.
Figure 13: Block diagram of the main algorithm of the platform
Figure 14: Structure of the database used in the Raspberry Pi

The electronic sub-system has been designed in such a way to withstand harsh environmental conditions in terms of humidity, temperature excursions, as well as mechanical stress, and vibration. It complies with the IP65 sealing class as per the international standard IEC 60529. The enclosure containing the electronic components and the antenna is mounted on the upper part of the platform and protected with vinyl to restrict access, whereas a glass window is used for inspection (see Figure 12).

3.4. Platform management software

The core of the code used for platform management is written in Python 3.7. The implemented algorithm executes two parallel threads. The first thread is relevant to identification, weight measurement, spraying, and data recording in the database. The second thread is used to process the data and store it in the Raspberry Pi unit before sending the relevant information to the server (see Figure 13).

The database is implemented in Raspberry Pi using the scheme described in Figure 14. As it can be noticed, the unique cow ID is reported in the database structures "raw data", "processed data", and "cow". This scheme allows using the internal memory of the Raspberry Pi more efficiently. The data collected through the platform is transmitted from the main database to the server via the Internet. The server is characterized by IP address 194.4.56.86: 8501 where 8501 is the port selected for receiving JSON packets. Each packet contains the following information: "cow ID", "cow weight", "time stamp", "weight indication". Thus, the information on the server reports the weight of the individual cow at every access to the watering site.

Figure 15: Testing the platform on a dairy farm

4. Experimental tests

The developed platform for live weight monitoring and identification has been tested at a dairy farm with 86 head of cattle having age of 10-12 months, kept in one pen. Two platforms were integrated with the existing drinkers while establishing the necessary wireless communication networks (see Figure 15).

Since the width of the drinker significantly exceeds the width of the scales (1.5 meters versus 0.6 meters), additional fences were realized and installed (see Figure 16). Please note that the animals have access to water only through the weighing platform. In this

way, all the livestock in the pen was monitored during the experiment.
Figure 16: 3D model of the platform at the closed drinking bowl

5. Data processing on server

Once the platform is activated, a wireless communication channel is automatically established (via WiFi, LoRa, GSM/GPRS) and the collected data is sent to the server through an Internet connection at http://194.4.56.86/.

To acquire relevant information from the weighting installation, a REST API web service has been specifically developed. The data is structured in JSON format, as illustrated in the following example:

```
{
    AnimalNumber: "KZC154000000",
    Date: "2019-12-16T13:15:00",
    Weight: 332.5,
    ScalesModel: "Mambetov 2"
}
```

In the database, the information relevant to the weighting process is stored in the evt_Weighing table, whereas the BaseEvent table contains the general data concerning the individual event which is associated with the reg_Cow table (where the data related to the animals is reported).
Figure 17: Weighing database structure on the server

In the central herd management system, the information is made available in tabular form as well as visually through diagrams as shown in Figure 18.

Figure 18: Data received from the platform and displayed on the server

6. Results

The pilot tests were initiated on August 8, 2019. Two platforms were used during these tests.

The data received from each animal has been combined into a single database. From 4 to 17 data packets are generated by each animal on a daily basis. Therefore, the total number of weight measurements per day could be in the range of 1000. Data processing will be discussed in a future work.

As an example, Table 1 shows the real-time weighing data relevant to an animal with ear tag ID 013716606d10, obtained on 2020-09-01 at 16:16:28, local time. The data is processed and stored in the memory of the single-board Raspberry Pi computer.

Table 1: Weight data relevant to the animal with ID 013716606d10

No	weight	No	weight	No	weight
1	193.70	36	205.81	71	204.53

35	205.81	70	204.88	105	

The average weight of 201.16 kg is reported on the server (see Figure 16).

Figure 19: Data on server relevant to ID 013716606d10 on 2020-09-01 at 16:16

It is worth noting that the median weight is 204.19 kg. The difference of 3 kg with respect to the average weight is caused by the presence of the value 15.25 kg in the weight data set. That is due to the fact that the weight reading occurred at the time when the animal was leaving the platform. To avoid such issue, changes have been made to the algorithm used for evaluation of the weight, so that the information relevant to the actual weight of the animals before starting the automatic weighting procedures is properly taken into account. This allows assessing not only the dynamics in weight changes, but also accurately displaying the weight of the animal. To this end, the data collected from the individual RFID tag on a daily basis is, also, properly averaged.

7. Conclusion

When comparing the developed platform with existing solutions available on the market, one can note that the proposed system is characterized by reduced costs and ease of installation to existing drinkers, both indoor and outdoor. The design has been optimized in such a way as to enable high reading quality at low power values. The use of LoRa protocol allows overcoming the lack of cellular communication networks in the field while enabling favorable energy savings.

The functionality of the presented platform is virtually unlimited in relation to the data collection. Thanks to the use of a single-board computer, it is possible to expand capabilities in terms of data storage and analytics within the platform, which may be relevant in conditions of poor communication. Components in the platform can be easily replaced without requiring changes to the design and control software. Furthermore, the system can be expanded with new types of sensors and actuators, improving its functionality in this way.

Thanks to the low energy consumption, the platform can be used in various animal grazing conditions. Another important feature is represented by the direct integration with the "Herd Management" software developed in the framework of this project.

In future works, statistical analysis and machine learning algorithms which are useful to determine the exact weight of the monitored animals will be illustrated.

Conflict of Interest

The authors declare no conflict of interest.

Internet of Things (IoT) is changing the world through a new wave of revolution for communications technologies that are no more limited to the human being. One of the main challenges that result from the exponential spread of IoT technology is the difference in the traffic characteristics between classical human communications and advanced things communications. The IoT traffic characteristics become essential for understanding and studying the parameters affecting the IoT traffic shape and thus all further studies related to traffic aggregation, topologies, and architecture designs. In this paper, a traffic aggregation in both the space domain and time domain is proposed whereas a matrix of traffic parameters is analyzed and simulated through building a practical lab case study to demonstrate the theoretical results. It is proven that the two proposed aggregation techniques could impact the traffic profile shaping existing IoT use cases for optimizing the network efficiency from several perspectives as 20% high throughput gain, 45% low collision probability, network congestion is limited to 800~1600 packets in the space domain and about 300~20 packets in the time domain, and overheads are minimized by about 50~27 Kbytes in the space domain and 9.5~0.59 Kbytes in the time domain.

1. Introduction

Internet of things is the fabric that enables the exchange of information between people, things, and processes which in turn leads to a growing data sphere and sophisticated traffic models as a result of diversified sources of data. The number of IoT devices is in an increasing exponential increase that is expected to reach 41.6 billion devices in 2025 with a corresponding data growth that is expected to reach 79.4 Zettabyte in 2025 within a compound annual growth rate of 28.7% over 2018 to 2025 [1]. The expected growth in adoption of IoT is attributed to several factors including:

- The diversity of industries that is perceiving the IoT as a key solution for their existing problems as healthcare, manufacturing, agriculture as well as smart communities and smart cities.
- The advances in network technologies could carry efficiently the IoT traffic. 5G network technologies are a good example.
- Presence of new cost-effective surveillance techniques as low cost embedded integrated cameras, drones technologies etc.

video surveillance data is expected to grow at a compound annual growth rate of 60% from 2018 to 2025.

Accordingly, traffic aggregation is becoming significant to shape the traffic generated by such a world of sensors and cameras efficiently. Traffic aggregation rules could be applied at different stages including sources, aggregators, routers, and gateways.

The data aggregation can accurately summarize and combine multiple stream data into one data chunk to reduce the number of packets to be sent in the large scale networks [2, 3].

In this paper, the main key IoT traffic challenges that are addressed by the aggregation techniques proposed are the massive number of terminal devices and a burst traffic profile of node with the massive amount of data transmissions (number of sent packets), Data volume (light or heavy), and payload size.

The paper contributed value is mainly in organizing the high network nodes (colocation) and the number of massive transmissions times (grooming time) using aggregation strategy as two main traffic aggregation techniques to shape and schedule

several IoT traffic profiles of the IoT smart city nodes for efficient IoT network.

A proposed model for IoT traffic data control includes the following;

- Traffic parametric analysis (space and time)
- Key factors affecting the traffic profile shaping
- IoT smart city architecture model for optimized traffic profile shaping
- Building real-time experiments (case study) based on the IoT smart city nodes before and after the two proposed aggregation techniques.

The smart city case study is analyzed with an associated lab setup for results measurements. In the lab work, the effect of several parameters (node-multiplex, time multiplex, data grooming…etc.) is studied against the traffic profiles. Traffic models are built as a function of those parameters and a traffic aggregation approach is proposed to model and shape the IoT traffic for efficient and reliable network operation. The experimental pilot shall consider single and multiple IoT devices against space and time multiplexing using a proposed colocation and grooming methodologies.

The paper is organized as follows: a literature review is presented in section 2. The proposed traffic aggregation techniques are discussed in section 3 followed by explaining the dimensions of network performance metrics in section 4. The experimental setup and the results are presented in section 5. The discussion and conclusion are discussed afterward.

2. Related Work

The previous works studied technologies related to two main traffic aggregation approaches in the IoT networks that are complemented by the following studies:

2.1. The node-based aggregation

Authors in [3] proposed hybrid Quality of Service-Aware Data Aggregation (QADA) scheme that is a combination between the data aggregation of the cluster nodes and the aggregation of the tree nodes to overcome the limitations in both existing tree and cluster aggregation processes in order to reduce the power consumption and increase the network lifetime. QADA architecture model of the 101 nodes are designed and simulated using NS2.35 network simulator, compared to the existing tree and cluster aggregation techniques to prove the concept.

Authors in [4] discussed the IoT traffic characteristics in the smart city use case. The authors proposed the smart city network architecture for collecting IoT traffic data of the smart city nodes of different scenarios as Logistics goods tracking, university campus, smart hospital, smart homes, mobile payment, Smart Shopping Centre, Intelligent Transport, and smart grid. They also collected the IoT traffic aggregation from different scenarios on one or many gateways for modeling the overall collected traffic using the Gamma-Modulated Wavelet model.

The Internet of Things Protocol (IoTP) is introduced in the IoT communication layer to aggregate data of the massive number of IoT devices into one aggregator in such IoT scenario model.

The protocol is programmed by using the P4 high-level language to be implemented on the switch aggregation that forwards the data aggregation into IoT gateway. The main findings in the IoTP are to improve the network efficiency, reduce the number of packets sent, total payload sent, control average aggregation delay, and average IoT device battery. However, the IoTP aggregation strategy is limited to handle 50 data blocks with a 200KB limit of the P4 register, also, to cover a very short-range communication technology as Bluetooth Low Energy (BLE) [5].

The authors in [6] grouped the sensors in the IoT network into different clusters using a fused resemblance matrix based on the sensor behavior as acoustic, light, and radio. The cluster-based data aggregation for IoT application is developed by multi-sensor data fusion workflow for obtaining the robust cluster that can provide an energy-efficient data aggregation over the IoT networks. However, the number of transmitted data packets is higher in the cluster-based aggregation than in other modalities.

The work in [7] proposed the dynamic aggregation approach based learning automata for the Routing Protocol for Low-power and Lossy-network (LA-RPL). The learning automata develops each node in the IoT hierarchical networks, including child nodes, parent nodes, and one Sink node to aggregate data on the parent nodes with the help of the Cooja emulator. The simulation results show that the LA-RPL routing algorithm outperforms other routing schemes (RPL, Adaptive RPL, Bounding Degree RPL, and Modified RPL) in terms of energy and the control overheads, average path length, average delay. Besides, the practice tests are implemented in this article to evaluate the drop packets, PDR, and aggregation percentage among the routing strategies.

The authors in [8] proposed the Cross-Layer Commit Protocol (CLCP) for data aggregation and its efforts for query-based search in the IoT smart city application. The NS2 simulator tests 50-nodes, deployed in the 600m×600m area and clustered into multiple groups to show an impact of CLCP based cluster head selection with or without aggregation on the network performance, compared to Energy Efficient Clustering Protocol (EECP) methods. It is noted that CLCP and EECP for data aggregation have the same actual residual energy values. However, the CLCP without aggregation outperforms other approaches in terms of the overheads and the throughput.

Compared to the Priority Queue Aggregation Scheduler (PQA) and Priority Queue Scheduler (PQ), the authors in [9] presented the Priority Frame aggregation (PFA) and the Priority Frame (PF) in the Wireless Body Area Network/ Wireless Area Network (WBAN/WLAN) healthcare system architecture. In the WBAN networks, a set of healthcare sensors are originated and deployed in the human body to be connected to the Personal Servers (PSs), which bridge with the WLAN Access Point (WLAN-AP) in the WLAN networks. The proposed PFA and PF schedulers perform scheduling of different data traffics, mapping between WBAN and WLAN, and data aggregation of WBAN sensors into WLAN frame. The PS device forwards it into the central server. The simulation results show that the two proposed PFA and PF schedulers outperform other techniques in terms of delay and throughput, and the dropped packets as the collision probability indicator.

2.2. The time-based aggregation

The authors in [10] presented the Aggregation Periodic Process (APP) to aggregate the periodic IoT data every sample time on the IoT gateway. The aggregated periodic IoT data characteristics are presented and compared to the Poisson Process (PP) to approximate the APP scheme by the PP scheme and then quantify an error between the periodic aggregation and Poisson aggregation.

In the previous study [11], the two statistical data aggregation schemes: the constant interval and constant number are analyzed and estimated to find the optimal aggregation parameters (optimal aggregation interval and the optimal aggregation number), which enable the aggregation model to minimize the mean total system time. But, the optimal aggregation results are suited for stationary arrival conditions.

Accordingly, the work-study in [12] proposed the adaptive aggregation number control based on the aggregation constant number scheme to minimize the latency for variation arrival rate conditions.

3. Proposed model

Despite the contributions of the related works aforementioned above, we explore the aggregation capabilities in the IoT smart city network for IoT traffic profile shaping on one side and optimizing the IoT network performance on the other side. The proposed traffic aggregation techniques can reap the benefits of the data aggregation approach in the WLAN network through the practical design methodology that had not been available yet.

As a key traffic shaping technique, two main IoT traffic multiplexing techniques are presented mainly (a) the space domain aggregation, and (b) the time domain aggregation. The two approaches play a significant role to shape the traffic profile to be optimum and efficient for carrier networks, compared to the present smart city networks. Accordingly, the composite traffic parameters shall include two main attributes, the space domain, and the time domain.

3.1. Space domain attribute

The space domain attribute or Colocation attribute indicates the number of the possible number of source nodes integrated into one hub node or more according to the network topology. Accordingly, the hub node could be modeled as a multiple-input (N) single (M) output node. In addition, the definition of the space domain attribute goes beyond the processing node down to the transducer level as the same source node could be connected to multiple transducer nodes for efficient operation. The number of transducer points (N) could be connected to one source node that in turn share with other numbers of nodes (M) a hub bandwidth. Thus, the N-sensor/M-node model is typed into Single-node type (N=M) and Multi-node type (N≠M, M=1) as seen in Figure 1. Like the previous works [3-9], the Single-node type collaborates the data traffic from M source nodes into the sink node. On the other hand, the Multi-node type can collect the data traffic from N sensors of the same source node into the sink node.
Figure 1: Colocation domain attribute (N sensor/M nodes model)
(a) Single node type(N=M), (b) Multi-node type (N≠M, M=1)

3.2. Time-domain attribute

As presented in the work [12], the time domain aggregation can aggregate data traffic every constant inter-arrival time from the Single-node/Multiple-node into the sink node to overcome the problem of the stationary arrival conditions in the related works [10, 11].

The time-domain attribute indicates the time aggregate of several data streams out of transducer level at the source node either aperiodic or periodic into one IoT output data stream including all protocols necessary to distinguish traffic from different sources and correlation of respective scenarios. In this paper, the term "grooming" will be used to describe the act of multiplexing to distinguish IoT traffic multiplexing concept against traditional multiplexing techniques. The concept is more towards aggregation buffering of data bytes sent at different random time slots into a periodic time slot with a minimal impact on the functional requirements of the applications.

It is assumed that n number of source nodes in the grooming process is asynchronous and homogenous. the grooming process is a random process at any instantaneous time t_i. Each source node sends multiplexed data packets uniformly every periodic inter-arrival time T_i. Let the source node i emits one message A_i every second. A unique message has a fixed-length L in bytes per node. For a constant sampling time duration, the data packets to be sent will be:

$$P_{K.i} = A_i L T_i \tag{1}$$

The grooming time T_G can be incremented by grooming index G to be multiple times as $T_G = GT_i$. Where G represents the grooming index or a multiplier factor that produces multiple numbers of inter-arrival times. The grooming function for a unique node (e.g. $i = 1$) becomes:

$$G_i(t) = \begin{cases} P_{K_{j.i}} & . \ t = t_i + jT_G \\ 0 & . \ otherwise \end{cases} \tag{2}$$

Where the K packets generated by a source node j times can be detected based on the experiment time $Texp$ and the waiting time as $(j = \frac{Texp}{T_G})$. The grooming function of n finite number of nodes in the network scenario seems to be an impulse signal (e.g. delta function), having $P_{K.j}$ amplitude and appears every T_G. It can be described as:

$$G(t) = \sum_{i=1}^{n} \sum_{j=0}^{J+1} P_{K_{j.i}} \delta(t - (t_i + jT_G)) \tag{3}$$

4. Network Performance Metrics

Network performance enhancement is one of the key objectives behind the traffic aggregation approaches. The techniques proposed in this paper targets an improvement in five main key performance indicators mainly:

4.1. Traffic volume

Traffic volume is the amount of data exchanged between a 2-dimensional traffic matrix of node pairs (traffic profile) in the IoT network. It can be measured by two main forms: the average data rate (Kbps) and packets data values (Kbits).

4.2. Throughput

The throughput is the amount of successful data delivered between two IoT source nodes over the wireless communication channel for a specified period, resulting in kilobits per second (Kbps) [13].

Recently, the throughput of the source $x(i)$ in the FAST TCP model is a source sending rate $\widehat{x_t^f}$ or $\widehat{x_t^b}$ multiplied by the forward packet size P_f as:

$$x_i = \begin{cases} \widehat{x_t^f} P_f & k_f < 1 \\ \widehat{x_t^b} P_f & k_f \geq 1 \end{cases} \tag{4}$$

Throughput is improved by high P_f when Asymmetry Factor (AF) k_f is greater than one. Where k_f represents a connection of asymmetric link between the two routers of a model. It is based mainly on asymmetry capacity ratio (ACR) and asymmetry packet ratio (APR) [14].

In the IoT technology, the asymmetry link has no effect on the wireless connectivity among IoT nodes in the same AP (router). the factor k_f is ignored. $\widehat{x_t^f}$ and $\widehat{x_t^b}$ of the forward and backward packets could be addressed into the sending rate R_i (packets/s) from one thing node (source/destination) to another one. Thus, the throughput can be derived from (4) as:

$$x_i = R_i P_i \tag{5}$$

while P_i is the packet size (bytes), excluded from the fixed overheads. Consequently, the throughput percentage is the ratio between the useful data packets to the total amount of data packets including overheads.

4.3. Collision probability

The number of collision packets to the total number of transmitted packets is the packet collision probability.

Recently, the collision of the IEEE802.11 standard occurs when multiple stations share the wireless channel to transmit data at the same time onto a receiver. The access technique caused more delay and packet data-flow degradation. In this technique, each node listens to the silence (idle) of the channel for the Distributed Coordination Function (DCF) Inter-Frame Space (DIFS) interval. The standard grants all $n-1$ nodes random backoff time $\overline{W}_{backoff}$ before the transmission or retransmission on the wireless radio channel. When DIFS time is released and the channel is not busy, the senders are ready to transmit data after variable backoff times. The randomization of this time led to an increase in the probability of packet collision, which is given as [15]:

$$P_{coll} = 1 - \left(1 - \frac{1}{W_{backoff}}\right)^{n-1} \tag{6}$$

The term $\frac{1}{W_{backoff}}$ describes the channel access probability. It is the probability that the station attempts to send data in arbitrary waiting time slots. By analogy, the same model could be applied on IoT networks including the parameters highlighted in the section above to be as follows:

$$P_{coll} = 1 - \left(1 - \frac{1}{GT_G}\right)^n \tag{7}$$

4.4. Network traffic congestion

With the increasing number of high data transmission rates in IoT use cases, Network congestion can arise from high request traffic in the network. The congestion control mechanisms have been discussed based on protocols and offloading approaches to avoid the buffer overflow in the IoT networks. In the protocol approach, congestion control mechanisms focus on the application layer and the network layer. Throughput and Packet Delivery Ratio (PDR) metrics are improved to reduce the number of lost packets caused by the congestion in the network layer. While throughput is aforementioned. PDR is the ratio of the total number of received packets in the destination (sink) node to the total number of sent packets in the source nodes [16,17].

On the other hand, the network traffic congestion could be evaluated by the number of sent packets by the source nodes in the IoT networks.

4.5. Control overheads

The control overheads are excess data or the control header behind the useful data in the packet format for a specific task. It is measured per bytes or Kilobytes.

5. Experimental Results Analysis

5.1. Experimental setup

An experimental lab is established to collect, analyze, and profile the traffic model based on practical smart city use cases. Based on the architecture highlighted in figure 2, the prototype built for proof of concept purpose is composed of:

- The sensor layer is designed to develop several scenarios related to smart city use cases from different perspectives as safety, security, energy, and environment. Table 1 shows the sensors used in an experimental study [18-20].

- The processing layer is based on the ESP micro-controller family including ESP 8266 MCU units and Wi-Fi 802.11b/g/n unit as a network interface module. ESP 8266 MCU unit is programmed to perform both the space domain aggregation and time-domain aggregation processes in the broker node. While the Wi-Fi unit enables the nodes to communicate with other nodes in the IoT network.

- The communication layer is architected according to the network diagram in figure 2, to enable different topologies to be configured and experimentally measured. Intermediate nodes are introduced to enable the traffic shaping and aggregation factors being applied as the broker node.
- The networking layer includes all network scenarios among IoT sensor nodes in the smart city architecture as physical security scenario, human safety scenario, energy scenario, device control and management scenario, and the environment scenario. Each scenario network has two or three connected IoT nodes with the TCP/IP connection protocol. The paper examines the human safety scenario nodes specifically scenario 3 (fire-node, smoke-node) and cloud scenario (fire-node and webserver) that is presented in the classical smart city networks [20].

Table 1: Sensor Layer Specifications [18-20]

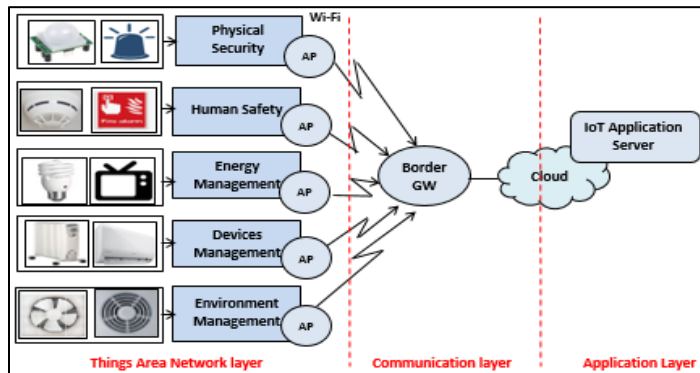
Parameters	Sensor model	Measurement range
Natural Gas	MQ-5	(0-1000ppm)
Smoke	MQ-2	(0-10000ppm)
Fire	KY026	(20-100Cm),60°
CO	MQ7	(20-2000ppm)
Light detector	TSL2561	(0.1-40,000) Lux
Temperature	DHT22	(-40-125°C)


Figure 2: IoT architecture model designed for experimental work [20]
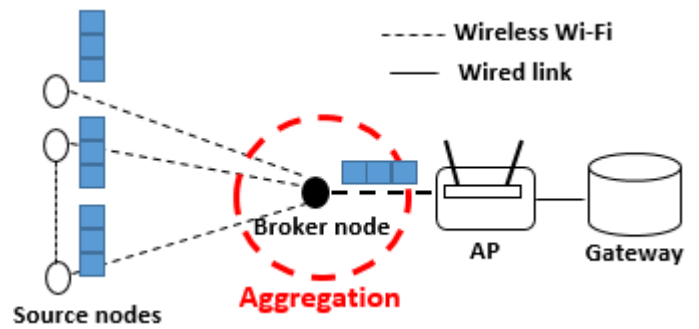
Figure 3: Proposed single-node scenario in the smart city networks
Figure 4: Proposed Multi-node scenario in the smart city networks


Figure 5: Proposed Time-domain scenario in the smart city networks

A set of experiments are designed to emulate the traffic patterns associated with each type of traffic aggregation either the space domain attribute or the time domain attribute, compared to that before (without) the aggregation process [20]. The experimental setup details are listed in table 2.

On the space domain side, a list of IoT nodes is operating on two models of operations as seen in figures 3 and 4. Figure 3 shows the network model of a Single-node type. While the Multi-node type is architected in figure 4.

In a Single-node experiment, 5-fire source nodes as senders can communicate with an individual smoke receiver node. Each fire-node comprises a fire-sensor subscribed to the processor node. After an initial step of one fire node connects to a unique smoke node, the number of fire nodes is incremented and the results are monitored on each step. As seen in figure 3, the smoke node is a broker that accumulates the traffic profile sent from each fire source node and then forwards it into the AP and the higher layers (gateway and internet). The Multi-node experiment follows the same methodology design of the Single-node experiment except for the five fire nodes of the Single-node type are replaced by five fire sensors that are connected directly to one processor node.

In the multi-node type, the unique fire source node can operate as a broker node, which accumulates traffic profiles of the connected fire-sensors into the traffic aggregation and send them to the destination smoke node.

The time-domain experiment is performed in both one source node experiment and N source nodes experiment as shown in figure 5. In one source node experiment, a single fire node is designed to store and buffer the sensed data and then send a multiplexed sensed data onto one smoke node as a broker node at grooming times T_G of about 1-16 minutes. Each T_G is incremented every 60 seconds. N-sensor nodes experiment is to establish five nodes of Single-node fire sensor and one smoke broker node to emulate the grooming pilot of N source nodes. The experiments are executed for a real-time experiment $Texp$ (960 seconds).

Table 2: Experimental setup details

Experimental parameters	Space-domain experiments	Time-domain experiments
P_i (bytes)	90-1548	
Header/packet (byte)	32	
T_G (minute)	N/A	1-16

Connection protocol	TCP/IP	
Wireless communication	Wi-Fi 802.11b/g/n	
N nodes/sensors	1-5 nodes	
Sensors type	Fire and Smoke	
$Texp$ (sec)	750	960

5.2. Results

Before the aggregation process, table 3 lists the limited key performance values of the fire-node in the classical smart city (scenario 3 and cloud scenario).

Table 3: Fire performance values in the classical scenario 3 network

	Throughput %	Overheads Kbytes	No. of sent packets	Traffic volume Kbits/Kbps
Sc. 3	62.65	85.00	2720	1934/2.01
Cloud	64.37	9.53	305	214/1.6

After the aggregation process, the measurement results of different experimental pilots are summarized into traffic profile results, and network performance metrics results.

In the space attribute, the role of the broker node is exploited as a method of traffic profile shaping for IoT networks. As shown in Figure 6, the Multi-node traffic profile is smoothed with low traffic volume (packets data values), compared to the Single-node type.

(a)   (b)
Figure 6: Traffic shaping of N-sensors M-nodes model
(a)   Five-sensors Five-nodes, (b) Five-sensors One-node

Generally, Figure 7 explains the difference of configuration on the space model. Figures 7.a shows the average data rate versus the low number of sensors/nodes for both types of the space domain attribute. An average data rate in the Single-node type begins to increase significantly with an increasing number of nodes. On the other side, the average data rate of the Multi-node type is approximately constant.

As shown in Figure 7.b, it is obvious that the number of sensors attached to the same node has a direct impact on the network throughput on an average of 0.1-0.2% on each additional sensor per node. The increase might not be a significant one however it is not the main target out of the space multiplex. While the Single-node type hasn't been impacted by the throughput.

Figure 8.a shows the relationship between the PDR and the low number of nodes in the Single-node type. The PDR decreases significantly with the increasing number of heavy traffic nodes. The PDR reduces from 99% in 1-node to 75% in 5-node whereas

the nodes send high traffic packets rates with an average of 13.8 packets/sec.

(a)   (b)
Figure 7: Space attribute (a) Average data rate, (b) Throughput

As shown in Figure 8.b, the number of packets sent by the node(s) increases with the increasing number of nodes in the Single-node type. On the other hand, the number of transmitted packets may decrease or remain constant in the Multi-node type.

(a)   (b)
Figure 8: Network congestion in the Space domain attribute (a) PDR, (b) Number of sent packets

Figure 9 shows the relationship between the control overheads on one side and the number of aggregated nodes/sensors on the other side. It is noted that the data overheads begin to significantly increase from one source node to five sources in the Single-node type. On contrary, the control overheads seem to be constant with an increasing number of sensors attached to one-node in the Multi-node type.
Figure 9: Control overheads in the space domain attribute

514

On the other hand, the time domain experimental results tested 16 levels of grooming index (i.e. multiplex of 16 channel of data streams on the same channel). The experiment shows a relationship between the grooming index G on one side, and the traffic profile on the other side from five experimental key observations: traffic volume, collision probability, throughput, network congestion, and BW overheads.

It is observed that the traffic volume (packets data values or average data values) increase as the grooming index increase as shown in Table 4. Figures 10 shows that the grooming time T_G between the two generated packets P_{K_i} and $P_{K_{i+1}}$ sent by a node i is highly impacted by the grooming factor G in a directly proportional relationship. Equation 8 describes the grooming traffic profile of Figure 10. The traffic volume is impacted by the data aggregation of one/multiple source nodes for G grooming times. The average data rate is reduced from 0.175 Kbps at G=2 to 0.164Kpbs at G=8. Similarly, the packet data size data rate is reduced from 168.8 Kbits at G=2 to 164.5 Kbits at G=8.

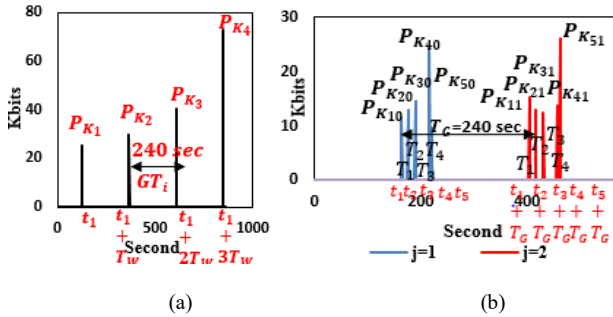
(a)　　　　　　　　(b)


Figure 10: Time-domain attribute for 4-level grooming index
(a) One fire node experiment, (b) Five fire node experiment

The collision probability in the grooming attribute results is affected by two main enablers: the number of nodes and grooming guard periods as depicted in (6). As shown in Figure 11.a, the collision probability increase as the grooming index increase, whereas the graph shows an exponential growth of collision probability versus the number of nodes for the first 400 nodes for grooming index G=2, while the same growth to lower values of collision probability from grooming index G=8 which in turn explains the high impact of grooming index of collision probability especially for a big volume of nodes that characterize IoT and WSN technologies.

The graph in Figure 11.b shows that the grooming index G has a considerable impact on throughput as it increases the throughput value from 72.8% at G=1 to 91.2% at G= 8 which indicates the 18.4 % gain in throughput value followed by a small growth rate at G>10. It is obvious that the throughput increase from 91.2 % to 92.6% as G increases from G=8 to G=16. It is noted that an effective impact of the throughput is for G less than or equal to 8.

For 5-fire source nodes in Figure 12.a, it is obvious that the PDR increases with a high G grooming index whereas, PDR is 43% at G=1 until reaches 74% at G=8. As shown in figure 12.b, it is noticed that the number of sent packets decreases for long grooming times.

Consequentially, it is obvious that BW overheads (Kilobytes) exponentially decrease with the increasing number of G grooming index as seen in Figure 13.

Table 4: Time-domain attribute results

Grooming index G	Packets data values (Kbits)				Average data rate
	P_{K_1}	P_{K_2}	P_{K_3}	P_{K_4}	
4 (240 sec)	25.45	29.52	40.64	72.75	0.175 Kbps
8 (480 sec)	85.0	79.3	---	---	0.164 Kbps

6. Discussion

Table 5 discusses the impact degree or an improvement gain of the two traffic aggregation techniques on the IoT network efficiency, compared to the classical smart city network before aggregation as:

6.1. Space domain attribute

In contrast to the existing aggregation techniques [3-9], it is noted that the traffic profile is shaped severely by applying the N

sensor /M node model as shown in Figure 6 as a result of the new architecture which in turn has a direct impact on the IoT network key performance indicators:

In the traffic volume, minimizing the number of processing to one is verified through the constant average data rate. It can maintain the average data rate by about 4Kbps with an increasing number of sensors in the Multi-node type as in Figure 7.a. While the average data rate is significantly increased by about 4~16 Kbps with an increasing number of nodes in the single nod type. Thus, the traffic data volume of the multi-node type is lower than that in the single-node type.

As listed in table 5, the traffic data volume (average data rate, data size) of the fie-node, resulting from the space domain

attribute is higher than that in the classical smart city scenarios (scenario 3 and cloud) before the aggregation process. The average data rate increases from 2.01Kbps and 1.6 Kbps in the classical

smart city scenarios (scenario-3 and cloud) to 3.2 ~2.9 Kbps and 3.2 ~15.4 Kbps in the multi-node type and single-node type, respectively. In the same manner, the amount of data size increases from 1934 Kbits and 214 Kbits in the classical smart city scenarios into 2285.5~2126.8 Kbits and 2285.5~11125.2 Kbits in the multi-node type and single-node type, respectively.

In the throughput, the impact of node aggregation architecture on network performance becomes very clear in Figure 7.b that shows a significant impact on throughput as a result of aggregating several sensors on the same node. The result is attributed to the network metadata added to the traffic header on each transmission. In the same case of n-sensors on the same node, the broker shall use the header once. As a result, the throughput gain per sensor is about 0.2% for 5 sensor case that is scaled up to a total 20% throughput improvement for a 100 sensor real case aggregated on one broker. Thus, throughput in the multi-node type is higher than that in the classical smart city scenarios by about 20% improvement gain for large scale networks (100-IoT nodes) as depicted in table 5. However, the single-node type is approximately the same as in the classical smart city scenario nodes.

High throughput and constant average data rate in the Multi-node type reduces network traffic congestion. On contrary, the low network congestion in the Single-node type is caused due to the low throughput and PDR values as in Figures (7.b, 8.a).

From the number of sent packets perspectives, the Multi-node type maintains the minimum number of packets by about 800 ~1600 packets for a low incremented number of sensors rather than the single-node type that has a significantly increasing number of sent packets for 5-source nodes by about 3700~13900. The number of sent packets is reduced from 2720 packets in the classical smart city network (scenario3) to 800~1600 packets in the multi-node type with an improvement gain of about 22% as depicted in table 5. Otherwise, both single-node type and multi-node type in the space domain attribute do not affect the number of sent packets in the classical cloud scenario.

From the overheads perspectives, it is remarked that overheads in the Multi-node type are lower than that in the Single node type as depicted in Figure 9 and Table 5. The control overheads in the proposed Multi-node type is reduced from 50 Kbytes in one-sensor to 27 Kbytes in five-sensors. The overheads in the multi-node type are less than that in both scenario 3 and the cloud scenario of the classical smart city networks with an improvement gain of 300% and 30% compared to scenario 3 and the cloud scenario.

6.2. Time-domain attribute

Rather than the previous time aggregation techniques [11-13], the traffic profile shaping concept is verified and proved in the time domain aggregation as shown in Figure 10. As the G number of grooming times increased, the collected data information to be sent will increase, and vice versa. the traffic profile of one/multiple nodes is shaped into a delta function. Its mathematical formula in (8) meets a theoretical time-domain concept in (3).

While the previous time aggregation techniques reduce an error and the latency [11-13], the main findings in this article are to improve the IoT network performance as follows:

Table 5: The improvement gain of the proposed techniques, compared to the classical system

Performance metrics in the IoT Smart city networks			IoT Network key performance indicators					
			Throughput (%)	Collision Probability (%)	Traffic volume		No. of sent packets	Overheads (Kbytes)
					Average data rate (Kbps)	Data size (Kbits)		
Proposed Techniques	Space domain attribute	Single-node type	64~65	N/A	3.2 ~15.4	2285.5~11125.2	3700~13900	116~434.75
		Multi-node type	64~84/ 100-nodes	N/A	3.2 ~2.9	2285.5~2126.8	800~1600	50~27
	Time domain attribute		72.8~ 93	95~50	0.175~0.164	168.8~164.5	300~20	9.5~ 0.59
Classical smart city Before aggregation	Human safety network (scenario3)		62.65	99.9	2.01	1934	2720	85
	Cloud scenario		64.37	99.5	1.6	214	303	9.3

The time-domain attribute reduces the traffic data volume whether the average data rate and data size from G=2 to G=8. The traffic volume in the time-domain attribute is less than or equal to that in the classical smart city scenarios. The time-domain attribute reduces the average data rate from 2.01Kpbs in the classical smart city scenarios (scenario 3) to 0.175~0.164Kbps. Similarly, it reduces the amount of data size from the 1934 Kbits and the 214Kbits in the classical smart city (scenario 3 and cloud scenario) to 168.8~164.5 Kbits. While the average data rate of the time-domain attribute (1.6Kbps) is moderated with that in the cloud scenario of the classical smart city.

The collision probability is reduced from 95% at G=2 to 50 % at G=8 for a dense number of nodes (400 nodes) in the non-real-time IoT applications. For the large scale networks with 400-nodes, the collision probability is mitigated by about 95~50 % with at least 45% improvement gain, compared to that in both classical smart city scenarios before aggregation (up to 99%). Thus, the proposed time-domain technique enables the dense number of nodes in IoT smart city networks to avoid the collision.

The percentage of the throughput in the time aggregation is raised by about 20% gain whereas this approach develops high throughput, gained from 72.8% at G=1 to 93% at G=10 as in Figure 11.a. It is noted that the throughput of 72.8~93% in the time-domain attribute outperforms the throughput of 62.65% and 64.37% in the classical smart city scenarios with an improvement gain of about 30%.

The number of transmitted packets in the time aggregation is reduced from 300 packets at G=1 to 20 packets at G=8. Also, throughput in Figure 10.b and PDR in figure 12.a are improved to avoid network traffic congestion in this technique. It is remarked that the number of sent packets is minimized from 2720 packets and 303 packets in both classical smart city scenarios (scenario3 and cloud) to about 303~20 packets based on G grooming times. The overheads are mitigated by a minimization factor of 9 at G =2 and 15 at G=8, compared to the overheads in scenario-3 and the cloud scenario.

The excess overheads are reduced from 9.5KB at G=1 until 0.59 KB at G=8 as shown in figure 13. The overheads are minimized from 85Kbytes and 9.3Kbytes in scenario 3 and the cloud scenarios of the classical IoT smart city to about 9.5~0.59Kbytes in the time domain attribute with an improvement gain that exceeds up to 150% at G=8 than overheads in scenario 3 and a minimization factor of about 90 at G=2 in the cloud scenario.

7. Future work

Our practical experiments (testbed lab) are established from 5-fire sensors, one-smoke-node, and 6-ESP 8266 MCU units as a case study in the IoT smart city networks to prove the concept. Our experimental setup could be extended to be applied for large-scale smart city networks and other IoT use cases in the future.

8. Conclusion

The two traffic aggregation techniques (space domain and time domain) have been proposed in this article to address the challenges of IoT traffic characteristics in the smart city networks as dense number of nodes, the massive number of transmissions,

Data volume (light or heavy), and the payload size. Compared to the classical smart city networks, the methodology design of the proposed work highlights shaping the individual traffic profiles in the classical smart city into the traffic aggregation of N source sensors/nodes via the space domain attribute and the traffic aggregation for G grooming times (delay) via the time-domain attribute for IoT traffic data control, thus optimizing the IoT network performance in the smart city use case from the five main perspectives (traffic volume, throughput, collision probability, network congestion, and the control overheads). The practical experimental lab model is built as one of several smart city networks (scenarios) before and after the proposed aggregation techniques to prove the concept. It is verified that the two proposed aggregation techniques have a better improvement gain than the existing smart city networks (without aggregation).

Last but not least, the practical study works focus on the smart city models, but the results could be extended to other non-real-time IoT use cases as smart metering, telemetry, and surveillance.

Conflict of Interest

The authors declare no conflict of interest.

A R T I C L E I N F O	A B S T R A C T
	This paper presents a new floating-point technology: Bounded Floating Point (BFP) that constrains inexact floating-point values by adding a new field to the standard floating point data structure. This BFP extension to standard floating point identifies the number of significant bits of the representation of an infinitely accurate real value, which standard floating point cannot. The infinitely accurate real value of the calculated result is bounded between a lower bound and an upper bound. Presented herein are multiple demonstrations of the BFP software model, which identifies the number of significant bits remaining after a calculation and displays only the number of significant decimal digits. These show that BFP can be used to pinpoint failure points. This paper analyzes the thin triangle area algorithm presented by Kahan and compares it to an earlier algorithm by Heron. BFP is also used to demonstrate zero detection and to correctly identify an otherwise unstable matrix.

1. Introduction

Standard floating point has been useful over the years, but unknowable error is inherent in the standard system. Though not indicated in standard floating point, a calculated result may have an insufficient number of significant bits. This paper, which is an extension of work originally presented in [1], uses a bounded floating-point (BFP) software model that emulates the BFP hardware implementation to identify the accurate significant bits of a calculated result, thus unmasking standard floating-point error.

2. Background – Standard Floating Point

2.1. Standard Floating-Point Format

Computer memory is limited; thus, real numbers must be represented in a finite number of bits. The need to represent a range of real numbers within a limited number of bits and to perform arithmetic operations on those real numbers, led to the early development of, and use of, floating-point arithmetic. The formulaic representation employed is reminiscent of scientific notation with a sign, an exponent, and a fraction [2]. Through the efforts of William Morton Kahan and others, a standard for floating point was published in 1985 by the Institute of Electrical and Electronics Engineers (IEEE) [3]. The current version is IEEE 754-2019 - IEEE Standard for Floating-Point Arithmetic [4], which has content identical to the international standard ISO/IEC 60559:2020 [5].

The standard floating-point format is shown in Figure 1. The sign of the value is represented by a single bit, S. The offset exponent is E with a length of e. The significand, T, has a length of t. The overall length of the representation is k.
Figure 1: Standard Floating-Point Format

The IEEE 754-2019 standard defines floating-point formats and methods for both base two and base ten. However, this work only addresses base two floating point. The formats most commonly used require 32 bits or 64 bits of storage, which are known as single precision and double precision, respectively.

The decimal equivalent of the standard representation is shown in (1), where S, T, t, and E are defined above and O is the exponent offset. For binary floating point, O is nominally $2^{e-1}-1$.

$$(-1)^S \cdot (1+T/2^t) \cdot 2^{E-O} \tag{1}$$

The expression (1) is used in expressing the value of the standard floating-point representation in various number bases, typically for the display of the value in number base ten.

519

2.2. Standard Floating-Point Representation Error

Floating-point error is the difference between the representation of the actual standard floating-point value and the infinitely accurate real value to be represented. It must be clearly stated that the IEEE floating point standard does <u>not</u> specify any mechnism for indicating nor defining floating-point error. Floating-point error is invisible to implementations of the IEEE floating-point standard.

Standard floating-point error occurs because only a limited number of real numbers can be expressed with the finite number of bits available.

Because binary floating point represents real numbers with a fixed number of bits, numbers that cannot be represented with a limited set of powers of two cannot be represented exactly [6]. As Goldberg succinctly describes it, "Squeezing infinitely many real numbers into a finite number of bits requires an approximate representation" [7]. Therefore, there are a finite number of values that can be represented with floating point, but an uncountably infinite number of values [8] that cannot be exactly represented with floating point. For instance, the values 0.1, 0.22, and transcendental values, such as π, cannot be accurately represented with binary standard floating point, but the values 0.5, 0.125. and 942.625 can be exactly represented with standard binary floating point. Thus, only those real numbers which can be represented with a constrained sum of the powers of two can be represented with no error. All other representations must have error.

Therefore, we can define floating-point representation error as the difference between the representation value, see (1), and the infinitely accurate real value represented.

2.3. Standard Floating-Point Operational Error

Accuracy in floating-point computations may be measured or described in terms of ulps, which is an acronym for "units in the last place." Kahan originated the term in 1960, and others have presented refined definitions [9], [7]. An ulp is expressed as a real function of the real value represented. Rounding to the nearest value, for instance, can introduce an additional error of no more than ±0.5 ulp.

The real solution to the floating-point error issue is knowing the number of significant bits of a computational result. The number of significant bits can be known by using BFP. When BFP identifies sufficient significant bits, a decision may be made, or an opinion may be formed.

Usually, the error of a single computation is insignificant, with the exception being catastrophic cancellation error. However, with large, complex floating-point computations, error can accumulate and can reduce the significant bits to an unacceptable level [10], [11]. Loss of significant bits may be propagated through recursive repetition. BFP tracks the current number of significant bits through recursion [12], [13]. Examples of such recursive calculations are spatial modeling of explosions [14], dynamic internal stress [15], weather [16], etc.

The repetition of such calculations accumulates floating-point error. Unfortunately, there are two types of error, rounding and cancellation, and these errors are incompatible since rounding error is linear and cancellation is exponential. However, just as apples and oranges cannot be added by species, they can be added by the "genus" fruit. In order to accumulate cancellation and rounding errors we must find a similar "genus" before such error can be accumulated. This genus in the BFP system is the logarithm of the accumulated error stored in the defective bits field D (Figure 3), which captures both the accumulated rounding error and cancellation error.

Three operations that must be performed during floating-point operations introduce error. These operations are the following: alignment, normalization (causing cancellation error), and truncation (leading to rounding error).

Alignment occurs during add operations (which include both positive and negative numbers) when one exponent is smaller than the other and the significand must be shifted until the exponents are equal or "aligned" [17].

Cancellation error occurs because the resulting significand after a subtraction, including the hidden bit, must lie between 1.0 and 2.0. If the operands of a subtract have similar values, significant bits of the result may be defective, or "cancelled" [2], [18]. This is called cancellation error, and when that error is significant it is called "catastrophic cancellation" [7]. Jorgensen mathematically defines "similar values" [6].

Rounding error occurs because nearly all floating-point operations develop more bits than can be represented within the floating-point format, and the additional bits must be discarded [4]. The floating-point standard describes how these discarded bits can be used to "round" the resulting value but necessarily must introduce error into the resulting representation of the real value [2].

Standard floating point provides no means of indicating that a result has accumulated error [4]. Therefore, such errors are invisible unless they cause a catastrophe. Even then the cause can only be traced to floating-point failure with substantial effort, as stated by Kahan in the conference article entitled "Desperately needed remedies for the undebuggability of large floating-point computations in science and engineering" [19].

Misuse of floating point and the accumulation of floating-point error has been expensive in terms of election outcomes [20], financial disruption [21], [22], and even lives lost [23].

This computational weakness has been known since the early days of computing and continues until today. Even as early as 1948 Lubken had noted that: "…it is necessary at some intermediate stage to provide much greater precision because of large loss of relative accuracy during the process of computation" [10]. To this day, floating-point error is a known problem. [13], [24], [11].

3. Background – Bounded Floating Point (BFP)

The BFP system is an extension or annex to the standard floating point format, which may be implemented in hardware, software, or a combination of the two. BFP calculates and saves the range of error associated with a standard floating-point value, thus retaining and calculating the number of significant bits [25], [26]. BFP does not minimize the floating-point error but identifies the error inherent within standard floating point.

BFP extends the standard floating-point representation by adding an error information field identified as the "bound" field B. The bound field B contains subfields to retain error information provided by prior operations on the represented value, but the field of primary importance is the "Defective Bits" field D. This field identifies the number of bits in the represented value that are no longer of significance, consequently defining the number of bits in the result that are significant. The value of D is not an estimate but rather is calculated directly from standard floating-point internals such as normalization leading zeros and alignment of exponent differences. (See Appendix). BFP identifies and reports floating-point error and has no direct means of reducing that error. Because it is a direct calculation, the bound is neither optimistic nor pessimistic. However, the conversion between binary significant bits and decimal significant digits is not one-to-one and introduces a small error of less than 1 decimal ulp on conversion.

BFP retains the exception features of standard floating point, such as detection of infinity, operations with not a number (NaN), overflow, underflow, and division by zero. Though zero is a special case in the standard, the standard does not detect zero as long as any bits remain in the significand. However, BFP exactly identifies zero when the *significant* remaining bits in the significand are all zero, as shown in the test results below.

3.1. Bounded Floating-Point (BFP) Format

The bound field B, as seen in Figures 2 and 3, is a field added, to the format of standard floating point to describe the bounds of the error of the represented value. The bound field B contains and propagates information about the accuracy of the value that is being represented by creating and maintaining a range in which the infinitely accurate value represented must reside.

S	E	T	B
Figure 2: BFP Format

3.2. Bound Field Specifics

Figure 3 presents the subdivisions incorporated into the bound field format.
Figure 3: Format of Bound Field and Subfields

The bound field B is of width b. The bound field B consists of two fields, the defective bits field D of length d and the accumulated rounding error field N of length n. The value of the defective bits is the number of bits of the representation that are not significant, that have no value. The defective bits field D stores the logarithm of the upper bound of the error represented in units in the last place (ulps) and, in effect, determines the number of significant bits of the result.

The accumulated rounding error, stored in the N field, is the sum of the rounding error in fractions of an ulp.

The accumulated rounding error field N consists of two fields, the rounding error count field C, of width c, and the rounding bits field R, of width r. The fraction of an ulp represented in the accumulated rounding error is $R/2^r$ ulp.

The decimal equivalent of the BFP representation is shown in the expression of (2), which is equivalent to the expression (1) above.

$$(-1)^S \cdot ((T+2^t)/2^t) \cdot 2^{E-O} \tag{2}$$

The IEEE standard [4] defines "precision" as the capacity of the significand plus one (for the hidden bit). This capacity-type precision is defined as the maximum number "of significant digits that can be represented in a format, or the number of digits to that (sic) a result is rounded" [4]. In contrast, BFP identifies the actual number of bits that are significant (have meaning). These significant bits (SB) are a subset of the IEEE precision, p. The BFP's defective bits field D represents the number of bits of the representation that are *not* significant, where D = t + 1 − SB. In IEEE standard representation, the value of D is not known, nor is the number of significant bits.

BFP provides a means of specifying the number of significant bits required in a BFP calculation. Additionally, when there are fewer significant bits than specified or required, BFP represents this condition with the quiet not-a-number representation, "qNaN.sig," indicating excessive loss of significance.

3.3. Alignment

For addition and subtraction, when the exponents of the two operands are unequal, the significand of the smaller operand must be right shifted by the exponent difference. This is known as alignment [2], [17], [27], [28].

To perform alignment, the significand of the operand with the smallest value is right shifted by the exponent difference [26].

In standard floating point, the bits that cannot fit within the space of the standard floating-point format are used to determine the guard bit, the rounding bit, and the sticky bit.

In BFP, the bits that cannot fit within the space of the BFP format are used to calculate the accumulated rounding error field N.

The bits that cannot fit within the space of the BFP format due to alignment shift are retained in the R_{PN} field and X_{PN} field of the post normalization result configuration of Figure 4. As in standard floating-point format, if alignment shifts one or more bits out of the range of the arithmetic unit, the sticky bit is set to one.

3.4. Dominant Bound

The results of BFP binary functions (functions with two operands) retain only the number of significant bits as the aligned operand with the least number of significant bits. For BFP this means the result having the larger number of defective bits.

For binary functions the dominant bound is selected from the larger of the largest operand bound or the adjusted (aligned) bound of the smallest operand. For add (and subtract) operations, the binary point of the smaller operand must be aligned by the exponent difference [26]. The adjusted bound of the smallest

operand is derived by subtracting the exponent difference from the smallest operand bound defective bits and shifting the significand of the smallest operand to the right by the exponent difference. This shift will reduce the number of defective bits in the significand of the operand with the smaller value by the exponent difference, perhaps even to zero.

The resulting bound is obtained by accounting for the changes to the dominant bound by the effects of normalization and the accumulation of rounding error. (See Appendix for more details.)

3.5. Normalization and Cancellation

Floating-point results must be normalized to align the binary point to values between 1.0 and 2.0 [28]. The result of a floating-point operation may not meet this requirement and, therefore, may require that the result be "normalized" by shifting right or left to meet this requirement [27]. The exponent and the associated number of defective bits must be adjusted by the amount of this shift. Since the most significant bit is always one when the normalized value is between 1.0 and 2.0, it need not be stored. It is known as the "hidden bit."

Figure 4 illustrates the format of the post normalization result in which H_{PN} is the hidden bit field, T_{PN} is the resulting normalized significand (which is placed in the T field of the standard floating result of Figure 2), R_{PN} is the most significant bits of the excess bits and is the resulting rounding bits field (which is added to the accumulated rounding error field N, of Figure 3), and X_{PN} is the extended rounding error. X_{PN} serves as the source for the BFP "sticky bit," as used in standard floating point.
Figure 4: Post normalization result configuration

Normalizing by left shifting shifts information into the least significant bits, possibly adding to the unknown bits that already exist. In BFP this must be added to the defective bits unless the result is known to be "exact." Exactness is identified by BFP as having zero defective bits (e.g. referring to Figure 3, when the defective bits field D of the dominant bound is equal to zero.)

3.6. Zero Detection

The number of remaining significant bits is the difference between number of bits available in the representation (t+1) minus the number of defective bits D. The number of bits to be shifted to normalize is the number of leading zeros of the result. If all of the <u>significant</u> bits are zero, the resulting value must be zero.

BFP detects this condition and sets all fields of the BFP result to zero.

3.7. Accumulation of Rounding Error and Contribution to Defective Bits

Referring to Figures 2, 3, and 4, the accumulated rounding error N is computed by adding the resulting rounding bits R_{PN} of Figure 4, to the accumulated rounding error N of Figure 3, contributing a fraction of an ulp. If the extended rounding error X_{PN} of Figure 4, is not zero, an additional one is added to the accumulated rounding error N of Figure 3, functioning as a sticky bit. The carries out of the rounding bits field R of Figure 3, add to

the rounding error count C of Figure 3. The rounding error count is the accumulated rounding error in ulps.

The rounding error count C cannot, however, contribute directly to the value of the defective bits field D because of the difference of scaling, linear versus exponential. For example, when there are 2 defective bits, there must be at least 4 accumulated rounding errors to advance the defective bits to 3, and 8 to advance to 4, etc. In other words, when the logarithm of the rounding error count field C is equal to the defective bits field D, the value of the defective bits is increased by one.

3.8. Resulting Range

The BFP range relative to zero is defined by a lower bound (3) and an upper bound (4), as follows:

$$(-1)^S \cdot ((T+2^t)/2^t) \cdot 2^{E-O} \tag{3}$$

$$(-1)^S \cdot ((T+2^t+2^{D-1})/2^t) \cdot 2^{E-O} \tag{4}$$

The infinitely accurate real value represented by a BFP value is within this range. This is the same as in standard floating point except that the term 2^{D-1} provides the upper bound where the value of the defective bits field D is the number of bits that are no longer significant.

4. BFP Solutions to Standard Floating-Point Problems

Not only does BFP deliver all of the advantages of standard floating point, but it also delivers solutions to problems inherent in standard floating point.

4.1. Exact Equality Comparison and True Detection of Zero

Standard floating point requires additional code to be written to decide as to whether a comparison result is within error limits. BFP inherently provides this equality comparison.

Standard floating point cannot provide true zero detection as BFP does, which is demonstrated in the square root test of Section 8 below.

4.2. Number of Significant Bits

Standard floating point has no means to indicate the number of bits that are significant, but BFP identifies and indicates the number of significant bits. Further, BFP allows programmatic specification of the required number of significant bits. When the required number of significant bits are not available, BFP provides notification.

4.3. Mission Critical Computing

In some computing applications, such as mission-critical computing, computations need to be extremely accurate. But standard floating point cannot determine any accuracy loss. In contrast, BFP provides calculations – in real time – that can be depended upon to have the required number of significant bits.

4.4. Modeling and Simulation

Computational modeling and simulation, supported by constantly improving processor performance, often requires solving large, complex problems during which error may accumulate. This error, though not identified in standard floating point, is reported when the BFP extension is utilized.

4.5. Unstable Matrices

In numerical computation "stability" implies that small changes in the data translate into small changes in the result. Significant problems arise when small changes in the data, such as rounding error, create substantial error in the results. This occurs in matrix calculations, for instance, when solving simultaneous linear equations, when the roots may be similar or equal. BFP is used in this work to determine when a matrix is invertible, while assuring that the requirement for accuracy is met.

5. Standard Floating-Point Error Mitigation

5.1. Error Analysis Versus Direct Testing

Algorithmic error analysis can be used to identify error that occurs when using standard floating point. Though it is costly, it is commonly used for complex computing in critical systems, the failure of which may have severe consequences. In contrast, BFP directly, and in real time, tests calculation results, thus removing the need for costly error analysis.

5.2. Software Testing of Floating Point

Standard floating point problem in that it has no indication of accuracy errors is challenging to detect, diagnose, and repair.. BFP detects accuracy errors in real time, thus providing a response to the plea of "Desperately Needed Remedies for the Undebuggability of Large Floating-Point Computations in Science and Engineering" [19].

5.3. Stress Testing of Floating-Point Software

Stress testing may also be used to determine error that accumulates when using standard floating point. In general, stress testing is a form of intense testing used to establish failure points or useful operating limits of a given system. It involves testing beyond normal operational capability, often to a breaking point, in order to observe the performance limits.

Stress testing, as commonly applied to software, determines data value limits (boundary value testing) or performance (memory required, response time, latency, throughput, and time required to complete the calculation). Chan describes software stress testing as a method for accelerating software defect discovery and determining failure root cause and assisting problem diagnosis [29]. However, determining the accuracy of floating-point calculations or diagnosing accuracy failures in floating-point calculations, in intermediate results, or in final results is problematic using standard floating point [19]. In fact, floating-point errors are invisible in standard floating point, as there is nothing within the IEEE Standard that describes or limits floating-point error.

BFP provides a new and unique method of stress testing. Stress testing floating-point application software using BFP determines the accuracy at any point in a calculation, or even at the point of failure of a given computation, by executing computations with successively higher values of required significant bits and analyzing failure points. This reduces the cost of diagnosis and repair of floating-point calculation failures [19].

5.4. Other Mitigation Techniques

Other real-time techniques attempt to mitigate error, but only do so by increasing the overhead. Some of these techniques have the goal of computing results within error bounds, such as interval arithmetic [30] and real-time statistical analysis [31], [32]. But these require two floating point operations and require the storage of two floating point values and, thereby, increase the needed time and memory.

Parallel computation with higher precision standard floating point [33] can also be used to mitigate error. In addition to substantially increasing overhead, only the probability of error is reduced. There is no indication of that amount of error, whereas BFP identifies the remaining significant bits.

6. Software Model Solutions Using BFP

This work presents a software model of the BFP hardware system as described in detail in [25], [26]. When using standard floating point, there are certain problem areas that are prone to floating-point error. This work provides results from computations using BFP compared to computations using standard floating point in three of these well-known floating-point problem areas.

6.1. 80-Bit BFP

The BFP software model used in the following examples is configured by the field sizes of the BFP data structure, which is an 80-bit BFP configuration. The sign, exponent, and significand fields of the BFP format are identical to the corresponding fields in the standard 64-bit floating-point format. This permits conversion from 64-bit standard floating point to 80-bit BFP with a single instruction that stores the standard floating-point value directly into the corresponding fields of the BFP structure.

The BFP model contains the basic operations BFPAdd, BFPSub, BFPMult, BFPDiv, and BFPSqrt.

The following experiments were conducted on an ACER Aspire PC with an Intel Core i5 7th gen processor, using GNU Compiler Collection (GCC) version "(i686-posix-dwarf-rev0, Built by MinGW-W64 project) 8.1.0" [34].

6.2. Significant digits

In computers, binary floating-point calculations are performed with a collection of binary bits. But to be useful in the scientific and engineering world, outputs from, and inputs to, the human interface must be in decimal digits. In other words, the calculated results must be displayed in decimal digits, and decimal information must be supled to the processing unit. However, there is no direct mapping between binary floating-point values and the decimal representation of these values [35]. The fixed number of binary bits available in the double-precision (64-bit) floating-point format can represent a range of decimal values with as few as 15 or as many as 17 decimal digits [13].

External representations of BFP results, as shown below in Tables 1-14, are constrained to the actual number of significant decimal digits of the real number represented; i. e. only the digits having significance are displayed. This contrasts with standard floating point in which decimal digits of unknown significance are displayed, which results, at times, in the display of multiple incorrect digits (digits without significance). The display of these insiginifcant decimal digits obtained by the use of standard floating point is shown in the Tables 1-14 below.

6.3. Significant Bits

The number of significant bits is identified by the binary BFP representation of an infinitely accurate real value. The number of significant bits, SB, is calculated as the total bits available, p, minus the number of defective bits, D, as shown in (5)

$$SB = p - D \qquad (5)$$

where p = t + 1.

BFP provides a default value for the required number of significant bits. Alternatively, a special command can specify the required number of significant bits. Whether the BFP default value is applied or the commanded value is applied, the required number of significant bits may not be generated in a calculation. In this case, a special not-a-number code "qNaN.sig" is produced, which is visible when externally displayed.

6.4. Modeling Overview

The following demonstrations address three problems presented above, which are floating-point error diagnosis, true detection of zero, and unstable matrices. The first utilizes Kahan's thin triangle problem where the area of a thin triangle is diminished until a specified number of significant bits is not met. The second is an illustration of zero detection by BFP, which uses an expression that mathematically evaluates to zero; however, standard floating point does not generate zero. The third demonstration solves for a matrix determinate identifying that the matrix is unstable.

7. Modeling Stress Testing - The Heron and Kahan Thin Triangle Problems

7.1. The Thin Triangle

Knowing the length of three sides of a triangle (Figure 5) is sufficient to determine the area of the triangle without knowledge of the angles [36]. Work from early in the first millenium CE, attributed to Heron, produced an area formula that has become known as "Heron's Formula." In 2014, Kahan produced an improved area formula.
The thin triangle problem considered here is from "Miscalculating area and angles of a needle-like triangle." [37]. This work extends the 1976 work of Pat H. Sterbenz who suggested a method to make Heron's Formula more accurate [38]. In that work Sterbenz states:

*"However, we can produce a good solution for the problem if we assume that A, B, and C are given **exactly** as numbers in (floating point)." (Emphasis added)*

However, when using standard floating point, A, B, or C may not be **exact**. And standard floating point does not provide any indication that A or B or C is exact. But BFP establishes exactness, where a representation is exact if and only if the dominate bound

defective bits field D is zero; this indicates that there are no insignificant bits in the representation. Using the BFP extension of standard floating point, this work shows when A or B or C is not exact.

In the tests shown below, values were chosen to reflect a thin triangle in which one side of the triangle, side C, is one half the length of the base A and in which the other side of the triangle, side B, is equal to the length of side C plus delta (δ). By injecting 1 ulp error in any one of the values, the values are no longer exact. In the tests below, a 1 ulp error was injected into A. And the injection of this small error into only one of the values causes the equation to produce a result that does not meet the required significant digits for a specified δ and a required number of significant digits.

In the examples, the value for A was increased by 1 ulp of error by adding one to the significand. For the equivalent result, in BFP the defective bits D value was set to 1 indicating that there is 1 ulp of error.

In the tests below, the area of the triangle is influenced by the value for δ. When δ is zero, the area of the triangle is zero.

Tables 1-14 present stress test results for Heron's and Kahan's area algorithms for thin triangles, A=2.0 + 1 binary ulp, C=1.0 and B= C+ δ, with decreasing values of δ and increasing values of the required number of significant digits. Results are presented for 64-bit (double precision) and 128-bit (quad precision) standard floating point and 80-bit BFP. Each test is conducted until the particular algorithm fails to provide the required number of signicant digits, at which point BFP displays "qNaN.sig." Tables 6, 7, and 14 present results for when δ is sufficiently small that the areas are significantly zero as detected by BFP.

The second row of each table (excluding Tables 6, 7, and 14) shows the results for the required significant digits immediately prior to the failure point (one decimal ulp prior to not meeting the required number of significant digits as determined by the BFP calculations). The third row of each table lists the results *at* the failure point, where BFP shows that the required number of significant digits has not been met.

The BFP output conversion routine only displays those digits known to be correct to + or – 1 in the last digit presented.

7.2. Heron's Formula

Heron's formula is shown in (6):

$$Area = SQRT(S(S-A)(S-B)(S-C)) \qquad (6)$$

where S= (A + B + C)/2.

The Heron stress test determines, for a specific triangle, where (6) fails for a specific number of required significant digits. For each of the triangles in the test reported in Tables 1-7 (using a given value of δ for each triangle), the required number of significant digits is increased until BFP indicates by qNaN.sig that (6) cannot be solved for the specific triangle while achieving the specified number of required significant digits.

In Tables 1-7 standard floating-point results for Heron's area algorithms for each required number of significant digits, 14, 13, ...7 are benchmarked against BFP results. Heron's area formula (6) was solved for successively smaller values of δ until the BFP calculation indicated (by qNaN.sig) that the required number of significant digits was not met.

Table 3, for example, shows that for δ =0.0001, a 10-digit result is obtained successfully, but requiring 11 significant digits fails.

7.3. Kahan's Formula

In 2014, Professor William M. Kahan demonstrated that the Heron formula yielded inaccurate results when computed with a modern computer using floating point. Kahan contributed (7), which provides more accurate results for the area of thin triangles than (6) [37].

Area = SQRT(A+(B+C))(C-(A-B))(C+(A-B))(A+(B-C)))/4   (7)

where A ≥ B ≥ C

The stress tests of Tables 8-14 determine, for a specific triangle, where (7) fails for a specific number of required significant digits. For each of the triangles (using a given value of δ for each triangle), the required number of significant digits is increased until BFP indicates by a qNaN.sig that (7) cannot be solved for the specific triangle while achieving the specified number of required significant digits.

Tables 8-14 list the standard floating-point computations benchmarked against the BFP computations of (7) for thin triangles for the required significant digits, which present results similar to the Heron solutions of (6).

For example, Table 10 shows that for δ =0.0001, an 11-digit result is obtained successfully, but requiring 12 significant digits fails. This demonstrates that the Kahan algorithm (7) provides more significant digits than does the Heron algorithm (6) as shown in Table 3 (described above).

Double precision (64-bit) floating point can represent up to 15 significant decimal digits. BFP computations with inexact values shows that neither (6) or (7) is capable of producing a thin triangle area result accurate to 15 significant digits, as shown Tables 1-14.

7.4. Stress Tests Summary

In summary, Tables 1-14 show that BFP identifies the failure point at the largest number of significant digits for a given δ that does not meet the required number of significant digits. BFP identifies the smallest δ that retains the required number of significant bits. And BFP identifies when the area of a thin triangle is significantly zero when standard floating point does not.

Table 15: Zero Detection – Standard Floating point (SFP) vs. Bounded floating point (BFP)

Function	GCC 64-bit Floating Point	GCC 128-bit Floating Point	80-bit BFP
sqrt(pi*pi)-pi	2.27682456e-017	-1.2246467991e-16	0.0
sqrt(pi)*sqrt(pi)-pi	-1.96457434e-016	-1.2246467991e-16	0.0

8. Modeling Square Root Problem – Zero Detection

Zero detection is important because standard floating point does not always accurately identify when the result of a subtraction is a zero.

In standard floating point, even a one ulp error may cause a significantly erroneous result. Standard floating point does not reliably provide zero as a result when subtracting significantly equal values. For example, when subtracting two values representing infinitely accurate numbers, if a one ulp error has been introduced into one of the floating-point values, the floating-point subtraction result will not be zero. Detection of this condition requires external testing of the comparison result. In contrast, BFP provides zero detection by detecting whether the significant bits of a comparison result are equal to zero. Using the software model, we examine a simple expression that should evaluate exactly to zero. Standard floating point does not solve this simple calculation correctly but BFP does.

Table 15 demonstrates BFP's zero detection capability as compared to the results of calculating the same expression (that mathematically equates to zero) in standard double capacity precision (64-bit) and quad capacity precision (128-bit) floating point [13].

9. Modeling Unstable Matrices

BFP can be used to determine if a determinant is significantly zero. Thus, BFP can be used to identify an unstable matrix, as shown in Table 16.

Common matrix expressions require the application of the inverse of a matrix. The inverse of matrix **A** is denoted as **A**$^{-1}$. The inverse of a matrix may be calculated only if the determinant of that matrix (|A|) is not equal to zero. Thus, it is important to know if the determinant is zero. But standard floating point may not properly yield zero because of floating-point error. To address this problem, many supplementary methods have been developed to determine if a matrix is invertible. Because these supplementary methods are otherwise unnecessary for the computation of the equation, they add unnecessary overhead in terms of computation time and memory space. Moreover, requiring the addition of code to enable these methods makes the code more complex and more prone to error.

However, if the software is written in BFP, this calculation is made directly during the solving of the equation. In solving the linear equation, Ax=b, the inverse of the A matrix is multiplied by the b vector. This produces a new vector, which is the solution to the equation. When BFP calculates the determinant, it identifies – during the calculation – if the determinant is zero. Thus, BFP efficiently identifies whether the equation can be solved, without requiring additional code as the supplementary methods do.

Table 16: Comparison of Determinant Calculation of an Unstable Matrix

Matrix	Standard 64-bit Floating Point	Standard 128-bit Floating Point	80-bit BFP
cavity01	4.9359402474e-045	4.9359402474e-45	0.0

Table 16 presents the comparison of the calculations of the determinant of an unstable matrix using 64-bit standard floating point, 128-bit standard floating point, and 80-bit BFP. The determinant is calculated using the upper triangle method, Gaussian Elimination [39].

The matrix selected, cavity01, is from the Matrix Market [40]. It was located searching the Matrix Market with the term "unstable."[1] The matrix selected is a sparce 317x317 matrix with 7,327 entries.

Table 16 shows that both 64-bit and 128-bit standard floating point provide a non-zero value for the determinant, where BFP does return zero, because at some point in the calculation the significant bits were all zero. Thus, using BFP identifies the problem efficiently *during* the calculation. Using standard floating point requires the incorporation of one of the supplementary methods into the code to prevent division by zero. Consequently, BFP directly determines if a matrix is not invertible.

Moreover, when the matrix is properly invertible, using BFP provides the accuracy of the result. The use of BFP identifies how many significant digits are in the result. In an example, a requirement is that the accuracy must be more than three significant digits. Even if the matrix is valid, there may be less than three significant digits remaining in the results, which BFP identifies.

Consequently, when BFP is used during matrix calculations, it not only determines if the matrix is invertible, but it also assures that the requirement for accuracy is met.

10. Summary

BFP adds a field to the standard floating point format in which error may be accumulated. The upper bound of that error is stored as the logarithm of that bound.

BFP makes floating-point error quantifiable and visible. It allows exact equality comparison. It provides notification when insufficient significant digits have been retained during floating-point computations. When implemented in hardware it affords real-time fail-safe calculations for mission critical applications.

Though designed for hardware implementation, a software model emulating the BFP functions was used in this paper. The BFP software model has been applied to three problems as follows: the failure of standard floating point to exactly detect zero in the presence of floating-point error, the failure of standard floating point to identify the number of significant digits (if any) of a result, and the lack of the ability to diagnose standard floating point accuracy errors.

This paper shows that BFP solves these problems by calculating and propagating the number of significant bits as described by the BFP algorithms presented. Three examples have been used, which are a precision stress test, true floating point zero detection, and detection of an unstable matrix.

The precision stress test of an algorithm increases the required precision for that algorithm under specific parameters until that required precision cannot be met. The algorithm parameters may be adjusted as well to determine the operational envelope for that algorithm for a given required precision.

Standard floating point does not return precisely zero when significantly similar, yet different numbers are subtracted. An example is provided where an expression clearly evaluates to zero, yet standard floating point does not return zero but BFP does return zero. Using this property of BFP, we evaluate the determinant of a matrix known to be unstable and note that BFP evaluates the determinant as zero.

Properly implemented in hardware, BFP will reduce the time and cost of the development of scientific and engineer calculation software and will provide run-time detection of floating-point error. This hardware implementation has begun using Verilog HDL.

11. Appendix – Post Revision Result Format

11.1. Bound Description

Definitions are from, or amended from, [26].

An 80-bit model was chosen to allow for using 64-bit standard floating point and a 16-bit bound field B. Table 17 specifies subfield widths for a 80-bit BFP model.

Table 17: 80-Bit Model Field Widths

Subfield Widths
#define r 4
#define d 6
#define c d
#define n (c+r)
#define b (d+n)

11.2. Notation Used

Each algorithm is preceded by a list of definitions of the variables (for example, *Op1Exp*) used in the algorithm. Each definition (for example, first operand exponent) is followed by an alphanumeric identifier (for example, 51A). That identifier refers to the patent reference number of [26]. Further, a letter (E, B, D, N, R, or C) may follow the identifier definition (for example, first operand exponent E). This refers to a specific portion of the data format identified in Figures 1 and 3.

11.3. Dominant Bound

The dominant bound (*DominantBound*) is the larger of the largest operand bound (*HiOpBound*) and the adjusted bound of the smallest operand (*AdjBoundLoOp*). This is the bound of the operand with the least number of significant bits.

The dominant bound (*DominantBound*) is determined from the first operand bound (*Op1Bound*), the second operand bound (*Op2Bound*), the exponent difference (*ExpDelt*), and the condition

---

1 This particular matrix is available in compressed form from
ftp://math.nist.gov/pub/MatrixMarket2/SPARSKIT/drivcav_old/cavity01.mtx.gz, accessed 4 August 2020.

(*Op2Larger*) in which the magnitude of the second operand (*Op2*) is greater than the magnitude of the first operand (*Op2*).

11.4.   Finding the Exponent Difference

The exponent difference (*ExpDelt*) is the magnitude of the difference between the first operand exponent (*Op1Exp*) and the second operand exponent (*Op2Exp*).

The exponent difference (*ExpDelt*) is determined from the first operand (*Op1Exp*) and the second operand (*Op2Exp*), as in Algorithm 1.

Algorithm 1: Finding Exponent Difference

Result: Exponent Difference
Op1 := first operand, 201;
Op2 := second operand, 202;
Op1Exp := first operand exponent E, 51A;
Op2Exp := second operand exponent E, 51B;
ExpDelt := exponent difference, 321;
Op2Larger := second operand > first operand, 302;
SmallerExp := smallest exponent E, 51E;
LargerExp := largest exponent E, 51D;

begin
    Op2Larger := |*Op2*| > |*Op1*|
    if *Op2Larger* **then**
        LargerExp := *Op2Exp*;
        SmallerExp := *Op1Exp*;
    else
        LargerExp := *Op1Exp*;
        SmallerExp := *Op2Exp*;
    end
    ExpDelt := *LargerExp* – *SmallerExp*
end

11.5.   Finding the Dominant Bound

As shown in Algorithm 2, the dominant bound (*DomBound*) is derived from the first operand bound B (*Op1Bound*), the second operand bound B (*Op2Bound*), the exponent difference (*ExpDelt*), and the second operand larger (*Op2Larger*).

Algorithm 2: Finding the Dominant Bound

Result: Dominant Bound
Op1Bound := the first operand bound B, 52A;
Op2Bound := the second operand bound B, 52B;
LoOpBound := smallest operand bound B, 52D;
HiOpBound := largest operand bound B, 52E;
LoOpBoundeBadBits := smallest operand bound
              defective bits D, 54A;
AdjLoOpBoundBadBits := adjusted smallest operand bound
              defective bits D, 54B;
ClampedBadBits := clamped defective bits D, 54G;
LoOpBoundAccRE := smallest operand bound accumulated
              rounding error N, 55A;
AdjBoundLoOp := adjusted bound B of the smallest
              operand, 52F;
HiOpBoundLargest := largest operand bound B is
              greatest, 431;

DominantBound := dominant bound, the bound of the
              operand with the least number of
              significant bits after alignment, 52H;

begin
    Op2Larger := |*Op2*| > |*Op1*|
    if *Op2Larger* **then**
        LoOpBound := *Op1Bound*;
        HiOpBound := *Op2Bound*;
    else
        LoOpBound := *Op2Bound*;
        HiOpBound := *Op1Bound*
    end
    AdjLoOpBoundBadBits
        := *LoOpBoundeBadBits* – *ExpDelt*
    if *AdjLoOpBoundBadBits* < 0 **then**
        AdjLoOpBoundBadBits := 0;
    end
    AdjLoOpBoundBadBitsE
        := *ClampedBadBits* |&| *LoOpBoundAccRE;*
    HiOpBoundLargest := *HiOpBound*
        > *AdjBoundLoOp*;
    if *HiOpBoundLargest* **then**
        DominantBound := *HiOpBound*;
    else
        DominantBound := *AdjBoundLoOp*;
    end
end

Where '|&|' is the field concatenation operator.

11.6.   Result Bound Calculation

The resulting bound of a calculation is determined by one of two mutually exclusive calculations, the bound calculation algorithm of Algorithm 3 or the bound rounding algorithm of Algorithm 4. When there is a subtract operation and the operands are sufficiently similar, the intermediate result has leading zeros (is not normalized). Under this condition the bound calculation algorithm determines the bound of the result. Otherwise, the bound rounding algorithm determines the result.

In any case, exact operands produce an exact result [6].

Operations other than add or subtract return the dominant bound.

11.7.   Bound Cancellation Algorithm

The result bound B (*ResultBound*) is determined from either the cancellation adjusted bound B (*AdjCaryBound*) or the carry adjusted bound B (*AdjCaryBound*). The result bound B requires the dominant bound (*DominantBound*), the significand capacity (*SigCap*), and the number of leading zeros (*LeadZeros*).

Algorithm 3 accounts for compensating errors.

Algorithm 3: Bound Cancellation

Result: Result Bound from Cancellation
Cancellation := cancellation detected, 620;
DomBadBits := dominant bound defective bits D, 54C;
LeadZeros := number of leading zeros prior to

---

normalization, 711;
SigCap := significant capacity, the number of bits in the
    significand (t+1), includes hidden bit H, 805;
AdjBadBits := adjusted defective bits D, 54D;
MaxedBadBits := max defective bits detected, 617;
ResultBadBits := resulting defective bits D, 54H;
DomAccRE := dominant bound accumulated rounding
    error N, 55B;
CancAdjBound := cancellation adjusted bound B, 52J;
ResultBound := result bound B, 52C;

if *Cancellation* **then**
    AdjBadBits := *DomBadBits* + *LeadZeros*;
    MaxedBadBits := *SigCap* <= *AdjBadBits*;
    if *MaxedBadBits* **then**
      ResultBadBits := *SigCap*;
    else
      ResultBadBits := *AdjBadBits*;
    end
    CancAdjBound := *ResultBadBits* |&| *DomAccRE*
    ResultBound := *CancAdjBound*
end

11.8. Bound Rounding Algorithm

The adjusted value of R is added to the dominate bound to provide the adjusted bound. When the logarithm of C is equal to D, 1 is added to D and C is set to zero in the resulting bound.

There is an externally applied limit, Required Significant Bits, which is defaulted and programmable. On external representation, when the available significant bits value (t+1-D) is less than or equal to the Required Significant Bits, "sNaN.sig" is displayed. A special command is provided that tests for this condition of an individual BFP value to produce a signaling exception sNaN.sig, which can be detected and serviced like any other hardware exception such as sqrt(-1) or x/0.

When there are significant bits and they are all zero, the value represented is truly zero and the resulting value is set to all zeros. (Zero has no significant bits/digits). This is true zero detection unavailable with standard floating point nor Interval Arithmetic (IA).

Algorithm 4: Bound Rounding

Result: Result Bound from Rounding
NormalizedRE := normalized rounding error R, 57A;
StickyBit := significand excess, logical OR of all bits of the
    normalized extension X, 741;

A R T I C L E I N F O	A B S T R A C T
	NFC (Near Field Communication) is a contactless communication technology based on a radio frequency (RF) field using a base frequency of 13.56 MHz. NFC technology is perfectly designed to exchange data between two devices via simple touch gestures. RFID is the process of identifying an object directly by radio frequency. There are two important components of an RFID system is the card or label (tag) and the reader. In each of tags have unique ID. In addition to the ID, the tag also contained a block that is used for security. On the application in the library, all the books that will be read by the reader have an RFID tag in it. With the tag on each book that is used for lending service, it can be made an application on a smartphone that supports NFC (Near Field Communication) which can be used by each user to borrow books independently, that does not need to come to the library staff to borrow books.

1. Introduction

With the development of ICT (Information and Communication Technology) by leaps and bounds, ICT can be applied to almost all existing activities, including at the university. One is the use of RFID on all student, lecturer and staff cards. So with RFID card, students and faculty can record the lecture attendance, borrow books, pay to eat, with just to put the RFID card on a card reader.

The library is one of the institutions that uses ICT to optimize its management which we know as library automation. Library automation is the use of automatic and semi-automatic data processing machines to maximize daily activities in the library, such as procurement, processing and circulation or services.

In library circulation service activities, library automation using RFID is widely used to borrow books from the library. Because in addition to student/lecturer cards, one of the applications of ICT is the use of RFID in all books in the college library. That way, the data of all books in the library can be connected and managed with ICT so that it can be used for circulation service activities in the library.

By using RFID in books in the library, librarians only need to put the books to be borrowed on the RFID reader (book reader), the RFID reader will read the tag ID books, check on the library database, then display the book data on the computer screen. If the library user agrees to borrow the book, the system will change the status of the book in the library database as a borrowed book on behalf of the student/lecturer ID. Then the RFID reader will disable the security block on the RFID tag in the book. So if the book was taken out of the library it wouldn't sound a security alarm. The borrowing process as above has been automated. So students or lecturer who will borrow the book, just put the card on a card reader and a book on book reader at a machine named "auto-borrow". The machine will then display the borrower data, including name, and the quota of books that can be borrowed, and also displays the books data. Then the borrower simply press the submit button, and the book status change to "borrowed". This auto-borrow machine is a normal PC connected to a card reader device. In the XYZ library there are 3 units of auto-borrow machines.

The process of borrowing books with an auto-borrow machine helps librarians, so that students, lecturers and staffs can perform self-service in the borrow books. However, the increase in the number of students and lecturers per day, as well as the increase in the number of books borrowed in a day, sometimes created queues on circulation officer and the book "auto-borrow" system.

Therefore, another system that has a similar function to the book auto-borrow system is needed but easy to implement. So, this will help students and lecturers who will borrow book.

*Corresponding Author: Rony Baskoro Lukito, rblukito@gmail.com

Figure 1: RFID System Phases in Libraries [1]

2. Objectives and Benefits

XYZ Library has an average of more than 1000 library visitors every year. Library users usually study in the library, read books, looking for journals or periodical, borrow/return books, and so on.

With the current number of smart phones that have been supported by NFC technology, smart phones can be made an application that can be used as an "auto-borrow" device. So students and lecturers who have smart phones with NFC and install the application on their smartphones, can borrow library collections books through their smartphones by attaching the NFC smartphone to the book tag ID, so the book data can be displayed on the smartphone screen.

The objectives of this research are facilitating librarian to collect data for book collection utilities, facilitate user to borrow library collection independently, reducing queues both in circulation staff and auto borrowing machines when borrowing traffic is high in certain times such as before library closes, and as back up systems when auto borrow machine is interrupted or less circulation staff available.

The benefit of this research is identifying and design systems that can optimize the use of RFID with NFC on smartphones in libraries, increase the efficiency and effectiveness of the collection borrowing process in the library, reducing dependence on a collection borrowing process, increasing the efficiency of the library collection procurement budget, and for evaluating library collections utilizations.

Limitation of this research is about systems to optimized use of RFID for auto borrowing library book collection by utilizing NFC Technology on Smartphone at XYZ Library.

Thus, library users who have smartphones with NFC and want to borrow book have another options besides queue at circulation desks or "auto-borrow" machines.

3. Literature Review

Libraries are institutions that manage collections of written works, printed works, and/or recorded works in a professional

manner with a standard system to meet the needs of education, research, preservation, information, and recreation of visitors. The law states that the purpose of the library is to provide services to users [2]. Furthermore, these services are described in Article 14, including: library services are carried out in a prime and oriented towards the interests of visitors, and each library needs to develop library services in accordance with advances in information and communication technology. One type of service in the library is circulation services. Circulation services are user services related to borrowing, returning, and extending collections [3].

3.1. Library automation

Library automation is a general term for Information and Communication Technology (ICT) which is used to replace the existing manual systems in libraries. Library automation refers to the use of computers and other peripheral media, such as magnetic media, hard disks, optical media, and so on, as well as the use of computers in accordance with library products and services in displaying all library functions and activities [4].

Below are the advantages of library automation [5]:

- Libraries get ICT infrastructure to support automation
- Optimizing time in doing work
- Avoid duplication of data
- Speed up access to information
- Technology used in library automation provides new learning for librarians.

3.2. RFID

RFID or Radio Frequency Identification is a generic term used to describe a system that transmits the identity (in the form of a unique serial number) of an object or person wirelessly, using radio waves [6]. RFID is usually used for identification and tracking [5].

Auto-ID technologies include bar codes, biometrics, smart cards, voice recognition, and RFID [7]. Auto-ID technology has been used to reduce the amount of time and labor required to manually enter the data, and to improve the accuracy of the data.

There are several components required to use an RFID system:

3.2.1. RFID Tag / RFID Transponder

Tag is a small radio device which is also known as a transponder, smart tags, smart labels, or radio barcode. The tag consists of a simple silicon microchip (usually less than half a millimeter in size) attached aerial and mounted on a substrate [8]. In addition, each tag has a unique ID

The RFID tag contain of at least 2 parts. One is an integrated circuit (chip) for storing and processing information, modulating and demodulating radio frequency (RF) signal, and other specialized functions. The other part is an antenna for receiving and transmitting signals.

This antenna that allows this tag is read by the contactless reader. The larger the antenna can be greater the distance the reader and tag. While chip is for storing the ID number and other information. This chip can be read-only (cannot write other information on this tag), read-write (tags can be read write many times) or write-once read-many (tags can only be written once, but can be repeatedly) [9].

RFID tags have various forms according to needs. For example, the tag for a book is a square form size 5x5cm. For

CD/VCD can use round tags that can be embedded in the middle of the CD/VCD. To tack on VHS tapes, RFID tags can be rectangular. In addition, there are also special tags such as tags for tracking fruits, tags that can be implanted under the skin and others.

3.2.2. ISO / IEC 15693 and ISO / IEC 14443g

So that RFID tags can be read by a tag reader from various vendors, RFID tags must have a standard that is used by the RFID reader to be able to communicate using the tag. There are 3 different standards for classifying RFID contactless smart cards [10].

Table 1: Standard contactless smart card

Standard	Card type	Approximate range
ISO/EIC 10536	Close-coupling	0-1cm
ISO/EIC 14443	Proximity-coupling	0-10cm
ISO/EIC 15693	Vicinity-coupling	0-1cm

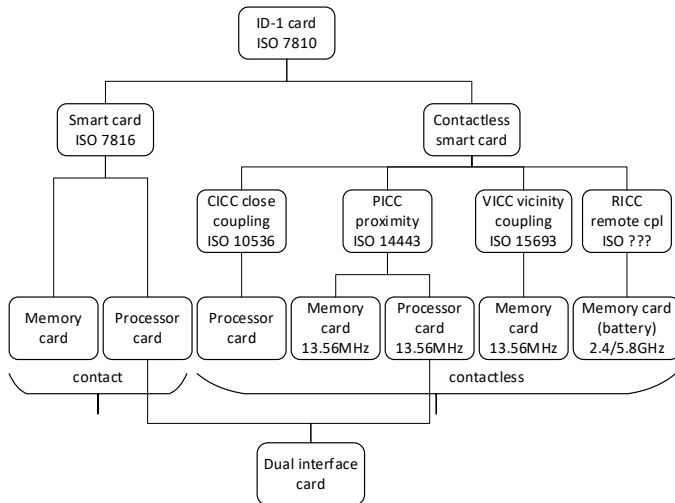
The RFID standard used by library books is ISO 15693, and RFID standard for student and lecturer ID cards uses ISO 14443. Here is a diagram of a standard smart cards, including the contact and contactless [11]


Figure 2: Family of contact and contactless smart card

3.2.3. Electronic Article Surveillance (EAS)

In a transponder/tag the ID contains a few bytes of data capacity up to several kilo bytes. But, there's 1 bit in special transponders used for security. One bit of data can provide status on the tag reader: 'transponder in the field' or 'transponders not in the field'.

One transponder bit is used in Electronic Article Surveillance (EAS) to check the status of goods. If the user brings goods / books through the EAS gate with the status 'transponders in the field', it will activate an alarm at the EAS gate [11]. Vice versa, if the tag status is 'transponders not in the field', the RFID tag will not activate the alarm.

3.2.4. Tag Reader

In addition to tags are also need a tool that serves to read the tags. This tool is called a tag reader. Readers are transceivers (a

combination of transmitters and receivers) whose role is to give commands to tags and receive data stored in tags [12]. Because this reader can read the unique ID contained in each tag.

Like tags, readers also have an antenna. Through this antenna, the reader can communicate with the tag. When the reader transmits radio waves, all tags within the transmission area and has the same frequency as the reader, will respond.

Communication between tag readers is done through 3 processes. First, the tag reader is activated by the tag reader radio frequency with 13.56MHz. Once active, the tag will wait for commands from the tag reader. Then, the reader will give commands to the tag and wait for the response from the tag. If the tag receives the valid command, then the tag will respond from the reader command earlier and sent back to the reader. All data transmissions are done through frequency 13.56 MHz [13].

Thus, communication between the reader and tag does not require physical contact (contactless), it can even pass, such as paper, wood, and so on [8].

3.2.5. Near-Field Communication (NFC)

At first, the NFC is not an RFID system, but the interface between the wireless data device, like the infrared or Bluetooth. However, NFC has some interesting characteristics in relation to RFID systems [14].

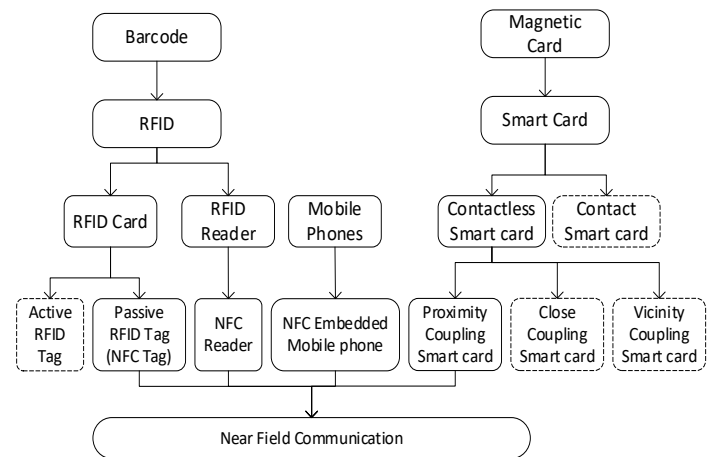
Data communication between 2 NFC interfaces using 13.56 MHz frequency. Because the same frequency used by the frequency of ISO 15693 and ISO 14443, the devices that support NFC can be used to read the tag ID. NFC is designed to be a secure form of data exchange. NFC device can be an NFC reader or NFC tag. This unique character allows communication between NFC devices [15]. Many smartphones sold in the market today have NFC interfaces. So with a particular application, the smartphone can read the tag ID ISO 15693.


Figure 3: NFC Technology Evolution [16]

NFC has 3 communication models [15]:

a. Peer-to-peer

NFC can be used to exchange data between devices, with data exchange rates of up to 424Kbps. It works on the NFCIP-1 protocol, whose details and electromagnetic properties are standardized to ISO 18092 and ECMA 320/440.

b. Reader-writer

NFC can be used to read / write (reader / writer) on tags and smart cards (smart cards). In this communication model, active NFC devices can act as initiators and passive tags act as targets. This mode allows data exchange rates of up to 106 Kbps.

c. Card emulation

In this mode the HFC-handset behaves as a standard smart card. In this mode, the NFC device emulates an ISO 14443 smart card chip. This smart chip is integrated into the mobile device and connected to the NFC module to allow communication to take place [15].

There are several benefits of NFC nowadays. Apart of facilitating cashless and easy payment, NFC can be used for access control, consumer electronic product, health world, facilities for collection and exchange information, coupon and loyalty, and transportation [17]

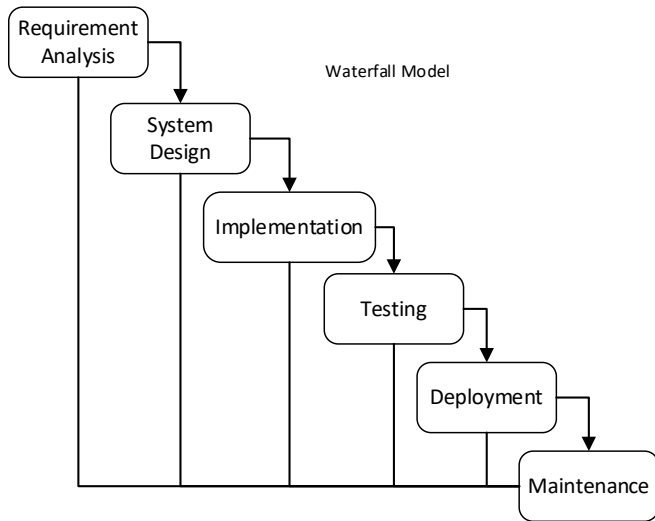
Figure 4: Utilizing NFC in several devices.


Figure 5: Waterfall Model

4. Research Methods

SDLC is the stages of work carried out by system analysts and programmers in building information systems and methods for developing these systems. The system built using SDLC will make it easier to identify problems and design the system as needed in solving these problems. One of the most frequently used SDLC in system development is SDLC Waterfall.

The SDLC Waterfall model is a software development method where the work must be carried out sequentially, each development progress is considered to flow downward, like a waterfall, through several stages that must be carried out. So that software development can be done successfully. In this waterfall model, all phases or stages must be carried out sequentially and until finished, before moving on to the next stage. So, in the waterfall model, each phase can be repeated several times until the phase is completely finished [18]. Researchers are expected to focus on one phase until completion and not work on other phases in parallel [19].

5. Results and Discussion

5.1. Library Database

With the implementation of the RFID system in the library, all the books must be affixed with RFID labels. Tag ID on the label associated with the data in the library books database. Here's an example in the table below:

Table 2: Example of book database

Book_tag_ID	Book_id	Book title
fef2d68f	20200200449	Accounting 1
fef37414	19991000919	Computer Network
fef57f30	20090100182	Database Systems
…	…	…

Therefore, if the book is placed/attached to the book reader (RFID reader) on the auto-borrow machine, on an NFC device, as well as in librarian computer, the system will search for the ID tag in the database and will display on screen the data the book data.

Like the book database, the users (lecturers/students/employees) XYZ University database is also connected with their ID card.

Table 3: Example Univ. XYZ Identity cards database

Card_tag_id	User_id	Name
b0ffc9da	0210335632	Anthony
1b9d52ac	0331970112	Brown
6385f8f4	0123502865	Charley
…	…	…

After borrowing the book, the user_id, book_id, and date of borrowing will be entered into a book borrowing transaction table. After the book is returned, the table will be updated with the book return date, as in the example below:

Table 4: Example Univ. XYZ Book transaction database

Book_id	User_id	Borrow_date	Return_date
fef2d68f	0210335632	05/20/2020 14:14	05/30/2020 10:10
fef37414	0331970112	07/07/2020 12:13	07/14/2020 09:09
fef57f30	0123502865	11/11/2020 11:11	NULL
…	…	…	…

5.2. Borrowing Process

For borrowing process using NFC smartphone is similar to borrowing using auto-borrow machine. At the auto-borrow machine, when the user who would like to borrow a book should put a membership card in the card reader and the book to be borrowed in the book reader. To borrow a book with the NFC smartphones, the user must first install the application which will be used for borrowing books. Then users should do the following steps:

- Login to the application using their university email and password.

- Once logged in, then the user can look their borrowing history, check borrowing status, check obligation or can scan a book with RFID tags that will be borrowed by the NFC smartphones.

- The application will look for the data to the library book database server (Table 2) about that book data and display it on the smartphone screen.

- User should click *Borrow* button if they are sure going to borrow a book.

- The application will update the book transaction database (Table 4) about borrowing the book.

- In addition, the application will tell the NFC device (smartphone) to disable security on the RFID tag a book, so that the book did not make the alarm sounds when taken out of the library area.

6. Use Case

Application use case in NFC smartphones can be described by using use case diagrams as in the picture below :
Figure 6: Use case business process NFC auto-borrow system

After the user (student/lecturer/employee) install an auto-borrow NFC application on a smartphone (which supports NFC), respectively, then the user have to login.

After logging in, users can attach their smartphone to the book to be borrowed. When the book ID tag is detected by the NFC smartphone, the application will search for the book data on the database server according to the ID tag that was read. Book data such as title, author, book code, edition, publisher, year published, and ISBN will display on the smartphone screen. If users want to borrow book, they only need to press the "submit" button. The application will update the book status in the database and disable the EAS (security) status on the book tag.

In addition to lending library books, this application can also be used to view the status of the user. Check history is used to see a list of books that have been borrowed by the user. Check Borrowing Status, useful for checking the current status of borrowed books, including title, author, and book returns due. Check Obligation is useful for viewing user obligations, such as the amount of fines to be paid for late returning the book.

7. Conclusion

From the results of research on the use of NFC on smartphones applied to automatic borrowing (auto-borrow) books in library, it can be concluded as follows:

a. Students, lecturers, and employees who have smartphones with NFC can use it to borrow books by them self, no need to queue for the library circulation staff or on auto-borrow computers to borrow books from the library.
b. With the NFC's smartphone capability to deactivate the EAS tag ID (security), it will trigger the programmer to create an application that can be used to disable EAS, and it is certainly influential in terms of the number of lost library books. Because if the EAS is not active, the book will easily be taken out of the library without turning on the alarm system.

8. Recommendations for further research

Application of systems that optimized use of RFID in XYZ library in doing auto borrowing book with utilization of NFC on Smart phone could be used not only for book collection on library but also on other kind of collection that using RFID as security systems. In XYZ library other collection that use RFID are periodical, final works and multimedia collection. Therefor further research, we will measure further optimization for this system for different rules of borrowing library material other than book. Also, its implication on collecting utilization data library collection that only can be read on the spot for library user.

A B S T R A C T

The textile industry is one of the prioritized industries, because it contributes to the country's foreign exchange, absorbs a large number of workers, and fulfills the need for national clothing. To increase work efficiency and productivity, the textile industry must use ERP. However, ERP implementation still has a relatively high failure rate. ERP readiness assessment is one of the main issues to achieve success in implementing ERP. Previous research is still limited to research about readiness for achieving success in ERP implementation. The research results have indicated that the maturity of the organization is a very significant dimension with a weight of 43.51%. By knowing the maturity level of the organization for ERP implementation can identify factors that become weaknesses for organizations to take corrective steps, so as to reduce the failure rate of ERP implementation in the industry. This research methodology uses a quantitative approach using R software to determine the principal component analysis and uses the Order Preference Technique with the Ideal Solution to weighted the identified factors. This research aims to determine organization readiness by developing the maturity level of ERP implementation in the industry in Indonesia which conducted a case study experiment in the textile industry in Indonesia. The result of this research is the development of an ERP readiness assessment to assess the maturity level of the organizations in ERP implementation.

1. Introduction

The textile industry is one of the industries that is prioritized for development because it has a strategic role in the national economy, namely as a contributor to foreign exchange, absorbing large numbers of workers, and to meet national clothing needs. To increase work efficiency and productivity, the textile industry must use ERP. ERP can improve the performance of an organization, but until now the ERP implementation for the industry still has complexity with a high failure rate, so this causes implementation costs to be expensive. Referring to previous research, the ERP readiness assessment can assess the readiness of an organization in implementing ERP. ERP readiness assessment can be reviewed from the perspective of top management, project management, people, change management, technical requirements [1]. By identifying the weaknesses factors

of the organization, management can develop ERP readiness assessment and make an evaluation to increase the organizational maturity level according to best practice [2-5]. The contribution of this research is the development of an ERP readiness measurement tool to increase the effectiveness of ERP implementation strategies for the industry, so that management can know the level of company readiness before making decisions for ERP implementation. Based on previous reseach, ERP implementations have a failure rate of 60% to 90%. The problem solution is to identify critical success factors in ERP implementation with a focus on organization, technology adaptation, and business processes [6, 7]. Also, by assessing the readiness of the organization, it can be evaluated the weaknesses and strengths of the organization to adapt to change, so that the company can achieve organizational agility and ERP implementation success [8-10]. Previous research shows that there is still little research that discusses the maturity assessment

of an organization before top management decides to implement ERP. The development of ERP readiness assessment is one of the main issues related to achieving success in implementing ERP. This research can help the top management of an organization or consultant party to assess the maturity level before deciding to implement ERP with a discussion of four perspectives such as processes, people, organizational, and technology which based on the development of the Leavitt Diamond Model [11]. The four components of Leavitt Diamond Model are people, tasks or processes, technology, and structure or organization prominent success factors for improving industry performance. This matter is considered for organizations to assess the readiness level of an organization in implementing ERP, so that top management of the organization can find out the factors that are the weaknesses and strengths of the organization, to be able to make improvements, so that the relatively expensive investment value can achieve successful ERP implementation for an industry. This research explain identify the factors of ERP readiness assessment and the characteristics of the maturity level of the organization in ERP implementation. This is the novelty of this research which is the development of previous research to help the top management of the industry to find out the readiness of a company to adapt to a change in order to achieve the best practices and agile organizations..

2. Experimental procedure

The experimental procedure of this research uses a study case in the textile industry in Indonesia by using a quantitative approach technique with R software to determine the Principal Component Analysis (PCA) [12]. The objective of PCA is to reduce the data dimension by eliminating the correlation of variables by transforming the original variable into a new uncorrelated variable so that the data can be interpreted. PCA is a non-parametric method that uses linear algebra to extract relevant information or patterns from a dataset with multivariate attributes. This research also use of Technique for Order Preference Technique with the Ideal Solution (TOPSIS) method to identify the weight factors. The TOPSIS method approach can be used as an ERP assessment tool to determine the weighting and ranking of factors for the main weight, the weight of sub-factors, and the final weight. TOPSIS is a decision-making method for ranking and prioritizing Multi Criteria Decision Making (MCDM). The stages of weighting the TOPSIS method are as follows [13]:

1. Building a normalized weighted matrix using the following formula:

$$Y_{ij} = \frac{X_{ij}}{\sqrt{\sum_{i=1}^{m} X^2_{ij}}}$$

2. Building a weighted normalized matrix by multiplying the normalized matrix with the weighting value of entropy weighting, with the normalization formula for the weighting matrix v as follows:

$$V = \begin{bmatrix} V_{11} V_{12} \dots .. V_{1n} \\ V_{21} V_{22} \dots .. V_{2n} \\ V_{m1} V_{m2} \dots .. V_{mn} \end{bmatrix} = \begin{bmatrix} W_{1r11} W_{2r12} \dots W_{nr1n} \\ W_{1r21} W_{2r22} \dots W_{nr1n} \\ W_{1rm1} W_{2rm2} \dots W_{nrmn} \end{bmatrix}$$

3. Determine the matrix for positive and negative ideal solutions. The positive ideal solution is denoted by A +, while the negative ideal solution is denoted by A-. With the following formula:

$$A^* = \left\{ \left[\max_i V_{ij} \,|j \in J \right], \left[\min_i V_{ij} \,|j \in J^1 \right] \right\} 1 = 1, 2, \dots . m \}$$

$$= \{V_1^* V_2^*, \dots \dots V_j^* \dots .. V_n^* \}$$

$$A^- = \left\{ \left[\min_i V_{ij} \,|j \in J \right], \left[\max_i V_{ij} \,|j \in J^1 \right] \right\} i = 1, 2, \dots m \}$$

$$= \{V_1^-, V_2^-, \dots \dots V_j^* \dots .. V_n^* \}$$

4. Calculate the distance between the value of each alternative solution with a positive ideal solution matrix and a negative ideal solution matrix. By using the following formula:

$$S_i^* = \sqrt{\sum_{j=1}^{n} (V_{ij} - V_i^*)^2}, \qquad i = 1, 2, \dots m$$

$$S_i^- = \sqrt{\sum_{j=1}^{n} (V_{ij} - V_i^-)^2}, \qquad i = 1, 2, \dots m$$

5. Calculating the preference value to an alternative ideal solution, with the following formula:

$$C_i^* = \frac{S_i^-}{S_i^* + S_i^-}$$

6. Ranking the value of Ci +. The best solution is to have the shortest distance to the ideal solution and the farthest distance to the ideal negative solution.

In processing the data of this study, the authors collected data from respondents using a questionnaire method. Then based on the results of the questionnaire, the authors validated the data using PCA. The results of data processing from PCA are to develop indicators as a basic concept in developing the ERP readiness assessment model. Based on the literature survey, the authors classify be indicators associated with these four dimensions. Based on the literature survey, the authors mapped the main variable (processes, people, organizational, and technology) with sub-variables and indicators related to the readiness of ERP implementation [14-18]. From the results of the literature survey, it was found that 24 sub-variables and 61 indicators affect organizational readiness in ERP implementation. Then the authors define indicators and make questionnaire statements, then the authors distribute data to respondents using a questionnaire method. A list of sub-variables, defining indicators and questionnaire statements can be seen in Table 1.

Table 1: Sub-variables, Indicators, Definition and Questionnaire Statement

No	Sub-variables	No	Indicators	Code	Definition	Questionnaire statement
1	Business processes	1	Committed to change	PR01	Business process change need the organization commitment to change to be standardized, understood and documented.	The role of management's commitment to standardized, understood, and documented changes to business processes
		2	Business processes change	PR02	Implementation success requires a change of business processes.	Changes in business processes to achieve successful ERP implementation.
		3	Business processes redesign	PR03	Redesigning the business processes of an organization to best practice processes.	It is necessary to redesign business processes based on best practice business processes.
2	Process standarized based on industry best practice	4	Integrated business process	PR04	Integrate business process and operations for improving organization business.	The integration of business processes and operations is necessary to improve the organization's business.
		5	Work processes standarized and documentation	PR05	Standarization of work processes and documentation.	Standardization of work processes and complete documentation are essential in ERP implementation.
3	Change Management	6	Cultural change management	PR06	Cultural change management is a concern to successfully implement.	Cultural change management must be done to ensure the change process runs well.
		7	Open minded for changes	PR07	Open minded for changes.	An open mind from all parties involved in accepting the change process.
4	Skill and competency	8	Management's skill and competency	PE08	Management's skills determines the strategy of utilizing ERP usage for business development.	Management expertise in determining strategies for utilizing ERP for business development.
		9	User's skill and competency	PE09	Skilled user to understand of process business of system used.	User expertise in understanding the business processes of the system used.
		10	IT staff's skill and competency	PE10	Specialized skills and competency of the IT team will increase the ERP implementation success.	The expertise and special abilities of the IT team in improving the success of ERP implementation.
5	Project Manager	11	Adequate ERP project experience	PE11	Project manager has adequate ERP project experience.	The project manager has sufficient ERP project experience.
		12	High level overview	PE12	Have a thorough understanding of the knowledge, experience, ability, and coordinate all the processes of the ERP Project.	Project Managers have a thorough understanding of the knowledge, experience, capabilities, and coordinate all processes in ERP implementation.
6	Training	13	Delivered to all parties	PE13	Training is obliged to be delivered to all parties, including program, mechanism, material.	Mandatory training is delivered to all parties involved, including programs, mechanisms and materials.
		14	Users adaptation to new process	PE14	Users can adapt to new processes from taking ERP implementation training.	Users can adapt well to the new process from taking ERP implementation training.
		15	Understand the overall concepts	PE15	Training goal to understand the overall concepts of the ERP system.	Training is useful for understanding the overall concept of an ERP system.
		16	Transfer knowledge	PE16	Transfer of knowledge to improve the quality of employees.	Knowledge transfer for users to improve the quality of employees is very necessary.
7	Project team	17	Formed project team	PE17	Formed project team accordingly to project the scope.	The project team must be formed according to the scope of the ERP project.
		18	Technical expertise	PE18	Technical expertise, understanding for business processes, processes knowledge, and ERP project experience.	There is a project team that has technical expertise, understanding of business processes, knowledge of ERP processes, and ERP project experience.
		19	Involved Business Process Owner	PE19	The involvement of a Business Process Owner in the project team to map and manage business processes according to ERP selected.	The involvement of a Business Process Owner in the project team to map and manage business processes according to the ERP that will be implemented.
8	Human Resource Management	20	Available Human Resource	PE20	Ensure the availability of adequate Human Resources to involved the ERP implementation process.	Ensuring the availability of adequate human resources to carry out the ERP implementation process.
		21	Development of competent human	PE21	Development, utilization, and maintenance of competent human force to achieve goals of an organization.	The process of developing, utilizing, and maintaining competent human resources to achieve organizational goals in ERP project implementation.
9	Clear roles and responsibilites	22	Clear roles of project	PE22	Clear roles of project stakeholders should be clearly defined, fully documented and understood.	The clear roles of project stakeholders must be clearly defined, documented and fully understood by all teams involved.
		23	Clear responsibilities of project	PE23	Determination of the responsibilities of the tim involved in ERP implementation.	It is very important to determine the responsibility of the team involved in ERP implementation.

No	Sub-variables	No	Indicators	Code	Definition	Questionnaire statement
10	Employee /staf/user involvement	24	Employee commitment	PE24	Commitment of employees to implement ERP projects.	Employee commitment in implementing ERP projects is very necessary.
		25	Employee involvement	PE25	Employees are actively involved in the process of ERP implementation stages.	Employees are actively involved in participating in ERP implementation activities.
11	Shared values	26	Project champion	OG26	Project champion is a reliable person and trusted to regarding implementation.	Project champions are needed in ERP implementation, because project champions are people who can be relied on and trusted in ERP implementation activities.
				OG27	Project champion can ensure implementation processes run or the possibility of project success.	The project champion is needed to ensure the implementation process runs well and also determines the success of the ERP project.
				OG28	Project champion in an ERP implementation is fundamental in implementation.	Project champion is fundamental in ERP implementation.
		27	Shared beliefs	OG29	Belief to benefits of using ERP in organizations.	All parties involved must have confidence in the benefits of using ERP in the organization.
		28	Cross functional support	OG30	Get support all function of organization.	Support from all organizational functions in achieving successful ERP implementation is needed.
				OG31	Cross department cooperation.	Cross-departmental collaboration is essential in achieving a successful ERP implementation.
12	Project Management	29	Measurement of performance specific, measurable, achievable, relevant, time bound	OG32	Performance measurement of ERP projects specifically in the planning, implementation, and post-ERP implementation processes.	Specific ERP project performance measurement in the planning, implementation, and post-ERP implementation processes is essential.
				OG33	Performance measurement of ERP projects that the measurable results of each stage of implementation.	Measurable ERP project performance measurement at each stage of ERP implementation is needed
				OG34	Performance measurement of ERP projects that the ERP implementation is achieved.	ERP project performance measurement that pays close attention to the target of achieving ERP implementation must be considered.
				OG35	Performance measurement of ERP projects that the relevant results according to the company's vision and mission.	ERP project performance measurement must pay attention to the results that are relevant to the company's vision and mission.
				OG36	Performance measurement of ERP projects that the performance of the ERP project in accordance with a predetermined target time.	ERP project performance measurement must be in accordance with a predetermined time schedule.
		30	Monitoring of performance	OG37	Focused on customer need.	ERP project performance measurement results should focus on customer needs.
				OG38	Controlling for implementation schedule.	The performance control process is indispensable in ERP implementation.
		31	IT Governance	OG39	Focus on IT governance with concerned to information quality.	IT governance must pay attention to the quality of information generated by ERP.
13	Knowledge Management	32	Knowledge sharing process	OG40	Knowledge sharing process can greatly improve employees' ability to learn and manage knowledge.	The process of knowledge sharing is needed in an effort to improve employee learning skills and manage their knowledge.
		33	Data and information standarized	OG41	Ensure information standarized in all business operations.	Data and information standarizedon all business operations supports the use of ERP.
14	Organizatio nal structure	34	Centralization	OG42	Activities of an organisation, planning and decision-making are controlled by the top management and project manager.	Planning and decision-making activities that are controlled by top management and project managers are required in ERP projects.
		35	Specialization	OG43	Specialization is a business strategy that focuses on specialized production for increasing productivity with ERP use.	A business strategy that focuses on specialized production is needed to increase productivity with the use of ERP.
		36	Formalization	OG44	Formalization as a process to define procedures, standardization processes, responsibilities, and completely documented.	Organizational formalization is needed in ERP implementation as a process in determining procedures, standardizing work processes, and fully documented responsibilities.
		37	Size of organization	OG45	The success of ERP projects may be impacted by organization size.	The size of the organization affects the success of an ERP project.
		38	CIO position	OG46	CIO's role is to determine the alignment of business and technology, ensure the availability, accuracy, accuracy and security of information as needed to achieve the organizational goals.	The role of the Chief Information Officer (CIO) is needed to determine the alignment of business and technology, ensuring the availability, accuracy, accuracy, and security of information according to management needs to achieve organizational goals.
		39	Top management commitment	OG47	Involved in every step of ERP project, monitor the progress ERP.	Top management must be involved in every process and monitor the progress of the ERP project.
				OG48	Focusing on top management's commitment and willingness to provide sufficient resources.	Top management commitment is needed to provide adequate resources and achieve a successful ERP implementation.

No	Sub-variables	No	Indicators	Code	Definition	Questionnaire statement
15	Organizational style	40	Communication	OG49	Communicate all activities in the ERP implementation process to all parties involved.	Communicating all activities in the ERP implementation process to all parties involved is very important.
				OG50	Sign off as proof of the communication and agreement on project work.	Sign off as proof of communication and agreement on ERP project work must be approved by the parties involved.
		41	Organizational culture	OG51	Organizational culture determines the right way to attitude and make changes, including with regard to ERP implementation.	Organizational culture determines the right way to behave and make changes in ERP implementation.
		42	Vision and mission	OG52	The clear of vision and mission as a guide ERP implementation.	A clear organizational vision and mission guides the implementation of ERP implementation.
				OG53	A clear vision and mission must be revealed and communicated into an important part that will support the ERP project.	A clear organizational vision and mission must be revealed and communicated to all parties involved to support the implementation of the ERP project.
16	Organizational strategy	43	Goals and objectives	OG54	Identification of measurable goals, the formation of the project organization, and the motivation of the project team.	The process of identifying measurable goals, establishing a project organization, and the motivation of the ERP project team are important factors in supporting ERP implementation.
				OG55	Define and must be communicated effectively among stakeholders involved.	Project objectives and objectivity must be defined and communicated effectively to the stakeholders involved.
		44	Project planning (scope, time, budget, risk, other resources)	OG56	Determine the scope of the ERP project.	Determination of a clear ERP project scope will determine the success of ERP implementation.
				OG57	Confirming the ERP project for determine target of go live time.	All ERP project activities must be confirmed with all parties involved in order to determine the target time to go live.
				OG58	Budget usage needs to be controlled rigorously throughout the ERP implementation.	Budget usage needs to be strictly controlled during ERP implementation.
				OG59	Project planning implementation can reduce the risk for the failure.	The implementation of project planning can reduce the risk of failure in ERP implementation.
				OG60	Project planning implementation requires the availability of complete resources.	ERP implementation project planning must have complete resource availability.
17	System rollout	45	Rollout system	TH61	Rollout system is a structured set of processes to anticipate events that cause ERP implementation setbacks.	A system rollout function to anticipate things that cause ERP implementation setbacks must be available.
	configuration	46	Configuration system	TH62	A configuration refers to the hardware and software that greatly affect ERP implementation success.	Correct configuration of hardware and software affects the success of ERP implementation.
18	System integration	47	IT infrastructure	TH63	Determine the software, hardware, and network infrastructure that will be needed for the ERP system.	Determining the correct software, hardware and network infrastructure is needed in ERP implementation.
				TH64	Adequate IT infrastructure, hardware and networking for ERP implementation.	It is necessary to conduct an assessment of the adequacy of IT infrastructure, hardware and networks before implementing ERP.
		48	Processes improvement	TH65	Process improvements need to be identified before the implementation of ERP.	Identification of process improvements must be done prior to ERP implementation.
				TH66	Information usable that provides benefits that support decision making related to ERP projects.	Useful information is needed to support decision making in ERP projects.
		49	Data management	TH67	Data comprehensive that supports decision making related to ERP projects.	Complete data comprehensively supports decision making in ERP projects.
				TH68	Data availability as needed to support decision making related to ERP projects.	The availability of data that is suitable for management needs for decision making in ERP projects is needed.
19	IT structure and legacy systems	50	IT structure	TH69	IT team structure to coordinate ERP project activities from planning to post-go live.	Good IT team structure to coordinate ERP project activities from planning to post-go live.
		51	Legacy systems	TH70	Good integration with legacy systems.	Integration with old systems in ERP implementation must be done well.
20	Technology selection & adaptation (Technological readiness)	52	Technology selection	TH71	The company's readiness in selection, providing, and implementing technology that supports business strategies.	An assessment of the company's readiness in selecting, providing, and implementing technology that supports business strategies must be carried out.
		53	Technology adaptation	TH72	Adaptation of technology used to support optimal ERP implementation strategy.	Adaptation of the technology used to support the ERP implementation strategy is needed.
21	System acceptance and usage	54	System acceptance	TH73	Acceptance of users to use ERP in completing work will increase the work more effective and efficient.	Acceptance of users to use ERP in completing work and improving a more effective way of working is very important
		55	System usage	TH74	The use of information technology can improve the performance of the organization.	The optimal use of information technology can improve overall organizational performance.
22	Trouble shooting	56	Helpdesk system	TH75	The available of a helap system to help users in providing fast response in troubleshooting related to ERP use.	The availability of a helpdesk system will help users quickly solve problems related to the use of ERP.
		57	Service to users	TH76	The available of an IT team to serve users in providing troubleshooting related to ERP use.	The availability of an IT team that provides services for users and provides solutions to problems related to the use of ERP is very much needed.

No	Sub-variables	No	Indicators	Code	Definition	Questionnaire statement
23	External consultant / expertise	58	Functional consultant	TH77	Analyzes running business processes and provides directions for following ERP business processes that can be implemented.	Consultants can analyze running business processes and provide directions for following ERP business processes so that they can be implemented properly.
		59	Technical consultant	TH78	Consultant expertise in providing directions and solutions for technical matters related to ERP implementation.	Consultants can provide direction and solutions for technical matters related to ERP implementation.
24	Vendor relationship and support	60	Vendor engagement	TH79	Relationships and angagement with vendors will speed up problem solving related to the ERP implementation process.	Relationships and agreements with vendors can speed up problem solving related to the ERP implementation process.
		61	Supply Chain Management	TH80	Network of interconnected department for fulfilling the material required by the other departments or by the customers.	Inter-departmental networks that are interconnected to meet material requirements for other departments or for customers are very necessary in ERP.

The characteristic of CMMI is initial, defined, managed, measured, and optimized [19]. Initial: Unpredicable, uncontrolled, no-automation. Defined: Some shared decision-making. Managed: Collaboration, analyze trend, and portfolios. Measured: Central automated process, standardized across the organization. Optimized: Focused on continuous improvement, stability provides a platform for agility and innovation. The related between characteristic of maturity level with readiness of ERP readiness assessment module, which can be seen in Figure 1.
Figure 1: ERP Readiness Assessment model

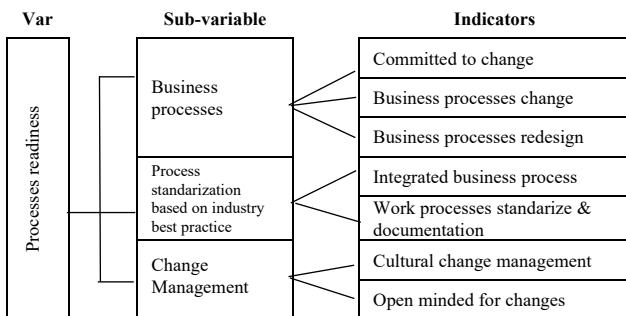
Based on these main variables (processes readiness, people readiness, organizational readiness, and technology readiness), it is derived into 24 sub-variables and 61 indicators. The grouping of processes readiness variables is derived into 3 sub-variables and 7 indicators can be seen in Figure 2.


Figure 2: Processes readiness of ERP Readiness Assessment

The grouping of people readiness variables is derived into 7 sub-variables and 18 indicators can be seen in Figure 3.

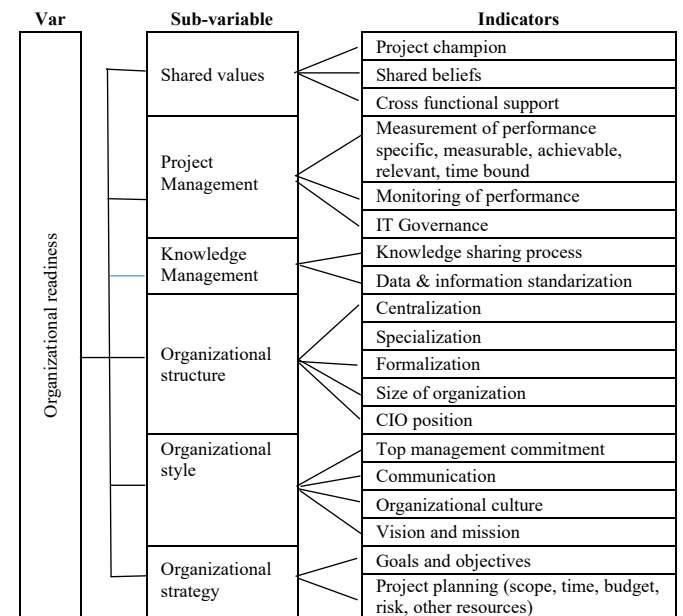
The grouping of organizational readiness variables is derived into 9 sub-variables and 25 indicators can be seen in Figure 4.
Figure 3: People readiness of ERP Readiness Assessment


Figure 4: Organizational readiness of ERP Readiness Assessment

The grouping of technology readiness variables is derived into 8 sub-variables and 17 indicators. The grouping of technology

readiness for each sub-variables and indicator can be seen in Figure 5.
Figure 5: Technology readiness of ERP Readiness Assessment

3. Result and discussion

3.1. Data processing of the questionnaires

As a result of distributing questionnaires to respondents, Authors made a characteristics profile of respondents which can be seen in Table 2.

Table 2: Characteristics profile of respondents

Respondent profile		Frequency	%
Gender	Male	96	73%
	Female	35	27%
		131	100%
Age	20-30 years	38	29%
	31-40 years	34	26%
	41-50 years	36	27%
	> 51 years	23	18%
Level of education	Strata-1 (bachelor)	90	69%
	Strata-2 (undergraduate)	36	27%
	Strata-3 (doctoral)	5	4%
Work experience	1-2 years	34	26%
	2-3 years	6	5%
	3-4 years	16	12%
	> 4 years	75	57%
Educational background	Information technology	68	52%
	Finance/Accounting	43	33%
	Marketing	5	4%
	Production	3	2%
	Others	12	9%
Level	Staff	57	44%
	Manager	60	46%
	Director	14	11%
Industry type	Textile industry	67	51%
	Garment industry	39	30%
	Consultant	25	19%

The authors grouping indicators the data collection to organizational readiness in ERP implementation, by determining

the following components to Gender: The authors included gender components because it can influence in emotions in decision making in the data collection according the character of the respondents. Age: The authors included age components because it can influence decision making in the data collection according to work experience from respondents. Work experience: Authors included work experience components because it can influence maturity in decision making in the data collection according the work experience using ERP from respondents. Educational background: The authors included educational background components in the data collection because it can affect the level of maturity in decision making. Position: Authors included a position components because it can influences the maturity level in decision making. Industry type: Authors included industry type components in data collection because it can be comparison of the data processing result. The authors forward to test of 61 indicators using the multivariate Principal Component Analysis (PCA) statistical approach using R software, which meets the following requirement, namely the p-value must be less than 0.05, and the Measure of Sampling Adequacy(MSA) value must be greater than 0.5. The results of PCA data processing using software R show that Kaiser-Meyer Olkin (KMO) = 0.866, where all indicators have "KMO > 0.5", so it can be interpreted that the KMO value has requirement. The results of data processing from the PCA test show that 61 indicators from into 24 Release Candidate (RC) with the sum of the squared loadings (SS Loadings) achieve contributes 83% cumulative variable. The SS loading value is the result of automatic calculation from the R software. Based on RC results of PCA data processing using R software by calculation for more than one of eigen value (SS Loading > 1) achieved at a cumulative variable 83% with RC is 24, this is the optimum value calculated achieve cumulative proportion 100%. The release Candidate result can be seen in Table 3.

Table 3: Release Candidate results

No	RC	SS Loading	Proportion variable	Cumulative variable	Proportion Explained	Cumulative Proportion
1	RC1	5.73	7%	7%	10,00%	10%
2	RC21	4.68	6%	13%	7,00%	17%
3	RC4	4.62	6%	19%	7,00%	24%
4	RC2	4.06	5%	24%	6,00%	30%
5	RC24	3.53	4%	28%	5,00%	35%
6	RC13	3.43	4%	32%	5,00%	40%
7	RC22	3.37	4%	36%	5,00%	45%
8	RC3	2.86	4%	40%	4,00%	49%
9	RC7	2.85	4%	44%	4,00%	53%
10	RC19	2.82	4%	48%	4,00%	57%
11	RC17	2.66	3%	51%	4,00%	61%
12	RC15	2.63	3%	54%	4,00%	65%
13	RC5	2.46	3%	57%	4,00%	69%
14	RC9	2.45	3%	60%	4,00%	73%
15	RC10	2.30	3%	63%	3,00%	76%
16	RC16	2.21	3%	66%	3,00%	79%
17	RC8	2.16	3%	69%	3,00%	82%
18	RC12	2.11	3%	72%	3,00%	85%
19	RC6	1.96	2%	74%	3,00%	88%
20	RC20	1.86	2%	76%	3,00%	91%

24	RC14	1.05	1%	83%	2,00%	100%

SS Loading is the sum of the squared loadings
RC is Release Candidate

Based on the results of R software data processing for 24RC, the authors analyze for finding the highest value of each indicator, then the authors classify according to each of RC with create a new group for 24RC. The PCA result of data processing using R software can be seen in Table 4.

Table 4: Principal Component Analysis

3.2. ERP readiness assessment factors

Based on the results of PCA data processing using R software, the authors identify a new name for the sub-variable of each RC can be seen in Table 5. Then the authors continue to analysis with the weighting of 61 indicators using TOPSIS method where the name of the grouping for 24 sub-variables is based on the highest score for the preference score. The results of the TOPSIS processing for 10 the readiness factors that affect the success of ERP implementation are as follows: cross functional support (9.87%), project champion (9.14%), communication (7.82%), vision and mission (6.98%), transfer knowledge (6.97%), process improvement (5.98%), project planning (5.19%), vendor engagement (5.13%), commited to change (4.12%), and open minded for changes (4.05%). The results of the weight of ERP readiness assessment can be seen in Table 5.

Table 5: The weight of ERP readiness assessment

RC	No	Indicators	Sub-variables	Main weights	Final weights	Weights factors	Preferences
RC01	1	OG28	Project champion	9.14%	15.75	1.44	0.77

	80	OG39			17.73	1.06	0.57

The results of data processing using TOPSIS, found that organizational variables have the main weight of 43.51%, variable technology has the main weight of 25.03%, variable people have the main weight of 22.06%, and variable processes have the main weight of 9.40%. Thus, the organizational variable is a very dominant variable that determines the level of readiness in implementing ERP for the textile industry in Indonesia. The main weight of variables can be seen in the Table 6.

Table 6: Main weight of variables

No	Variable	Main Weight
1	Organizational	43.51
2	Technology	25.03
3	People	22.06
4	Processes	9.40
		100.00

Meanwhile, the teen sub-variables that have a significant main weight can be seen in the Table 7.

Table 7: Weight of sub-variables

No	Sub-variables	Main weight
1	Cross functional support	9.87
2	Project champion	9.14
3	Communication	7.82

4	Vision and mission	6.98
5	Transfer knowledge	6.97
6	Processes improvement	5.98
7	Project planning (scope)	5.19
8	Vendor engagement	5.13
9	Committed to change	4.12
10	Open minded for changes	4.05

3.3 Measuring the level of organizational maturity

Based on the weighting of 24 indicators which are the results of data processing using TOPSIS, the authors make a list of questions as a basis for designing an ERP readiness assessment

module. The list of assessment questions is in the form of a rubric assessment with the maturity level of the Capability Maturity Model Integration (CMMI) model with being considered the characteristic of initial, defined, managed, measured, and optimized with the readiness of process, people, organizational and technology. The list of Rubric Maturity Assessments can be seen in Table 8.

This rubric assessment will be a reference for the top management or the consultant to test each department involved to get good feedback before implementing ERP for the industry.

Table 8: Rubric Maturity Assessment

No	Sub-variables	MATURITY LEVEL				
		INITIAL	DEFINED	MANAGED	MEASURED	OPTIMIZED
1	Project champion	The function of a Project Champion in project ERP has not been defined	The function of a Project Champion in project ERP has been defined	The function of a Project Champion in project ERP have been standardized in SOP	The function of a Project Champion in project ERP has been socialized	The function of a Project Champion in project ERP has been evaluated for improvement
2	Cross functional support	Support from organizational functions in ERP implementation is still informal	Support from organizational functions in implementing ERP has been standardized in SOPs	Support from organizational functions in implementing ERP has been disseminated	Support from organizational functions in implementing ERP has been integrated across departments	Support from organizational functions in implementing ERP has been evaluated for improvement
3	Configuration system	The system hardware and software configurations affecting the success of ERP implementation have not been identified	The system hardware and software configurations that affect the successful implementation of ERP have been identified	The configuration of the hardware and software systems that affect the success of ERP implementation has been standardized in the SOP	The configuration of hardware and software systems that affect the success of ERP implementation has been socialized	The hardware and software system configurations that affect the success of ERP implementation have been evaluated for improvement
4	Vendor engagement	Relationships and agreements with vendors that can speed up problem solving related to the ERP implementation process have not yet been identified	Relationships and agreements with vendors that can speed up problem solving related to the ERP implementation process have been identified	Relationships and agreements with vendors that can speed up problem solving related to the ERP implementation process have been standardized in the SOP	Relationships and agreements with vendors that can speed up problem solving related to the ERP implementation process have been integrated with the customer	Relationships and agreements with vendors that can speed up problem solving related to the ERP implementation process have been evaluated for improvement
5	Committed to change	Management's commitment to change business processes is still informal.	Management's commitment to changing business processes has been standardized in the SOP.	Management's commitment to changing business processes has been socialized	Management's commitment to change business processes has been synchronized with business strategy	Management's commitment to changing business processes has been evaluated for improvement
6	Project planning (budget)	The budget usage that must be strictly controlled during ERP implementation has not been defined	The use of budgets that must be strictly controlled during ERP implementation has been determined	The use of budgets that must be strictly controlled during ERP implementation has been standardized in the SOP	The use of budgets that must be strictly controlled during ERP implementation has been socialized	The use of budgets that must be strictly controlled during ERP implementation has been evaluated for improvement
7	Helpdesk system	The availability of a helpdesk system can help users quickly solve problems related to the use of ERP that have not been identified	The availability of a helpdesk system can help users quickly solve problems related to the use of ERP that have been identified	The availability of a helpdesk system can help users quickly solve problems related to the use of ERP that have standardized in the SOP	The availability of a helpdesk system can help users quickly solve problems related to the use of ERP that have been socialized	The availability of a helpdesk system can help users quickly solve problems related to the use of ERP that have evaluated for improvement

4. Conclusion

The ERP implementation process for the industry has a high complexity, which will risk a high failure rate. However, the problem of the complexity of ERP implementation in the textile industry can be resolved by identifying readiness factors that focus on four main components such as processes, people, organizational, and technology before implementing ERP. Thus, the organizations can identify weaknesses and anticipate improvements, thereby increasing the success rate of ERP implementation. The research result shows that the score of organizational variable is 43.50% and the domain factors that influence ERP readiness assessment with significance factors are project champion (9.14%), cross-functional support (9.87%), project planning scope (5.19%), vision and mission (6.98%), and communication (7.82%). For this reason, it is necessary to develop of ERP readiness assessment, so that the managerial level can easily analyze the maturity level of the organization that need to be improved. The author realizes that this research has limitations in conducting case studies in the textile industry. For this reason, this research can be continued with case studies in the wider industry, and this research can also be developed by developing an ERP readiness assessment module as an information system for the management level in deciding to continue implementing ERP.

Vehicle accidents, particularly in small and large urban areas, are rising tremendously day by day worldwide. As a recent research subject in automaton transportation, the subsequent collision has become a vital issue and emergency. Internet of things (IoT) and the Internet of Vehicles (IoV) have become very popular these days because of their versatility, and robust cybersecurity underpin these new connected services. Aggressive driving among improper driving behaviours is a mainly responsible cause of traffic accidents that endanger human safety and property. Identifying dangerous driving is a significant step in changing this situation by analyzing data recorded through different gathering devices. The focus of aggressive recognition research has recently shifted to the use of vehicle motion data, which has emerged as a new technique for understanding the phenomenon of traffic. As aggressive driving refers to abrupt changes in actions, it is possible to classify them based on the vehicle's movement data. This paper presents a method to identify driving behaviours categorized into four groups: dangerous, aggressive, safe and normal behaviour to reduce the risk of accidents based on real-time data recorded from vehicles and reference data provided by previous researchers. Comparison and statistical methods have been done to determine the best way to collect driving data based on independent-samples t-test using Statistical Package for the Social Sciences (SPSS) statistics to compare the means between groups on the same continuous, dependent variable. Results have also shown that a small difference of speed between the mobile application and the On-Board Diagnostics (OBD-II) speed with $t(4024.1) = 1.8$, $p = .071$, which can be considered acceptable. Furthermore, the OBD-II adapter and mobile application speed were significantly different from the independent GPS device with $t(3184.9) = 10.8, p = 0$ and $t(4416.5) = 13.2, p = 0$. Consequently, it is expected to improve drivers' awareness of their driving behaviours.

1. Introduction

Population growth and the rapid promotion of the new urban motorization process have led to a rise in vehicles in recent years. The lack of efficient traffic management has led to traffic problems such as traffic congestion, traffic accidents, air pollution and energy consumption, which become an ever-increasing problem in the worldwide [1-5]. The challenges that a driver faces every day are growing dramatically due to the increasing worldwide demand for transportation. The situation review states that those significant casualties are due to improper driving behaviours. According to

study figures for injuries, 75% of lethal accidents are caused by human factors like lack of attention, loss of orientation, tiredness, stress and medical condition. The unexpected behaviour is the cause of the 24% of total accidents, and only 0.7% of injuries are attributed to technological failures (Figure 1) [6-9]. Vehicle to Vehicle (V2V) Communication plays an important role in smart transportation services, be the main factor for the success of Intelligent Transportation Systems (ITSs), and able to exchange a variety of information including acceleration, speed, direction and location forthwith with nearer vehicles and connected infrastructure [2, 10]. Connected vehicle technologies are nearly able to take off, commercially viable and used by the overall public in a vast selection of conditions. Technological advancements are
Figure 1: Accident causes, adapted from [7]

rushing on the automated technology time toward this destination [11].

Safety-based V2V applications can generate high-interest applications in road safety as a mechanism for prevention in critical circumstances. Implementing intersection collision avoidance coupled with driver assistance systems, could help provide a look around the corner effect, even in highly obstructed channel conditions [12-14]. The National Highway Traffic Safety Administration (NHTSA) sets out guidance on how different levels of vehicle automation can minimize vehicle accidents and how the use of short-range on-board sensors coupled with V2V technologies can help facilitate contact between vehicles [15]. Driver behaviour modelling is an important part of understanding the driver and evaluating traffic flow within the traffic system. The interactions with time and space between the main components of vehicular traffic can be seen as a traditional human-machine system [16, 17]. A significant aspect that quickly contributes to unsafe driving is violent driving behaviour. The press and the public have also given ample attention to this dangerous conduct [8]. In the last ten-year period, speeding has consistently been cited as a contributing factor in most fatal crashes which have been wholly or partially the fate of speeding behaviour. With real-time information, forthcoming driving behaviour could be predicted [17, 18]. Monitoring driving behaviour is not enough for ensuring driver safety. On the contrary, the achievement of safe and efficient driving needs to recognize reckless or "accident-prone" drivers who could encourage more successful traffic safety work coupled with the most appropriate incentives to avoid them [19, 20]. In this paper, we try to use a method for modelling drivers' acceleration to quantify and analyse individual driver behaviour using online data recorded from instrumented vehicles using different data collection devices. Experimental results are presented using graphs and analysis for multiple scenarios. The major contributions of this work are summarized as follows:

- Defining desired safe behaviours through direct observation

- Observing behaviour and quantifying safe/unsafe or at-risk behaviour

- Monitoring and evaluating changes in safe behaviour, performance; and providing feedback.

This paper is organized as follows. Section 2 presents related work while in Section 3, along with the system description, we present tools and software used for driving behaviours data collection using the instrumented vehicle. In Section 4, show study sites and research participants. In Section 5, the main system workflow explained. In contrast, in Section 6, we introduce the numerical results and statistical analysis of speed and acceleration data on the relaying strategies and the optimization results. Finally, we conclude in Section 7.

2. Related Work

Driving behaviour is the subject of comprehensive research. A growing number of studies have used technological advancements and gained particular attention to enhance our understanding of driver behaviour due to the advent of emerging technologies to gather more accurate and richer data [17, 21]. Driving event is generally understood as maneuvers occurring during the driving task, such as acceleration or deceleration, lane change and turning, which can be used to identify driving style [22]. Reference [23] indicated that data obtained from a collection of vehicle sensors could be analyzed to recognize a series of driving maneuvers using certain recognition methods and that the parameters of these driving maneuvers could be extracted and then used to classify driver characteristics or determine the abilities of the driver. In [24], the authors suggest a method to classify driver behaviours that take into account three acceleration and direction anomalies: a) sudden movements (acceleration and deceleration); b) shifts in lanes; c) excessive speed. Therefore, the algorithm classifies drivers into the following categories: cautious, distracted, hazardous and very risky. A non-intrusive method for a real-time framework to detect and identify driver distraction was presented in reference [25], using Machine Learning (ML) algorithms and dynamic vehicle data as inputs to the model. Authors in [26] developed a driver model capable of predicting each normal driver driving on a specific road segment with a reasonable degree of accuracy based on nonlinear regression methods using Artificial Neural Network (ANN). The primary benefit of this form of experiment is the tremendous degree of control over the factors that may impact driving behaviour. In a designed environment, however, controlled experiments are most often conducted. That

makes it more difficult for the effects of real traffic to be transferred [6].

Several works about the data exchange efficiency between vehicles and roadside infrastructure are investigated in [27] using a beaconing mechanism in the connection setup. Studies in [21] have employed GPS, accelerometers, video cameras and distance sensors. Authors in [4] assessed WiFi-based V2V data collection experiments to communicate with other vehicles. Experiments conducted on very slow speed vehicles with a maximum range of 100 ft. Reference [28] introduces the AutoNet2030 system used to drive convoys.

Furthermore, [29] presents an inquiry into V2V contact and data collection based on commercial on-board units (OBU) and incorporated into two research vehicles for light detection and ranging (LiDAR). Some existing services are already seeking to use the OBD interface for various purposes. The Driving Styles approach is provided in [30]. The proposed architecture incorporates data mining techniques and neural networks, classification of driving style is produced by studying driver activity along each path. Specifically, based on OBD parameters such as engine rpm, acceleration and revolutions per minute (RPM). A neural network based algorithm was introduced by the authors that can characterize the type of road on which the vehicle is traveling, as well as the degree of aggression of each driver. In [31], authors propose an Android application that tracks the vehicle via an OBD interface, allowing accidents to be detected.

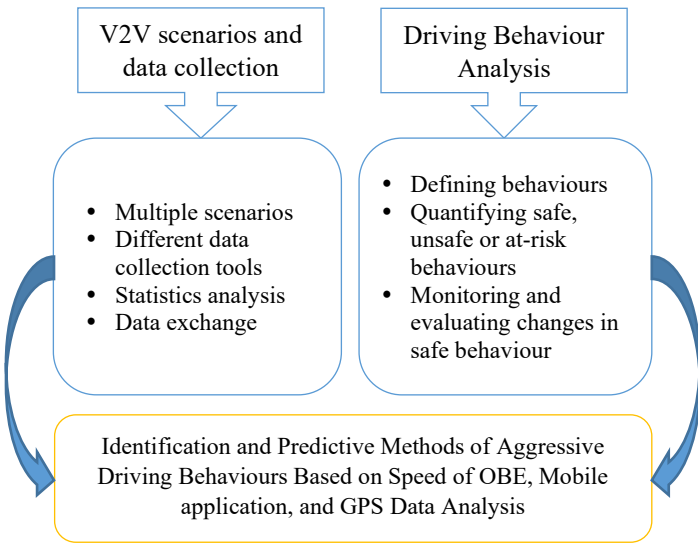

Figure 2: Study of gap from the related articles

Experimental findings using a real vehicle show that in less than 3 seconds, the application is able to respond to incidents in a very short time, validating the effectiveness of smartphone-based solutions to improve road safety. Moreover, [32] proposed a driving behaviour-based Collision Warning System (CWS) study to determine the collision risk level, according to its driving behaviour. In this experiment, the radar used was the ESR 1.0 model (Delphi), the capacity to output up to 174 m. The driving vehicle's speed, acceleration pedal, and brake pedal values were recorded using the OBD. Data output from the radar and OBD, through the Vector and the CANoe programs via the VN5610

network interface. These important studies have shown that the stability, protection, and efficiency of traffic flow are dramatically improved based on driving behavior communication technology. Based on the literature review, it can be seen that the assessment of drivers' behaviours using their trajectory data is a fresh and open research field. Most studies related to driving behaviours in terms of acceleration and deceleration are concluded after making an experimental trip where drivers' behaviour is calculated and recognized. Furthermore, as far as searching was feasible, it was a lack of studies that address the identification of aggressively driving based on real time data collection and analysis using different devices in a near real time. In our paper, we aimed to clarify the difference between OBD, GPS and mobile application to provide real measurements for further study and solutions that can be used (Figure 2).

3. Driving Behaviour Data Collections Tools

Driving behaviour recognition is a fundamental prerequisite for traffic studies and generates benefits, especially in three main areas: analysis of road safety; simulation of microscopic traffic; and ITSS. For various tasks in transport engineering, driving behaviour studies are of great benefit. That involves the collection of data both for statistical analysis and for driving model recognition and modelling parameter estimation.

Driving data are collected using an instrumented vehicle, as shown in Figure 3, equipped with GPS, microcontroller and other sensors. Many instruments are available to monitor driving behaviour, some of which work on the roadside and others on board. First, while driving on an instrumented location, an unconscious driver is tracked in the case of roadside sensors; different technologies can be used to track driving behaviours. Second, in the case of on-board sensors mounted on an instrumented vehicle, more extended measurements are allowed under more versatile experimental conditions, with the prospect of observing those maneuvers of particular interest in a controlled manner. An instrumented vehicle can be defined as a standard vehicle, the kinematics of which are registered for the study. In this system, the driving behaviours data collection have been gathered and analysed using on-board sensors.

Figure 3: Instrumented vehicle for data collection

3.1. On-board Diagnostics Adapter

On-Board Diagnostics OBD-I refers to the self-diagnostic and reporting capacity of a vehicle used in modern vehicles compliant with standard computer protocols. This adapter enables the vehicle network to be accessed by a computer. In service, it is similar to a computer modem or a gateway, that transfers messages from one

protocol to another; the data normally flows both ways to and from the Electronic Control Unit (ECU). Current OBD system, or called OBD-II replaces the deficient former system, namely OBD-I. The main advantage of OBD-II is its standardization. In other words, only one set of OBD-II scanning instruments can perform the diagnosis and can search for a number of vehicles fitted with and assisted by this adapter [33]. There are 16 pins in the system socket which are normally mounted below the driving plate. Nine of these 16 pins have fixed functions, and the remaining pins are left at the discretion of the car's manufacturer. Since the OBD-II interface is not a normal general computer system, Bluetooth and Wi-Fi adapters were built for data collection to accommodate the PC to obtain vehicle status as shown in Figure 4 which used in the data collection phase.

| (a) | (b) |

Figure 4: OBD-II adapter, (a) ELM327 Bluetooth, (b) ELM327 Wi-Fi

Besides, the proposed system also uses the Freematics ESP32 OBD-II Package. "This kit, together with the 1.3" OLED monitor and Freematics OBD-II UART Adapter, is based on Freematics Esprit, the Arduino compatible ESP32 dev board, as shown in Figure 5. This kit is simple to start yet has a lot of potential for prototyping advanced connected car applications. The board is completely plug-and-play. Freematics Esprit is in the same form of Arduino UNO board with additional pinouts for I2C and two serial UARTs [34].

Figure 5: Freematics ESP32 OBD kit

3.2. Torque Mobile Application

Torque is a software used as a diagnostic tool for any device that runs the Android operating system. When used in conjunction with OBD-II Bluetooth or Wi-Fi adapters for Android (Figure 6), it allows to access the many sensors within a vehicle management system and enable to view and clear trouble codes. This device is a cutting-edge Android Mobile diagnostic and performance scanner application for vehicles. This application can use internal cell phone GPS systems along with other sensors that graph useful acceleration, braking and overall vehicle performance data.

Figure 7: Data recorded with Torque pro's application

Different parameters added to the Torque software such as GPS Time, longitude, latitude, GPS speed (Meters/second), acceleration, engine load, engine RPM, speed (OBD), GPS Accuracy (m), GPS vs OBD Speed difference (km/h) and finally GPS speed (km/h). All these parameters are used in the analysis phase of the proposed system to monitor each trip. After setting everything in the application, Torque begins creating logs of the data by click Start Logging on the display screen to track the information and log all Parameter Identifications (PIDs) that were selected. Eventually, to save all logs recorded click Stop Logging on the display screen, choose the CSV (Comma Separated Values) format as shown in Figure 7. These data are used for further analysis and subsequent comparisons to determine the drivers' behaviours based on the information recorded from the acceleration of the drivers.

3.3. Digital Dashboard GPS Pro Application

Digital Dashboard is a performance tool for any device that runs the Android operating system. It can track speed, distance, time, location, and get start time, time elapsed, average speed, maximum speed, altitude and longitude. This software is the second type of software used in the design of the proposed system and the Torque software to compare the information obtained from mobile GPS and OBD-II adapter to determine the best way to extract data to predict the behaviour of the driver. The main features of this application are to save tracking information with map integration of any trip without the need for direct connection to the vehicle as shown in Figure 8.

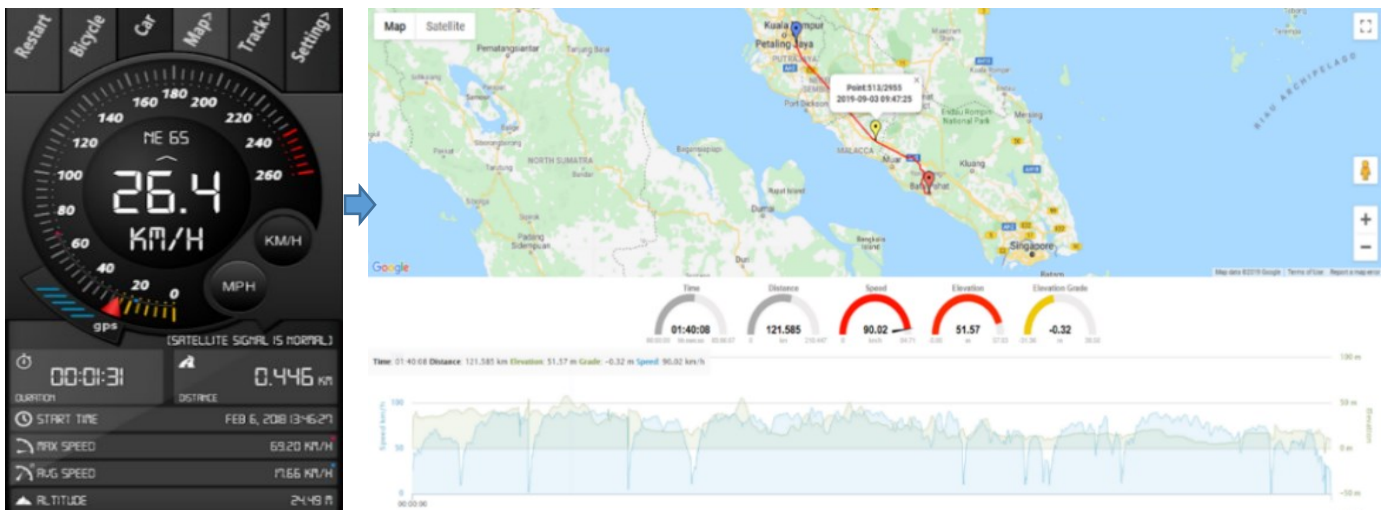

Figure 8: Map integration of digital dashboard GPS Pro software

Figure 9: Data recorded with digital dashboard GPS pro application

This application also provided complete information related to the experiments (time, speed, distance, Latitude and Longitude) as shown in Figure 9. The main difference between dashboard GPS Pro application and the Torque does not use the OBD-II adapter to record and save the data since it depends on the GPS signal available in the smartphone. The goal is to compare the data recorded in terms of accuracy and efficiency to use it in the proposed system to define drivers' behaviours.

3.4. Adafruit Ultimate GPS Breakout System

The Global Positioning System (GPS) is a radio navigation system based on satellites which provide a GPS receiver with geolocation and time information. The GPS does not require the user to send any data and functions independently of any telephonic or internet reception. However, these technologies can enhance the utility of GPS positioning information. The GPS provides military, civil, and commercial users around the world with essential positioning capabilities. An Adafruit Ultimate GPS Breakout - 66 channel w/10 Hz updates - Version 3 used in the data collection phase for further research designed around the MTK3339 chipset, a high-quality GPS module with an outstanding high-sensitivity receiver that can track up to 22 satellites on 66 channels (-165 dBm tracking), and a built-in antenna [35]. The system can build up to 10 position updates a second for high speed, high sensitivity logging, or tracking. Next, we can go forward and wired up the GPS device with the microcontroller as shown in Figure 10.

Figure 10: Adafruit ultimate GPS breakout Arduino wiring

Each GPS satellite transmits a radio signal continuously containing the current time and its location data. GPS receiver tracks and uses several satellites to assess their positions and the time it takes for the signals to reach them. At a minimum, four satellites must view the receiver for it to get a location fix. We used the Adafruit Ultimate GPS Breakout connected to an Arduino as our GPS receiver. It's very easy to set up by installing the Adafruit GPS library on the Arduino then proceed with parsing sketch which gave us all information required for the experiments to define driving behaviours as shown in Figure 11.

Figure 11: Arduino serial monitor for the Adafruit ultimate GPS breakout

4. Sites Study and Research Participants

In driving behaviour experiments, data are collected and extracted using different devices to quantitatively described and discussed for implementing in the proposed system. An instrumented vehicle was used to collect data on actual roads fitted with different sensors that detect the vehicle's speed, position, acceleration or deceleration, the RPM and total distance travelled by the vehicle. Data for driver behaviours were continuously observed in different periods of time. Ten drivers who participated in this study during data collection with different types of vehicles and scenarios using two periods for gathering driving data.

Figure 12 shows the road layout examples with varying sites of study from Google maps.

The first data collection was carried out in Malaysia for two months from mid of July to September 2019 recorded in Batu Pahat and Kuala Lumpur. In these experiments three drivers in three vehicles with a total of eight experiments done using (i) Perodua MyVi, 1.3 EZI - Facelift - 4 SP automatic, manufacture year is 2009, (ii) Toyota Estima X - 6 SP automatic, manufacture year is 2007 and (iii) Proton WAJA 1.6 - 5 SP automatic, manufacture year is 2006) (Figure 13).

The second data collection was carried out in Iraq for two months from December 2019 until end of January 2020 recorded in Baghdad and Babylon. Involve of seven drivers, three vehicles with a total of fifteen experiments; (i) Hyundai Sonata 2.4 - 6 SP automatic, manufacture year is 2015, (ii) Hyundai Santa Fe 3.5 - 6 SP automatic, manufacture year is 2011, (iii) Renault Safrane 2.0 - 5 SP automatic, manufacture year is 2010 (Figure 14). Drivers rode along a predetermined route and calculated and reported data on the driver's normal driving behaviour. In Batu Pahat, Malaysia, field experiments were carried out using mobile software to record driving styles to collect data for vehicle speeds of 10 and 20 km/h. Moreover, tests at an intersection on an urban road with a speed limit of 30 km/h extracted the vehicle's deceleration rate when the driver followed a lead vehicle and slowed down and then stopped at a stoplight. We conducted field experiments within UTHM to collect data for vehicle speeds between 30 and 50 km/h.

Figure 13: Vehicles used in this research in Malaysia

As with the previous studies, the experimental procedures were the same. At the time that, it slowed down behind a lead vehicle and stopped at a predefined point, we extracted the deceleration rates of the driver's vehicle. An intersection on a rural road with a speed limit of 40 km/h (one lane in each direction) was selected. Next, vehicle's speed to more than 60 km/h. The data collection process took place on the highway between Batu Pahat, Johor and Kuala Lumpur in Malaysia to collect data that represent high speed for analysis and definition of drivers' behaviours.

Moreover, all experimental procedures were repeated the same as the previous experiments, using different data collection types and done in other places. In the second period of the experiments that were in Iraq, we carried out the same scenarios as in Malaysia with different drivers, vehicles and devices used, noting that the steering wheel in the two countries is different. Still, this point emphasized in our experiments since the main goal is to collect driving data using different devices to reach the best, fastest and least expensive device to build the final system in the next steps, as it is mainly based on integrating drivers' behaviours with the V2V system. Several types of data collection devices were used

for drivers in different places, as shown in Table 1. It is found that drivers tend to be more unstable and sometimes aggressive in some situations, depending on the vehicles and the road. We propose an assessment method of driver behaviour to overcome these disadvantages. We evaluate the driver behaviour based on real behaviour observed in an experiment (Figure 15) instead of using estimated experimental data since the use of field experiment data for the driving behaviour can be fully reproduced which can be collected from different road environment.

In different road traffic scenarios, driving activity data may be obtained from one participant, which is used for the calculation, since the participant does not receive feedback about his/her exposure to the target situation. During a brief period of driving, an experiment was carried out to observe the driving profile. The behavior discussed in this study relates to speed, acceleration and driver control of the accelerator pedal. The data available from the OBD-II adapter used in the study are date, time, vehicle speed using an OBD adapter (km/h), vehicle speed using GPS (km/h), engine RPM (r/min), distance travelled (m), and vehicle position (latitude, longitude).

Figure 15: Installation of OBD-II adapter inside the vehicle

An accelerator pedal position (%) referring to a percentage of pedal movement from an existing position is secondary data required to validate the OBD-II adapter's data. The zero percent of the accelerator pedal position means that the pedal was disengaged, while the 100 percent pedal position indicates that the accelerator pedal was completely pressed (Figure 16). Since it is possible to obtain the acceleration and deceleration during the driving period using engine diagnostic and by analyzing the speeds that obtained, it is possible to determine the driver's general behaviour, whether it is dangerous or safe. The accelerator pedal is closely related to the fuel used, as it is related to the engine's fuel flow control. This project does not clarify the mechanical components' specifications, as it is out of the analysis scope.
Figure 16: Accelerator pedal position diagram recorded from OBD-II adapter

5. Data Processing

The driver's behaviour described in this work refers to an individual driving operation using various test vehicles. The behaviour mentioned was the usual feat that the driver often controls (speed, acceleration, accelerator pedal press). Initially, it should mention the following three concepts regarding the final design: speed, velocity, and acceleration to use in the proposed system to determine the driver's behaviour while driving. Speed

refers to the distance travelled during a period of time. Speed is a scalar quantity, and it is measured in units of distance divided by time. The commonly used formula for speed calculates average speed rather than instantaneous speed. In contrast, the instantaneous speed shows the speed at any given moment of the trip, as shown on the vehicle's speedometer. Therefore, in the proposed system, we rely on the current speed. Velocity refers to the rate at which, in a certain direction, an object changes location. It is determined by the displacement of space in a specific direction per unit of time. Directional velocity matters in the short term, but speed does not. In the equation, the instantaneous velocity shown in (1).

$$v = \frac{\Delta d}{\Delta t} = \frac{d_f - d_i}{t_f - t_i} \tag{1}$$

Δd represents the change in distance (final - initial), and Δt represents the change in time. Acceleration is a measure of how speed shifts rapidly. Acceleration is a vector quantity, like velocity, so any change in a moving body's direction is an acceleration, too. An increase in the magnitude of a moving body's velocity called a positive acceleration; a decrease in speed called negative acceleration. The acceleration expression is shown in (2).

$$a = \frac{\Delta v}{\Delta t} = \frac{v_f - v_i}{t_f - t_i} \tag{2}$$

Δv is the change of the velocity, which is equal to the difference between the initial speed and the final speed over time Δt, representing a change in time. To calculate the instantaneous behaviour of each driver, different OBD-II PIDs codes are used to request data from a vehicle to define driving style. The most commonly PIDs are defined in OBD library and used in the proposed system presented in Table 2. The adapter used can be plugged directly into the OBD-II port of the vehicle, providing a high efficiency module serial data interface (UART or I2C) and easy (up to 100Hz) access to all OBD-II PIDs available in the vehicle ECU.

Table 2: OBD-II PIDs details used in the system

Mode (hex)	PID (hex)	Data bytes returned	PID command	Unit	Description
01	0C	2	PID_RPM	RPM	Engine RPM
01	0D	1	PID_SPEED	Km/h	Vehicle speed
01	1F	2	PID_RUNTIME	Sec	Engine run time
01	21	2	PID_DISTANCE	Km	Distance traveled

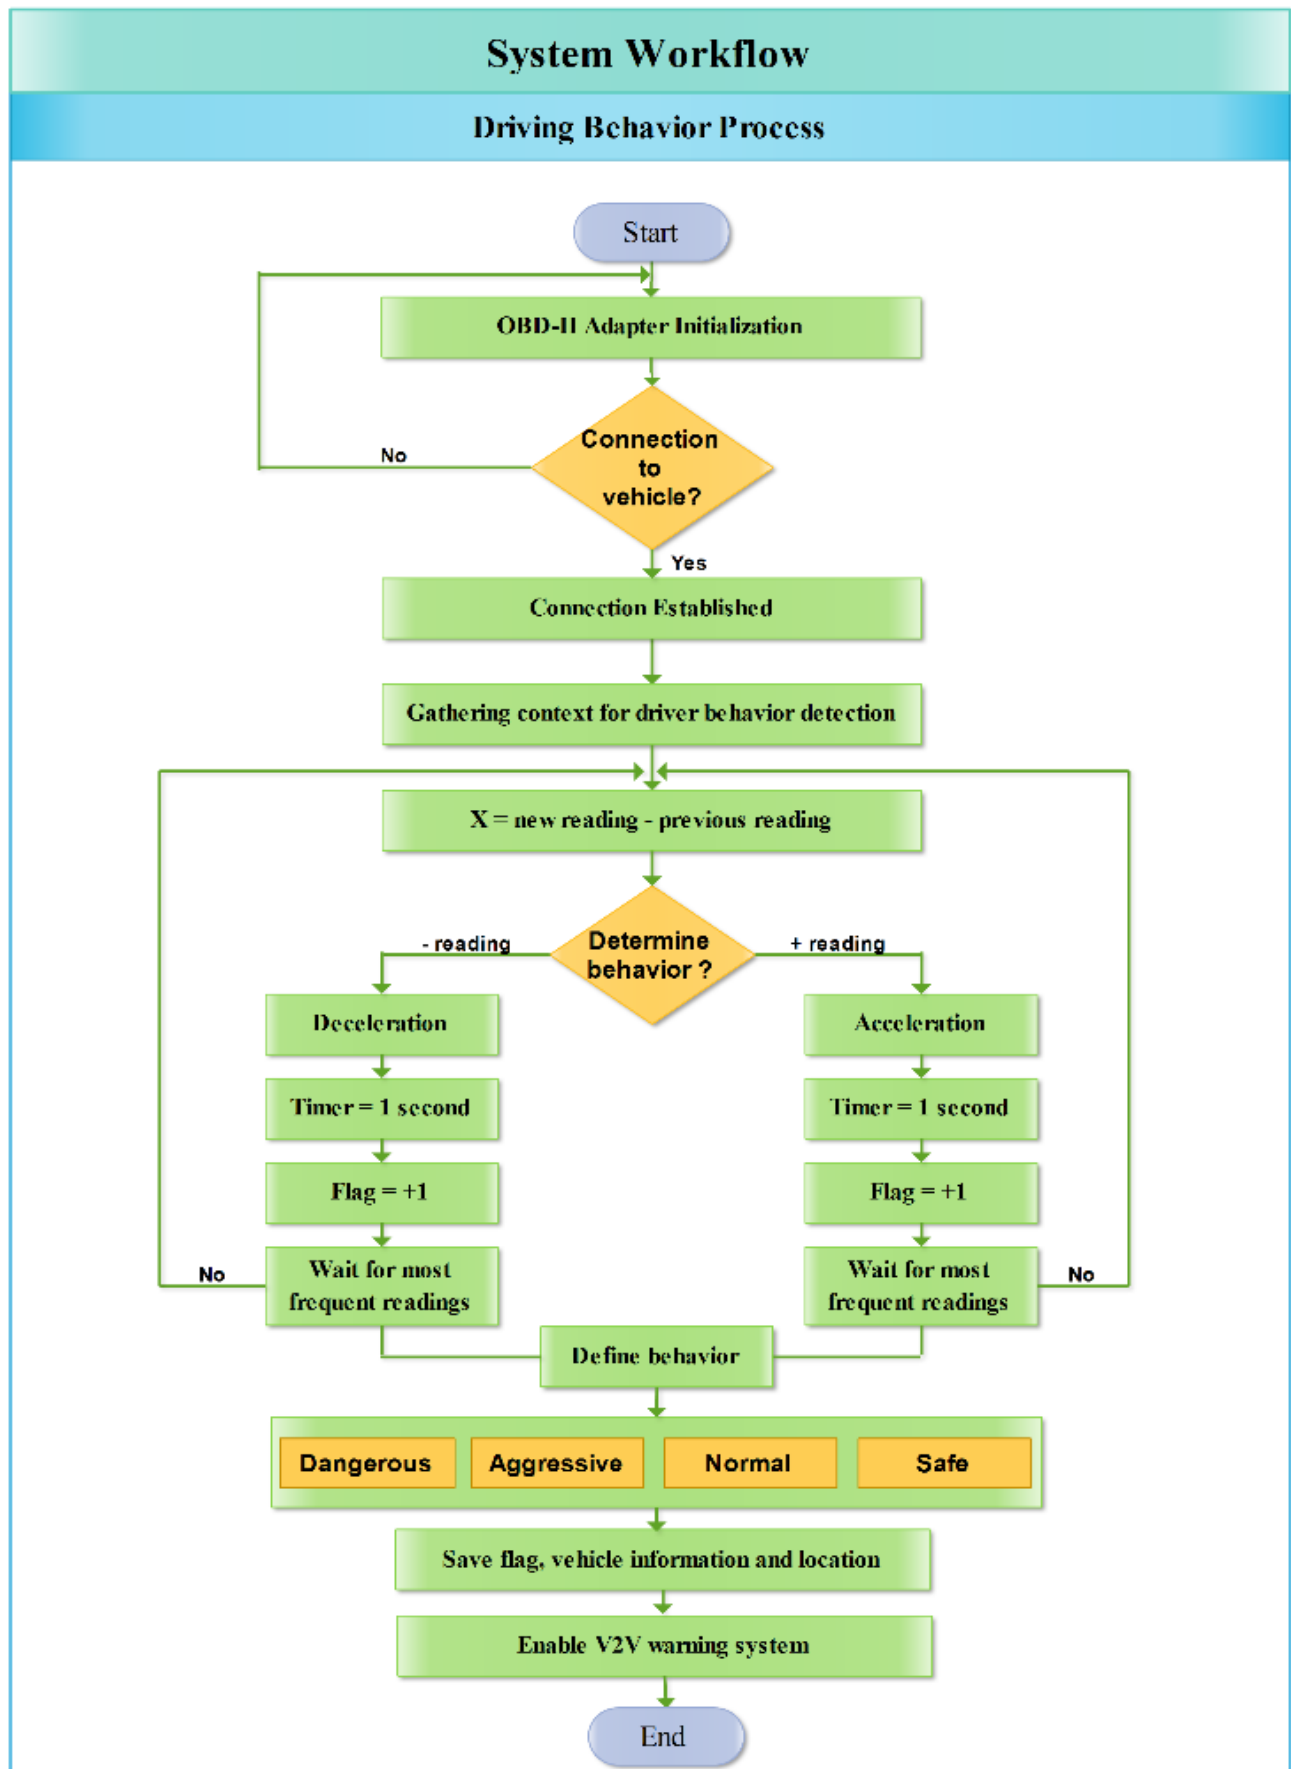
Engine start date and time, second-by-second vehicle location (latitude and longitude), heading, and speed are monitored by the onboard equipment. The equipment also provides up to ten engine and emission-related parameters directly connected to the OBD-II engine computer port from the onboard diagnostic system. For each engine ignition event, the equipment starts and saves a trip


Figure 17: Driving behaviours system flowchart

file. The trip file remains open recording second-by-second operations data until the vehicle operation stops and the driver shuts off the engine. This phase is done to check the research requirement, the restriction and the time needed to complete the research, then to develop a method to select the destination vehicle for the transmission of information gathered by the proposed system using wireless communication to exchange information between vehicles and to notify the driver of the aggressive drivers on the road. The first requirement for this calculation is to identify the subject driver with some certainty. The second requirement is to obtain valid and reliable measurements of speeding behaviour performance. Now to test the proposed method, firstly, the system defines drivers' immediate behaviour whether in acceleration or deceleration by taking a set of readings (5, 10 or any predefined value) in each second based on sensors used where Δt between any consecutive readings is one second. Next, the microcontroller converts vehicle speed (km/h) to acceleration values (m/s2) by taking advantage of the instantaneous values in Δt. After that, these values are stored with a special identifier to compare with the reference table to classify the behaviour according to the recorded values. Next, these data forwarded and stored in a matrix to find out the most frequent values and weighted as a momentary behaviour for that driver during the time period that passed (Figure 17).

The main program workflow represents the procedure of the driving behaviours data collection and identification process. Since the OBD does not have the User Interface (UI) to communicate with the driver, the proposed system would use an LCD screen to display the driving information and provide a driver-based V2V system collision warning. If the nearby vehicle can pass safely, the 'safe' signal is displayed. If the passing vehicle need to be aborted because it is unsafe, a 'not safe' signal displayed. This system gets the driving information of the surrounding vehicles using wireless transceiver device. We choose the nRF24L01+ PA LNA wireless transceiver. The nRF24L01+ PA LNA is common in the market and can be obtained at a very low price. It provides much better coverage than other devices. It can communicate over a four-pin serial peripheral interface with a maximum data rate of 10 Mbps. The power amplifier (PA) enhances the power of the signal, whereas the low-noise amplifier (LNA) amplifies the weak signal from the antenna to a more useful level to expand the transmission range of the antenna (to approximately 1000 m). Furthermore, all readings also stored in the form of flags in the Secure Digital (SD) card connected to the microcontroller to save all driving data for each day. As a result, drivers are required to increase awareness of their driving behaviour, as well as to alert transport and insurance providers of each driver's way of driving.

6. Numerical Results and Discussions

6.1. Speed collection and analysis

The speed collector devices used in experimental vehicles are the Freematics ESP32 OBD-II kit, ELM327- OBD-II Bluetooth and Wi-Fi adapter, Adafruit ultimate GPS breakout system and Digital dashboard GPS based on the mobile application. Based on the rotation speed of the vehicle wheels, the OBD-II speed is reported directly from the vehicle engine, while the speed recorded by a GPS system and mobile application based on sequential vehicle positions are used to validate the OBD-II speed. The investigation found a delay in speed data from location-based devices (Adafruit ultimate GPS breakout system and digital dashboard GPS pro application) compared to OBD-II adapter speed. This delay is known as the 'transit-time delay' which is used to triangulate location by the ground-based GPS receiver. The comparison between speeds was plotted graphically as shown in Figure 18.
Figure 18: Comparison of OBD-II adapter, mobile application and GPS device speed

Kurtosis	-0.227014659	-0.221509659	2.041838842
Skewness	0.75352705	0.738426854	1.489783928
Range	124	116.56	117

Count	1650	1650	1650

The independent-samples t-test using Statistical Package for the Social Sciences (SPSS) statistics compares two groups' means on the same continuous, dependent variable. In SPSS Statistics, we separated the groups for analysis by creating a grouping variable called a type of device used together with the recorded speed in real time. Descriptive statistical analysis was performed in SPSS and used to determine the extent of any differences between OBD-II adapters, GPS device and mobile application speed for all vehicles used in these experiments as shown in Table 3. It was found that the trend in OBD-II adapter speed was similar to that of mobile application speed data with some differences compared to the GPS device. As can be seen from the Table 3, the mean, standard deviation and skewness of the speed recorded by OBD-II adapter ($M = 42.2$, $SD = 30.7$, $SE = 0.75$) and mobile application ($M = 40.1$, $SD = 28.8$, $SE = 0.71$) which it can be observed that the results are close, with some variations from the GPS device ($M = 31.6$, $SD = 25.4$, $SE = 0.62$). Moreover, from observations the highest speed recorded by the OBD-II adapter (124 km/h) while the highest speed recorded by the remaining devices is almost the same (116.56 km/h and 117 km/h) for mobile application and GPS device respectively.

Table 3: Descriptive statistics of speed factor of OBD-II adapter, mobile application and GPS

Speed factor	OBD-II adapter	Mobile application	GPS
Mean	42.26727273	40.06415152	31.62424242
Standard Error	0.75732929	0.708743157	0.62654144
Median	35	34.585	26
Mode	0	0	24
Standard Deviation	30.76286118	28.78928315	25.45023361
Sample Variance	946.3536281	828.8228242	647.7143907

Furthermore, a detailed analysis was performed to find the similarities and differences between each of the devices used in the data collection of driving behaviour experiments. The analysis was carried out by comparing the OBD-II adapter speed and digital dashboard pro to find the individual value errors between them, as shown in Figure 19. Descriptive statistics and an independent T-test analysis were performed to determine the similarity of the OBD-II adapter and mobile application based speed profiles. The results are shown in Table 4 and Table 5. There was no significant difference in speeds recorded from experiments between OBD-II adapter speed ($M = 39.0$, $SD = 28.8$) and digital dashboard pro ($M = 37.5$, $SD = 27.8$); $t(4024.1) = 1.8$, $p = .071$.

Results show that device type in these experiments does not affect speed profiles at .05 level of significance. A small difference in the mean speed of OBD-II adapter and mobile application can be considered acceptable.

Table 4: OBD-II adapter and mobile application speed statistics

		Statistics			
	Device type	N	Mean	Std. Deviation	Std. Error Mean
Speeds recorded	OBD-II adapter	2042	39.0984	28.80644	.61485
	Digital dashboard pro	2037	37.4984	27.76627	.63953
Figure 19: Comparison of OBD-II adapter and mobile application speed

Table 5: OBD-II adapter and mobile application speed independent T-test

		Levene's Test for Equality of Variances		t-test for Equality of Means					95% Confidence Interval of the Difference	
		F	Sig.	t	df	Sig. (2-tailed)	Mean difference	Std. Error difference	Lower	Upper
Speeds recorded	Equal variances assumed	5.431	.020	1.798	4078	.072	1.59999	.88964	-.14418	3.34417
	Equal variances not assumed			1.804	4024.147	.071	1.59999	.88716	-.13933	3.33931

Different experiments and detailed analysis were performed to determine the extent of the differences between speeds for the OBD-II adapter and GPS device. The comparison between speeds was plotted graphically, as shown in Figure 20. It found that at certain times the OBD-II adapter speed was slightly different from the GPS speed. This can be clarified by the fact that the GPS estimates speed is based on position and the accuracy which depends on the number of satellites available to the receiver.
(a) differences points
(b) comparison between speeds

Figure 20: OBD-II adapter speed and GPS device speed

A descriptive statistics and an independent T-test analysis were performed to determine the extent of any differences between the OBD-II adapter and Adafruit Ultimate GPS based on speed profiles. The results are shown in Table 6 and Table 7.

There was a significant difference in the mean and standard deviation of speeds recorded from experiments between OBD-II adapter speed ($M = 42.7$, $SD = 30.8$) and Adafruit Ultimate GPS ($M = 31.6$, $SD = 25.4$); $t(3184.9) = 10.8, p = 0$. These results are shown that device type in these experiments affects speed profiles at .05 level of significance.

Further experiments were carried out to compare digital dashboard pro application with Adafruit Ultimate GPS to determine the extent of any differences based on speed profiles. The comparison between speeds was plotted graphically as shown in Figure 21. Descriptive statistics and an independent T-test analysis were performed as presented in Table 8 and Table 9. This showed that at certain times the Mobile application speed was slightly different from the GPS speed. There was a significant difference in speeds recorded from experiments between digital dashboard pro speed (M=41.3, SD=27.1) and Adafruit Ultimate GPS (M= 31.3, SD=23.9); t(4416.5) = 13.2, p= 0. Results have also shown that device type in these experiments has an effect on speed profiles at .05 level of significance.

For each of the measured parameters, the on-board data obtained in this research constructs a set of time series. However, the pace was still vulnerable to errors that were clearly seen once the acceleration was measured. In the GPS system, the speed was estimated based on the position of the vehicle. The efficiency of GPS speed data is highly affected by numerous factors, as presented in Table 10. The speed dissimilarity with a GPS device commonly occurred upon reaching high speeds (high acceleration) and once the vehicle stopped (high deceleration); while the OBD-II speed is logged directly from vehicle engine based on the rotation speed of the vehicle wheels. According to these points of view, the OBD-II adapter's speed was used for all analysis and the proposed system. To validate the OBD-II speed, the speed reported by a GPS system and mobile application was used based on sequential vehicle locations.

Table 10: Factors affecting the accuracy of GPS speed [36]

Factor	Description
Atmospheric effect	GPS precision can degrade atmospheric effects from satellite signals passing through the troposphere and ionosphere
Multipath effects	Multipath is when an item is bounced off by a GPS satellite signal and then hits a receiver. This influence distinguishes the time of signal arrival from what it would have been without reflection
Pit configuration	Shallow mines are perfect GPS candidates because they appear to have an open view of the sky.
Satellite geometry	When the overhead satellites have good spatial distribution instead of being clustered together in a portion of the sky, the best positional readings occur

6.2. Acceleration and RPM collection and analysis

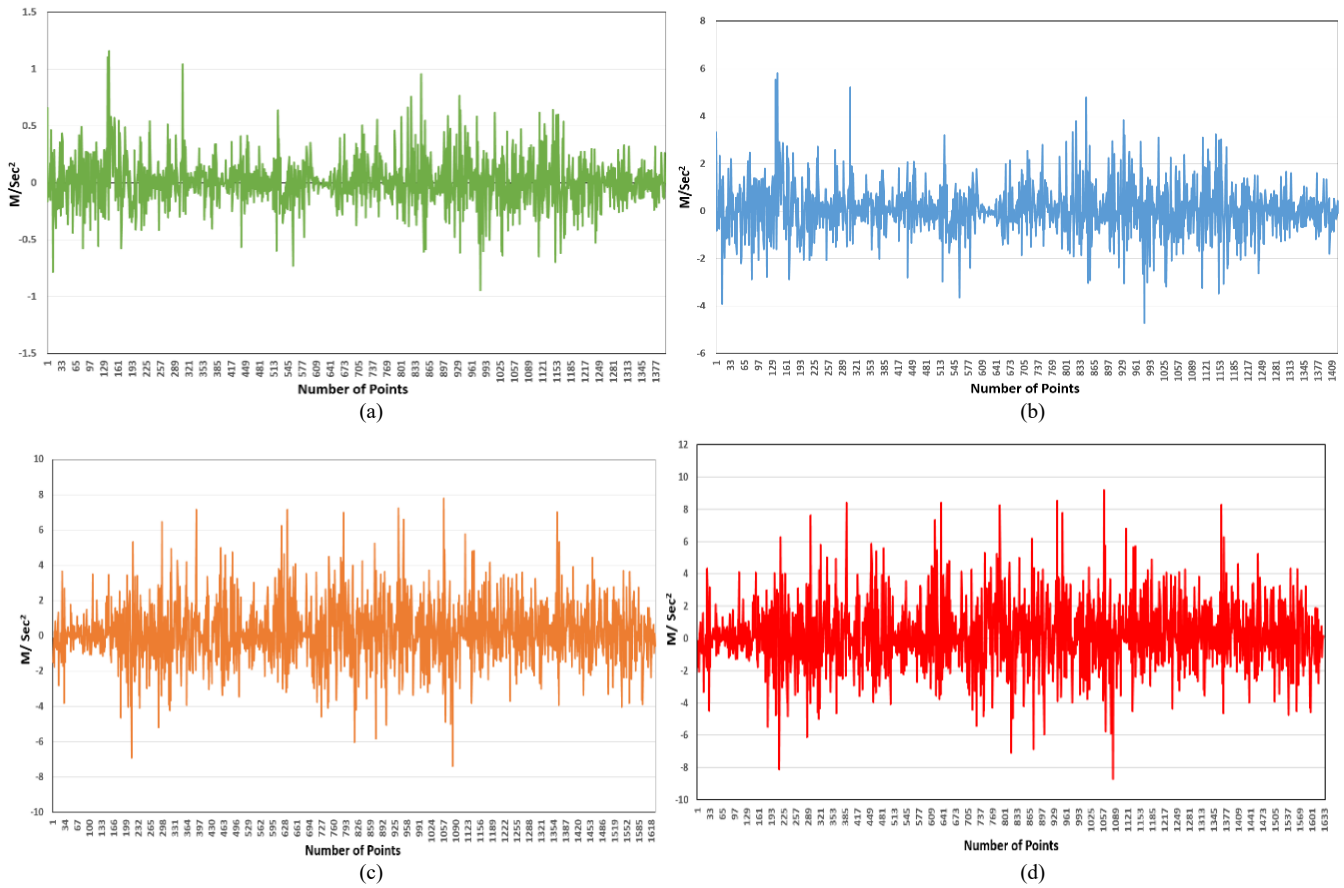
The prediction of the driving style based on the analysis of the drivers' behaviour and environmental data was one of this research's objectives. Acceleration and Engine RPM define a vehicle's motion. These parameters are also important for determining a driver's behaviour. To this end, the study of instantaneous vehicle parameters recorded by actual road tests is useful. Because of the developments in mobile sensing technologies and the technological capabilities of these devices, a variety of objective car and driving style data can be obtained, which can be used for driver style recognition based on OBD-II adapters. During a real test on the road, longitudinal and lateral accelerations on the y and x-axes can be reported on a vehicle. Through the study of parameters correlated with their driving, these parameters were used to classify the driver. To gather data for driving activities, we conducted a real-world experiment. In these experiments, while a driver carried out specific driving events, an Android application captured vehicle engine data. To produce the ground-truth for the experiment, the beginning and end timestamps of the driving events were recorded. When all the information was obtained, it was exported to the excel sheet. Each data form was placed on a separate table with the "acceleration and deceleration" key field, referring to the time of the case. Once the pre-processing was done, the data was prepared according to the actions of the drivers for the analysis phase. Several researchers discussed thresholds of acceleration linked to causality and a high risk of crash participation. The risk of collision start from -4.0m/s2 according to [20] while in [32, 37] similar results were obtained with a risk accident involvement around -5.0m/s2. In [17], the author proposed an acceleration/deceleration intensity stratification focused on numerous publications to provide an overview about the driving styles. In case of acceleration present the following parameters (dangerous (7.0 m/s2 - 12.0 m/s2), aggressive (3.5 m/s2 - 7.0 m/s2), normal (1.5 m/s2 - 3.5 m/s2) and safe (0 m/s2 - 1.5 m/s2)) and for deceleration (dangerous ((-9.0 m/s2) - (-14.0 m/s2)), aggressive ((-5.5 m/s2) – (-9.0 m/s2)), normal ((-3.0 m/s2) – (-5.5 m/s2)) and safe (0 m/s2 – (-3.0 m/s2)). Considering the mentioned works, we try to suggest an acceleration stratification consisting of a number of groups to test driver acceleration and braking based on our experiments to create a driving style table to enable the V2V alert system based on driving behaviours. It is possible to categorize driving behaviour into four major classes by calculating in-vehicle acceleration based on real time experiments: safe or non-aggressive drivers, normal, aggressive and dangerous drivers as shown in Figure 22.


Figure 22. Driving behaviour analysis based on acceleration data: (a) Safe acceleration, (b) Normal acceleration, (c) Aggressive acceleration, (d) Dangerous acceleration

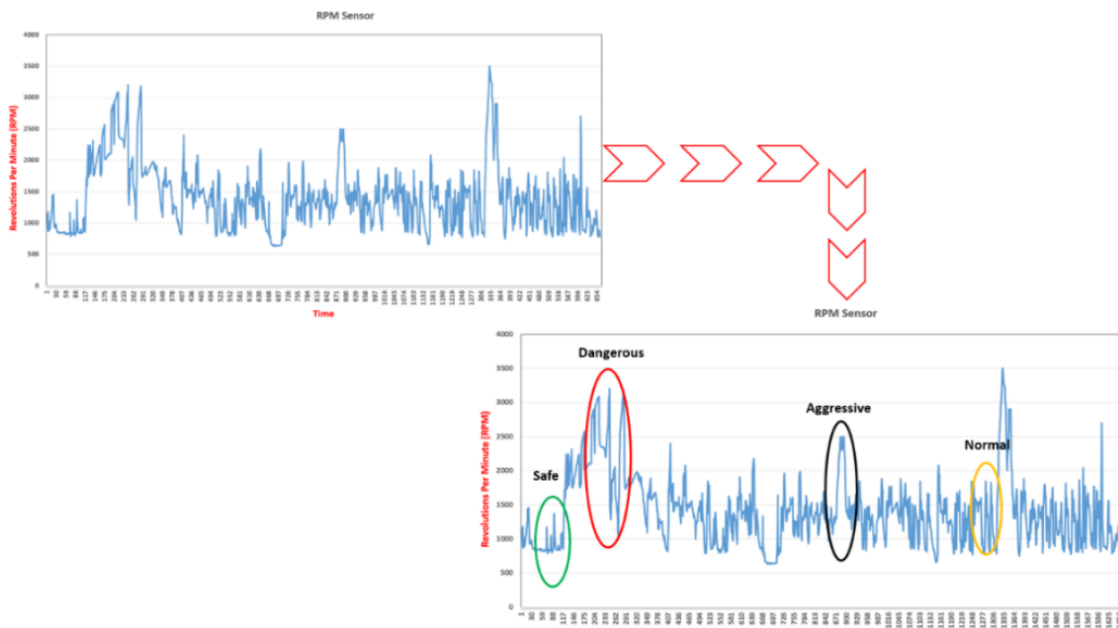
Furthermore, in driving behaviour data collection, different drivers and vehicles used to record the engine rotation represent Revolutions per minute (RPM) using the OBD-II adapter located below the driving panel. The pedal position test was carried out by pressing the accelerator pedal during different trips. The drivers informed when they had pressed the pedal as far as possible, and the duration was recorded. Furthermore, the accelerator pedal position over the time scatter plot as clarified in Figure 23 demonstrate that the maximum accelerator pedal ratio ranging from 1000 RPM to 4500 RPM recorded from different trips.


Figure 23: The visualization of Revolutions Per Minute (RPM) statistics

6.3. System deployment based on driving behaviours

The system algorithm provides an alert message and estimation distance for the vehicles about drivers' behaviour within the coverage area provided by the proposed system. Recognition of driving behaviour is a subjective mechanism that relies on the driver's interpretation and response to the changing external pressures of time. It is well known that the driving environment and behaviour are founded on a high degree of variability in individual experience and calculation. A high-level architectural framework that incorporates current technology and cognitive structures to build a new approach to the identification of trends in driving behaviour is, therefore a critical question. The results obtained from the different experiments (Figure 22), present accelerations data close to the values provided by previous researchers with some minor differences. These data have been injected into the proposed system to classify the driving performance as shown in Figure 24.

(a)

(b)

Figure 24: Network layout of point-to-point link: (a) transmitter, and (b) receiver

In this study a stratification of acceleration proposed in Table 11 with four main groups in acceleration and deceleration speed which represent one of the most reference tables used in the proposed V2V system.

Table 11: Defining behaviours based on experiments

Deceleration data (m/s^2)	Type of driving	Acceleration data (m/s^2)
0 to -2	Safe	0 to 2
-2 to -4	Normal	2 to 4
-4 to -7	Aggressive	4 to 7
Less than -7	Dangerous	More than 7

The safe driving behaviour is characterized by acceleration value that ranges from about ±2 m/s2. Normal driving, however, can also require more efficient but still planned braking, leading to more intense acceleration values ranging from 2 m/s2 to 4 m/s2. The risk of collision starts from 4 m/s2, which represented in this study the aggressive drivers. The dangerous evaluation indicates that the driver applies sudden movements in term of speeding starting from 7 m/s2. In the deceleration process and during these start and stop phases the lowest value of deceleration derivatives of safe and normal braking registered between -1 m/s2 and -3 m/s2, while conflict situations showed derivatives ranging from -3 m/s2 down to -8 m/s2 which represent the aggressive and dangerous driving style respectively. These differences in the acceleration data were observed for potential conflicts because of the difference of the drivers who carried out the experiments, as we note that some of them were driving in a natural way and the other was somewhat aggressively. The test results are successful, where it can be seen that the driver's behaviours were displayed based on the real-time acceleration readings taken from the OBD-II device connected to the vehicles as shown in Figure 25.

Figure 25: Test results of the proposed methods: (a) safe and (b) Normal. (c) Aggressive and (d) dangerous driving

The proposed algorithm uses OBD-II and nRFL24L01 transceiver, which can be installed in the passing vehicle. These sensors may give information such as the speed, position, and distance of the impeding and opposing vehicles. At each interval Δt, the sensors send a signal to search the lane for any oncoming traffic. Using a reading sensor and a processing unit with a driver-vehicle interface (DVI) unit, the algorithms follow the procedures to determine whether or not a "safe" message should be displayed for the driver of the passing vehicle. Furthermore, when the behaviour of the transmitted vehicle change, such as speed or acceleration, the system starts to calculate the accumulated behaviour for the last ten seconds then extract the most frequent

values. The risk of collision starts from 4 m/s2, which represents the aggressive drivers which indicates that the driver's behaviour starts to shift from the normal to the aggressive behaviours. These values in the acceleration data were observed for potential conflicts because of the difference of the drivers who carried out the experiments, as we note that some of them were driving in a natural way and the other was somewhat aggressively. Based on these data, the warning system is activated taking the advantages of the GPS device connected to the main board to extract the vehicle's current location in the term of longitudes and latitudes values then calculate these values in degrees. Moreover, these data were sent to the neighbouring vehicles and vehicle type and the flag status through the nRF24L01. On the other side at the receiving vehicle, the system displays the transmitted flag and use the GPS unit mounted on the receiving board to measure the distance between the two moving vehicles then switch on the orange LED with a continuous updating of the distance between the two vehicles whether the threat is approaching or drifting away as long as the sending vehicle is within coverage range of the receiving vehicle. An example of a warning signal displayed by the LCD is shown in Figure 26.
Figure 26: Test results of the proposed method for aggressive driving warning

$$Driver\ Safe\ Ration = \frac{number\ of\ safe\ flag\ behaviour}{number\ of\ safe\ flag\ behaviour + number\ of\ at\ risk\ behaviour} \times 100 \quad (3)$$
(a) Safe driving (87% total safe flags)
(b) Dangerous driving (40% total safe flags)

Figure 27: Test results of the proposed methods: (a) Safe flag and (d) dangerous flag driving

Recall from the introduction section, that behavioural safety programs operate based on measuring and monitoring safe behaviour performance. The opposite of safe behaviour in at-risk behaviour, which can be defined as behaviour that has been identified as critical to safe performance. A key concept for the research, taken from behavioural safety analysis, is the calculation of safe behaviour performance using a percent safe value calculated as (3).

Generally, in driving behaviours data collection experiments, multiple drivers participated in this study during the period of data collection using the proposed system with different types of vehicles and scenarios using. Figure 27 show the results of different examples with varying sites of study.

7. Conclusions

Despite the increasing research interest in V2V communication, limitations remain in existing studies in this area. Studies indicate that further research and development are needed to address these limitations, especially in driving behaviour. This work introduces a real-time V2V warning system based on driving behaviour. Comparison of the OBD-II and GPS data streams became available during the measurement on the smartphone screen with charts and other views. The independent data from mobile application and GPS device speed were used to validate and check the data collected from OBD-II adapter speed. Considering the mentioned works, we used the OBD-II adapter attached to the vehicle to trigger the V2V alert system based on driving actions, and we suggest a stratification of acceleration consisting of a variety of classes to test driver speed and braking based on our experiments. A severity stratification of acceleration/deceleration presented with the following parameters (dangerous (more than 7 m/s2), aggressive (4 m/s2 – 7 m/s2), normal (2 m/s2 – 4 m/s2) and safe (0 m/s2 – 2 m/s2)). In future studies, we would like to use the obtained data sets as input values for a machine learning environment to forecast parameter values in the future with prediction algorithms, decision trees, or time series analysis. Future studies could also use different communication modules such as Wi-Fi, Bluetooth and ZigBee. Different data types can be used during the test scenarios, including videos and voices data. In addition to that, the network can be tested up to the capacity of the transceiver. Such improvement would help to produce more understanding towards the purpose of the V2V installation, usage, cost, and the equipment of the developed system.

Conflict of Interest

The authors declare no conflict of interest.

A B S T R A C T

Revised Bloom's Taxonomy (RBT) is proposed in general to look more forward in responding to the demands of the developing educational community, including how students develop and learn and how teachers prepare Learning Objects (LO). The variety of characteristics of students' abilities in a class has always been a problem that is often faced by a teacher. Unfortunately, cognitive classifications to develop students' knowledge to a high level have not been used to plan a learning path that is appropriate for their cognitive level. The purpose of this study is to recommend a learning path that matches the cognitive abilities of students from a learning object ontology. The method used in this research is Hybrid Particle Swarm Optimization (HPSO) which integrates Binary Particle Swarm Optimization (BPSO) and Discrete Particle Swarm Optimization (DPSO). The Connection Weight (CW) function is used to test the quality of the connection between the learning objects of an ontology subject controlled by the cognitive class. Based on experimental studies, the HPSO method can recommend a suitable learning path for cognitive classes, namely Low Cognitive (CL), Medium Cognitive (CM), and High Cognitive (CH). The similarity of the sequence of learning paths based on population in CL-class is 87.5%, CM class 75%, and CH class 87.5%.

1. Introduction

In general, learning groups are designed to be heterogeneous. That is, a class is inhabited by students with various types of learning and characters. There are students with a fast learning type. While others are slow and even very slow. Therefore, it is difficult for teachers to follow an approach that is suitable for every student. In an effort to reach all students, teachers often design class lectures and activities. To remedy this situation requires personal support and guidance so that individual needs and difficulties can be addressed. However, given the number of students a class has, it is not easy for a teacher to deal with the diversity of levels and needs of students at all times [1].

Curriculum Sequencing (CS) is a technique to give students flexibility in planning the most appropriate sequence of individual learning tasks [2]. Produce an individual learning method in which each student dynamically chooses the most optimal teaching operation through presentations, examples, questions, or problems. Meanwhile [3] found the optimal learning sequence through the pretest to identify the weaknesses of students. Thus, CS aims to

replace the rigid, generic, modeled learning structure set by the instructor or pedagogical team, with a more flexible and personalized learning path.

CS development according to [4] must consider students' learning abilities, background, and motivation. Even for certain students, the requirements can change according to their increased knowledge due to learning. According to [5] states that CS not only helps students find the most efficient and appropriate learning path but also helps instructors to organize program structures, content, or learning objects and make improvements. Meanwhile [6] stated that individualization of teaching materials was a challenge in choosing the right LO and making the LO sequence easy to learn. Thus, optimal results will be obtained because the learning path of learning is following students' abilities. Learning paths that have been developed have not used cognitive classification as a controller of the learning object ontology of a subject. The Evolutionary Computing (EC) algorithm approach has been widely used in solving Curriculum Sequencing problems.

According to [7] the EC method that is most widely used to solve CS problems is grouped into two main approaches, namely the social sequencing approach and the individual sequencing

approach. Genetic Algorithm (GA) is a metaheuristic method which is famous because it has good performance for various types of optimization problems. There have been many GA studies in the CS domain including [8]-[11].

In [12] present a Personalized e-Course Composition approach based on Particle Swarm Optimization (PC2PSO). A binary particle encoding is used, in which each dimension determines whether the object of learning is included in sequence (1) or (0). The initial particles are generated randomly. The fitness function is used to determine Gbest and Pbest based on the level of compatibility between the pedagogical targets of students and the learning concept: learning material, level of compatibility, difficulty level, the time limit for learning, and student checks on the material that has been studied. Comparative evaluation in terms of average fitness and stability functions shows that the PSO method is better than the GA method. While the newer optimization method is swarm intelligence.

Swarm intelligence is an optimization method based on a distributed agent system, where each agent has simple abilities that can solve complex problems together. The approach to swarm intelligence is very different from EA because swarm intelligence emphasizes cooperation rather than competition. To support the concept of cooperation, each agent has a simple ability to learn from experience and also communicate with fellow agents. Metaheuristic methods based on the concept of swarm intelligence are Particle Swarm Optimization (PSO) and Ant Colony Optimization (ACO).

The PSO algorithm was originally proposed in 1995 [13]. In the PSO, each particle represents the solution to the problem. Particle learning consists of two factors, namely particle experience called cognitive learning and the combination of learning from the whole swarm is called social learning. Cognitive learning as Pbest is the best position that a particle has ever reached, while social learning as Gbest is the best position of all particles in the swarm. One of the uses of PSO in the e-education domain includes research conducted by [14] using the PSO method to offer formative value in e-assessment and turn it into a learning tool.

This research proposes a learning path model based on the cognitive classification of Revised Bloom's Taxonomy and an ontology of learning objects. Cognitive classification is based on RBT into three cognitive classes (Cognitive Low (CL), Cognitive Medium (CM), and Cognitive High (CH)). Hybrid Particle Swarm Optimization (HPSO) algorithm is used to solve combinatorial problems, namely learning object ontology with Discrete PSO which is controlled by cognitive class using Binary PSO. So that a learning path model will be produced that is following the cognitive abilities of students through optimization of the assessment of the LO relationship between RBT and the ontology of a subject.

2. Literature Review

2.1. Learning Object

Primary reference sources in the form of journals and dissertations, and secondary sources in the form of books, many have provided explanations about learning objects. However, in general, there is a common view of the concept of learning objects. The definition of a learning object is broadly described as all entities that are related or used as learning and training materials.

From this understanding, all general and conventional learning materials such as worksheets, modules, handouts, etc. are also included in the learning object category. Researcher [15] as well as a learning practitioner defines learning objects as each learning resource in the form of a digital entity that can be used repeatedly as a learning resource. While other researchers [16] presented various definitions of LO, the simplest description refers to data objects, content, or information.

The Institute of electrical and electronics engineer (IEEE) defines learning objects, namely as any digital or non-digital entity that can be used, then reused and can become a reference for technology-assisted learning. Thus LO is any entity (digital or non-digital) that can be reused or referenced including multimedia content, instructional content, software, people, organizations, or events for technology-supported learning. This definition leaves room for the entire curriculum to be seen as an LO.
Figure 1: Examples of learning object structures

Figure 1 shows that in one topic or one subject, the description of the content of the course is followed by the related learning material. In other words, subject content is usually arranged based on ontology, where the yellow circle represents the learning content while the blue rectangle represents LO [17].

2.2. Particle Swarm Optimization

The PSO algorithm works based on particles in the population that work together to solve existing problems disregarding the physical position. The PSO algorithm combines local and global search methods that balance exploration ability to conduct investigations in different areas of the search area to get the best optimal value and exploitation ability to concentrate around the search area for fix solution. The similarity of PSO and GA is that the system starts with a population formed from random solutions, then the system seeks optimization through random generation changes [18]. Each particle holds traces of position in the search space as the interpretation of the best solution (*fitness*) that had been achieved.

The basis of the PSO algorithm consists of three steps, namely determining the particle position and velocity, updating the velocity, and updating the position [19]. Each particle tries to update its position using information such as the current position, the current velocity, the distance between the current position to *Pbest*, and the current position to *Gbest* which mathematically updates the particle velocity calculated (1).

$$v_{i,j}^{t+1} = v_{i,j}^{t} + c_1 r_1 \left[Pbest_{i,j}^{t} - x_{i,j}^{t} \right] + c_2 r_2 \left[Gbest_{j}^{t} - x_{i,j}^{t} \right] \quad (1)$$

The achievement of the results is obtained from a new velocity calculation for each parallel based on the distance from the Pbest

it has and the distance from the Gbest position updating the particle position $x_{i,j}^{t+1}$ is shown in (2).

$$x_{i,j}^{t+1} = x_{i,j}^{t} + v_{i,j}^{t+1} \qquad (2)$$

Personal best (*Pbest*) according to [20] is the best value that a particle has, the value in the next time step, t + 1, where t ∈ [0,…, N], update *Pbest* is shown in (3),

$$Pbest_{i,j}^{t+1} = \begin{cases} Pbest_{i,j}^{t} & \text{if } fitness\left(x_{i,j}^{t+1}\right) \leq fitness\left(Pbest_{i,j}^{t}\right) \\ x_{i,j}^{t+1} & \text{if } fitness\left(x_{i,j}^{t+1}\right) > fitness\left(Pbest_{i,j}^{t}\right) \end{cases} \quad (3)$$

While the Global best (*Gbest*) is the best value that takes into account all particles in the population calculated using (4)

$$Gbest = max\{Pbest_{i}^{t+1}\}, \text{where } i \in [1, \dots, n] \text{ and } n > 1 \quad (4)$$

Each iteration, each particle is given information about the latest *Gbest* value so that a one-way information sharing mechanism occurs to carry out the process of finding the best solution with a fast convergence shift.

2.2.1. Binary Particle Swarm Optimization (BPSO)

In [21] developed PSO to operate in binary search space because real value domains can be converted into binary valued domains. The proposed algorithm is called the PSO binary algorithm (BPSO) in which particles represent positions in binary space and the particle position vectors can take a binary value 0 or 1 where $x_{ij} \in \{0,1\}$. In this case, it maps from the binary space of the dimension B^n (an eg string of bits of length n) to the real number $f = B^n \rightarrow R$ (where f is the fitness function and R is the set of real numbers). That means that the position of the particle must belong to B^n to be calculated by the fitness function [22]. In BPSO, the particle velocity v_{ij}^{t} is connected to the probability that the particle position x_{ij}^{t} is 0 or 1. Equation (1) for updating particle velocity is still used in BPSO. Then the sigmoid function S_{ij}^{t} shown in (5) is used to update the particle velocity.

$$S_{ij}^{t} = \frac{1}{1+e^{-v_{ij}^{t+1}}} \qquad (5)$$

The position of the particle x_{ij}^{t} is influenced by (6), where u_{ij}^{t} is a random number selected from the distribution (0, 1) and S_{ij}^{t} of the sigmoid function.

$$x_{ij}^{t} = \begin{cases} 1 \text{ if } u_{ij}^{t} < S_{ij}^{t} \\ 0 \text{ if } u_{ij}^{t} \geq S_{ij}^{t} \end{cases} \qquad (6)$$

2.2.2. Discrete Particle Swarm Optimization (DPSO)

In 2000, Clerc modified the DPSO algorithm formulated by Kennedy and Eberhart. Clerc modifies the representation of the position of the particle, the shape of the velocity produced by the particle, and the effect of velocity on the position of the particle. This modification hopes that it can be applied to problems with discrete models, especially combinatorial types [23]. The velocity update formula that has been modified by Clerc is defined in (7), while for fixed position updates using (1).

$$v_{i}^{t+1} = c_1 \cdot v_i^t \oplus c_2\left(\left(Pbest_i^t + \frac{1}{2}(Gbest_i^t - Pbest_i^t)\right) - x_i^t\right) \qquad (7)$$

3. Methodology

The Hybrid Particle Swarm Optimization algorithm is applied to overcome combinatorial problems in a more practical and orderly manner in determining learning pathways. Determination of the order of learning objects through LO ontology based on cognitive classes from the learning vector quantization method and using RBT to assess connection quality. The expected result is that each student gets a recommendation for a learning path that is appropriate to their cognitive level.

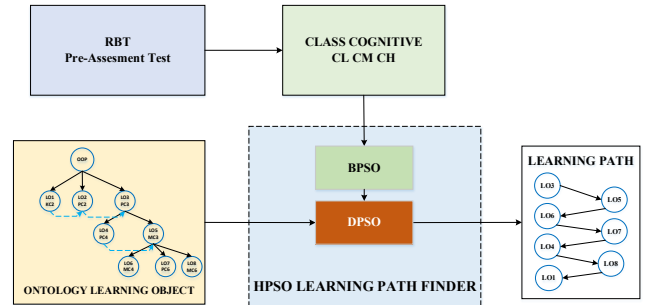
The model used in this study consists of three components, cognitive classification with LVQ, learning object ontology based on RBT, and hybrid discrete particle swarm optimization. The general architecture of the proposed model can be seen in Fig. 1.


Figure 2: The Architecture of The proposed Model

3.1. Particle Representation BPSO

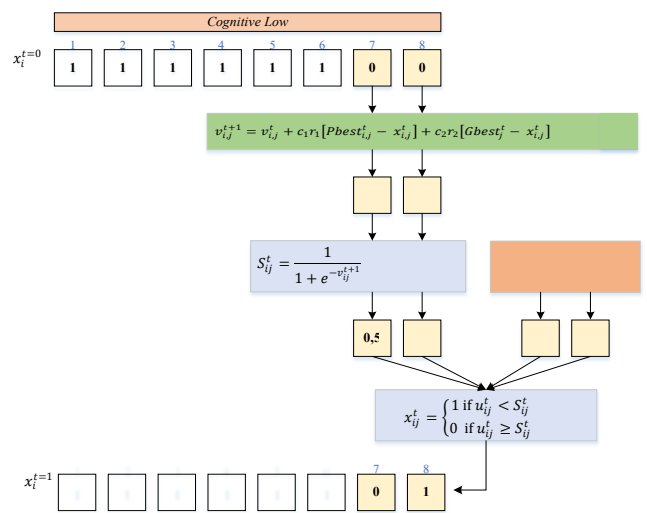
The representations of the particles of the three cognitive classes (CL, CM, CH) were arranged according to a predetermined LO sequence. Each cognitive class is placed in 8 data slots, so it takes 24 data slots. The Cognitive Low class on particles 7 and 8, the Cognitive Medium class on particles 1, 4, 8, and the Cognitive High class on particles 1, 2, 4, have a value of 0. This value of 0 indicates that the value at the position of these particles can change from 0 becomes 1 depending on the speed and position of the particles. Meanwhile, the value of particles with a value of 1 is determined as LO which must be followed and the calculation is carried out which is not affected by the particle velocity. The updated particle velocity and position of the CL cognitive class are presented in Figure 3.


Figure 3: Update velocity and position in cognitive class

3.2. Particle Representation DPSO

LO particles consist of eight particles arranged based on object-oriented programming lessons that have been determined based on

the depth and breadth analysis of RBT, namely Table I. The representation of LO-LO sequence particles is shown in Figure 4 randomly from three groups of particles.

Figure 4: Learning Object Particle Representation

Update the position of the learning object using (1) while for speed update using (7). The process of updating the speed of learning objects begins with the process of reducing *Gbest* with *Pbest*, where $Gbest_i$ [5 3 4 8 1 7 6 2] is used as a reference in the transposition process. The transposition stage starts with a shift in the learning object starting from (1,5) and several times the position shift from position (2,6) - (3,4) - (5,7) - (6,7) and stops at the position shift (7,8) after equal to the reference value $Gbest_i$ [5 3 4 8 1 7 6 2]. Based on (7) the temporary velocity value is multiplied by 0.5 to produce the velocity, namely (1.5) (2,6) (3,4).

3.3. BPSO – DPSO Integration

HPSO is the part that performs the process of determining the learning path, consisting of BPSO and DPSO. Cognitive classes (CL, CM, and CH) are represented as particles in the BPSO method and ontology learning objects are represented as particles in the DPSO method. The integration of BPSO and DPSO through the fitness function will produce a learning path model that is suitable for students' cognitive abilities.

Figure 5 shows the process of updating the speed and position of particles for DPSO and BPSO in each iteration so that it will ensure changes in LO and cognitive class (CL, CM, CH). Update the velocity and position of DPSO particles on the learning object update through (7) to update the particle velocity, and use (2) to

update the position. Meanwhile, the update of the speed and position of BPSO particles in the cognitive class is through (1) to update the speed, (5) to calculate the sigmoid S_i^t value, and (6) to update its position.

3.4. The Proposed HPSO Algorithm

The fitness function is used as a measuring tool to select the best object from a set of existing objects. The fitness function is identical to the objective function of the optimized problem, which is to make the best individual learning route according to their cognitive abilities. The objective function is determined based on the highest fitness value. The higher the fitness value, the results are closer to the objective function.

The objective function defined in this research is to create individual learning paths or routes based on student cognitive data, namely CL, CM, and CH with the learning object ontology of a subject. Thus, the fitness function is to find the best Connection Weight (CW) value between LO in ontology-based on students' cognitive classes, namely CL, CM, and CH as illustrated in Figure 6.

Connection Weight (CW) was used to assess the relationship of LO in RBT ontology as cognitive level evaluators (8).

$$cw = \frac{k}{t_1 \cdot |DBO| + t_2 \cdot |DBB|} \tag{8}$$

This study uses Distance by Bloom (DBB) to measure the cognitive distance depth and breadth ($d_{k,l}$) between LO using (9),

$$d_{k,l} = \sqrt{(k_2 - k_1)^2 + (l_2 - l_1)^2} \tag{9}$$

Equation (10),(11),(12) FC_L , FC_M , FC_H is fitness function to determine LO relationships in CL,CM,CH class,

$$FC_L = cw_L + \frac{1}{\beta_L * \sum ULO_L} \tag{10}$$

$$FC_M = cw_M + \frac{1}{\beta_M * \sum ULO_M} \tag{11}$$

$$FC_H = cw_H + \frac{1}{\beta_H * \sum ULO_H} \tag{12}$$

with:
$\beta_L, \beta_M, \beta_H$ is 0 -1.
cw_L, cw_M, cw_H is *connection weight* for each class cognitive
ULO_L, ULO_M, ULO_H is *unsed LO* for each class cognitive.
Figure 5: DPSO-BPSO integration in updating the velocity and position of particles

$$cw = \frac{k}{t_1 \cdot |DBO| + t_2 \cdot |DBB|}$$
Figure 6: Illustration of Determining the Fitness Function

The objective function value is calculated for all the particles generated earlier. The PBest position is determined from the objective function value obtained. The initial velocity of the particles is the absolute difference between the initial position and the personal best position of the particles. The particle with the maximum objective function value is the GBest particle and the corresponding position is the global best position [24]. The calculation of the fitness function stops until the iteration value limit has been determined.

The Hybrid Particle Swarm Optimization algorithm with a learning object transposition function is presented in detail in Table 1.

4. Results

Testing the HPSO algorithm to recommend a learning path model that suits the CL, CM, and CH cognitive classes through steps, i.e:

a. Testing the next computational program, test the consistency of the PBest fitness function for each population to become GBest through five particle populations, ten particle populations (ten LO groups), and fifteen populations (fifteen LO groups).

b. Groups of students in cognitive classes CL, CM, and CH will get the best learning path recommendations based on their respective GBest.

4.1. Connection Weight for Fitness Fuction

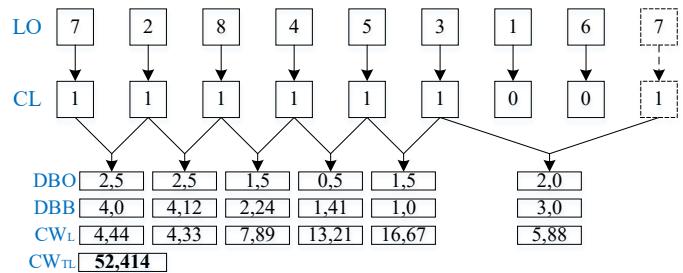
A CW calculation process occurs when one LO is paired together with CL of value 1. The calculation starts with finding the DBO, DBB, and CW values of each LO. In the state of one LO paired together with CL is 0 then the LO is not used in the connection weight calculation process. The mechanism for testing connection weight according to in accordance with the procedure shown in Figure 7.


Figure 7: Representation of Connection Weight

The fitness function in the CL,CM,CH-class is calculated using (10),(11),(12) ,the $Pbest_i^t$ fitness value data with 15 groups of particles is shown in Figure 8.
Figure 8: Pbest Values for Each Cognitive Class

Pbest tests through the fitness function in the CL, CM, and CH classes show that the higher the iteration used, the more optimal the solution will be from the system, marked with the increasing fitness results. This is due to the increasing number of iterations used to make the particles move to find the optimal solution so that the particles can find the optimal solution.

4.2. Learning Path Recommendation

Gbest is the best value that takes into account all particles in Gbest the population in each CL, CM, and CH class. Each iteration, each participant is given information about the latest Gbest value so that there is a mechanism for sharing one-way information to carry out the process of finding the best solution with a fast convergence movement.

Learning path recommendations based on the *Gbest* values shown in Table 2 indicate that an increase in the number of particles affects the value of the resulting learning path sequence, but is still within the schema of each cognitive class.

Table 2: Learning Path Recommendation

No	Class Cognitive	Number Of Particles	Learning Path	
			HPSO	Manual Set
1	CL	10	1-3-2-5-4-6-7-8	1-2-3-4-5-6-7-8
2		15	1-2-3-5-4-6-7-8	
3	CM	10	3-5-6-7-4-2-8-1	1-2-3-4-5-6-7-8
4		15	3-5-7-6-2-4-8-1	
5	CH	10	8-5-7-6-4-3-1-2	1-2-3-4-5-6-7-8
6		15	8-5-7-6-4-3-2-1	

The HPSO algorithm can create learning pathways by CL, CM, and CH cognitive classes. The cognitive class CL tendency of its learning path (1-3-2-5-4-6-7-8) shows the order of the basic LO to a higher LO. Whereas the cognitive class CH of the learning path tendency (8-5-7-6-4-3-1-2) shows a sequence of high LO to the basic LO. In CM cognitive class the tendency of learning path is (3-5-7-6-4-2-8-1). The similarity of the learning path sequence based on the number of CL cognitive particles is 87.5%, CM is

75%, and CH is 87.5%, so the average similarity of the learning path sequence is 83.3%.

The results of the learning path model research using HPSO have been presented and explained to three education experts. The recommendation of three education experts stated that cognitive classification with LVQ and the logical flow learning path model was acceptable. Researchers can prove the use of RBT through the results of learning paths based on cognitive low (CL), cognitive medium (CM), and cognitive high (CH). The HPSO learning pathfinder is a very important part of combining the output of the LVQ cognitive classification with the ontology learning object.

The advice given from education experts is as follows, the dynamics of the interrelation between the depth of the material and the breadth of the material can be determined by the teacher or teacher based on competency targets to produce a learning path in accordance with the characteristics of students. This research can be developed in the realm of attitudes and skills in accordance with learning evaluation competencies, namely, attitudes, knowledge, and skills.

5.   Conclusion

The Hybrid Particle Swarm Optimization method, which consists of DPSO for learning object ontology and BPSO in cognitive classes, can be applied more practically and regularly to produce a learning path recommendation. Based on experimental studies and verification of education experts, the HPSO algorithm in this research can recommend a suitable learning path for students classified in the CL, CM, and CH cognitive classes.

Further research is the integration of the Learning Vector Quantization method with Hybrid Particle Swarm Optimization in a platform that is supported by the provision of standard learning object ontologies that can be the right and efficient solution in the development of smart e-learning mode during the Covid-19 pandemic.

We introduce a sign algorithm based on the normalised least mean square with Hammerstein adaptive filtering using adaptive averaging step-size mechanism, which is derived by the minimised absolute a posteriori squared error. To improve the performance by reducing computational complexity, we suggest an adaptive averaging using energy of errors to update step-size variant. The analysis of convergence behaviour and mean square performance are derived. Experimental results reveal that the proposed algorithm can perform better than the least mean square approach based on the Hammerstein model of adaptive filtering.

1 Introduction

Advantages of the adaptive linear filters are simply used in various applications. However, the linear models underperform when comparing with the nonlinear models. Over the last few years, the spline adaptive filter (SAF) structure [1], [2] i.e. Hammerstein spline filtering [3] in cascade architecture [4] has been applied in many practical engineering fields as for example. SAFs based on the set-membership approach [5] and infinite impulse response [6] have been introduced for using in the impulsive noise environment.

In some particular nonlinear problems, the Hammerstein SAF (HSAF) [3], the combined Wiener-Hammerstein SAF [1], and cascade SAFs or sandwich SAF models [4] based on the least mean square (LMS) can operate effectively to identify for nonlinear systems identifications. It provides a good potential for low cost implementation in hardware. Based on the normalised version of LMS (NLMS) on HSAF have been performed in [7]-[10]. In [7], the authors have pointed out the derivation of HSAF on NLMS. In [8], the authors have proposed the performance analysis of HSAF based on the stochastic gradient algorithm. To counteract with impulsive noises, the sign normalised Hammerstein spline adaptive filtering

has been proposed in [9] and its performance shown in [10].

In order to reduce the computational requirements of NLMS, the simplifications of NLMS approach in the form of a sign algorithm has been presented in several applications [11]-[16]. To further diminish and protect the impulse noise, the sign normalised SAF [11], [12] and sign subband adaptive filterings with variable step-size parameter [13]-[15] have been designed. In [16], the robust shrinkage normalised version of sign algorithm has been implemented.

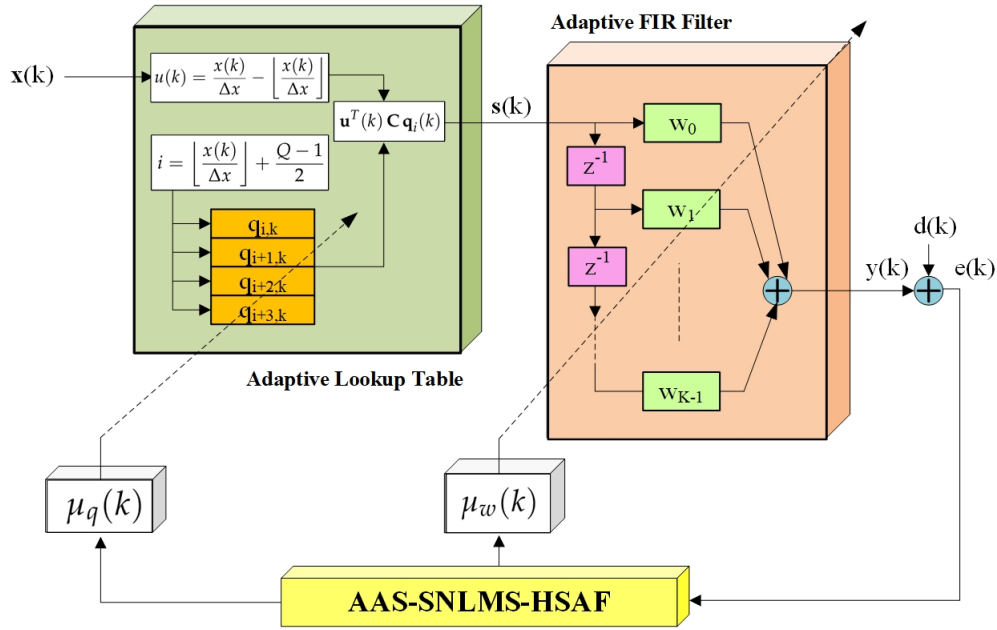
Recently, an approach based on the stochastic gradient method for improving the convergence rate based on SAFs has been established in [3], [17]-[19] resulting in the low computation and high performance. For nonlinear systems, the authors in [17] have presented NLMS for SAF. In [18], the adaptive step-size mechanism for SAF has been proposed with the fast convergence and robustness. In [19], the authors have proposed the normalised version of least mean square algorithm for spline adaptive filtering based on the adaptive step-size method with the averaging energy on the previous and present errors and their properties of stability analysis have been introduced.


Figure 1: Proposed Adaptive Averaging Step-size Sign Normalised Least Mean Square algorithm for Hammerstein Spline Adaptive Filtering (AAS-SNLMS-HSAF).

In this paper, we propose a statistical behaviour analysis of a Hammerstein spline adaptive filter based on the sign version of normalised least mean square algorithm with adaptive averaging step-size (AAS-SNLMS-HSAF). To enhance the convergence speed with low computational complexity, the adaptive averaging step-size algorithm is suggested.

Also, the performance analysis of sign version of NLMS-HSAF based on adaptive step-size mechanism using averaging energy of errors are derived. We encounter the relationship between the step-size parameter and the mean square error from the analysis that can be examined numerically in the computer simulations for an example of system identification.

This paper is organised as following. Section 2 clarifies the HSAF structure based on LMS approach in brief. Section 3 introduces the constraint criterion of the cost function based on the stochastic gradient descent with the adaptive averaging step-size mechanism. The energy of errors is exploited to update the variant of step-size parameter. Section 4 explains how to derive the convergence analysis of HSAF-based algorithm that consists of the convergence properties and the mean square behaviour analysis. Furthermore, the simulation experiment design and experimental results are detailed in Section 5 and Section 6. Finally, Section 7 discusses and Section 8 concludes the proposed algorithm.

2 Hammerstein Spline Adaptive Filtering

The structure of Hammerstein spline adaptive filtering (HSAF) is depicted in Figure 1. It consists of a nonlinear model controlled by adaptive lookup table (LUT) [20] in which the adaptive control points vector is interpolated by the spline function and adaptive linear finite impulse response (FIR) filter [7].

The vectors $\mathbf{x}_k$ and $\mathbf{s}_k$ at symbol k appear the input and output vectors of adaptive LUT as

$$\mathbf{s}_k = \mathbf{u}_k^T \, \mathbf{C} \, \mathbf{q}_{i,k} \, , \tag{1}$$

$$\mathbf{u}_k = [u_k^3 \;\; u_k^2 \;\; u_k \;\; 1]^T \, , \tag{2}$$

where C is a spline matrix, $\mathbf{q}_{i_k}$ is the control point vector as $\mathbf{q}_{i,k} = [\; q_{i,k} \;\; q_{i+1,k} \;\; q_{i+2,k} \;\; q_{i+3,k} \;]^T$. The local parameter u_k and index i can be estimated as [3]

$$u_k = \frac{x_k}{\Delta x} - \left\lfloor \frac{x_k}{\Delta x} \right\rfloor \, , \tag{3}$$

$$i = \left\lfloor \frac{x_k}{\Delta x} \right\rfloor + \frac{Q-1}{2} \, , \tag{4}$$

where Δx is the uniform space between two-adjacent control points, Q is the number of control points, and operator $\lfloor \cdot \rfloor$ is floor operator.

We can obtain the minimised cost function based on LMS for HSAF as

$$J(\mathbf{w}_k, \mathbf{q}_{i_k}) = \min_{\mathbf{w}, \mathbf{q}} \left\{ \frac{1}{2} \, e_k^2 \right\} \, , \tag{5}$$

where e_k is given as [3]

$$e_k = d_k - y_k = d_k - \mathbf{w}_{k-1}^T \, \mathbf{s}_k \, , \tag{6}$$

where y_k is the HSAF output, d_k is the desired signal and $\mathbf{w}_k$ is the adaptive FIR coefficient vector.

By using the chain rule, the cost function in (5) is derivative with respect to (w.r.t.) $\mathbf{w}_k$, $\mathbf{q}_{i,k}$. The result is set to zero to find optimal points. So, the adaptive FIR coefficient vector $\mathbf{w}_k$ and the update control points coefficient vector $\mathbf{q}_{i,k}$ are demonstrated in the recursive form as

$$\therefore \;\; \mathbf{w}_{k+1} = \mathbf{w}_k + \mu_w \, \mathbf{s}_k \, e_k \, , \tag{7}$$

$$\therefore \;\; \mathbf{q}_{i,k+1} = \mathbf{q}_{i,k} + \mu_q \, \mathbf{u}_k \, \mathbf{C}^T \, \mathbf{w}_k \, e_k \, , \tag{8}$$

where μ_w and μ_q are the fixed step-size parameters.

3 Proposed Adaptive Averaging Step-size Sign Normalised Least Mean Square Algorithm

We extend the scope of sign algorithm into Hammerstein spline adaptive filtering (HSAF) based on the normalised version of LMS, named SNLMS-HSAF derived by minimised absolute *a posteriori* error as shown in Figure 1.

The constraints of this optimisation problem are formulated as

$$\min_{\mathbf{w}} \{ e_k'^2 \} = \{ d_k - \mathbf{w}_{k+1}^T \mathbf{s}_k \}^2 \ , \tag{9}$$

subject to

$$\| \mathbf{w}_{k+1} - \mathbf{w}_k \|^2 \le \xi^2 \ \text{ and } \ \| \mathbf{q}_{i,k+1} - \mathbf{q}_{i,k} \|^2 \le \xi^2 \ , \tag{10}$$

where e_k' is *a posteriori* error and ξ^2 is a small parameter in the gradual update of coefficient vectors.

From [9], the constrained cost function using Lagrange multiplier can be illustrated by

$$\Im(\mathbf{w}_k) = \min_{\mathbf{w}} \{ e_k'^2 \} + \frac{\lambda_0}{\mathbf{u}_k^T \mathbf{u}_k} \cdot \left[\| \mathbf{w}_{k+1} - \mathbf{w}_k \|^2 \le \xi^2 \right] , \tag{11}$$

where λ_0 is the Lagrange multiplier.

Hence, the derivation of $\Im(\mathbf{w}_k)$ in (11) w.r.t. $\mathbf{w}_k$ is set to zero,

$$-2 \, \mathbf{s}_k \cdot \text{sgn}\{e_k'\} + 2 \, \frac{\lambda_0}{\mathbf{u}_k^T \mathbf{u}_k} \cdot \| \mathbf{w}_{k+1} - \mathbf{w}_k \| = 0$$

Therefore, the adaptive FIR vector $\mathbf{w}_k$ is recursively formulated by

$$\mathbf{w}_{k+1} = \mathbf{w}_k + \mu_{w_k} \frac{\mathbf{s}_k \cdot \text{sgn}\{e_k'\}}{\mathbf{u}_k^T \mathbf{u}_k + \varepsilon} \ , \tag{12}$$

where μ_{w_k} is an adaptive step-size of $\mathbf{w}_k$ and $\text{sgn}\{\cdot\}$ is the sign function. The regularisation parameter ε is a small constant.

Similarly, the constraints of the cost function regarding with $\mathbf{q}_{i,k}$ can be shown as

$$\Im(\mathbf{q}_{i,k}) = \min_{\mathbf{q}} \{ e_k'^2 \} + \frac{\tilde{\lambda}_0}{\mathbf{u}_k^T \mathbf{u}_k} \cdot \left[\| \mathbf{q}_{i,k+1} - \mathbf{q}_{i,k} \|^2 \le \xi^2 \right] . \tag{13}$$

Considering the derivation of $\Im(\mathbf{q}_{i,k})$ in (13) w.r.t. $\mathbf{q}_{i,k}$ is equal to zero, we have

$$-2 \, \mathbf{u}_k^T \cdot \mathbf{C} \cdot \mathbf{w}_k \cdot \text{sgn}\{e_k'\} + 2 \, \frac{\tilde{\lambda}_0}{\mathbf{u}_k^T \mathbf{u}_k} \cdot \| \mathbf{q}_{i,k+1} - \mathbf{q}_{i,k} \| = 0 . \tag{14}$$

Finally, the updated control points vector $\mathbf{q}_{i,k}$ is

$$\mathbf{q}_{i,k+1} = \mathbf{q}_{i,k} + \mu_{q_k} \frac{\mathbf{u}_k^T \cdot \mathbf{C} \cdot \mathbf{w}_k \cdot \text{sgn}\{e_k'\}}{\mathbf{u}_k^T \mathbf{u}_k + \varepsilon} \ , \tag{15}$$

where μ_{q_k} is an adaptive step-size of $\mathbf{q}_{i,k}$ and the regularisation parameter ε is a small constant.

To enhance the performance by reducing computational complexity, we modify an estimation of the energy of errors for updating

average step-size parameter from the present and previous errors of systems [21].

Since, the adaptive averaging step-size μ_{w_k} of $\mathbf{w}_k$ can be implemented following [19]

$$\mu_{w_k} = \gamma_w \cdot \mu_{w_{k-1}} + \rho_w \cdot \zeta_k^2 \ , \tag{16}$$

$$\zeta_k = \sigma \cdot \zeta_{k-1} + (1 - \sigma) \cdot e_k'^2 \ , \tag{17}$$

where ρ_w is a scaling variable, σ is close to 1 and $0 < \gamma_w < 1$.

Therefore, the adaptive step-size μ_{q_k} of $\mathbf{q}_{i,k}$ is determined by

$$\mu_{q_k} = \gamma_q \cdot \mu_{q_{k-1}} + \rho_q \cdot e_k'^2 \ , \tag{18}$$

where $0 < \gamma_q < 1$ and $\rho_q > 0$.

The summary of the proposed sign normalised version of least mean square algorithm using adaptive averaging step-size approach for HSAF (AAS-SNLMS-HSAF) is presented in Table. 1.

4 Convergence Analysis

In this section, we focus on the derivation and analysis of the relationship between the step-size and the mean square error. These approaches are to ensure the optimal convergence at the steady-state condition.

4.1 Convergence Properties

According to enhance the performance of SNLMS-HSAF-based algorithm, we examine the optimal learning rate of step-size parameters for adaptive FIR coefficient vector $\mathbf{w}_k$ and update control points vector $\mathbf{q}_{i,k}$ as follows.

We determine the *a posteriori* error e_k' as

$$e_k' = d_k - \mathbf{w}_{k+1}^T \cdot \mathbf{s}_k \ . \tag{19}$$

The desired response d_k can be decomposed into the input vector $\mathbf{s}_k$ and the residual error is defined as

$$d_k = \mathbf{w}_{opt}^T \cdot \mathbf{s}_k + e_k^{min} \ , \tag{20}$$

where $\mathbf{w}_{opt} \in \mathcal{R}^N$ is the optimal Wiener solution vector and e_k^{min} is the residual error assumed as a Gaussian noise with zero mean and finite variance.

Substituting (20) into (19), then we can obtain an expression to estimate error as

$$e_k' = e_k^{min} - \Delta \mathbf{w}_k^T \cdot \mathbf{s}_k \ , \tag{21}$$

where $\Delta \mathbf{w}_k \in \mathcal{R}^N$ is the difference of the adaptive FIR coefficient vectors $\mathbf{w}_k$ defined by

$$\Delta \mathbf{w}_k = \mathbf{w}_{k+1} - \mathbf{w}_k = \frac{\mu_{w_k} \cdot \mathbf{s}_k \cdot \text{sgn}\{e_k'\}}{\mathbf{u}_k^T \mathbf{u}_k + \varepsilon} \ . \tag{22}$$

Substituting (22) into (21) gives

$$e_k^{min} - e_k' = \mu_{w_k} \frac{(\mathbf{s}_k^T \cdot \mathbf{s}_k) \cdot \text{sgn}\{e_k'\}}{\mathbf{u}_k^T \mathbf{u}_k + \varepsilon} \tag{23}$$

By taking the norm of both sides in (23), the adaptive step-size μ_{w_k} of adaptive FIR coefficient vector $\mathbf{w}_k$ can be approximated by

$$\therefore 0 < \mu_{w_k} < \frac{\mathbf{u}_k^T \mathbf{u}_k}{\mathbf{s}_k^T \mathbf{s}_k + \varepsilon} \ . \tag{24}$$

where $|e_k'| < |e_k^{min}|$.

Correspondingly, we investigate the convergence properties of the update control points vector $\mathbf{q}_{i,k}$ using Taylor series expansion of estimated *a posteriori* error e_k' as

$$e_{k+1}' = e_k' + \frac{\partial e_k'}{\partial \mathbf{q}_k} \cdot \Delta \mathbf{q}_k \ , \tag{25}$$

where the difference of update control points vector $\Delta \mathbf{q}_k$ is given by

$$\Delta \mathbf{q}_k = \mu_{q_k} \frac{\mathbf{u}_k^T \cdot \mathbf{C} \cdot \mathbf{w}_k \cdot \text{sgn}\{e_k'\}}{\mathbf{u}_k^T \mathbf{u}_k + \varepsilon} \ . \tag{26}$$

Differentiating e_k' in (19) w.r.t. $\mathbf{q}_{i,k}$ by the chain rule [19], we can get

$$\begin{aligned}
\frac{\partial e_k'}{\partial \mathbf{q}_k} &= \frac{\partial}{\partial \mathbf{q}_k}\Big(d_k - \mathbf{w}_{k+1}^T \cdot \mathbf{u}_k \cdot \mathbf{C}^T \cdot \mathbf{q}_{i,k}\Big) \\
&= -\mathbf{u}_k \cdot \mathbf{C}^T \cdot \mathbf{w}_{k+1} \ .
\end{aligned} \tag{27}$$

Substituting (26) and (27) into (25) gives

$$e_k' - e_{k+1}' = \frac{\mu_{q_k} \cdot (\Psi_k^T \cdot \Psi_k) \cdot \text{sgn}\{e_k'\}}{\mathbf{u}_k^T \mathbf{u}_k + \varepsilon} \ , \tag{28}$$

where Ψ_k is

$$\Psi_k = \mathbf{u}_k^T \cdot \mathbf{C} \cdot \mathbf{w}_k \ . \tag{29}$$

Similarly, we take the norm of both sides (28), the adaptive step-size μ_{q_k} of update control points coefficient vector $\mathbf{q}_{i,k}$ can be evaluated as

$$\therefore 0 < \mu_{q_k} < \frac{\mathbf{u}_k^T \mathbf{u}_k}{\Psi_k^T \Psi_k + \varepsilon} \ . \tag{30}$$

where $|e_k'| > |e_{k+1}'|$.

4.2 Mean Square Behaviour Analysis

In this section, we investigate the convergence analysis in forms of the mean square error performance in the steady-state condition.

Remark 1: *We assume that the estimated coefficient error vector V_{w_k} is under the independent and identically distributed condition with zero mean and finite variance.*

We consider following [4] the estimated coefficient error vector $\mathbf{V}_{w_k}$ involved the adaptive FIR vector $\mathbf{w}_k$ as

$$\mathbf{V}_{w_{k+1}} = \mathbf{V}_{w_k} - \frac{\mu_{w_k} \cdot \mathbf{s}_k \cdot \text{sgn}\{e_k'\}}{\mathbf{u}_k^T \mathbf{u}_k + \varepsilon} \ . \tag{31}$$

Table 1: Proposed adaptive averaging step-size algorithm based on sign normalised least mean square algorithm for HSAF (AAS-SNLMS-HSAF).

1: **ALGORITHM** AAS-SNLMS-HSAF ()

2: $\quad \mathbf{w}(0) = \delta \cdot [1\ 0\ \ldots 0]^T$, $\quad \mathbf{u}_k = [u_k^3\ u_k^2\ u_k\ 1]^T$

$\quad \mathbf{x}_k = [\ x_k\ x_{k-1}\ \ldots\ x_{k-K+1}\ ]$

$\quad \mathbf{q}_{i,k} = [\ q_{i,k}\ q_{i+1,k}\ q_{i+2,k}\ q_{i+3,k}\ ]$

3: $\quad$ **FOR** $k = 1$ **TO** $K - 1$.

4: $\quad\quad \mathbf{s}_k = \mathbf{u}_k^T \mathbf{C}\ \mathbf{q}_{i,k}$

5: $\quad\quad u_k = \frac{s_k}{\Delta x} - \lfloor \frac{s_k}{\Delta x} \rfloor$

6: $\quad\quad i = \lfloor \frac{s_k}{\Delta x} \rfloor + \frac{Q-1}{2}$

7: $\quad\quad e_k' = d_k - y_k = d_k - \mathbf{w}_{k+1}^T \mathbf{s}_k$

8: $\quad\quad \mu_{w_k} = \gamma_w \cdot \mu_{w_{k-1}} + \rho_w \cdot \zeta_k^2$

9: $\quad\quad \zeta_k = \sigma \cdot \zeta_{k-1} + (1 - \sigma) \cdot e_k'^2$

10: $\quad\quad \mu_{q_k} = \gamma_q \cdot \mu_{q_{k-1}} + \rho_q \cdot e_k'^2$

11: $\quad\quad \mathbf{w}_{k+1} = \mathbf{w}_k + \mu_{w_k} \frac{\mathbf{s}_k \cdot \text{sgn}\{e_k'\}}{\mathbf{u}_k^T \mathbf{u}_k + \varepsilon}$

12: $\quad\quad \mathbf{q}_{i,k+1} = \mathbf{q}_{i,k} + \mu_{q_k} \frac{\mathbf{u}_k^T \cdot \mathbf{C} \cdot \mathbf{w}_k \cdot \text{sgn}\{e_k'\}}{\mathbf{u}_k^T \mathbf{u}_k + \varepsilon}$

13: $\quad$ **NEXT** k

14: **END ALGORITHM**

We can also determine the squared coefficient error vector as

$$\|\mathbf{V}_{w_{k+1}}\|^2 = \|\mathbf{V}_{w_k}\|^2 - \frac{2\,\mathbf{V}_{w_k}\mu_{w_k} \cdot \mathbf{s}_k \cdot \text{sgn}\{e_k'\}}{\mathbf{u}_k^T \mathbf{u}_k + \varepsilon} + \left\| \frac{\mu_{w_k} \cdot \mathbf{s}_k \cdot \text{sgn}\{e_k'\}}{\mathbf{u}_k^T \mathbf{u}_k + \varepsilon} \right\|^2 \ . \tag{32}$$

Remark 2: *We consider the condition, that*

$$E\{\|\mathbf{V}_{w_{k+1}}\|^2\} \approx E\{\|\mathbf{V}_{w_k}\|^2\} \ , \ k \to \infty \ .$$

By using Remark 2, we can rewrite (32) as

$$2\,\mathbf{V}_{w_k}^T \cdot \mathbf{s}_k \cdot \text{sgn}\{e_k'\} = \frac{\mu_{w_k} \cdot \|\mathbf{s}_k\|^2 \cdot |e_k'|^2}{\mathbf{u}_k^T \mathbf{u}_k + \varepsilon}$$

$$2\,\epsilon_{w_k} \cdot \text{sgn}\{e_k'\} = \frac{\mu_{w_k} \cdot \|\mathbf{s}_k\|^2 \cdot |e_k'|^2}{\mathbf{u}_k^T \mathbf{u}_k + \varepsilon} \ , \tag{33}$$

where ϵ_{w_k} is denoted by

$$\epsilon_{w_k} \approx \mathbf{V}_{w_k}^T \cdot \mathbf{s}_k \ . \tag{34}$$

We proceed the *a posteriori* error involved with the adaptive FIR vector $\mathbf{w}_k$ as

$$e_k' = \epsilon_{w_k} + \mathbf{V}_{w_k} \ . \tag{35}$$

By taking the expectation on the left-side of (33) and using (35) at the steady state condition, we can see that

$$E\{\epsilon_{w_k} \cdot \text{sgn}\{e_k'\}\} = E\{\epsilon_{w_k} \cdot \text{sgn}\{\epsilon_{w_k} + \mathbf{V}_{w_k}\}\} \approx E\{\epsilon_{w_k}^2\} \ . \tag{36}$$

The expectation of the squared *a posteriori* error is then

$$E\{(e'_k)^2\} \simeq E\{(\epsilon_{w_k} + \mathbf{V}_{w_k})^2\}$$
$$= E\{\epsilon^2_{w_k} + \zeta^2_{w_k}\} . \qquad (37)$$

where $\zeta^2_{w_k}$ is given by

$$\zeta^2_{w_k} = 2\epsilon_{w_k} \cdot \mathbf{V}_{w_k} + \mathbf{V}^2_{w_k} . \qquad (38)$$

Substituting (36) and (37) into (33), we then obtain

$$2 E\{\epsilon^2_{w_k}\} = \frac{\mu_{w_k} \cdot \|\mathbf{s}_k\|^2 \cdot E\{\epsilon^2_{w_k} + \zeta^2_{w_k}\}}{\mathbf{u}^T_k \mathbf{u}_k + \varepsilon}$$

$$E\{\epsilon^2_{w_k}\} = \frac{\mu_{w_k} \cdot \|\mathbf{s}_k\|^2 \cdot E\{\zeta^2_{w_k}\}}{2\mathbf{u}^T_k \mathbf{u}_k + \varepsilon - \mu_{w_k} \cdot \|\mathbf{s}_k\|^2} \qquad (39)$$

where $\mu_{w_k} \ll 1$ is assumed.

Therefore, the excess mean square error (MSE) ξ^w_{ex} involved with the adaptive FIR vector $\mathbf{w}_k$ can be given by

$$\therefore \xi^w_{ex} = E\{\epsilon^2_{w_k}\} = \frac{\mu_{w_k} \cdot \|\mathbf{s}_k\|^2 \cdot E\{\zeta^2_{w_k}\}}{2\mathbf{u}^T_k \mathbf{u}_k + \varepsilon} . \qquad (40)$$

Please note that (40), an approximation of (39), is valid only for small step-size parameter.

In a similar way, we consider the estimated coefficient error vector $\mathbf{V}_{q_k}$ concerned with the update control points vector $\mathbf{q}_{i,k}$ as

$$\mathbf{V}_{q_k} = \mathbf{q}_{i,k} - \mathbf{q}_{opt} , \qquad (41)$$

where $\mathbf{q}_{opt} \in \mathcal{R}^N$ is the optimal control points vector and $\mathbf{V}_{q_k} \in \mathcal{R}^N$.

We can then rewrite the update control points vector $\mathbf{q}_{i,k}$ in (15) by using the coefficient error vector $\mathbf{V}_{q_k}$ as follows.

$$\mathbf{V}_{q,k+1} = \mathbf{V}_{q,k} - \frac{\mu_{q_k} \cdot \mathbf{u}^T_k \cdot \mathbf{C} \cdot \mathbf{w}_k \cdot \text{sgn}\{e'_k\}}{\mathbf{u}^T_k \mathbf{u}_k + \varepsilon} . \qquad (42)$$

The square of coefficient error vector in (42) is computed as

$$\|\mathbf{V}_{q,k+1}\|^2 = \|\mathbf{V}_{q,k}\|^2 - \frac{2 \cdot \mathbf{V}_{q,k} \cdot \mu_{q_k} \cdot \mathbf{u}^T_k \cdot \mathbf{C} \cdot \mathbf{w}_k \cdot \text{sgn}\{e'_k\}}{\mathbf{u}^T_k \mathbf{u}_k + \varepsilon}$$
$$+ \left\| \frac{\mu_{q_k} \cdot \mathbf{u}^T_k \cdot \mathbf{C} \cdot \mathbf{w}_k \cdot \text{sgn}\{e'_k\}}{\mathbf{u}^T_k \mathbf{u}_k + \varepsilon} \right\|^2 . \qquad (43)$$

Remark 3: *We assume the condition, that is of*

$$E\|\mathbf{V}_{q_{k+1}}\|^2 \approx E\|\mathbf{V}_{q_k}\|^2 , \ k \to \infty .$$

We can get and rewrite (43) using Remark 1 as

$$2 \cdot \epsilon_{q_k} \cdot \text{sgn}\{e'_k\} = \frac{\mu_{q_k} \cdot \|\Psi_k\|^2 \cdot |e'_k|^2}{\mathbf{u}^T_k \mathbf{u}_k + \varepsilon} , \qquad (44)$$

where ϵ_{q_k} is given by

$$\epsilon_{q_k} \approx \mathbf{V}^T_{q_k} \cdot \Psi_k . \qquad (45)$$

where Ψ_k is defined in (29).

We calculate the *a posteriori* error with the updated control points vector $\mathbf{q}_{i,k}$ as

$$e'_k = \epsilon_{q_k} + \mathbf{V}_{q_k} . \qquad (46)$$

After taking the expectation on the left-side of (44) and using (46), we get

$$E\{\epsilon_{q_k} \cdot \text{sgn}\{e'_k\}\} = E\{\epsilon_{q_k} \cdot \text{sgn}\{\epsilon_{q_k} + \mathbf{V}_{q_k}\}\}$$
$$\approx E\{\epsilon^2_{q_k}\} . \qquad (47)$$

We determine the square *a posteriori* error and take the expectation as

$$E\{e'_k\} \simeq E\{(\epsilon_{q_k} + \mathbf{V}_{q_k})^2\}$$
$$= E\{\epsilon^2_{q_k}\} + E\{\zeta^2_{q_k}\} , \qquad (48)$$

where $\zeta^2_{q_k}$ is given by

$$\zeta^2_{q_k} = 2\epsilon_{q_k} \cdot \mathbf{V}_{q_k} + \mathbf{V}^2_{q_k} . \qquad (49)$$

Substituting (47) and (48) into (44) gives us

$$2 \cdot E\{\epsilon^2_{q_k}\} = \frac{\mu_{q_k} \cdot \|\Psi_k\|^2 \cdot [E\{\epsilon^2_{q_k}\} + E\{\zeta^2_{q_k}\}]}{\mathbf{u}^T_k \mathbf{u}_k + \varepsilon}$$

$$E\{\epsilon^2_{q_k}\} = \frac{\mu_{q_k} \cdot \|\Psi_k\|^2 \cdot [E\{\zeta^2_{q_k}\}]}{(2\mathbf{u}^T_k \mathbf{u}_k + \varepsilon) - \mu_{q_k} \cdot \|\Psi_k\|^2} , \qquad (50)$$

where $\mu_{q_k} \ll 1$ is assumed.

Therefore, the excess MSE ξ^q_{ex} with the update control points coefficient vector $\mathbf{q}_{i,k}$ can be expressed by

$$\therefore \xi^q_{ex} \simeq E\{\epsilon^2_{q_k}\} = \frac{\mu_{q_k} \cdot \|\Psi_k\|^2 \cdot [E\{\zeta^2_{q_k}\}]}{2\mathbf{u}^T_k \mathbf{u}_k + \varepsilon} . \qquad (51)$$

Notice that (51) is an approximation of (50) is only applicable for small values of the step-size parameter.

5 Simulation Experiment Design

In this section, the experiments are conducted with the system identification through computer simulations to verify the proposed nonlinear adaptive filtering. Flow chart of the proposed AAS-SNLMS for HSAF is shown in Figure 2.

The input color signal x_k composes of 10,000 samples by averaging over 100 Monte Carlo trials can be generated by the following equation as [3]

$$x_k = \omega \cdot x_{k-1} + \sqrt{1 - \omega^2} \, \varphi , \qquad (52)$$

where φ is a unitary variance of zero mean white Gaussian noise and ω is a parameter to determine the correlation level between adjacent samples [2], where $0 \le \omega < 1$.

In these experiments, we set $\omega = 0.15, 0.75$ and signal to noise ratio (SNR) is of 20, 25, 30dB. As shown in [3], simulation parameters are comprised of

$$\mathbf{w}_0 = [0.6, \ -0.4, \ 0.25, \ -0.15, \ 0.1, \ -0.05, \ 0.001] .$$

The target function of nonlinear memoryless determined by a 23-point LUT of update control points vector $\mathbf{q}_0$ is interpolated by a uniform third degree spline function using an interval sampling $\Delta x = 0.2$ [3]

$$\mathbf{q}_0 = \{-2.20, -2.00, -1.80, -1.60, -1.40, -1.20, -1.00, -0.80,$$
$$- 0.91, -0.40, -0.20, 0.05, 0.0, -0.40, 0.58, 1.00, 1.00,$$
$$1.20, 1.40, 1.60, 1.80, 2.00, 2.20\}.$$

The constant matrix $\mathbf{C}$ is called a *Catmul-Rom* spline matrix as given by [5]

$$\mathbf{C} = \frac{1}{2}\begin{bmatrix} -1 & 3 & -3 & 1 \\ 2 & -5 & 4 & -1 \\ -1 & 0 & 1 & 0 \\ 0 & 2 & 0 & 0 \end{bmatrix}.$$

For HSAF models, the initial parameters are in the following terms: $\delta = 0.001$, number of tap length $M = 7$, number of control points $Q = 23$, $\mu_w = 1.15 \times 10^{-3}, 4.25 \times 10^{-3}$, and $\mu_q = 1.15 \times 10^{-3}, 2.55 \times 10^{-3}$.

Other initial parameters of the proposed adaptive averaging step-size sign normalised least mean square algorithm based on the Hammerstein spline adaptive filtering (AAS-SNLMS-HSAF) consists of $\mu_w(0) = 7.5 \times 10^{-4}, 7.5 \times 10^{-3}, 7.5 \times 10^{-2}$ and $\mu_q(0) = 5.5 \times 10^{-4}, 5.5 \times 10^{-3}, 5.5 \times 10^{-2}$. And the fixed parameter for adaptive averaging step-size approach of the adaptive FIR vector $\mathbf{w}_k$ and the update control points $\mathbf{q}_{i,k}$ are set as: $\gamma_w = 0.97, \gamma_q = 0.975$, $\sigma = 0.975, \rho_w = 2.75 \times 10^{-3}, \rho_q = 2.95 \times 10^{-3}$, and $\varepsilon = 1 \times 10^{-6}$.

6 Experimental Results

The first experiment is carried out to show the effectiveness of the proposed AAS-SLMS algorithm for HSAF performs against the white Gaussian noise. In particular, the mean square error (MSE) of HSAF-based algorithm with the different of $\omega = 0.15, 0.75$ with $SNR = 25, 30$dB presented in Figures 3 and 4 that manifests the proposed AAS-SNLMS-HSAF and the conventional least mean square algorithm based on Hammerstein spline adaptive filtering (LMS-HSAF) [3] with the two different choices of ω given in (52). It shows that the MSE directions of the proposed AAS-SNLMS-HSAF algorithm can achieve faster convergence rate compared with to the LMS-HSAF algorithm at the steady state condition.

In addition, Figure 5 shows the trajectories of μ_{w_k} of tap-weight vector $\mathbf{w}_k$ at different initial value of step-size as $\mu_w(0) = 1.75 \times 10^{-2}, 1.75 \times 10^{-3}, 1.75 \times 10^{-4}$ at $\omega = 0.75$ with $SNR = 20$dB. Figure 6 conducts the step-size curves μ_{q_k} of control point $\mathbf{q}_{i,k}$ at different initial step-size $\mu_q(0) = 1.55 \times 10^{-2}, 1.55 \times 10^{-3}, 1.55 \times 10^{-4}$ at the same environment.

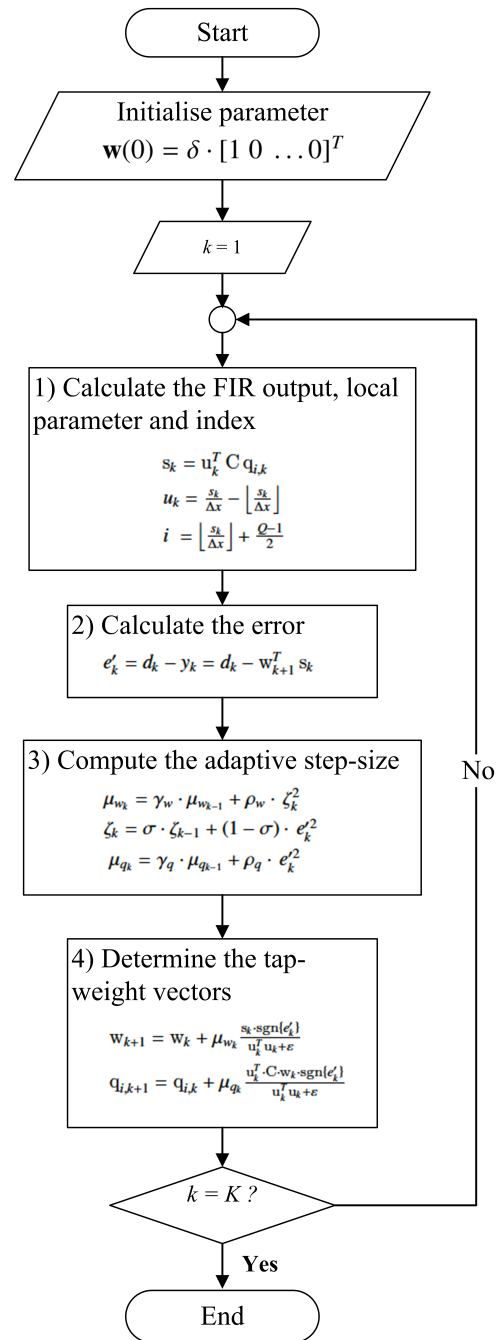
Figure 7 depicts the trajectories of μ_{w_k} of tap-weight vector $\mathbf{w}_k$ at different initial value of step-size as $\mu_w(0) = 7.5 \times 10^{-2}, 7.5 \times 10^{-3}, 7.5 \times 10^{-4}$ at $\omega = 0.75$ with $SNR = 25$dB. Figure 8 shows the step-size curves μ_{q_k} of control point $\mathbf{q}_{i,k}$ at different initial step-size $\mu_q(0) = 5.5 \times 10^{-2}, 5.5 \times 10^{-3}, 5.5 \times 10^{-4}$ at the same environment.


Figure 2: Flow chart of proposed AAS-SNLMS-HSAF algorithm

Figure 9 presents the trajectories of μ_{w_k} of tap-weight vector $\mathbf{w}_k$ at different initial value of step-size as $\mu_w(0) = 1.75 \times 10^{-2}, 1.75 \times 10^{-3}, 1.75 \times 10^{-4}$ at $\omega = 0.75$ with $SNR = 30$dB.

Figure 10 shows the step-size curves μ_{q_k} of control point $\mathbf{q}_{i,k}$ at different initial step-size $\mu_q(0) = 1.55 \times 10^{-2}, 1.55 \times 10^{-3}, 1.55 \times 10^{-4}$ in the same environment.

Considering the learning rate of the proposed step-size mechanism in terms of both the adaptive step-size parameter μ_{w_k} of $\mathbf{w}_k$ and the adaptive step-size μ_{q_k} of $\mathbf{q}_{i,k}$ with different SNR values, they can quickly converge to steady-state conditions compared with the fixed step-size.
Figure 3: MSE of proposed AAS-SNLMS-HSAF with the different initial step-size of $\mu_w(0), \mu_q(0)$ and LMS-HSAF [3] with the fixed step-size μ_w and μ_q, when $\omega = 0.15, 0.75$ and SNR = 25dB.
Figure 5: Trajectories of step-size μ_{w_k} of coefficient vector $\mathbf{w}_k$ with the different initial step-size parameters $\mu_w(0)$, when $\omega = 0.75$ and SNR = 20dB.
Figure 4: MSE of proposed AAS-SNLMS-HSAF with the different initial step-size of $\mu_w(0), \mu_q(0)$ and LMS-HSAF [3] with the fixed step-size μ_w and μ_q, when $\omega = 0.15, 0.75$ and SNR = 30dB.
Figure 6: Trajectories of step-size μ_{q_k} of control points coefficient vector $\mathbf{q}_{i,k}$ with the different initial step-size $\mu_q(0)$, when $\omega = 0.75$ and SNR = 20dB.

In the second experiment, the electrocardiogram (ECG) [22] from the MIT-BIH Atrial Fibrillation Database [23], [24] is used as a real biomedical input signal, shown in Figure 11. ECG is sampled at 250Hz. Figure 12 shows the proposed AAS-SNLMS-HSAF and LMS-HSAF [3] using the ECG dataset with the different ω can achieve better convergence rate compared with the LMS-HSAF algorithm, even the ECG input signal is small.

Figure 13 demonstrates the trajectories of μ_{w_k} of coefficient vector $\mathbf{w}_k$ at different $\omega = 0.15, 0.75$ and the initial value of step-size $\mu_w(0) = 1.75 \times 10^{-3}$ and $\mu_q(0) = 1.55 \times 10^{-3}$ with $SNR = 25$dB using the ECG dataset at [24]. Figure 14 presents the the learning curves of μ_{q_k} of control point $\mathbf{q}_{i,k}$ at the same environment. It reveals

that the proposed adaptive step-size algorithms for both μ_{w_k} and μ_{q_k} can converge to equilibrium points using the real ECG dataset.

7 Discussion

The comparison over 100 Monte Carlo trials shows the robustness and superiority of the proposed AAS-SNLMS algorithm over the conventional LMS algorithm for HSAF model. The learning curves of adaptive step-size μ_{w_k} and μ_{g_k} of the proposed AAS-SNLMS algorithm after 10,000 iterations can expedite the convergence rate even the initial values are varied.
Figure 7: Trajectories of step-size μ_{w_k} of coefficient vector $\mathbf{w}_k$ with the different initial step-size $\mu_w(0)$, when $\omega = 0.75$ and SNR = 25dB.
Figure 9: Trajectories of step-size μ_{w_k} of coefficient vector $\mathbf{w}_k$ with the different initial step-size $\mu_w(0)$, when $\omega = 0.75$ and SNR = 30dB.

Figure 10: Trajectories of step-size μ_{q_k} of control points coefficient vector $\mathbf{q}_{i,k}$ with the different initial step-size $\mu_q(0)$, when $\omega = 0.75$ and SNR = 30dB.

8 Conclusion

This paper presents a sign algorithm based on the normalised least mean square with Hammerstein adaptive filtering by applying an adaptive averaging step-size scheme. The proposed algorithm is developed using the minimised absolute *a posteriori* squared error. We modify an adaptive averaging step-size mechanism by using the energy of the estimated *a posteriori* error to update the step-size variant.

Furthermore, we derive the behaviour and mean square performance analysis of a sign algorithm based on the normalised version of least mean square algorithm for Hammerstein spline adaptive

filtering with the adaptive averaging step-size algorithm. That leads to discover the relationship between the step-size parameter and the mean square error from the analysis. Experimental results clearly show that the proposed algorithm outperforms the conventional least mean square based on the Hammerstein adaptive filter approach.

Hammerstein models are being particularly interested in fields of engineering such as adaptive signal processing, biomedical engineering and data analysis in the nonlinear processes.

Conflict of Interest   The authors declare no conflict of interest.

Prototype of an Augmented Reality Application for Cognitive Improvement in Children with Autism Using the DesingScrum Methodology

Misael Lazo Amado [*] ,Leoncio Cueva Ruiz, Laberiano Andrade-Arenas

Systems Engineering Program, Universidad de Ciencias y Humanidades, Lima, 27, Peru

A R T I C L E   I N F O

A B S T R A C T

In this COVID-19 pandemic, it has been registered that children with autism are not learning properly with this virtual modality in Peruvian education. The main objective of this research work is to design a mobile application with augmented reality so that autistic children can improve their cognitive development in their virtual and face-to-face classes, the chosen methodology is DesingScrum which is a hybrid of the union of Design Thiking and Scrum, which will have 10 phases (empathise, define, devise, planning meeting, sprint backlog, daily meeting, sprint review, retrospective sprint, prototype, testing), in the case study the Balsamiq tool was used for the design of the mobile application. The results are the responses from the public in Lima - North of the survey carried out on the prototype for its improvement and also the result of the design of the games with augmented reality that was applied with the tools (Tinkercad and App Augmented class). The conclusion drawn from the research work is to be able to help autistic children to improve their cognitive development with the mobile application developed through augmented reality.

1   Introduction

Autism Spectrum Disorder (ASD) is a life-long disorder with several characteristics that can affect how you relate to different people in what you choose to distance yourself from and mostly tend to have trouble learning, in school or in other activities you do [1], almost 70% of autistic people do not have an intellectual disability [2], 1 in 160 children worldwide is diagnosed with ASD [3]. As there is no quick diagnosis to know this disorder, it takes time since it will be analyzed by specialized doctors who observe the child's behavior, these are identified from 18 to 30 months. In Europe and North America they are diagnosed at school, this is identified by problems such as anxiety, hyperactivity or other mood disorders, however when they become adults 10 and 33% have a verbal and non-verbal character, they are able to work but need support, in the USA only about 25% live in their own homes and the rest live with their families [4]. The Covid-19 became a pandemic and many governments have declared their social distancing, due to this the children of ASD are distanced from their therapists and different problems arise in the homes as the children are not adapted to stay at home and are not controlled by the parents [5]. The impact that covid-19 is having on the parents of children with Autism Spectrum Disorder (ASD), is the stress that the parent develops by giving their child peace of mind, that they do not need a nanny, teachers and therapists, it becomes a real challenge for their control [6].

In the city of Quito in 2017 an evaluation was carried out to find signs of autism in which 51,463 students were evaluated, where 0.11% of children were diagnosed with autism and 0.21% with suspected ASD [7]. Due to ASD this diagnosis is made during the first three years of birth and more cases are found in men than in women.

This data from the Institute of National Statistics and Information Technology in Peru recorded 5.2% of the population of Peru with this disability, in which 10,223 people have autism spectrum disorders [8]. Considering that we found four factors that are related to socioeconomic status (SES), level of maternal education or having public health insurance, low income measure in the census or having a diagnosis of ASD in the records, because of these factors we cannot make a correct balance in Peru on how many exact people suffer from ASD or the autism spectrum [9]. The importance of our project will help the ASD child to develop cognitively, emotionally and socially, as this augmented reality system consists of fun activities and games for their development.

The objective is to make a prototype of a mobile application for the cognitive development of ASD children using augmented reality so that parents can use this application for therapies or learning of children with autism, taking into account that in the Covid-19

---

pandemic, children do not have physical contact with their therapists or educators.

This work will be structured in the following way, in section 2 the methodology to be used will be explained, in section 3 the case study of the research work will be developed, in section 4 it will be explained in detail what were the results and discussions during the tests carried out, in section 5 will be the conclusions obtained through the evidence made of the results.

2   Methodology

To begin with, we will show how you will start our methodology in which we will use 2 methods, Design Thinking and Scrum. These two methodologies will form a hybrid, which will have 10 phases (Empathise, Define, Ideate, Planning Meeting, Sprint Backlog, Daily Meeting, Sprint Review, Sprint Retrospective and Test) and to finish we will talk about the tools that will be used for the design of the prototype.

2.1   Design Thinking

This methodology has brought a lot of interest to the Professionals as it is new in the field of Innovation and Problem Solving [10]. Design Thinking has 5 phases (empathise, define, devise, prototype and test), it is mostly used to realise products, processes and business environments that require the help of users to identify strategies and future solutions, [11] as shown in Figure 1.
Figure 1: Design Thinking

2.2   Scrum

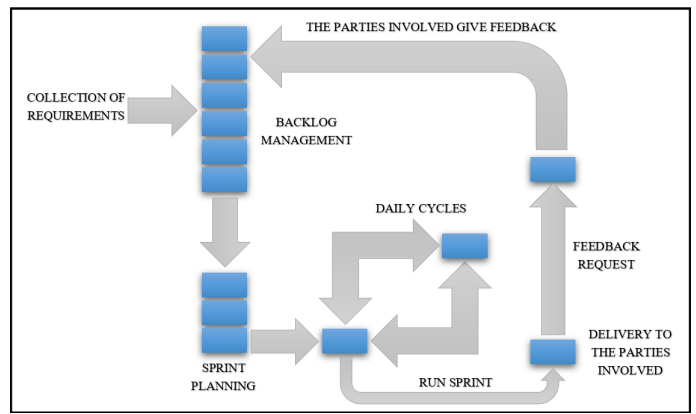
Scrum allows us to have a better iterative and incremental approach that prioritizes flexibility and adaptability to changes and in a complex environment, scrum is not a standardized process as it involves several steps to ensure a quality product. Scrum starts from the initial meeting to having the user capture, these are collected characteristics that are prioritized / through the product list, through the planning sprint, followed by the execution sprint and ending with the review and the retrospective [12], as shown in Figure 2.


Figure 2: Methodology Scrum

2.3   Phases of the Hybrid Methodology

This part will explain a little of the hybrid methodology between Design Thinking and SCRUM that is being carried out, which will have 10 phases as shown in Figure 3.

2.3.1   Empathize

Empathy is centred on the users, it is dedicated to the observation of their behaviour, iteration and personal interviews which allows the designer to have a greater understanding of the needs of those involved [13].

2.3.2   Define

The team will use the first phase to define the problems and complexities of the User [13].

2.3.3   Ideate

This stage is connected with the second phase, its objective is to brainstorm, to generate solutions, this allows the team to choose the ideal solution [14].

2.3.4   Planning Meeting

The user stories that will go into the backlog will be defined. The user stories are a set of simplified stories or requirements that identify a user, who and why they want this system functionality and the backlog is a list of user stories [15].

2.3.5   Sprint Backlog

The sprint backlog contains a set of tasks for each team member this will allow you to have a better implementation in the system, this are divided into sprint that would be like the deliverables that would have as a date for each deliverable to be made with the ability that you can work in a more orderly manner, taking into account this is done through the user stories.

2.3.6 Daily Meeting

The daily scrum meeting is the main way to review the adaptation processes in the scrum practice, the ideal is to meet for 15 minutes at the beginning, each team member declares his or her work to be done, taking into account that the meetings will discuss: What have I done since the last meeting, what am I going to do from now on, and what impediments do I have or will I have?

2.3.7 Sprint Review

At this stage the sprint will be checked, the check takes approximately four hours per month for each deliverable. In the sprint check an evaluation is made which is achieved during the sprint, the scrum team which inspects the increase and adapts to the delayed product if necessary checks the product and is responsible for defining the product and then moves on to the next sprint [13].

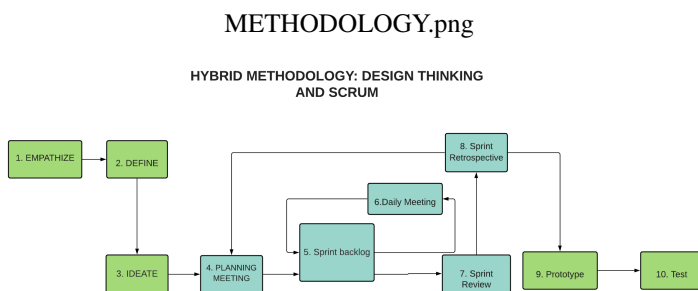
2.3.8 Sprint Retrospective

In this sprint we will identify which improvements can be implemented in the next sprint or in the current one to solve any issue or problem we find in the device [16].

2.3.9 Prototype

Finished with Phase VIII , this phase allows us to show the final prototype of our research.

2.3.10 Testing

In this final phase, feedback is requested from the user, with the aim of improving the Prototype.


METHODOLOGY.png

Figure 3: Hybrid methodology: Design thinking and scrum

2.4 Tools for Designing our Prototype

The tools for The tools for the design of the prototype with Balsamiq Mockups 3, Tinkercad and Augmented Class App will be defined, and finally the technical innovation explaining the technical development of augmented reality will be shown.

2.4.1 Balsamiq Mockups 3

Balsamiq Mockups is a tool to design mobile and web prototypes [17], with the components of the tool this will serve us to design our mobile application.

2.4.2 Tinkercad

Tinkercad is a tool that provides the creation of 3D models. It is currently free and runs from the browser [18], allowing the creation of simple or complex objects [19]. This tool will be used to perform in the design for the games and the 3D image will be exported so that it can then be imported into the Augmented class application.

2.4.3 App Augmented Class

It is an application to create augmented reality projects, this app is in Play Store which is currently in free mode, we use it to import the images that were designed in Tinkercad and we show it our prototype of the cognitive games.

2.4.4 Technical innovation

There are several ways to develop augmented reality, but in this article, the development of augmented reality with Unity 3D and Vuforia SDK will be explained.

Unity 3D is a 3D game engine in which it allows the design, creation and operation of a video game, integrates a multiplatform developed by Unity Technologies Co.Ltd. Unity 3D can add several virtual scenes sunlight, fog, water, fire, among other animated scenes. With the support of an extension called Vuforia SDK they can make several applications and games with Augmented Reality [20].

Vuforia SDK is an augmented reality software development kit used to capture flat images or 3D objects in real time which developers use to place virtual objects through a camera [20].

In this Figure 4 it can be seen that the mobile phone camera captures the real scene and Tracker is in charge of processing the image or rather tracking or analysing an image since together with the Targets they can recognise the 3D object, after matching the identification of the 3D object through the Frames of the camera (its function of the Frame is to capture image and convert it to a different resolution) The aim is to find matches in the database and thus create an augmented reality.

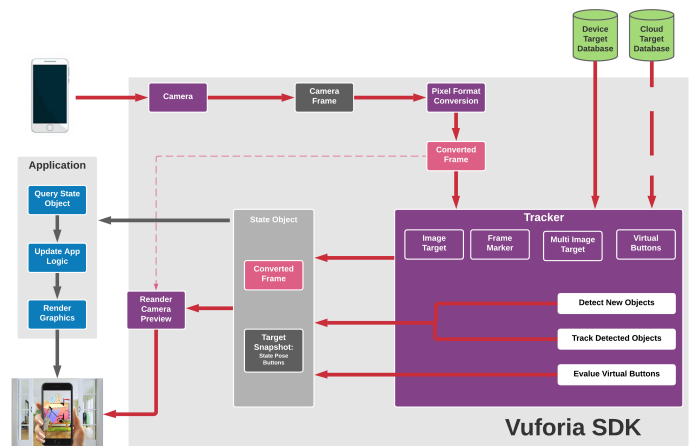


Figure 4: Vuforia SDK Architecture

3 Case Study

3.1 Empathize

We started with the first phase that was commissioned by applying surveys to parents about their children's education or how they feel in this new virtual mode so we used the Google Forms tool to formulate the questions.

Table 1 shows the questions (Q1 to Q10) that are formulated for the parents, which will have to complete the data of the children, age, gender, district, if the child learns correctly at home, if the child has stress at the time of his virtual classes, what type of autism the child has, it also shows at what level of autism the child is, the activity he likes, the family situation and if he currently has therapeutic treatment.

Table 1: Survey on the problems of autistic children in Lima-North

Questions	
ID	**Questions**
1- Q1	Child's age
2- Q2	Gender of the Child
3- Q3	District
4- Q4	Do you feel that your child is not learning properly at home?
5- Q5	Does your child get stressed out by virtual classes?
6- Q6	What type of autistic child does your child have?
7- Q7	What level of autism is your child at?
8- Q8	What activity does the child like?
9- Q9	What is the family situation in the child's home?
10- Q10	Does the child currently have therapeutic treatments?

3.2 Define

In this phase we will define the problems that are found according to the survey answered by the public.

In this Table 2, the problems presented by the survey will be indicated. Q1 through Q10, means the questions shown in Table 1 and their most relevant responses from the survey.

1. Q1 : It is understood that 7 to 9 years old are the most likely to have responded to the survey and have ASD.

2. Q2 : It shows that more male cases were found in children with ASD.

3. Q3 : It indicates that in Lima - North, in the district of Los Olivos it has a greater number of children with autism.

4. Q4 : It indicates that 51% of children are not learning properly in their educational training.

5. Q5 : This survey indicates that children are stressed out by the new virtual platform provided by the State of Education.

6. Q6 : This survey has identified that there are more children with Austistic Disorders and is followed by Asperger's Syndrome in Lima-North.

7. Q7 : A balance has been made that 47.1% suffer from a slight level of autism in the area of Lima-North.

8. Q8 : The survey shows that games are the activity most chosen by children.

9. Q9 : The survey shows that 54% of children with a disability are cared for by their parents.

10. Q10 : The survey indicates that 54.9% have therapeutic treatment, while 45.1% have no therapeutic treatment.

Table 2: Relevant answers according to the problems of the Public.

Answers	
ID	**Answers**
1- Q1	8 Years 31.4% , 9 Years 19,6% , 7 Years 11,8% .
2- Q2	Male 68,9 % , Female 31,4%
3- Q3	Los Olivos 25,5% , Comas 19,6% , Carabayllo 19,6%.
4- Q4	Yes 49% , No 51%.
5- Q5	Yes 62,7% , No 37,3%.
6- Q6	Autistic Disorder 52,9% , Asperger's syndrome 19,6%
7- Q7	43,1% Level 1(Light) , 47,1% Level 2(Medium) ,9,8% Level 3(Heavy)
8- Q8	Playing 39.2% , Dancing 25.5% , Drawing 19.6%
9- Q9	The father and mother live together, both raise the child 54%.
10- Q10	Yes 54,9% , No 45,1%

These statistics were taken from the survey that was conducted in September and October 2020 to parents who have children suffering from this disease, it was found that there was an increase of autistic disorder with level 1, level 2 and level 3 in northern Lima, taking into account that the district with more cases was the olive trees.

3.3 Ideate

According to the Problems identified in Phase 2, these solutions have been successfully devised to improve the cognitive development of ASD children. The team has then implemented a score from 1 to 20 and the best solution will be selected to develop it as shown in Table 3.

1. S1 : In this first solution it was identified that a mobile application for the cognitive development of autistic children can be elaborated using augmented reality in which their score is estimated by each working member (M1, M2 and M3), the M1 estimates 19 points, the M2 estimates 19 points and the M3 estimates 17 points and adds up to a total of 53 points.

2. S2 : In this second solution it was identified that it is possible to elaborate a Web Application for the child with autism to improve with cognitive activities in which his score is estimated by each work member (M1, M2 and M3), the M1 estimates 14 points, the M2 estimates 14 points and the M3 estimates 13 points and adds up to a total of 41 points.

3. S3 : In this third solution it was identified that it is possible to elaborate a Mobile Application for therapies and orientations for ASD children in which their score is estimated by each working member (M1, M2 and M3), the M1 estimates 14 points, the M2 estimates 12 points and the M3 estimates 11 points and adds up to a total of 53 points.

Table 3: Punctuation of the Ideas

Punctuation of the Ideas				
Solutions	M1	M2	M3	Total
S1- To make a Mobile Application with games for the cognitive development of autistic children using Augmented Reality	17	19	17	53
S2- Developing a Web Application for the child with autism to be trained with cognitive activities	14	14	13	41
S3- Developing an application for therapy and guidance for children with ASD	14	12	11	37

At the end of this phase, the solution with the highest score (S1) was identified by the members of the work team, which they used to carry out the project.

3.4 Planning Meeting

In the following table 4, the user story was important for the creation of the prototype design, which required an in-depth analysis of table 1. Table 2. Table 3. Which allows us to have the following 7 user stories.

1. H1 : The first user story will create an interface where any user will be able to create a new account to be registered in the system.

2. H2 : In the following user history 2, it will be possible to enter the system using the user and password that were created in the H1.

3. H3 : In the third user history, an option will be implemented so that the user can recover his or her password if for any reason it has been forgotten or lost.

4. H4 : In the user history 4 there will be an option where you can select your corresponding age, depending on your age that the user has you will be shown a list of available games.

5. H5 : In the user history 5 you can choose the game mode where you will get the games with their respective categories, this will depend on which option you have chosen in the H4.

6. H6 : In the following user story 6, the client will be able to rate the game, where he can leave his comment if he liked the game or what things we should change to make it more interactive and fun.

7. H7 : In the user history 7 you can check your history, where an interface will appear showing you how many hours you have played, your username and the date.

Table 4: User Stories.

User Stories	
1- H1	The user needs to register a new account (user, age, email and password) to enter the application.
2- H2	The user needs to log in by entering their registered username and password to access the application.
3- H3	The user needs to recover his password every time he forgets it.
4- H4	The user needs to select his/her age to enter the list of games.
5- H5	The user can select the game mode to get a list of the chosen mode.
6- H6	The user can indicate the rating of the game.
7- H7	The user will have a history of the games used.

3.5 Sprint Backlog

In this phase the four sprints will be carried out, according to the user stories that have been defined in the previous phase as shown in Table 5.

Table 5: Sprint Backlog.

Sprint Backlog		
ID	DESCRIPTION	SPRINT
1- H1	- The user needs to register a new account (user, age, email and password) to enter the application.	Sprint 1
2- H2	- The user needs to log in by entering their registered username and password to access the application.	
3- H3	-The user needs to recover his password every time he forgets it.	
4- H4	- The user needs to select his/her age to enter the list of games.	Sprint 2
5- H5	- The user can select the game mode to get a list of the chosen mode.	
6- H6	- The user can indicate the rating of the game.	Sprint 3
7- H7	- The user will have a history of the games used.	Sprint 4

As shown in Figure 5 the first deliverable that would come to make the sprint 1, would be made up of the first interface that would come to make the home page that has 2 options to register and log

in, then the next would be to register if a new user, log in if you already have a registered account and finally recover password if the user forgot the password of the login.

Figure 5: Sprint 1

Sprint 2 in Figure 6 shows h4 and h5, which would make the selection of the game mode by age and the selection of the game mode chosen by the user.

Figure 6: Sprint 2

In this Figure 7 will go the h6, this will include the sprint 3 that dealt with the qualification of the game and comment this would serve to ask the user what he thought about the experience of the game and what improvements he would recommend.

Figure 7: Sprint 3

As shown in sprint 4 of Fig 8 of h7, you can see the user's history by date, the name of the game, start time, end time and how

many hours they have played, this will serve to see how much time they spend on the game.
Figure 8: Sprint 4

3.6 Daily Meeting

When each Sprint is carried out, it is essential to hold these meetings for 15 people in order to better position ourselves in the collective work. The Scrum Master is in charge of generating the meeting and asking these questions: What did you do yesterday? What are you going to do today?.

3.7 Sprint Review

After finishing each Sprint, it is necessary to carry out this review by the team, you will have a maximum of 3 to 4 hours for evaluation, and they must be explained to the Product Owner for him to accept, then be shown to the users or assistants to obtain some comment or an improvement of the product. After the assessment is completed, the next Sprint is issued and if all Sprints are completed, the next phase is performed.

3.8 Sprint Retrospective

In this case the process will be evaluated and the Scrum Master generates a meeting with the Product Owner and the Work Team, to improve the next process, then it asks itself: What did we do well, what can we improve and what should we stop doing?.

3.9 Prototype

In this phase, the Final Prototype will be shown as it can be seen in Figure 9 that will be made with Balsamiq Mockups 3, this will be the final sample of the Application that will be used by means of the Augmented Reality where 4 games were made.

3.10 Testing

In this final stage a survey will be carried out on Google Forms where 5 questions of the prototype will be asked (QP1 to QP5),

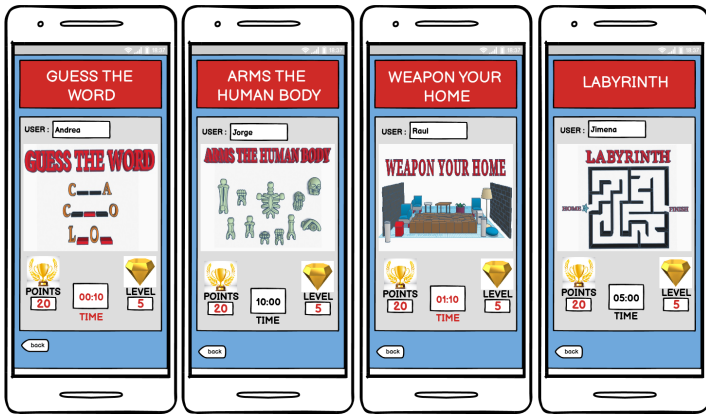
the public will give their point of view about the prototype or what improvements would be applied as shown in Table 6.


Figure 9: All Games

Table 6: Survey about the Prototype for the Cognitive Development of ASD children applying Augmented Reality

Questions	
ID	Questions
QP1	Tell us what you thought of the Prototype.
QP2	Tell us how you found the Cognitive Games for your child.
QP3	I would recommend this application for TEA children.
QP4	You think your child will learn using this application.
QP5	Write your opinion on how we can improve the application.

3.11 Mobile Application Algorithm

The design algorithm of the mobile application is shown in Figure 10 and will be explained in detail in the following description.

1. Identification of cognitive problems for autistic children: The research work started on how we could identify cognitive problems in autistic children.

2. Are there any cognitive problems? : The first conditional was made if a problem was found, the cognitive problems in the autistic children had to be identified again, but if no problem was found in the identification, the next process was made.

3. Analysis of the problems identified: In the 2 process an analysis of all the problems was made on all the processes that have been accepted from point 1.

4. Feedback: In the 3 process we made a feedback where we are going to analyze all the requirements we need together with the new ideas of the work team.

5. Do you meet the requirements? : We carry out the 2 conditional where we ask ourselves the question of point 4 if it

fulfils all the requirements to go on to the next process. If it does not, new requirements will be reconsidered in order to be accepted.

6. DesignScrum Methodology: Then in the 4 process we apply the DesignScrum methodology which will carry out the research work

7. Mobile Prototype: In process 5 we started to create the prototype of the mobile application after having identified all the problems and created the necessary requirements.

8. Do parents agree with the prototype? : On the 3rd conditional a survey was sent to all parents who are using the prototype to find out their opinion and what new ideas we should add. If the parents did not agree, we would have to go back to the previous point to restructure the prototype of the mobile application. If they accepted, we would go on to the next process.

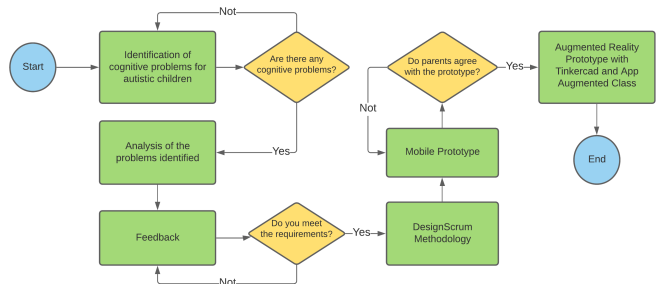
9. Augmented Reality Prototype with Tinkercad and App Augmented Class: In the sixth process, the application was begun with Tinkercad and the Augmented Class App. This will serve to add the design of the prototype and add the Augmented reality to the project in which the project will be completed.


Figure 10: Mobile Application Algorithm

4 Results and Discussions

In this chapter we show our results according to the analysis of the survey of the last phase of the survey carried out, The Application of the Prototype and the methodology.

4.1 About the Survey

In the last part of the case study, a survey was carried out with 5 questions on the final prototype (QP1 to QP5). In this result from Table 7, we show the relevant responses indicated by the public about our prototype.

1. QP1: In this result he indicates which prototype the parents think is good.

2. QP2 : Parents indicate that they find games very good for the cognitive development of autistic children.

3. QP3 : It indicates that in Lima - North, in the district of Los Olivos it has a greater number of children with autism.

4. QP4 : Parents feel confident that their children will learn using the application.

5. QP5 : Good feedback was obtained on the improvement of the Prototype of the mobile application.

Figure 11: Game 1

Table 7: Relevant answers according to the prototype shown to the public.

Answers	
ID	Answers
1- QP1	Good 46,2% , Very Good 23,1% .
2- QP2	Very Good 38,5% , Good 23,1%
3- QP3	Yes 84,6% , No 15,4%.
4- QP4	Yes 84,6% , No 15,4%.
5- QP5	The public indicate that they must do better in developing more games for their children.

According to the responses from the public, it can be seen that the vast majority of the respondents are satisfied with the prototype, which was our expectation when the work started. In the survey, 46.2 % of the respondents were satisfied with the prototype and 23.1 % were very satisfied, which shows that they found the prototype very interesting. It is also noted that cognitive games have 38.5 % very good and 23.1 % very good, which impresses us that the public is comfortable with the games, taking into account that 84.6 % of respondents say that the mobile application will be recommended and that their children with autism strengthen or improve their cognitive development. Finally we obtained positive recommendations from the public as it encourages us to improve the prototype, fulfilling the objective of the methodology.

4.2 Prototype Application

According to the design of the prototype of the game, it was possible to design the games with Augmented Reality using the Tinkercad tool and Augmented class.

In Figure 11 you can see the prototype is working correctly in the mobile phone by means of augmented reality, the game being presented the child will have to guess the correct word as shown on the screen of the mobile phone.

As shown in Figure 12 the prototype works correctly, the game will be a maze where the child will have to identify the correct path so that he can reach the end of the maze and move on to the next level.

Figure 12: Game 2

Figure 13: Game 3

As shown in Figure 13, the child will try to assemble the human body where he will have several opportunities to finish the first level of the game.

Figure 14 shows the last set made of the prototype working correctly on the mobile phone. It tries to allow the child to build his house with the objects shown on the mobile phone.
Figure 14: Game 4

4.3 About the methodology

4.3.1 Advantages

The union of two methodologies was made to carry out the hybrid methodology. This gave us a usefulness since it allowed us to better structure the phases of the research work. Scrum allows us to work on different projects with different requirements. With a compromise, this offers to guarantee a model that benefits all the needs of the project having the facility to put together other methodologies and tools [21]. Design Thinking will include these benefits as transformation, innovation to improve decision making as well as results [22], allowing the combination of empathy, creativity, coherent analysis of information and adjustment to the environment according to the solutions [23].

4.3.2 Disadvantages

The disadvantage of the hybrid methodology that is being applied is a little complex as it has 10 phases. Therefore, what is disadvantageous is that some fundamental steps cannot be eluded, taking into account these phases require a longer time of analysis to develop the processes.

4.3.3 Comparison

According to what was evaluated, from the scrum methodology and Design Thinking it was decided to carry out a hybrid methodology where it would contain 10 phases so that it would have a better structure when developing the research work. On the other hand, the difference of these two methodologies with the hybrid methodology is that scrum is structured more to the software part and Design thinking is structured to the analysis part, taking into account the hybrid methodology focuses on the software and analysis part allowing a better understanding when deploying the project.

5 Conclusions

The application was developed to work with augmented reality allowing to improve the cognitive development of all the autistic children. For the mobile application different games were added, where each category will have its corresponding game so that the user can choose the game the option he wants. Allowing us to

implement the hybrid methodology where the application was developed, helping us to innovate and manage the development of the mobile application. In the case study, we defined how the application was structured so that the child could learn with the use of technology. It would be of great help to use the mobile application for cognitive development for the treatment of all children suffering from different cases of autistic disorder, so that children can have a better experience, allowing to generate a great impact of learning in education in Peru. For future research work it is recommended to use Tinkercad's tools with Arduino, this will allow for a better optimization when developing the application. It is also possible to use unity3D for the operation of the application while vuforia SDK would serve to apply augmented reality to any system, be it web or mobile application.

	The phasor Measurement Unit is a modern tracking tool mounted on a network to track and manage power systems. PMU is accurate and time-synchronized device that gives voltage phasor measurements in nodes and current phasor measurements connected to those nodes where the PMU is installed. This study introduces the Genetic Algorithm for optimization of allocation of PMUs to enable maximum observation of the power network. The optimal PMU placement (OPP) problem is developed to minimize the quantity of PMU to be placed. The set and optimized model can efficiently position PMU in any network, considering the regular operation and zero injection (ZIN). Thus, the allocation algorithm implemented on IEEE 14-bus systems, the result was compared to that of existing works which achieved the same system of redundancy index. As a further study, the proposed approach is applied to the Nigerian 330kV new 52-bus systems, under operational arrangements for maximum observability of the network system. The technique formulated to handle normal operation and zero injection node succeeded in producing comparable results with other available techniques.

1. Introduction

Electric power system is a complex system with multiple sections, subsections and various components. Any analysis or model to set up a power system or upgrade the existing one must be very robust and adequate. Considering optimal location of distributed generator within distribution arm of electric power system [1, 2], reconfiguration of a section of power system [3-5], etc., all these required robust model and methodology to successfully obtain useful results.

In Nigeria, most of the power system network is overseen physically which is an issue. This physical management of the power network brought about constraints, in order to solve this challenge, the obvious path to take will be the incorporation of smart devices into the network to monitor, operate and control the power system which will increase interaction between the utility and the grid.

Phasor measurement unit is the leading device for monitoring power system network which is based on global positioning system technique. The phasor measurement unit measures different locations where it is installed which are time-synchronized to communicate the condition of the power system in real time to help

operators with more instant and accurate information. By placing phasor measurement units in several buses in a power network the system becomes more stable and reliable. However, Phasor measurement units are expensive so it is not economical to place a unit on every node in a power network [6]. Thus, an appropriate approach is essential to reduce the quantity of phasor measurement units while sustaining the power network to be observed completely.

Phasor measurement unit (PMU) has certain variations as follows from standard Supervisory Control and Data Acquisition (SCADA) measures. Synchro phasors provide phasor details while traditional state estimate (SE) utilizes voltage magnitude, branch current magnitudes, and active power and reactive power measurements for infusion, voltage phasor at neighbouring nodes without PMU can be directly calculated utilizing the phase angle information. PMU information gives 30-70 samples every second, while SCADA devices mainly give new data samples every 4-5 seconds. Therefore, dynamic observability is given of the effect of irregularities that spread through critical sections of the network [7, 8].

In [9, 10], the authors carried out a study to investigate an ideal method for placing PMUs in any power system network. They proposed a method known as inverse of connectivity which utilizes the information of connectivity and the inability to monitor any

[*]Corresponding Author: Tobiloba Somefun, km 10, Idiroko Road, Canaanland, Ota, Nigeria, +2348037632337, tobi.shomefun@covenantuniversity.edu.ng

node in the power system network. They chose the ideal bus to place the PMUs basically by selecting adjacent buses through weighing factors to observe a minimal connectivity buses; this procedure continues until the power system network is observable. In [11] the authors worked on calculated allocation of PMU to observe the power system taking consideration of redundancy measurement. In this research they tackled the ideal PMU allocation issue with binary valued factors actualized by a dual-stage branch and bound formulation, but their approach did not consider Zero injection node (ZIN). In stage one of the suggested formulations, GA is worked out by depth foremost search technique. When a first whole number solution is gotten, stage two includes breadth foremost search system to find the solution position. Beginning from a subjective introductory position, the executed formulation finds other solutions at the most minimal target capacity worth guaranteeing global optimality [12]. In this way, the reliance of the suggested two-stage branch and bound by the foremost position provides the ability to the end-user to distinguish ideal arrangements without the existence of spiral nodes in the power network [13,14].

In [15], the authors used topology-based method and genetic algorithm to solve the optimal PMU placement problem. In their approach they put into consideration zero-injection nodes in the network for finding solution to the optimal PMU placement problem. The outcome was compared to previously applied method. They achieved complete observability of the power system utilizing GA which solved the optimal PMU placement problem successfully [15]. Measurement redundancy was not considered in this research.

In [16], the authors analyse techniques used for observing the most topological network, while recursive tabu search which is obtained when numerical and tabu search method are combined was developed to attain maximum observability of a power system with full redundancy. This optimizing approach executed the solution better than the previous solution that was achieved by greedy algorithm. The process put into consideration different approaches as well as moving target search (MTS) to achieve the least quantity of PMUs to solve the optimization problem [17]. Though Placement of PMU in ZIN was not allowed in the initialization it was validated through simulation results that the recursive tabu search was more efficient that the MTS approach. Authors [18,19] gives more detailed comparisons of the recursive tabu search and other methods.

In [20-23], the authors presented the cost of installing different PMUs in a power network and the reliant factors such as branch neighbouring numbers at the node and the communicating situations. They utilized the particle swarm optimization tool to attain the best solution proving the optimization to be better than conventional techniques. The authors did not only determine the highest number of PMUs that can observe the system, they also determined the cost of installing the least quantity of different PMUs and chose the best with least cost [24].

This study serves as a pioneer study for placement of PMU in the new NG 52 bus, as there is no previous study before it. In this study, optimal placement of PMU considering normal operation and ZIN is proposed. The uniqueness in this algorithm used to place PMU on the 52 bus network is the combination of distinct

values of the chromosome, mutation function, mutation rate, selection function and crossover function.

This research paper is systematized in four sections. The "introduction" gives a brief description of PMU, also a review on existing works. The "Materials and Method" section shows the GA steps and the parameters used. Details of the inequality constraint and connectivity matrix for IEEE 14-bus and NG 52-bus was presented in PMU placement formulation. Measurement redundancy presents the BOI and SORI used to check the quality of each placement set. The "results and discussion" presented the outcome of the simulation. In "conclusion" the procedures and the outcomes are summarized.

2. Materials and Method

This section presents the placement formulation used in obtaining the minimum amount of PMU, the procedure of the Genetic algorithm, and the measurement redundancy.

2.1. PMU Placement Formulation

The purpose of the optimal PMU placement is to obtain the least quantity of PMUs needed and its position in the network in order to obtain complete observability of the network. The goal here is to minimize the utilization of PMUs and make the whole power system fully observable. The formulated objective function is therefore given as:

$$min \sum_{k=1}^{N} Z_k \tag{1}$$

subject to:

$$[A] \times [Z] \geq [b] \tag{2}$$

where N is a number of network nodes and $[A]$ is a binary connectivity matrix. Entries for matrix $[A]$ are defined by equation 3:

$$A_{i,j} = \begin{cases} 1 & if \ i = j \\ 1 & if \ nodes \ i \ and \ j \ are \ joined \\ 0 & if \ nodes \ i \ and \ j \ are \ not \ joined \end{cases} \tag{3}$$

Meanwhile $[Z]$ is defined as a binary decision variable vector given in equation 4 where $[z_1 \ z_2 \ z_3 \ ... \ z_N]^T$ and $z_i \in \{0, 1\}$:

$$z_i = \begin{cases} 1 & if \ PMU \ is \ installed \ on \ node \ i \\ 0 & if \ PMU \ is \ not \ installed \ on \ node \ i \end{cases} \tag{4}$$

[b] is a column vector where

$$[b] = [1 \ 1 \ 1 \ ... 1]_{N \times 1}^T \tag{5}$$

2.2. Genetic Algorithm Approach

For this research, genetic algorithm was selected as the optimization solver for optimal placement of PMUs on the Nigerian 330kV network. Genetic algorithm operates on a population made up of certain outcomes whereby the number of outcomes is known as population size. Every outcome is named

an individual. Every single outcome has in it a chromosome. The chromosome is defined as a collection of features that characterize the individual. Each separate chromosome has a collection of genetic factors. Each genetic factor is often interpreted as being a sequence of zeros and ones. Every individual has a fitness value, too. An objective function is employed to locate the fittest characters. The objective function outcome is the fitness value which signifies the outcome's performance. The greater the fitness value, the greater the outcome is in effectiveness.

In the breeding process the characters are known as parents. Any pair nominated parents within the breeding population will give dual offspring. Through breeding just fine-quality characters, a finer quality offspring is produced better than their parents. That will eliminate the bad individuals from producing more bad people. Through having fine-quality characters chosen and paired, there would be better chances of only having the good individuals and tossing bad individuals out. Eventually, the ideal or appropriate solution will end in the cycle. But the offspring already produced utilizing the chosen parents still have their parents' features, and no more without alterations. There is no difference added to it and therefore the latest offspring would still have the same disadvantages in its parents. Some improvements must be added to each offspring to produce new characters to solve these problems. The group of all freshly produced characters would be the recent population and will substitute the existing population that was formerly utilized. Each produced population is called a generation. The method of exchanging the existing population with the current one is known as replacement. Figure 1 gives a rundown of the genetic algorithm phases.

The genetic algorithm flow chart is outlined in Figure 1. Simulation results obtained on the premise that each PMU has the highest quantity of channels and the cost is the same for each PMU.

The Genetic algorithm procedure for the OPP problem is given below:

- Study the configuration arrangement of the power network
- Take variable/chromosome size equal to quantity of nodes
- Create the initial population
- For each selected variable, calculate the objective function
- Apply tournament selection function
- Apply single point crossover function
- Apply a uniform mutation function and a mutation rate of 0.01
- Go back to calculate the objective function if the number of generations are completed.

Two experimental cases are used to show the feasibility of the proposed approach in achieving the optimal PMU placement problem. All cases are described by using IEEE 14 and Nigeria 52 bus network model as demonstrated below and simulated utilizing MATLAB, respectively.

Case 1: not considering standard measurement for maximum network observability

In this scenario, measurements of the ZIN and the power flow are not taken into account. Furthermore, no PMU is pre-assigned to the radial node which is incident. The binary connectivity matrix A is generated from Figure 2 by use of equation 3 as follows:

Figure 1: Process flow of genetic algorithm
Figure 2: IEEE14 test bus system

Connectivity matrix [A] for IEEE-14 bus system =

$$\begin{bmatrix} 1 & 1 & 0 & 0 & 1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 1 & 1 & 1 & 1 & 1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 1 & 1 & 1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 1 & 1 & 1 & 1 & 0 & 1 & 0 & 1 & 0 & 0 & 0 & 0 & 0 \\ 1 & 1 & 0 & 1 & 1 & 1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 1 & 1 & 0 & 0 & 0 & 0 & 1 & 1 & 1 & 0 \\ 0 & 0 & 0 & 1 & 0 & 0 & 1 & 1 & 1 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 1 & 1 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 & 0 & 0 & 1 & 0 & 1 & 1 & 0 & 0 & 0 & 1 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 1 & 1 & 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 1 & 0 & 0 & 0 & 1 & 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 1 & 0 & 0 & 0 & 0 & 0 & 1 & 1 & 0 \\ 0 & 0 & 0 & 0 & 0 & 1 & 0 & 0 & 0 & 0 & 0 & 1 & 1 & 1 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 1 & 0 & 0 & 0 & 1 & 1 \end{bmatrix}$$

The final inequality constraints of matrix A are formulated as shown in the expression below with respect to each node:

$Node_1 = Z_1 + Z_2 + Z_5 \geq 1$

$Node_2 = Z_1 + Z_2 + Z_3 + Z_4 + Z_5 \geq 1$

$Node_3 = Z_2 + Z_3 + Z_4 \geq 1$

$Node_4 = Z_2 + Z_3 + Z_4 + Z_5 + Z_7 + Z_9 \geq 1$

$Node_5 = Z_1 + Z_2 + Z_4 + Z_5 + Z_6 \geq 1$

$Node_6 = Z_5 + Z_6 + Z_{11} + Z_{12} + Z_{13} \geq 1$

$Node_7 = Z_4 + Z_7 + Z_8 + Z_9 \geq 1$

$Node_8 = Z_7 + Z_8 + \geq 1$

$Node_9 = Z_4 + Z_7 + Z_9 + Z_{10} + Z_{14} \geq 1$

$Node_{10} = Z_9 + Z_{10} + Z_{11} \geq 1$

$Node_{11} = Z_6 + Z_{10} + Z_{11} \geq 1$

$Node_{12} = Z_6 + Z_{12} + Z_{13} \geq 1$

$Node_{13} = Z_6 + Z_{12} + Z_{13} + Z_{14} \geq 1$

$Node_{14} = Z_9 + Z_{13} + Z_{14} \geq 1$

Case 2: Consideration of ZIN for maximum network observability

According to Figure 2, node 7 is ZIN, node 8 is radial node. Since node 8 is a radial node, it is chosen to be integrated with the ZIN in accordance with Rule A as stated in the suggested approach section. This integration procedure indicates the node 7 constraint is eliminated from the equation and node 8 is now joined to node 4 and node 9. Following, because this procedure includes a radial bus, it is important to pre-assign a PMU to one of the nodes incidents to it.

However, because neither node 4 nor node 9 is a ZIN, there is no pre-placement of a PMU to enable more potential solutions. In the situation of node 4 being a ZIN a PMU would be pre-assigned

to node 9 in order to guarantee that node 8 is observed as shown in Figure 3.
Figure 3: Illustration of ZIN integration

This change of topology implies that the node constraints for nodes 4,7,8, and 9 have been modified. Remember that the node 7 constraint is removed because it no doesn't occur after the change of topology. For the meantime, the node constraints 4,8, and 9 are revised to show the modification of topology that was made during the integration process. The modified constraints are given as follows:

$Node_4 = Z_2 + Z_3 + Z_4 + Z_5 + Z_8 + Z_9 \geq 1$

$Node_8 = Z_4 + Z_8 + Z_9 \geq 1$

$Node_9 = Z_4 + Z_8 + Z_9 + Z_{10} + Z_{14} \geq 1$

A minimum of three PMUs must be installed at node 2, 6, and 9 to guarantee maximum network observability from these newly created constraints.

Thus, the same model is applied to Nigeria 330kV new 52-bus system for total observability on the quantity of PMUs needed. Measurements of the ZIN and power flow are not considered in this case.

2.3. Measurement Redundancy

Because Genetic algorithm is a heuristic technique, there will be an amount of PMU placement group that includes exact quantity of the least PMUs necessary for total observability. To ensure to assessing the efficiency of each PMU allocation group, measurement redundancy method of bus observability index (BOI) and system of redundancy index (SORI) are used. The BOI is specified as the quantity of times the PMUs placement set observes a node, while the SORI refers to the BOI summation for all nodes. The PMU allocation group which holds the maximum quantity of SORI signifies that the PMU allocation group has a superior performance and more efficient solution for likely contingencies compared to the PMU allocation group which has a lower quantity of SORI. Hence, this principle will be utilized in this research to test and compare the PMU allocation sets generated in terms of measurement redundancy from the suggested technique and previous studies. The following definitions in equations 6 and 7 refer to the BOI and SORI:

$$BOI_i = A \times Z_i \tag{6}$$

$$SORI = \sum_{i=1}^{N} BOI_i \tag{7}$$

3. **Results and Discussion**

This section sets out the outcomes gotten from MATLAB software simulations. The proposed technique is implemented on

IEEE 14-bus, and the Nigeria 330KV network for the purpose of verifying the operation of the suggested approach to solve the optimal PMU placement problem. The purpose of the suggested approach is to achieve the least quantity of PMUs which maintain total observability while maximizing the redundancy of measurements. Because genetic algorithm is meta-heuristic, it is anticipated to have various allocations of PMUs and to distinguish the efficiency of each PMU allocation set having the exact quantity of PMUs, the set with the most SORI will be chosen as the ideal outcome. The PMUs allocation set with the most measurement redundancy, as stated above, indicates that it is superior to the PMU allocation sets with lower measurement redundancy. Furthermore, in order to assess the efficiency of the suggested approach in finding solution to the optimal PMU placement problem, the SORI outcome for the PMU allocation set acquired from the suggested approach is compared with previous research. The suggested approach is implemented to find solution to the problem by taking consideration of two cases namely normal operation, and zero injection cases for IEEE 14 bus system and NG 52 bus system.

Case 1: Normal Operation

IEEE 14-Bus

Table 1 shows the result obtained for the IEEE-14 bus system, with respect to number of required PMU, the position of the PMU and other indices that were used in the model.

Table 1: PMU Locations for IEEE 14 Bus- Normal Operation

Network	IEEE 14-bus
Number of PMU	4
PMU Positions	2, 6, 7, 9

Figure 4: IEEE 14-bus graph considering normal operation

As can be observed, Figure 4 shows the iteration against the number of PMUs. It can be observed that at zero iteration the number of PMUs is over 14 and as the iteration increases the

number of PMU decreases until it gets to 52 iterations where the constraint converges.

NG 52-Bus

The values of the parameters used in obtaining the number of PMUs required for NG 52-bus including their locations are given in Table 2.

Table 2: PMU Locations for NG 52-Bus Normal Operation

Network	NG 52-bus
Number of PMU	17
PMU Positions	3, 4, 6, 8, 10, 16, 19, 24, 26, 27, 32, 35, 39, 41, 42, 46, 51
SORI	71
Npmu/NBus	0.32692

Figure 5: Diversity graph for NG 52-bus considering normal operation

The Figure 5 shows the iteration against the number of PMUs. It can be observed that at zero iteration the number of PMUs is over 52 and as the iteration increases the number of PMU decreases until it gets to 102 iterations where the constraint converges.

Table 3: BOI and SORI for Normal Condition

Having established the authenticity of the proposed method, the authors therefore deployed the proposed method to ascertain the number of PMU required on NG 52 bus system (appendix) as well as optimal location of the PMUs installation. The results for the NG 52-bus shows that PMU is required to be placed at 17 nodes for maximum observability. These nodes are, 3-Ikot-Ekpene, 4-Port-Hacourt, 6-Ikeja-West, 8-Aja, 10-Ajaokuta, 16-Aladja, 19-Aliade, 24-Kanji, 26-Onitsha, 27-Benin North, 32-Damaturu, 35-Egbema, 39-Ganmo, 41-Yola, 42-Gwagwalada, 46-Kaduna, 51-Jebba.

4. Conclusion

This study explores the capability genetic algorithm to optimally site PMU for electric power system network. From the outcome of this algorithm, it can be concluded that the utilization of optimization technique in the Nigerian power system network for complete observability in the most economical way will precisely position PMU in strategic nodes. This greatly improves the efficiency of the outputs and increase the grid monitoring rate. There are endless prospects for installing PMU in the national grid, as it can also be used to control the entire power system. The technique formed to handle ZIN succeeded in producing comparable results with other available techniques. For IEEE 14 and NG 54 bus reached the convergence of their constraint at 52 and 102 iterations respectively. The suggested approach also shows that to find ideal PMU location, it can be combined with the power flow calculation.

Conflicts of Interest

The authors declare that there is no conflict of interest.

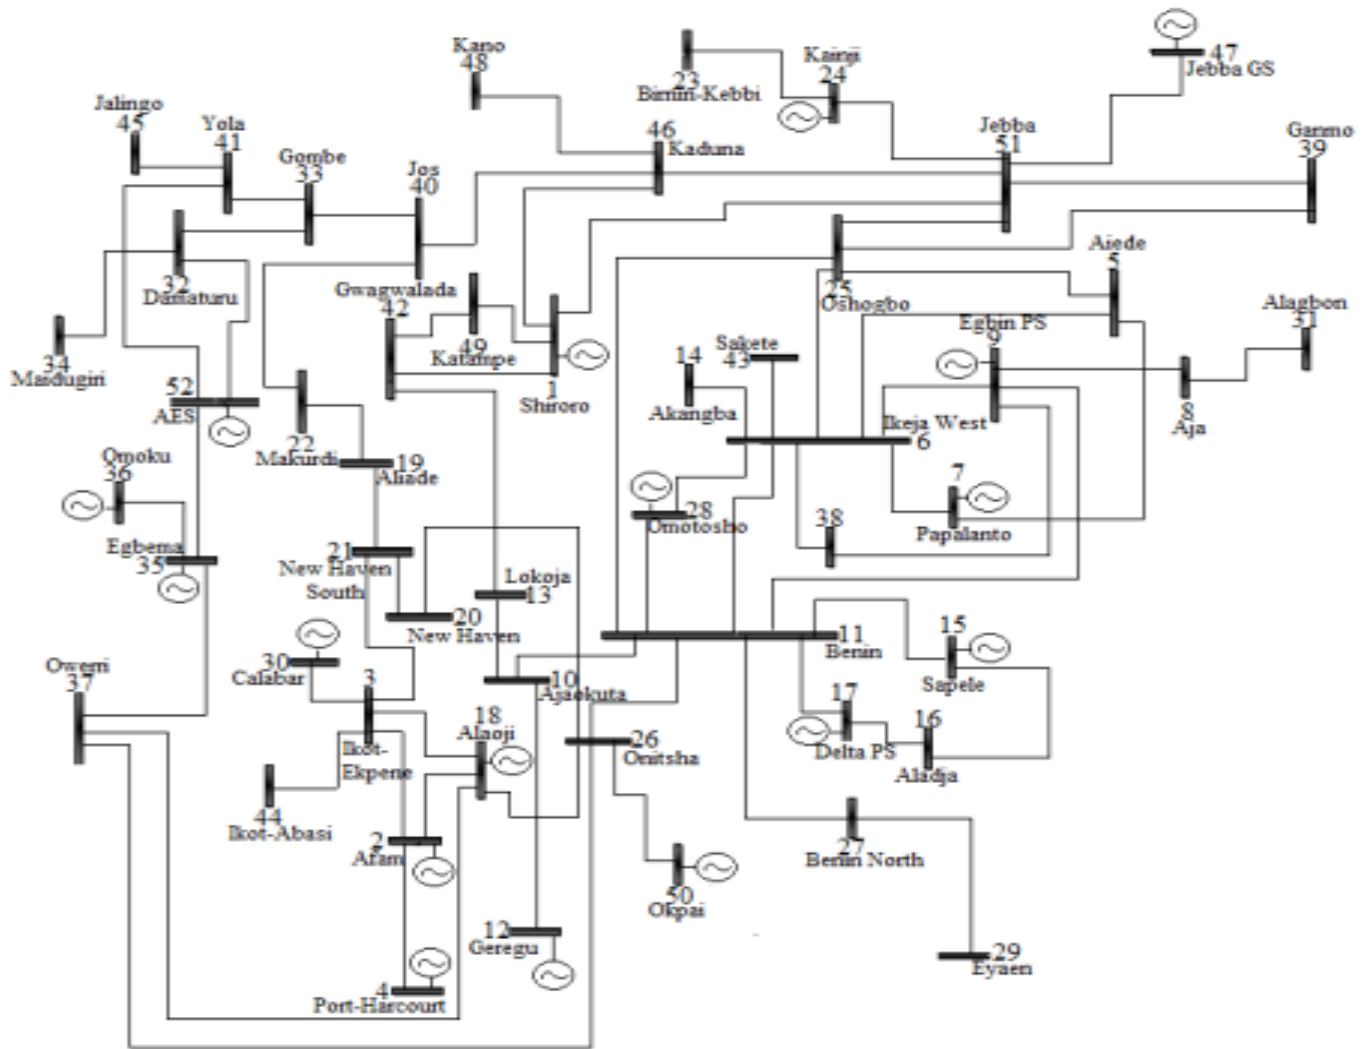
APPENDIX


Decision Support Model using FIM Sugeno for Assessing the Academic Performance

Deddy Kurniawan*, Ditdit Nugeraha Utama

Computer Science Department, BINUS Graduate Program – Master of Computer Science, Bina Nusantara University, Jakarta, Indonesia 11480

A R T I C L E   I N F O

A B S T R A C T

Assessing academic performance is a common way of evaluating and assessing the abilities of students in tertiary institutions. Usually it is practically performed based on the cumulative grade point average (GPA) at the end of each semester passed. Unwittingly there are many factors that are able to influence student performance results apart from GPA as a performance measure; i.e. gender, hometown, sibling, family status, residence, father education, mother education, family income, motivation, mileage, traveled time, transportation, scholarship, community, social media, and hang-out. Academic performance assessment is proposed through the decision support model (DSM) applying the fuzzy logic (FL) Sugeno technique. The model output generates a decision value (linear or constant equation) for academic performance based on the calculation of the measured fuzzy parameter value (ax) and conventional parameter value (bx). The DSM with the FL Sugeno method is able to provide sharp output in assessing student academic performance. In this case, the model is able to be applied then to assist academics in higher education in determining educational strategies for students with poor academic performance results.

1. Introduction

The academic performance is one indicator of the education quality in universities. It generally is able to be measured with the value achievements record of the grade point average (GPA) [1]-[3]. The GPA is greatly influenced by various factors. Those factors are such as the social, family, economic and educational environment of each individual [1], [4], [5].

The assessment process is a part of the evaluation process toward student academic performance which is done by higher education academics. Academic performance appraisal is one of the effective solutions to detect student failure problems. Analyzing stored student data can help provide important information in their academic performance appraisal process.

The new models to support objectives in the academic performance assessment process are still being investigated and researched scientifically. One of them is a study related to decision support models (DSM). The research has been carried out by a number of researchers with DSM as the main issue. Creating DSM to solve difficulties related to mosque rebuilding. Fuzzy method

was operated to determine the priority value of eleven parameters [6]. Also, eco-DSM for treating medical waste was constructed by involving the fuzzy method as the main part of the model [7]. Then, the model for determining the amount of production, especially in the business world, functioned the fuzzy Sugeno technique [8].

In addition, [9] created DSM to measure the performance of logistical companies based on various indicators performance. In [10], the author created a model to calculate the exact number of goods ordered, this affects the level of inventory and the sales of goods. The determination of the venue for the national multi-sport event or called the national sport week (NSW). The determination of the best location was carried out in Indonesia with thirty-four provinces that had various distinctive features and cultural uniqueness [11].

This paper is DSM development in fulfilling research objectives for the assessment of student academic performance which is implemented in the education area (universities), exclusively operated in a calculation using the fuzzy logic method as well as using the data asset for 100 students at the faculty of Teacher Training and Education (FKIP) at the University of Mulawarman, East Kalimantan. Fuzzy logic (FL) has been widely used in various fields in the real world. FL is technically the principal method used in calculating mathematics as well as it is

*Corresponding Author: Deddy Kurniawan, Computer Science Department, BINUS Graduate Program - Master of Computer Science, Bina Nusantara University, Jakarta, Indonesia 11480, +6285391192622, deddy.kurniawan@binus.ac.id

used to assess uncertainty in various fields. FL plays an important role in changing the complex symptoms of problems and cannot easily be translated into mathematical models, with the aim of providing a best solution approach to problems [12]. The assessment result can provide early warning to academics to be able to pay attention in taking quick steps to improve student academic performance in bad conditions.

2. Related Works

The concept of fuzzy logic is a popular method used in decision-making support. In [13], the author was applying the fuzzy method in engineering asset management (EAM), checking the condition of assets is an important aspect of EAM because it is able to identify symptoms of potential failure and suggest corrective actions before operational disruptions. In [14], the author was creating a conceptual model for evaluating the performance of social sustainability and has been tested for later implementation in India in automotive component manufacturing organizations.

In addition, from year to year, various researchers conduct research on the issue of academic performance (AP) appraisal as the main topic in their research [15]-[17]. In [15], the author chose to take AP as the main topic of their research. They observed twenty student data based on three characteristics in the one academic period involving, exam 1, exam 2 (theoretical), and exam3 (practical). The results of the study were compared with traditional evaluation methods and gave similar results. They concluded that the evaluation results with the proposed approach could be a practical method in evaluating AP.

In [16], the author introduced the new fuzzy expert system (NFES) to be used in evaluating student AP based on the concept of FL by considering two parameters, semester 1 and semester 2 scores. In order to make decisions about learning in the next period. In [17], the author applied the fuzzy method in the evaluation of AP control of twenty students in the engineering laboratory at the faculty of Engineering Education Marmara University, department of Electricity Education. The semester 1 and semester 2 grades are used as the input that counts. In [17], the author concluding that there are variations in the evaluation results from the results of comparisons made to classical evaluation methods. The fuzzy method provided the advantage of flexibility in AP evaluation and provides many evaluation options.

3. Prepare Your Paper before Styling

As mentioned in the introduction part, the purpose of the assessment is part of a big task in the process of evaluating academic performance. Figure 1 describes the step by step of the whole study.
Figure 1: Research Stages

The first step we take is to study real case (in the case is academic performance measurement) supported by reviewing several scientific manuscripts. Two these stages operated to enrich our knowledge of case we face. Furthermore, we define the parameters related to the assessment of academic performance based on the study results of the related research literature involving 17 validated ones (Table 1) and are taken into account in influencing the AP assessment. Then the parameters will be configured which include; parameter grouping and parameter weighting. The preparation process for the parameters is successfully carried out, then data collection is carried out for further preparation as a dataset for this study.

Then, the construction of the model is carried out. The model is built with FL method to be operated as the main method, in addition to conventional methods used. The concept of FL (fuzzy – inference – de fuzzy) begins with building membership functions (MF) and linguistic variables (LV) as calculation scales. The LV definition of the fuzzy parameter is used to describe the input value in the form of the condition level of each academically calculated fuzzy parameter. It is then designed via MF fuzzy triangle-trapezium on each fuzzy parameter. Further preparing the vague ground rules as reference engine rules in determining the results of considerations so that we found 3,456 basic rules. The final stage of FL is de fuzzy, the result of FL decision is determined using the centroid method of sugeno technique.

Table 1: Parameters and their Value

Variable	Parameters	Parameter Value
P1	Gender	Male (M), Female (F)
P2	Hometown	Town (T), Out of town (OT)
P3	Sibling	1, 2, 3, 4, 5
P4	Family Status	Living together (L), Divorce (D), Died (DE)
P5	Residence	With parents (P), Hostel/Rental (H)
P6	Father Education	Not Education (0), Primary School (1), Junior High School (2), Senior High School (3), Undergraduate (4), Graduate (5), Postgraduate (6)
P7	Mother Education	Not Education (0), Primary School (1), Junior High School (2), Senior High School (3), Undergraduate (4), Graduate (5), Postgraduate (6)
P8	Family Income	0-5000000 (in Million rupiah)
P9	Motivation	Dream (D), Association (A)
P10	Mileage	1-20 (in KM)
P11	Traveled Time	1-60 (in Minute)
P12	Transportation	Private (PR), Public (PB)
P13	Scholarship	No (N), Yes (Y)
P14	Community	No (N), Yes (Y)
P15	Social Media	1, 2, 3 ,4, 5, 6, 7, 8, 9, 100 (in Hours/day)
P16	Hangout	1, 2, 3 ,4, 5, 6, 7, 8, 9, 100 (in Hours/day)
P17	Grade Point Average (GPA)	0.00-2.50 (Poor), 2.51-2.99 (Good), 3.00-3.59 (Very Good) and 3.60-4.00 (Excellent)

3.1. Data Collection

Collecting data as a research dataset using a combination of data collected through two methods; 1) online questionnaire is applied in collecting actual information from student personal data, 2) list of GPA scores from the academic database for the five initial periods of learning downloaded from the academic database for 100 data from FKIP to be studied.

The collected data is prepared for research. The dataset is combined and prepared by eliminating defective data samples and by manually adding missing pieces of data to the data sample.

3.2. Grouped Parameters

Seventeen parameters configured to prepare the entire parameter can be used on the model. Parameter configuration is done through two stages, grouping and weighting parameters. The first configuration is done by grouping parameters based on the calculation operation to be used in each parameter group. The grouping was successfully formed into fuzzy groups (ax) and conventional groups (bx). Parameter grouping shapes described in Table 2.

Table 2: Parameter Grouping Based on Calculation Method

Grouped Parameters	Parameters
Fuzzy (ax)	Sibling (P3), Father Education (P6), Mother Education (P7), Family Income (P8), Mileage (P10), Traveled Time (P11), Social Media (P15), Henge Out (P16), Grade Point Average (GPA) (P17).
Conventional (bx)	Gender (P1), Hometown (P2), Family Status (P4), Residence (P5), Motivation (P9), Transportation (P12), Scholarship (P13), Community (P14).

Some researchers stated that there were several parameters in the bx section that only had a small effect on the achievement of AP. According to [18], there is no significant result for the effect given by the gender parameter on student AP results. From the results of the study in [19], the author stated that three other parameters also had a small effect on the PA results including; number of siblings, mileage from faculty and gender. At bx each attribute of the parameter contains a nominal value, where in the conventional group concept (stated as bx) the shape of the attribute effect of the parameter is stated in integer form (0 and 1) represented by conventional values (VC) and shown in Table 3.

Table 3: Conventional Group Value

Parameters	Parameter Value	VC
Gender	Male (M)	0
	Female (F)	0
Hometown	Town (T)	1
	Out of town (OT)	0
Family Status	Living together (L)	0
	Divorce (D)	1
	Died (DE)	1
Residence	With parents (P)	0
	Hostel/Rental (H)	1
Motivation	Dreams (D)	0
	Association (A)	1
Transportation	Private (PR)	0

	Public (PB)	1
Scholarship	Yes (Y)	1
	No (N)	0
Community	Yes (Y)	1
	No (N)	0

3.3. Weighted Parameters

The second configuration of the parameters is done by weighting the parameters. The weighting technique is carried out in two stages; 1) the initial stage is carried out by using the Rapid Miner tool to determine the weight level of each parameter in giving an effect on student academic performance based on the case data used in this study, 2) the next stage is to normalize the initial weighting results. The normalization process aims to avoid systematic technical effects in the form of sufficient data gaps between parameters to ensure that technical bias has minimal impact on the results [20]. The normalization process uses a formula as in equation (1).

$$Normalization = \frac{w_j}{\sum w_j} \qquad (1)$$

The results of normalized weights are shown in Table 4. Where is the fuzzy group (referred to as ax) and the conventional group (referred to as bx), and the weight value of the parameter (referred to as W). The total weight value for ax is represented by ($\sum W_{Fuzzy}$) and the total weight value for bx is represented by ($\sum W_{Conventional}$). The total weight value ax produces a greater total weight value than conventional parameter groups in influencing the final calculation results in the AP.

Table 4: Normalize the Parameter Weights

No	ax	W	No	bx	W
1	CGPA	0.32969	1	Scholarship	0.03398
2	Traveled Time	0.27696	2	Transportation	0.02487
3	Mileage	0.06018	3	Family Status	0.02296
4	Mother Education	0.05371	4	Motivation	0.01871
5	Father Education	0.04136	5	Gender	0.01552
6	Family Income	0.03585	6	Hometown	0.00177
7	Sibling	0.03308	7	Community	0.00081
8	Hang-Out	0.02721	8	Residence	0.00026
9	Social Media	0.02308			
	$\sum W_{Fuzzy}$	**0.88100**		$\sum W_{Conventional}$	**0.12000**

3.4. Fuzzy Logic Model

After getting the data collected, we create a fuzzy set by determining the LV of each fuzzy parameter (FP) shown in Table 5. Where FP is a fuzzy parameter of academic performance parameters, LV is a linguistic variable, and then MF domain are domain membership functions based on the LV of each FP. After the LV is determined successfully. It is then designed to create a MF.

The degree of membership is obtained by first making a graph of each selected FP. The parameters for the number of siblings,

father and mother education, social media, and traveling have 2 fuzzy sets, namely: low and high. The parameters of family income, mileage, and travel time have 3 LV, namely: low, medium and high. CGPA parameter has 4 LV, namely: poor, good, very good, and excellent. All MFs are determined in Figure 2 to Figure 10.

Table 5: Membership Function Value

FP	LV	Domain
Sibling	Low (L)	[0, 3]
	High (H)	[2, 5]
Father Education	Low (L)	[0, 4]
	High (H)	[3, 6]
Mother Education	Low (L)	[0, 4]
	High (H)	[3, 6]
Family Income	Low (L)	[0, 2000000]
	Medium (M)	[1500000, 3500000]
	High (H)	[3000000, 5000000]
Mileage	Low (L)	[0, 8]
	Medium (M)	[6, 14]
	High (H)	[12, 20]
Traveled Time	Low (L)	[0, 20]
	Medium (M)	[15, 45]
	High (H)	[30, 60]
Media Social	Low (L)	[0, 6]
	High (H)	[4, 10]
Henge Out	Low (L)	[0, 5]
	High (H)	[4, 10]
Grade Point Average (GPA)	Poor (P)	[0,00, 2,75]
	Good (G)	[2,50, 3,25]
	Very Good (VG)	[3,00, 3,75]
	Excellent (E)	[3,50, 4,00]

Figure 10: Membership Function for Parameter CGPA

Academically, fuzzy rules are defined to be characterized as fuzzy academic performance (FAP) values based on fuzzy input parameters. The number of fuzzy rules has as many as 3,456 rule bases. It is based on parameters and linguistics. Thus, that can be

validated based on the study of related research literature (shown in Table 6) is used to obtain the FAP value.

Table 6: Fuzzy Rules

Rule 1	IF P1(Low) AND P2(Low) AND P3(Low) AND P4(Low) AND P5(Low) AND P6(Low) AND P7(Low) AND P8(Low) AND P9(Poor) THEN Performance Bad
Rule 2	IF P1(Low) AND P2(Low) AND P3(Low) AND P4(Low) AND P5(Low) AND P6(Low) AND P7(Low) AND P8(Low) AND P9(Good) THEN Performance Bad
…	…
Rule 3455	IF P1(High) AND P2(High) AND P3(High) AND P4(High) AND P5(High) AND P6(High) AND P7(High) AND P8(High) AND P9(Very Good) THEN Performance Good
Rule 3456	IF P1(High) AND P2(High) AND P3(High) AND P4(High) AND P5(High) AND P6(High) AND P7(High) AND P8(High) AND P9(Excellent) THEN Performance Good

3.5. Calculation Academic Performance

In building the model, we apply two separate calculation operations with the Sugeno technique fuzzy method as the main counting operation on the model, specifically in producing the decision value for the final score of academic performance appraisal. The application of the FL Sugeno method provides a systematic approach to generate fuzzy rules from a given input to the output. To calculate the resulting output, Sugeno technique uses weighted average where the resulting output can be a separate characteristic with the final result not in the form of a fuzzy set but a linear or constant equation [21], [22].

From each of the total weight values of ax and bx that were found. Later it will be used to operate as a multiplier index for each calculation operation in the parameter group. The value of $(\sum W_{Fuzzy})$ is used as a multiplier index to multiply the total value of the FAP value calculation operation to produce the total value of the effect of ax on academic performance $((\sum(ax))$ which is mathematically written in equation 2.

$$\sum(ax) = FAP * \sum W_{Fuzzy} \qquad (2)$$

whereas the value $(\sum W_{Conventional})$ used as a multiplier index to multiply the total value of the simple CV addition calculation operation to produce the total effect value of bx on academic performance $(\sum(bx))$ which is mathematically written in equation 3.

$$\sum(bx) = VC * \sum W_{Conventional} \qquad (3)$$

The final calculation stage for the assessment of academic performance, equation (4) is used in calculating the results of the value of academic performance decisions, where each calculation result of the coefficients $(\sum(ax))$ and $(\sum(bx))$ is added up to obtain the final score for the assessment of academic performance. Where the final assessment results as a decision value (DV) in this model produce a decision value in the form of a firm value to assess the results of student academic performance.

$$DV = \sum(ax) + \sum(bx) \qquad (4)$$

4. Result and Discussion

4.1. Experiment Results

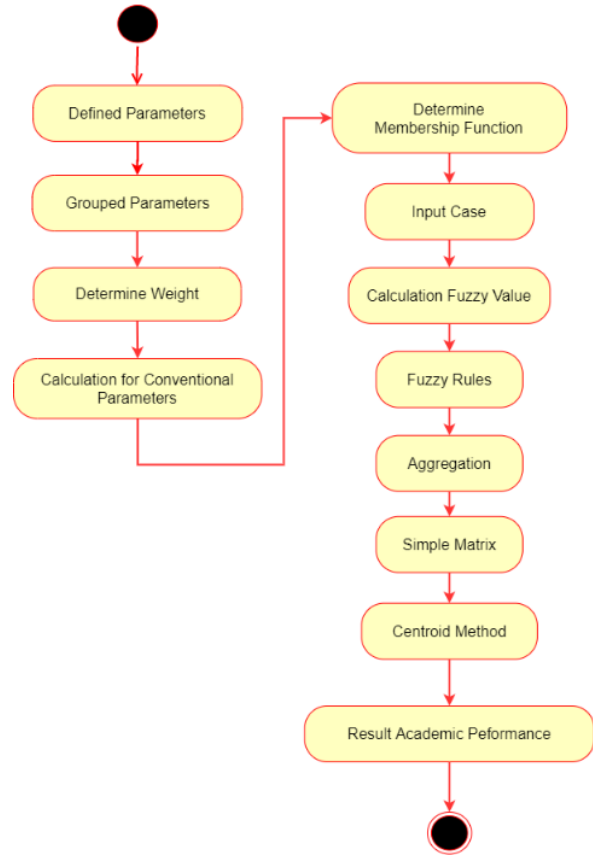
The DSM model built for academic performance appraisal using the FL method Sugeno technique which is a popular method in the DSM field. It is also quite elastic in dealing with complex problems in the real world in the form of linear or nonlinear systems. It works by mapping problems into the form of fuzzy reasoning to obtain a decision. The complete flow of activity in the model is depicted in Figure 11.


Figure 11: Model for Assessing Academic Performance

The initial activity begins by configuring all the parameters used as model input. The configuration at the initial stage is done by grouping the existing parameters into fuzzy groups (ax) and conventional groups (bx). Furthermore, the configuration for weighting is carried out to identify each weight value (W) of each parameter and the total weight value for axis represented by $(\sum W_{Fuzzy})$ and the total weight value for bx is represented by $(\sum W_{Conventional})$.

Furthermore, the counting operation for bx is carried out separately from the FL Sugeno method. The calculation is done by multiplying the number of CV against the $(\sum W_{Conventional})$ value to produce the total effect value of bx on academic performance $(\sum(bx))$.

The counting operation using the FL Sugeno method for ax is carried out in the next step. The main concept of the FL method includes the "fuzzy - inference - defuzzy" stage which is carried out sequentially based on the fuzzy rules created. The rules then

produce a FAP value based on fuzzy input parameters. At the end of the Sugeno FL method, the FAP value is used to multiply the ($\sum W_{Fuzzy}$) value to produce the total effect of on academic performance ($\sum(ax)$).

The final process of assessing academic performance is carried out by adding up the respective values of ($\sum(ax)$) and ($\sum(bx)$) that were successfully obtained in the previous stage. The final result of the academic performance appraisal is formed as a DV which is in the form of a linear or constant equation. DV based on the determination of the index value for the performance criteria is determined. Where the good performance criteria have an index value of 80 while the bad performance criteria have an index value of 50. The sample results from our calculations are shown in Figure 12.
Figure 12: Result Assessing for Academic Performance

The bar graph in Figure 11, represents the 10 data cases used. The visualization on the bar graph in Figure 11 shows that our 5 test data resulted in good academic performance scores with the highest score at 71.08, 2 data are poor academic performance scores with the lowest score at 44.29, with an average of 62.03 results for the assessment of academic performance that we have done.

4.2. Discussion

The measurement of AP results in the classical method is usually expressed in numerical form (GPA) obtained at the end of the learning period [15]. Therefore, it can be said that the classical method is a form of presentation based on the comparison of student performance results with the predetermined standard performance value category.

The academic performance assessment of FKIP students at Mulawarman University focuses more on the indication of the achievement of GPA. Policymakers tend to focus more on the GPA score. That makes various policies focused on increasing the GPA over a period of time.

One shortcoming is found for the classical method used in the current AP assessment. Where it only focuses on increasing the GPA score in a certain period without any criteria instead of using the GPA indicator for the final result [16]. While the GPA indicator is an assessment of university accreditation as well. However, the supporting factors of achieving GPA scores are not used such as; gender, hometown, sibling, family status, residence, father education, mother education, family income, motivation, mileage,

traveled time, transportation, scholarship, community, social media, and hang-out. The results of the model assessment of AP from the GPA of the results of the conventional method are compared and displayed in Table 7. It is proven academically, that PA produced by the constructed DSM does not has similar rank (priority) to PA measured based on GPA.

Table 7: Comparison of Assessing Performance

No	Performance (Fuzzy Logic Sugeno Method)	Performance (Classical Method)
1	71.08	3.56
2	70.85	3.15
3	70.73	2.98
4	70.73	3.46
5	70.73	3.56
6	61.71	2.96
7	61.48	2.97
8	54.26	2.89
9	44.41	2.41
10	44.29	2.46

Table 7 shows that the results of the academic performance assessment using the model we built can be a solution. That can be used practically. As well as it can give freedom to academics as policymakers to be able to assist in the process of academic performance evaluation by providing the results of an effective approach. The final results of the assessment are carried out using various parameters outside of the educational factors for the family, economic, social, and environmental factors that we calculated on the model.

We identify the influence great value of each parameter from the fuzzy group (ax) and the conventional group (bx) on our AP assessment (Figure 12). The symbolized parameters refer to Table 1. The Traveled Time (P11) parameter has a significant effect by being the second largest influencer (0.27696) on ax after the CGPA parameter (P17) which has an effect of (0.32969), which simultaneously is the main indicator in making an assessment AP, while the social media parameter (P15) is the smallest one (0.2308).

In (bx), each parameter does not seem to have much influence on the AP assessment, with the Scholarship parameter (P13) as the biggest influencer (0.03398) and the Residence parameter (P5) giving an effect of (0.00026). Figure 12 shows that the AP assessment process is heavily influenced by various parameters on ax with the influence great value of ax is (0.88100) and the parameter on (bx) has little effect (0.12000) on the AP assessment.

Besides the various parameters that we use, which are parameters related to academic performance from various factors such as social, family, economic, and educational environments. Many studies have been carried out related to academic performance by proposing to use parameters derived from educational factors themselves.

According to research that has been done [16], [17], and [18], the assessment of academic performance is influenced by factors originating from the educational side which includes, record of student semester scores. [8] stated that the use of the parameter of semester scores is relevant in conducting performance appraisals. Where the semester scores in learning period 1 60% affect

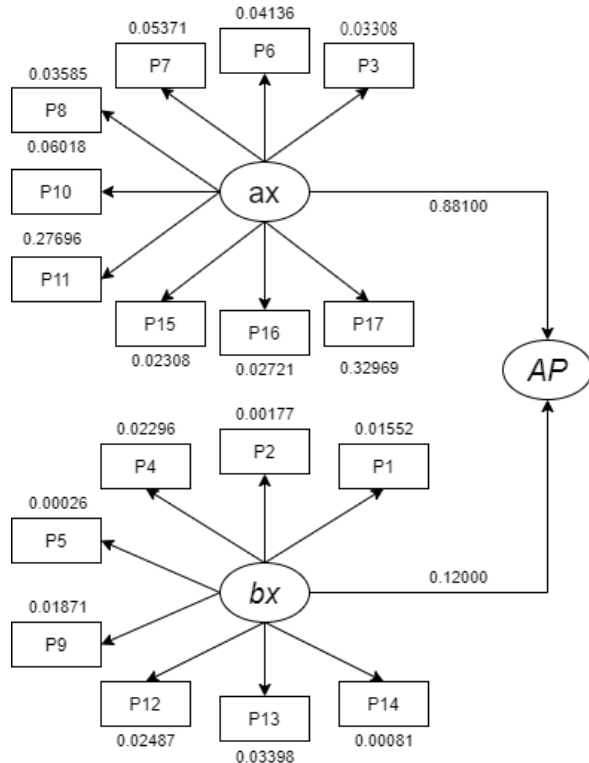
performance results while 40% of semester scores in periods 2 affect academic performance results.


Figure 13: Similarity Structure of Assessing Academic Performance

5. Conclusion

The process of assessing the results of student academic performance is generally applied to universities using the classical method (based on performance categories). The DSM model is built using the FL method Sugeno technique which is a form of practical solution that can be used in the world of education to assess academic performance which is part of the AP evaluation process.

As the model using the FL Sugeno method provides advantages with the elastic properties. Thus, it can be adjusted to the needs of the study while still providing sharp outputs as an effective form of decision approach based on a series of fuzzy rules from the input given to the output.

The academic performance appraisal process is carried out by involving relevant seventeen parameters to the performance appraisal based on validated previous research. Parameters are grouped into fuzzy groups (ax) and conventional groups (bx). The fuzzy group (ax) is identified to have a significant effect on the assessment of academic performance compared to the conventional group (bx) with only a slight influence on the assessment process.

	Monoacylglycerol (MAG) and diacylglycerol (DAG) are structured lipids that have been widely used in various pharmaceutical, cosmetic, and food industries. MAG and DAG are generally produced by chemical glycerolysis. Chemical catalysts have been shown to be more efficient, economical, and effective. This study summarizes and discusses the factors that affect the synthesis of MAG and DAG by chemical glycerolysis, such as temperature, reaction time, and type and concentration of catalysts that affect the resulting MAG and DAG concentrations. Homogeneous catalysts such as KOH and NaOH are very effective for generating MAG and DAG conversions up to 91%, but they have a disadvantage, mainly because they cannot be used repeatedly. However, heterogeneous catalysts have great potential to be developed into catalysts with high activity, environmentally friendly, and can be used repeatedly.

1. Introduction

The need for emulsifiers is increasing along with the development of emulsion-based food products, especially emulsifiers from the mixture of monoacylglycerols and diacylglycerols, which are the most considerably used in the food industry, which is about 75% [1]. Commercially, MAG and DAG are used in food products such as cake products, butter, margarine, and confectionaries because they have good emulsification, stabilization, and conditioning properties [2,3]. Mono and diacylglycerols are also used in the pharmaceutical, cosmetic, textile, and plastic industries in consequence of their plasticizing and lubricating properties [4,5]. Applications of MAG and DAG in various products can be seen in Table 1.

Naturally, MAG and DAG are minor components in various vegetable oils with a maximum content of 10% [6]. MAG consists of three isomers, namely enantiomers (sn-1 and sn-3) and regioisomers (sn-2) [7]. DAG be composed of 2 fatty acyl chains, which are esterified into glycerol backbone and can have the shape of 1,3-DAG and 1,2 (or 2,3)-DAG [8]. MAG and DAG are non-ionic molecules that have a free hydroxyl group, which is a hydrophilic group, and a fatty acid ester group, which is a lipophilic group [9]. The double affinity of MAG and DAG or often called amphiphilic, means that they can be used as emulsifiers. MAG with one fatty acid group and two free hydroxyl

groups on glycerol makes it behave like fat and water. MAG is an emulsifier that is not very sensitive to acidic conditions. The way the emulsifier works is by lowering the surface tension between the two phases and then stabilizing the products [10].

Commercially, the synthesis of MAG and DAG can be conducted by various methods, namely glycerolysis, direct esterification, and partial or alcoholic hydrolysis [5]. Various types of catalysts are also used, such as homogeneous base catalysts, heterogeneous bases, homogeneous acids, and heterogeneous acids. Several studies have shown a relatively high yield when using a homogeneous base catalyst and a heterogeneous base catalyst, while acid catalysts produce a relatively lower yield. In general, the synthesis of MAG and DAG on a large scale is carried out using the chemical glycerolysis method of oil, which is reacted with glycerol using an alkaline catalyst (such as NaOH and KOH) at high temperatures [2,11].

Table 1: Applications of MAG and DAG in Various Products.

Source of MAG/DAG	Products	References
Palm-based oils/fats	Emulsifier	[12]
Palm oils	Emulsifier	[13]
Vegetable oil	Emulsifier	[14]
Palm mild fraction	Shortening	[15]
Sunflower oil, palm kernel olein	Margarine	[16]

Chicken fat	Structured fat	[17]
Corn oil	MAG-DAG Oils	[18]
Vegetable oils	MAG-DAG Oils	[19]
Palm olein	MAG-DAG Oils	[20]
Monostearate	Oleogels	[21]
Monostearate, monopalmitate	Organogels	[22]
Saturated fat	Organogels	[23]
Saturated fat	Oleogels	[24]

Chemical glycerolysis at high temperature has several disadvantages, such as dark-colored products and high energy consumption. Several studies have reported that chemical glycerolysis of oils and fats can produce MAG and DAG of about 45-55% and 38-45%, respectively [3]. Subsequent molecular distillation is required to acquire monoacylglycerols with a purity of 90% [25], needed for the pharmaceutical, cosmetic, and food industries. Recent research studies about the glycerolysis reaction at low temperatures using a solvent or without a solvent; the concentration of MAG and DAG generated by this reaction ranges from 40-80% [26].

Another alternative used to substitute chemical catalysts is to use enzyme catalysts [27]. However, the use of enzymes has several drawbacks, such as the glycerolysis reaction requires special conditions and slow reaction kinetics. Besides, the high price of enzymes is a consideration for industrial applications [4]. The use of cheap and easy to obtain raw materials is an important factor in the manufacture of MAG and DAG on an industrial scale. Over the past few years, means have been made to produce high MAG using chemicals and enzymes as catalysts, and methods have been promoted with the aim of increasing the yield of MAG and DAG [28].

Various methods and various types of catalysts can be used to produce MAG and DAG, which can be applied to various food industries. This study discusses the effect of various types of chemical catalysts and their concentrations on the production of MAG and DAG using the glycerolysis method by considering other factors such as the molar ratios of oil to glycerol, temperature, and reaction time. In addition, the NaOH catalyst, which is a homogeneous catalyst, has not been widely discussed, so it is interesting to study in-depth because it has high catalytic activity and is efficient.

2. Characteristics of Mono- and Diacylglycerols

MAG and DAG are non-ionic molecules that have hydrophilic and hydrophobic groups [9]. MAG is an anionic emulsifier with excellent emulsifying properties because it has two hydrophilic groups (hydroxyl) and one hydrophobic group on the fatty acid chain. These emulsifying characteristics are used in food products, cosmetics, plasticizers, detergents, and pharmaceutical formulations [29]. On the other hand, DAG can be used as an emulsifier, especially in emulsion systems of water in oil (o/w). DAG can also effectively prevent the accumulation of fat and diseases related to obesity, so it is often used as a functional ingredient and including lipids that are good for health [30].

MAG and DAG are needed in almost all types of food products. Its main use includes bakery products, margarine, convenience foods, and frozen desserts. MAG and DAG are used as part of fat products and are often associated with other emulsifiers. Lipophilic characteristics cause MAG and DAG to have excellent properties as emulsifiers in water in oil (w/o) system, as required in the manufacture of margarine and shortening [15,16,31].

One of the uses of MAG and DAG is as an emulsifier. The use of emulsifiers is to maintain moisture and softness of bakery products, improve the stability of crystal emulsions in ice cream products, reduce stickiness in candy products, and so on [32]. In addition, other uses of emulsifiers are maintaining emulsion stability in margarine, preventing fat bloom in chocolate products, and improving palatability in cake products [33].

Based on research in [34], the emulsification ability produced from an emulsifier containing a mixture of 91% MAG and 9% DAG was stable when compared to commercial emulsifiers because the emulsion capacity was 95.55% after heating, the percent stability of the emulsion only decreased a little, namely to be 90.44%. Based on research in [35], the emulsification ability produced from a mixture of 50.89% DAG and 11.68% MAG had emulsion stability of about 95.44% and an emulsion capacity of 93.63%.

The melting point of MAG and DAG is higher than their triacylglycerol forms. The difference in melting points is caused by the difference in the number of hydrogen bonds in the carboxyl bonds and the hydrophobic interactions along the hydrocarbon chains. The melting point increases as the MAG and DAG content in the fat/oil increases [36]. MAG has a faster crystal conformation compared to TAG [37]. MAG and DAG can be utilized separately (pure of MAG and pure of DAG) or simultaneously. The application of MAG as an emulsifier requires high purity because MAG has better emulsification characteristics than different acylglycerol mixtures [38].

Food emulsifiers are generally in the form of semisolids containing fatty acids such as stearic, lauric, palmitic, and oleic acids. In general, the commercially saturated MAG is MAG containing stearic acid. Saturated MAG has a high melting point but has restricted emulsifying characteristics. Nevertheless, unsaturated MAG has a modest structure but is restricted in application due to its low oxidation stability [39].

A decrease in oxidation stability can be caused by changes in the position of fatty acids in the acylglycerol structure, include MAG and DAG [40]. Partial hydrogenation can be an effective way to rectify the oxidative stability of fats/oils [41]. Zhang et al. [39] conducted a study that rivets on partial hydrogenation of corn oil to increase the MAG oxidation stability of corn oil. The oxidation stability measured based on the induction period (IP) value of the MAG from the hydrogenation of corn oil was 13.68 hours, while the IP value of the MAG of corn oil was 0.51 hours. Thus, hydrogenation increases oxidation stability. However, partial hydrogenation can lead to the formation of trans-fats, which can be harmful to health.

3. Synthesis Methods of Mono- and Diacylglycerols

3.1. Enzymatic Methods

The enzymatic synthesis method can be carried out through esterification, alcoholysis or hydrolysis, and glycerolysis. Highly

stable lipases in solvents offer the potentiality of using a variety of approaches for catalyzed enzyme synthesis, such as selective alcoholysis or hydrolysis by specific lipases, glycerolysis of oils/fats, and esterification of free fatty acids with glycerol [42]. The reaction of glycerolysis by enzymatic catalysts has been extensively investigated using low temperatures (<80 °C) to generate MAG and DAG. MAG and DAG resulting from the enzymatic glycerolysis have good quality, but enzymatic glycerolysis has several shortfalls, including limited availability of enzymes, low reactant conversion factors, long reaction times, and high cost [43]. In addition, enzymatic glycerolysis has low efficiency, which is largely due to the inhomogeneous nature of oil or fat with lipophilic properties and lipase enzymes with hydrophilic characteristics when the reaction is carried out at low temperatures. It is notable for maintaining homogeneity between oil or fat and enzymes using the suitable solvent [44].

Based on research in [45], the glycerolysis between several samples of oil and fat with glycerol using lipase as a catalyst without using solvents and emulsifiers in a batch system produced 90% MAG resulting from the glycerolysis of olive oil, while the lowest yield was 30% that results from hydrogenated fat. Based on research in [3], the glycerolysis reaction of sunflower oil samples using Novozyme 435 with tert-pentanol and tert-butanol as the single solvent produced MAG in the range of 68-82%.

Based on research in [46], the enzymatic glycerolysis reaction of Lipozyme TL IM 15% using tert-butanol and iso-propanol (80/20 w/w), glycerol to oil molar ratio 3.5: 1, and solvent to oil ratio 4:1, at a temperature of 45 °C for 4 hours produced MAG about 72%. In [4], the author compared the glycerolysis between the enzyme-catalyzed reaction and the NaOH-catalyzed reaction. The reaction rate of the NaOH catalyzed was faster than the Novozym 435. Although the enzymatic approach has yielded good results; nevertheless, the high cost, reaction rate, and stability of the catalyst remain major barriers to the wide-spread use of enzymes for the commercial production of MAG and DAG.

3.2. Chemical Methods

Commercially MAG and DAG can be produced through several methods, namely: (i) direct esterification with fatty acids catalyzed by strong acids such as H_3PO_4 or H_2SO_4 at a high temperature of 90-120 °C or alkaline catalysts, (ii) glycerolysis of oil or fat which is catalyzed by homogeneous bases such as KOH or NaOH at a high temperature of 120-260 °C under an inert atmosphere, (iii) transesterification of fatty acid esters and (iv) partial or alcoholic hydrolysis [2,47].

In [48], the direct esterification using the ratio between lauric acid and glycerol of 1:1 at 112 °C using a mesoporous sulfonate catalyst 0.5% (w/w) produced MAG with a concentration of 53%. Meanwhile, under the same reaction conditions, but using Amberlyst-15 as a catalyst, it produced MAG with a concentration of 44%. The MAG produced using a mesoporous sulfonate catalyst was higher because it contains alkyl, and sulfonic acid can act as a catalyst [49]. In [50], the heterogeneous catalyst Amberlyst-15 was affected by several factors, namely the pore diameter and catalyst surface area. The use of H_2SO_4 as a homogeneous acid catalyst at a lauric acid and glycerol ratio of 1:1, a temperature of 130 °C for 6 hours, and a 5% (w/w) H_2SO_4

catalyst produced 31.05% monolaurin after going through a purification using column chromatography techniques [51].

Most of the MAG and DAG is generated by glycerolysis of TAG with excess glycerol at high temperatures in the presence of a catalyst. The addition of a catalyst to the glycerolysis reaction aims to acquire a high conversion in a relatively short time. This reaction can be performed in the existence of a base catalyst or an acid catalyst. The reaction with an alkaline catalyst is usually faster than an acid catalyst [52].

The glycerolysis reaction occurs randomly following the equilibrium to produce a certain composition of MAG, DAG, and TAG. Theoretically, the glycerolysis reaction involves 2 moles of glycerol, which will react with 1 mole of TAG and generate 3 moles of MAG. The glycerolysis reaction is used in producing MAG and DAG because it is more economical in terms of raw material prices and requires less glycerol [53]. According to [4], KOH and NaOH are catalysts that are more effective in their use in the glycerolysis process at low temperatures compared to SiO_2 and Al_2O_3.

4. Types and Concentrations of Catalysts for Chemical Glycerolysis

Chemically synthesizing MAG and DAG by glycerolysis requires a catalyst. Catalysts are substances that speed up reactions but do not react with them. The catalyst speeds up the reaction by decreasing the activation energy. The greater the concentration of catalyst and reaction temperature, the greater the reaction rate so that the product produced is also more significant [54]. Catalysts can be classified into two types, namely homogeneous catalysts and heterogeneous catalysts. The catalyst selectivity has several differences. Homogeneous catalysts are generally used for universal substrate types but are only suitable for batch reactors and cannot be used in continuous systems. In comparison, heterogeneous catalysts are more suitable for substrates or reactants that are less viscous and suitable for reactions in continuous systems [55].

In the use of a homogeneous catalyst, the catalyst is in the same phase as the reactants. The reactants and catalyst are in a single phase of liquid or gas. There are two types of homogeneous catalysts, namely homogeneous acid catalysts and homogeneous base catalysts. Homogeneous base catalysts for glycerolysis include KOH and NaOH [56]. These catalysts have advantages related to their characteristics, including high catalytic activity that only requires a short reaction time, low cost, high stability, and easy use [57]. There are also homogeneous catalysts in the form of homogeneous acid catalysts, include H_2SO_4, HCl, and H_3PO_4. However, the utilize of a homogeneous acid catalyst requires a long reaction time, causes corrosion in the reactor, and requires high temperatures [58].

In the use of heterogeneous catalysts, the catalyst and reactants are in different phases. Heterogeneous catalysts tend to be easier to separate and reuse from the reaction mixture because the phase used is different from the reaction product. The heterogeneous catalyst used is in the form of a solid phase while the reactants are liquid [59]. The most commonly used heterogeneous base catalysts are alkaline earth metal oxides compounds, such as MgO, CaO, SrO, and BaO [60].

Apart from metal oxide catalysts, there are several non-oxide catalysts that can be used, including 1-Butyl-3-Methylimidazolium Imidazolide [61]. The catalyst is also effectively used in chemical glycerolysis to produce DAG reaching about 60% at a concentration of 15%, a temperature of 80 °C for 4 hours.

Chemical catalysts are more widely used because they are easier to handle, cost less, easy to separate, and can be used in relatively low concentrations. Several types of chemical catalysts used in the glycerolysis reaction for the production of MAG and DAG are presented in Table 2.

Table 2: Several Types of Chemical Catalysts Used in the Glycerolysis Reaction for the Production of MAG and DAG.

No	Catalysts	Source of fat/oil	Reaction condition	Yield of MAG & DAG	References
1	NaOH 0.18%	Soybean oil	The molar ratio of oil:glycerol (1:2.5), 230 °C, 25 min	58% & 33%	[27]
2	NaOH 3%	Palm olein and palm stearin	The molar ratio of oil: glycerol (1:1.5), in tert-butanol, molecular sieve 12%, at 80 °C for 3 h	58.64%	[35]
3	NaOH 0.3%	Palm oil	The molar ratio of oil:glycerol (1:2), 240 °C, 60 min	58%	[62]
4	NaOH 0.45%	Soybean oil	Glycerol 4,6 g; Oil 8.8 g; in t-butanol; 50 °C, 1 h	81.76%	[4]
5	NaOH 2%	Palm stearin	The molar ratio of oil:glycerol (1:2.5), 200 °C; 20 min	65.4%	[1]
6	NaOH 3%	RBD Palm stearin	The molar ratio of oil: glycerol (1:5), in tert-butanol, molecular sieve 13%, at 90 °C for 6 h	91.00% & 9.00%	[34]
7	KOH 0.45%	Soybean oil	Glycerol 4,6 g; Oil 8.8 g; in t-butanol; catalyst 0.04 g; 50 °C, 1 h	68%	[4]
8	Amberlyst-15	RBD Palm stearin	The molar ratio of oil: glycerol (1:5), in tert-butanol, 90 °C, 9 h	16.44% & 14.49%	[34]
9	MgO	Rapeseed oil	The molar ratio of oil:glycerol (1:4), 249.85 °C, 2 h	66%	[29]
10	Ca(OH)$_2$ 1%	Sunflower oil	The molar ratio of oil:glycerol (1:4), 200 °C, 1 h	48.3% & 42.3%	[63]
11	CuO-nano+ NaOH 0.3%	Palm oil	The molar ratio of oil:glycerol (1:2), 240 °C, 40 min	71%	[62]
12	ZnO-CaO/AlO$_3$	Rapeseed oil	The molar ratio of oil:glycerol (1:4), 249.85 °C, 2 h	57%	[29]
13	1-butyl-3-methylimidazolium imidazolide	Soybean oil	Catalyst concentration if 15%, glycerol/TAG mole ratio was 5:1, 80 °C, 4 h	17.4% & 61.7%	[61]

The reaction mechanism of the glycerolysis catalyzed by homogeneous and heterogeneous chemical catalysts is almost the same but has some differences, especially in the active groups of cations or anions that are owned by heterogeneous catalysts. The chemical glycerolysis mechanism is described as follows. In glycerolysis using a homogeneous catalyst such as NaOH, in the early stages, the hydrogen in the glycerol molecule is abstracted by NaOH, which is a strong base to form sodium glyceroxides, which then easily form glyceroxides at high temperatures (90-240 °C). Meanwhile, the OH- anion produced from NaOH can act as a proton abstraction agent that can attract protons from the OH group on glycerol by forming surface glyceroxides. Na$^+$ cations also take part in the stabilization of negatively charged intermediates. In this condition, the Na$^+$ cation also plays a role in activating the triacylglycerol molecule (polarization of the C=O

bond). The Na$^+$ cation further assists or facilitates the overrun of the glyceroxide anion on the positively charged carbonyl carbon present in the TAG. In a later stage, there is a nucleophilic attack on the carbonyl group of the TAG by the glyceroxides to produce MAG and the appropriate anion of 1,3 or 1,2-DAG known as diglyceroxide. The next stage is the conformation of the suitable alkyl ester (DAG) and glycerol anions (glyceroxides) by the second molecule of glycerol reacting with the adsorbed diglyceroxide. In the last stage, the alteration of TAG or DAG to MAG is carried out following the same mechanism. In contrast to homogeneous catalysts, heterogeneous catalysts that act to abstract hydrogen on the glycerol molecule are not Na$^+$ cations, but depending on the active groups that heterogeneous catalysts have, for example, are sulfonic or CuO groups. In addition to acting in hydrogen abstraction, this group also plays a role in

polarizing the ester group (C=O) on TAG. Meanwhile, the other mechanism stages are almost the same, namely through nucleophilic attacks and ending with the conversion of TAG and DAG to MAG [64,65].

Table 2 shows that the type and concentration of the catalyst affect the results of the MAG and DAG concentrations. However, glycerolysis is also influenced by reaction conditions (temperature, the molar ratio of oil to glycerol, and reaction time). Homogeneous catalysts and heterogeneous catalysts have advantages and disadvantages. Homogeneous catalysts such as NaOH or KOH are preferred because they can readily dissolve and react with glycerol in the reactant system. Based on research in [34], the MAG produced followed by fractionation was 91.00%. The increase in MAG levels is due to differences in the melting point and the thermomechanical separation process through crystallization, namely MAG, which has a higher melting point, will be separated from DAG and TAG with lower melting points. At a fractionation temperature of 30 °C, MAG will crystallize while DAG and TAG remain dissolved in hexane and then filtered. In addition to fractionation, molecular distillation can increase monoacylglycerols with a purity of 90% [25].

Based on research in [62], using the homo-hetero system in the glycerolysis reaction resulted in almost the same triacylglycerol conversion using either NaOH or CuO-nano + NaOH catalysts. However, the product distribution was different where the MAG concentration in the use of a CuO-nano + NaOH catalyst is higher than the reaction using a NaOH catalyst. The adjunct of a small amount of NaOH (0.01% w/w) could increase the TAG conversion. In addition, the catalyst systems of CuO-nano + NaOH showed an increase in the yield of TAG to MAG conversion, reaching 90%. The use of CuOnano + NaOH catalyst resulted in a higher yield MAG than for the NaOH system; this shows that in the reaction system, CuO also acts as a catalyst.

Based on the results of the research that has been conducted, it is possible to consider three main factors that affect the glycerolysis process. These three factors are the strength of the base catalyst, the radius of the catalyst pore, and the solubility of the catalyst in the glycerol and oil system [29]. In the research of [29], using a ZnO-CaO/ AlO$_3$ catalyst, the results of the MAG concentration were lower than using the MgO catalyst. Based on research in [4], by comparing eight commonly used basic catalysts, namely Al$_2$O$_3$, SiO$_2$, MgO, Na$_2$CO$_3$, K$_2$CO$_3$, CaO, KOH, and NaOH. Only NaOH and KOH are effective in catalyzing chemical glycerolysis at low temperature (50 °C).

The homogeneous catalysts (KOH and NaOH) have high catalytic activity and result in high product yields [66]. The reason for this case remains to be investigated. This is also thought to be caused by differences in the capability to extract hydrogen from glycerol. Both KOH and NaOH have the same solubility in the tert-butanol. However, at temperatures higher than 240 °C, the Ca(OH)$_2$, MgO, and CaO catalysts are all functioning even in solvent-free systems, which exhibit easier alkoxide formation [67]. This is also supported by several studies presented in Table 1, that a high temperature of 200-250 °C produces a high MAG concentration of 77% (solvent-free system). Therefore, high temperature not only increases the solubility of oil/fat and

glycerol but also helps the catalyst to extract hydrogen from glycerol to create alkoxides.

According to [5], the surface polarity of the catalyst has a key role in increasing the concentration of MAG and DAG. The glycerol concentration on the catalyst surface will be greater than the fatty acid ester for MAG formation because the high glycerol concentration will limit the forming of DAG and TAG. However, hydrophobic oils also have difficulty accessing the surface of the catalyst, thus reducing the reaction kinetics. Therefore, the catalyst must be very active, the reaction temperature used is higher, and also use a solvent to accelerate the reaction [68].

As previously explained, the glycerolysis reaction is a slow-running reaction without the addition of a catalyst. The use of various concentrations of NaOH is also expected to produce high mono- and diacylglycerols. According to [4], the catalyst concentration influences the reaction rate over a particular range, an increase in the NaOH concentration causes an increase in the reaction rate. The concentration of catalyst affects the yield of the resulting product; the higher the concentration of the catalyst in the solution, the smaller the activation energy of a reaction, so that more products will be formed [69]. However, the addition of excessive catalyst concentration can also encourage the reaction to form soap [70].

Various researches to get the type of catalyst in the glycerolysis reaction continue to develop. Recommendations that can be taken from this review are that NaOH catalysts are very effective catalysts for chemical glycerolysis reactions, but have the disadvantage of not being used repeatedly, are not environmentally friendly, and cannot be used for continuous reaction systems. Therefore, a more in-depth research is needed, especially on heterogeneous catalysts, in order to obtain a catalyst that is inexpensive, high activity, stable, able to be used repeatedly, can be used for continuous reaction systems, and environmentally friendly.

5. Conclusion

Research on the synthesis of MAG and DAG has been carried out using various enzymatic and chemical methods. Chemical catalysts have been shown to be efficient and effective catalysts, so that the chemical glycerolysis is an effective and efficient method for MAG and DAG production. However, the type and concentration of catalysts are very influential in chemical glycerolysis. Catalyst activity is affected by three main factors, namely the strength of the base catalyst, the radius of the catalyst pore, and the solubility of the catalyst in the glycerol and oil system. Homogeneous catalyst (NaOH) concentrations of 0.2-0.5% produce high yields of MAG and DAG (in the solvent systems). In the solvent-free systems, NaOH at concentrations of 3% produces high yields of MAG and DAG. Homogeneous catalysts such as NaOH and KOH are very effective for generating MAG and DAG conversions up to 91%, but they have a disadvantage, especially in that they cannot be used repeatedly. However, heterogeneous catalysts have great potential to be developed into catalysts with high activity, environmentally friendly, and can be used repeatedly.

Conflict of Interest

The authors declare no conflict of interest.

Power converters are electronic devices widely applied in industry, and in recent years, for renewable energy electronic systems, they can regulate voltage levels and actuate as interfaces, however, to do so, is needed a controller. Proportional-Integral-Derivative (PID) are applied to power converters comparing output voltage versus a reference voltage to reduce and anticipate error. Using PID controllers may be complicated since must be previously tuned prior to their use. Many methods for PID controllers tunning have been proposed, from classical to metaheuristic approaches. Between the metaheuristic approaches, bio-inspired algorithms are a feasible solution; Particle Swarm Optimization (PSO) and Genetic Algorithms (GA) are often used; however, they need many initial parameters to be specified, this can lead to local solutions, and not necessarily the global optimum. In recent years, new generation metaheuristic algorithms with fewer initial parameters had been proposed. The Grey Wolf Optimizer (GWO) algorithm is based on wolves' herds chasing habits. In this work, a comparison between PID controllers tunning using GWO, PSO, and GA algorithms for a Boost Converter is made. The converter is modeled by state-space equations, and then the optimization of the related PID controller is made using MATLAB/Simulink software. The algorithm's performance is evaluated using the Root Mean Squared Error (RMSE). Results show that the proposed GWO algorithm is a feasible solution for the PID controller tunning problem for power converters since its overall performance is better than the obtained by the PSO and GA.

1. Introduction

Power converters have an important role in Industry applications; their main purpose is to regulate power in electronic appliances and adjusting current and voltage signals to desired levels by a high frequency switching control device [1,2]. One of the most significant modern applications for power converters is related to Renewable Energy Sources (RES), since the power generated for these sources highly depends on environmental conditions power converters are a reliable solution to stabilize output voltage and current of RES. A Boost Converter is an electronic device whose main purpose is to raise an input voltage and stabilize it to a desired highest level [3,4]. Since voltage regulation on power converters, and therefore, boost converters, depends on a switching signal, is needed a controller to generate a proper pulse width modulation (PWM) to modify the duty cycle of the switching signal. PID controllers are commonly used for this kind of applications, however, PID controllers need to be tunned prior its use [5]. The PID controller tunning can be a challenging task, many methods had been proposed for this purpose, from classical modeling and analysis based on system response [6] to modern techniques based on metaheuristic algorithms [7]. Nature had been an inspiration for modern metaheuristic algorithms, most of them based on animal behavior, for system design and control optimal parameters finding [8]. Bio-inspired algorithms imitate animal collective intelligence to explore, find, and exploit food and resources. Collective intelligence is the sum of individual behavior based on simple rules, and these behaviors and strategies can be translated into computational optimization algorithms. The most common bio-inspired algorithms are Genetic Algorithms (GA) and

Particle Swarm Optimization (PSO) algorithms. Among these bio-inspired optimization algorithms applications are control of load frequency [9], systems optimal sizing and design [10], power flow applications [11], predictive control for microgrids based on renewable energies [12], power converters optimal design [13] and regulation for voltage [14]. In [15], an evolutionary approach using Symbiotic Organisms Search (SOS) algorithm, which is based on PSO algorithms and the trophic chain of the ecosystems, and a two-round fuzzy inference engine were presented for energy management in microgrids. Since PSO is general modeling for animal behavior, there had been developed and studied variants of PSO based on particular animal species [16,17]. Authors in [18] applied a Whale Optimization Algorithm for an optimal design of a PID controller for a DC-DC converter using a transfer function and step response approach to analise the system performance; they found beter transciente response in comparison to a compared GA algorithm, however, they did not considered fluctutanting input voltages or load changes. In 2014, the author presented the Grey Wolf Optimizer (GWO), based on hunting strategies of wolves herds [19]. The GWO had been studied in comparison to other optimization algorithms as well as some engineering applications. Authors in [20] applied GWO to a PID controller to optimize the system response of a steam pressure system, they found an improvement in system stability and response. In [21] the GWO was applied to a modeled levitation system, improving time domain response and reducing the system error in comparison to the PID tunning MATLAB tool. Also, GWO had been applied to power systems.

In this paper, an optimal tunning for a PID controller using the GWO algorithm applied to a boost converter is presented. The boost converter is modeled unsung state-space equations and then simulated in MATLAB/Simulink. The proposed GWO-PID tunned algorithm performance is compared with PSO and GA algorithms in terms of the RMSE and the system response for variable load and variable input voltage. The paper is organized as follows: Section 2 depicts the boost converter model and description. Section 3 presents the GWO, PSO, and GA optimization algorithm basis. Section 4 shows the optimization methodology for the boost converter. Section 5 summarizes the results and, finally, Section 6 are the conclusions of this study.

2. Mathematical model of the Boost Converter

The boost converter is an electronic device that rises input voltage to the desired highest output voltage. Voltage regulation is made by a PWM signal, applied to an inductor (L) and capacitor (C) arrangement, carried out by a fast-switching transistor that according to the control signal. Changes in the PWM signal modifies the L-C charge and discharge cycles and change the output signal [22]. The boost converter configuration is shown in Figure 1.
Figure 1: Electric diagram for the Boost converter.

Modeling of the boost converter was carried out using state-space equations, then MATLAB/Simulink software was used for simulation.

State-space equations were obtained employing Kirchhoff's voltage and current laws analysis for each system switching state determined by the u control signal value. Since u the signal can only adopt a 1 o 0 value, there are two possible Boost converter electric configurations, that correspond to charge and discharge cycles for the L and C elements. The two possible circuit configurations are condensed in a single matrix form of state-space equations as showed in (1).

$$\begin{bmatrix} \dfrac{dv_o(t)}{dt} \\ \dfrac{di_L(t)}{dt} \end{bmatrix} = \begin{bmatrix} \dfrac{1-u}{C} & -\dfrac{1}{CR} \\ 0 & -\dfrac{1-u}{L} \end{bmatrix} \begin{bmatrix} v_o(t) \\ i_L(t) \end{bmatrix} + \begin{bmatrix} 0 \\ \dfrac{1}{L} \end{bmatrix} v_i(t) \qquad (1)$$

In (1) L is the inductor, C is the capacitor, $i_L(t)$ is the current in the inductor, $v_o(t)$ is the output voltage, $v_i(t)$ is the voltage ant input of the boost converter, and u is the PWM control signal generated by the PID controller.

3. Optimization Algorithms

A performance comparison between three optimization algorithms: PSO, GA, and GWO is presented in this paper, the main objective of this research is to get insights on the best optimization algorithm for PID controllers tunning applied to a power converter. A brief description of each of the optimization algorithms is presented in the following subsections.

3.1. Grey Wolf Optimizer

Wolves had a strong hierarchy inside their herds, they are organized in a group of 5 to 12 wolves. Each herd had a leading wolf, called alpha α wolf; secondary wolves called beta β wolves; wolves subordinated to α and β wolves are delta wolves δ ; and finally, follower wolves are omega ω wolves. The optimization using the GWO is carried out in three main stages that mimic the hunting process of grey wolves' herds in nature: encircling, hunting, and attacking.

Encircling stage

In this stage, each wolf updates its position in the search space according to the relative best position to prey, dictated for α wolf. The encircling and corral behavior of the prey is modeled mathematically by (2-5).

$$\vec{X}(t+1) = \vec{X}_{pos}(t) - \vec{A}\vec{D} \qquad (2)$$

$$\vec{A} = 2a\vec{r}_1 - a \qquad (3)$$

$$\vec{C} = 2\vec{r}_2 \qquad (4)$$

$$\vec{D} = \left| \vec{C}\vec{X}_{pos}(t) - \vec{X}(t) \right| \qquad (5)$$

where $\vec{A}$ $\qquad \vec{C}$ $\qquad\qquad \vec{X}_{pos}$

$\vec{X}$ vector is the position of the wolf, t is

current iteration, r_1 and r_2 values randomly generated between zero and one, and, vector a value decreases linearly according to iterations.

Hunting stage

The position of wolves is rearranged according to their proximity to the prey. The wolf with the closest distance to the prey is assigned to be the alpha α wolf, β and δ wolves are assigned according to their position to prey. Equations (6-8) describe the wolve position updating.

$$\overline{X}_i(t+1) = \frac{\overline{X}_{i1} + \overline{X}_{i2} + \overline{X}_{i3}}{3} \tag{6}$$

$$\left.\begin{array}{l}\overline{X}_{i1} = \overline{X}_\alpha(t) - \overline{A}_1\overline{D}_\alpha \\ \overline{X}_{i2} = \overline{X}_\beta(t) - \overline{A}_2\overline{D}_\beta \\ \overline{X}_{i3} = \overline{X}_\delta(t) - \overline{A}_3\overline{D}_\delta\end{array}\right\} \tag{7}$$

$$\left.\begin{array}{l}\overline{D}_\alpha = \left|C_1\overline{X}_\alpha(t) - \overline{X}_i(t)\right| \\ \overline{D}_\beta = \left|C_2\overline{X}_\beta(t) - \overline{X}_i(t)\right| \\ \overline{D}_\delta = \left|C_3\overline{X}_\delta(t) - \overline{X}_i(t)\right|\end{array}\right\} \tag{8}$$

where $\overline{X}_i(t+1)$ is the wolf that has the best position to the prey and i is the current iteration number of the GWO algorithm.

Attack stage

Attack to prey occurs when the heard is upon the prey, before this, it is necessary to minimize the distance between wolves and the prey. The prey is the optimization problem's best global solution. Must be defined as a vector A, shown in(3), to make a decreasing coefficient dependent on the iteration number. The vector A value is reduced as the value index a value is reduced according to (9).

$$a = 2 - t\left(\frac{2}{T}\right) \tag{9}$$

The GWO pseudo code is as follows,

GWO: pseudo code.

Result: The best set of particles for the fitness function.
X generation; creation of an initial population of wolves.
Parameters initialization (a,A,C);
Evaluation of position X(0);
Selection of new (a, β and δ);
Selection of new position X(0);

  for *each wolf$_i$ in* ω set **do**;
    for *i = 0 to* DIMENSION
    do;
      Position(i,j) updating;
    end for
  Change (a,A,c) factors;

      Calculate *X(t+1)*
      position
    end for
  end for

3.2. Particle Swarm Optimization

PSO algorithms are based upon the swarm behavior that some animal species show when they search for resources in their environment. Since PSO is based on collectiveness, each search agent must be modeled. For this purpose, agents are modeled as particles of a swarm, having their position relative to exploration space, velocity, and acceleration rates. At the beginning of the PSO algorithm, several particles are set up in a search space where somewhere in is the global solution for the optimization problem. Finding a global solution depends on the evaluation and minimization of the defined objective function. Iteration by iteration positions, velocities, and acceleration of particles are updated to converge to the global solution. For each particle, a fitness function is numerically evaluated. The best value obtained for all the particle's fitness function is called to be the best global g_{best}. During the iteration process, each best particle fitness function value is called to be the personal best p_{best}. During iterations, the speeds of the particles are accelerated toward the best global solution and the best personal according to (10).

$$v_n = w * v_n + c_1 rand() * (g_{best,n} - x_n)$$
$$+ c_2 rand() * (p_{best,n} - x_n) \tag{10}$$

Where v_n is the speed update of particles, W is a factor of inertia whose value is decreased from 0.9 to 0.4 over time, c_1 and c_2 are coefficients of acceleration pointing to the best global and the best personal.

3.3. Genetic Algorithm

Genetic Algorithms are based on the genetic evolution process, imitating the genes mutation and crossover to create the best-adapted organisms to the environment. Mathematical modeling of these mechanisms allows the algorithm to refine solutions carrying out artificial genes crossover, while the mutation mechanism adds uncertainty to experiment with not expected genes, this makes the algorithm avoid local solutions where it could be trapped. During iterations, the best set of artificial genes is obtained, and therefore, a best-adapted species to the environment. The best group of genes for i generations are said to be the found best solution for the optimization problem.

GA can be expressed as a four-step algorithm,

Step 1. An initial population is created. Crossover rate and mutation rate are randomly generated; generation number is setup.

Step 2. Is evaluated the defined fitness function for each set of artificial genes.

Step 3. Starts the crossover process and mutation process to set the next generation of artificial genes.

Step 4. Return to Step 2 until the stop criterion is reached.

4. Tunning of a PID controller for a Boost converter using optimization algorithms

PID controllers allow the system to operate near desired output values, ensuring good response in the face to possible disturbances. The proposed Boost Converter includes a PID controller for voltage regulation for load changes. The PID controller carries out proportional, integrative, and derivative actions to reduce and prevent error $e(t)$ between output and reference signals of the system. The controller signal $u(t)$ is mathematically modeled according to (11).

$$u(t) = K_p e(t) + \frac{K_p}{T_i} \int_0^t e(t)dt + K_p \frac{T_d de(t)}{dt}] \quad (11)$$

In (11) K_p, T_i and T_d are the proportional, integration time and derivation time constants, respectively. By adjusting the values of these constants, the error in the system can be reduced. The integration and derivative time can be expressed in terms of K_p according to (12-15).

$$K_p = k \quad (12)$$

$$K_i = \frac{K_p}{T_i} \quad (13)$$

$$K_d = K_p T_d \quad (14)$$

where k is the constant of proportional gain K_p, K_i is the constant of integrative gain, and K_d is the constant of derivative gain for the PID controller. The goal of the GWO, PSO, and GA algorithms is to find the best K_p, K_i, K_d values so the error $e(t)$ is minimized. A vector X is defined to include the constant values according to (15). To minimize the Error $e(t)$ the Root Mean Squared Error (RMSE) is defined to be the objective function for the optimization problem according to (16).

$$\vec{X} = [K_p, K_i, K_d] \quad (15)$$

$$RMSE = \sqrt{\frac{\sum_{t=0}^{T_{sim}} \left(v_{out}(t) - v_{reference}(t)\right)^2}{T_{sim}}} \quad (16)$$

Where T_{sim} is simulation time, $v_{out}(t)$ is the output voltage of the power converter, and $v_{reference}(t)$ is the reference voltage signal. The Figure 2 illustrates the overall flowchart for the optimization to find the values for the PID controller constant gains using the GWO, PSO, and GA, the first step of all three algorithms evaluated is to generate a random search agent population, that according to the algorithm is the number of wolves, particles, or gene population, then for each agent, the objective function is evaluated in an iterative loop until the best solution is found.
Figure 2: Overall flowchart for the optimization to find the optimal values PID controller constant gains for the proposed optimization algorithms.

5. Simulation, results, and discussion

The optimization algorithms of GWO, PSO, and GA were implemented using MATLAB and Simulink software. Several simulations run for each of these algorithms were performed to find the best PID controller gains values. The difference between each run is the variation of the limits of the search space for the optimization variables, that is, different minimum and maximum values for each gain constant of the controller. A scan was made with different values to determine the search space with the best possible solution for the algorithms evaluated for this particular application. The Boost Converter configuration parameters are shown in Table 1.

Table 1: Boost Converter Configuration

Description	Value	Units
Capacitor	250	μF
Inductor	1.5	mH
Input voltage	12	V
Reference voltage	24	V
Load	3-15	Ω

Since optimization algorithms require some constant parameters these values must be specified at the beginning of each test. One of the most significant benefits of using GWO is that fewer initial parameters are required in comparison to PSO and GA. The parameters initial values for each algorithm used in this work are shown in Table 2. For all three optimization algorithms, the search

K_p, K_i and K_d were varied from 0 to 100 for each PID controller gain.

Table 2: Algorithm parameters initial values

Algorithm	Initial Values	
	Description	*Value*
GWO	Wolves number	12
	Maximum Iterations	7
PSO	Particles	50
	Factor of inertia	0.4-0.9
	Weight of self-adjustment	3
	Weight of social adjustment	1
GA	Size of populations	50
	Rate of crossover	0.9
	Rate of mutation	0.6
	Maximum generations	120

The Table 3 summarizes the PID controller constant gains obtained after the simulation process for each algorithm. The performance is evaluated using RMSE.

Table 3: Best PID gains values and RMSE.

Parameter	Algorithm		
	GWO	*PSO*	*GA*
K_p	0.0532E-5	1.7223E-5	0.1269E-5
K_i	1.6048	2.8391	4.0815
K_d	4.8572E-5	7.2477E-5	4.1911E-5
T_i	3.3151E-7	6.0664E-6	3.1092E-7
T_d	91.3008	4.2082	33.0268
RMSE	1.0683	2.1755	2.2367
Simulation time (s)	1286	1997	1175

As observed in Table 3, the obtained PID controller gains for all the three algorithms had no significant value for de K_d constant, in this sense, the proposed controller built by the metaheuristic algorithms is a PI controller. Using (13) and (14) it is possible to calculate T_i and T_d for each PID controller tunned by the three algorithms, as shown in Table 3. For a greater T_i than K_p value a significative integrative action of the controller is observed according to (11) and (13); and when K_p value is much smaller than T_d the PID controller will have a small derivative action over the plant, according to (11) and (14). The controller performance evaluated by the RMSE shows that the GWO has the lowest error since its RMSE is about 50.89% lower than the one obtained by the PSO and 44.70% lower than the one obtained using the GA. Since the three evaluated algorithms differ in their search

mechanisms, different convergence curves to the best solution found by GWO, PSO and GA algorithms were found. The Figure 3 shows the convergence curve for each of the evaluated algorithms for the Boost converter PID controller tunning optimization problem.
Figure 3: Convergence curves to the best solution found by GWO, PSO, and GA algorithms.

As can be observed in Figure 3, the GWO algorithm is faster to get closer to the best solution set of K_p, K_i and K_d in comparison to PSO and GA whose convergence curves are slower to decrease the resulting RMSE value.

Once the GWO was chosen as the best algorithm for this application, more simulation runs were made varying the search space limits for the optimization variables and with a different number of wolves to ensure a more refined PID gains constants optimal solution for the Boost Converter. The main results of this second round of tests made with the GWO are shown in Table 4.

Table 4: Second round of test for GWO algorithm

Run	Obtained optimal values					
	Search space limits [Kp, Ki, Kd]	*Kp*	*Ki*	*Kd*	*RMSE*	*T*
1	[0-10,0-10,0-10]	0.0012	0.8681	0.0502 E-3	1.1436	948.43
2	[0-0.5,0-5,0-0.5]	0.0025	0.7626	0.0263 E-5	1.1099	968.40
3	[0-0.25,0-2.5,0-0.25]	0.0191	0.0167	0.0098 E-3	8.6105	953.45
4	[0-0.01,0-0.5,0-0.01]	0.0033	0.3118	2.9451 E-5	0.7768	9030.77
5	[0-5,0-32,0-0.005]	0.0532 E-5	1.6048	4.8572 E-5	1.0683	1286.00

As observed in Table 4, the best PID controller gains were obtained in run number four, where the RMSE is minimum with a value of 0.7768. Different RMSE results were obtained for different search space limits; the best results were obtained for the search space limit of [0 to 0.01, 0 to 0.5, 0 to 0.01] corresponding to the $\overrightarrow{X} = [K_p, K_i, K_d]$ optimization variables vector. However, when plotting the system, see Figure 4, response for each run, it is found that the system response of the fifth run, with an RMSE of

1.0683, has a faster response to achieve the reference voltage depicts the higher oscillation rates obtained. Best PID controller gains values must be selected according to the needs: a faster response with oscillations, or a slower response with fewer oscillations. The fifth run is chosen as the best solution since a faster response is desirable for this application.
Figure 4: Comparison between run 4 (a) and run 5 (b)for the best GWO simulation results

Once the best solutions for the three evaluated algorithms were chosen, a test of the performance to varying load conditions was carried out to evaluate the system response for the GWO, PSO, and GA tunned PID controller. In Figure 5 the system response for variable load and variable input voltage condition comparison is shown for each algorithm best solution.

As observed in Figure 5, the PID controllers tuned by PSO and GA have similar system responses, presenting important oscillations for load R=15 Ohm. The input voltage to the converter is a signal that varies over time between 11.7 and 12.3 V for the time scale used. The PID controller tunned using the GWO has a better performance to stabilize system response under load and voltage changes in comparison to GA and PSO, despite having a slightly slower response than the other algorithms.

6. Conclusion

In this paper, the tunning of a PID controller for a boost converter was presented. Three algorithms were implemented and compared for this purpose using MATLAB/Simulink: PSO, GA, and GWO. The power converter is modeled using state-space equations. Several simulations are performed to find optimal values. Results are evaluated using the RMSE and the system response for variable conditions of input voltage and load at the output of the power converter. The GWO-PID tunned controller had the best performance with an RMSE about 50.89% lower than PSO and 44.70% lower than GA. The differences between the obtained RMSE using the three algorithms showed in Table 3, gives insights on the greater susceptibility of PSO and GA to be trapped in local optimum solutions, while the lower RMSE value obtained using the GWO algorithm for the same search space limits indicates that this algorithm manages in a better way to circumvent a greater number of local optimum solutions to find a better optimal solution than the PSO and GA algorithms for this application. After the controller was tunned using each algorithm and the best gain constants were found, the system response was evaluated under input voltage and load changes. The system

response for variable load also showed a better performance for the GWO with fewer oscillations for load changes in comparison to PSO and GA. Also, the GWO algorithm had the advantage over the PSO and GA that GWO requires fewer configuration parameters for the optimization process. However, the PID tuned through the GWO was a little slower to reach the reference voltage than the other algorithms. This work gives insights into the GWO algorithm for controller design and control applied to power converters

Cardiovascular diseases are the group of conditions produced in the heart or blood vessels. This is one of the main causes of death in Peru and the world, produced mostly by non-communicable diseases and harmful habits, which makes it an extremely predictable disease. These factors include body mass index, smoking, diabetes, age, blood pressure, total cholesterol, and high-density lipoproteins. Therefore, this study aims to identify patients who go to the medical office of a private health center in North Lima who do not have a prior history of a cardiovascular accident, using the cardiovascular risk calculator provided by the Organization World Health. The present research work had a quantitative, non-experimental, descriptive, and cross-sectional approach, in a population of 99 adult and elderly patients. Regarding the results, it was found that 46.5% presented a low cardiovascular risk, 37.4% a moderate risk, 11.1% a high risk and 5.1% an extremely high risk. The information found contrasts with the number of deaths caused by this disease and may be an indicator of greater prevention by populations with higher economic income. Finally, it is concluded that diabetes, smoking and the age group are predisposing factors to an increased cardiovascular risk.

1. Introduction

Cardiovascular risk is specified as the probability of a heart or blood vessel condition occurring [1]. The origin of cardiovascular diseases (CVD) is closely linked to harmful habits or non-communicable diseases, from which derives its progressive and highly predictable nature [2].

According to the Framingham Heart Study, conducted from 1948 to the present, the main predictors of a CVD are age, body mass index, HDL and total cholesterol, smoking, diabetes, and treated high systolic blood pressure or untreated [3], [4]. Therefore, these predictors are also connected to illnesses and harmful habits, present and increasing mainly in developed and developing countries.

In Peru, according to data collected by the Instituto Nacional de Estadística e Informática (INEI), from 2015 to 2018 the Peruvian population has had an annual increase in cases with high blood pressure (14.8%), diabetes mellitus (3.9%) and obesity

(23%), which are mainly concentrated in Lima, while cases of overweight (37%), cigarette consumption (19%) and daily cigarette consumption (1.7%) make up almost constant in the years of study [5]. Likewise, its importance in relation to cardiovascular risk (CVR), death attributed to diabetes also increased [6], which gives an indication of inefficient control of the disease. Consequently, as mentioned above, each year the cardiovascular disease (CVD) threat is amplified and the people with the longest longevity are affected.

On the other hand, in [7], a study was carried out in Peruvian youth and adults between 20 and 59 years old who were users of popular dining rooms, these premises being focused on food supply in areas of poverty and extreme poverty. The research found a prevalence of abdominal obesity (51.6%), low HD-C (42.2%), hypertriglyceridemia (35.3%), overweight (35.8%), high blood pressure (21.0%) and hyperglycemia (14.1%), thus conforming an overall metabolic syndrome of 40.1%. This not only allows to infer that the state of this type of population makes them prone to CVD, but also without a preventive measure that takes an active role in the search for these patients, the risk will

probably not be reduced until they are close to suffering a condition of this type, because despite having insurance focused on low-income populations, regular visits in search of prevention are not usually integrated in Peru.

In the study [8], carried out in a public hospital for internal medicine inpatients, vascular age and cardiovascular risk were evaluated in 238 participants who were between 30 and 74 years old without previous cardiovascular events. The objective was to determine these variables as well as the predominant risk factor. This study concluded with a medium and high cardiovascular risk in the highest percentage of the population, a difference between chronological and vascular age of 6.9 years old, and finally, diabetes and male sex were identified as predominant factors.

According [9], a research carried out in Spain, they were able to note that heart disease is the main cause of morbidity in a tertiary hospital and men between 50 and 60 years old are the ones with the highest morbidity in this pathology, causing high rates of incapacity for work, in addition the problem goes beyond the hospital setting because these patients will require cardiac rehabilitation. They also point out that emphasis should be placed on prevention, since studies have documented that of the patients who were discharged, 75% of patients re-entered for any cardiac complication.

In [10], a study was carried out in an educational institution of 100 schoolchildren from 10 to 19 years old, with the aim of determining cardiovascular risk. The study found a prevalence of cardiovascular risk of 84.6% in adolescents (15-18 years old), as well as that the consumption of alcoholic beverages and unhealthy eating habits are related to the increase in cardiovascular risk. So, it is suggested that prevention from an early age is essential to reduce its appearance in more advanced stages of life.

The objective of this research work is to identify cardiovascular risk in patients with no prior history of CVD, excluding hypertension in untreated cases, and who go to a cardiology office in a private health center, using a calculator provided by the Organization. Pan American Health (PAHO). Because of having an alteration in the cardiovascular system that is not a serious alteration, patients of the cardiology service are one of the groups to be suspected of having a cardiovascular condition that may cause irreversible damage or death of the patient.

The instrument used in this study is the CVR calculator provided by PAHO, based on a form proposed by the World Health Organization (WHO) to evaluate CVR in Latin American and Caribbean countries [11]. This instrument uses a risk score that is based on the Framingham study, which also is adapted to the characteristics of the region and these data will be processed in matrix form by the IBM SPSS statistics 25 program. This application deals with to assess CVR quickly and easily in patients, which is mainly focused as an aid to medical health personnel, but due to the simplicity of its use, this can be a great option for the recruitment of risk patients who are in areas that are difficult to access or that lack medical personnel.

The organization of the work carried out is structured in the following way: in Section II, the development carried out for the identification of cardiovascular risk in patients who go to the medical office will be found. In section III, it will find the results of the data collected for the measurement, as well as the most relevant values of the CVR found. In section IV, the discussion of the research work and finally in section V, the conclusions, as well as the expectations that are had for the use of this research work.

2. Methodology

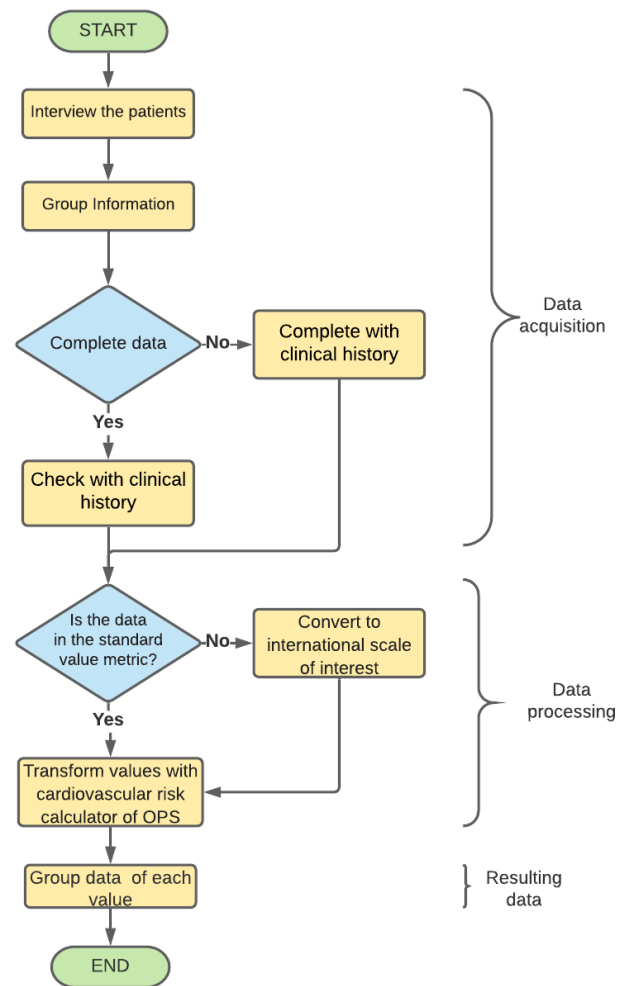
This section is made up of the process followed for the cardiovascular risk assessment, which are: data acquisition, data processing and finally the results with their corresponding risk values. The steps in carrying out the cardiovascular risk assessment are represented in a flowchart in Figure 1. All this was passed through the ethics committee, to give the authorization for the research work, followed by the ethical principles in part for the study in patients, such as beneficence, autonomy, non-maleficence, and justice.


Figure 1: Flowchart for cardiovascular risk data collection

2.1. Data Acquisition

This study has a quantitative, non-experimental, descriptive, and cross-sectional approach. For the acquisition of the data, coordination was required with a private polyclinic located in the jurisdiction of North Lima, in which the patients of the cardiology service were evaluated in the first quarter of the year. Likewise, the data collected in the research work was cataloged in

sociodemographic data of the patient and descriptive parameters of cardiovascular risk, the subdivisions are shown in Table 1.

Table 1: Sociodemographic data and descriptive parameters of cardiovascular risk of people from a cardiology clinic of a Private Polyclinic in North Lima

Sociodemographic Data	Gender
	Degree of instruction
	Occupation
Descriptive parameters of cardiovascular risk	Maximum / Systolic Pressure
	Smoking
	Total cholesterol
	Diabetes
	Age

Population and Sample

The population is made up of 110 adult patients (49-59) and older adults (60 or more) from the jurisdiction of the health center, but the sample size was made reaching 99 since the remaining patients did not want to participate voluntarily in the study.

Inclusion and Exclusion Criteria

The inclusion criteria that were considered at the time of data collection were: Patients who are between the ages of 49 and 79, who have high blood pressure, who are continuing or go to medical office more than once, who belong to the jurisdiction of the polyclinic and agree to participate voluntarily in the study.

In addition, the exclusion criteria corresponding to the study were: patients who depended on a wheelchair for mobilization and those who suffered from cognitive or hearing impairment.

Figure 2: WHO/ISH AMR B risk prediction table, for settings in which blood cholesterol can be measured

2.2. Data Processing

The data corresponding to the descriptive parameters of cardiovascular risk were transformed into the international system of measurement units that were adequate or preferable for the measurement of each parameter and subsequently entered the cardiovascular risk calculator provided by PAHO that takes place during the month of November. These data were cataloged by the calculator according to the percentage of CVR of the patient suffering from a cardiovascular condition in the subsequent 10 years corresponding to the table displayed in Figure 2.

The table displayed in Figure 2 subdivides cardiovascular risk into 5 subsectors, relating them to one color according to the range of cardiovascular risk that occurs, these being: green, for a CVR <10%, yellow for a CVR from 10% to <20%, orange from 20% to <30%, red from 30% to <40% and dark red for values> 40%.

Likewise, the acquired data were entered in matrix form to the IBM SPSS Statistics 25 software, for subsequent management and analysis. The variables considered for data analysis are ID, gender, degree of institution, family type, occupation, smoking, diabetes, maximum systolic pressure, total cholesterol, cardiovascular risk, age, and Age 2, these two being the last ages corresponding to the adult and older adult age groups.

The participation of health personnel in the process of obtaining data is significant due to the complications that may arise due to the patient's lack of knowledge regarding the topic corresponding to each variable, the patient's mistrust of a person who do not work in the public health service, as well as greater efficiency in the collection of data in the clinical history and in the reliability when measuring the value of blood pressure.

3. Results

99 adult and elderly patients from the cardiology service were evaluated in the first quarter of the year. Sociodemographic data and descriptive parameters of cardiovascular risk were identified in each of them, as shown in Tables 2, 3 and 4.

Table 2: Sociodemographic data of patients from a cardiology clinic of a Private Polyclinic in North Lima

Sociodemographic data	N	%
Age [1/]		
Adult	57	57.6%
Older adult	42	42.4%
Gender		
Female	35	35.4%
Male	64	64.6%
Degree of instruction		
Illiterate	2	2.0%
Primary	16	16.2%
Secondary	73	73.7%
Technical	5	5.1%
University	3	3.0%
Occupation		
Does not work	17	17.2%
Retired	10	10.1%
Laborer	12	12.1%
Employee		15	15.2%
Informal work		45	45.5%
Total		**99**	**100.0%**

[1/]Mean = 57.7; Standard Deviation (SD) = 11.08

These results indicate that the mean age of the patients was 57.7 years, the majority being adults representing 57.6%, likewise, 64.6% were men, 73.7% had a secondary level, 45.5% worked informally and 35.4% have an extended family as shown in Table 2.

Table 3: Cardiovascular risk parameters in patients of a cardiology office of a Private Polyclinic in North Lima

Cardiovascular risk parameters	**□ ± SD [1/]**	
Maximum Systolic Pressure (mmHg)	132.9	11.6
Total Cholesterol (mg/dL)	225.6	22.4
Smoking	**N**	**%**
Yes	52	52.5%
No	47	47.5%
Diabetes		
Yes	84	84.8%
No	15	15.2%

[1/] Mean (□); Standard Deviation (SD)

Table 3 shows that the mean maximum systolic pressure was 132.9 mmHg, and the mean total cholesterol was 225.6 mg/d. On the other hand, 52.5% were smokers and 84.8% had diabetes.

Table 4: Cardiovascular risk and descriptive parameters of cardiovascular risk

			Cardiovascular Risk				Total
			Low	Mode rate	High	Very High	
Age group	Adult	N	34	20	3	0	57
		%	34.3%	20.2%	3.0%	0.0%	57.6%
	Older adult	N	12	17	8	5	42
		%	12.1%	17.2%	8.1%	5.1%	42.4%
Smoking	Yes	N	15	24	10	3	52
		%	15.2%	24.2%	10.1%	3.0%	52.5%
	No	N	31	13	1	2	47
		%	31.3%	13.1%	1.0%	2.0%	47.5%
Diabetes	Yes	N	34	36	10	4	84
		%	34.3%	36.4%	10.1%	4.0%	84.8%
	No	N	12	1	1	1	15
		%	12.1%	1.0%	1.0%	1.0%	15.2%

Table 4 shows that: adults are 57.6%, with 34.3% belonging to a low CVR, while older adults are 42.4%, and their CVR is mostly moderate with 17.2%; those who smoke make up 52.5% of the population, their CVR being mostly moderate with 24.2%, while those who do not smoke make up 47.5% and their CVR is mostly

low with 31.3%; finally, those with diabetes make up 84.8% of the population and their CVR tends to be moderate with 36.4% or low being 34.3%, while those without diabetes make up 15.2% and most of them have a low CVR representing the 12.1%. These data help to deduce the trend of cardiovascular risk in relation to its risk factors in private health center.

On the other hand, the chi square results were 0.001 for the age group and cardiovascular risk, 0.027 for diabetes and cardiovascular risk, and 0.001 for smoking and cardiovascular risk for P <0.05, confirming that the differences in the proportions observed between the two groups are statistically significant. These results allow to identify the relationship of risk factors with cardiovascular risk in populations that go to a private health center, as well as to differentiate their situation from the current situation in Peru.

Table 5: Cardiovascular risk in patients of a cardiology office of a Private Polyclinic in North Lima

Cardiovascular Risk	**N**	**%**
Extremely high Risk	5	5.1%
High Risk	11	11.1%
Moderate Risk	37	37.4%
Low Risk	46	46.5%
Total	**99**	**100.0%**

Table 5 shows that 46.5% of adult and elderly patients presented a low cardiovascular risk, 37.4% a moderate risk, 11.1% a high risk and 5.1% an extremely high risk.

The knowledge of these results is important because it will allow to identify cardiovascular risk in patients with no prior history of CVD, and it also helps to know the risk factors to which many people, such as smokers, are exposed. This information allows to realize that the greater control there is over risk factors, whether through a change in lifestyle (healthy eating, playing sports, etc.), the less likely there is to have cardiovascular risk.

4. Discussion

The results confirm that there is a significant relationship between smoking, age group and diabetes with cardiovascular risk, thus agreeing with the findings of the Framingham heart study.

On the other hand, the prevalence of CVR found is mostly belonging to a low-risk one, in other words, a population that has a less than 10% risk of suffering cardiovascular disease in the next 10 years, which contrasts significantly with the analysis carried out in [12], which lists circulatory diseases as the third cause of death for large groups and cardiac ischemia as the second cause of death. As it is a private health center, it can indicate a greater emphasis on prevention by a sector of the population with higher economic incomes.

Peru is a developing country where child malnutrition and respiratory diseases are still considered highly relevant problems and their financing is a high priority. For this reason, this research is not only focused on identifying the status of patients entering

cardiology offices, but also on the scientific contribution, because its use is also expected to promote the use of this instrument for the early recruitment of patients, both by health personnel and residents through self-evaluation, because due to its easy access and simplicity it can mean a great advance for the prevention of cardiovascular diseases, in a country where, as declared in [13], self-knowledge, adherence or control of hypertension are still below to other Latin American countries.

5. Conclusions

It is concluded that in patients who go to the medical office of the private health center in North Lima, diabetes, smoking and the age group are predisposing factors to increased cardiovascular risk in patients.

It is also concluded that the majority were adults, with a secondary institution degree and who work informally. As well as 5 out of 10 patients were smokers and 8 out of 10 had diabetes.

Finally, it is concluded that cardiovascular diseases are made up of a series of characteristics that can be regulated to prevent a cardiovascular risk, such as smoking, diabetes, total cholesterol, and maximum systolic pressure. As well as that the problem increases in relation to the old age of the population and therefore measures should be taken focused on these age groups.

This research work was studied to contribute to the lack of scientific information with the use of the PAHO cardiovascular risk calculator, in addition to promoting its use in the Peruvian community nursing setting for the recruitment of risk patients, because despite having problems such as malnutrition in the child population, the obstacle that CVDs pose to life expectancy in adults and older adults cannot be ignored.

The Strength in our research work is teamwork to be able to carry out this research work

The limitation in the research work is access to people to be in the study, since many of them mentioned that they preferred to enter their consultations than to be in the study.

Conflicts of Interest

The authors declare no conflict of interest.

ARTICLE INFO	ABSTRACT
	The article proposes an approach to evaluate human-computer interaction in the collective decision-making model. It is believed that all team members interact with each other through a distributed information system. The approach involves considering, when modelling, the personality characteristics of perception, each member of the team as a set of cognitive styles. Within the scope of the proposed technique, it is believed that information flows are interconnected with the processes of collective decision-making, which makes it possible to model the process of collective decision-making, monitor and analyse the effectiveness of the collective's activities. Experimental studies accomplished with statistical data processing were carried out and discussed.

1. Introduction

This paper is an extension of the work originally presented in Big Data, Knowledge and Control Systems Engineering (BdKCSE'2019) Conference [1]. The article further develops aspects of human-machine interaction in a distributed information environment. Here the emphasis is on collective decision-making taking into account the cognitive features of perception of team members.

The relevance of research in this area is due to a number of reasons, including the processes of globalization of the economic development of industrial sectors, the creation of a great number of large-scale, distributed corporations, concerns, holdings, and, accordingly, the decentralization of management processes controlled by parent organizations. Information interaction of such corporations is carried out through distributed information systems. The distributed information landscape is a genuine development of computerized, data and interaction technologies. The challenge of human communication with the distributed information ecosystem is gaining growing methodical and pragmatic importance.

A significant problem in the management of large-scale, distributed organizations are collective decision-making processes, which require the interaction of many people; this inevitably leads to the complication and delay of the decision-making process, as well as to the possible emergence of contradictions in the process of solving the problem.

The importance of taking into account the opinion of each member of the team, the importance of obtaining a coordinated, balanced solution to complex problems, the importance of ensuring transparency of the decision-making process in the team - all of the above emphasizes the relevance of developments in the field of creating automated tools to support collective decision-making. The development of mechanisms and techniques that provide modelling and visualization of collective decision-making processes will increase the efficiency and effectiveness of decision-making in a geographically distributed team through the implementation of modes of human-computer interaction.

When studying the processes of interaction in large-scale distributed information networks, we can talk about information flows connecting all users of the information system. As a result of the advance of information and computer technologies, now there are opportunities for the development of intelligent modules that allow to analyse, visualize and improve the efficiency of interaction processes in a team, including such as collective decision-making processes.

This article is devoted to the development of methods for modelling and presenting processes related to collective decision

*Corresponding Author: Tatiana Atanasova, atanasova@iit.bas.bg

making. First, the development of decision theory over time is discussed. It is then proposed to use a cognitive modelling methodology to rank team members in the collective decision-making process. The reflection of the cognitive styles of the participants in the human-computer interaction with distributed information system is emphasized in further consideration. Experimental studies accomplished with statistical data processing were carried out. The cognitive styles of the collective members were investigated through an experimental study to be included in the cognitive map modelling. Finally, the results of the experiments are discussed.

2. The Basis of Decision Theory

The fundamental basis of decision theory in mathematics, computer science and economics is the provision of rational human behaviour and the theory of utility.

The game theory was introduced in 1944 by John von Neumann and Oskar Morgenstern in their book, entitled "Game Theory and Economic Behavior". However, in a number of researches works, for example in [2], it is shown that human behaviour is not always rational, and often, on the contrary, is irrational (from the point of view of gaining a win). As an example, to demonstrate the features of human behaviour, we can cite the paradox proposed by [3]. As a result of presenting lotteries to various groups of people, it was shown that people prefer the lottery where the risk of losing is excluded or minimal. Whereas the computer calculates probabilities and acts rationally, i.e., maximizes utility (or gain).

A study of the evolutionary development of work in the expansion of decision support systems as a scientific direction shows that from the moment Atanasoff and Berry began to develop the first digital computing device in 1939 (at Iowa State College) and before the 1980s, the main goal was "to teach the computer to think like a person". Since the early 1980s up to the present time, the central paradigm has been the concept of "artificial intelligence" [4-10]. According to artificial intelligence professionals, the effectiveness of intelligent systems is determined both by formal mathematical schemes based on mathematical logic and by the knowledge of experts in a specific subject area, which can be explicated in the process of knowledge extraction. The analysis of scientific works in the field of knowledge extraction shows that, despite the significant success achieved in the advancement of intelligent, information systems, the key problem of creating any intelligent system is the process of extracting expert knowledge, as well as original heuristics used by specific experts to solve problems [11-15].

To date, technologies and methodologies for the design of knowledge-based intelligent systems have been developed, in which the sequential passage of the stages of acquiring expert knowledge is realized:

- the stages of extracting [16] and

- conceptual analysis of expert knowledge [17-21].

However, the actual problem of modelling and visualizing the collective decision-making process, as well as modelling and visualizing the information interaction between experts, has not received sufficient consideration, partly because this problem is

interdisciplinary, as it is at the intersection of information technology, mathematics, sociology and psychology.

3. Cognitive Maps for Modelling

The use of models to study an object, phenomenon or process is a well-established and well-proven research method. By the term model, in this article, we mean a formal representation of an object, (process, phenomenon) in some form, intended for the study of this object. Formal representation of an object (process, phenomenon) can be:

- mathematical,

- simulation,

- sign-symbolic.

In the present study, cognitive maps were used as a basis for the model of making decision in information interaction within a distributed information system. Using of models based on cognitive maps made it possible to visualize information processes of remote (distributed) interaction in a team, including the processes of creating groups, monitoring remote activities of team members, etc. For visualization and ranking of team members, it is proposed to use the methodology of cognitive modelling [11, 22-27]. According to the methodology, it is supposed to build a fuzzy model, visualized as a fuzzy graph (cognitive map), in which the vertices are team members, and the weighted arcs are information flows, relationships and social significance (weight, authority, awareness, experience, etc.) of each member of the team, the weight of each arc of the graph reflects the strength of the influence of a particular individual on the process of making a collective decision.

Information flows between team members, in general, can be verbal and non-verbal, mediated by the electronic information environment and not mediated. In this work, only flows mediated by a distributed information system are investigated. The considered information flows are subdivided into explicit and implicit, stable and unstable, as well as formal and informal.

Formally, a cognitive map can be symbolized as a directed sign graph *(F, W)*, where *F* is the set of vertices - team members, $W=|w_{ij}|$ - adjacency matrix. The dynamics of the decision-making process is presented as a sequential set of situations *X(t−1), X(t), X(t+1),…, X(t+n)*, which are the situation state vectors at successive discrete times: *t−1, t, t+1, …, t+n*, where *t* is some number of such moment in time.

The interactions can be determined by summing all of them, according to the formula (1):

$$X_i(t+1) = X_i(t) + \sum_{i=1}^{n}(X_{i-1}(t+1) - X_{i-1}(t))W_{i,i-1} \quad (1)$$

The use of cognitive maps allows modelling and visualizing not only the information flows, but also the configuration of the team in the process of collective decision taking, that is, the use of cognitive maps allows displaying the dynamic processes occurring in the team in the process of deciding.

4. Cognitive Styles of the Collective Members in the Model

The need for specific information (information flow) for each team member is determined by several factors influencing the

request for information of a team member, namely: knowledge, skills, job responsibilities, style of activity, and personality characteristics of perception. By personal characteristics of perception, we mean the set of cognitive styles inherent in each member of the group. At the same time, we make it a condition that we consider in the model only personal characteristics of perception, since a person's personality traits are not limited to a set of cognitive styles.

4.1. Cognitive-Style Characteristics

According to several scientists, individual ways of processing information are largely determined by cognitive styles [28, 29]. Cognitive styles actively participate in the process of choice and making decisions in work, manage the emotional and behavioural characteristics of human activity [30]. Scientific works show the essential part of the cognitive and stylistic aspects of the subject in the execution of actions that involve self-government and answerability in during process of making decisions, particularly in highly uncertain conditions. In parallel, the assignment of psychological patterns as form-creating (combining, central) elements in the process of choosing an appropriate option is highlighted [31]. Of the entire set of cognitive styles given in the work [32], we will consider only three cognitive styles, namely: the "field dependence/field independence" style, the "narrow/wide range of equivalence" style, the "impulsivity/reflectivity". Detailed justification and appropriateness of the choice of the above styles are given in the work [33].

4.2. Identifying the Cognitive-Style Characteristics

As follows, we briefly describe the cognitive styles studied and present the methods used for the research.

The style "field dependence/field independence" is traditionally considered as a way of an individual to solve perceptual problems, and the presence of "the ability to overcome a complex context" (according to G. Witkin). To diagnose cognitive-style features, G. Witkin's "*Included Figures*" technique was used (evaluation of field dependence - field independence, individual variant) [34].

The style "narrow/wide range of equivalence" reflects the predominant orientation of the individual to the features of similarity or differences of classified objects, their obvious or hidden features. To diagnose these cognitive-style features, the method "*Free sorting of objects*" by R. Gardner and V. Kolga was used.

The style "impulsivity/reflectivity" characterizes individual differences in the speed and correctness of decisions made in situations of uncertainty and the presence of many alternatives. To diagnose these cognitive-style features, the method "*Comparison of similar drawings*" by J. Kagan (assessment of impulsivity - reflectivity as the cognitive pace of decision-making) was used [35].

The choice of these particular styles for research is due to the fact that the team members united in the work on the project must have a good idea of the general structure of the entire project, understand the specifics of the work and the distinct (individual) tasks of other team members within the framework of this project, and have a proportionate cognitive pace of decision-making, carry out synthesis and analysis of project tasks.

In the framework of this study, the relationship between the cognitive-style characteristics of team members and the effectiveness of decision-making when working on a common project was studied.

5. Experimental results

To examine the cognitive-style characteristics of team members in the model, an experimental study was conducted. The most important phases of human interaction with the information system were modelled as the subject was needed to:

- familiarize s/himself with the content of the texts specially developed for this study,
- analyse the content of the texts,
- classify the content of the texts,
- then answer the proposed questions.

Also, during the study, the above mentioned cognitive-style characteristics were identified.

For this experiment, several texts from 2 to 8 pages in volume (250 - 300 words per one page) were prepared specifically. Throughout the experiment, the subject of investigation has to read these specifically arranged texts. After reading, the subject of the investigation was asked to answer questions about the structure of the text and to give a quantitative calculation of the discovered options. The volume of the presented material was taken into account to model the interaction with the information system. Gaze movements were recorded using specialized SMI equipment (http://www.smivision.com), which tracks the trajectory of the subject's gaze.

Several quantitative criteria for assessing the activity of information interaction have been established [1]. Statistical methods for data processing were applied together with using Student's t-test and Mann-Whitney U-test. Spearman's correlation coefficient was used to assess the relationship between variables. Student's t-test was used to analyse two independent data samples to compare the mean of the two populations. Mann-Whitney U-test determines whether the area of overlapping values between the two series is small enough.

The research results are shown in the Table. Questions of type 1 were used for the quantitative assessment, and questions of type 2 were questions about the structure of the text.

Note: Indicators for the assessment of the success and effectiveness of the activity are time for reading of the presented text (document); the keyword usage rate, i.e., how often the subject rereads the reference words; time for answering questions; coefficient of correct answer; coefficient of confidence in decision making i.e., how long the subject analyses the alternatives.

As an outcome of the analysis of the results obtained, the following interdependencies were revealed: 1) the more work experience, the less time during which the subjects look at the text of the document presented on the computer screen, and the less time spent on making a decision regarding the choice of an alternative, 2) on the contrary, the "coefficient of correctness of answers" is directly proportional to the indicator "work experience". That is, subjects with work experience more often solve problems correctly.

Table 1: Correlation relationships between performance criteria and characteristics of socio-demographic status.

Indicators	Gender	Age	Education	Experience
Stage I. Reading text without pivot words				
Reading time	0,61	0,54	0,21	-0,72
Answering time of quantitative questions	0,17	0,27	-0,03	-0,41
Correctness of answer to quantitative questions	-0,04	-0,41	0,28	0,68
Decision confidence factor	0,43	-0,05	-0,01	0,06
Answering time of questions about text structure	0,35	-0,16	0,31	0,10
Correctness of answer to questions about structure	-0,41	0,15	-0,07	-0,37
Coefficient of confidence of answer about text structure	0,05	0,15	-0,37	-0,22
Stage II. Reading text with pivot words				
Reading time	0,26	0,37	-0,03	-0,52
Answering time of quantitative questions	0,17	0,22	0,07	-0,52
Correctness of answer to quantitative questions	-0,61	-0,44	-0,41	0,41
Decision confidence factor	0,48	0,26	0,04	-0,46
Answering time of questions about text structure	-0,43	-0,32	-0,08	0,72
Correctness of answer to questions about structure	-0,10	0,20	0,40	0,17
Coefficient of confidence of answer about text structure	0,78	0,68	0,48	-0,68

It should also be noted that statistical data processing not only made it possible to reveal the relationship between the "coefficient of correctness of answers" and the availability of work experience - this fact is quite expected and natural, but it made it possible to use the cognitive characteristics of the user in developing the model, making them dependent on the style of decision-making in the process of collective activity, with the efficiency and effectiveness of collective decision-making.

6. Conclusion

This article proposes an approach to developing a model of collective decision-making, which makes it possible to consider the cognitive features of a user in the process of interacting with a distributed information system. In the course of the research, it was revealed that respondents characterized by the breadth of the equivalence range (i. e. "synthetics") were the most successful in dealing with the intended tasks on reading, analysing and classifying the proposed texts, as compared with the respondents, style features of which are more inherent in the area of "narrow range of equivalence" (i.e. "analytics"). The results obtained also indicate that such a property as "field independence" allows individuals to cope with tasks more successfully than "field dependent" research participants.

In the process of modelling, analysis and monitoring of information flows were carried out to support the processes of remote group interaction based on a distributed information system. Information flows are interconnected with collective decision-making processes, which allow monitoring and analysing the effectiveness of the team's activities. For this purpose, it is

possible to use the method of extracting specialized data samples from information arrays [36], where based on the analysis of the relationship of information flows; two classes-functions of collective information interaction were isolated:

- function-tasks - an interconnected sequence of information flows due to a sequence of actions team members aimed at solving a specific problem, as a result of which they have their own aspects and specifics in each case;

- functions-operations - an interconnected sequence of information flows due to the sequence of actions of team members, which are formal, standard and universal operations in the process of information interaction and are not aimed at solving a specific problem [37].

Based on the monitoring and analysis of the developed model, systematization, ranking and quantitative assessment of information flows were conducted.

Conflict of Interest

The authors declare no conflict of interest.

	Soil moisture is one of the most important variables to monitor in agriculture. Its analysis gives insights about strategies to utilize better a particular area regarding its use, i.e., pasture for cows (or similar), production forests, or even to answer what crops should be planted. The vertical structure of the soil moisture plays an important role in several physical processes such as vegetation growth, infiltration process, soil – atmosphere interactions, among others. Despite a set of tools are currently being evaluated and used to monitor soil moisture, including satellite images and in-situ sensor, several drawbacks are still persisting. In situ data is expensive for high spatial monitoring and vertical measurements and satellite data have low spatial resolution and only retrieval information of soil moisture for the top few centimeters of the soil. The present work shows an experiment design for collecting soil moisture data in a specific Andean basin with in-situ sensors in different kinds of soils as a promising tool for reproducing soil moisture profiles in areas with scarce information, employing only surface soil moisture and simple soil characteristics. Collected data is used to train machine learning supervised parametric (Multiple Linear Regression - MLR) and non-parametric models (Artificial Neural Networks - ANNs and Support Vector Regression - SVR) for soil moisture estimation in different depths. Conclusions show that parametric methods do not meet goodness of fit assumptions; so, non-parametric methods must be considered, and SVR outperforms parametric methods regarding regression accuracy allowing to reproduce the soil moisture content profiles. The proposed SVR model represents a high potential tool to replicate the soil moisture profiles using only surface information from remote sensing or in-situ data.

1. Introduction and problem statement

This paper is an extension of work originally presented in *CISTI 2020* [1]. Soil moisture is one of the most critical variables to be monitored in soils [2]. Understanding the behavior of the soil moisture makes it possible to determine the soil use [3], i.e., if it is suitable for cropping, for animal's pastures [4], and even, as a critical variable to understand if a particular terrain may be considered to real estate projects [5]. Another important application of soil moisture analysis belongs to risk management, such as landslides prevention and prediction [6]. For hydrologic applications, the soil moisture represents one of the most important variables controlling the interactions between the atmosphere and land through the evapotranspiration and evaporation processes. Additionally, the soil moisture represents a key variable for the infiltration process and direct surface runoff production in hydrological models.

In that way, different knowledge disciplines, such as hydrology [7], environmental management [8], geology [9], topography [10], among others, deal with soil moisture to deeply study its effects in plenty of different applications. Nonetheless, getting information about soil moisture is commonly a difficult task: available sources are scarce and are associated with satellite images, which causes low resolution regarding spatial distribution [11], that is, soil moisture is measured in broad areas and cannot be explicitly determined in points. During the last decades satellite images have emerged as a powerful tool to retrieve information about soil moisture in the superficial soil surface, even though data in other depth horizons is mandatory to model the behavior in a lot of applications.

Given the importance and drawbacks mentioned above, several techniques based on Artificial Intelligence (AI) theory are currently employed to estimate and predict the soil moisture for several engineering and scientific applications. Knowledge-based systems that apply AI are considered as easy and user-friendly tools [12, 13], as they have advantages in terms of neither requiring a pre-defined conceptual relationship between the input-target parameters nor requiring expensive experimental and field measurement apparatus [14].

In this sense, several studies have been proposed to determine the best Machine Learning (ML) or (AI) model to estimate the soil moisture, considering different variables like meteorological data and satellite images, among others. There are two main ML models used: Support Vector Regression (SVR) and Artificial Neural Networks (ANN) in different configurations. It is the case of [15], three approaches are proposed to generate the SVR regression model for soil moisture estimation: in the first approach, the authors use the soil moisture and meteorological data (air temperature, relative humidity, average solar radiation, and soil temperature at five and 10cm) at time step $t-1$ and t for predict soil moisture at $t+4$ and $t+7$, where t is in days. For the second approach, they use only the meteorological data, while in the third approach, they use only soil moisture at the same time step. The results of this study show that the SVR models performed better forecasting than a simple ANN model. In the same line, [16] proposes the use of SVR for soil moisture prediction using remote sensing data coming from 10 sites in the Lower Colorado River Basin (US). The data includes backscatter and incidence angle from Tropical Rainfall Measuring Mission (TRMM), and Normalized Difference Vegetation Index (NDVI) from Advanced Very High-Resolution Radiometer (AVHRR). The authors trained an SVR with five years of data (time series) and tested on three years of data. The results show a Root Mean Square Error (RMSE) less than 2%. Additionally, results are compared with an ANN and a Multivariate Linear Regression Model (MLR), showing that the SVR has a better performance than the other models.

The latest studies show a tendency for the use of deeper ANN like shows [17] in their review. The authors classify the use of ANN in three categories according to the types of training data. For the first category, the ANN is trained with model-generated data. For the second category case, the ANN is trained with in-situ measurements, with the restriction that the spatial scale could mismatch between point-scale measurements. Finally, the third category encloses the ANN trained with global Land Surface Model (LSM) simulations for soil moisture estimation at large scales.

Other useful applications using ANN are related to the infilling missing soil moisture records such as the research presented in [18], who were using five statistical methods, and nine ANN categorized into Feedforward, Dynamic, and Radial Basis Network methods estimate missing soil moisture records. The obtained values were validated against known values for 13 soil moisture monitoring stations for three different soil layer depths in the Yanco region in southeast Australia. The results show that the nonlinear autoregressive neural network performs in similar quality than other typical methods such as the rough sets method, and monthly replacement. Other studies employing ANN for hydrologic variables are [19–22].

Although SVR and ANN are the most used techniques, several works can be found related to soil moisture prediction that use other techniques of AI and ML. Some authors include multiple techniques, like, where Classification and Regression Trees (CART), Boosted Regression Trees (BRT), Random Forest (RF), Multivariate Adaptive Regression Splines (MARS), and Flexible Discriminant Analysis (FDA), are tested, all with promising results. In this sence, [14] using several input variables such as dielectric constant, soil bulk density, clay content, and organic matter for 1155 soil samples, proposed a hybrid Adaptive Neuro-Fuzzy Inference System (ANFIS) - Grey Wolf Optimization (GWO) intelligent model for simulating soil moisture content. The results based on several statistical parameters verified the feasibility of these kinds of models improving accuracy by around 50% when compared with other similar models as ANN, SVR, and standalone ANFIS models.

Despite the increasing usage of Artificial Intelligence (AI) theory tools related to soil moisture estimation, most of the studies have the same thing in common; none of them is focused on the estimate of the soil moisture at different depths. The data estimate corresponds to a depth between 5 and 10 cm approximately or the root zone. Few studies such as [23], employed surface soil moisture (0–5 cm) values and Hydrological Soil Groups (HSGs) information to perform a Statistical Soil Moisture Profile (SSMP) model to transfer the spatial variations of soil moisture profile with the change in soil hydraulic properties. The proposed model was based on correlation techniques with preceding time steps of soil moisture fields. In another study, [24] employed multispectral imagery from Unmanned Aerial Vehicle (UAVs) and a method based on the combination of an evolutionary algorithm and artificial intelligence called genetic programming (GP), to propose a methodology to simulate soil moisture at different levels. The results were compared to ANN and SVR methods.

With this idea in mind, the present work shows a methodology to fit some ML models with in-situ sensor data, which transmit real-time information by using IoT tools and methods to overcome limitations associated with the number of sensors to determine soil moisture at different depths using surface topsoil moisture estimates. The proposed methodology represents a high potential tool for reproducing the soil moisture profiles using only surface information from satellite or in-situ data for scarce information areas. Specifically, we use the most known statistics-based parametric method: Multiple Linear Regression (MLR) and perform the corresponding Analysis of Variance (ANOVA) [25] as well as the Goodness of Fit metrics (normality, independence, homoskedasticity). We also use two widespread ML non-parametric methods: SVR and ANN [26, 27]. All the models are primarily assessed by a case study, with collected data in the Las Palmas basin, at the Andean region, in Medellín, Colombia.

The rest of this paper is organized as follows: section 2 shows a short theoretical framework; section 3 stands the methodology and experiment design; section 4 shows the models fitting; in

section 5, the analysis over results is carried out. Finally, conclusions, future work, acknowledgments, and references are presented.

2. Theoretical framework

In this section, some key concepts will be defined to understand the work better.

2.1. Soil moisture

A given portion of soil is composed of solid particles and the rest of the voids. A part of the holes is occupied by water and the rest by air. The volume occupied by water is measured using the soil moisture content, which is defined as θ as in equation (1) :

$$\theta = \frac{Volume_{water}}{Volume_{total}} \qquad (1)$$

The study and knowledge of soil moisture are essential due to its influence on hydrological processes and energy flows on the earth's surface. It is also critical because of its connection with precipitation, runoff generation, nutrient transport, and groundwater [28–30]. Recent research identifies that a surplus or lack of soil moisture can favor floods or droughts occurrence [31]. Likewise, the feedback of soil moisture on evapotranspiration is essential for temperature variation and the appearance and persistence of heatwaves, as well as for precipitation generation and location [32]. Besides, the role of soil moisture in photosynthesis, ecosystem dynamics, soil respiration, and the terrestrial carbon balance is undeniable.

Therefore, soil moisture variation is critical in hydrological, ecological, and environmental studies [33] and, in particular, as a support for agriculture and biomass production [34]. Combinations of the factors mentioned above cause variations in spatial and temporal soil moisture content, which makes it a significant limiting factor for crop growth. Indeed, low crop yields should be more often related to insufficient soil moisture than insufficient rainfall [35,36], which causes that soil moisture plays a vital role as a critical resource for vegetation growth that supports agricultural production. In this sense, it is identified that soil moisture contributes in a crucial way to understanding the global climate system. For this reason, it has been highlighted by the Global Climate Observing System (GCOS) as one of the "essential climate variables". Therefore, monitoring temporal and spatial soil moisture variability is essential to estimate water availability limits and to quantify its climatic variations sensitivity and human pressures [32].

2.1.1. Soil moisture sensing technologies

Currently, several techniques are used to measure soil moisture, allowing monitor of humidity on a large scale: in-situ sensors (to take humidity measurements at the site where the sensor is located), and remote sensing from towers, aircraft, and satellites, using radiometers in the microwave region, scatterometers, synthetic aperture radars, and radar combinations-radiometers. According to [28], the products obtained with passive and active sensors have different correlation values around the world, when compared with in-situ measurements.

Although there are many possible sources of information, in the case of the tropics and specifically in the study area, there could

be limitations for the use of satellite information. Some derive from the possibility or not of having reliable and spatially coherent in situ soil measurements of soil moisture, which makes it challenging to carry out a cohesive evaluation of the accuracy and information content of remote sensing products. Besides, the use of inadequate techniques for downscaling can generate alterations in data quality. Another difficulty could arise due to the impossibility of obtaining quality data with fair spatial and temporal resolution in the study area, primarily due to its geographical location, which may limit some sensors use, especially optical ones. In this sense, in the visual spectrum, one of the significant limitations is the limited surface penetration due to high cloudiness. However, visible and infrared sensors and microwave sensors are not limited by cloud cover and night conditions [35]. Observations can be made at any time of day and are not dependent on sunlight [37].

Soil moisture in-situ sensing, In Colombia and many other tropical regions, there is very little information available on soil moisture taken from in-situ monitoring stations that can be used to understand the behavior of this variable for different applications. Although it is true that in-situ measurements require a costly investment and have low coverage of the territory, they allow the analysis at a local scale (as is the case of a basin). Additionally, they are necessary to validate the data from remote sensors that generally have a low spatial resolution.

The primary function of a soil moisture sensor is to report its current state, by using an electric variable (commonly voltage), to any acquisition system, i.e., datalogger, or IoT end node. The voltage reported is scaled to get the corresponding measurement, which is commonly given in cubic meters of water over cubic meters of soil material (m^3/m^3).

The most used operation principle in soil moisture sensors is the variation of capacitance as the moisture changes. Soil acts as a dielectric material between two plates, and it changes when this variable varies. However, conductivity sensors are also applied to sense moisture. Water content allows flowing electric currents between two electrodes, and it is proportional to soil moisture.

2.2. Parametric and non-parametric methods for data fitting

To fit some models for regression of moisture data and perform the comparison, we have chosen some of the most used methods in the literature. MLR, SVR, and ANN algorithms will be reviewed in this section.

2.2.1. Multiple Linear Regression (MLR)

MLR is one of the most used parametric strategies for data fitting. The general model is shown in equation (2):

$$\hat{Y} = \sum_{i=0}^{n} [\hat{\beta}_i X_i] + \varepsilon \qquad (2)$$

Where $\hat{Y}$ is the regression value of the dependent variable, $\hat{\beta}_i$ is a set of n+1 predictors (coefficients) which are determined by using least-squares optimization, X_i are n independent (predicting) variables, and ε is the regression error. If a categorical variable is in the predictors, a set of dummy variables is included, depending

on the number of levels of the factor. The goal, then, is finding the values of each $\hat{\beta}_i$ such that the global error ε is minimal.

Once the predictors are determined, an Analysis of Variance (ANOVA) must be performed [25], to determine if the means of the prediction variables are equal, that is, if all the variables are representative for the analysis.

Finally, to check if the model is statistically valid, some goodness-of-fit tests must be performed: normality, by using the Kolmogorov-Smirnoff test [38]; autocorrelation, by using Durbin-Watson test [37]; and homoskedasticity, by using Breusch Pagan test [39]. Due to the model usage is limited to the goodness of fit, many datasets do not meet this strategy.

2.2.2. Support Vector Regression (SVR) [40, 41]

The goal of this supervised learning strategy is to find one (or more) hyperplanes that separate previously tagged classes. By finding the support vectors, it is possible to predict, in the case of regression, the value of a new continuous variable based on a set of inputs. Figure 1 shows the geometric concept for two input characteristics.
Figure 1: SVR geometric concept

The objective is to find the hyperplane that separates two classes with the maximum margin between them, therefore, finding the model is reduced to an optimization problem, where the coefficients w must be found, as shown in equation (3).

$$Min\ Z = \frac{1}{2}\|W\|^2 \tag{3}$$
$$St: |y_i - w_i x_i| \le \varepsilon$$

where y_i are the predicted variables, x_i are the independent variables (or features) and ε is the minimum tolerance between the separation hyperplanes and the features. For SVR, a slack variables set is added to equation (3), such that, for each value that falls outside ε, its deviation is recorded to make it minimal. The hyperparameter cost (C) is introduced to penalize said deviations, which is tuned through cross-validation. Thus, equation (3) is re-written, as shown in equation (4) (called the primal problem):

$$Min\ Z = \frac{1}{2}\|W\|^2 \ + C\sum_{i=0}^{n}|\xi_i| \tag{4}$$
$$St: |y_i - w_i x_i| \le \ \varepsilon + |\xi_i|$$

However, in many cases, the classes are not linearly separable, for this reason, it is recommended to use kernel functions, K [41, 42], to perform a transformation that increases the number of dimensions, allowing separating such classes, as shown in equation (5):

$$K(x_i, x_j) = \langle \phi(x_i), \phi(x_j) \rangle \tag{5}$$

where ϕ is a nonlinear mapping function and $\langle , \rangle$ is the inner product operator.

The dual problem to the primal problem is given by equation (6):

$$Min\ \frac{1}{2}\alpha^T Q\alpha \ - e^T\alpha \tag{6}$$
$$St: \begin{matrix} y^T\alpha = 0 \\ 0 \le \ \alpha_i \le C, i = 1, \dots, n \end{matrix}$$

where e is a vector of all ones, Q is a positive semidefinite matrix with $Q_{ij} = y_i y_j K(x_i, x_j)$ and α_i are the dual coefficients.

Using this model, the prediction function of the equation (7) is obtained:

$$f(x) = \sum_{i=1}^{n/2} y_i \alpha_i K(x_i, x) + b \tag{7}$$

where b is the bias term.

It is important to remark that the standard SVR model in equation (7) considers only real-valued functions [43]. Additionally, it is a discriminant method, i.e. produces a mapping from the data points to the class labels without computing probability distributions, allowing the method to be less computationally expensive, but more sensitive to noise than generative methods [44]. . The main advantage of SVR is that can deal with sparsity, non-linearity, and high dimensionality of the input data [45].

Regarding the SVR hyperparameter tuning (section 4.2), it is performed through cross-validation, and finally, the RMSE that exhibits the best results will be chosen. In the same way that MLR, if there are categorical variables in the set of X, *dummy variables* can be used.

2.2.3. Artificial Neural Networks (ANN). [40, 41]

This bio-inspired strategy is used in a lot of applications, where regression and classification are needed. The structure of a neural network emulates a meta-heuristic concept, based on interactions of neurons within the brain. The most known ANN is known as Multilayer Perceptron, and its architecture is shown in Figure 2. From this figure, a set of m input variables (x) in the Input layer are used to predict the values of n output variables (y) in the output layer. The prediction is achieved by choosing the correct number of neurons in different hidden layers h, which are fully connected with both previous and next layers. The effects of each connection are weighted by a set of constants W, which are determined by an optimization iterative method (commonly Gradient Descend). The main advantages of this kind of ANN (feedforward networks) are that they do not have a priori assumptions about the relationships between the independent and dependent variables [46], their

nonlinear modeling capability [47], and their minimal assumptions needed about the data [48]. In the same way that MLR, if there are categorical variables in the set of X, dummy variables can be used.
Figure 2: Multilayer Perceptron Architecture with backpropagation feedback [49]

Although using ANN can outperform other methods regarding its accuracy, its application must be extensively checked using cross-validation, since a common phenomenon known as *overfitting* makes that ANN cannot be a general model sometimes.

3. Methodology and experiment design

This section shows the steps to fit the different models. First, a measurement phase is proposed, where both instruments and locations are chosen. Then, with the set of data from in-situ sensors, some models are fitted. Finally, the performance evaluation is carried out, choosing the model which exhibits fewer regression errors.

3.1. Measurement phase

In this section, some considerations regarding the measurement are presented.

3.1.1. Location selection

Soil moisture is highly influenced by climatic characteristics of a region, specifically by rain amount and intensity, evapotranspiration [50], vegetation type, topography [51], soil properties (apparent density, porosity, organic matter content, texture, and structure), among other factors [52].

This is how changes in land use and land cover, in interaction with soil physical characteristics and climate, play a key role in soil moisture variations at different scales [53]. In the Colombian case, the soil moisture variability has been less studied and there is not enough information to understand its spatial and temporal dynamics, and much less has its contribution to water flows regulation been quantified.

This is the case in some areas of the Antioquia region, where precipitation is the only source of soil water and recharge of its surface layers. Therefore, soil moisture in deep layers cannot be replenished with contributions from rain and groundwater. For this reason, soil wet front movement study at different depths is key to understanding its variability and impact on agricultural production and ecosystems in tropical basins.

In different studies [54–56] it has been found that drought conditions affect variations in soil moisture content, while topography and vegetation type are the dominant factors that control the humidity in different soil layers. Specifically, soil water storage is mainly affected by topography at shallow depths, while in deep soil layers it is mainly controlled by vegetation type.

Considering the above, for the present study Las Palmas basin was selected, which has as characteristics of interest that it is in the tropical Andean zone of the municipality of Envigado, Antioquia, Colombia (coordinates: 6 ° 11'26.1 "N 75 ° 31'47.6" W), and which has undergone processes of change in land use and land cover, among which transition from crops and pastures to recreational and commercial uses stands out. There are also some small fragments of forest and secondary vegetation. This basin has an area of 31.31 km^2, with elevations from 2,500 to 2,600 meters above sea level and its predominant climate is cold humid to very humid and with an average annual rainfall of 2781 mm.

The basin also has different soil associations (Figure 3), which determine physical characteristics, as well as different depths in soil profiles [57]. The Tequendamita Association (TE) is found mainly in the Basin, formed by deep to moderately deep soils, well-drained, with medium textures, low to moderate fertility, mild to moderate erosion. A characteristic of these soils is that they are formed by metamorphic rocks (schists, gneisses) covered with volcanic ash. Soil samplings were made, and results were verified with previous studies such as the "General Study of Soils and Zoning of Lands of the Department of Antioquia" [58], and the" Semi-detailed study of soils in zone 13 of the municipality of Envigado for potential use purposes" [59].

Considering that the soil moisture content suitable for plant growth depends on the type of soil [60] and the physical explanation mentioned above related to the main variables affecting the soil moisture variability through the soil layers (vegetation, soil type, topography, among others), such parameters were considered to determine the sites where soil moisture monitoring stations were installed. Therefore, three types of vegetation cover representative of the basin (pastures, crops, and forest) were selected and combined with three different phases of the Tequendamita Association and one phase of the La Ceja Association (see Table 1). It is important to mention that the sensors were located having the characterization of soil profiles in the basin, which allowed determining the average depth of same, in each of the points where the monitoring stations were located. This means that an edaphological criterion was used for the location of each of the sensors. Additional criteria used to guarantee that the data collected were representative are the following: *i)* The points were located near access roads and agricultural areas located toward the higher part of the catchment where installation and security could be achieved with lower cost, *ii)* availability of connection to the telecommunications network to transmit data in real-time, *iii)* accessibility.

3.1.2. IoT end nodes

Soil moisture stations were designed and built using IoT tools and methods. Four stations are installed in the upper part of the basin, where a mobile network operator offers full 2G/3G coverage. At each point, three soil moisture sensors were put into

operation at different depths, depending on land cover (crops, pastures, and forest), and soil physical properties. The first layer, the depths per sensor, according to land cover, are shown in Table 1. Installed sensors are from the brand Meter Group, reference EC-5, measurement range from 0 up to 100%, with a resolution of 0.001 m^3/m^3 of Volumetric Water Content (VWC) and accuracy of ± 0.02 m^3/m^3. Sensor output is voltage, from 0 up to 2 Vdc, and is collected by a microcontroller unit ESP32, with an Analog-to-Digital Converter of 12-bit resolution. To ensure that the measurements are stable to be transmitted, the next conditioning protocol is used: *i)* take *n* measures from the sensor, *ii)* arrange samples from the lowest to highest, *ii)* extract the samples in the positions *n/2* and *1+n/2,* and *iii)* take the mean. Engineering units are scaled from ADC units to VWC by using a two-point scheme, by comparing readings of moisture in both water and air and using a Meter Group EM-50 as a calibration pattern. In-situ end-nodes are depicted in Figure 4.

Figure 3: Study area location in Antioquia and Colombia and soil associations present in the Las Palmas basin

After collecting measurements, data is sent to an IoT backend by using the protocol Message Queue Telemetry Transport (MQTT). The chosen IoT platform is Ubidots [61], and it also helps to store information and to provide a frontend user interface to visualize real-time indicators, as shown in Figure 5.

Table 1: Soil moisture sensor depths according to soil use

Land Cover	Soil association	Sensor 1 depth range (cm)	Sensor 2 depth range (cm)	Sensor 3 depth range (cm)
Crop	La Ceja Consociation (LCb)	0-23	23-37	>37
Pasture 1	Tequendamita Association (Ted2)	0-22	22-33	>33
Pasture 2	Tequendamita Association (Ted3)	0-33	33-60	>60
Forest	Tequendamita Association (Ted)	0-16	16-35	>35

Figure 4: IoT soil moisture end nodes in (a) crops, (b) pasture type 1, (c) pasture type 2 and (d) forest
Figure 5: IoT backend / frontend platform [61]

3.2. Model fitting phase

First, all data is extracted from the Ubidots platform, using a temporal window from December of 2019 to June 2020, with an equi-temporal sampling rate of 15 minutes. All data is put together into a unique database table, including timestamp, moisture values per sensor, depths per sensor, and soil type. The models are fitted to output a moisture value at a particular depth, regarding the readings of the other two sensors, their corresponding depths, and the soil use.

To fit all the models, R Studio V 1.2.5019 was used. All the basic statistics measurements were inspected: quartiles, means, medians, and standard deviations (for continuous data), and counters (for categorical data). Regression expressions were adapted with *dummy variables* to allow that the categorical variable *soil type* could involve all the factors with different coefficients. Then, a preprocessing phase for continuous variables was carried out with two different strategies, according to the equations (8) and (9):

$$x_i' = \frac{x_i - \bar{x}}{s^2} \qquad (8)$$

$$x_i' = \frac{x_i - \min(x)}{\max(x) - \min(x)} \qquad (9)$$

where x_i' is the ith transformed sample, x_i is the ith sample of the continuous variable x from the dataset, $\bar{x}$ is the mean of x, s^2 is the standard deviation of x, $min(x)$ is the minimum value of x, and $max(x)$ is the maximum value of x.

Finally, the model fitting for MLR, SVN, and ANN was performed according to the corresponding method. The database has 77848 observations and is split into two sets, with a pseudo-random strategy: training (70%, that is, 54493 examples) and test (30%, that is, 23355 examples). Moreover, some additional tests were run for MLR, to ensure goodness of fit: Kolmogorov-Smirnov [38], Durbin-Watson [37], and Breusch Pagan [39].

3.3. Results analysis phase

After the models were fitted, the regression was carried out with each model, by using the test set. An initial graphical inspection was performed, and three performance metrics are used: RMSE (Root Mean Square Error), Index of Agreement (Willmott), and R^2. These metrics and the graphical approximation served to determine the accuracy of the models regarding field measurements. The pertinent analysis was developed.

4. Model fitting

For the sake of clearness, we will adopt the following notation: M_i is the ith sensor, D_i is the depth of ith sensor, i is an integer index to identify the sensor position ($i = 1$ is the superficial sensor, $i = 2$ is the middle sensor, and $i = 3$ is the deepest sensor), and P_1, P_2, and F are dichotomic *dummy variables* for representing the factors *pasture type 1*, *pasture type 2* and *forest*, in the categorical variable *soil type*. All the processes are executed in a laptop Lenovo G40, with a processor Intel Core i7 4500 @ 1.8 GHz and RAM = 12 GB.

A previous graphical inspection is performed to qualitatively behold if there are relationships among different moistures, as shown in Figure 6. Some statistical metrics are presented in Table 2.
Figure 6. Trends of moisture data. M_1 is the superficial sensor, M_2 is the middle sensor, and M_3 is the deepest sensor. Index interval from 0 up to 21.000 corresponds to crops, from 21.000 to 44.000 corresponds to pasture 1, from 44.000 up to 64.000 corresponds up to pasture 2, and from 64.000 up to 79.000 corresponds to the forest.

From Figure 6, it can be noticed that effectively there is a relationship between the moistures at different depths since when an external variable, i.e., rainfall, causes a perturbation, each moisture varies. Moreover, according to Table 2, medians and means of moistures are arranged from M_1 to M_3 from the least to the greater, indicating that the deep the soil is, the high VWC is. It also can be noticed that the standard deviation of M_3 is the least, supporting that more superficial moisture changes in a wider range than the others, so external variables (rainfall or solar radiation) affect the most to the moistures closer to the soil surface. To validate the hypothesis of correlation among moistures, by using the Pearson correlation coefficient, the next results are obtained: $cor(M_1,M_2) = 0.85$; $cor(M_1,M_3) = 0.91$; $cor(M_2,M_3) = 0.97$.

Table 2: Statistical metrics for soil moistures

	M_1	D_1	M_2	D_2	M_3	D_3
Min	0.047	0.08	0.1918	0.255	0.117	0.33
Q1	0.27	0.11	0.332	0.275	0.382	0.33
Median	0.312	0.115	0.388	0.3	0.425	0.37
Mean	0.3308	0.1215	0.3772	0.3321	0.4322	0.4212
Q3	0.383	0.165	0.457	0.465	0.508	0.6
Max	0.552	0.165	0.553	0.465	0.582	0.6
SD	0.0786	0.029	0.0786	0.085	0.0735	0.113

4.1. MLR

Taking into account that there is a direct correlation among soil moistures, MLR can be fitted according to the process in section 2.2.1. So, the general model in equation (2) is re-written to the particular dataset, as shown in equation (10):

$$\widehat{M}_2 = \hat{\beta}_{0,2} + \hat{\beta}_{1,2}M_1 + \hat{\beta}_{2,2}D_1 + \hat{\beta}_{3,2}D_2 + \hat{\beta}_{4,2}P_1$$
$$+ \hat{\beta}_{5,2}P_2 + \hat{\beta}_{6,2}F + \varepsilon_2 \qquad (10)$$
$$\widehat{M}_3 = \hat{\beta}_{0,3} + \hat{\beta}_{1,3}M_1 + \hat{\beta}_{2,3}D_1 + \hat{\beta}_{3,3}D_3 + \hat{\beta}_{4,3}P_1$$
$$+ \hat{\beta}_{5,3}P_2 + \hat{\beta}_{6,3}F + \varepsilon_3$$

where all the $\hat{\beta}$ are the model estimators, and ε is the error model. Note that, in the first instance, it is needed to fit two models for M_2 and M_3, depending on the variables associated with the superficial moisture and the *soil type*. However, due to the high correlation between M_2 and M_3, it is essential to find the optimal $\hat{\beta}$ values, the strategy of minimization of *least squares* is applied [62], searching for a hyperplane that minimizes the cumulative errors from measurements and the predicted variable. The R function *lm* is used, getting the results in Table 3, for training data without preprocessing, and with the preprocessing strategies in the equations (8) and (9). From this table, the dichotomic coefficients $\hat{\beta}_{4,2}, \hat{\beta}_{5,2}, \hat{\beta}_{4,3},$ and $\hat{\beta}_{5,3}$ are not determined, due to there are a multicollinearity effect with the other variables; that is, such variables explain the effects thoroughly without needing the inclusion of the variable *soil type* if it is a crop, pasture 1, or pasture 2. The multicollinearity effect is tested by using the *alias* method proposed in [63]. This method shows how a collinear variable is explained by the others, as shown in Table 4.

According to Table 4, for example, the coefficient $\hat{\beta}_{5,2}$ (which corresponds to the binary variable P_2, pasture type 2) is explained by the others, being D_1 (superficial moisture sensor depth), the variable that explains the most the behavior of P_2. A similar analysis can be performed for other variables.

Table 3: Regressor values for the model in equation (8). P-values less than 0.05 indicate that the regressor is significative

Once MLR models are fitted, an Analysis of Variance must be performed for the raw data and the two preprocessing strategies in the equations (8) and (9), to check if all the variables are significant. This analysis is carried out by using the R function *ANOVA,* obtaining the results in Table 5, showing that hypothesis tests performed to validate that all the model variables are significant, excepting the *soil type* for crops, pasture type 1, and pasture type 2.

To assess the best preprocessing strategy, we calculate the R^2, the RMSE and the Index of Agreement for each model with the training data, for both M_2 and M_3 (Table 6). Because the preprocessing strategies change the scale of the measurements, it is evident that the R^2 and the Index of Agreement are similar for all the subsets, however, the RMSE is less for the raw data, since all the moistures are in the range 0.2 up to 0.6 m^3/m^3, and because the standard deviations are from 0.029 to 0.113 (Table 2), the span of the transformed sets is higher than the raw data, according to equations (8) and (9).

Table 6: Performance metrics for the sets of raw and preprocessed data for (a) M_2 and (b) M_3

(a)

	R^2	RMSE	Index of Agreement
Raw data	0.9685	0.14	0.9217

Max / Min	0.9808	0.0218	0.9402
SD / Mean	0.9807	0.1387	0.94

4.2. SVR

An SVR is trained to perform the regression of M_2 and M_3, based on M_1, D_1, D_2 or D_3, F, P_1, and P_2. Three types of kernels

are tested: linear, polynomial, and Radial Basis Function (RBF) [64]. A cross-validation process is carried out to determine which of the kernels exhibits better performance, by using the function *tune* in R Studio, considering the inverse of the regularization parameter cost, known as lambda (λ) and kernel width (γ) as hyperparameters. Since predictions with linear and polynomial kernels did not exhibit acceptable errors, we selected the RBF kernel to show the regressor tuning process. The steps developed to tune the SVR are as follows (for each preprocessing scheme): *i)* split raw data and preprocessed data into training and test sets, *ii)* configure a 2D grid with the values of the hyperparameters λ = (0.0001, 0.001, 0.01, 0.1, 1, 10, 100) and γ = (0.001, 0.01, 0.1, 1, 10, 100), *iii)* determine an SVR model for each subset of hyperparameters, *iv)* evaluate the regression errors of each model, and *v)* choose the model with the least regression error. After tuning all the SVRs, we found the best hyperparameters configuration. Regarding the training sets, Figure 7(a) shows the regression errors for the raw data of M_2 (which exhibited the least regression error = 4.36 x 10^{-6}), considering the hyperparameters λ =1 x 10^{-7} and γ = 0.001, and Figure 7(b) shows the regression errors for the raw data of M_3 (which exhibited the least regression error = 1.59 x 10^{-6}), considering the hyperparameters λ =1 x 10^{-5} and γ = 0.1. Besides, the regression errors for each preprocessing configuration (for the training sets) are shown in Table 7. Finally, for M_2, we obtained R^2= 0.985, RMSE = 0.0115, and Index of Agreement = 0.9422. Similarly, for M_3, we obtained R^2= 0.9885, RMSE = 0.0078, and Index of Agreement = 0.9542.

4.3. ANN

An ANN is proposed to predict soil moisture. Two multilayer perceptrons are trained to perform the regressions of M_2 and M_3, based on M_1, D_1, D_2 or D_3, F, P_1, and P_2. A cross-validation process was carried out aiming to tune the hyper parameters of the ANN, i.e., *i)* best number of hidden layers, taking into account a tradeoff between low estimation error and simplicity, *ii)* weights values for each connection and *iii)* activation function the neurons (binary step, linear, sigmoid, tanh and Rectified Linear Unit -RELU- were considered). We have followed the next procedure to choose the best configuration: *i)* take raw data, or preprocessed data with the equations (8) or (9) and divide them into training

(70%) and test (30%) sets, *ii)* train a perceptron with a hidden layer and a number of neurons from 2 up to 10, and a decay from 0 up to 1 with steps of 0.1, *iii)* for each pair of hyperparameters, evaluate R^2, RMSE and the Index of Agreement (Willmott) for the training set, *iv)* inspect and select the best preprocessing scheme, *v)* plot errors for the selected preprocessing scheme according to the set of hyperparameters chosen, and *vi)* select the configuration of the neural network. Figure 8 and Figure 9 show different regression errors for the different preprocessing schemes for M_2 and M_3.

(a)

(b)

(c)
Figure 9: ANN regression performance for each preprocessing scheme for (a) R2, (b) RMSE, and (c) Index of Agreement (Willmott) for M_3

From Figure 8 and Figure 9, it can be seen that all the configurations of ANNs have better performance with raw data, since R^2 and Index of Agreement are close to 1, and RMSE is close to 0. Thus, we selected the raw data to get the best ANN configuration, as shown in Figure 10 and Figure 11.

(a)

(b)

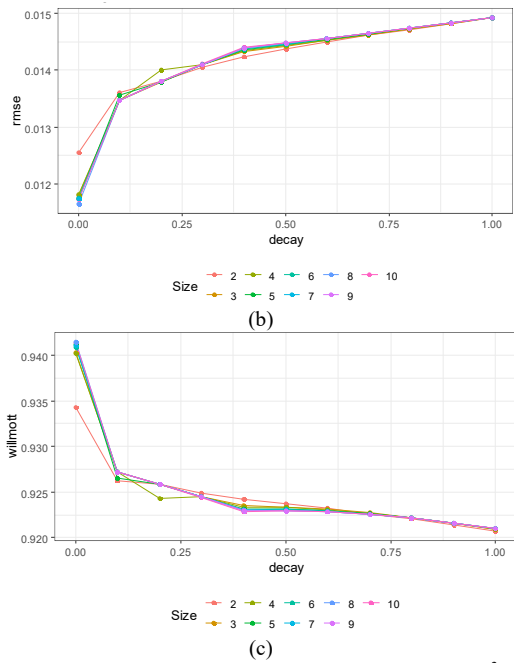

Figure 10: ANN regression performance for raw data for (a) R^2, (b) RMSE, and (c) Index of Agreement (Willmott) for M_2

(a)

(b)

(c)
Figure 11: ANN regression performance for raw data for (a) R^2, (b) RMSE, and (c) Index of Agreement (Willmott) for M_3

From Figure 10, we obtained the best ANN configuration for M_2 as follows: an input layer with six neurons, a hidden layer with eight neurons, an output layer with one layer, and a decay = 0 (R^2=0.9781, RMSE=0.0116, and Index of Agreement=0.9414). Similarly, for M_3, we found the best configuration with a hidden layer of 7 neurons and a decay = 0 (R^2=0.9884, RMSE=0.0079, and Index of Agreement=0.9534). The ANNs' configurations are depicted in Figure 12.

(a)

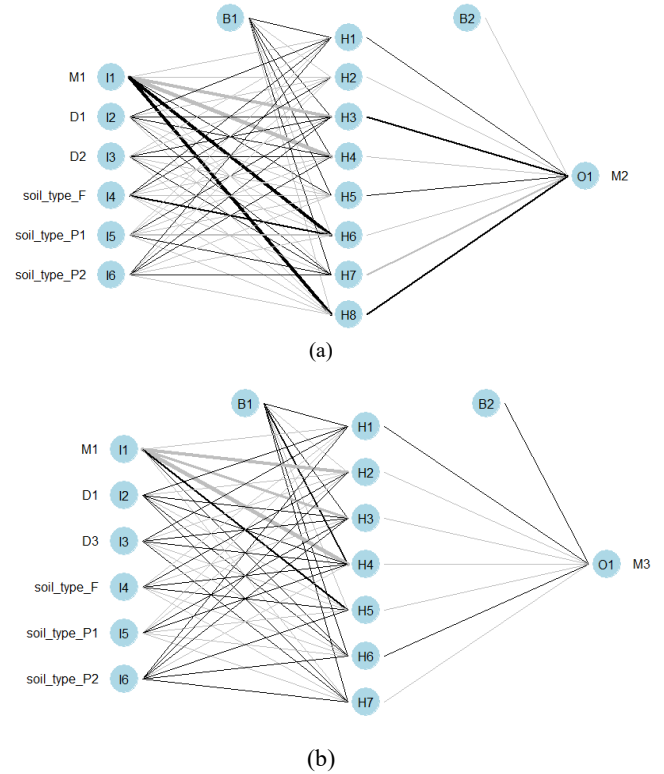
(b)


Figure 12: Multilayer perceptron ANN for (a)M_2 estimation and (b) M_3 estimation

In Figure 12, the darker and broader the line between two neurons is, the greater the weight is, which represents the relative importance (positive) of such connection. On the other hand, the grayer and broader the line between two neurons is, the lesser the weight is, which represents the relative importance (negative) of such connection. The tuned weights are shown in Table 8.

Table 8: Tuned weights for neurons connections of the ANN. Table (a) shows the weights from the input layer to the hidden layer for M_2 estimation, table (b) shows the weights from the hidden layer to the output for M_2 estimation, table (c) shows the weights from the input layer to the hidden layer for M_3 estimation, table (d) shows the weights from the hidden layer to the output for M_3 estimation.

5. Results

After fitting the parametric and non-parametric methods, some performance metrics will be applied to test what method could be used with better results to represent the soil moisture variability toward the soil profile for different type of soil and land cover configurations. It will indicate what model could be applied to extrapolate the soil moisture profiles toward areas with scarce information. To evaluate the models' performances, R^2, RMSE, and the Index of Agreement are proposed, as shown in Table 9. It can be noticed that, at first glance, the general performance of the

methods is almost the same with slightly worse results for the MLR method for the sites presented. A deeper analysis can be carried out from the error dispersions of each method, as depicted in Figure 13 and Figure 14, where it can be noticed that error dispersion is higher for MLR, and the absolute error performances of ANNs and SVR are similar. Furthermore, when plotting the time-series (Figure 15 and Figure 16), it can be noticed that a deeper analysis should be carried out regarding the soil types.
Figure 15: Regression results for the test set of M_2. Index interval from 0 up to 6.500 corresponds to crops, from 6.501 to 13.100 corresponds to pasture 1, from 13.101 up to 19.100 corresponds up to pasture 2, and from 19.101 up to 23.355 corresponds to the forest
Figure 16: Regression results for the test set of M_3. Index interval from 0 up to 6.500 corresponds to crops, from 6.501 to 13.100 corresponds to pasture 1, from 13.101 up to 19.100 corresponds up to pasture 2, and from 19.101 up to 23.355 corresponds to the forest.

It can be noticed that the methods (ANN, MLR, and SVR) exhibit similar results for the crop, pasture 1, and pasture 2 in terms of average variability of the soil moisture (Figure 15 and Figure 16). Nonetheless, SVR outperforms the other two methods in terms of high variability when comparing versus the measured data. In the case of the forest, it is more evident that SVR can better predict the real values of both M_2 and M_3. On the other hand, none of the methods are accurate enough to predict behaviours in pasture 2. Due to this visual inspection, RMSE, R^2, and Index of Agreement are recomputed but segmented by each *soil type,* as shown in Table 10.

Table 10: Performance metrics for regression models ANN, MLR, and SVR differenced by *soil type*

Soil type – Moisture	Performance metric	R^2	RMSE	Index of Agreement
Crop M_2	Test ANN	0.8095	0.0425	0.7922
	Test MLR	0.8129	0.0424	0.8027
	Test SVR	0.6542	0.1168	0.6031

Crop M_3	Test ANN	0.9307	0.0044	0.8725	
	Test MLR	0.9325	0.0043	0.8782	
	Test SVR	0.9344	0.0044	0.8993	
Pasture 1 M_2	Test ANN	0.8176	0.0583	0.7722	
	Test MLR	0.8174	0.0588	0.7695	
	Test SVR	0.8246	0.0049	0.7715	
Pasture 1 M_3	Test ANN	0.8439	0.0077	0.7824	
	Test MLR	0.8444	0.0081	0.7902	
	Test SVR	0.8585	0.0074	0.8136	
Pasture 2 M_2	Test ANN	0.2836	0.0551	0.2526	
	Test MLR	0.2770	0.0551	0.2468	
	Test SVR	0.3386	0.0196	0.3121	
Pasture 2 M_3	Test ANN	0.3749	0.0125	0.3185	
	Test MLR	0.3560	0.0128	0.3054	
	Test SVR	0.4419	0.0119	0.4112	
Forest M_2	Test ANN	0.8247	0.0785	0.8063	
	Test MLR	0.8245	0.0795	0.7985	
	Test SVR	0.8264	0.0079	0.8111	
Forest M_3	Test ANN	0.8247	0.0185	0.7954	
	Test MLR	0.3245	0.0796	0.2212	
	Test SVR	0.9207	0.0059	0.8924	

It can be noted, according to Table 10, that SVR outputs better results in most of the cases, excepting for M_2 in the crop, where MLR fits better data with the test set. In the rest of the cases, ANN outperforms MLR. Since the R^2 value depends on the individual standard deviations, it is possible that the segmentations conducted for analyzing the individual performance regarding the soil type present different fitting values than the case of the whole dataset.

For the sake of statistical validity, some goodness-of-fit tests must be carried out for the parametric method (MLR): normality, autocorrelation, and homoskedasticity. All the tests are calculated using residual errors. For normality, the Kolmogorov Smirnov test [38] is applied, obtaining a p-value = 2 x 10^{-16}, so residuals are not normal. For autocorrelation, the Durbin test is applied, obtaining a DW = 0.02. According to [37], if the value is too far from 2, there is a autocorrelation. Finally, for homoskedasticity, the Breusch Pagan test [39] is carried out, obtaining a p-value=2 x 10^{-16}, which means that residuals are heteroskedastic. Because there is no normality, correlation, nor homoskedasticity, the linear regression model could not be applied.

6. Conclusions

In this paper, a comparison between parametric and non-parametric methods for fitting soil moistures in Las Palmas Andean Basin. This research was motivated due to scarce information from satellite images and in-situ measurements toward the tropical areas where the soil moisture plays an important role in climate variability, so more in-depth soil moisture research is not possible.

The proposed methodology based on parametric and non-parametric methods employing a database collected from three typical land covers: crop, pasture, and forest, and typical soil types demonstrated that there are high correlations between superficial and intermediate soil moistures, as well as superficial and deepest soil moistures, so it is possible to propose prediction models to avoid the need to install many instruments per point or even the high ability of the proposed method to use surface information from satellite data to obtain soil moisture profiles.

A model fitting using MLR, SVR, and ANN was carried out, aiming to predict the soil moisture, by using as predictor variables the superficial soil moisture, its depth, the depth of the soil moisture that wants to be predicted, and the *soil type*. All models offer similar performance metrics, except for forest, where the SVR outperforms the other methods. However, goodness-of-fit tests are not met by residual errors of the MLR model, so it cannot be used with statistical validity. In that way, SVR is the best model to fit moistures based on superficial soil moisture.

Finally, it is important to state that the traditional hydrological models had been calibrated employing few information of the full complex and non-linear hydrological rainfall runoff transformation process (normally flow in specific points), avoiding the understanding of the spatial variability along the full catchment and imposing calibration parameters representing just a small part of the physical phenomenon. The inclusion of distributed spatial parameters in the calibration process such as infiltration parameters or soil moisture profiles can increase strongly the quality of the results obtained along the full catchment or even increase the understanding of the physics involved. In this direction the proposed methodology represents an important contribution to several engineering and hydrological applications.

7. Future work

We are planning to install two additional soil moisture stations in another forest, and residential soil uses, to better tune the models.

Conflict of Interest

The authors declare no conflict of interest.

A Novel Blockchain-Based Authentication and Access Control Model for Smart Environment

Nakhoon Choi, Heeyoul Kim[*]

Department of Computer Science and Engineering, Kyonggi University, Suwon 16227, Republic of Korea

A B S T R A C T

With the increase of smart factories and smart cities following the recent 4th industrial revolution, internal user authentication and authorization have become an important issue. The user authentication model using the server-client structure has a problem of forgery of the access history caused by the log manipulation of the administrator and unclearness of the responsibility. In addition, users must independently manage the authentication method for each service authentication. In this paper, to solve the above problem, the researchers propose an integrated ID model based on a hybrid blockchain. The proposed model is implemented as two layers of Ethereum and Hyperledger Fabric: the former layer is responsible for integrated authentication, and the latter layer is responsible for access control. The physical pass or application for user authentication and authorization are integrated to one ID through the proposed model. In addition, the decentralized blockchain ensures the integrity and transparency of the stored access history, and it also provides non-repudiation of authority and access history.

1. Introduction

This paper is an extension of work originally presented in ICACT 2020 (International Conference on Advanced Communication Technology) [1].

With the increase of smart factories and smart cities in accordance with the 4th industrial revolution, user authentication and access control are emerging as important issues. A smart factory automates factory facilities to reduce process failure rates and is operated by a small number of employees [2]. However, there is a problem of responsibility in case of an accident. In addition, users of smart city may need different authentication means for each city service, and there is a risk of manipulation of access history.

The administrator of the centralized access control model of the existing server-client structure can modify and delete the access history. With the above problem, it is possible to avoid responsibility through internal corruption in case of an accident. In addition, the user proves the authority through different authentication methods including physical means and mobile applications for each service. This makes it inconvenient for users to issue and manage various authentication methods, and it is troublesome for users to prove their authority history and career.

[*]Corresponding Author: Heeyoul Kim, Department of Computer Science and Engineering, Kyonggi University, Suwon, 16227, Korea, Email: heeyoul.kim@kgu.ac.kr

To solve the above problem, the authors in [3] proposed integrated authentication using smart cards for integrated access control of various services. However, there is a problem that the administrator can modify the authority and access details arbitrarily, such as the access control list or the capability list.

In order to solve the above problem through the blockchain, the model in [4] stores the information in DHT(Distributed Hash Tables) and performs access control for information based on the Bitcoin system. However, it is not possible to store access details, and there is a problem of processing speed with low TPS(Transaction per Second) of Bitcoin. Also, it is necessary to verify practicality and suitability. These studies are inadequate for authentication and access control in smart environments.

This paper proposes an integrated authentication and access control model in smart environments that solves the problems above with the help of blockchain technology. The proposed model processes user authentication and access request through a hybrid blockchain system using private and public blockchain together. The proposed model enables users to acquire and prove various access rights through one authentication means, thus it integrates the authentication of various smart factory services and smart city services. In addition, the proposed model prevents problems such as access history manipulation that occurs in the existing central model based on the integrity and transparency of the blockchain. Moreover, the user's history recorded in the blockchain can be easily used as the proof of the user's career.

The rest of this paper presents the following. Section 2 introduces blockchain platforms utilized in the proposed model. Section describes the architecture and process of the model. Section 4 displays the results of implementing the model. Section 5 provides application scenario using the model and Section 6 contains conclusions.

2. Background

The flexible connection of vertical or horizontal organizations became important in the wake of the Fourth Industrial Revolution [5]. This paper uses blockchain platform to build reconfigurable network of existing organizations. The integrity of information is secured in the relationship of organizations through the decentralized characteristics of blockchain. Users can also benefit from all the benefits without noticing that the blockchain has been used on the surface.

2.1. Ethereum

Ethereum [6] is a representative public blockchain using PoW(Proof of Work) [7] consensus algorithm like Bitcoin. PoW consensus algorithm is the process of selecting block creators among unreliable participants on blockchain networks. Participants compete to find a hash value that matches the target condition to elect a miner. The public blockchain introduces the economic concept of cryptocurrency, which leads to the correct consensus by compensating the cryptocurrency to the miner elected. The block generated through the consensus is distributed to the participants of the blockchain network and is connected to the previous block through the 'previous block hash' included in the block header to ensure the integrity of the previous block. All blocks and transactions are open to the public with ensuring transparency, and the decentralized network evolves continuously without administrators.

Ethereum supports the creation and distribution of smart contract [8] for the development of DApp(decentralized Application). A smart contract is written in Solidity, a Turing completeness language, and recorded in the distributed ledger with ensuring the integrity of the results according to automated execution and input [9]. Figure 1 represents the operation of the smart contract in Ethereum. The smart contract made with Solidity is compiled and stored in the form of the EVM(Ethereum Virtual Machine)-bytecode in the ledger. Calling the code through Ethereum clients such as Geth(Go-Ethereum) is executed in the EVM environment.
Figure 1: Operation of Smart Contract in Ethereum Client

2.2. Hyperledger Fabric

Hyperledger Fabric [10] (hereinafter referred to as "Fabric"), as part of the Linux Foundation's Hyperledger project, is a representative private blockchain platform commonly used for enterprise environments. Unlike public blockchains, it uses certificates and PKI(Public Key Infrastructure) to authenticate participants with a restricted network, and is managed through a MSP(Membership Service Provider), an authentication management system that defines the role and access rights of nodes in the network.

A peer is a node of organizations that compose the Fabric network and manages ledgers and chaincodes, and the peers are divided into endorser, committee, anchor, and leader according to their roles. Transactions for the execution of chaincodes in the network are performed through three steps: execution, ordering and validation. The chaincode plays the same role as Ethereum's smart contract and updates or queries data to the ledger. Currently, development of chaincodes is possible through Golang, Node.js, etc. Fabric does not require much resources in the consensus, unlike PoW, by ordering transactions through Ordering service to create blocks. Therefore, it has much better performance than the public blockchain platforms.

2.3. Metamask

The blockchain wallet stores the user's personal key as well as managing the balance of the blockchain account, and creates a transaction on behalf of the user and submits it to the network. In this sense, wallet is the easiest approach to using blockchain for normal users. The proposed model uses Metamask [11] for convenient use in PC or mobile environment.

Metamask is the most representative web-based Ethereum wallet extension program executed in browser, and is currently supported by Chrome, Firefox, Opera, etc., and beta test is being conducted in mobile environment. It supports Ethereum account management, digital signature generation, and transaction creation. users can easily access the smart contract of the blockchain through Metamask.

In order for users to access the Ethereum network, they must participate in the network as a blockchain node through the Ethereum client. This method lowers user accessibility, so Metamask uses Infura API [12], a cloud service for network connection to wallet users. Through the Metamask, users can access the Ethereum network in the web environment without operating the node directly, and operate the smart contract and receive the results.

3. A Blockchain-based Authentication and Access Control Model

3.1. Model Architecture

The proposed model uses a hierarchical hybrid blockchain where a public Ethereum network is connected to multiple private Fabric networks. Figure 2 shows the layered architecture of the proposed model. The public layer based on Ethereum is an integrated authentication management layer. The private layer is composed of various subsystems for smart factories and smart

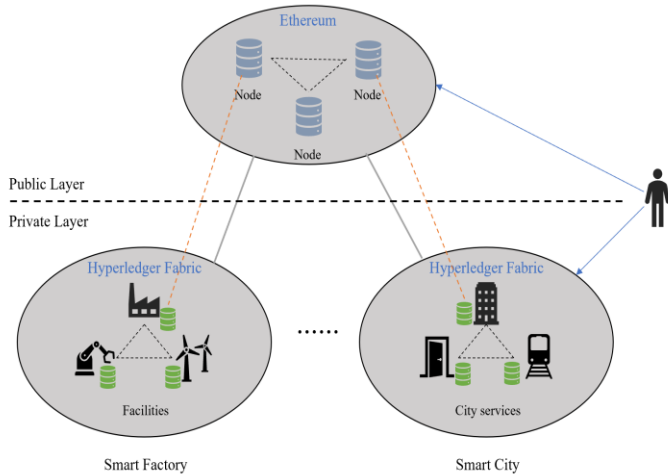
cities (hereinafter referred to as "Organization"), and each organization operates Fabric network separately for authorization and access control.


Figure 2: Layered Architecture of the Proposed Model

The proposed model uses a hierarchical hybrid blockchain where a public Ethereum network is connected to multiple private Fabric networks. Figure 2 shows the layered architecture of the proposed model. The public layer based on Ethereum is an integrated authentication management layer. The private layer is composed of various subsystems for smart factories and smart cities (hereinafter referred to as "Organization"), and each organization operates Fabric network separately for authorization and access control.

3.1.1. Public Layer - Integrated Authentication Management

Through this public layer, users create their own IDs based on their Ethereum accounts. The ID of a user is composed of the user's Ethereum account, a secret computed by hashing the user's personal information, a set of tokens used for user authentication by organizations, and a contact method (e.g., E-Mail) as shown in Figure 3. The proposed model provides a smart contract named IAM (Integrated Authentication Manager) utilized by the users to create and control their IDs. The functions in the IAM is described in Table 1, and these functions except for query functions have an access control mechanism on the IDs based on the function modifier in Solidity. In other words, it is guaranteed that only the legitimate owner of the ID can modify the secret and register tokens via these functions.

Figure 3: The structure of a user's ID

Table 1: Description of Functions in the IAM Smart Contract

Function	Purpose
createId(secret)	To create an ID and register the secret based on the user's Ethereum account
modifySecret(secret)	To modify the secret registered
regToken (token, tkName)	To register tokens and their aliases for the authentication by organizations
queryUser(secret)	To find the registered user by given secret and to retrieve user information
queryByToken(token)	To verify whether the token was successfully registered by the user

3.2.2. Private Layer – Access Control Management

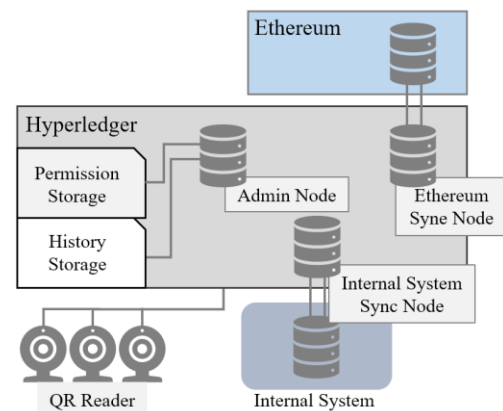
In the private layer, there may be several Organizations managing smart environments respectively. Figure 4 represents the architecture of an Organization. Several nodes compose a Hyperledger Fabric network for the Organization. Among them, the admin node provides the ordering service for consensus and is handled by the administrator. The Ethereum sync node is connected to the Ethereum in the public layer and responsible for delivering the user's ID information for authentication.


Figure 4: Architecture of an Organization in the Private Layer

Our model provides role-based access control (RBAC), and the role and access rights of each user are recorded in the Fabric blockchain via the chaincode named PM (Permission Manager). Table 2 shows the functions provided by the PM, and only the administrator can execute these functions for creation and modification of the authority. The access history is written by another chaincode called by the client application. The information stored in the Fabric blockchain is transparent and open to the legitimate participants in the Organization.

Table 2: Description of Functions in the PM Chaincode

Function	Purpose
userReg(secret)	To register a new user identified by the secret
permSet(account, role)	To set the role and authorization of the user having the given account
queryPerm(account)	To check and verify the user's role and access rights

3.2. Process Description

3.2.1. Creating an Integrated ID

A new user joining in the proposed model first performs the process of creating an integrated ID. The user first generates a secret by hashing his personal information as follows:

$$secret = Keccak\text{-}256(Birth,\ Name,\ Phone) \qquad (1)$$

Formula 1 shows the creation of the user's secret, and Keccak-256 is a hash function adopted in the SHA-3 competition of the NIST (National Institute of Standards and Technology) [13].

Then, with assuming that the user already has an Ethereum account, he makes a transaction via Metamask to request the smart contract IAM for the creation of his integrated ID. Since the transaction is signed by his Ethereum private key, the IAM can identify and authenticate the requester. The secret can be seen by anyone after recorded in the blockchain. However, his personal information is not exposed due to the one-wayness of the hash function.

3.2.2. Registering User's Access Rights in Organization

When a user who has completed creating his ID newly joins in a specific Organization, his access right is registered by the process shown in Figure 5. The detailed process is as follows.

1) A new user Alice provides his personal data used for computing secret to the Organization.
2) The internal system of the Organization computes secret of the user by Equation (1), and then send it to the Ethereum sync node in the Fabric network.
3) The Ethereum sync node approaches the smart contract IAM to obtain the user's ID with the received secret.

4) The admin node issues a user-specific validation token T_{Alice}. The purpose of this token is to verify the ownership of the ID obtained in step 3). This token is the hash value of a seed generated per each user, and it is signed by the private key of the admin node (Equation (2)). Then, the token is sent to the user.

$$T_{Alice} = Sign(Keccak\text{-}256(seed_{Alice}),\ Org\ admin) \qquad (2)$$

5) Alice registers the received token in his integrated ID through the smart contract IAM. This step only can be done by the creator of the ID because the IAM compares the requester of this register transaction with the owner of the target ID.
6) If the registration of T_{Alice} is successfully accepted by the IAM contract, the Ethereum sync node can recognize it and is convinced of Alice's ID ownership.
7) The administrator registers both the authority information of Alice and his Ethereum account in the permission storage of the organization.

3.2.3. Access Control

Our model provides a role-based access control with registered users' authorization information. Figure 6 shows the process when Alice requests access to the manufacturing control system in a smart factory. A QR reader attached to the control system is used to interact with the user. Our model determines whether the user's role has appropriate access right or not as follows.

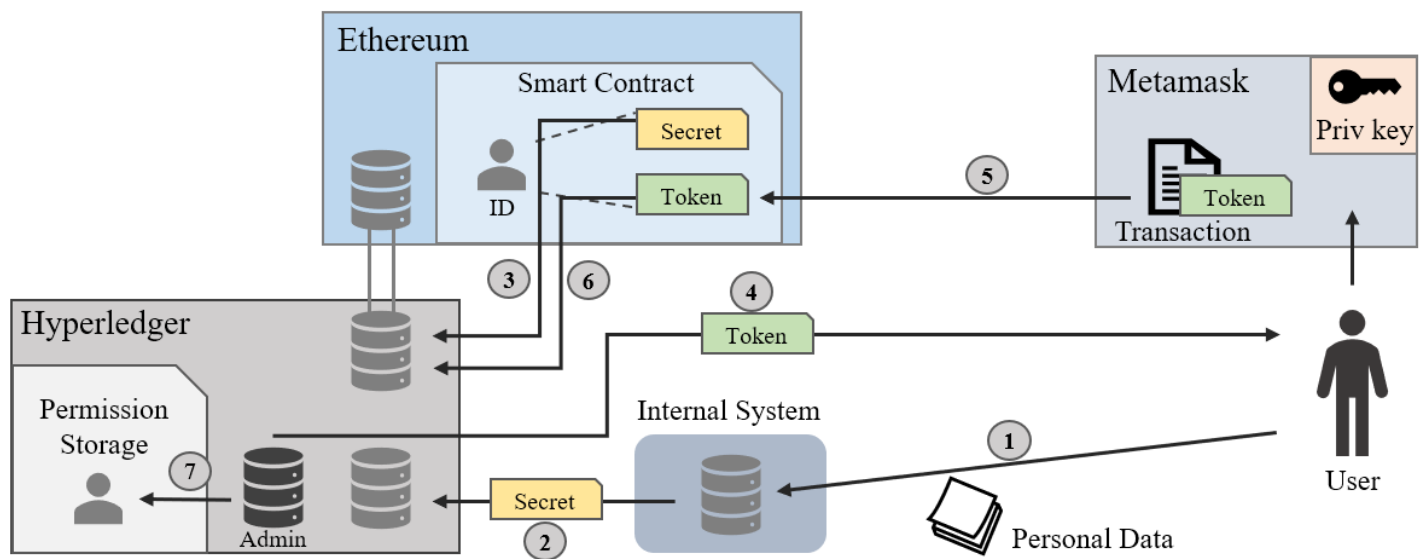
1) Alice generates a QR code which includes both a timestamp for preventing replay attack and a digital signature generated by his Ethereum private key. Our model uses ECDSA [14] based on elliptic curve 'secp256k1' as well as Ethereum. Let G be the base point of the curve E where n is the order of G. Alice's private key is d, and his public key is $Q=dG$. The signature (r, s, v) is computed as follows.


Figure 5: The Process of Registering User's Access Rights in an Organization

① Calculate the hash value $h = hash(m)$ of the message m to be signed, and let z be the l leftmost bits of h where l is the bit length of n.

② Generates a random number k within $[0 \sim n\text{-}1]$.

③ Compute $R = kG$ and obtain the x-coordinate r of point R.

④ Compute $s = k^{-1}(z + rd) \mod n$.

⑤ Compute $v = 27 + (y \% 2)$ (y: y-coordinate of Q).

⑥ (r, s, v) is the digital signature value.

2) The QR reader scans the QR code generated by Alice, and as a Fabric client it delivers the timestamp, signature, and the *object_serial* (ID of the QR reader) to the Fabric node.

3) The Fabric node verifies received signature (r, s, v) with the help of Ethereum's *ecRecover()* method. If it is valid, as a result of this method call, the node discovers Alice's Ethereum account.

4) The authority information of the discovered Ethereum account is retrieved from the permission storage.

5) If Alice's role has been approved for access to the subject to which the *object_serial* is assigned, this request is granted.

6) Alice's access attempt is recorded in the history storage.
Figure 6: The Process of Access Control in an Organization

4. Implementation and Experiment

The proposed model was implemented, and its soundness was confirmed through an experiment. Table 3 describes the implementation environment of each component. The web dApp runs on the Chrome browser with Metamask installed, and it registers the user's secret for creating ID and the Organization's token for registering the user's access rights. The smart contract IAM and the chaincode PM provides the functions described in Section 3.1. QR generator is an application where the user's Ethereum private key is stored, and it generates a QR code containing the user's signature to obtain access right. QR reader is a Fabric client attached to the protected resources.

Table 3: Development Environment

	Environment	Chrome, Metamask
Web dApp		
	Language	JavaScript
Smart Contract IAM	Environment	Ethereum Ropsten Testnet
	Language	Solidity ^0.5.0

	Environment	Hyperledger Fabric 2.1
Chaincode PM		
	Language	Node.js
QR Generator	Environment	Android Emulator
	Language	Java
QR Reader	Environment	Raspberry Pi
	Language	Node.js

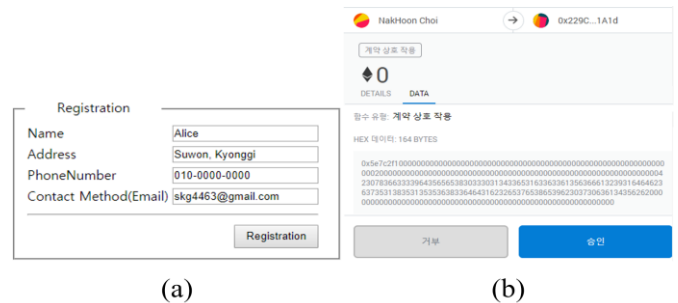
Figure 7 shows the screenshots when a user creates his integrated ID via the web dApp. As can be seen in Figure 8(a), a user inputs his personal data to compute secret. Then, the installed Metamask generates and transmits an Ethereum transaction requesting creation of the user's integrated ID.


Figure 7: Screenshots when Creating Integrated ID. (a) Input of User Data for Computing Secret, (b) Generation of Ethereum transaction with Metamask

Figure 8 shows the logs when an organization registers a user Alice's role after verifying authentication. With given Alice's personal data, the organization computes Alice's secret (Figure 8(a)). Then, the organization checks whether Alice's integrated ID exists or not in the smart contract IAM by calling the *queryUser(secret)* function. If the ID exists, a validation token is issued for Alice (Figure 8(b)). After Alice successfully registers his token in his ID, the organization's Ethereum sync node can detect this event by implementing an event listener for IAM. As can be seen in Figure 8(c), the organization discovers Alice's Ethereum account from this event, and then assigns Alice's role and access right. In this experiment, the role 'level_2' is assigned to Alice and he is granted to access 'object 001'.

Figure 8: Logs when Registering Alice's Access Right in an Organization. (a) Computation of Alice's Secret by the Organization, (b) Issuance of a Validation Token for Alice, (c) Detection of Token Registration and Assignment of Alice's Role

Figure 9 shows an example QR code generated when Alice wants to access a protected resource in the organization. The QR generator installed in Alice's smartphone generates this QR code

by using of the stored private key (Figure 9(a)). As can be seen in Figure 9(b), the QR code contains two values (q0 and q1), where q0 is Alice's ECDSA signature and q1 is the Unix timestamp. Then, Alice provides this QR code to the QR reader attached to the resource.
Figure 9: An Example QR Code Generated for Access. (a) Screenshot of QR Generator, (b) The Information stored in the QR Code

The QR reader transmits both its *object_serial* ('0001' in Figure 10) and the signature obtained by scanning the QR code to the Fabric node. The node recovers Alice's Ethereum account by using of the *ecRecover* function. Also, it verifies the validity of both ECDSA signature and timestamp. Then, it can get Alice's registered role from the permission storage with the account, as shown in Figure 10. Finally, the node decides whether to grant or deny Alice's access request based on his role, and then it informs the QR reader of the decision result.

Figure 10: Logs when Alice's Access Request is Granted

5. Application Scenario using the Proposed Model

To help understanding the proposed model and claim its usefulness, we provide an application scenario using the model from a user point of view in this section. Let us assume that a new user Alice having an Ethereum account Eth_A decided to use the proposed model. He visits the web dApp and creates his own integrated ID (ID_A) by registering both his email address and secret based on his personal data.

Since then, Alice has moved into the smart city K-city (Organization #1) to seek employment. The K-city already has adopted the model extensively, and it participates as an organization. He visits the government office of the city to register himself. The office checks the existence of ID_A and then issues a token T_{Alice}^{Org1}. Alice registers this token in his ID_A by using of his

Ethereum private key. Then, the office assigns the role 'citizen' to Alice and registers his access right to use various public facilities in the city.

Now Alice can prove his identity and use various facilities with his smartphone where the QR generator application is installed. Suppose Alice visits a public library to get hiring information. He just generates a QR code and shows it to the QR reader attached to the gate of the library. Then, his access is allowed, and he can enter the library.

Before long, Alice is hired by a smart factory F-factory (Organization #2). Similarly, in the enrollment process, he can easily register himself with a newly issued token T_{Alice}^{Org2}, without creating a new identity to be used in the factory. Then, the role 'engineer' is assigned to Alice and his access right for the control panel in the factory is registered. As a result, he can control the panel by generation a valid QR code whenever he needs to access it while at work.

Suppose someday Alice commits a mistake in operating some equipment in F-factory, which causes enormous damage to the factory. He gets into a panic, and he may try to avoid suspicion by deleting or manipulation evidences such as CCTV videos. However, since the access history of the users is stored in the immutable blockchain ledger of the F-factory nodes, he cannot hide the fact that he accessed the equipment at that time. Thus, the F-factory can identify Alice's behavior and call him to account.

In another case, suppose an attacker Trudy pretending as Alice tries to access the control panel. He cannot generate a valid QR code because he cannot discover Alice's private key. The attacker may eavesdrop Alice's QR code and try to use it later. However, the timestamp in the QR code prevents this kind of replay attack. Moreover, even if a security incident occurs, the factory can perform a security audit with the immutable access history.

6. Conclusion

Currently many companies and organizations use a centralized model for authentication and access control, so there is internal corruption caused by manipulating access history and it is possible to avoid responsibility in case of an accident. This paper proposes an access control model for smart factories and smart cities using blockchain, a decentralization platform, to solve the problems of existing centralized model and to ensure the integrity and immutability of access history.

The proposed model allows a user to prove their access rights through one integrated ID based on his Ethereum account without creating a new ID separately for each organization. In the aspect of an organization, it is needless to establish separate authentication mechanism, and the organization can easily authorize the users belong to it to access its protected resources. In addition, the proposed model records the access history in the internal blockchain of the organization not only to prevent arbitrary modification and deletion but also to provide non-repudiation.

The proposed model provides a clue to how various smart environments cooperate closely. Both the concept of integrated ID and the hybrid blockchain combining public blockchain and private blockchain can help secure, pragmatic, and user-friendly smart systems. In addition, flexible scalability in a smart environment is secured through a blockchain, and reliability of services and information provided to users is guaranteed.

Modulation type classification is a part of waveform estimation required to employ spectrum sharing scenarios like dynamic spectrum access that allow more efficient spectrum utilization. In this work multiple classification features, feature extraction, and classification algorithms for modulation type classification have been studied and compared in terms of classification speed and accuracy to suggest the optimal algorithm for deployment on our target application hardware. The training and validation of the machine learning classifiers have been performed using artificial data. The possibility to use instantaneous values of the time domain signal has shown acceptable performance for the binary classification between BPSK and 2FSK: Both ensemble boosted trees with 30 decision trees learners trained using AdaBoost sampling and fine decision trees have shown optimal performance in terms of both an average classification accuracy (86.3 % and 86.0 %) and classification speed (120 0000 objects per second) for additive white gaussian noise (AWGN) channel with signal-to-noise ratio (SNR) ranging between 1 and 30 dB. However, for the classification between five modulation classes demonstrated average classification accuracy has reached only 78.1 % in validation. Statistical features: Mean, Standard Deviation, Kurtosis, Skewness, Median Absolute Deviation, Root-Mean-Square level, Zero Crossing Rate, Interquartile Range and 75th Percentile derived from the wavelet transform of the received signal observed during 100 and 500 microseconds were studied using fractional factorial design to determine the features with the highest effect on the response variables: classification accuracy and speed for the additive white gaussian noise and Rician line of sight multipath channel. The highest classification speed of 170 000 objects/second and 100 % classification accuracy has been demonstrated by fine decision trees using as an input Kurtosis derived from the wavelet coefficients derived from signal observed during 100 microseconds for AWGN channel. For the line of sight fading Rician channel with AWGN demonstrated classification speed is slower 130 000 objects/s.

1. Introduction

This paper is an extension of the work "Multiple Machine Learning Algorithms Comparison for Modulation Type Classification for Efficient Cognitive Radio" originally presented in Milcom 2019 [1].

The global market of mobile devices and services actively using the electromagnetic spectrum is continuously growing.

Traditionally the electromagnetic spectrum utilization has been performed using a robust static approach developed almost a century ago: it rations access to the spectrum in exchange for the guarantee of interference-free communication spectrum is divided into the rigid, exclusively licensed bands, allocated over large, geographically defined regions. In conditions when some of these license bands are being nearly unused, while the others are overwhelmed, the problem of spectrum scarcity arises [2]. To cope with the increasingly populated spectrum, the electromagnetic spectrum utilization policies have been reformed

in recent years with the objective to allow the unlicensed secondary users to access licensed bands without causing interference to the licensed primary users [3].

Blind waveform estimation techniques can be used with an intelligent transceiver, yielding an increase in the transmission efficiency by reducing the overhead. Waveform information is critical to implement spectrum sharing scenarios like frequency hopping spread spectrum (FHSS) and dynamic spectrum access (DSA). Modulation type classification is a part of the waveform estimation together with the central frequency and symbol rate estimation. Multiple artificial intelligence algorithms have been successfully applied to solve the modulation classification problems. The availability of abundant data, breakthroughs of algorithms, and the advancements in hardware development during recent years have been driving forward vibrant development of deep learning [4]. Modulation classification using convolutional NN has been presented in [5] and [6]. Mathworks deployed a hands-on practical implementation of deep learning-based modulation classification in [7]. In [8], the authors have demonstrated successful launch of the optimized AlexNet on ZYNQ7045 FPGA: the inference execution times of CNNs in low density FPGAs has been improved using fixed-point arithmetic, zero-skipping and weight pruning. However, in this work the choice has been made to use less computationally demanding supervised ML algorithms. Conventional artificial intelligence (AI) algorithms like machine learning (ML) require preprocessing of the input signal and feature extraction. Received signal features used for the modulation classification could be classified into spectral-based and cyclostationary features. The spectral-based features exploit the unique spectral characters of different signal modulations in three physical aspects of the signal: the amplitude, phase, and frequency. The authors have summarized some of the well-recognized spectral features designed for modulation classification including the following and suggested a decision tree classification [9]. The authors have applied instantaneous amplitude, instantaneous phase, and spectrum symmetry together with the set of new features from both spectral and time domain including linear predictive coefficients, adaptive component weighting, zero-crossing ratio, linear frequency bank spectral coefficient for the classification of commonly used digital modulations including ASK, FSK, MSK, BPSK, QPSK, PSK, FSK4 and QAM-16 [10]. Gardner pioneered the area of cyclostationary signal analysis [11]. Gardner and Spooner first implemented cyclostationary analysis for modulation classification problems in [12].
Figure 1: Optimizing sensing and transmission times.

The aim of this work is to determine the optimal modulation classification algorithm and suggest the subset of the strongest and robust features derived from the received signal that could be used to blindly classify the modulation type in our hardware application: a software-defined radio-based network consisting of multiple digital cognitive radio nodes. SDR-based nodes are operating in the frequency band from 70 MHz to 6 GHz with up to 56 MHz of instantaneous bandwidth are used as the hardware platform for the cognitive functionality deployment with FHSS capabilities. Available computational resources are Dual-core ARM Cortex A9 CPU, 2x512 MB of DDR3L RAM, and 512 MB of QSPI flash memory. The operation system is Embedded Linux. The radio part is based on Analog Devices AD9364 radio transceiver and Xilinx' Zynq-7020 FPGA. It is supporting multiple digital modulations including both linear: QPSK, BPSK, 8PSK, 16PSK, and non-linear: 2FSK. Symbol rate could be also adjusted between 10 KSymbols/s and 1 MSymbol/s to generate the cognitive waveform. Our target application predefines most of the boundary conditions and operational requirements such as required decision-making speed and computational resources available. In this work time required for radio scene analysis $t_{Analysis}$ is defined as a sum of time required for radio scene observation $t_{Observation}$ and processing $t_{Processing}$ for the received signal on the receiver front end. Time allocated for the active data transmission is data transmission time, $t_{Transmission}$ and total time is the sum of observation and transmission time as illustrated by Figure 8. Allocating the sensing time and transmission time at the MAC layer is involving a tradeoff between ensuring the PUs user's QoS requirements as opposed to maximizing the data throughput. To meet real-time operation requirements on the target hardware the following real-time performance characteristics must be met by the proposed algorithms. The maximum time available for radio-scene environment observation is $t_{observation}$=500×10^{-6} seconds. Our application is a time-slotted communication system, where 500 microseconds corresponds to one-time slot, also maximum processing time has been selected likewise $t_{processing}$=500×10^{-6} seconds, which requires the minimum classification speed of 2000 objects per second. Modulation classification is required to be performed for SNR values above the demodulation threshold of 12 dB, which corresponds to bit-error-rate BER=10^{-8} and BER=3.4×10^{-5} for BPSK and 2FSK, respectively.

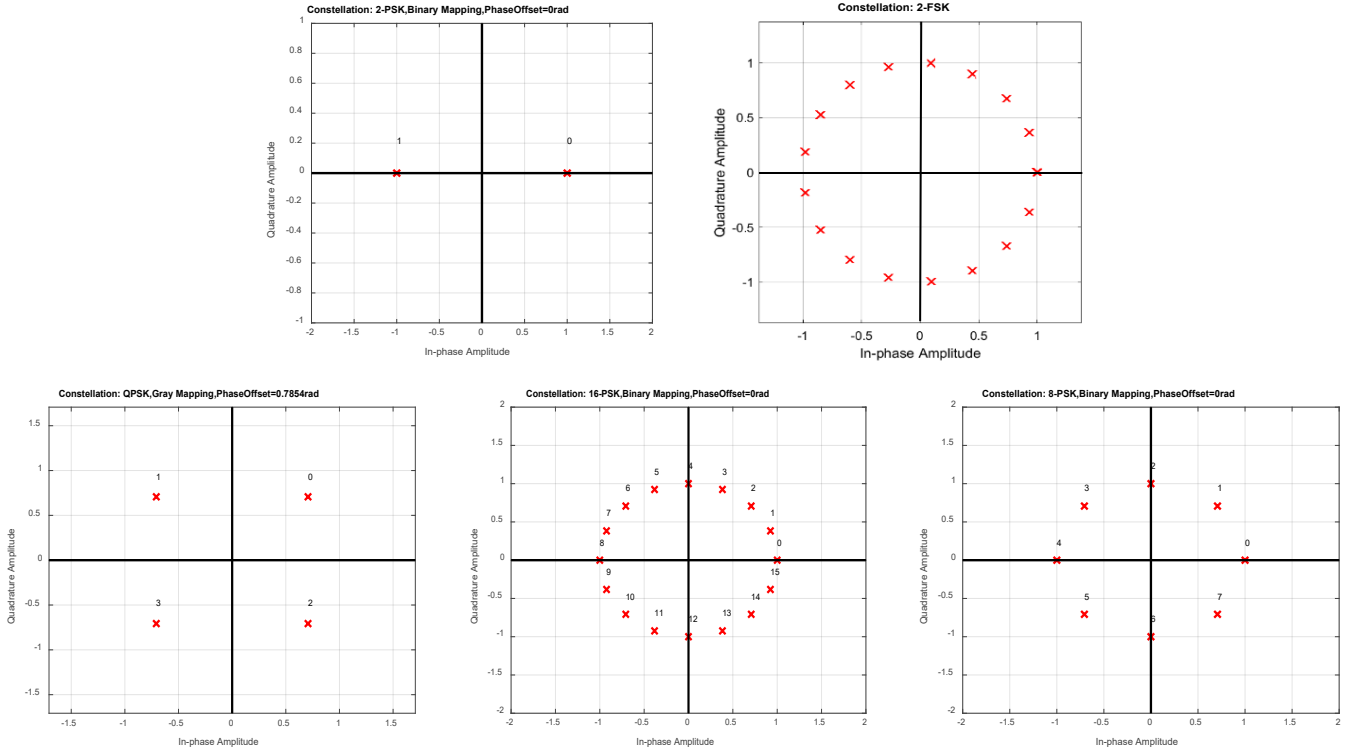
The frequency of the radio scene environment sensing (how often sensing should be performed by the cognitive radio) and sensing time (the duration the sensing is performed) are key parameters affecting the throughput. While higher sensing times ensure more accurate radio scene environment sensing, this may result in a comparatively smaller duration for actual data transmission during the total time for which the spectrum may be used, thereby lowering the throughput [13]. To achieve the optimum between sensing time and throughput, for example, in IEEE 802.22 two-stage sensing (TSS) mechanism is implemented that includes: fast sensing, done at the rate of 1 ms/channel, and fine sensing performed on-demand. In this work, we have evaluated the possibility to perform the classification based on instantaneous values to shorten the spectrum sensing time and reduce computational costs. To improve classification accuracy, classification based on spectral-based statistical features derived from the wavelet transform of the received signal observed during the certain observation time frame has been proposed. In this study observation times of 100 and 500 microseconds have been used. The lowest observation time has been selected 100 microseconds to accommodate the lowest symbol rate of 10 KSymbols/second supported in our target application for cognitive waveform generation.
Figure 2: Modulation classification using a) instantaneous values of the time domain signal input; b) time series statistics input.


Figure 3: Constellation plots for studies modulation classes BPSK, 2FSK, QPSK, 8PSK, 16PSK.
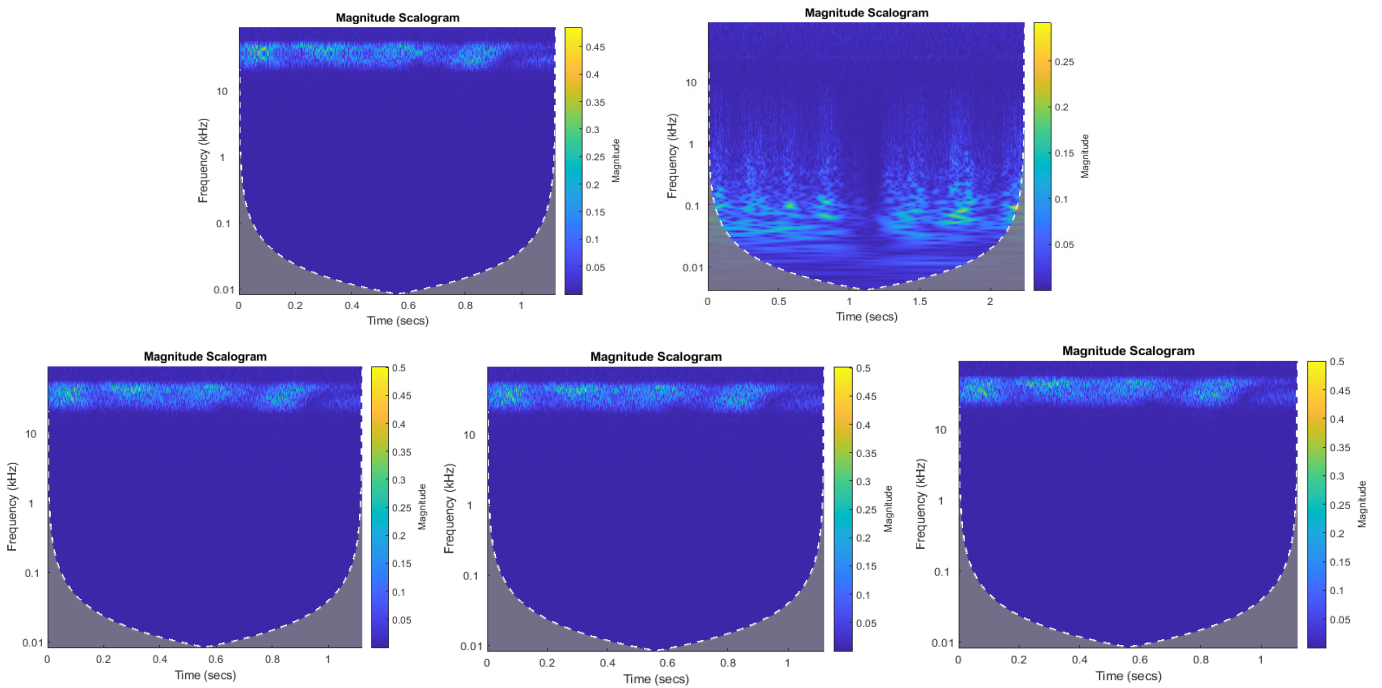

Figure 4: Scalograms obtained from Haar transform. wavelet coefficients for BPSK, 2FSK, QPSK, 8PSK, 16PSK. Observation time 500 microseconds signal.

The highest: 500 microseconds that correspond to one time slot in our time-slotted target application. Wavelet transform has been used in this work for the feature extraction, since obtained wavelet coefficients could be reused also to detect the vacant frequency channels and estimate the symbol rate, what could potentially save time and computational resources spent on radio scene analysis. Cyclostationary based algorithms have also been named in the literature as a powerful algorithm for modulation type and symbol rate estimation and vacant frequency channels detection. However, they are prone to cyclostationary noise and require longer observation time and is relatively computationally complex [14], and therefore this work has been focused on wavelet-based algorithms. Multiple supervised machine learning classifiers have been tested to perform classification based on instantaneous values and time-series statistics. The performance of tested classifiers has been evaluated in terms of classification accuracy and speed.

2. Methodology

Both feature extraction and classification algorithms applied in the literature to solve the modulation classification problem has been studied and evaluated. Primary, modulation type classification has been performed based on the input values of the instantaneous values of the in-phase and quadrature components of the time domain digital signal. Classification results have been satisfactory for the case of the binary classification between 2FSK and BPSK modulations. However, once the classification task has been extended to the higher-order modulations, the suggested classification approach has shown unacceptably low classification accuracy of 78.1 %. The highest classification accuracy of 84.9 % has been observed in the validation phase for classifying five modulations into two classes: linear and non-linear modulations using a fine SVM classifier.

Therefore, to improve the classification accuracy for higher-order modulations we have looked at multiple statistical features extracted from the time series containing the received signal observed during observation times of 100 and 500 microseconds. The following criteria have been considered when selecting classification features and feature extraction algorithm:

1. Robustness to noise; 2. Computational complexity; 3. Possibility to reuse preprocessed data for solving other radio scene environments observation tasks such as vacant bands detection and symbol rate estimation. Nine spectral-based statistical features derived from Haar wavelet transform coefficients calculated from the frequency domain signal observed during the selected observation time. The Haar transform has been selected as the simplest and less computationally demanding of all wavelet families. From the vector of wavelet coefficients, nine statistical features have been derived. To determine the strongest features to be used as inputs to ML classifier fractional factorial design analysis has been performed.

In statistics, a full factorial experiment is an experiment whose design consists of two or more factors, each with discrete possible values or "levels", and whose experimental units take on all possible combinations of these levels across all studied factors. Fractional factorial designs are experimental designs consisting of a carefully chosen subset or fraction of the experimental runs of a full factorial design. Significance is quantitively measured and referred to as the main effect [15]. A fractional factorial design approach has been used to analyze the main effects of every of nine statistical features and observation time on two studied response parameters: classification speed and accuracy in conditions of noise represented by two levels: AWGN and AWGN and multipath Rician channel model. Two levels have been applied and studied: first-level "-1" corresponds to not including the classification feature into classification and second level "+1" corresponds to including the studied feature into classification input. Observation time has also been varied according to two levels: first "-1" corresponds to 100 microseconds and the second level "+1" corresponds to 500 microseconds observation time. MATLAB and Simulink environment has been used for training and validation data sets generation including the modulator and propagation channel models, MathWorks classification learner ML Classification Learner tool has been used to train and validate classifiers. Twenty-four supervised ML classification algorithms have been studied and evaluated in terms of classification accuracy and classification speed for two studied channel models: AWGN and Rician multipath channels with AWGN.

3. Input data and feature extraction

To suggest optimal feature extraction and classification algorithms for our target radio application seven artificial data sets, consisting of signal samples modulated into 2FSK, BPSK, QPSK, 8PSK, 16PSK have been generated. Data sets are described in detail in Section 4. Figure 3 presents the constellation plots of five studied modulation types.

3.1. Classification using instantaneous values

The classification performed using instantaneous values of the time domain signal and SNR as classification inputs does not require any feature extraction: the raw values of the in-phase and quadrature component and SNR (recorded by transceiver as RSSI) have been used directly as an input to the classifier.
Figure 5: Generalized model used for data set generation.

Table 1: Spectral-based features derived from time series used for modulation type classification

N	Feature	Factor	Description
1	Mean	A	Mean value of the wavelet coefficients obtained from single-level discrete wavelet transform of the frequency domain signal.
2	Standard Deviation	B	Standard deviation of the wavelet coefficients obtained from single-level discrete wavelet transform of the frequency domain signal.

3	Kurtosis	C	Kurtosis is a statistical measure that defines how heavily the tails of a distribution differ from the tails of a normal distribution calculated from the wavelet coefficients obtained from single-level discrete wavelet transform of the frequency domain signal [16].
4	Skewness	D	Skewness is a measure of the asymmetry of the probability distribution of a real-valued random variable about its mean. Calculated from the wavelet coefficients obtained from single-level discrete wavelet transform of the frequency domain signal [16].
5	Median absolute deviation	E	It is a measure of the statistical dispersion: a robust measure of the variability of a univariate sample of quantitative data. It is more resilient to outliers in a data set than the standard deviation. It is calculated from the wavelet coefficients obtained from single-level discrete wavelet transform of the frequency domain signal [17].
6	Root-mean-square level	F	The RMS value of a set of values (or a continuous-time waveform) is the square root of the arithmetic mean of the squares of the values, or the square of the function that defines the continuous waveform [18].
7	Zero crossing rate	G	It is the rate of sign-changes along a signal: the rate at which the signal changes from positive to zero to negative or from negative to zero to positive [19].
8	Interquartile range	H	The interquartile range (IQR) is a measure of variability: calculated based on dividing a data set into quartiles [20].
9	75th Percentile	I	The percentile rank of a score is the percentage of scores in its frequency distribution that are equal to or lower than it [21].
10	SNR	J	Signal-to-Noise ratio corresponds to RSSI value for the received signal measured by transceiver.

3.2. Classification using time-series statistics.

Nine spectral-based statistical features have been derived from the received signal observed during the observation time. Primary fast Fourier transform has been applied to switch to the frequency domain. Then discrete wavelet transform has been applied to the frequency domain signal using Haar wavelet. This transform cross-multiplies a function against the Haar wavelet with various shifts and stretches. Figure 4 presents scalograms plots for studied modulations obtained by Haar wavelet transform. Then from the derived wavelet coefficients, nine spectral-based statistical features summarized in Table 1 have been calculated.

4. Data set

Seven data sets used for training and validation have been generated and are described briefly below. Three labeled artificial data sets consisting of three features: instantaneous values of in-phase and quadrature components of the time domain signal and SNR and four data sets consisting of nine statistical features extracted from time-series recorded during 100 and 500

microseconds and SNR for two channel models: AWGN and Rician channel with AWGN. Figure 5 describes the generalized model used to generate data sets.

Data Set 1: *Binary classification between BPSK and 2FSK using instantaneous values.* Data set for training and validation has been generated using a virtual model presented in Figure 5. The random input signal has been generated by Bernoulli binary random signal generator and modulated into BPSK or FSK. The modulated signal is transmitted by transmitter AD9364 TX. AWGN channel model has been selected to emulate the propagation environment, where SNR ranges from 30 to 1 dB. Data set consisting of 408000 rows and 4 columns, where two first columns correspond to the instantaneous values of the signal in the time domain: in-phase and quadrature components, the third column corresponds to SNR value and the fourth column represents the data label. 80 % of the data set has been used for training the classifiers and 20 % has been used for validation.

Data Set 2: *Classification of BPSK, 2FSK, QPSK, 8PSK, 16PSK into two classes linear and nonlinear using instantaneous values.* Data set of total size 910000 rows by 4 columns consisting of BPSK, 2FSK, QPSK, 8PSK, 16PSK has been generated in a similar way as Data Set 1: two first columns are corresponding to the instantaneous values of the signal in the time domain: in-phase and quadrature components, the third column corresponding to SNR value and the fourth column represents the data label corresponding to two classes: linear or non-linear modulation. Also, 80 % of the generated data set has been used for training the classifiers and 20 % of the generated data set has been used for validation of the classifiers.

Data Set 3: *Classification of BPSK, 2FSK, QPSK, 8PSK, 16PSK into five classes using instantaneous values.* Data set 3 consisting of five modulations described above has been used to train classifiers to classify all five modulation types. In this data set only the fourth column corresponding to the label has been changed to accommodate five output classes. Also, 80 % of the data set has been used for training of the classifiers and 20% for validation.

Table 3: Classifiers performance reached in validation. Classification between linear and non-linear modulations. Non-Linear: FSK, linear: BPSK, QPS, 8PSK, 16PSK modulations. AWGN channel (SNR ranging from 1 to 30dB). Data set 2.

Ensemble RUS Boosted Trees	78.1	150 000

Data Set 4: *Classification of BPSK, 2FSK, QPSK, 8PSK, 16PSK into five classes using statistical features derived from time series observed during 500 microseconds for AWGN channel.*

Data set 4 consists of 1500 samples (300 signal samples for every modulation type) resulting in a matrix of 1500 rows by 11 columns where the first nine columns correspond to statistical features column 10 corresponds to SNR and the last column corresponds to data class label. Statistical features for every signal sample have been derived from the received signal observed during 500 microseconds in conditions of the AWGN propagation channel (SNR ranging from 1 dB to 30 dB). Also, 80 % of the data set has been used for training, and 20 % for validation.

Data Set 5: *Classification of BPSK, 2FSK, QPSK, 8PSK, 16PSK into five classes using statistical features derived from time series observed during 100 microseconds. AWGN channel.* Data set 5 consisting of 1500 samples (300 signal samples for every modulation type) resulting in a matrix of 1500 rows by 11 columns where the first nine columns correspond to statistical features, column 10 corresponds to SNR and the last column corresponds to data class label. Statistical features for every signal sample have been derived from the received signal observed during 100 microseconds in conditions of AWGN propagation channel with

SNR ranging from 1 to 30 dB. Also, 80% of the data set has been used for training, and 20% for validation.

Data Set 6: *Classification of BPSK, 2FSK, QPSK, 8PSK, 16PSK into five classes using statistical features derived from the received signal observed during 500 microseconds for Rician multipath channel.* Data set 6 consisting of 1500 samples (300 signal samples for every modulation type) resulting in a matrix 1500 rows by 11 columns where the first nine columns correspond to statistical features, column 10 corresponds to SNR and the last column corresponds to data class label. Statistical features have been derived from time-domain signal observed during 500 microseconds in conditions of Rician multipath line-of-sight fading channel model with AWGN (SNR = 30). Three fading paths have been chosen with path delays selected for outdoor environments 0; 9×10^{-5} and 1.7×10^{-5}. Path delay ranging 10^{-5} is suggested for the mountains area. Average path gains have been chosen [0 -2 -10]. The Rician K-factor has been selected K-factor = 4, it specifies the ratio of specular-to-diffuse power for a direct line-of-sight path, it is usually in the range [1, 10] and 0 corresponds to Rayleigh fading. Maximum Doppler shift has been chosen 4 dB, which corresponds to a signal from a moving pedestrian [22]. Also, 80% of the data set has been used for training the classifiers and 20 % for validation.

Data Set 7: *Classification of BPSK, 2FSK, QPSK, 8PSK, 16PSK into five classes using statistical features derived from time series observed during 100 microseconds. Rician multipath channel.* Data set 7 consisting of 1500 samples (300 signal samples for every modulation type) resulting in a matrix 1500 rows by 11 columns where the first nine columns correspond to statistical features column 10 corresponds to SNR and the last column corresponds to data class label. Statistical features for every signal sample have been derived according to the steps summarized in feature extraction from time-domain signal observed during 100 microseconds in conditions of Rician multipath channel model with AWGN with SNR = 30 dB. The properties of the Rician channel have been selected the same as in data set 6. 80% of the data set has been used to train classifiers, 20% for validation.

Table 4: Classifiers performance reached in validation. Classification between FSK, BPSK, QPSK, 8PSK and 16PSK modulations using statistical features derived from the wavelet transform of the time series recorded during 500 microseconds. AWGN (SNR ranging from 1 to 30 dB) channel. Data set 4.

5. ML classifiers training and validation results

Selected twenty-three classifiers have been trained and validated multiple times using every data set described above to investigate the effect of the extracted features and observation time on classification accuracy and speed. Among the trained classifiers we have studied decision trees, KNN with the various kernels, support vector machines (SVM), ensembles with bagging and boosting sampling, and discriminant methods. Also, principal component analysis PCA has been applied to keep enough components to explain 95 % of data variance for the dimension reduction. To protect against overfitting five-fold cross-validation method was used.

5.1. Classification using instantaneous values

Modulation type classification has been performed based on the input values of the instantaneous values of the in-phase and quadrature components of the time domain digital signal. Primary Classifiers have been trained three times using data set 1: 1. using PCA, 2. Using all three features: in-phase, quadrature components and SNR 3. Using two features including in-phase, quadrature components. Table 2 summarizes the validation results for the AWGN channel with SNR ranging from 1 to 30 dB. The effect of input features available in the data set 1 on classification accuracy, and speed has been studied. The highest classification accuracy has been achieved using all three available features: in-phase, quadrature components, and SNR. However, removing SNR from classification resulted in a reduction in the average classification accuracy by only 3 %. The highest average classification accuracy of 86.9 % was observed for the Fine Gaussian SVM, which on the other hand has been observed to be the slowest. Ensemble boosted trees with 30 decision trees learners trained using AdaBoost sampling and 20 splits and fine decision trees have shown optimal performance in terms of both classification accuracy and speed with an average classification accuracy of 86.3 % and 86.0 %, classification speed of 1200000 objects per second, which is faster than required 2000 objects per second.

Data set 3 containing also instantaneous values of the time domain signal and SNR consisting of five modulations has been used to train classifiers to classify all five modulation types. However, the average classification accuracy has not met the requirement of 85 %. The highest classification accuracy of 78.1 % has been reached by customized decision trees with the number of splits set to 2689, Gini's diversity index has been used as a split criterion.

Among the other tested classifiers, there were ensemble bagged trees, ensemble boosted trees, RUS boosted trees which have demonstrated even worse classification accuracy than decision trees. To capture more of the fine differences between the received signal modulated into different linear modulations it is suggested to use the spectral features derived from the signal observed during the selected observation time.

5.2. Classification using time-series statistics.

Training and validation for both propagation channels AWGN (SNR from 1 dB to 30 dB) and AWGN (SNR = 30 dB) with Rician fading have been performed using data sets 4-7. Primary, the training of the studied classifiers has been performed using time series recorded during observation time corresponding to 500 microseconds using data sets 4 and 5 for AWGN and Rician channel with AWGN, respectively. Classifiers have been trained four times: 1. using PCA, 2. Using all ten spectral-based statistical features 3. Using five features including mean, standard deviation, root-mean-square level, zero crossing rate, 75th percentile of a data set, and 4. Using only one input feature: the mean value of the wavelet coefficients. Tables 4-5 summarize the validation results for the AWGN channel with SNR ranging from 1 to 30 dB and Rician multipath with AWGN (SNR = 30 dB) channel. The best performing classifiers that have reached 100% classification accuracy have been retrained on the features derived from the time series observed during 100 microseconds. Tables 6 and 7 present the validation results for AWGN and multipath Rician channel trained and validated four times as for the time series recorded during 500 microseconds. Tables 6 and 7 show that four out of the five selected classifiers including fine decision trees, fine KNN, ensemble bagged trees, and ensemble subspace KNN that demonstrated classification accuracy of 100 % on the time series recorded during 500 microseconds have demonstrated classification accuracy close to 100 % when trained using PCA, using all ten features and using five features for both AWGN and multipath channel also when have been trained on time series recorded during 100 microseconds. However, SVM has shown worse performance when trained with a reduced number of features.

Applying PCA has resulted in a drastic decrease in the classification accuracy for ensemble subspace KNN for both AWGN and multipath Rician channels. For most classifiers, like fine decision trees, ensemble bagged trees applying PCA has resulted in the decreased classification speed. Fine KNN has shown 100% classification accuracy for classification using only one input to the classifier: mean value and the highest classification speed of 56000 and 91000 objects/s for AWGN and multipath fading channel, respectively. However, KNN is still slow even using only one feature than fine decision trees using five features classifying 110000 and 120000 for AWGN and multipath channel.

6. Classification feature analysis using fractional factorial design

The fractional factorial design has been applied to determine the most significant classification features referred to as the design.

Table 6: Classifiers performance reached in validation. Classification between FSK, BPSK, QPSK, 8PSK and 16PSK modulations using statistical features derived from the wavelet transform of the time series recorded during 100 microseconds for AWGN (SNR ranging from 1 to 30 dB) channel. Data set 6

factors that have the highest main effect on the response parameters: classification accuracy and speed We have been looking at both the main effects of the independent variables and interactions between the input parameters (A-J) and observation time (K) for the best performing classifier in terms of accuracy and speed. We have 10 design factors corresponding to the features referred as (A-J) and observation time referred to as (K) with 2 levels for each design factor corresponding to: high (+1) the feature is used for classification or low (-1) the feature is not used for

classification. Observation time has been also varied at two levels (+1) high corresponding to 500 microseconds and (-1) low corresponding to 100 microseconds. We have considered one noise factor corresponding to the propagation channel model with two levels corresponding to the AWGN (-1) channel with SNR ranging from 1dB to 30 dB and Rician multipath propagation and AWGN with SNR=30 dB (+1). The full factorial design will result in 2^{10} number of experiments, to reduce the number of experiments this study has been limited to fractional factorial design with 13 experiment runs performed, where the first ten runs with only one feature used for classification independently from the others for 100 microseconds observation time, since we are mostly interested to study the performance for the shortest observation time. The eleventh run has been selected to investigate the effect of observation time; the twelfth and thirteenth runs have been included to study the effect of observation time independently from the classification features with all nine spectral-based statistical features used as classification input.

The main effect is defined as the overall effect of an independent variable in the complex design. The definition of an effect is the difference in the means between the high (+1) and the low level (-1) of a factor. From this notation, A is the difference between the mean values of the observations at the high level of A minus the average of the observations at the low level of A. Interaction is defined here as the effect of one independent variable

depending on the other independent variable, i.e it describes the combined effect of the independent variables considered simultaneously [15]. Tables 9-13 summarize the experimental design and results: main effect of every factor on classification accuracy and speed for five best performing classifiers: fine decision trees, fine KNN, weighted KNN, ensemble bagged trees with 59886 splits, and 30 learners and ensemble subspace KNN with 9 subspace dimensions and 30 learners.

The overall highest main effects on classification accuracy and speed have been observed for the fine decision trees classifier. In tables 9-13, we have obtained a relatively high main effect for using/not using SNR for classification. In tables 9-13, summarizing the performance of the classifier, it is possible to see that removing the SNR value as an input to the classifier does not affect the response parameters significantly, on the other hand using SNR value only for classification as in the experiment run N10 (what in reality does not make any sense) result in the very low classification accuracy. Since the main effect is a difference between the mean values of the high and low, we observe here the high main effect of SNR as a classification input parameter. For example, the main effect of using SNR (J) as classification input on classification accuracy for fine decision trees is –20.0, while for Kurtosis (C) it is 19.6. Classification accuracy if we use only (C) for classification experiment run N3 is 100% for both Rician and AWGN channels and if we use only (J) for classification is 8.6% for both Rician and AWGN channels. This makes the highest main effect of SNR input a questionable result for practical application. Also, the value of the main effect should be interpreted only in combination with the value of the response parameter: classification accuracy and speed.

The highest classification speed of 170 000 objects per second for 100% classification accuracy has been demonstrated by fine decision trees using only one classification input the skewness of the wavelet coefficients derived from signal observed during 100 microseconds for AWGN channel model. For Rician and AWGN, channel classification speed has been slower 130 000 objects/s. Both skewness and kurtosis has shown the highest main effect on classification accuracy for fine trees. Using mean value as the only input parameter to fine trees classifier, however, has shown less robust results in terms of the classification accuracy: 94.5% has been demonstrated for Rician and AWGN channel, while for AWGN channel 100%. The mean value shows the second-highest main effect on the classification accuracy 19.5 for the fine decision trees and the highest main effect of 10.9, 11.1, 11.5, and 10.9 for the other four classifiers including fine KNN, weighted KNN, ensemble bagged trees and ensemble subspace KNN, respectively. It also shows the highest main effect on the classification speed for all five selected classifiers.

Slightly slower classification speed has been demonstrated by KNN classifiers: 110000 objects per second have been observed for fine KNN for AWGN channel and 89000 objects per second for AWGN channel with Rician multipath. The slowest from all studied are ensembles, for example, ensemble subspace KNN has demonstrated a classification speed of 4500-6800 objects per

second. However, classification speed for ensembles does not decrease as much as for the fine trees with the increasing number of features. For ensemble bagged trees for AWGN channel the same classification speed of 11000 has been demonstrated for classification using only mean A and using all calculated features (A-J).

Since the decision trees are the fastest classifier reaching an accuracy of 100%, the study of the interactions has been limited only to fine decision trees. Interaction between observation time and every of the spectral-based statistical feature (A-J) has been studied and plotted in Figure 6. Non-parallel lines corresponding to the main effects in Figure 6 indicate the presence of interaction between spectrum observation time and all the studied features. The study of interactions between extracted features has been discarded because they have been extracted from the same source: Haar transforms coefficients derived from frequency domain signal and therefore are not considered to be fully independent variables. The most prominent interactions are observed between 75th percentile and observation time, SNR as a classification feature and observation time, root-mean-square level and observation time, skewness and observation time, kurtoses, and observation time.

7. Conclusions and future work

In the scope of this work we have studied the possibility to classify the modulation type using instantaneous values of the time domain signal and SNR as inputs to the classifier. The main advantage of this approach is that it has potential to increase throughput by shortening the spectrum observation time and decreases the computational complexity: the raw values of in-phase and quadrature components of the signal are used as an input to the classifier and therefore there is no need for any preprocessing or feature extraction. This approach is applicable for binary classification between BPSK and 2FSK modulations, however it fails in case the classification task is extended to multiple classes containing higher order modulations. The possible reason for this is the missing data that is not included in the pair of in-phase and quadrature component. If the input values pair lies on the x axis the modulation could be classified as any of four types: BPSK, 2FSK, 8PSK or 16PSK. In case of the input pairs are located on the y axis it could be classified as any of three modulation classes: 2FSK, 8PSK, 16PSK. We have confirmed that to reach the classification accuracy of at least 85% or higher for classification between multiple high order modulations it is required to observe the received signal and perform feature extraction. In this study we have studied nine spectral/based

statistical features derived from the wavelet coefficients obtained by applying the Haar wavelet transform to the frequency domain received signal. The highest classification speed of 170 000 objects/second and 100 % classification accuracy has been demonstrated by fine decision trees using as the single input kurtosis (C) derived from the wavelet coefficients derived from signal observed during 100 microseconds for AWGN channel. For line-of-sight fading Rician channel with AWGN demonstrated classification speed is slower 130 000 objects/s. Skewness and kurtosis have shown the highest main effect on classification accuracy for fine decision trees. The mean value demonstrated the highest main effects on classification speed for fine decision trees, fine KNN, weighted KNN, ensemble bagged trees, ensemble subspace KNN.

In the scope of the future work it is planned to implement the proposed fine decision trees classification algorithm on our target application hardware. Also, it is intended to extend this work to the multiple propagation channel models including Rayleigh and Rician for doppler shifts corresponding to target application embedded in the ground and aerial unmanned platforms moving with speeds 100-200 km/hour.

The paper treats a problem for detection and recognition objects in computer vision sector, where researchers recommended OpenCV software and development tool, it's several and better-remembered library resource for isolating, detecting, and recognition of particular objects, what we would find an appropriate system for detecting and recognition traffic roads signs. The robustness with optimization is a necessary element in the computer vision algorithms, we can find a very large number of technics in object detection, for example, shapes transformation, color selection, a region of interest ROI, and edge detection, combined all these technics to reach high precision in animated video or still image processing. The system we are trying to develop, is in high demand in the automotive sector such as intelligent vehicles or autonomous driving assist systems ADAS, based on intelligent recognition, applying Artificial Intelligence, by using Deep Learning, exactly Convolutional Neural Network (CNN) architecture, our system improves the high accuracy of detection and recognition of traffic road signs with lower loss.

1. Introduction

Computer vision belongs to a large family of Artificial Intelligence-based systems, more precisely, it is to AI what eyes are to humans, an extremely powerful tool capable of analyzing, recognizing an image pattern, and even analyzing several images simultaneously, in other words, a video stream. To achieve this, computer vision relies on different technologies, firstly image processing, which applies operations and algorithms directly on the image, and secondly Deep Learning through neural networks using a large amount of data. In the automotive world, Industry 4.0 [1] has already chosen its IoT camp, the automotive groups have announced that their autonomous vehicles will embed an onboard camera, and not only electronic sensors, aiming to reduce a maximum accident's risk and also helping the driver to safely control his car to avoid dangers. The re-manufacturing sector has also already started to conquer computer vision, the major

objective of the automotive industry, is to make non-polluting vehicles, e.g. electric or hybrid vehicles, to integrate intelligent options [2], to make vehicles easier, to move in and out of the city area, with road safety for both cars, users, and pedestrians. The procedure that we are going to follow in our system development, that integrates a series of automotive embedded systems, among the most famous of these systems, is the ADAS system that has accelerated the vehicle sector and improved its features, which has made the semi-automatic vehicles, to facilitate the tasks of conduction and avoid all possible dangers [3]. The human being is based essentially on his eyes, to make a description and a global analysis of his environment, because this description will allow him to manage these reactions, that he has to make either in the present or the future. Therefore, the equivalence of this behavior enters the field of computer vision or robotics, where it is called object detection [4, 5], which in our case are the traffic road signs, that help traffic management. Every year, researchers offer us a new advanced, highly precise technology, and slightly object detection error injection. Our traffic road signs system detection [5], which is based on the colors of the environment description, to detect the desired specific colors of the specified objects.

*Corresponding Author: Anass BARODI, Laboratory of Advanced Systems Engineering (ISA), National School of Applied Sciences, Ibn Tofail University. Kenitra, Morocco, barodi.anass@uit.ac.ma, https://orcid.org/0000-0003-3022-4761

The fact of making this description, therefore, required a test its effectiveness, based on onboard vehicle cameras, and then to integrate it into the developed algorithm. So detecting the colors of traffic roads signs with accuracy, is the necessary factor, so that we can recommend the approach, that can be applied in the future or improved, and applied to Industry 4.0 [6], but we're not going to stop only on the colors [7], we're also going to base it on the geometry of the traffic roads signs, to reduce detection errors. The general procedure of our system, is based on human characteristics, that it can easily detect objects, and avoids encountering difficulties due to light reflection. The performance will increase, if we have combined the colors and geometries of the traffic road signs, which will conduct us to reach an interesting and robust algorithm [8]. In computer vision and image processing, the detection or recognition of specific objects in movements, in unknown or a known environment, is commonly elaborate by different researches studies every year, the most technique based on the invariance properties of the interest objects, it can be the appearance of the objects, the geometry of the scene or objects, photometry or color, for example, space-time constraints.

Video is a media that poses complex problems, because of the large data volume to be processed, with the difficulty of extracting the representative information from its content. At present, indexing the content of images, and dividing the video into elementary unit shots, representative images only partially meets this growing need. But, the content of an image is often too rich in itself, and contains several objects of interest, i.e. semantic objects. When a target is located in a video frame, it is often useful to follow this object in the following images, each image target successfully tracked, can provide a lot of information or feature, about its activity with the identity, the visual characteristics most using are colors. Usually, the RGB represents color space, but this space doesn't a uniform perceptual, because the differences calculating between colors in this space by machines, do not correspond to the difference perceived by humans, besides, the RGB dimensions are highly correlated. But the HSV is an approximately uniform color space [9], with a high degree of sensitivity to the noise, for example, can be used to extract a characteristic for histogram-

based appearance, for detected the contour-based edges of all or specific objects; that existed in images, in general, many tracking algorithms in real-time uses and recommend this space.

Object recognition is an important topic in computer vision, it has a huge evolution during these years, combined with Artificial Intelligence, which has been finalized by the appearance of Deep Learning [10], Deep Learning has touched different areas, such as automotive, robotics, industry. In computer vision, object recognition or object classification is a method for identifying the presence of an instance, or a class of objects in a digital image, for example, the application face detection and the detection of persons [11]. These methods often involve supervised learning, and have applications in multiple fields, such as, Biometric recognition using biometric technology, Surveillance, Industrial inspection, Robotics, Medical analysis, our case is applied for Intelligent Vehicle Systems, which are necessary for recognize and tracking the traffic road signs, as well as autonomous vehicle [12].

2. Methodology

The strategy is to develop a homogeneous system for detection and recognize traffic road signs, the system combines three essential parts, the first, detection of traffic road signs by methods that are proposed, and well described later on. Secondly, when the sign detected, strongly is going to be cropped with dimensions defined in real-time, finally, the last phase, is the recognition of the traffic road using Artificial Intelligence, establishment an architecture has the same concept of the human being analyzes with his brain, for classification or recognize the correct place different objects in the environment.

The paper organized as follows; section 1 contains an introduction to the essential for detection and recognition. Section 2 presents a system diagram, then section 3 describes the detection approach. Section 4, related work for different work of detection and our proposed approach, section 5 and section 6 for the discussion and implementation in real-time. Section 7 with section 8, to recognize road signs by deep learning and evaluation the performance of the system proposed.
Figure 1: Traffic road signs detection and recognition System diagram
Figure 2: Traffic road sings detection diagram [5]

3. Road Signs Detection

In the figure. 2, the system tries to determine which road signs have a circular shape and specific colors.

The colors of the traffic road signs, are unique in the whole world, fixing the relevant colors or those that represent the majority, are blue and red. The second part, which is based essentially on the detection of the geometries of the traffic roads signs, which are also by default unique, can find either the geometry: rectangular, circular, triangular, and square, therefore for our study, based the circular, because it a percentage of 50% of the traffic roads signs, and at the same time contains the colors, to achieve our objective, it must to a play on the elements, that characterize the circular form, so the circle is described mathematically, by center position and radius.

4. Related Work

The paper has the main objective, to implement an application aiming to detect and recognize traffic signs in real-time, most of the techniques use the color detection presented in this paper [13], or based only on the shapes of signs treated in this paper [14], our approach combined between colors and shapes of traffic road signs, by applying the Canny matrix transformation. This approach uses the OpenCV library, because integrated powerful functions, to properly detect the edges in the image. Before the process detects shapes of signs, following sub-steps, firstly, the conversion input image from the RGB space to the HSV space for segmentation. secondly, applying the Gaussian smoothing filter, to minimize false detection results, as the color-based one just isolates red and blue colors of interest.

4.1. Color detection

The image can be represented by function G (X, Y), the X and Y are the spatial coordinates for two-dimension, besides this, the amplitude at any point G (X, Y) corresponding in general to gray level or mostly to intensity, and when the amplitude is discretized, the image is categorized to a digital image. The digital image also referred to as a scene, has a marker as an indication, each frame or image different from other mathematically, based mainly on its height (H) and width (W).

In image processing has several descriptions of images, for simplicity, can be a binary image, a rectangular matrix contains these values, 0 represented the blacks, or 1 represented the whites. Also, can be a grayscale image, the total number of pixels is 256,

distributed from 0 (black) to 255 (white), these values means that each pixel encoded on 8 bits, grayscales are very powerful for recognition or detection of the most objects in a complexed scene [15]. Finally, the color image has 3 color channels, described respectively in this order by pixels number of red (R), green (G), and blue (B), it's coded or ranging between 0 and 255, which results in 255^3=16,777,216 possible colors, that it takes 24 bits to code a pixel. In the general hierarchy of video data present in a sequence, which means that contents one or more images groups, and ends with an end-of-sequence code, this grouping of one or more images facilitating direct access, thus, the image is the elementary unit for coding the video sequence [16].

As shown in figure 2, the first step based on color detection, to have a system capable of detecting; the colors of road signs with high accuracy, our approach proposes the conversion from RGB to HSV space, this conversion is essentially, based on the equations above [5], the first one is used to normalize each color channel, which makes the interval ordered [0,255] to [0,1], to calculate delta, C_{min} and C_{max} [17].

$$R_1 = \frac{R}{255} \; ; \; G_1 = \frac{G}{255}; \; B_1 = \frac{B}{255} \tag{1}$$

$$C_{max} = \max(R_1, G_1, B_1) \tag{2}$$

$$C_{min} = \min(R_1, G_1, B_1) \tag{3}$$

$$\Delta = C_{max} - C_{min} \tag{4}$$

The HSV space is considered to be a natural representation model, which means has the same physiological color perception seeing by the eye of a human, in generally decomposing the colors consists of physiological criteria. This space decomposes the color, according to more intuitive characteristics close, to the current vocabulary to describe a color, based on pure color. Finally, these equations above serve to complete the conversion, to determine each channel: Hue, Saturation, and Value [5].

- The Hue Channel (H), corresponding to the perception of color:

$$H = \begin{cases} 0°, & \Delta = 0 \\ 60° \text{x} \left(\frac{G_1 - B_1}{\Delta} \bmod 6 \right), & C_{max} = R_1 \\ 60° \text{x} \left(\frac{R_1 - B_1}{\Delta} + 2 \right), & C_{max} = G_1 \\ 60° \text{x} \left(\frac{R_1 - G_1}{\Delta} + 4 \right), & C_{max} = B_1 \end{cases} \tag{5}$$

- The Saturation Channel (S), describing the color purity, which can be bright or dull:

$$S = \begin{cases} 0, & C_{max} = 0 \\ \dfrac{\Delta}{C_{max}}, & C_{max} \neq 0 \end{cases} \qquad (6)$$

- The Value Channel (V), indicating the light amount in the color, that can have a light or dark appearance:

$$V = C_{max} \qquad (7)$$

4.2. Canny matrix transformation

The deployment between the Canny filter and the Hough transformation, to detect edges and locate shapes wants, a well-known algorithm for pattern detection, Hough transform do a parametric estimation method. The pattern recognition method, proposed by Hough are morphological study methods, but they require a large computation time, in the case of complex geometrical shapes or discontinuous contours, the Canny contour detection method, allowed us to highlight rather wide contours, that are perfectly suited to pair correlation localization, to achieve the work with higher detection accuracy.

4.3. Edge Detection

Canny a multi-step process for edge detection, First of all, it is a question of reducing the noise of the image to optimize contour detection, this reduces strong responses during the gradient calculation, leading to false positives, the solution using Gaussian Filter, very powerful filter, has a kernel of convolution operator in a 2D Gaussian plan [18], this operation due to Gaussian probability law, demonstrated in equation (8), σ^2 represent the variance of each variables couple (x, y) with the peak (μ). The main condition for using this type of filter, whether the image is in gray level so that it can be processed to standard deviation Gaussian σ.

$$G_0(x,y) = A e^{\frac{-(x-\mu_x)^2}{2\sigma_x^2} + \frac{-(y-\mu_y)^2}{2\sigma_y^2}} \qquad (8)$$

A canny filter is based on Sobel's algorithm, it has additional steps that allow us to work on more complex images [19]. This method allows, by changing the intensity of edge detection, to eliminate linearization and noise defects and at the same time to have wide contours. The width is important for the correlation localization algorithm that follows this contour detection algorithm [20].

$$\text{Angle:} \ \ \theta = \tan^{-1}\left(\frac{G_y}{G_x}\right) \qquad (9)$$

$$\text{Edge:} \ \ G = \sqrt{G_x^2 + G_y^2} \qquad (10)$$

The Angle and Edge algorithm-based, has been designed to be optimal according to three criteria:

1) Good detection: low error rate in contour signaling;
2) Good localization: minimizing detected and real contours gap;
3) Answer clarity: one answer per outline, no false positives.

After calculating the norm and the direction of the gradient, in each pixel of the image, these methods extract contours of a single-pixel, thickness by selecting the local maxima of the gradient norms. One can mention the detectors of Canny, Deriche, Marr - Hildreth, or the more recent one of Bao [20]. For the operators of Canny and Deriche, an additional variable allows us to adjust the

detection sensitivity at the expense of the spatial precision of the contour and vice versa. Moreover, it can be noted that the contours detection in areas, with strong gradients does not necessarily, correspond to an object. In this case, post-processing can be effective, these useful methods yield good results for non-textured image analysis, high-contrast objects with marked contours.

4.4. Shape extraction

The international road safety regulations, are essentially based on laws, that must be respected by everyone, either drivers of automobiles or passengers, so the majority of its laws have been modeled by traffic road signs, that have unique shapes, for example triangular, rectangular, square, or circular, keeping only the circular shapes that exist in the images.

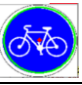
So, the objective of our approach, is to improve or increase the accuracy of the system, that based on artificial intelligence, will have accuracy to detect traffic road signs, we focus the studies on the circular shape, applying the Hough circles method of OpenCV [18] modeled by this equation:

$$(x - X_{center})^2 + (y - Y_{center})^2 = r^2 \qquad (11)$$

Paul Hough invented a pattern recognition technique, named Hough transform, this technique allows us to recognize any shape in an image, for example, the circles or lines, this technique will serve, to identify circles presences in an image, it can be very easily extended to circle recognition, compared to other models, the Hough technique is a simple mathematical model and robust. This produces sinusoids curves, can be accumulated in a space called Hough space, its role is to draw all points set of the circles, to find out the places when the curves intersect, which means the presence of a circle, mathematically the circle is characterized, by (r) radius and center (X_{center},Y_{center}) in equation (11).

For forming a cone with a vertex ($X_{center} = x$, $Y_{center} = y$, $r = 0$), based essentially on the set number of circles, passing through a given point N (x, y) according to the axis r, and the best points correspond to the maximum intersection of cones. On the other hand, if the circle radius is specified, in a two-dimensional the (a, b) plane, in this plane, the set of circles passing through a given point N is described by the circle of center ($X_{center} = x$, $Y_{center} = y$) and radius r, also the best points that bring together the intersection of several circles. Finally, in accumulation, an M matrix is constructed, each element M (i, j) contains the number of circles passing through the point, but the method consists to construct a hyper-matrix for accumulation when the radius is unknown, which each value of cells M (i, j, k), corresponds to a cubic space (a, b, r), characterized by scanning between 1 pixel up and the dimension of the image.

5. Implementation

5.1. The manual threshold applied to images


We have tried to roughly summarize the procedure or essential steps in the traffic road signs detection process. Based essentially on the colors by setting the lower and upper limit markers for each color, and the geometry of the signs- see the evolution in Table. I.

5.2. Manual thresholding in Real-time

At this level, we try to apply the detection in real-time, for evaluation of our algorithm the detection of traffic road signs,

especially circular shape, which have the colors either Red or Blue, been using a web camera of Asus laptop.

Color	HSV space	Canny Edge	Panel Detection
Red			
Blue			

The results obtained contains two essential windows: One window shows the color images conversions, that have several objects detected with Gaussian filtering to eliminate noise, to easily convert it into grayscale images, the other represents the Canny outlines that facilitate the detection of the desirable object outline, at each figure 4: (a) and (b). We took real-world images of two road signs of different colors: red for the "No-entry" sign and blue for the "Bicycle" sign, but the more relevant thing, the extraction or detection of objects were not perfectly detected. So, we ask several questions where this error comes from, but most probably the two HSV space filters are not perfectly established.

6. Discussion

The goal of our approach is to have or ensure high accuracy for the detection of traffic road signs, specific circular shapes, then we will be able to apply it to all geometric shapes. We have concluded from what we have obtained previously that the HSV space filter terminals did not prove our approach, indirectly the

manual thresholding. In image processing, to have a high resolution or in-depth studies on images, we establish a histogram to have an idea of distributions pixels, because our objective is to reach automatic thresholding for the two test images used previously.

If we have visualized well or focused our attention on the two histograms, we interpret the results obtained, that we have a peak that seems to be the maximum of the pixels distributed for each histogram, in an interval from 250 to 255, it is the V channel in blue concerning the other channels H and S, for the figure. 4 (a) and (b). So, what we can conclude is to look for new values of the HSV space filters and make tests until we get high precision, it's hard because there are several factors among these factors is the luminance, the solution, we will unproven our work by using the automatic thresholding, we use the most robust is the OTSU method.

6.1. Automatic thresholding

The OTSU method based on a histogram of images, uses discriminant analysis to separate the text from the background, its principle is to divide the image into classes, and then look for the optimal threshold, by minimizing the variance function inter or intra classes. Otsu's method [21] tries to find or to get the optimal threshold, by separate the histogram into two segments, that maximize the inter-segment variance or minimizes a measure of intra-segment variance, the determination of these variances, based on the histogram normalization. The variances σ_i^2 for each threshold is given by equation (12), The ω_i designed weights of the probability for each class (i), which means the threshold separation.

(a)   Red signs   (b)   Blue signs
Figure 3: Traffic Signs detection manual thresholding [5]
(a)   Blue signs   (b)   Red signs

Figure 4: Traffic road signs histogram [5]

$$\sigma_w^2(t) = \omega_1(t)\sigma_1^2(t) + \omega_2(t)\sigma_2^2(t) \qquad (12)$$

The Otsu method advises, for its technique to be effective, by minimizing the intra-class variance, due by maximizing the inter-class variance [20].

$$\omega_1(t) = \sum_{i=1}^{t} P(i) \quad \omega_2(t) = \sum_{i=t+1}^{I} P(i) \qquad (13)$$

$$\mu_1(t) = \sum_{i=1}^{t} \frac{iP(i)}{\omega_1(t)} \quad \mu_2(t) = \sum_{i=t+1}^{I} \frac{iP(i)}{\omega_2(t)} \qquad (14)$$

$$\sigma_1^2(t) = \sum_{i=1}^{t}[i - \mu_1(t)]^2 \frac{P(i)}{\omega_1(t)} \quad \sigma_2^2(t) = \sum_{i=t+1}^{I}[i - \mu_2(t)]^2 \frac{P(i)}{\omega_1(t)} \qquad (15)$$

The approach to detect regions of objects, therefore leads directly to a partition of the image, in this approach, we applied different methods consisting of manual or automatic thresholding, the simplest method for thresholding in image processing, through segmentation. From a grayscale image, image thresholding can be used to create an image with only two values, black or white, we have applied this method to the basic images that are shown below in Table. 1. The automatic thresholding applies a multi-level per Otsu's method, it consists to determine the number of regions, the optimal values of the different thresholds, based on the variance of the subdivisions. To have an algorithm for the detection of traffic roads signs with high efficiency and precision, from what we understood from the OTSU method, that is based on the classes average μ_1 and μ_2, also the class probabilities ω_i, which will be applied to the pixels of the road signs, either for blue or red, and we fly at the end of the binarized images.

Our strategy for the binary image was formed by the function of the OpenCV library, the bitwise function. Then we merged the three thresholds h, s, v resulting from the three binary images, to obtain at the end a single threshold value. Still, for the detection of traffic roads signs contours, we use Canny because it has proven its high precision in contour descriptions according to the previous tests, even when there is noise, it guarantees high detection and localization of objects for all two-dimensional applications. Before applying the Canny outline, it is preferable to apply a Gaussian filter. Table. 2 shows the manual thresholding values, which contain the bounds of the HSV space values and automatic thresholding.

Table 2: Identification signs for manual and automatic thresholding [5]

Threshold	HSV space	Canny Edge	Detection panels forms
Automatic			
Manual			

Starting from the fact that we are trying to detect the presence of the circle shape in an image, Firstly, the Hough transform consist of searching for the parameters of the structure to be detected, the second step aims to find the points of the image that may belong to the structure, typically the points where the gradient goes beyond a certain threshold. At each of these points, a representative of the structure will pass through and calculate its parameters, the values of these parameters correspond to a point in the parameter space, the third step consists of marking the curve represented by the calculated parameters as a possible representation of the structure being searched.

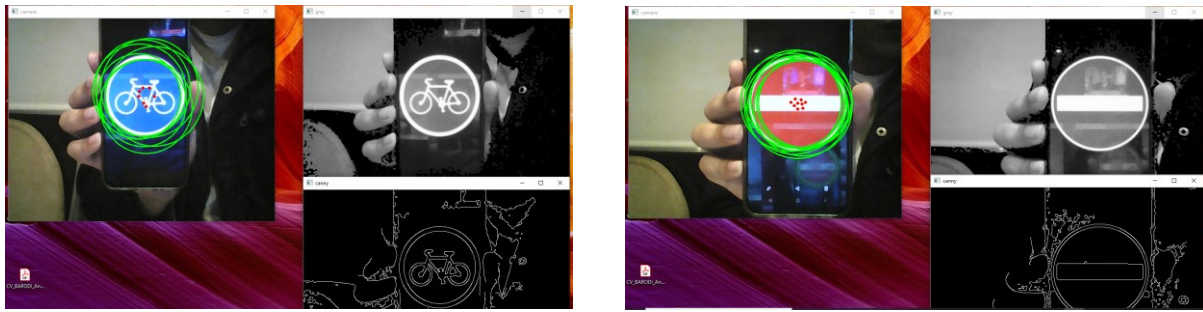
Table 3: Manual and automatic thresholding [5]

Threshold	Colors	Filter	Hue	Saturation	Value
Automatic	Red			Auto	
	Blue				
Manual	Red	Upper	180	255	255
		Lower	136	87	111
	Blue	Upper	130	255	255
		Lower	110	50	50

For the identification of colors in HSV space shown in the Table. 3, it is certainly necessary to specify very essential elements, for each color of the high and low filters. Our case is the colors that represent the majority of blue and red traffic roads signs, obtaining the values of channels H, S, and V after extensive experimentation and testing, but the trick is to note that these values can make a service or a work perfectly in an environment A and not sure certainly for an environment B. The solution is to apply automatic thresholding by applying the method of OTSU. OTSU adapts to each environment, to find optimal values for the HSV space that leads easily to the detection of traffic road signs. Finally, we are not only going to press on the color, but we are also going to combine the color and the detection of the circular geometry, it shows in table 3 we have an improvement that makes the algorithm more robust to detect the desired object with real-time optimization.

Practically, we are going to vote for parameters. The curve whose parameters obtain the most votes is therefore the one that best describes the structure. To collect the votes, we need an accumulator table, the size of this table is equal to the number of unknown parameters. The size of each dimension is equal to the maximum value of the corresponding parameter. Once the parameters have been calculated, they represent a cell of the accumulator table, we will increase the value of this cell by one unit. At the end of the process, we are going to explore the accumulator to find the boxes that have obtained the most votes, their corresponding parameters describe the occurrences of the structure we are looking at in table.2, which is the circular shape.

6.2. Real-time based Automatic thresholding

At this stage we try to make a real-time test for traffic road signs detection, we will produce the same scenario in an urban environment by using a webcam as shown in the two figures.5 (a) and (b). The relevant thing is that the detection of circular signs is made with high accuracy, so the automatic thresholding by the OTSU method has a great effect than the HSV space. For the three windows that make up the two figures, we have a very high image quality, which makes it easy for Canny to locate the outline of traffic road signs in a very powerful and robust. Otsu has a methodology able whatever the environments, to perform


(a) Blue signs   (b) Red signs

Figure 5: Traffic road signs automatic thresholding [5]

automatic thresholding from the shape of the image histogram, so we deduce, that the conversion from gray-level space to binary space, makes it easier to calculate background and foreground classes, for optimal thresholding for each separate between classes, to comply with the condition, that intra-class variance to be minimal.

6.3. Cropping of the panels detected

The Hough feature descriptor used for road signs detection, calculated on a 32 × 32 patch of an image. Let an image of road signs with a size of 128 × 128. A patch with a size greater than 50 × 50 is selected for the calculation of the Hough descriptor. This patch is cropped from an image and resized to a size 32 × 32 in Table.4.

Table 4: Cropped traffic road signs

Cropped Blue Signs	Cropped Red signs
7. Recognizing Detected Road Signs

In the recognition part, applying model based on images of traffic road signs in Germany [22], the work is doing it with the Keras libraries for learning and classification, importing python

framework, by using some simple and efficient techniques, such as data augmentation [23] and dropout [24].

7.1. Deep Learning

Figure.6 clarify the second part of the approach, for recognizing images, exactly the traffic roads signs [22] using Artificial intelligence, these images cropped from the first part of detection, so this second part, demonstrate how to apply Convolution Neural Networks (CNN) architectures in general, we are going to use in our approach the field of Deep Learning (DL), because this family of architecture, has made it possible to make significant progress in the fields of image classification and recognize different objects, the DL models contains multi-layer of perceptron described above, with more intermediate layers. Each intermediate layer, subdivided all images datasets, for getting sub-parts of features, and providing simpler results to the next layer, CNN currently the powerful models for classifying images [25].

In figure.6 demonstrate two distinct parts of the CNN model, training and performance evaluation, for the first part, in input color images exist, which consist of pre-treatment, the conversion of the color space from RGB to grayscale, for providing a matrix of pixels has two dimensions for a grayscale image, and normalization by value 255 for each image, forget the images ranging between 0 and 1. After the step of pre-treatment, starts training the model, then select the best training model, and then choose based essentially, the curve of accuracy function and loss function. For the second part, the best model passed by strict steps, to evaluate performance; so, we use confusion matrix and rapport classification each class image.
Figure 6: Traffic road signs CNN-based recognition model

(a)   Accuracy curves

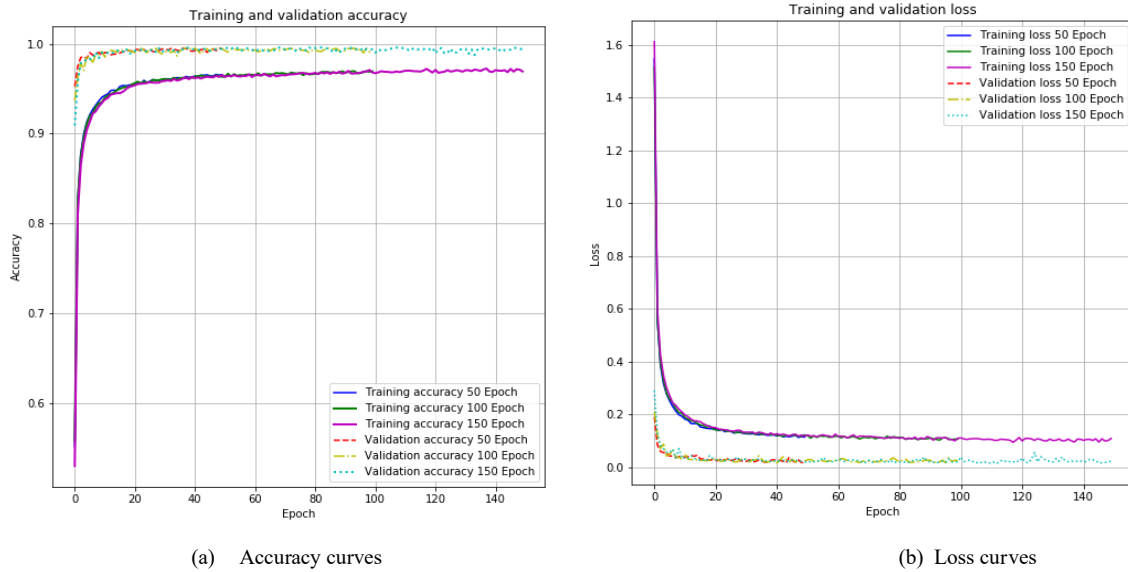
(b) Loss curves


Figure 7: Results of training CNN Model proposed in Table.5

7.2. CNN-based Model Description

The first part of a CNN is the convolutional part, strictly speaking, functions as an extractor of the characteristics of the image, because the images pass through a succession of filters, or convolution cores, creating new images called convolution maps some broker filters reduce the images resolution, by using a local maximum of operation. After the convolution layers or maps, are flatteners and reassemble into a vector of features.

The CNN base on the MLP (Multi-Layer Perceptron) [26], and inspired by the behavior of the visual cortex, although effective for image processing, MLPs have great difficulty in handling large images, which are due to the exponential growth in the number of connections to the image size, for example, if taking an image size of 32x32x3, so the first hidden layer, need fully-connected neuron of the MLP, to have in inputs 3072 neuron, but for 224x224x3 size images, lead to being processed in inputs, need 150,528 neuron, which means when the images size are larger, the number becomes enormous of neurons.

A CNN architecture formed by an ensemble of different processing layers, the important layers are:

❖ The convolution layer (Conv2D) a receiver field the data, explained before.

❖ The pooling layer (MaxPooling2D) compresses or reduces the image size by subsampling.

Table 5: Architecture CNN Model

Layers	Output	Parameters
Conv2D	(None, 28, 28, 60)	1560
Conv2D	(None, 24, 24, 60)	90060
MaxPooling2D	(None, 12, 12, 60)	0
Dropout	(None, 12, 12, 60)	0
Conv2D	(None, 10, 10, 30)	16230
Conv2D	(None, 8, 8, 30)	8130
MaxPooling2D	(None, 4, 4, 30)	0
Dropout	(None, 4, 4, 30)	0
Flatten	(None, 480)	0
Dense	(None, 500)	240500
Dropout	(None, 500)	0
Dense	(None, 43)	21543
Total parameters: 378,023		
Trainable parameters: 378,023		
Non-trainable parameters: 0		

Table.5 is composed of four convolution layers, two layers of Max-pooling, and two layers of fully connected. The input image is 32*32 in size; goes to the first convolution layer, this layer composed of 60 filters of 5*5 size, with ReLU activation function forces neuron to return positive values, after this convolution, then 60 feature maps of size 32*32 are obtained, which represent the input of the second convolution layer, also composed of 60 filters. The Max pooling layer was applied afterward, to reduce the image size. At the output of this layer, we will have 60 feature maps of size 12*12. We repeat the same thing with the last convolution layers composed of 30 filters; the ReLU function always applies to each convolution, and Max-pooling layer valid all the time, at the output of these layers, the features vectors of sizes 480. Finally, using a neural network composed of two fully connected layers, the first layer composes of 500 neurons, where the ReLU activation function was used, the second layer uses softmax function, for calculating the probability distribution of the 43 classes of traffic roads signs.

7.3. Trained Model

According to Figure.7 (a), the curves of training accuracy increase when several epochs increases, the same observation for curves of validation accuracy, reflecting the fact of epochs, can conclude the model learns more information. If the validation

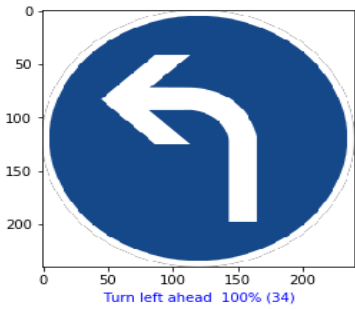
accuracy can't follow training accuracy, during the training model, this means that the CNN architecture, did not extract enough characteristics, for each class from the road sign images, called the underfitting, and when validation accuracy decreases during the training model, may result to overfitting, can conclude more features, allowing to model learn enough. Therefore, the curves of training loss decrease to achieve minimum error values, according to the number of epochs in the figure.7 (b), and the same for curves of validation loss. For all the graphs shown, the model does a very good job and powerful, according to the best scores shown in the figures previously during training, has reaches 11% in error rate and the totality for a 97% accuracy rate.

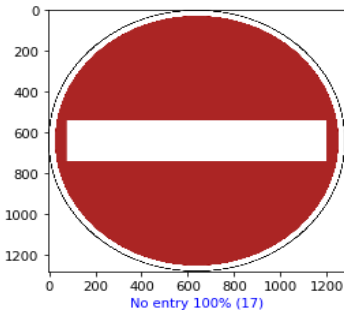
Table 6: Scores of accuracy and loss

Model	Epoch	Test Loss (%)	Test Accuracy (%)	Processor Type
CNN Model	50	06.93	97.91	NVIDIA GeForce 920M (GPU)
	100	11.64	97.05	
	150	11.31	97.11	

7.4. Training model description

Table.6 shows the results of scores accuracy and loss, using the test dataset, the execution time is too expensive, this comes

back to the large size of the base which requires to use GPU that CPU [27]. The model presented the best results found, the number of epochs and convolution layers reflect these good results; however, the execution time was very expensive because of the number of epochs.




In general, a deep convolutional neural network gives good results and the performance of our network degrades, if the number of epochs increases. For example, according to the table, the increase leads to a loss of about 0.86% of the performance of the network. Therefore, depth is crucial to achieving good results. The results obtained have improved as we have deepened our network with the number of epochs. The learning base is also a crucial element in convolutional neural networks, you need a large learning base to achieve better results in the future.

8. System Performance Evaluation

8.1. Cropped images recognition

As can see in Table.7, after the detection of circular-shaped panels with high accuracy in a real-time environment. Then we cut the road signs, the next phase is the most important for our system, the recognition of the road signs, identifying it to which class or category belongs in an intelligent way using deep learning. The objects that contain both images have been classified correctly without any errors. The red sign has been classified or recognized with a prediction of 100% No-entry, the same for the blue sign with a percentage of 100% Turn left. So, we have good results that can be a basis for the improvement of ADAS systems in the automotive sector that will serve the evolution of industry 4.0.

Table 7: Recognition of TRAFFIC ROADS SIGNS cropped

Cropped Signs	Recognition Signs
	Turn left ahead 100% (34)
	No entry 100% (17)

Figure 9: The classification rapport of the CNN model

8.1. Confusion Matrix

The Confusion Matrix [28] is used to evaluate the performance of our model, since it reflects the metrics of True Positive, True Negative, False Positive, and False Negative. Figure.8 closely illustrates the position of these metrics for each class. For example, the model ranked the automotive images well and is ranked or confused by the images of the other classes. We notice that there is a little confusion in classification on everything for the first class, which reduced the classification rate a little.

The average classification rate, as shown in the figure. 9 is 98%, which indicates our good system, for precision and recall, and high classification values for all categories.

9. Conclusion

Object detection in images and more specifically the detection of road signs images is a problem addressed by artificial vision. Among its fields of application are video surveillance, road safety, detection assistance systems. In our work, we were interested in the detection of signs. A bibliographical study has been carried out to determine the possible detection adopted methods and the most used descriptors in this case. Image classification is an important task in the computer vision field, object recognition, and machine learning. Through Deep Learning, the future of artificial intelligence enhances large and very fast developing algorithms. We discussed how the detection process and image classification took by a camera device during the discussion of the concepts of the neural network. To realize our classification work we used deep learning, which has shown its performance in recent years and we chose the CNNs method as the classification method, this choice is justified by the method's simplicity and its efficiency. During the tests phase, the obtained result confirms our approach effectiveness. Our work is only in its initial version and remains open for comparison with other classification methods [29].

The objective was to create a system for the automotive sector that combines detection and recognition. Detection based on the color and geometry of road signs, recognition based on deep learning based on CNN architecture, we got a score of 100% for classifying the test images captured from a real environment. Our work to be complimentary for our next work of detected geometry: triangular and rectangular, and classified it using Artificial Intelligence. This approach can be applied to the development of embedded systems for the automobile, which will serve road safety for all road users, either the passenger or the driver.

Dismantle Shilling Attacks in Recommendations Systems

Ossama Embarak*

Computer Information Science, Higher Colleges of Technology, Abu Dhabi, 51133 UAE

A R T I C L E I N F O	A B S T R A C T
	Collaborative filtering of recommended systems (CFRSs) suffers from overrun false rating injections that diverge the system functions for creating accurate recommendations. In this paper, we propose a three-stage unsupervised approach. Starts by defining the mechanism(s) that makes recommendation vulnerable to attack. Second, find the maximum-paths or the associated related items valued by the user. We then rule out the two attacks; we will need to pull two different measures. (a) We will pull user ratings across all reviews and measure their centre variance. (b) We will then pull each individual user rating and measure them according to the original rating. Detected attack profiles are considered untrusted and, over time, if the same user is detected as untrusted, the profile is classified as completely untrusted and eliminated from being involved in the generation of recommendations. Thus, protect CFRS from creating tweaked recommendations. The experimental results of applying the algorithm to the Extensive MovieLens dataset explicitly and accurately filter users considering that a user could seem normal and slightly diverge towards attack behaviours. However, the algorithm used assumes that the framework has already begun and manages user accounts to manage the cold start scenario. The proposed method would abstractly protect users, irrespective of their identity, which is a positive side of the proposed approach, but if the same user reenters the system as a fresh one, the system will reapply algorithm processing for that user as a normal one.

1. Introduction

This paper is an extension of work originally presented in 2019 Sixth HCT Information Technology Trends (ITT) [1]. Personalization Collaborative Filter Recommending Systems (CFRSs) is becoming increasingly popular in well-known e-commerce services such as Amazon, eBay, Alibaba, etc. [2]. Most people are rating products or services without even realizing it is something they can do [3]. However, CFRSs are highly vulnerable to "profile injection" attacks; often referred to as "shilling" attacks [4]. It is common for attackers to pollute the recommended systems with malicious ratings. They either demote a target item with the lowest rating; called a nuke attack or promote a target item with the highest rating; called a push attack to reach their target or minimize the recommendation's accuracy. It is therefore necessary to develop an effective detection system for detecting and removing attackers before the recommendation [5–7].

Detection methods based on the attacks gained much coverage. Since the similarities between attackers are higher than the actual users, some have been presented based on the similarity between users. Traditional similarity metrics, including the Pearson Correlation Coefficient (PCC),[8,9]. However, the detection efficiency of these methods relies

largely on the estimation of similarity. How to reduce the time consumption of the measurement of similarity is also a difficult problem, particularly when dealing with large datasets[10]. In addition, some attackers imitate the rating data of some legitimate users in order to increase their reliability. Only the use of similarities is difficult to discriminate incomplete [11]. In order to overcome these problems, a more efficient form of detection should be considered in the following aspects:

A. Applied algorithm complexity should be acceptable.

B. The proposed method should be able to defeat various kinds of "shilling" attacks.

This paper proposes an unsupervised detection method for detecting such attacks, consisting of three phases. The purpose of the proposed method is to filter out more legitimate users, and at the same time hold, all attackers step by step. Firstly, the recommendation system admin needs to understand the attacker's strategy based on the recommendations working mechanisms. Secondly, we constructed users' maximal paths that represent his/her loop less-visited nodes or rated items in an association, then calculate the maximal path's mean and standard deviation considering all ratings done by users visited that particular maximal path. Thirdly, we detected untrusted users by detecting the user's zone (normal, freeze or melt zone area) which reflect the gap between the user's ratings in the

*Corresponding Author: Ossama Embarak, oembarak@hct.ac.ae

maximal path (items) and the genuine profiles' ratings of the same path(items) considering the maximum expected calculated deviation. The proposed algorithm prevents untrusted users' maximal sessions should not be added to the system profiles used for generating recommendations, and the user is labelled as untrusted profiles in which the system should not consider such profiles towards generating recommendations.

Recommendation systems are massively used to support online systems provides services through the internet. As an alternative to passive search engines that simply accept as "true" the displayed results, these collaborative filtering systems attempt to take the perspective of the user's needs and what they are searching for and identify similar results based on that [12]. Decisions that depend on a user's previous demands can be made with a recommendation system; a recommendation system is a set of techniques used to process and generate recommendations. In order to inject the ratings of biased users into recommender systems, users attempt to influence the system by injecting biased ratings for a specific product they are interested or associated with. Through a process known as a rating bot attack, which can plough the ratings up or down, change the ratings of services or items to the highest or the lowest available levels, or launch attacks against them [13]. In order to avoid shilling attacks, the company has attempted to implement various suggestions, such as asking users to rate items by using certain code, or by only allowing ratings to occur after a certain amount of time, or by simply making profiles harder to create or by increasing the price of creating a profile? Because of the ways in which these methods can eliminate attacks, the participants in rating and evaluating services became much smaller than normal [14]. E-commerce web-systems suffer from attackers who push specific items to the recommendations list and promote the target item via manipulating recommendation systems [15]. The attackers create numerous profiles by injecting unusual identities and putting very high-ratings for their target items. An attacker's profile will camouflage itself by keeping track ratings for other non-target items, and the system will use that information to predict the attacker's targets. The manipulations of recommendations systems of injecting misleading and false data make a recommendation system's operation is negatively affected [16]. Recommendations systems powered by user-generated reviews will only be representative of individuals with very few reviews. Initial profiles will greatly affect future processing and output. Moreover, this system does not generate suitable recommendations, and occasionally, it breaks down the whole system; It causes the system to lose its credibility and respect by people in the community. Therefore, several research groups' main goal is to develop a system that can filter out fake profiles that could make those systems able to provide accurate recommendations [17].

This paper looks into a different type of attacks for recommendation systems and propose a solution to detect and isolate attackers. It contains the following sections: Section 1 introduction to recommendation systems and its attacks. Section 2, the background of recommendation systems different forms of attacks. Section 3, we discuss the previous researches and approaches for handling different attacks. Section 4 identify the study problem. In section 5, we explore the proposed solution. Section 6 demonstrate experimental results. Finally, The paper and the future work will be concluded.

2. Background

Numerous different sorts of recommenders are used on different sites. Studies in the past have shown dramatic growth in the methods used to improve recommendations. Recommendation systems can be broadly classified into content-based and collaboration-based [18]. Content-based filtering suggests products based on users browsing history. There are downsides to this type, such as over-specialization, which recommends only similar products to what was consumed before. Collaborative filtering takes into account past behaviour, considering that users will behave similarly. Shilling attacks manipulate recommendation systems by inserting malicious user profiles into the filter data [19]. The target item is either promoted or demoted. Attacks can be categorized as push or nuke strikes, a product may therefore be promoted or dismissed for advantages over competitors [20]. Over time, numerous attacks models have been developed. There are many detection techniques and algorithms to counter such attacks. All of the attack models are designed to generate vicious users. The discrepancies are recognized in how the strike profiles are established. Malicious users' domain items can be considered as $S = \{ I_s, I_p, I_n, I_\emptyset \}$, where I_s is the set of items that matched with the genuine users. *while* I_p is the set of items the malicious user promote, and I_n is the set of items he/she demote, and $I_\emptyset$ items that are not ranked yet by the trouble user.

Over the years, several attacks were developed. All such attacks can be classified either as a high-level attack or as a poor-knowledge attack based on their motivation and knowledge [21, 22]. Attacks with little knowledge are more practical and are more likely to impact the real world, but such attacks' effectiveness is also low. On the other hand, high-level attacks can have a huge impact on Recommender Systems' performance, but they are more difficult to pull out. *RandomBot attack* is the plainest form of a shilling attack. Items rated by the attackers selected in random, except for the target item. The rankings for such items are based on the overall system norm [22].

A maximum or minimum rating will be given on the basis that it is a push or a nuke attack. The purpose of a random attack is usually more effective in disrupting the Recommender Systems' performance than in promoting the target item. *Average Attack* is similar to Random Attack when selecting items. The randomized distribution of individual items is based on their distribution of ratings. The average rating of each filling item is assigned. This attack can only be carried out if the attacker knows the system's dataset. While random attack and average attack differ only from filler ratings, the average attack impact is much higher. *Bandwagon Attack* is the kind of attack where attacker profiles are filled with popular high rating items. Naturally, attack profiles are closer to many people. The highest value is given to the target item. Depending on the rating scheme used to provide the filler items, this attack can further be divided into random and bandwagon averages. Bandwagon is also classified as a low-knowledge attack since the attacker only needs public data. *Bandwagon Reverse Attack* is the exact reversal of an attack on a bandwagon. This attack is used to demote the target product by rating the items with high negative ratings low and giving the target item the least rating. *Segmented Attack* targets a particular group of users who can buy the target item in the e-commerce system. Segment attacks typically occur in collaborative item-based filtering [23, 24].

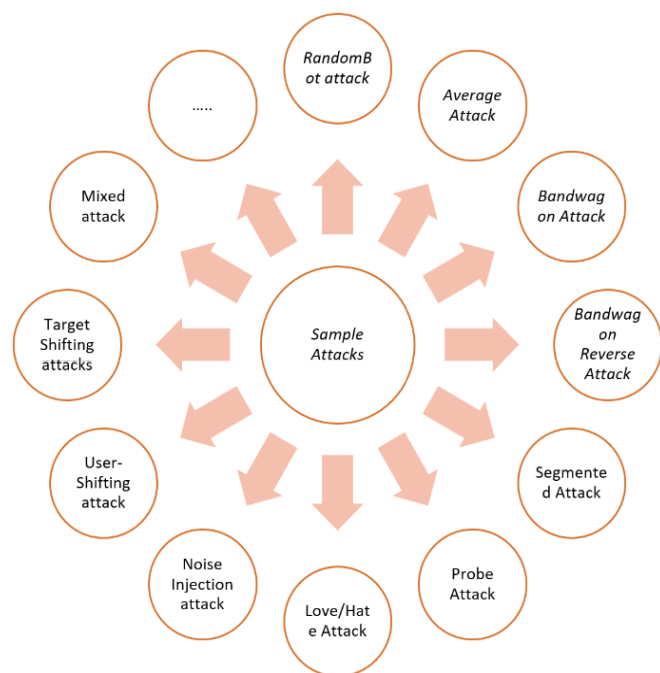
The ratings and items are based on knowledge of the segment from the attacker. The important benefit of this method is its ability to reach potential clients over other approaches. *Probe attack* occurs when an attacker provides genuine ratings for items based on their knowledge of the predicted rating scores. The attacker uses this detail to rate items, enabling it to appear similar to other ratings. The attacker composes the acceptable items list based on the rated items. This collaborative scheme allows attack profiles to remain close to their neighbours. It also facilitates an attacker in gaining more information about the system. *Love/Hate Attack,* where the attacker randomly chooses filler items and gives them the highest rating and lowest rating on the target item. It can also be known as a push attack by changing the highest ratings [25]. *Noise Injection attack* generates random numbers multiplied by a constant to each rating for a subset of rated profiles. The more obfuscation, the more constant. It can be effectively applied to obfuscate its signature to all standard methods. A slightly decreased ability to withstand an attack is observed in response to noise injection. *User-Shifting attack* where a subset of users revises ratings [26]. The attack subsets were selected randomly to reduce their similarities. Ratings are scaled differently for different subsets of the ratings [27]. *Target Shifting attacks* shift the targeted item rating to a lower level in push attacks than maximum. For nuke attacks, the minimum rating is shifted up by one. *The mixed attack* is made using the same proportions of random, average, bandwagon and segmented attacks. The detection technique should be able to detect all the standard attacks successfully. The various methods for attacking the same target item are used. It helps to avoid various methods of detection [28].


Figure 1: Sample Attacks Types

3. Related Works

A well-known class of attacks is called the Shilling attacks, which attempts to inject some profiles to influence the targeted system's performance [13]. This attack is divided into two attacks: push attack- which uses a malicious profile to rate a specific item highly (greater than most items) and nuke attack- which uses malicious profiles to lower rating for a specific item (s). Playbooks attacks reflect a series of actions undertaken to

maximize a certain item's importance and increase its profits [29]. Some systems produce low-quality recommendations, so that once the users discover such attacks, the system loses its users' respect and loyalty [30]. Unfair rating attack occurs when a system uses trusted agents' ratings and compares them against each other for a service entity. This attack leads to predictions that are not actually correct [31]. Re-entry attacks occur when an agent is transferred between accounts using different names to avoid low ratings [29]. Sybil attacks reflect a fake identity to give different ratings. So far, a robust recommendation system is essential for any application of a recommendation system. Robustness measures a model's ability to produce good predictions with noisy data [32]. Whenever a user rates something, the system updates its databases, which means we have no way of knowing if the ratings are real or not. Ratings can sometimes be tedious, which could be caused by users' carelessness, and malicious users may attack. In robustness, there are two different aspects, *the first* of which is the accuracy of recommendation, which are the products that were recommended by the systems after the attack took place. *The second thing a system must do is be very stable,* which means won't recommend slightly different products if it detects an anomaly or attack.

Before storing user ratings into the system, the attack type must be detected to maintain its good reputation before affecting its performance. Injecting profiles another example of forged data being injected by malicious users into recommendations systems to manage recommendations [33]. Collaborative filters are susceptible to profile attacks by user-based and item-based recommendations. In this sort of attack, the attackers try to evaluate target and non-target items to make ratings appear normal by forging rating profiles and injecting them in rating systems [34]. Studies show that group attack profiles manipulate the target object ranking recommendation. Many attackers work together in a given time frame to attack certain target items to quickly put some items into a preferred list. The next section will provide a breakdown of the experiment and its results.

4. Identifying the Problem

Recommendation systems may provide health recommendations that reflect the preferences of users. However, injecting false ratings or trying to push or nuke ratings of the offered items differs in the system's performance. Many proposed solutions are almost implemented after attacking or generating recommendations that burden many computations and increase system time complexity. Furthermore, depending on the specific fixed average rating, the dynamic change in items' ratings over time is not reflected. Therefore, we propose a new approach to filter users into normal, fully trusted and untrusted users based on their maximal traversing path or items movable threshold.

5. The Proposed Solution

Details of the proposed method are implemented in three stages in this section. In the first phase, we need to understand the attacker's strategy based on recommendations generation mechanisms. In the second phase, we constructed users' maximal paths and calculated the maximal path's mean and variance, considering all users' ratings visited that particular

maximal path. In the third stage, we detected untrusted users by detecting the user's zone (normal, freeze or melt zone area), which reflect the gap between the user's ratings in the maximal path (items) and the genuine profiles ratings of the same path(items) considering the maximum expected calculated deviation. All detected untrusted users' maximal sessions should not be added to the system profiles used for generating recommendations, and the user is labelled as untrusted profiles in which the system should eliminate his future participations.

5.1. Users Profiles

Recommendation systems collect user ratings – items used to form an object rating matrix that includes three elements: users, items and ratings.

$$U = \{ u_1, u_2, \ldots, u_{m-1}, u_m \}$$

where *U* refers to set of *m* users.

$$I = \{ I_1, I_2, \ldots, I_{n-1}, I_n \}$$

where *I* refers to a set of n items.

All users can rate few or all items; a user-item rating matrix generated from all the ratings is used to find attackers and make many recommendations.

$$\begin{bmatrix} I_{u_1}^1 & \cdots & I_{u_1}^n \\ \vdots & \ddots & \vdots \\ I_{u_m}^1 & \cdots & I_{u_m}^n \end{bmatrix}$$

Figure 2:   Items-users ratings matrix

where $I_{u_1}^1$ reflect the rating of the first item by the first user, while $I_{u_m}^n$ is the rating of the item number n by the user number m.

A regular user weight items in the overall round the norm. Similarly, both the push and nuke attackers aim to rate items extremely far from the item threshold. We call it a *freezing* zone, as the rates are very far from the item average rates measured, and the nuke attackers aim to rate items that are extremely low from the item thresholds, we call it a *melting* zone, as the rates are very far back from the item thresholds. We measure each user's ratings and can detect any change in weight in either "Freeze" or "Melting" zones by measuring the weighted mean of all ratings.

5.2. Attackers Background

The attackers usually deliberately attempt to change the efficiency of the recommendation system. They know how the system operates and use their expertise and understanding to affect the system's efficiency.

There are three types of systems in terms of user awareness of the Recommendation Mechanisms.

1. Systems that depend on the popularity threshold (like Insider) to produce recommendations are simply showing popularity to users. As a result, attackers know exactly what will be recommended, attempt to modify popularity

by revisiting the same path(route) or increase or decrease other paths' ratings.

2. Systems that depend on each item's popularity to produce a recommendation, the popularity displayed to users with a list of recommendations can also use the association rule to show that items x are frequently selected with item y, such as YouTube videos. As a result, attackers have full knowledge of how ratings are allocated in the recommended device profiles. Attackers attempt to manipulate the specific item(s) by raising or decreasing the item(s) ratings or increasing or decreasing the related items' ratings.

3. Systems that show recommended items without a strong indication of popularity or affiliation between items, such as Amazon. As a result, attackers have no understanding of the system mechanisms.

Recommendation system developers must consider the attacker tactics and program the system to identify and remove any untrusted users from being part of the profiles used to produce recommendations.

5.3. Constructing Maximal User Path

As shown in the figure below, each user targets items and gives their ratings of those items. The ratings influence those items to be the top choices. Others will probably allocate very little to nuke individual objects at the lowest level far below the average weighted μ of the item. An average is normally relative to all items rated.
Figure 3:   User-Targeted Items

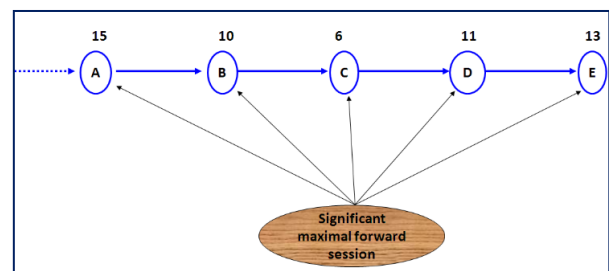
We consider a maximal route occurred during a visit (session), as shown in the figure below, where there is no loop happened in a maximal path. The user may have several visits during which the rating occurred, as shown in the below figure, the user might be a genuine or an attacker. Whether a genuine person or an attacker, a user tries to check certain nodes, so we need to assess his traversing rates.


Figure 4:   User Maximal Path

We begin with each user session, and gradually explore the data, moving from s_i. And as for all of the rates R_i, they do not exceed the limits. The user session is entered into the system of that session.

$$s_i = \{ R_1, R_2, \ldots, R_{n-1}, R_n \}$$

By measuring the session maximal path average rate, we can find the rate deviation of the user's rating of the node's visited and rate by looking at the other user's ratings of the user rated objects.

$$\mu_{s_i} = \frac{\sum_{i=1}^{n} R_i}{n} \qquad (1)$$

$$\sigma(s_i) = \sqrt{\frac{\sum_{j=1}^{l}(|\mu_{s_i} - R_{u_j}^i|)^2}{n}} \qquad (2)$$

where μ_{s_i} represents the mean weight of that path by all users and $\sigma(s_i)$ represents the calculated standard deviation of all rates happened on that maximal path.

5.4. Detect Untrusted Users

The two types of attacks are very severe from average users, but this does not mean that a normal user does not score an object at a low or high rate. However, it is uncommon for the same user to rate multiple items with very low or very high ratings relative to other users that rate the same item on similar maximum paths.

We then found the following rule to use every rate state (melting, freezing, or normal).

where $F(s_i)$ is the evaluation function of each session as a collection of rankings made through a visit, $\Im_+$ represents the case when the user aims to push ratings far from the normal ratings (the freeze status), and $\Im$ reflects ratings happened within the threshold boundaries, while $\Im_-$ reflects the case when the user aims to downgrade target items (the melting status) as shown in the figure below.
Figure 5: User Rates Zone

where,
Freeze case ($\Im_+$) = $\{R_i \mid R_i > \Im_+\}$
Meting case ($\Im_-$) = $\{R_i \mid R_i < \Im_-\}$
Normal case ($\Im$) = $\{R_i \mid R_i \cong \Im \text{ or } R_i \cong \mu_{s_i}\}$

Therefore, $\Im_+$ & $\Im_-$ users should be eliminated from being part of recommendation generation processing.

Table 1: Attack Status

Attack model	Zone	Status
push attack	Freeze zone	$\Im_+$
No attack	Normal	$\Im$
Nuke attack	Melting zone	$\Im_-$

Table 1 shows that $\Im_+$ reflects the highest rates could be reached by attackers in the rating; for specific items or maximal path, far beyond the standard deviation. And $\Im_-$ reflect the customer's minimum prices relative to the measured average rate and the selected products' standard deviations. While $\Im$ reflects the normal rates of the trusted user obtained by the recommendation systems.
Figure 6: Suggested Model Stages

5.4.1. Algorithm for Detecting an Attack

The following algorithm demonstrates the followed steps to detect a user rating zone.

Input: users ratings or maximal path in a session.
Output: filter users into trusted, untrusted (melting, freeze).
1. Read a user u_i session s_i
2. $\forall_i \in s_i$, calculate μ_{s_i}, and $\sigma(s_i)$
3. Read **UT**
4. **While not UT**
   For R *in* s_i:
   a. *if* $R_i > \Im_+$
      i. *Detected Freeze case*
      ii. Refuse the whole session
      iii. Untrusted user is highlighted
      iv. **Update UT ← u_i**
   b. Else if $R_i < \Im_-$
      i. *Detected Melting case*
      ii. Refuse the whole session
      iii. Untrusted user is highlighted
      iv. **Update UT ← u_i**
   c. Else
      i. Detected Normal case
      ii. Accept the whole session ratings
      iii. Trusted user is highlighted
      iv. **Update U ← u_i**
5. Return zone

---

where R reflects items ratings in a session s, and **UT** reflects the untrusted users discovered and recorded on the system. The system would automatically maintain its functionality by upgrading any identified untrusted user to untrusted profiles that make sense of removing any ratings received from these users in the future. In contrast, the normal user ratings should be updated to the normal profiles used to produce recommendations.

5.5. The Contribution of the Manuscript

This paper's main contribution is implementing a new algorithm to filter user rating injections and item rating injections to prevent false similarities. A matrix of ratings is used in the processing to identify the trust of the user. Therefore, if the user ratings exceed a particular computed ceiling, the system routinely denies the user scores and moves

them in an untrustworthy category, and the user ratings are not considered in the recommendation creation.

6. Experimental Results

We use the available online Movie Lens 1M data set to apply and test the proposed algorithm, comprising 1,000,000,000 unidentified reviews of roughly 3,900 films received by 6,040 users of Movie Lens. All scores are 1 to 5 integers, with 1 being the lowest, and 5 being the highest. There are 18 separate domains in the data set and all users with at least 20 films rated. The proposed algorithm (see section 3.4.1) was able to detect cases near the freezing, and those were very close to the melting zone. Total cases were 11364): Normal ratings (2677), Malting near (3943), Freeze near (4611), found attacks (133) as demonstrated in the table below.

Table 2: Users- Malicious Detection

Domain name	Normal	Malting touch	Freeze touch	Detected Attacks
Action	240	158	154	3
Adventure	123	216	349	2
Animation	157	226	216	0
Children	125	152	173	9
Comedy	151	267	248	50
Crime	104	348	247	0
Documentary	177	326	536	4
Drama	173	158	195	15
Fantasy	123	234	165	0
Film-Noir	140	217	300	3
Horror	157	154	172	8
Musical	125	150	150	0
Mystery	141	148	141	11
Romance	177	178	272	0
Sci-Fi	173	353	467	12
Thriller	176	277	286	0
War	105	211	380	7
Western	110	170	160	9

In each movie domain, the following figure shows user patterns; it is clear that several freezes touch cases when user ratings exceed the normal ratings; the same is obvious in the melting zone. The experimental results showed that the algorithm detected 50 attacks from the comedy group, while many cases were under border conditions. The clearly reported attacks in the trained data showed that the attached percentage are as follows, in Action (2%) , Adventure(2%),Animation (0%), Children (7%), Comedy(38%), Crime(0%), Documentary(3%), Drama(11%), Fantasy(0%), Film Noir(2%), Horror(6%), Musical(0%), Mystery(8%), Romance(0%), Sci-Fi(9%), Thriller(0%), War(5%), Western(7%).
Figure 7:   Attacks Detections For 300 Users

We expanded the data set and considered 450 users; the algorithm could detect more attacks, as seen in the figure

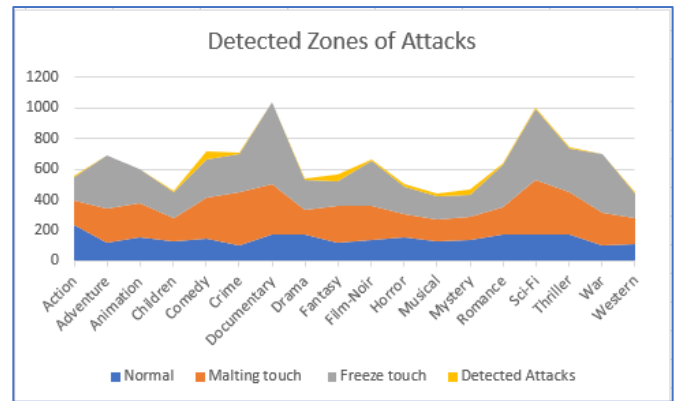
below. This represents the incremental number of maximum paths that are being tested and the rise in the number of attacks observed by improvements in the slander of the deviation and the zones' size.


Figure 8:   Attack Detection For 450 Users

The following table demonstrates a comparison between the proposed algorithm and another two algorithms were used to detect malicious attacks in recommendation systems.

Table 3: Algorithms Comparison

Points	Proposed algorithm	Rating behaviour	Profile similarity
Processing	Find the maximal path or sequence of items ratings	Pinpoint lower rating values considering that it has a minimal contribution to the systems	Discover profiles similarity
System behaviour	Classify users in three zones Normal, Melting and Freeze before updating their datasets	Detect all lower rating profiles.	Detect all identical profiles in ratings
Actions	Use trustworthy users to make recommendations	Ignore low rate profiles and only use moderately to highly qualified profiles	Ignore all identical profiles
Privacy concerns	Users' demographic data are not collected, only their maximum routes or sequence of items are collected. No privacy concerns.	The issue of privacy is valid.	Privacy is a valid issue.
Effective against	Various attack forms.	Random and Reverse	Average, Segment,

		Bandwagon attacks	and Bandwagon attacks
System reacts	The system will continue to serve untrusted users but will ignore their preferences for making recommendations.	The system eliminates profiles of an attacker	The system removes the profiles of attackers

Different attacks can be conducted using the proposed algorithm by finding the maximum path and measuring how far it is from the abstract user path. This helps classify users into different three zones; Normal, Melting (extreme below the threshold), and Freeze (extreme high from the threshold). The system then can ignore both Melting& Freeze cases and maintain only the normal cases for recommendation processing.

7. Conclusion and Future Works

Shilling attacks are a significant challenge to collaborative filtering recommendation systems. These attack profiles are likely to have similar rating information to many legitimate profiles to make them difficult to identify. This paper proposed an unsupervised detection method for detecting attacks (or irregular ratings) consisting of three phases. In the first phase, we need to understand the attacker's strategy based on the recommendation generation mechanisms. In the second phase, we built users' maximal paths and calculated the maximal path's mean and standard deviation considering all users' ratings visited that particular maximal path. In the third stage, we detected untrusted users by detecting the user's zone (normal, freeze or melt zone area) which reflect the gap between the user's ratings in the maximal path (items) and the genuine users' ratings of the same path(items) considering the maximum expected calculated deviation. All detected untrusted users' maximal sessions should not be added to the system profiles used for generating recommendations, and the user is labelled as untrusted profiles in which the system should eliminate any future participation. Experimental results showed that with a greater number of maximum routes used by the recommendation systems, the model could detect more attacks and thus discover untrusted users and prevent them from affecting their performance. The proposed method's main limitations include the following two aspects: (a) How the system could work in the launching phase when there are no ratings in the system collected from users. However, in the beginning, various methods can be used to overcome such systems' cold start, such as developing a suggestion considering the like-minded users when navigating the system. (b) The proposed approach abstractly handles users regardless of their identities, representing a good side of the proposed approach, but if the same user joins the system as a new user, the system will perform the calculations again for that user. One of our future objectives is to apply the suggested algorithm on a larger data set and apply it to live stream data in collaborative systems.

Conflict of Interest

The authors declare no conflict of interest.

Optimal Hydrokinetic Turbine Array Placement in Asymmetric Quasigeostrophic Flows

Victoria Monica Miglietta[*], Manhar Dhanak

The Coriolis force in the ocean at mid to high latitudes can cause significant deviation of flow over bottom topography, including formation of Taylor columns. Structures in a tidal zone will experience zero inertial current between every tidal change. Around periods of directional change, the Coriolis force may be tapped into for energy. Factors like timescales and other environmental factors like local currents could influence the flow characteristics in an undesirable way and are outside of the scope of this study. The focus of this study is to assess how the design of a structure influences the asymmetric flow patterns produced around it by an incident quasigeostrophic flow. Analytical solutions existing for inviscid quasigeostrophic flow over isolated elongated elliptical topography are used for flows with small Rossby numbers. These solutions are used to predict and explore the characteristics of the flows expected during a change in the tidal cycle. Results show that a linear array placed perpendicular to a quasi-geostrophic flow will experience flow acceleration on the left-hand side when looking downstream. On the other hand, a linear array placed parallel to the quasi-geostrophic flow will experience a sharp velocity gradient over the array. This suggests that an array placed perpendicular to the quasi-geostrophic flow will provide for a more robust design when compared to a linear array placed parallel to the flow.

1. Introduction

Special considerations for large underwater turbine farms or arrays at mid and high latitudes will be necessary because at such latitudes the Coriolis force can measurably impact the dynamics of flow in asymmetric patterns. A thoughtful and robust array design can position turbines to harness the Coriolis force[1]. Array design requires knowledge of the local dynamics and an understanding of all forces including the Coriolis force. Tools for evaluating such an ocean engineering endeavor includes numerical solutions for flows moving past extended obstacles in instances when rotational forces are required to describe the flow [2].

The Coriolis force is a pseudo force caused by Earth spinning on its axis. Typical ocean engineering problems ignore Coriolis effects because they are minimal on the typical scale of ocean engineering problems. Also, local inertial forces often dominate engineering problems where a good approximation allows for the Coriolis force to drop out of consideration. But for tidal currents, the local inertial speeds will drop to zero at least twice daily, and it is at these periods where the Coriolis force may impact an array. A renewable energy system's array which produces electricity for

a municipal power grid will be sensitive to electrical and therefore environmental energy fluctuations. For locations with higher values of latitude the Coriolis force should be considered at periods surrounding slack tide.

Often tidal current power sites are limited to channels and bays [3-7], however tides are not limited to these locations. Tides occur throughout the Earth's oceans. Here the design of a turbine array in open water is analyzed. Vertical boundaries are far from the array and the domain's distinct boundaries are the surface of the water and the seafloor. A very long array, capable of being economically viable, composed of a single line of turbines is considered. The turbine array is taken to be 10,000m long. The large dimension is comparable to a topographic feature and certainly would allow for the array to meet a production goal on the order of megawatts of electricity. It is hypothesized that a very large array in the ocean would experience the same amplification of flow rate around it that a seamount experiences [8, 9].

Studies of seamounts, and underwater ridges indicate flow behavior around large obstructions in the ocean are influenced in a measurable way by the Coriolis force [2, 8, 10]. The largest dimension of 10,000m would put a turbine array on the scale of a

*Corresponding Author: Victoria Monica Miglietta, vmiglietta2013@fau.edu

small seamount and on par with the scale of a seamount [10]. It has been observed that flows past/around seamounts are amplified and that the flow above them is best described as stagnant [10]. These are rotational effects and have been of interest to marine biologists and oceanographers [9, 11].

The flow patterns and Coriolis effects on an underwater turbine array differ from those of wind turbine arrays because of the huge density difference between air and water. The nature of air and water differ in a way where the rotational phenomenon of Taylor columns are not found in the atmosphere for quasigeostrophic flow conditions [12, 13]. These Coriolis effects are not seen around wind farms or wind turbines because they disappear in a density gradient.

2. Background

2.1. Not a channel

Studies like [4-6] look at tidal channels being utilized for tidal current power. However, taking over an entire tidal channel or even a good portion of one for power generation would have serious consequences for the established use of a channel. Many channels have daily uses which include maritime traffic for shipping, fishing and recreation. Obtaining permits and backing of local communities to re-purpose heavily used tidal channels for power production would likely be a challenge. If the tidal power project was for a remote community or some remote operations then challenges could be different. However, for large coastal communities looking to harness tidal power across a tidal channel such challenges could be expected. For example, the offshore wind development off the coast of Massachusetts, Vineyard Wind, has experienced a lot of push back by the fishing industry in the area. The project has been on hold since 2019 while the Interior Department conducts a review. Harnessing tidal current power in more open areas, could be less oppressive to current users of waterways. In this study the ideal deployment area is far from boundaries like shorelines, piers, or breakwaters.

2.2. Static Obstruction in a Rotational Fluid

Here the effects of the static physical presence of an obstruction to flow in a changing tide were studied. The review of studies of the effects of seamounts on the flow around them shows that large obstructions, like that which could be expected from a tidal turbine array, produce asymmetric patterns seen in rotational fluids [14]. These rotational effects are caused by the spinning of the Earth. The fundamental physical dynamics for an obstruction to flow in a rotational fluid with a small inertial current is similar for a bottom seated obstruction and an obstruction suspended in the water column [14]. An array would have similar effects for both bottom seated and moored or suspended turbines in the water column.

Furthermore, the research presented here would be applicable to the tidal array design engineering as well as the deployment site assessment. The physical phenomenon of Taylor columns and their associated flow patterns could develop locally at the site of the engineered structure itself, and it could also develop on/around

a bathymetric feature like a ridge or seamount where an array or turbine is deployed. The University of Strathclyde encountered what was described as a spatial-temporal eddy with a 'calm' center when it was testing a tidal current turbine [15]. This could have been caused by a Taylor column which has a stagnant interior. The latitude for their deployment was approximately 55N.

2.3. Unchanging Coriolis Parameter in the f-plane

This study evaluates an array so large it can be viewed at the scale of topography, i.e. the array will define the 'landscape' in the area it is deployed. The *f*-plane approximation is made, where the Coriolis parameter does not change. If the array was to extend over several degrees of latitude the Coriolis parameter would change and a structure so great in size would need to be analyzed in the β-plane. For the *f*-plane approximation, the absolute velocity of the tidal current will be the parameter that changes the blocking parameter cyclically over time i.e. with the tidal cycle.

2.4. Blocking Parameter

The blocking parameter correlates the size of the obstruction with environmental parameters to indicate the degree of influence the structure has on the local flow patterns. A critical blocking parameter predicts the formation of a Taylor column. A Taylor column is a hydrodynamic phenomenon, parallel to the axis of rotation, which appears like an extension of an object, obstructing flow when the blocking parameter is at a critical value. The critical value of the blocking parameter S, is $O(1)$. There is no consensus on a more exact value for the blocking parameter. For the [10] observations the blocking parameter appeared to be approximately 0.7. The exact blocking parameter is likely to be site specific and will vary on a range of environmental parameters. Important parameters include the height of the array, h; the depth of the water, d, and the latitude which changes the Coriolis parameter, f.

This study uses the definition of the blocking parameter by [16],

$$S = h/(d \cdot R_0)$$

$$S = fhL/(d \cdot U) \qquad (1)$$

There is no consensus on the calculation of the blocking parameter or its critical value. The formation of a Taylor column was initially linked to the Rossby number dropping below the value of $1/\pi$ [12]. Effectively this original critical blocking parameter was when the Rossby number, R_0, was $1/\pi$ or smaller.

Further research [16] on rotational fluids added a coefficient to the inverse of the Rossby number, the ratio of the height of the obstruction to the depth of the water, h/d. Decades later [17] used the ratio of the greatest horizontal length of the obstruction to the water depth as the coefficient to the inverse of the Rossby number. The similar thread in all these blocking parameters is the Rossby number. The Rossby number is the ratio of inertial forces to rotational forces. The rotational forces are represented in the Rossby number by the terms fL. Where L is the characteristic length, the longest horizontal dimension of the object. The Coriolis parameter is larger for higher latitudes. The Rossby number will

decrease for higher latitudes because at these locations rotational forces are stronger. The Rossby number is inversely proportional to the Coriolis parameter

$$R_0 \propto 1/f \tag{1}$$

and the blocking parameter is proportional to the Coriolis parameter

$$S \propto f \tag{2}$$

Consequently, a structure located at a higher latitude will experience a higher blocking parameter; with velocity, and structure size, and water depth all remaining constant.

The Rossby number includes *L*, the characteristic length of an object. The [16] blocking parameter is the most complete because it not only includes the characteristic length of an object, but it also includes its height. The [17] blocking parameter is redundant in that it uses the length of the obstruction in its coefficient and the length also appears in the Rossby number. So effectively the [17] blocking parameter uses the square of the characteristic length. Returning to the perspective of a tidal current, the velocity will change and with it the blocking parameter will change. Recall that the blocking parameter is inversely proportional to the velocity

$$S \propto 1/U \tag{3}$$

Looking at the critical blocking parameter for various latitudes, faster speeds can bring about a critical blocking parameter at higher latitudes. This means that the period of the tidal cycle where the blocking parameter is critical will be longer at higher latitudes.

3. Problem Statement

Since it is during the slack tide that the Coriolis force could impact the dynamics of a turbine array, this period cannot be passed over simply as the period where tidal current turbines will not produce electricity. At slack tide, the water is in quasigeostrophic flow; meaning that the inertial current is minimal and the Coriolis force is needed to describe the flow. In quasigeostrophic flow, the consequence of a small inertial current is that it prevents the equilibrium of the pressure force and Coriolis force (this equilibrium is described as geostrophic flow).

During each tidal change the blocking parameter becomes critical. The critical value of the blocking parameter is associated with the formation of a Taylor column. When this happens the array (the obstruction) will behave like a taller structure, or it will have a sort of physical shadow above it (and possibly below it). Also, for a critical blocking parameter the flow can be described well by a 2-D approximation, where the velocity does not vary in the water column. This flow described by the 2-D approximation, i.e. a Taylor column, can appear almost instantaneously in a laboratory tank. The question addressed is what are the characteristics of the flow influenced by the Coriolis force in the immediate vicinity of a linear array? The equipment in a tidal zone is likely to experience rotational effects during periods when currents change direction. Asymmetric flow for quasigeostrophic conditions have been observed around seamounts and in this study modelling was used to predict how a large linear array would experience such conditions.

3.1. Method

The blocking parameter, *S*, will have a spiked value at every tidal change because it is inversely proportional to the velocity. Numerical [2] solutions were used to plot the velocity around a linear array when the blocking parameter was critical or *O(1)*. The solutions depend on the angle of the incident flow, *α*, and also depend on the ratio, *γ*, of the largest dimension, *L*, to the smallest dimension, *l*, in the X-Y plane.

$$\gamma = L/l \tag{4}$$

The solution is insensitive to the details of the shape of the obstacle [2]. Solutions model flow patterns closely to those in the oceans where the bathymetry is more complex than a simple ellipse [2]. The solution is for a homogeneous, inviscid, incompressible flow, with a constant depth, in a rotating frame, and it satisfies the conservation of potential vorticity. The stream function used [2] in elliptical coordinates (μ, θ) is:

$$\Psi = \begin{cases} \dfrac{1}{32} a^2 [(1 - e^{-2\mu_0} \cosh(2\mu)] \cos(2\theta) \\ \qquad\qquad + \dfrac{1}{32} a^2 [\cosh(2\mu) - \cosh(2\mu_0)], \quad \mu < \mu_0 \\ \dfrac{1}{32} a^2 \sinh(2\mu_0) \left(e^{-2\mu} \cos(2\theta) + 2(\mu - \mu_0) \right), \mu > \mu_0 \end{cases}$$

where $0.5a \sinh(\mu_0) = 1$, and $0.5a \cosh(\mu_0) = \gamma$.

4. Results

An idealized smooth diurnal tide, with equal peaks is considered for analysis. The far field velocity, *U*, changes the blocking parameter, *S*, as the tidal velocity changes. The height, *h*, is taken to be 10m, and the water depth, *d*, to be 35m. Aspect ratios between 1,000 and 250 do not vary the results remarkably. For steady quasigeostrophic flow the streamlines do not vary in the *Z* direction as long as there is no density gradient. The results show that directly at, or adjacent to, the structure is where the system could be impacted by the unique dynamics of periods dominated by quasigeostrophic flow. The character of the rotational effects is asymmetric and for the linear array placed in quasigeostrophic incident flow, the flow around it is distinctly asymmetrical when modelled with [2] analytical solutions. The results for different blocking parameters were considered as "snapshots" of what may occur over time because the time variability of these processes is not understood. The velocity fields at both ends of an array placed perpendicular to the quasi-geostrophic flow were examined for a number of velocities/blocking parameters and plotted against time. The plots reveal that the accelerations on the left-hand side looking downstream were greater than the decelerations on the opposite side, Figure 1. The corresponding effect on power over the period of quasi-geostrophic flow may be estimated from a plot of velocity cubed against time, Figure 2. The flow adjacent to the structure is most affected by the Coriolis force.

For such a perpendicular array (Figures 3 and 4) the flow is accelerated by a factor of 2 on one end, while on the opposite end it the flow rate is 1/2 to 1/5 of the far field velocity. The velocity coefficients at the end points do not change significantly as the blocking parameter increases. For blocking parameters larger than one, the location of the minimal flow (i.e. smallest velocity coefficient) moves away from the structure. The location of the most accelerated flow does not move away from the structure in the same manner. When the blocking parameter increases, flow adjacent to a greater area of the structure experiences acceleration. Furthermore, there is a steady decrease in velocity across the perpendicular array for critical blocking parameters of $O(1)$.

For an array placed parallel to the quasi-geostrophic flow (Figures 5 and 6) the velocity gradient is very sharp over the array. It is remarkable that for such a parallel array, the location of greatest flow deceleration moves significantly farther from the structure when the blocking parameter increases. The sharp velocity gradient appears unrealistic and indicates occurrence of flow separation and high turbulence.
Figure 3: Modeled flow velocity change factors are plotted in color for flow at the depth of the array during quasigeostrophic flow with a blocking parameter, S, equal to 1 and 2. Flow direction is from the left to the right. The coordinate system is normalized using l, the minor axis of the elliptical body, which is 10m for the proposed array. The major axis L is 10,000m. A velocity coefficient of 1 corresponds to the far field velocity U.

Figure 1: Graph of the idealized far field tidal velocity U and the different velocities at both ends of a linear array aligned perpendicular to the tidal velocity. Solutions for perpendicular flow and $\gamma = 1,000$

Figure 4: Modeled flow velocity coefficients are plotted in color for flow at the depth of the array during quasigeostrophic flow with a blocking parameter equal to 2. A reduced velocity will increase the blocking parameter. The decelerated flow has moved away from the obstruction, as compared with S=1. More of the flow adjacent to the obstruction has a velocity coefficient >1 when compared with S=1. Flow direction is from the left to the right. The coordinate system is normalized using l, the minor axis of the elliptical body.

Figure 2: The power produced from an ocean current is proportional to the velocity cubed. A change in the flow around the structure during a tidal change may be experienced by sensitive power generation systems.
Figure 5: The asymmetry of the flow is striking for an array oriented perpendicular to the current. The area adjacent to the array has the greatest change in flow velocity. The array is modeled as static. Flow past the array has a blocking parameter, $S = 1$. The far field velocity has a velocity coefficient of one. The coordinate system is normalized using l, the minor axis of the elliptical body.
Figure 6: Flow past the array during quasigeostrophic flow with a blocking parameter, S = 2. The darkest blue point is the minimum velocity in the vicinity of the structure and this point has moved a significant distance, approximately half the characteristic length, *L*, away from the structure.

4.1. Design Plan

For a line of tidal current turbines at mid to high latitudes rotational flow effects caused by the Coriolis force can impact local dynamics at periods with small inertial currents. The strongest changes in flow dynamics can occur directly adjacent to a structure obstructing a quasigeostrophic flow. Flow acceleration and deceleration can occur around the structure asymmetrically. It appears prudent to make the following design considerations:

1) ensure that the linear array is placed perpendicular to the flow;

2) review local tidal current data and decide if both ebb and flood currents, or just one direction, will be used for power production;

3) prepare your system for an asymmetric velocity gradient, down the line of the array, at periods of tidal change.

One design recommendation for a site where both ebb and tide are utilized for energy production would be to separate the array into a minor and a major field with the two fields separated by supporting equipment. The major field placed on the left side of the array (looking downstream), for the strongest tidal direction. Dummy turbines could be included in the central field of supporting equipment to elongate the array if the asymmetric flow pattern is especially desirable for a production location.

An array parallel to the incident flow is not recommended because of the sharp velocity gradient modeled over it for quasi-geostrophic flow. The modeled gradient is not realistic and suggests occurrence of flow separation and high turbulence.

5. Final Comments

Site specific investigations are crucial for effective array design and deployment. All sites will have unique bathymetry and unique local currents. The variables affecting the layout of the array will include the angle of incident flow; the aspect ratio of the array; the water depth and height of the array; and the latitude at which the array is placed. Placement at higher latitudes will produce higher blocking parameters. The Taylor column phenomenon can be produced by an engineered structure, bottom seated or suspended in the ocean, or by a larger bathymetrical feature on which an engineered structure is placed.

Conflict of Interest

The authors declare no conflict of interest.

An Innovative Angle of Attack Virtual Sensor for Physical-Analytical Redundant Measurement System Applicable to Commercial Aircraft

Antonio Vitale[*], Federico Corraro, Nicola Genito, Luca Garbarino, Leopoldo Verde

CIRA – Italian Aerospace Research Centre, On-Board Systems and ATM, Capua (CE), 81043, Italy

A R T I C L E   I N F O

A B S T R A C T

The angle of attack is a critical flight parameter for commercial aviation aircraft, because automatic envelope protection systems rely on it to keep the aircraft within its safe flight envelope. Faulty measurements of the angle of attack could have catastrophic effects, leading to aircraft loss of control in flight and fatalities, as demonstrated by the recent accidents involving the Boeing 737-MAX. This paper presents a novel approach to the measurement of the angle of attack, which uses one virtual sensor and two physical sensors to implement a physical-analytical redundant system that is robust to a single fault of the physical sensors. The virtual sensor is based on an innovative and reliable estimator of the angle of attack. It was originally developed to provide General Aviation pilot with an accurate indication of trend toward stall, and has been suitably customized to fit its application to commercial aviation. One of the peculiarities of the redundant measurement system is that its implementation on-board several existing commercial aviation aircraft only needs the integration of a software code and does not require any installation of additional physical sensors. The proposed approach demonstrated very interesting performance, assessed in simulation through several Monte Carlo analyses. Its exploitation could contribute to reduce the angle of attack related accidents, improving the safety of the air transport system.

1. Introduction

This paper is an extension of work originally presented in SYSTOL'19 [1]. The original work defined an innovative method for the estimation of the angle of attack (AoA), which does not require any physical sensor dedicated to the measurement of the AoA. The present paper proposes a novel measurement system. It exploits the innovative estimator described in [1] and two physical sensors of the AoA, usually available on commercial aircraft, to compute a more reliable measurement of the angle of attack, which is robust to a single fault of the physical sensors. The paper defines the architecture and the algorithms of the proposed measurement system and discusses in depth its performance, which has been assessed through Monte Carlo simulations.

Loss of Control – In Flight (LOC-I) defines a condition in which the flight crew is unable to maintain the control of an aircraft while it is flying, resulting in an unrecoverable deviation from the intended flight path. LOC-I is the most significant cause of fatal accidents in General Aviation (GA): there are approximatively 37 fatal LOC-I accidents per year in Europe involving GA aircraft, leading to 67 persons on average losing their lives every year (for fixed-wing aircraft only) [2]. The LOC-I accidents can result from several contributing factors, which can act individually or in combination. They often result from failure to prevent or recover from a stall. An aircraft stalls if it exceeds the critical angle of attack and it may occur at any indicated airspeed. Hence, the only use of an airspeed indicator is unreliable to detect the proximity to stall. The measurement of the angle of attack could complement the airspeed information, prevent to enter an upset condition and allow performing safer manoeuvers. General Aviation aircraft often are not equipped with AoA sensors. The availability of suitable methods or affordable and reliable instruments to estimate or measure the angle of attack and to display its current value to the pilot would be dramatically beneficial for this aircraft category. Indeed, it could facilitate earlier detection of danger conditions and could permit adjusting power and configuration to avoid displacing the aircraft from the intended path. Additionally, the knowledge of the angle of attack could reduce the pilot workload [3], [4].

[*]Corresponding Author: Antonio Vitale, Italian Aerospace Research Centre, via Maiorise, 81043, Capua (CE), Italy, Email: a.vitale@cira.it

Based on these motivations, several methods for the estimation of the angle of attack are described in the literature. Many methods use the Kalman Filter [5]-[9], which exploits nonlinear kinematics equations for the propagation of the AoA estimation, and measurement models, coupled with suitable measurements, to correct the estimation. Usually, this approach is model-based and requires the knowledge of the aircraft aerodynamic model [5]-[7]. The estimator proposed in [8] does not need the aerodynamics of the aircraft neither other aircraft parameters; but the method works properly only if the aircraft dynamics are excited by continuously changing pitch and yaw angles. Model-based estimation methods that do not use the Kalman Filter are proposed in [10] and [11]; both these approaches require as input a detailed model of the aircraft aerodynamics. In [10] the data fusion of GPS (Global Positioning System) and IMU (Inertial Measurements Unit) sensors together with the aerodynamic information allow computing the angle of attack, whereas in [11] a Bayesian estimator provides it. In [12] the angle of attack calculation only relies on inertial data, but obtained estimation accuracy is not good in windy and turbulent conditions. The authors of [13] estimate the AoA by using a complementary filter. The steady state low frequency component of the estimation is obtained by solving algebraically the angle of attack kinematic equation, in which the AoA derivative is set equal to the pitch rate. The angle of attack high frequency content is considered coincident with the pitch rate. However, this simple method provides estimations which are characterized by high mean error and standard deviation. A Virtual Sensor is presented in [14]. It uses a Functional Pooling Non-linear Auto-Regressive with eXogenous excitation (FP-NARX) methodology that provides very good performance. However, this method requires the availability of a wide set of flight data, which shall cover the whole flight envelope of the aircraft in order to identify the NARX model that reconstructs the AoA behavior. Model-free virtual sensors for the angle of attack measurement are available in the literature, too. They mainly use neural networks [15], [16], which has the drawback to need huge amount of data for the training of the network.

This paper is an extension of the work presented in [1], which describes an innovative approach to estimate the angle of attack, developed and patented [17] by the Italian Aerospace Research Centre (CIRA) and ASPEN Avionics. The new AoA estimator aimed at dramatically improving the safety of GA aircraft, by providing an immediate, accurate, and clear visual display of trend toward stall and stall margin. It does not need the installation of external dedicated sensors, which is the key factor in limiting the adoption of angle of attack instruments by General Aviation pilots. The AoA computation exploits an Extended Kalman Filter and the measurements provided by navigation sensors that are more reliable than physical angle of attack sensors. The main innovative feature of the proposed method with respect to what already proposed in the literature is that it does not need detailed information about the aerodynamics of the aircraft neither huge amount of flight data for calibration/training. It only requires the knowledge of few aircraft parameters, easily gathered from the Pilot Operating Handbook (POH), and the execution of a short calibration flight, to carry out just once. This calibration flight is aimed at identifying the relevant aircraft aerodynamic parameters needed to tune the algorithm for the estimation of the angle of attack. The proposed estimator is operative on-board several

hundreds of private General Aviation aircraft since July 2015 without experiencing any problem.

The availability of reliable information about the angle of attack is very valuable to commercial aircraft, too. Higher levels of automation support the piloting tasks of commercial aircraft: the envelope protection systems exploit the angle of attack measurement to implement automatic corrective actions if the aircraft is approaching its flight envelope boundaries. These systems should improve the flight safety. However, in case of wrong angle of attack measurement, they could lead to LOC-I and fatalities, especially if the aircraft is performing critical flight phases such as take-off or landing. In fact, LOC-I is the leading cause of fatal accidents in commercial aviation and it is one of the accident categories with the lowest survivability ratio [18].

These statistics are confirmed by the recent flight accidents in March 2019 [19] and in October 2018 [20], which involved the Boeing 737-8 (MAX) operated by the Ethiopian Airlines and by the Lion Air, respectively. The investigation reports state that both the aircraft had a failure of one angle of attack sensor that dramatically affected the behavior of the envelope protection system. The Boeing 737 MAX has two independent physical sensors to measure the angle of attack, one sensor on each side of the forward fuselage. These sensors consist of an external vane, which rotates to align with the local airflow, connected to an internal resolver that measures the rotation angle. The aircraft is also equipped with a stability augmentation function, called the Maneuvering Characteristics Augmentation System (MCAS), which aims to improve the aircraft handling characteristics. Specifically, the MCAS was introduced to counteract the aircraft tendency to pitch-up when it flies at elevated angles of attack. This unwanted behavior is an effect of the new engines that were installed in the 737 MAX with respect to the previous 737 models. During the Ethiopian Airlines accident flight, soon after the lift-off, the left and right vanes provided different measurements of the AoA: the left measurement reached 74.5 degrees, while the right sensor showed a maximum value of 15.3 degrees. The difference between left and right AoA measurements (about 59 degrees) remained constant until the end of the recording [21]. The erroneous measurement of the angle of attack was not detected and it affected the pitch command. Indeed, the MCAS considered valid the left sensor's measurement and pushed down the nose of the aircraft several times. The crew tried to keep the aircraft along its planned flight path, but lost the control and the aircraft crashed. Figure 1, that is an excerpt of [21], shows the angle of attack measurements before the crash, pointing out the failure of the left sensor. The Flight Data Recorder of the Lion Air accident also registered differences between the measurements of the angle of attack (about 20 degrees) provided by the left and right sensors, as shown in Figure 2, taken from [22]. The erroneous angle of attack measurement produced multiple alerts and repetitive MCAS activations, which combined with pilot distractions due to numerous ATC communications contributed to the flight crew difficulties to control the aircraft and leaded to the crash after a steep dive.

Faulty angle of attack measurement was the cause of other incidents in the past, such as the crash of the Airbus A320-232 operated by XL Airways Germany on 27th November 2008 [23] and the incident of the Airbus A321-231 operated by Lufthansa

(flight 1829) on 5th November 2014. In this last case, the fault of the angle of attack sensor caused the anti-stall system to push down the nose of the aircraft, but since the aircraft was flying at high altitude, the crew was able to react, avoiding catastrophic results [24]. All these incidents remark that the availability of a fault tolerant system for the measurement of the angle of attack is very valuable. Triplex redundancy of physical sensors could be a solution to be robust with respect to a single sensor fault; however, triplex hardware redundancy is not always implemented for angle of attack sensor (the Boeing 737 MAX is an example).
Figure 1: AoA measurements for the Ethiopian Airlines accident [21]
Figure 2: AoA measurements for the Lion Air accident [22]

The authors of the present paper deem that a suitable customization of the AoA estimator developed for GA aircraft and presented in [1] and [17] could help addressing the issues discussed for Commercial Aviation aircraft. Indeed, it could be exploited as an additional virtual sensor that, coupled with existing physical sensors and suitable voting algorithms [25]-[27], allows to implement a physical-analytical redundant measurement system that is robust to a single fault of the physical sensors. This measurement system could significantly improve the safety of the aircraft, reducing the occurrence of LOC-I related accidents, saving human lives, and avoiding the economic impact on the airliners and the aircraft manufacturers consequent to those accidents. The main benefit of this research to the industry consists in the possibility to achieve this result without the need for hardware modification to the existing aircraft, installation of additional physical sensors or change to the avionics hardware architecture. In fact, the proposed approach just requires the installation of the software code for the computation of the robust angle of attack measurement, which exploits as input the measurements provided only by the sensors already available on-board.

The next sections of the paper detail the proposed approach. The innovative AoA estimator is first described in section 2. Next, a possible application to commercial aviation aircraft is proposed, defining the architecture and the algorithms to implement a robust fault tolerant measurement system. Finally, section 4 shows the performance of the proposed method, assessed in simulation through Monte Carlo analysis. A section of conclusion ends the paper.

2. Angle of Attack Virtual Sensor

The design of the proposed angle of attack estimator was originally based on the following requirements:

- to be applicable to a wide set of aircraft;

- to exploit the information commonly available for GA aircraft;

- the installation of specific additional sensors shall not be required.

These requirements imply that the estimation method shall not require the knowledge of the detailed aerodynamic model, that is specific of each type of aircraft.

The proposed approach works in two steps. First, the parameters of the estimation algorithm are tuned through a calibration procedure, which consists in performing a flight test that shall be executed just once. Next, normal operations are carried out, that is, the estimator could compute the angle of attack during the flight.

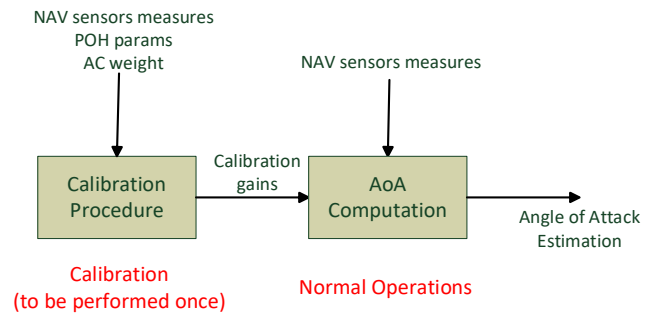
The proposed method uses the measurements provided by sensors which are usually exploited for primary navigation and does not need a dedicated angle of attack sensor. It guarantees that the measurement's accuracy is independent upon the installation of the AoA sensor. It is worthy to note that the same set of sensors is used both for the calibration and in the normal operations. Figure 3 shows the basic concept of the virtual sensor. The following subsections details the calibration procedure and the angle of attack computation.


Figure 3: AoA virtual sensor basic concept

2.1. Calibration Procedure

The calibration procedure aims at identifying the lift curve of the aircraft and consists in flying steady and wing leveled at two different airspeed values (set points), which are close to the boundaries of the aircraft flight envelope. The test is repeated for each aircraft configuration that has significantly different aerodynamic characteristics. The calibration requires the knowledge of:

- few parameters available in the POH: MTOW (Maximum Take-off Weight), SEW (Standard Empty Weight), Stall Speed and Maximum Speed in clean and flapped configurations

- aircraft weight (it is worthy to remark that the weight shall be known only during the calibration flight and not during normal operations of the virtual sensor).

The lift (L) is assumed linear with respect to the angle of attack (α) and to the deflection of the longitudinal aerodynamic surfaces (δ_i):

$$L = QSC_L = QS\left(C_{L0} + C_{L\alpha}\alpha + \sum_i C_{L\delta}^i \delta_i\right) \quad (1)$$

where Q is the dynamic pressure, C_L is the lift coefficient, S is the aerodynamic reference surface, C_{L0}, $C_{L\alpha}$ and $C_{L\delta}^i$ are the lift aerodynamic derivatives. The contribution to the lift of all the longitudinal surfaces deflection is assumed negligible, except for the flaps (δ_F). Two flap configurations are considered for GA aircraft, clean and full flap. Each configuration has a different lift curve, which is still assumed linear and is uniquely identified by its slope ($C_{L\alpha}$) and intercept (C_{L0}). The calibration procedure is performed for both the configurations, the corresponding aerodynamic derivatives C_{L0}, $C_{L\alpha}$ are computed, and a linear variation for these derivatives is assumed to compute their values for intermediate configurations of the flaps. This approach implies that the values of C_{L0} and $C_{L\alpha}$ depend on the deflection of the flaps, whereas the explicit dependence in equation (1) of L on δ_F could be delated; therefore, the equation (1) could be reformulated as:

$$L = QS(C_{L0}(\delta_F) + C_{L\alpha}(\delta_F)\alpha) = QW\left(\hat{k}_0(\delta_F) + \hat{k}_1(\delta_F)\alpha\right) \quad (2)$$

where W is the aircraft weight and the parameters $\hat{k}_0, \hat{k}_1$, named calibration gains, are defined as follows (the dependence of C_{L0}, $C_{L\alpha}$, $\hat{k}_0$ and $\hat{k}_1$ on δ_F is not shown for the sake of conciseness):

$$\hat{k}_1 = \frac{S}{W} \cdot C_{L\alpha} \quad (3)$$

$$\hat{k}_0 = \frac{S}{W} \cdot C_{L0} \quad (4)$$

During the calibration flight, the aircraft weight is denoted as W_{cal} and the calibration gains (a set for each configuration) are computed as defined in [17]:

$$\hat{k}_{1cal} = \frac{S}{W_{cal}} \cdot C_{L\alpha} = \left(\frac{1}{Q_2} - \frac{1}{Q_1}\right) / (\vartheta_2 - \vartheta_1) \quad (5)$$

$$\hat{k}_{0cal} = \frac{S}{W_{cal}} \cdot C_{L0} = \left(\frac{1}{Q_1} - \frac{1/Q_2 - 1/Q_1}{\vartheta_2 - \vartheta_1} \cdot \vartheta_1\right) \quad (6)$$

where ϑ is the pitch angle. All the variables on the right-hand sides of the above equations represent measurements gathered during the calibration flight and the subscripts 1 and 2 refer to the set point index (two set points for each aircraft configuration). Therefore, the calibration gains could be easily evaluated.

Replacing (5) and (6) in (2) and rearranging, we get the lift equation applicable during normal operations [17]:

$$L = QW_{conv}(k_0 + k_1\alpha) \quad (7)$$

$$\hat{k}_{0cal} = \frac{S}{W_{cal}} \cdot C_{L0} = \left(\frac{1}{Q_1} - \frac{1/Q_2 - 1/Q_1}{\vartheta_2 - \vartheta_1} \cdot \vartheta_1\right) \quad (8)$$

where W_{conv} is the actual aircraft weight if it is known, otherwise it is a conventional weight given by [17]:

$$W_{conv} = max\{W_{cal}, [C_0 + W_{SEW} + C_1(W_{MTOW} - W_{SEW})]\} \quad (9)$$

The values of the constants C_0 and C_1 are computed with the aim to optimize the angle of attack estimation error.

2.2. Angle of Attack Computation

After the completion of the calibration procedure, the virtual sensor can estimate the angle of attack. The estimation algorithm exploits an Extended Kalman Filter (EKF), which combines the knowledge of the lift curve, identified during the calibration, with the measurements get from ADS (air-data system), GPS and IMU. The EKF state vector includes five variables, that is, the angles of attack (α) and sideslip (β) and the wind velocity components (W_N, W_E, W_D), expressed in North-East-Down (NED) reference frame. Classical kinematic equations in polar form [28] describe the dynamics of the aerodynamic angles, whereas stochastic zero-order Gauss-Markov processes [29] are used to represent the wind velocity behavior. These equations are applicable to any type of aircraft [17]:

$$\begin{aligned}
\dot{\alpha} = &\frac{1}{TAS\cos\beta}(a_z\cos\alpha - a_x\sin\alpha) + q \\
&- \tan\beta\,(p\cos\alpha + r\sin\alpha) \\
&+ \frac{1}{TAS\cos\beta}[u_w q\cos\alpha \\
&- v_w(r\sin\alpha + p\cos\alpha) \\
&+ w_w q\sin\alpha] + \eta_\alpha
\end{aligned}$$

$$\begin{aligned}
\dot{\beta} = &\frac{1}{TAS}(-a_x\cos\alpha\sin\beta + a_y\cos\beta \\
&- a_z\sin\alpha\sin\beta) + p\sin\alpha \\
&- r\cos\alpha \\
&+ \frac{1}{TAS}[-u_w(r\cos\beta \\
&+ q\sin\alpha\sin\beta) \\
&+ v_w(p\sin\alpha\sin\beta \\
&- r\cos\alpha\sin\beta) \\
&+ w_w(p\cos\beta \\
&+ q\sin\beta\cos\alpha)] + \eta_\beta
\end{aligned}$$

$$\dot{W}_i = \eta_{W_i} \qquad with\ i = N, E, D \quad (12)$$

where:

- a_x, a_y and a_z are the inertial acceleration components in the body reference frame (provided by the IMU);
- p, q and r are the angular rates components (roll, pitch and yaw rate) in the body reference frame (provided by the IMU);
- TAS is the module of the true air speed (provided by the ADS);
- $\eta_\alpha, \eta_\beta, \eta_{W_N}, \eta_{W_E}$ and η_{W_D} are process noises, which are assumed zero mean multivariate Gaussian with covariance matrix Q_{noise};
- u_w, v_w and w_w are the wind velocity components expressed in the body reference frame and computed as:

$$\begin{bmatrix} u_w \\ v_w \\ w_w \end{bmatrix} = \bar{\bar{R}}_{BI}^{-1} \times \begin{bmatrix} W_N \\ W_E \\ W_D \end{bmatrix} \quad (13)$$

- $\bar{\bar{R}}_{BI}$ is the Transformation matrix from body axes to NED axes.

The measurement vector is given by the inertial velocity components (V_N, V_E, V_D) in the NED reference frame (provided by the GPS) and the normal load factor (N_z) in body axes (provided by the IMU). The following equations are used [17]:

$$\begin{bmatrix} V_N \\ V_E \\ V_D \end{bmatrix} = \bar{\bar{R}}_{BI} \times \begin{bmatrix} TAS \cdot \cos\alpha \sin\beta \\ TAS \cdot \sin\beta \\ TAS \cdot \cos\beta \sin\alpha \end{bmatrix} + \begin{bmatrix} W_N \\ W_E \\ W_D \end{bmatrix} + \begin{bmatrix} v_{V_N} \\ v_{V_E} \\ v_{V_D} \end{bmatrix} \quad (14)$$

$$N_z = Q \cdot (k_1 \cdot \alpha + k_0) + tg(\alpha) \cdot N_x \quad (15)$$

where:

- N_x is the axial load factor;
- v_{V_N}, v_{V_E} and v_{V_D} are measurement noises, which are assumed zero mean multivariate Gaussian with covariance matrix R_{noise};
- k_1 and k_0 are the calibration gains.

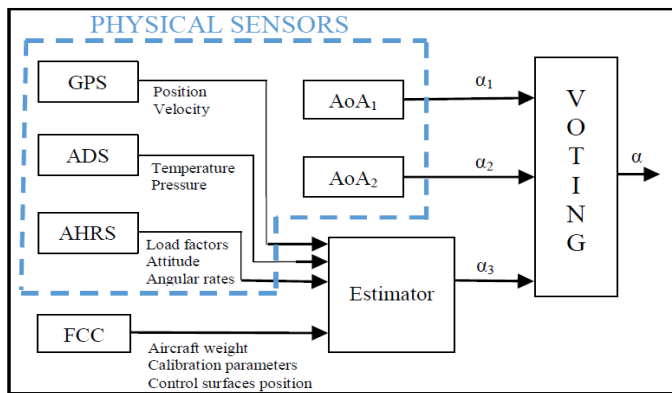
The last measurement equation holds in the hypotheses of thrust aligned to the X-body axis (that is, with negligible contribution to the normal load factor) and small angle of attack approximation. If a measurement of the current thrust is available, then the contribution along the normal load factor could be added in the equation to remove the approximation. Finally, it is also worthy to note that if the calibration gains k_1 and k_0 are computed using the conventional weight instead of the actual one, then an approximation is introduced that affects the computation of the right-hand side of the equation (15) and consequently of the angle of attack. The availability of the measurement of the actual weight allows removing this approximation and improving the estimation results.


Figure 4: Physical-analytical redundant angle of attack architecture

3. Fault Tolerant Angle of Attack Measurement System for Commercial Aircraft

The proposed angle of attack estimator is applicable to commercial aviation aircraft after a suitable customization. Commercial aircraft are already equipped with one or more (but sometimes less than three [25]) physical angle of attack sensors. Indeed, the angle of attack measurement is nowadays a critical flight parameter as well as other primary navigation measurements. The introduction of a virtual sensor provides an

additional and independent measurement, which in conjunction with the physical sensors, allows implementing a single fault tolerant measurement system based on physical-analytical redundancy. Figure 4 shows a possible architecture of the proposed angle of attack measurement system, which exploits two physical sensors of the AoA.

The following subsections detail the customization of the estimator with respect to the one developed for GA aircraft and the voting algorithms applied to compute the consolidated AoA measurement out of the three AoA inputs.

3.1. Virtual Sensor Customization to Commercial Aviation

Some of the assumptions introduced in the design of the estimator for GA application can be removed if the estimator is applied to commercial aircraft.

First, in commercial flight an estimation of the aircraft weight is entered in the aircraft Flight Control Computer (FCC) before each flight, therefore it is a known parameter (although roughly) that can be provided as input to the AoA estimator. The use of a fuel consumption model allows computing the weight variation during the flight execution. Consequently, in the equations (7) and (8) the conventional weight can be replaced by the actual one and equation (9) is not used. Moreover, it is worthy to note that the availability of two physical sensors of the angle of attack allows improving the knowledge of the aircraft weight online while the aircraft is flying. Indeed, when the physical measurements coincide (that means supposedly the physical sensors are working properly), the value of the aircraft weight in the AoA estimation algorithm could be tuned (within a reasonable range) to force the virtual sensor measurement to converge to the physical ones. A suitable strategy can be defined to perform periodically this check and possibly to update the aircraft weight.

Second, commercial aircraft have several control aerodynamic surfaces and their configuration affects the lift curve of the aircraft. The deflection of each of these control surfaces is available to the FCC and it shall be used as an additional input to the AoA estimation algorithm. This consideration implies a modification to the aerodynamic modelling. The lift equation is more complex than the one defined by equation (7). It shall consider the effect of all the relevant aerodynamic surfaces, which in first approximation are assumed having a linear effect (however, quadratic, cubic or in general polynomial effects could be also used). Accordingly, the lift is given by:

$$L = QSC_L = QS\left(C_{L0} + C_{L\alpha}\alpha + \sum_i C_{L\delta}^i \delta_i\right)$$
$$= QW\left(k_0 + k_1\alpha + \sum_i k_\delta^i \delta_i\right)$$

where δ_i is the deflection of the i-th aerodynamic surface and k_δ^i is an additional calibration gain for each surface (more than one gain could be introduced for each surface if nonlinear effects are considered). Concerning the calibration process, the main differences with respect to the General Aviation aircraft are:

- an increased number of set points during the calibration flight shall be gathered, due to the increased number of calibration gains that shall be computed;

- the measurement of the deflection of each aerodynamic control surface is available and could be used as input to the calibration computation;

- the angle of attack measurement is available during the calibration (provided by the physical sensors), therefore it shall not be replaced by the pitch angle measurement.

The calibration test is performed first gathering two set points at different speeds (close to the aircraft's envelope limits) in clean configuration. The measurements in these set points allow the computation of the gains k_0 and k_1 by using equations (5) and (6), in which the angle of attack measurements replace the pitch angle ones. Next, two additional set points are gathered for each aerodynamic surface. These set points are collected again at two different speeds; only the aerodynamic surface related to the gain to be computed is deflected, whereas the deflections of all the other surfaces are null. Each gain is computed through:

$$k_\delta^i = \frac{S}{W_{cal}} C_{L\delta_i} = \left(\frac{Q_{i1} - Q_{i2}}{Q_{i2}\delta_{i2} - Q_{i1}\delta_{i1}}\right) k_0 + \left(\frac{Q_{i1}\alpha_{i1} - Q_{i2}\alpha_{i2}}{Q_{i2}\delta_{i2} - Q_{i1}\delta_{i1}}\right) k_1 \tag{17}$$

where the subscripts i_1 and i_2 identify the two set points related to the i-th surface; α, δ and Q are measured and k_0 and k_1 are already computed at this stage.

The availability of measurements of the actual weight of the aircraft and of the aerodynamic control surfaces deflection allows removing the approximations introduced in the estimator algorithm designed for GA application, leading to a significant improvement of the estimation accuracy.
Figure 5: Effect of faulty AoA measurement on the airspeed computation [21]

Finally, it is worthy to remark that, during normal operations, the angle of attack computed by the estimator shall be completely independent from the AoA measurements provided by the physical sensors, in order to implement correctly the analytical redundancy. The estimator, as shown in Figure 4, exploits the measurements from GPS, AHRS and ADS sensors. GPS and AHRS are completely independent from the vane sensor. On the other hand, the AoA measured by the vane is usually exploited to correct the raw value of the static pressure measured by the ADS, in order to compensate for errors due to sensor position and aerodynamic effect. The corrected static pressure is then used by the air data computer to calculate the true airspeed, which therefore is influenced by the AoA measured by the vane. The effect of the AoA on the computation of the airspeed is pointed out by the data of the Ethiopian Airlines accident flight. Figure 5, excerpt of [21], shows the computed airspeed based on the static pressure corrected with left and right angle of attack measurements. The erroneous AoA values, provided by the left

sensor, produced corrected static pressure values greater than the true ones and consequently the computed airspeed values are lower than the true ones.

The row static pressure values (before applying the correction based on the AoA measurement) from both sides were identical, as shown in Figure 6 [21]. The different static pressure measurements highlighted in Figure 5 were therefore only due to the AoA correction. This effect should be considered in the selection of the inputs to the angle of attack estimation algorithm. Specifically, the uncorrected values of all the air data sensors shall be provided to the estimator. Possibly corrections of these inputs depending on the angle of attack shall be based on the AoA value computed by the estimator itself, at the previous computation time step. This approach guarantees the independence of the measurements provided by the analytical and physical sensors and used as input to the voting algorithm.
Figure 6: Static pressure reconstruction without AoA correction [21]

3.2. Voting and Signal Validity Check Algorithms

The voting algorithm consists in generating one single angle of attack measurement (consolidated value) out of three input signals of a triplex redundant architecture. Different voting techniques are available in the literature. The proposed approach applies a weighted voting, in which the consolidated signal is computed through a weighted mean of the valid inputs:

$$\alpha = \sum_{i=1}^{3} p_i \alpha_i \tag{18}$$

$$\sum_{i=1}^{3} p_i = 1 \qquad with \qquad 0 \le p_i \le 1 \tag{19}$$

where α is the consolidated value, α_i is the i-th measurement, and p_i is the i-th weight. Several choices could apply to the definition of the weights. They can be all equal, or a bigger weight could be assigned to the median input [25], or the weights could be all different, based on some metrics or criteria [26]. For each signal we define a weight that is inversely proportional to the supposed precision of the sensor providing the measurement. Assuming the input measurements are affected by a Gaussian error with standard deviation σ_i, the following weights are used:

$$p_i = F_i \frac{\frac{1}{\sigma_i}}{\sum_{i=1}^{3} \frac{1}{\sigma_i}} \tag{20}$$

where F_i is the validity flag of the i-th measurement, which is null if the input measurement is invalid, otherwise it values 1. To check the validity of each input, the algorithm computes at each time step the difference between the measurements of the angle of attack provided by the available sensors, and for each couple of sensors compares the difference (D_{ij}) with a suitable threshold (T_{ij}):

$$D_{12}(t_k) = |\alpha_1(t_k) - \alpha_2(t_k)| < T_{12} \qquad (21)$$

$$D_{13}(t_k) = |\alpha_1(t_k) - \alpha_3(t_k)| < T_{13} \qquad (22)$$

$$D_{23}(t_k) = |\alpha_2(t_k) - \alpha_3(t_k)| < T_{23} \qquad (23)$$

If both the differences related to the i-th measurement exceed the related thresholds (that is, the above relations involving the signal α_i are not satisfied) continuously for a predefined number of samples N_s, the i-th measurement is declared invalid and F_i is set equal to zero. Consequently, the computation of the consolidated value does not use the i-th measurement, because related weight is null. The thresholds are given by:

$$T_{ij} = C_{ij}(\sigma_i + \sigma_j) \qquad (24)$$

The values of both the constant C_{ij} and the number of samples N_s used to check conditions (21) to (23) are selected as a trade-off, in order to maximize the capability to detect invalid signals while minimizing the false alarm rate.

4. Angle of Attack Measurement System Performance

The performance of the proposed measurement system has been assessed in simulation through Monte Carlo analyses. The Monte Carlo technique is a procedure for numerically obtaining an estimation of the statistical characterization (mean, variance, cumulative probability, etc.) of a function's output. To this end, the input parameters of the function vary independently according to their statistical characterization, and the output of the function is computed for each realization of these inputs. The statistics of the output are then evaluated. Results presented in this section concern the angle of attack estimator (also including the calibration procedure) and the triplex redundant measurement system. A simulation tool was implemented as test harness to execute the analyses.

4.1. Simulation Tool

The simulation tool is implemented in Matlab/Simulink environment and is composed of:

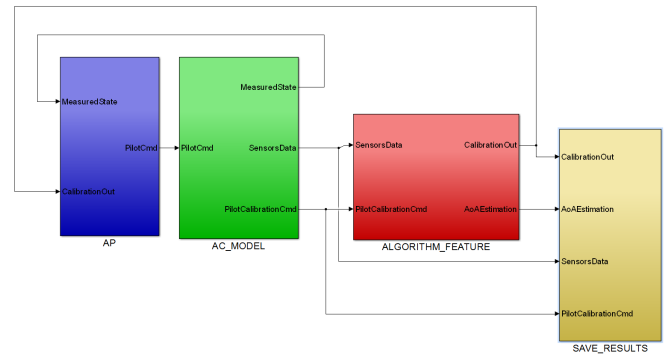
- The main routine, which allows:
  o setting up the flight test manoeuver,
  o varying the inputs of the Monte Carlo analysis according to their statistical characterization
  o computing the performance metrics.
- A simulation model, presented in Figure 7, which includes:
  o AC Model – the detailed parametric models for the simulation of the aircraft, the atmosphere (winds and turbulence) and the on-board sensors.
  o AP – an autopilot that is able to perform automatically the requested test manoeuver.
  o Algorithms Feature – a module implementing the algorithms for the angle of attack estimation.
  o Save Results – a module that saves the simulated inputs and computed outputs.


Figure 7: Simulation model for Monte Carlo analyses

- A routine that implements the triplex redundant AoA measurement system and computes the consolidated angle of attack.

The aircraft is modelled using the flight mechanics equations of a six degrees of freedom rigid body [30] and comprises a detailed aerodynamic model, also reproducing the stall phenomenon. The aircraft model has been validated in flight through the CIRA experimental aircraft [31]. The simulation of the relevant atmospheric phenomena is based on the ISA standard atmosphere [30] and the Dryden turbulence model [32]. The atmosphere model includes horizontal constant winds (variable with altitude), three-dimensional turbulence disturbances, and vertical gust (represented through "1-cosine" model) [32]. The three-dimensional turbulence is modelled by applying appropriate forming filters to band-limited white noise; the longitudinal, lateral, and vertical components (Φ_u, Φ_v, Φ_w) of the spectra of these forming filters are given by:

$$\Phi_u(\omega) = \frac{2\sigma_u^2 L_u}{\pi TAS} \frac{1}{1 + \left(\frac{L_u \omega}{TAS}\right)^2} \qquad (25)$$

$$\Phi_v(\omega) = \frac{2\sigma_v^2 L_v}{\pi TAS} \frac{1 + 12\left(\frac{L_v \omega}{TAS}\right)^2}{\left[1 + 4\left(\frac{L_v \omega}{TAS}\right)^2\right]^2} \qquad (26)$$

$$\Phi_w(\omega) = \frac{2\sigma_w^2 L_w}{\pi TAS} \frac{1 + 12\left(\frac{L_w \omega}{TAS}\right)^2}{\left[1 + 4\left(\frac{L_w \omega}{TAS}\right)^2\right]^2} \qquad (27)$$

where (L_u, L_v, L_w) and (σ_u, σ_v, σ_w) represent the turbulence scale lengths and intensities, respectively. The vertical gust velocity (V_{vg}) is computed through:

$$V_{vg}(x) = \begin{cases} 0 & x < 0 \\ \frac{V_m}{2}\left[1 - cos\left(\frac{\pi(x)}{d_m}\right)\right] & 0 \le x \le 2d_m \\ 0 & x > 2d_m \end{cases} \qquad (28)$$

where V_m is the maximum gust magnitude and d_m is the gust half-width.

The sensors model simulates actual sensors (ADS, AHRS, GPS) that measure the signals needed by the algorithms under test. The models of the ADS and AHRS compute the measurements of the generic signal (s_m) at time t_k by adding bias (b_s) and Gaussian noise (v_s) to the true signal value (s_t):

$$s_m(t_k) = s_t(t_k) + b_s + v_s(t_k) \qquad (29)$$

A low pass filter is then applied to the signal s_m, in order to emulate the sensors dynamics (frequency band limitation). The GPS model also introduces a data latency (δt) in the measurements, which is assumed negligible for the other sensors [33]:

$$s_{mGPS}(t_k) = s_t(t_k - \delta t) + b_s + v_s(t_k - \delta t) \qquad (30)$$

The data sheets of commercial off the shelf sensors are used to define bias, noise, latency and low pass filter characteristics. The sensors model allows injecting a failure in the measurement, such as additional bias, drift, or data freezing. In the Monte Carlo analyses, this feature was used only to simulate the failure of the angle of attack physical sensors.

4.2. Monte Carlo Analyses

Three different Monte Carlo analyses were performed to assess the performance of the following functionalities:

- calibration of the AoA estimation algorithm,
- AoA estimation,
- fault tolerant AoA measurement system.

The first two analyses were carried out considering three different classes of GA aircraft (light, medium and heavy airplanes). Indeed, the AoA estimation algorithm and its calibration procedure were originally designed for this category of aircraft. It is worthy to remark that this choice is conservative, because, as explained in the previous sections, improved results are obtained if the AoA estimator is applied to commercial aircraft. In the considered analyses the following parameters of the simulation model varied according to their statistical characterization, in order to obtain an accurate statistical assessment of the algorithms under investigation:

- aircraft weight, centre of gravity and inertia matrix;
- sensors' measurement error (bias and white noise);
- initial flight conditions;
- atmospheric conditions: horizontal wind (direction between 0 and 360 degrees, intensity up to 20Kts), turbulence (three levels of turbulence intensity), vertical gusts (cosine shape).

Uniform distribution is assumed for all these parameters, in order to get conservative results [34].

The last Monte Carlo analysis assumes the availability of a triplex AoA measurement (two physical sensors plus the AoA estimator) and assesses the performance of the proposed angle of attack measurement system, only considering the angle of attack trajectories and regardless of the aircraft being a GA or a commercial aircraft.

4.3. Performance Assessment Results

The first Monte Carlo analysis allowed getting a statistical characterization of the calibration gains and then of the aircraft lift model. The analysis comprised 1000 simulation runs for each of the considered aircraft classes. The actual aircraft weight, which is

required as input to the procedure, was corrupted with a measurement error

$$W_m = W_t(1 + v_W) \qquad (31)$$

where W_m and W_t are measured and true weights, respectively, and v_W is a random noise that varies from one simulation run to the other with uniform distribution in the range [-0.03, 0.03] (that is, the measurement error is in the range ±3% of the true weight). Concerning the model of the atmosphere, the turbulence level varied randomly between 0 and 1. Figure 8 and Figure 9 present the results for one of the considered aircraft categories, showing the estimation of the coefficients C_{L0} and $C_{L\alpha}$ normalized with respect to their true values, which are known in simulation.
Figure 8: Normalized C_{L0} ceofficient computed in the calibration
Figure 9: Normalized $C_{L\alpha}$ ceofficient computed in the calibration

Due to the turbulence and to the poor performance of the used autopilot, not all the 1000 calibrations were successful (the success rate was about 75%), that is, the aircraft was not able to keep the required stationary flight condition for a predefined period. The mean error on the C_{L0} estimation, computed on the successful tests, is about 20%, whereas the mean value of the estimated $C_{L\alpha}$ is very close to its true value. In order to assess the effect of these errors on the AoA estimation, a subset (250 samples) of the calculated couples (C_{L0}, $C_{L\alpha}$) was used to estimate the angle of attack in the same conditions flown to perform the calibration. The accuracy of the estimation, evaluated as the mean of the root mean square error (RMS), is 0.64 degree.

The second Monte Carlo focused on the AoA estimation. Several typical manoeuvers were considered, such as level flight, turn, climb, descend, stall, stall in sideslip, stall in turn. A dedicated Monte Carlo analysis was performed for each of these

manoeuvers. In each run, the calibration gains k_1 and k_0 were randomly drawn from the results obtained in the calibration Monte Carlo analysis for the same aircraft category. The number of simulations performed in each Monte Carlo Analysis was chosen in order to have a stable root mean square (RMS) error and to get the 95% confidence level on the probability to have the RMS below a given threshold. Indeed, given a condition P_X to check (such as, the RMS error is below the threshold), the confidence interval on the satisfaction of the condition can be computed as [35], [36]:

$$Low = \frac{k_{suc}}{N_{test}} + \frac{3}{4}\frac{1 - \frac{2k_{suc}}{N_{test}} - \sqrt{1 + 4\vartheta_P k_{suc}\left(1 - \frac{k_{suc}}{N_{test}}\right)}}{1 + \vartheta_P N_{test}} \quad (32)$$

$$Upp = \frac{k_{suc}}{N_{test}} + \frac{3}{4}\frac{1 - \frac{2k_{suc}}{N_{test}} + \sqrt{1 + 4\vartheta_P k_{suc}\left(1 - \frac{k_{suc}}{N_{test}}\right)}}{1 + \vartheta_P N_{test}} \quad (33)$$

$$\vartheta_P = \frac{9}{8log\left(\frac{2}{\varepsilon}\right)} \quad (34)$$

$$Pr\{Low < P_X < Upp\} > 1 - \varepsilon \quad (35)$$

where N_{test} is the number of tests performed in the Monte Carlo analysis, k_{suc} is the number of tests in which the condition P_X is satisfied, Pr denotes the probability, and ε is the fixed confidence parameter ($\varepsilon = 0.05$ in our case). Figure 10 and Figure 11 show the trend of RMS mean and standard deviation for one Monte Carlo, used to select the number of runs.

The metrics applied to assess the estimator performance are:

- the mean estimation error (MEE), which represents a measurement of the estimation accuracy in static conditions;
- the root mean square error (RMS), which indicates the overall accuracy of the estimation;
- the correlation between true and estimated angle of attack (CORR), which measures the capability of the estimator to track the dynamic behavior of the true value.

The assessment of the estimator's performance considers all the error's sources that are present during operative conditions, including unknown aircraft weight, sensors' error, and the effect of wind, turbulence and vertical gust. Of course, it produces a degradation of the accuracy with respect to ideal conditions. In level unaccelerated flight, under all possible aircraft configurations and turbulence levels, the MEE is lower than 1.5 degrees. The estimator is able to compute the angle of attack with RMS error varying from about 0.9 degrees for level flight under all possible environmental disturbances to less than 3 degrees for dynamic stall manoeuver, representing the worst-case condition. The average correlation factor between estimated and true angle of attack is bigger than 0.9, confirming the capability to track the dynamics. A sensitivity analysis highlighted that the main source of estimation error is the approximation introduced on the aircraft weight. Indeed, while actual aircraft weight in the simulator randomly varied with uniform distribution within the range [W_{SEW}, W_{MTOW}], the weight used by the estimator is constant in all the simulation runs and is equal to the conventional weight. The value of the conventional weight was selected to get conservative errors when approaching stall, that is, the angle of attack estimation is bigger than its actual value, also at cost of increasing maximum error.

This choice derives from the need to anticipate the stall condition. It also allows using optimized algorithms (not described in the present paper) to post process the error when the AoA increases, in order to get very reliable and accurate indication about stall approaching. The knowledge (also rough) of the actual aircraft weight (usually available for commercial aircraft) could significantly improve the estimation performance. Figure 12 presents the estimation of the angle of attack in level flight condition and in presence of a vertical gust, with length equal to 150 meters and maximum amplitude equal to 1600 feet per minute.
Figure 10: Mean of the RMS error versus number of simulation runs
Figure 11: Standard deviation of the RMS error versus number of simulation runs

The final Monte Carlo aimed at assessing the capability of the redundant measurement system to detect a faulty sensor before its effects become significant and dangerous. To this end, one of the physical measurements of the angle of attack is corrupted by injecting one of the following faults, at a given time of the flight:

- constant bias, randomly selected in the range [5, 15] degrees;
- drift with slope randomly selected in the range [0.5, 5] degrees per second;
- signal freezing at a constant value.

The simulation lasts 90 seconds for each run (for the stall manoeuver it can end before 90 seconds if the aircraft stalls). The measurements are sampled at 10 Hz and the fault is injected 10 seconds after the start. The performance of the system is assessed by measuring the error of the consolidated angle of attack (output of the triplex redundant measurement system) with respect to the true angle of attack. Specifically, the mean and the standard deviation of the RMS error are evaluated. Moreover, the percentage of missed fault detections (that is, the percentage of faults that are not detected by the system) and of nuisance alarms

(that is, the percentage of declaration of invalid measurement when the fault is not present) are assessed. Monte Carlo analyses are carried out in four different flight conditions: climb, descent, cruise disturbed by a vertical gust, stall. In the first three conditions, the angle of attack is almost stationary; therefore, only bias and drift faults are added to the measurements of one physical AoA sensor (the freezing of the signal does not produce relevant errors). Bias, drift and signal freezing are used in the stall manoeuver, in which the angle of attack varies significantly during the test. All the Monte Carlo analyses are repeated twice. In the first set of analyses, the measurement system does not compensate for the estimation error due to the approximated aircraft weight (due to the use in the estimation of the conventional weight instead of the actual one). Table 1 shows the results for this test case. In the second set of Monte Carlo simulations, the estimated AoA is corrected by removing a constant offset, before providing it as input to the voting algorithm. The offset is computed as the mean difference, on a sufficiently long time, between the estimated AoA and the angle measured by the physical sensors, when these sensors measure about the same values (that means supposedly they are working properly). This procedure allows to compensate for, although roughly, the error due to the approximated weight. Table 2 presents the results for the second set of Monte Carlo analyses, whereas Figure 13 shows the results of one simulation run, in which the aircraft performs a stall manoeuver and one physical sensor of the angle of attack experiences a constant bias fault.
Figure 12: Angle of attack estimations for level flight with vertical gust

Table 1: Results of Monte Carlo analyses for the triplex redundant measurement system (without compensation for unknown aircraft weight)

	Fault	RMS mean [deg]	RMS std [deg]	False alarm %	Missed alarm %
Climb	Bias	0.67	0.18	6.4%	0%
	Drift	0.47	0.15	7.2%	0%
	None	0.24	0.09	1.6%	0%
Descent	Bias	0.68	0.19	0.8%	0%
	Drift	0.48	0.16	0.8%	0%
	None	0.23	0.08	0.4%	0%
Cruise	Bias	0.70	0.17	4.8%	0%
	Drift	0.49	0.16	4.0%	0%
	None	0.24	0.09	0%	0%
Stall	Bias	1.34	1.00	22.4%	5.6%
	Drift	1.08	1.11	26.4%	0%
	Freeze	1.08	1.06	28.8%	0%
	None	0.26	0.08	13.6%	0%

Table 2: Results of Monte Carlo analyses for the triplex redundant measurement system (with compensation for unknown aircraft weight)

	Fault	RMS mean [deg]	RMS std [deg]	False alarm %	Missed alarm %
Climb	Bias	0.62	0.16	0%	0%
	Drift	0.39	0.09	0%	0%
	None	0.20	0.06	0%	0%
Descent	Bias	0.63	0.16	0%	0%
	Drift	0.40	0.08	0%	0%
	None	0.20	0.06	0%	0%
Cruise	Bias	0.64	0.15	0%	0%
	Drift	0.40	0.08	0%	0%
	None	0.20	0.06	0%	0%
Stall	Bias	0.89	0.30	1.6%	0%
	Drift	0.63	0.22	2.4%	0%

	None	0.21	0.04	1.2%	0%
Figure 13: Angle of attack measurement for a stall manoeuver and a constant bias fault on one physical sensor

The improvements due to the weight error compensation are significant in all the examined metrics. As expected, a better estimation of the angle of attack leads to a reduction of the RMS error on the consolidated measurement and to a more effective detection of the faulty sensor. For all the considered flight phases and fault types, the mean RMS error is far below 1 degree also when the fault is present. The false alarm rate is always null, except for the stall maneuver in which however it is very low. The measurement system is able to detect all the injected faults, except for the case of measurement freezing, in which only 7 cases on 250 are missed (2.8%). Although these results are already very good, an optimization of the parameters of the voting and signal validity check algorithms could improve the result for both false and missed alarm percentage. Further investigations will be dedicated to this issue in the future.

5. Conclusion

This paper presented an original angle of attack measurement system applicable to commercial aviation aircraft. The system is based on a triplex physical-analytical redundancy, which only requires two physical sensors of the angle of attack. Indeed, the third sensor is virtual; it is an innovative angle of attack estimator, originally developed to provide General Aviation pilots with a maintenance free and low cost but accurate indication of trend toward stall and stall margin. This estimator does not require any angle of attack dedicated sensor, neither detailed information about

the aerodynamics of the specific aircraft, which is identified during a short calibration flight, carried out just once. The customization of the virtual sensor for the application to commercial aircraft, described in the present paper, allows getting better performance, due to the possibility to exploit additional information (such as, aircraft weight and deflection of the aerodynamic control surfaces), which usually are not available to General Aviation aircraft.

The physical-analytical redundant architecture defined in this paper provides a measurement system which is robust to a single fault of the angle of attack sensors. It could significantly improve the safety of the aircraft, reducing the occurrence of LOC-I related accidents, saving human lives, and avoiding the economic impact consequent to those accidents. It has the peculiarity to be applicable to the existing commercial aircraft by installing just a software code that implements the proposed algorithms, without the need to modify the on-board avionics instrumentation.

The performance of the proposed measurement system was assessed through Monte Carlo simulations. To this end, a high-fidelity simulation environment was implemented, which includes the models of aircraft, atmosphere, on-board sensors and an autopilot. The simulations highlighted very interesting results of both the angle of attack estimator and the overall measurement system. The latter is able to provide a consolidated angle of attack measurement with a mean RMS error far below 1 degree, also when a fault is present. Concerning the detection of the faults, it is generally successful; both missed and false alarm percentages are close to zero for all the examined cases. An optimized tuning of the proposed algorithms will probably further improve these results.

Future works will be focused on the validation of the system through real-time simulations and in-flight trials.

Capturing similarity in gene sequences of a target organism to detect significant regions of comparison will most likely occur because genes share a related descendant. Local sequence alignment for the targeted organisms can help preserve associations among sequences of related organisms. Such homologous genes possess identical sequences with common ancestral genes. The genes may be similar to common traits, and varying purposes, but they descend from a common ancestor. Basic local alignment search tool (BLAST) from the National Center for Biotechnology Information. (NCBI) has been used by different researchers to resolve the various forms of alignment problems. However, much literature to bare the efficacy of standard protein-protein BLAST (BLASTp) on the MATLAB platform has not been seen. In this study, a position-specific iteration BLASTp of 20 anopheles insecticide target protein sequence was performed on NCBI Ensembl against genomes of Anopheles (target organism), then against humans, fruit-fly, zebrafish, and chicken genomes (non-target organisms) to eliminate the targets with homology to non-target organisms. Furthermore, the same iteration was repeated for the genomes of Anopheles and non-target organisms using a posterior probability algorithm built into MATLAB as a tool for protein to protein search BLAST. Outputs from NCBI and MATLAB were put forward to determine the optimality of an optimized search algorithm on MATLAB. The MATLAB-Blastp method based on the application of posterior probability has helped to avoid errors occurring in the early stages of alignment. Moreover, the same results were obtained for the sought features on NCBI Blastp with a refined understanding of how feature values are generated from MATLAB posterior probability built-in algorithm for position-specific BLAST.

1. Introduction

Local alignment algorithms are suitable for unrelated sequences that are assumed to comprehend areas of comparable sequence motifs within a larger sequence framework [1]. Alignment is a mutual procedure of two sequences exhibiting positions where sequences are similar or dissimilar. A sequence alignment establishes residue-to-residue correspondences among sequences such that the order of residue in each sequence is preserved. Sequence analysis is a subject of deoxyribonucleic acid (DNA), ribonucleic acid (RNA) or peptide sequence for wide variations of analytical techniques to comprehend its purpose, structure, and development [2].

Many dynamic programming algorithms such as Smith-Waterman, FASTA, and BLAST algorithms were developed for accomplishing local alignment. The Smith–Waterman algorithm

accomplishes the task of local alignment of sequences for defining comparable neighborhoods of regions between two nucleotides or protein sequences. The algorithm captures the segments of all likely lengths and optimizes a comparative measure, instead of stretching over the entire sequence being process [3]. FASTA program was written for comparing protein sequences but it was later modified to conduct searches on DNA [4]. FASTA software uses the principle of finding similarity between two sequences statistically. This software matches one sequence of DNA or protein with the other by local sequence alignment method. It searches for local region for similarity but not the best match between two sequences. Since this software compares localized similarities at a time, it can come up with a mismatch. FASTA takes a small part of a sequence known as k-tuples where a tuple can be from 1 to 6, matches it with k-tuples of other sequence and once a threshold value of matching is reached it generates result. It is a program that is used to shortlist prospects of matching large sequences because it is very fast.

BLAST is frequently used for relating data sequences, recovering, and extracting sequences from databases in bioinformatics [5]. It has shown useful contributions in molecular biology, computational biology, and molecular genetic [6]. BLAST presents reliable and fast statistical reports, flexible search algorithm, and heuristic search methods [7]. BLAST based algorithms seek to extract a snippet of a query sequence that has a perfect alignment with a fragment of a targeted sequence found in a database. In the original BLAST algorithm, the chopped fragment is becoming the input to extend alignment in both query and subject database. BLAST searches for short sequences in an input query that matches short sequences in a database [8]. The nucleotide-nucleotide search, megaBLAST, BLASTN, BLASTP, BLASTX, TBLASTN are other architypes of BLAST algorithms [9].

Dynamic programing through the BLAST algorithm with various variants has made homologous search on genome databases of organisms possible. The aim of such analysis was to predict genes that are homologous in similar or dissimilar species. Gene prediction depends mostly on comparing a genomic sequence with a complementary DNA (cDNA), or protein database. However, most results are inaccurate for several reasons, including incomplete reference databases and lack of contribution to analysis of species. Position specific iterative BLAST (PSI-BLAST) is a program that finds distance relative to a protein. It creates a list of all closely related proteins that were combined into a general "profile" sequence, and summarizes significant features found in protein sequences. A query against a protein database is performed with in-built profile to extract larger group of proteins. The posterior probability is implemented using Bayesian theorem that involves revising a prior profile sequence that is extracted by psi-blast. This algorithm takes into consideration a new sequence profile information, which is a larger profile sequence group used to construct a profile and the process was iterated for four identical non-target organisms. It is believed that PSI-BLAST is much more sensitive in picking up distance based evolutionary relationships than a standard normal protein-protein BLASTP [10].

In this study, a local alignment algorithm has been developed based on BLASTP (protein query sequence against protein database search) and PSI BLAST (for more sensitive protein–protein similarity searches) to determine the effectiveness of the two search algorithms. A literature review to extract one of the best local search algorithms (Smith Waterman algorithm) was conducted. The NCBI BLAST was used to implement a protein query against protein database with a known essential protein sequences with PSI-BLASTP combined with posterior probability to generate an updated list of corresponding homologous protein from four other closely identical organisms. NCBI BLAST is widely used to implement sequence alignment, but very few works have implemented the local BLAST on MATLAB environment. Consequently, we are proposing a distinct way of elucidating homologous genes of a target organism when compared to selected non-target organisms through sequence alignment. This work is relevant for predicting genes that must be targeted in anopheles when formulating new compounds for drug target. If such gene is tampered with in the target anopheles during insecticidal spray, what happens to non-target organisms such as human, fruit flies, chickens, and fishes.

There is a high tendency of harming non-targeted organisms during insecticidal spray if homologous genes are not eliminated in the target gene list before insecticidal compounds are formulated and recommended for use. Local sequence alignment for a targeted specie can help preserve associations among sequences of related specie. Such homologous genes possess identical sequences with common ancestral gene and are useful for function prediction and characterization.

2. Related Works

Orthologs are homologous genes that diverge after a speciation event, and still have their main functions conserved. A homologous gene is inherited from two species by a common ancestor and homologous genes can be similar in sequence. But homology is the existence of the same body morphological structures in different organisms. It is an important concept of evolution and comparative biology [11]. The availability of genome sequence of several species has provided an opportunity to elucidate the effects of evolution on every nucleotide and protein in a genome [12-14]. It is easy to identify nucleotide sets that descended from a common ancestral nucleotide with sequence alignment because the problem of identifying an evolutionary related nucleotide and protein is the sequence alignment [15]. Strategies for aligning multiple and entire genomes of organisms include 'local' alignment and 'global' alignment [13, 15]. Their work has demonstrated a typical example of evolutionary scenario that involved the replication of double-stranded DNA in a parent cell (target organism) and division into two child cells. Their result showed two positions of an undirected duplication because of slippage replication, and occurrence of a directed duplication involving an RNA intermediate.

Studies on efficiency of alignment algorithm for homologous sequence similarity search in a genomic database was performed on a single [3]. The dynamic programming was deployed to isolate similar regions in gene sequences as a form of comparative analysis [16]. The authors discovered a suitable technique to calculate similarity in protein gene sequences within and across related organisms. They proposed a technique that computes sequence similarity, and their algorithm was evaluated using data sets from various species. The 'best-in-genome' method has been introduced [17], where a pairwise local alignment [18] between rat (target genome) and human genome (non-target genome) was initiated. The filter kept the best alignment for each position in rat genome and generated many to one relationship between rat genome and human genome but did not capture all orthologous relationships. The result was a reference-based multiple alignment with a property that gave every column, at most one position from each genome. A vertebrate local aligner with a faster nucleotide and more sensitive cross-species protein alignments has been constructed [19]. A web-based BLAST server for human genome makes homologous search possible and serves the purpose multiple genome alignments for yeast, insects, and vertebrates [20]. Aligning human, mouse, and rat genome [21] with progressive extension pairwise alignment orchestrated for human to mouse alignment has been reported [22]. Researches have combined strategies and tools for whole genome alignments [23-27], but none of the previous works have been found to specifically provide the Psi-Blastp by Bayes theorem

posterior probability for generating homologous alignment of anopheles to human, fruit-fly, zebra-fish and chicken genomes as provided in this work.

3. Experimental

This work has been implemented using minimum hardware and software requirements of a computer system with at least 16GB of RAM, 1TB hard disk capacity, Intel Core i7 Microprocessor, with VGA monitor compatible of at least 640/480 resolution and enhanced keyboard with a mouse. The software requires windows operating 7, or higher version, a Blosum62, BLAST standalone database, MATLAB R2016B, and online Ensembl NCBI Database [28] and [29]. The 20 essential genes identified to be potential insecticidal targets for malaria vector were used as input data for Mosquito *Anopheles Gambiae* [30]. The original data for analysis were extracted from Kyoto Encyclopedia of Genes and Genomes (KEGG) database and AnoCyc database on BioCyc, https://biocyc.org/organism-summary?object=ANO [31]. The detailed summary of Anopheles gambiae, version 24.1 KEGG described a collection of databases dealing with genomes, biological pathways, diseases, drugs, and chemical substances. BioCyc is a swarm of about 5700 pathway/genome databases (PGDBs) specific to various organisms. Each PGDB houses a predicted metabolic network and full genome of a specific organism, including reactions, metabolites, metabolic pathways, enzymes, proteins, genes, and lots of other components [32]. The protein sequence of these genes was extracted from protein database at NCBI as flat file or FASTA format from Genebank. Table 1 shows the dataset features of twenty genes as enzyme name, protein name, gene name, enzyme commission (EC) number and gene identity (ID).

The implementation of a basic local alignment method using a query against protein database was performed in this study using posterior probability function in MATLAB. The goal was to ascertain the creation of position specific score profile matrix from an alignment. The BLASTp program in MATLAB Bioinformatic tool was designed to map sequences of 20 previously identified *Anopheles* gambiae insecticidal target genes unto all available protein sequence databases of a specified organism, disease, population, or proteome. Bayesian posterior probability was calculated from psi-blast output to capture the related proteins from distance species during its search. This has resulted into a larger profile sequence group used to construct the final profile information. The process was repeated for the four non-target organisms investigated in this study.

Table 1: Dataset Features

S/N	AnoCyc (BioCyc) Enzyme Name	Uniprot Protein Name	Gene Name (Uniprot)	EC Number	Gene ID

Block substitution matrix (BLOSUM), which is the default matrix for a protein BLAST algorithm is a substitution matrix used for sequence alignment of protein. The matrix is based on local alignment. Based on block comparisons of sequence from database blocks, it contains multiple aligned un-gapped segments that correspond to the top-most conserved protein regions. The goals are to identify "biologically significant" patterns in protein families by emphasizing regions that are thought to be important to protein function. To look for good "discriminators" that emphasize and identify known family members, while excluding known non-members and to pro-site patterns of "motifs". The standalone BLAST is a suit of programs that were designed to mimic the NCBI BLAST server, and include "blastall"," megablast", and "blastp" that exist in NCBI BLAST suit. Its ease of use and user friendliness features are strong inspiration for its application in this study.

4. Results and Discussion

The protein sequences for each of the 20 insecticidal target genes was blasted against protein databases of four non-target organisms. The organisms are *Homo Sapiens* (Taxonomy ID: 9609) - human genome, *Drosophila* (Taxonomy ID: 7227) – fruit fly genome, *Danio Rerio* (Taxonomy ID:7955) – Zebra fish genome and *Gallus Gallus* (Taxonomy ID: 9031) – chicken genome. The selection procedure certifies that homologous gene of target organism (anopheles) exists in these four non-target organisms. There is possible homology match, which was identified and should be catered for in case of gene inhibition during insecticidal development. In fact, about 30 sequences were blasted against the whole genome per single iteration. The BLAST was matched with parameters before commencing on further BLASTP commands. The BLAST of proteins was run against the protein database of four targeted organisms. The BLASTP algorithm was implemented on Blosum62 Ensembl database section. During this process we were looking for homologs, which is a measure of relationship between two genes that descended from a common ancestral protein. Their various e-values and percentage identities were identified as the unique selection criteria. It confirmed the literature [33] that homologous

genes can be predicted and validated by sequence alignment method.

The e-value measures level of a likelihood that any match in sequences is purely by chance. Consequently, a lower e-value determines the less significant matches made but gives an idea of potential relations among query organisms and database organisms. This is a result of random chance and therefore the most significant gene matches in those non-target organisms were selected as the homologous. Selecting a homolog like the target sequence analyzed, the match with the lowest e-value and highest percentage was classified a significant match or hit. The e-value threshold was set at 0.00001 as a standard with NCBI Ensembl database that was deployed, while the position specific iteration BLAST threshold was set at 0.005. Figures 1 and 2 represent two sample result pages of 20-protein sequences blasted against the four non-target genome databases investigated with e-values and IDs of its homologous gene.

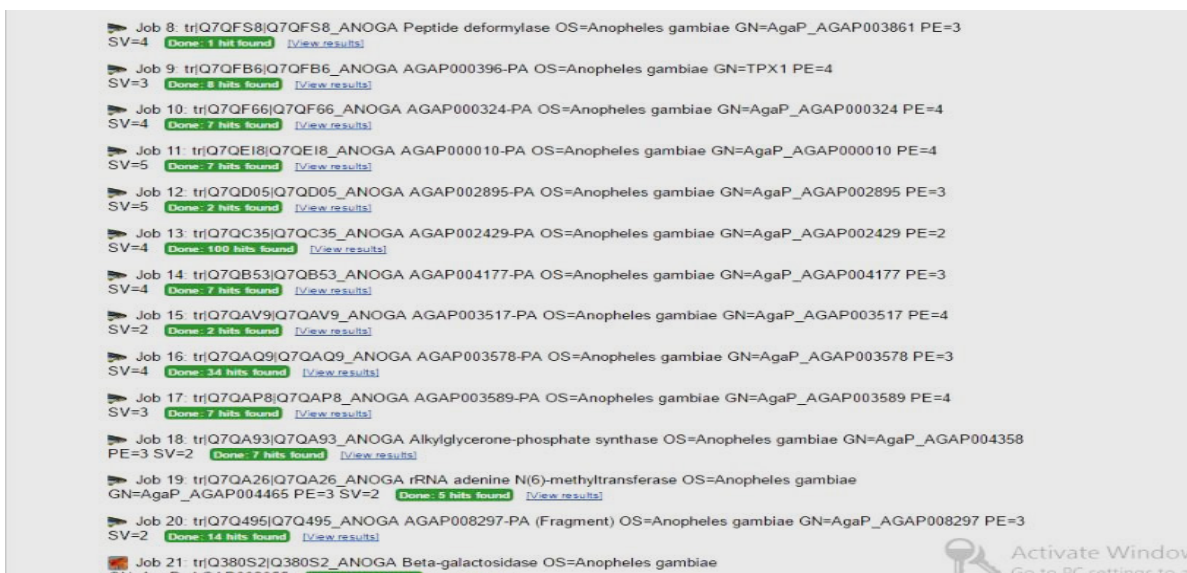
Different values were collected for various organisms blasted on ensembl platform. These values are the homolog, e-value, and percentage identity. Tables 2 and 3 show results of human and zebra fish homologous genes of the four organisms blasted in this study. The extracted database files from the Ftp site for the Anopheles was extracted from ftp://ftp.ncbi.nlm.nih.gov/genomes/ and available on Figure 3 shows this result for the case of human genomic information. The figure constitutes the precise data files and human genome information from NCBI genome databases and similar results were obtained for Zebrafish, Fruit-fly, and Chicken. The databases from the Ftp site were downloaded as GenBank files and converted to Microsoft (MS) Access database. The MS access file was linked as input to the MATLAB for implementation. BLASTP search was performed using MATLAB. A position specific iteration blast for protein query against protein (PSI–BLASTP) was completed for each sequence of anopheles against non-target organism (Human, Zebrafish, Fruit-fly, and Chicken) genome database. This was done to eliminate targets with homolog to non-target organism.


Figure 1: BLAST result page on ensembl.org
Figure 2: Extracted result with e-value and ID of its homologous gene

Finally, 20 anopheles protein targets were screened with two target genomes of Homo sapiens and Drosophila melanogaster. This was to identify isoforms from two organisms when screened with genomes of anopheles. The result of anopheles protein isoforms when screened with homo sapient and drosophila genomes is presented in Table 4. These isoforms can formulate a potential class of protein and can elucidate more molecular and functional variations ciphered in the genome by further functional analysis.

The search for protein isoform in this study may be out of scope because we do not have plans to conduct clinical or computational proteomics analysis and transcriptomic analysis. However, protein isoform is seen as the same protein existing in many different forms, rather it is a new class of protein that may be useful as biomarkers for early diagnostic of clinical proteomics [34]. Studies have shown that traditional methods of protein isoform determination have proved that isoforms can only be determined quantitatively at the transcript level, not in the protein level. Moreover, that condition came with several other disadvantages, high throughput analysis has made it possible, but the data used in this study are not confirmed transcriptomic dataset.

5. Conclusion

In this study, BLAST which is a frequently used to determine sequence similarity by querying various sequences type against databases of various datatypes was experimented. BLAST with 20 *Anopheles* protein sequence was queried against four non-target organism databases. The results of this study have revealed the same e-values, which indicates that there is no significant homology (all e–values > 0.001) between the data on *Anopheles* when compared to humans, fruit-fly, zebrafish, and chicken databases. Posterior probability in MATLAB was used for experimentation in this study. The study results have shown obvious insecticidal targets in *Anopheles gambiae* with no significant homology to humans, fruit-fly, zebrafish, and chicken. Further analysis like synthesizing these targets in an experimental scenario can help close dangling ends in search for new insecticide compounds. This may be a useful endeavor for future research.

6. Data Availability Statement

The original source of data for this study is from a standard and structured public repository KEGG and AnoCyc on BioCyc, (https://biocyc.org/organism-summary?object=ANO). Protein sequence of these genes was extracted from the protein database at NCBI as flat file or FASTA format from Genebank. In addition, contents were extracted from UniProt Knowledgebase @ UniProtKB (https://www.uniprot.org/database/DB-0023). This represents some details from Cross-referenced databases on UniProtKB, Protein knowledgebase and UniParc Sequence archive. This is because our analysis involved fetching data from various public databases to generate outputs as the algorithm required in pursuit of research objective. Links to all data supporting the conclusions of this study is publicly available as indicated by web links.

E-learning, among the most prominent modes of learning, offers learners the opportunity to attend online courses. To improve the quality of online learning, social learning through social networks promotes interaction and collaboration among learners. As part of the learning process management in these environments, the implementation of recommendation systems facilitates the provision of content adapted to the needs and requirements of learners and generates recommendations likely to arouse their interest. Many researchers have been involved in several recommendation techniques such as the development of Machine Learning algorithms and the incorporation of social interactions between learners. However, the behavior within a learning environment can diverge from one learner to another. This must therefore be taken into consideration when generating recommendations, i.e., it is initially important to form groups of homogeneous learners prior to proposing recommendations. In this respect, the recommendations generated will be more appropriate to the learners' profiles and level of interaction. On this basis, we raise an important issue which is the importance of grouping learners into homogeneous groups in a recommendation system. In the recommendation system we advocate, we group learners based on the degree of interaction within the learning environment before generating the recommendation list based on a hybrid approach for each cluster. The overall system is, therefore, based on the identification of communities based on the k-means algorithm and the generation of recommendations list for each community separately. Finally, we compare the results of the system integrating the classification of learners as a preliminary step to the system excluding the k-means algorithm. The results reveal that the integration of the clustering algorithm leads to improvements in terms of performance and accuracy.

1. Introduction

This paper is an extension of the work originally presented at the Fourth International Conference on Intelligent Systems and Computer Vision [1]. Currently, e-learning is emerging on a large scale around the world. When face-to-face learning is not available, e-learning allows students to bring order to their ideas and to continue to lead students in their learning process [2], [3]. Social networks, a modernized version of learning, fully promotes interaction and collaboration among learners [4], [5]. When a traditional learning platform is sometimes unable to provide effective collaboration between learners, social networks offer a multitude of options for learners encouraging responsiveness between them. However, the availability of online courses is not the only factor that contributes to the success of the learning process. Learners require a more highly organized learning environment responsive to their needs and profile. In this respect, recommendation systems are the perfect medium to perform this task and to manage learning resources within e-learning [6], [7]. The role of recommendation systems is to filter the information that aims to present different learning objects. Through recommendation systems, a certain organization is implemented within the learning environment and learners are more able to explore what is most interesting to them. Many recommendation systems have been proposed in the literature, including: the content-based approach, collaborative filtering and hybrid approaches [8]-[10]. Within the e-learning context, each proposed recommendation system addresses specific questions and handles an underlying issue identified at the recommendation system level. By way of example, several researchers address collaborative filtering to generate recommendations to learners [11]. Others

*Corresponding Author: Sonia Souabi, soniasouabi@research.emi.ac.ma

focus their attention on hybrid approaches to improve the performance of their recommendation system. Machine Learning algorithms have also been proposed as part of learning recommendation systems, including supervised and unsupervised algorithms [12]. Most recommendation systems use explicit feedback from learners, i.e., assessment by learners to generate recommendations. However, explicit feedback is sometimes an unreliable indicator for recommendations. On the other hand, an e-learning environment can include hundreds or thousands of learners with varying degrees of interactivity, constituting divergent groups, interactive and non-interactive learners. Most studies conducted on recommendation systems do not consider that point with respect to online learning. In this regard, we propose to group learners into homogeneous groups before generating recommendations. Our work aims at implementing a preliminary step in the calculation of recommendations, namely the detection of communities with the same level of interactivity. In our previous work, we proposed a hybrid recommendation system based on the activities performed by the learners. Within the same framework, the current work presents a continuity of the previous work while improving the old system with a new recommendation strategy integrating the k-means algorithm as a preliminary step. In this sense, we propose to classify learners according to well-defined criteria of interactivity within a social learning network, and then generate recommendations for each community separately. In this way, each community will receive its own recommendations adapted to its specific needs. The approach we propose brings considerable added value as it categorizes learners according to their level of interactivity before calculating recommendations.

The document is divided as follows: Section 2 deals with the research work related to the recommendation systems proposed in e-learning, especially those that consider Machine Learning algorithms. Section 3 explains the global recommendation approach based on correlation, co-occurrence and the k-means algorithm, section 4 presents the results of the tests performed on the approach without k-means and the approach with k-means with interpretation, and section 5 summarizes the work done in the paper.

2. Literature review

2.1. Recommender systems in E-learning

There are several types of recommender systems: content-based recommender systems, collaborative filtering recommender systems and hybrid recommender systems. Hybrid recommender systems generally combines between content-based techniques and collaborative filtering approaches. In E-learning, all these types of recommendations were addressed, but differently from one proposition to another. Some researchers discuss the analysis of activities in collaborative filtering within the educational field [13]. This work aims to use ontology and the semantic web to provide efficient recommendations. Others propose a recommendation approach to guide learners in developed countries to select more appropriate resources [14]. Calculations are based on developed knowledge and rating predictions. A recommendation system was suggested based mainly on two primary steps: pre-processing and prediction [15]. Multiple algorithms was used: SVM, KNN, Random Forest, and Naïve Bayes. A personalized recommendation system was developed based mainly on ontology using the java programming language [16]. Learning style and level of knowledge were addressed in a proposed recommender system [17]. The approach contains four modules relating to courses and learners.

2.2. Related works

In Machine Learning, unsupervised learning includes algorithms that should perform based on unannotated examples. K-means, one of the important unsupervised algorithms, is used to identify clusters with the similar characteristics and properties by working with gravity centres. The optimal number of clusters is usually obtained through several methods, including: elbow method, average silhouette method, gap statistic method. In online learning, k-means is handled for many purposes, for instance classifying learners according to their attitudes, their performance, interaction rates (...). In the literature, there is a multitude of works addressing k-means as an algorithm for classifying not only learners, but also items, users, in different contexts and areas, such as recommender systems.

A learning content recommendation system was implemented within a learning platform to generate recommendations in an intelligent way based on the learners' interest [18]. The proposed system aims to combine ontology and clustering algorithms using the collected ontology. A new recommendation system that combines the content-based approach and the k-means algorithm simultaneously was proposed [19]. The approach consists of performing a transformation on user data. Then, learners are grouped into clusters based on the content approach and the clustering algorithm, and thus recommendations will be generated from the detected clusters. Some researchers focus on methods to optimize k in the clustering algorithms in order to maintain the variance of each cluster [20]. The clustering was based on movie genres and tags. The objective is to correctly evaluate the recommendation algorithm based on user classification and use sophisticated measures such as mean square error, proximity centrality. Abnormal profiles in the context of recommendation systems was detected. A hybrid recommendation system that integrates both the k-means algorithm and ant colony optimization was suggested [21]. The evaluation was based on several measures including precision, recall and accuracy. Several approaches are based on clustering techniques in recommendation systems that are mainly based on group preferences. Several algorithms were compared to identify which algorithm gives better accuracy and higher results [22]. Some use k-means, others use k-NN, and the results were compared in terms of performance and number of clusters obtained. Instead of working with a traditional clustering algorithm, a mutli-clustering approach working on a set of clusters was proposed [23]. The advantage of this algorithm is its ability to visualize the neighbourhood in a clearer and more refined way, and the time efficiency is high. Contextual information was used to generate more relevant recommendations [24]. The proposed technique seeks to use the k-means algorithm to cluster contexts and generate new user matrices.

Based on researches in terms on recommender systems based on clustering algorithms , it comes out that k-means has been approached in many areas, such as e-learning, e-commerce, movies in order to generate more appropriate recommendations. Thus, we can notice that clustering algorithms has been adopted in recommender systems for different purposes in all the cited works.

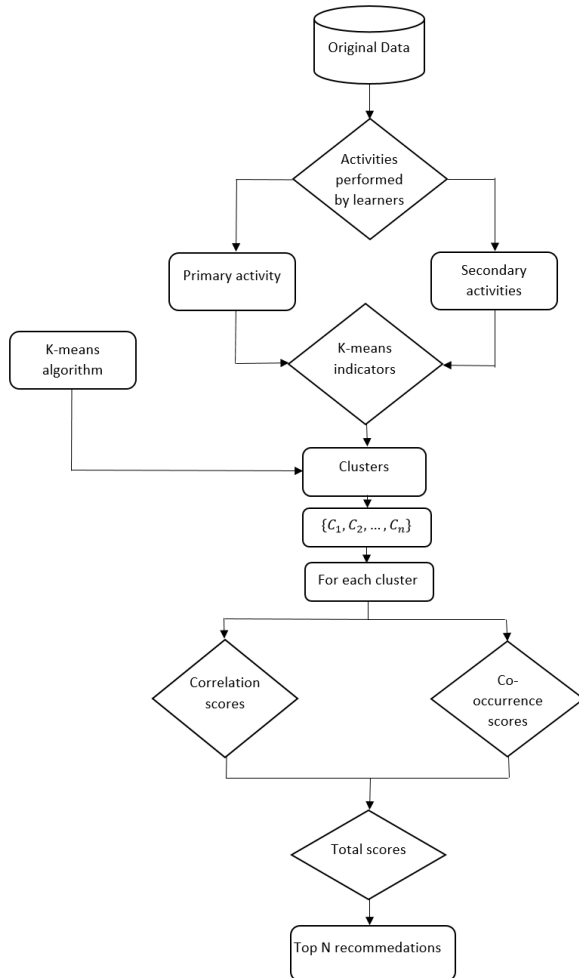
On the other hand, clustering algorithms have not been adequately addressed in e-learning. In our context, we propose to use the k-means algorithm within a pure learning context and to combine it with a hybrid recommendation approach in order to generate more relevant recommendations. Our goal is to classify learners according to their degree of interactivity before calculating recommendations to generate a more relevant list of recommendations.


Figure 1: The recommendation system model proposed

3. Our proposed approach

3.1. K-means algorithm

Before proceeding to the description of our recommendation system, we will first define the k-means algorithm. The k-means algorithm is considered among the most widespread clustering algorithms. It consists of the analysis of a dataset containing several descriptors. The final goal is to group similar data in the same clusters. The idea is straightforward, all you need to do is to calculate the distance between the descriptors of two data to decide whether they are part of the same cluster. In a set of data, and to implement the k-means algorithm, there are the so-called centroids. Centroids are the key elements of the algorithm. The k-means relies on the centroids to detect the data closest to each centroid, and this loop continues until there is no further improvement in the distances between similar data, i.e. until the

algorithm converges. The algorithm below summarizes the different parts of the k-means algorithm (algorithm 1).

Algorithm 1: Concept of K-means Algorithm

Input
K optimum number of clusters
Output
Clusters or groups
Method
Selecting randomly K points. These are the centroids.
REPEAT
(1): Assign each point to the closest group according to centroids.
(2): Modifying centroids according to new clusters.
UNTIL CONVERGENCE

3.2. The proposed recommender system

The following flowchart (Figure 1) summarizes our recommendation approach.

The flowchart consists of several parts core to the proposed approach:

- The learners' actions in the database (sharing, communicating, downloading ...).
- The reconsideration of the initial data.
- The k-means algorithm.
- The different learning resources.
- The recommendation part.

In this part, we will describe each phase of the proposed approach separately:

a- First phase: The first phase consists in detecting the learners' actions in the database that have been carried out within the learning environment, for instance: sharing learning resources, sending private messages to other learners, downloading resources, exploiting resources. These actions are then grouped into two main categories: primary and secondary actions. The primary action is the action that can directly reflect learners' real preferences, for example, liking content, searching for content. It is through this indicator that we can ascertain learners' preferences. Secondary actions are also indicators of learner preferences, but are less consistent than the primary action.

b- Reconsideration of the initial data: This part consists in converging the data table into data that translate the interaction between learners and each learning object with respect to the selected actions, i.e. it is mandatory to restructure the database so that it meets our requirements for calculating recommendations.

c- The k-means algorithm: After restructuring the database, the next step consists in grouping the learners in clusters by selecting a number of descriptors. Each learner has a number of descriptors which are used to build the most similar clusters. Therefore, the choice of descriptors is an obvious prerequisite for applying the k-means algorithm.

d- Recommendations part: the last part consists of calculating the recommendations after detecting the clusters of the most similar learners. We will therefore generate the recommendations for each cluster separately. The idea is to consider the notions of correlation and co-occurrence in the calculation of recommendations, and thus to generate the final recommendations.

The hybrid recommendation algorithm combined with k-means algorithm is described below (algorithm 2).

Algorithm 2: Recommendation algorithm with k-means

Input
Learners data
Actions performed by learners
Output
Recommendations generated for each group
Method
1: Describing each learner by descriptors.
2: implementing the K-means algorithm based on previous list of learners and their descriptors.
3: Assign each learner to a specific cluster.
For each cluster
1: Calculate correlation and co-occurrence matrices.
2: Calculate recommendation scores based on previous step.
3: Find top N recommendations for each learner.
End for each

3.3. First stage: the k-means algorithm

➢ Define the descriptors

The database contains the learners' history, including the actions that are performed by the learners. We restructure the database to group learners according to two main descriptors:

- The first descriptor describes the level of interaction based mainly on the number of times an action has been performed.
- The second descriptor reflects the discrepancy between the actions performed by a learner.

Based on these two descriptors, it is possible to group learners into several clusters using the k-means algorithm within the learning platform. The indicators or descriptors are calculated as follows:

For a particular learner, the history of actions $\{a_1, a_2\}$ such as a_1 presents the primary action et a_2 is the secondary action, and the following resources $\{i_1, i_2\}$ (table 1 and table 2).

Table 1: Activities vs learning items structure

	a_1	a_2
i_1	x_1	x_2
i_2	x_3	x_4

Table 2: K-means descriptors

Learner 1	
First descriptor	$x_1 + x_3$
Second descriptor	$(x_1 + x_3) - (x_2 + x_4)/2$

For each learner, we will perform this operation, which allows us to classify learners according to these two indicators.

➢ Optimum number of K:

In order to properly apply the k-means algorithm, it is of paramount importance to define the optimal number k of clusters to be identified. One of the most successful methods for calculating the optimal number of k is the elbow method. It actually allows to specify the most adequate number of k to be considered since the

parameter k can change and can take several values. The elbow method consists in describing the variation according to the number of clusters. But in this case, what would be the optimal number? The optimal number k is simply the value from which the curve starts to take a constant value. So we will ensure that the value of k we selected represents the most accurate value for our context.

3.4. Second stage: The hybrid recommendation part

Now that the k-means algorithm is applied and clusters are detected, we now have the different groups of learners with similar behaviour in terms of interaction level. The rest of the work consists in generating recommendations through the calculation of recommendation scores for each learner pertaining to a given class. The proposed recommendation system is based on the calculation of correlation and co-occurrence scores through the analysis of the actions performed by the learners. In the following section, we will describe the mathematical model of our recommendation approach in detail:

The history matrix of learners =

	i_1			...			i_n		
l_1	a_1	...	a_m	a_1	...	a_m	a_1	...	a_m
⋮	⋮			⋮			⋮		
l_p	a_1	...	a_m	a_1	...	a_m	a_1	...	a_m

$\{i_1, \dots, i_n\}$: *Learner objetcs.*

$\{a_1, \dots, a_m\}$: *History actions performed by learners.*

$\{l_1, \dots, l_p\}$: *Learners.*

Referring to the basic matrix, which presents the learners' interaction with contents according to the selected actions, we generate recommendations for each cluster detected separately through the calculation of recommendation scores.

➢ Correlation

Correlation allows to identify the existing connection between two variables. Our context consists in calculating the correlation between the primary action and the secondary actions. The purpose is to situate the importance of the secondary actions in relation to the primary action to be used in the calculation of recommendations. We opted for the spearman correlation since it is the type of correlation that best suits our case, since it provides a way to evaluate the correlation in case of a non-normal distribution. We explain the notion of correlation in what follows (table 3 and eq. 1).

Table 3: General structure of correlation matrix

	a_1	...	a_m
a_1	1	...	$cor(a_1, a_m)$

⋮	⋮	⋮	
a_m	$cor(a_1, a_m)$	...	1

$$Correlation\ score = Total\ history\ matrix \times$$
$$\begin{bmatrix} 1 \\ \vdots \\ cor(a_1, a_m) \end{bmatrix} = \begin{bmatrix} s_{11} & \cdots & s_{1n} \\ \vdots & \cdots & \cdots \\ s_{l1} & \cdots & s_{ln} \end{bmatrix} \quad (1)$$

$\{(s_{11}, \ldots, s_{1n}), \ldots, (s_{l1}, \ldots, s_{ln})\}$ are scores of correlation for each particular learner towards each learning resource.

➢ Co-occurrence

Co-occurrence is defined as a measure to determine how many times two actions occur simultaneously in the same database. Learners generally do not react to the same actions in the same manner. They can be active in one action without engaging in another action. In this case, the co-occurrence between these two actions might be very weak. The role of co-occurrence is to define where two actions are linked at this level (table 4 and eq. 2).

Table 4: General structure of co-occurrence matrix

	a_1	...	a_m
a_1	$occurence(a_1)$	...	$co-occ(a_1, a_m)$
⋮	⋮	⋮	
a_m	$co-occ(a_1, a_m)$	...	$occurrence(a_m)$

$$Co-occurrence\ score \qquad\qquad (2)$$
$$= Total\ binary\ history\ matrix$$
$$\times \begin{bmatrix} occurrence(a_1) \\ \vdots \\ co-occ(a_1, a_m) \end{bmatrix} = \begin{bmatrix} p_{11} & \cdots & p_{1n} \\ \vdots & \cdots & \cdots \\ p_{l1} & \cdots & p_{ln} \end{bmatrix}$$

To generate the total recommendation scores, we proceed as follows (eq. 3).

$$Total\ score = Correlation\ score + co-occurrence\ score$$
$$= \begin{bmatrix} s_{11} + p_{11} & \cdots & s_{1n} + p_{1n} \\ \vdots & \cdots & \cdots \\ s_{l1} + p_{l1} & \cdots & s_{ln} + p_{ln} \end{bmatrix} \quad (3)$$

From the scores obtained, we extract the top N recommendations according to scores ranking.

4. Tests and results

In this work, we propose a recommendation system that aims to integrate the k-means algorithm within the system to generate more pertinent and reliable recommendations. Our intention is to prove that the k-means was efficient in generating more relevant recommendations and results. In order to test our recommendation approach for both cases, without k-means and with k-means, we selected two groups from a social network containing data on learners' interaction with the learning environment:

- The very first database consists of a set of 100 learners with many learning objects. We limited the number of learning objects to 10 and two actions, the primary action being the number of likes and the secondary action being the number of shares.
- The second database contains the same 100 learners from the first database, but interacting in a different social learning group. We selected some learning objects for the aforementioned actions: the number of likes and the number of shares.

The purpose of choosing these two databases is to highlight the performance of our recommendation system which incorporates the k-means algorithm, and which emphasizes the importance of grouping learners with similar attitudes in the same cluster. Homogeneity will be a major advantage in this case in terms of generated recommendations.

➢ Recommendation system evaluation:

The evaluation of the recommendation system is a prerequisite to measure its performance. In this respect, we divide the database into two major parts:

- The first part which consists in creating the recommendation model by referring to 80% of the data.
- The second part consists in measuring the accuracy and performance of the system by referring to 20% of the data.

We highlight the following measures (eq. 4 and eq. 5) according to specific parameters (Table 5).

$$Accuracy = \frac{TP + TN}{TP + TN + FP + FN} \quad (4)$$

$$Precision = \frac{TP}{TP + FP} \quad (5)$$

Table 5: Accuracy and precision parameters

	Recommended	Not recommended
Preferred	True positive (TP)	False positive (FP)
Not preferred	False positive (FP)	True positive (TP)

Before moving on to the application of k-means, it is important to identify the optimal number of clusters. In this sense, we use the elbow method which allows to plot the variation as a function of the K number. The optimal value we reach for both databases through the elbow method is 2.

In what follows, we will compare the results obtained through the application of the recommendation system not considering the k-means and the recommendation system identifying the number of clusters in the database before generating the recommendations (Table 6).

Table 6: Accuracy and precision for both recommender systems in the two databases

Database		Accuracy	Precision
First database	Without clustering	0,375	0,5
	Cluster 1	0,4	0,52
	Cluster 2	0,416	0,526
	Average between	0,408	0,523

	cluster 1 and cluster 2		
Second database	Without clustering	0,3	0,44
	Cluster 1	0,40625	0,55
	Cluster 2	0,406	0,525
	Average betwen cluster 1 and cluster 2	0,406	0,5375
Figure 2: Accuracy and precision according to the two types of recommender systems (with k-means and without k-means)

Based on the results obtained (Figure 2), it appears that the recommendation system based on the classification of learners provides a higher performance compared to the recommendation system where community detection is not considered. A difference of 0.408-0.375=0.033 in terms of accuracy and 0.526-0.5= 0.026 in terms of precision. Apparently, the difference seems insignificant since the database is not of considerable size. Therefore, if the test is performed on a larger database the difference will be more noticeable. The same holds true for the second database where the difference in accuracy is 0.406-0.3=0.106 and the difference in precision is 0.5375-0.44=0.0975. These results highlight the importance of grouping learners according to their degree of interactivity before proceeding with the assignment of recommendations. Grouping learners with similar patterns of behaviour within the same community allows the generation of more adapted recommendations to their needs. Generating recommendations to learners with no prior classification reduces the performance of the recommendation system and provides recommendations that do not necessarily fit the needs of each community separately from the other. We recognize that the k-means algorithm brings considerable added value to the recommendation system due to the accuracy and performance improvements achieved. Grouping learners in homogeneous clusters facilitates the generation of recommendations.

5. Conclusion

The following work proposes a hybrid recommendation approach merging learner classification as a preliminary step before proceeding with recommendation calculations. In addition to the implicit feedback from learners that was integrated into the initial recommendation system, our approach proposes to group learners into communities with the corresponding degree of interactivity to improve the quality of the recommendations generated. Our approach consists in classifying learners according to specific interactivity criteria, then calculating recommendations for each community based on all the activities performed by the learners within the learning social network. On the one hand, the two notions of correlation and co-occurrence are combined in a unique hybrid recommendation system valuing the implicit feedback from the learners. On the other hand, the approach fosters the detection of homogeneous communities and clusters in order to generate recommendations more adapted to each community separately. The test was carried out on two databases of two different social learning groups, each consisting of 100 learners. The objective was to collect implicit feedback from learners within the learning environment. The results indicated that the recommendation approach based on the k-means algorithm leads to higher performance than the system without the k-means algorithm. This highlights the importance of classifying learners into homogeneous groups before generating recommendations. Our future work will consist of:

- Testing our recommendation approach on a larger database.
- Applying other algorithms other than k-means.

	This paper aims to clarify the lower limit of the gaze time required during reading by investigating at a display time of 98 msec or less using the visual information processing analyzer developed in the previous research. The image display range and display time at the point of gaze was controlled by moving the window in conjunction with the eye movement. As a result, it was found that normal reading, as if there were no window or visual field restriction, could not be performed with a display time of 42 msec or less, but that normal reading could be performed when sentences were displayed in a window of 7 characters at 56 msec. In this way, we believe we can obtain useful knowledge that is necessary for studying more effective methods of displaying text on electronic device.

1. Introduction

In recent years, information terminals such as smartphones and tablet terminals have been driving the spread of e-books. Before the popularization of smartphones and the like, many terminals exclusively for electronic books (e-books) were produced by various manufacturers, but since the introduction of the Apple iPhone in 2007, the use of e-books on smartphones rather than dedicated terminals has become mainstream. Not only does this make books highly portable, but books of various genres are also easily available online, making them more accessible.

Regarding research on electronic books, evaluations of the hardware include assessments of the size, weight, and resolution of the terminal on which the reading material is displayed, and the possibility of e-books replacing paper media has also been examined [1]-[3]. In addition, it has been reported that text on an electric display provides the same reading experience as text printed on paper if it is displayed at a high resolution [4]-[6]. Nevertheless, differences in reading between a display and paper, and differences in reading due to differences in display performance and operation have also been reported [7]-[9].

We have been studying e-books and traditional paper books, focusing on the differences in eye movements during reading. In particular, in the case of a paper book, the reader often gazes at the various places on the paper while turning a page and the reader's eye movements depend on how the page is turned. On the other hand, with an e-book, the reader's gaze moves linearly from the

end of the sentence of the previous page to the beginning of the next page [10]. By developing research on visual information processing with such eye movements, we will be able to develop a new display method for e-books that incorporates the characteristics of visual information that make it most easily absorbed by readers.

Human eye movements include saccade (intermittent and rapid step-like movement), smooth pursuit movement (smooth movement that occurs when following a moving object), and miniature eye movement (miniature involuntary movement that occurs when gazing at one point) [11]. The eye movement that occurs during reading is not a smooth pursuit eye movement that moves smoothly over the letters, but a repetition of a fixation, which is composed of miniature eye movements and occurs at a gazing point, and a saccade, which skips between fixation points. In addition to moving in the direction of sentence progression when reading, there is also a return movement, called regression, that moves in the opposite direction.

Research on eye movement during reading has a long history of more than a century, and many different researchers have reported useful results using various measurement methods.

In 1878, Javal, who observed and recorded eye movements reflected in a mirror, first reported that reading eye movements are repeated saccades and fixations [12]. Later measurement following Huey's method using an equipment like a contact lens made of a thin hardened layer of gypsum powder and a kymograph found that the number of fixations per line was 4 to 5 when the viewing distance was 33 to 42cm, and that that number did not change even

if the size of the characters was changed or the viewing distance was doubled; fixation duration likewise remained steady at about 200 msec. Furthermore, it has been reported that the average size of saccades is 3° to 4° [13]-[15]. Regarding fixation duration, Dearborn reports durations of 100 to 500 msec, with most falling between 200 and 300 msec [16]. Results for saccade and fixation similar to those in Huey's report have been found for reading in Japanese. It was reported that 2 to 8 characters are grasped observed in a single fixation and that the size of the saccade is also 2 to 8 characters [17], [18]. In addition, differences in the reading direction of sentences are being examined, and there have been many reports on eye movements during vertical and horizontal writing. Ohtomo reports that there was no difference in direction based on reading experiments of on vertical and horizontal writing in kanji and hiragana, kanji and katakana, hiragana, katakana, and romaji [19], [20]. Additionally, one report for a large influence of reading experience [21]. Although these studies were carried out early in the study of eye movements during reading, their results are still considered to be useful.

After the early research of the 1930s, the analysis of eye movements during reading received particular attention during the period from 1970 to 1980 with the development of computers and eye movement measurement devices. Past research on the perceptual range (effective visual field) during reading and the recognition of characters within the gazing point are considered to be highly compatible with e-books that can change display information in real time. In other research [2], a visual information processing analyzer that can control the image display range and display time at the point of gaze was also developed with reference to those eye movement studies. Furthermore, in experiments using this developed experimental device, it was reported that normal reading without restriction of the visual field can be performed by displaying images for 98 msec during gazing.

Therefore, this paper aims to clarify the lower limit of the gaze time required during reading by investigating at a display time of 98 msec or less using the visual information processing analyzer developed in the previous research. In this way, we believe we can obtain useful knowledge that is necessary for studying more effective methods of displaying text on electric device.

In this paper, previous research plays a major role. Therefore, Chapter 2 summarizes two similar studies on the perceptual range (effective field of view) that had significant effects on the previous study [22], and Chapter 3 describes the analyzers developed in the previous study and an experiment involving an image display time of 98 msec in detail. Chapter 3 indicates the approach of this research, Chapter 5 describes the method and results of this experiment, and Chapter 5 describes the conclusions and future developments.

2. Related Works

Since all parts of the visual field are not equally visible, it is thought that the amount of information processed is different if two locations in the field of view where information is presented are different. When performing various visual tasks, the part of the visual field from which information that is necessary for the tasks can be obtained is called the effective field of view. In this paper, "visual task" refers to reading.

There are various methods for investigating the effective visual field, including instantly presenting a character string or word using a tachistoscope (instantaneous presentation device) and estimating the readable range. Another method is that the number of characters viewed at a gazing point was estimated based on the record of eye movements in one line. All of these methods are based on estimation, and the departure from estimation is a method called windowing. The window is the area on the screen where the image is displayed. This method investigates the effective visual field by moving the window in conjunction with eye movement and changing the display information in the window during a period called saccadic suppression, in which the function of visual information processing in the brain decreases. If this window is smaller than the effective field of view, the reading time will be longer because less than the maximum amount of information will be obtained. Conversely, if the window is larger than the effective field of view, it will not be useful for reading, so the reading time becomes constant.

Research using the window method began with experiments by [23] and by [11], [24], [25]. The research by [22] solved the problems in these studies by developing a new analyzer. This section describes two studies of Saida and Ikeda and McConkie and Rayner and introduces the issues raised by Kushima and describes in detail the equipment developed by Kushima used in this study.

First, we explain the experiments of Saida and Ikeda. An image of the experimental equipment is shown in Figure 1. The subject's eye movements were acquired by the Limbus tracking method (a method of irradiating non-visible light such as near infrared rays to the black and white eye regions and calculating the difference of the reflected light). The acquired X-Y position information of the eye is input to the oscilloscope, and a rectangle is displayed at that position. Two TV cameras are prepared, the oscilloscope video is shot with TV camera 1, and a board with written text is shot with TV camera 2. The image of the rectangle shown on TV camera 2 is switched by the video switcher to the image on TV camera 1 using the wipe process. In this way, the displayed rectangular area, which is linked to eye movement, display the written text of the specified window width. The results of this experiment showed that if the size of the window exceeds 13 characters, it is possible for a viewer to read it as well as they would normally read without a window.
Figure 1: Experimental equipment by Saida and Ikeda [26]

Kushima point out the following issues regarding this experiment.

- In their experiment, a rectangle was displayed on the oscilloscope directly with the eye movement being the output, and the gaze area was not switched after the gazing point was detected.

- Since a camera and cathode ray tube (CRT) display were used at that time, it is expected that there would have been afterglow and an afterimage, but there was no description of this.

- Since the window moves in conjunction with eye movement, the display time of the window is considered to change depending on the gazing time, so the display time was not controlled.

On the other hand, in McConkie and Rayner's experiment the display (DEC Model 340) with built in uppercase and lowercase characters was controlled by inputting the eye movement acquired by the Limbus tracking method to a PDP-6 minicomputer. Since a character incorporated display was used, not only the masking of the gaze area, but also six patterns in which the characters in the window were replaced with X, x, characters with similar shapes, etc., were tested. The results of this experiment showed that the effective visual field was 13 characters, similar to the experiments of Saida and Ikeda. The following issues were raised in this experiment.

- Afterglow was only described as short afterglow, and it is not possible to determine how much afterglow or afterimage remained after switching.

- The saccade was not detected. If the eye movement exceeded a certain distance from the left edge of the sentence, the image in the window was switched, so the window was not displayed in the gaze area.

- There was no description of the display time of the characters in the window.

3. Research

An analyzer that overcomes the issues introduced in the previous chapter was developed in a previous study [22].

3.1. Overview of the developed analyzer used in this study

Table 1 shows the equipment used, Figure 2 shows the configuration diagram, and Figure 3 shows the flowchart.

Figure 2: System configuration diagram

Table 1: Experimental apparatus

Eye Movement Measuring Device	EMR-9 EYEMARK RECORDER (NAC Imaging Technology)
Sampling Rate	60Hz (serial communication), 120Hz, 240Hz
Resolution	0.1[degree]
Data Processing PC	OS Windows 7 Professional, Memory 32 GB, CPU core i7 3770
CRT Display	IIyama HM204A

The video output of the analyzer consists of a liquid crystal display for the experimenter and a CRT display (Figure 4; afterglow of 1 msec or less) for the subject. Liquid crystal displays are not used as displays for subjects because afterimages remain longer in the window after images are switched compared to CRT displays. The subject's CRT display shows only text, and the experimenter's LCD displays the EMR-9 (Figure 5) visual field camera image, allowing the subject's gazing point and text to be displayed. The system executes two threads in parallel. One thread acquires the position of the rectangle displayed on the CRT from the image of the EMR-9 field of view camera, and the other thread (on the left in Figure 3) obtains eye movement data from the EMR-9 by serial communication. Since the position of the rectangle shown on the CRT display is always obtained, head movement can be detected from the movement of the rectangle, and so the experiment can be performed in a natural posture without fixing the head. The saccade is detected by calculating the gazing point position, moving speed, rotation angle of eye movement, and

Figure 3: Flow chart

angular acceleration from the acquired eye movement data. When a saccade is detected, a window image is presented on the gazing point of the CRT display (Figure 3, left). When no saccade is detected, only the first three characters of each line are displayed. It was initially thought that it would be sufficient to display only the line that the subject is reading, but the subject does not always look at the center of the sentence. Since the size of the fovea, which has high visual acuity, is about 1°, the subject can read normally even if his or her gazing point deviates from the center of the character by ±1°. Since the center of the window is set at the center of the gazing point, in the case of horizontal writing the characters remain displayed in the window even if it shifts horizontally. However, if the window shifts vertically, part of each character may not be displayed inside the window when only one line is displayed. Furthermore, considering the accuracy of the EMR-9 (±0.1°), the upper and lower sentences were also displayed, so the size of the window was 3 lines in the vertical direction, and the number of characters in the horizontal direction was changed as a parameter.

Figure 6 shows an example of the change in the screen seen by the subject during the experiment. In Figure 6, the red filled circle represents the present gazing point (the red open circle represents the previous gazing point), and the blue frame shows the area displayed to the subject. When the gazing point moves and the termination of saccade is detected, a window image is displayed $\Delta t1$ seconds after the detection as shown in the lower right of Figure 6. The displayed window image is the text extracted from the sentence based on the size of the window. After the window image is displayed for $\Delta t2$ seconds, the masking image is displayed for one frame in the area where the window image was displayed. This process is repeated until the subject finishes reading, and the experimenter performs experiments by arbitrarily changing the values of $\Delta t1$ and $\Delta t2$. Kushima. measured eye movements during fixation to fixation movement imitating eye movements during reading, and suggest that eye movement speed (42 degrees/sec) is most appropriate for detecting the start and end of saccades as the threshold [22]. Therefore, eye movement velocity (42 degrees/sec) was used as the threshold value in the present study.

Since the retinal image is greatly blurred during the saccade, the perceptual function is reduced before and after the saccade so that the blurred image is not perceived. This phenomenon is called saccadic suppression [26]. The switching of the displayed image in the window must be performed within the period of saccadic suppression. Figure 7 shows the temporal ow of the processing. From Figure 7, it can be seen that there is a delay of 52 msec when the eye movement measurement device sends out the eye movement data by serial communication, and it takes about 2/60 sec (about 33 msec) to extract the gazing point; thus, it takes about 85 msec to detect the termination of a saccade. This means that the gazing period starts from 52 to 85 msec before the gaze point is extracted, and therefore the "fixation term" includes this period, as shown in Figure 7. Saccadic suppression continues after the saccade ends. The decrease in the detection rate due to the saccadic suppression recovers to 60% about 100 msec after the saccade, and to almost 100% in about 200 msec [27]. Considering this and the detection time of the saccade, Δ1 and Δ2 are varied.

Figure 4: CRT display

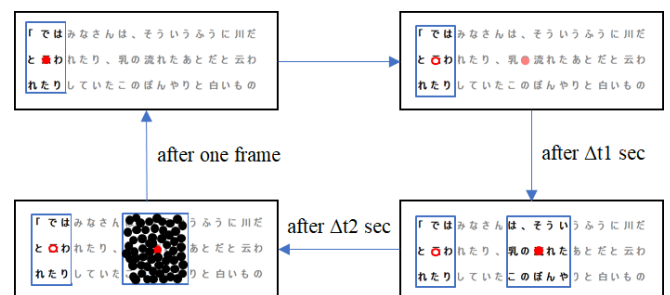
Figure 5: Eye movement analyzer


Figure 6: Example of screen change seen by the subject
Figure 7: Time flow of processing

As described above, it is necessary to control the image replacement time of the gazing area in msec units. At a typical display refresh rate of 60 Hz, for example, drawing is performed approximately every 16.7 msec, so a delay of up to 16.7 msec is expected. In addition, if image switching of the gazing area occurs after the display is drawn, there is a possibility that image switching of gazing area does not occur on the display. To prevent this phenomenon, Kushima. implemented a vertical synchronization function to synchronize display drawing and program drawing.

Table 2 shows the differences between past research and research using the equipment developed by Kushima. First, in research by Saida and Ikeda, because the eye movement data are directly input into the oscilloscope and the rectangle is displayed, the window is not always displayed in the gazing area. However, since the gazing point is always acquired, a window can be displayed at the gazing point by the system developed by Kushima. Second, the study by Saida and Ikeda suggests that afterglow and an afterimage occurred because a camera and cathode ray tube (CRT) display were used together and, while McConkie and Rayner describe the afterglow as "short," they do not state how many characters remained when switching images. Under the system developed by Kushima, afterimages do not remain after image switching, and technological advances have reduced the afterglow time of CRT displays to less than 1 ms. Third, in the Saida and Ikeda's study, window display time was not controlled, and in McConkie and Rayner's research, since the gazing point is not detected, the image cannot be replaced for a certain period within the gazing time. However, since the gazing point is always acquired, the image can be switched within the gazing time, and the switching period can be controlled accurately by implementing the vertical synchronization function used in the system developed

by Kushima. Finally, because the gazing point is not detected, the image is switched in McConkie and Rayner's study according to the distance of the eye movement from the edge of the screen. In contrast, under the system developed by Kushima, the gazing point is always acquired, saccade detection is performed, and then the image is switched.

Here, we describe the experiments performed by Kushima in a previous study [2]. The subject in this experiment was a 21-year-old student. The experiment consisted of a training session and two main sessions. In the training session, the window width was changed from 17 characters to 3 characters at 2-character intervals for practice, and in the main session the window width was changed from 3 characters to 17 characters and from 17 characters to 3 characters. These experimental methods were based on the experiments of Saida and Ikeda, who conducted experiments using Japanese text. In the experiment, since the refresh rate of the CRT display was set to 72 Hz, image switching could be performed every 13.9 msec. Therefore, the experiment was performed with $\Delta 1$ set to 14 msec and $\Delta 2$ set to 98 msec.

Figure 8 shows the subjects' average reading time in the two main sessions. The horizontal axis in Figure 8 shows the window width, and the vertical axis shows the reading time(s). As shown in Figure 8, the reading time was greatly reduced between window widths of 3 and 5 characters, and the reading time did not change significantly when the window width was larger than 9 characters. Experiments by Saida and Ikeda showed that normal reading was possible when the window width was larger than 13 characters. As mentioned in the previous section, it was reported that the experiment by Kushima. showed the same tendency as the experiment by Saida, considering that the first three letters of each line were always displayed during Kushima' s experiment.

Table 2: Differences between past research issues and the equipment developed by Kushima

Issues in the research of Saida and Ikeda	Changes with the system developed by Kushima.
Because the eye movement data are directly input to the oscilloscope and the rectangle is displayed, the window is not always displayed in the gazing area.	Since the gazing point is always acquired, a window can be displayed at the gazing point.
It is thought that afterglow and an afterimage occurred because a camera and CRT display were used at that time.	Afterimages do not remain after image switching, and technological advances have reduced the afterglow time of CRT displays to less than 1 msec.
Window display time is not controlled.	Switching at the speed of the refresh rate of the CRT display is possible by implementing vertical synchronization function.
Issues in the research of McConkie and Rayner	**Changes with the system developed by Kushima.**
Description of the afterglow as "short" does not indicate how many characters were actually left when switching.	There is no afterimage when switching the display.
Since the gazing point is not detected, the image cannot be replaced for a certain period within the gazing time.	Since the gazing point is always acquired, the image can be switched within the gazing time, and the switching period can be controlled by implementing the vertical synchronization function.
Because the gazing point is not detected, the image is switched according to the distance of the eye movement from the edge of the screen.	The gazing point is always acquired, saccade detection is performed, and then the image is switched.
Figure 8: Average reading time [22]

4. The Approach of this research

In their research, only experiments with a display time of 98 msec were performed, and experiments with other display times were not performed. However, we think that reading is possible even with a shorter display time. Therefore, in this experiment, we decided to investigate the lower limit threshold of the gaze time that was necessary for reading by performing a similar experiment with a display time of 98 msec or less. The past research did not involve control of image switching time and display time, which are features of this device. Therefore, the approach in this paper is very novel, and we believe that it can show new possibilities for visual information processing during reading. In addition, since the experimental method was complicated and difficult, the authors deliberately described past research and Kushima' s research and clarified the position and purpose of the present research.

5. Experiments with variable window display time

5.1. Experimental method

An experiment was conducted to investigate the reading time at six different display times. The experimental method was based on the experiment of Kushima. In this experiment, it is necessary to align the literacy levels of the subjects and select the subjects who can acquire eye movements with high accuracy in advance. The measurement accuracy of the eye movement measuring device depends on the characteristics of the subject's eye, in addition to careful pre-calibration. That is, in order to maintain the accuracy of eye movement measurement at the character size level from the start to the end of the experiment, it is important to select the subject in addition to careful pre-calibration. Therefore, in a preliminary experiment conducted in advance, eight subjects aged 21 to 23 years (male) were selected from among many candidate subjects.

The experimental procedure consisted of a main session and two training sessions. The window width consisted of 8 images in the training session, and each window changed from 3 to 17 at 2-character intervals. Also, in the main session, 8 images were presented, and the characters were changed from 3 characters to 17 characters (up) and from 17 characters to 3 characters (down). The analysis was performed by averaging the reading times of the up series and down series measured in the main session for each

window width. The displayed images are excerpts from three novels from the copyright-free Aozora library: "Night on the Galactic Railway, "I Am a Cat," and "Bochan." As an example of the display image, "Night on the Galactic Railway," which was used in the training session, is shown in Figure 9. We used the early part of each novel to minimize any reading difficulty due to the content of the text. An example of the experimental environment is shown in Figure 10. The CRT display was placed at a viewing distance of 60 cm so that the subject's dominant eye was at the center of the image. The subject placed an eye patch on his or her non-dominant eye and stabilized his or her head on a chin rest. $\Delta t1$ was set at 14 msec, the same as in the previous study, and $\Delta t2$ was varied among 84, 70, 56, 42, 28, and 14 msec, all of which were 98 msec or less. A total of six types of $\Delta t2 \times 8$ different window sizes = 48 conditions. It is difficult to perform 48 experiments on a single subject with an eye patch on one eye. Therefore, we conducted experiments of 18 conditions per person so that reading times for 3 people could be obtained for each $\Delta t2$ and window size. We also experimented with combinations of subjects and sentences so that one subject did not read the same sentence multiple times. It has been found that the characteristics of saccades differ between reading with an emphasis on understanding sentences and reading with an emphasis on reading quickly [7]. In this experiment, in order to have the reader read in the former way, we informed the subjects before the experiment that they would perform a comprehension confirmation test after the experiment to align reading behavior among subjects.

5.2. Experimental result

Figure 11 shows a comparison of the average reading times measured for each display time. Here, the reading time was defined as the time from the start of reading to the end of reading. This comparison will clarify the display time that enables normal reading, and in the next step, additional subjects will be added to this display time for statistical examination. From Figure 11, it can be seen that the reading time is longer when the display time is shorter, and the reading time is shorter when the display time is longer. When the display time is 56 msec or more, the reading time does not change significantly when the window width is 7 characters or more, and when the display time is 42 msec or less, the reading time is longer than with the 56 msec display time, and the change in the reading time is large regardless of the window width expansion. In Kushima' s experiments, the reading time did not change significantly when the window width was 9 characters or more, so the tendency was similar to that in Saida's experiment. In the present experiment, the reading time converged when the display time was 56 msec or more and the window width was 7 characters or 9 characters or more, which is considered to be close to the tendency shown in Kushima' s results. On the other hand, when the display time was 42 msec or less, the reading time tended to be extended or to fluctuate without depending on the enlargement of the window width. This suggests that reading cannot be performed normally with a display time of 42 msec or less. However, from Figure 11, it is not possible to determine exactly whether the starting point at which the reading time did not change was the window width of 7 characters or 9 characters. Regardless of the window width, the trend remains the same as in previous studies, but a detailed investigation will improve the novelty of this experiment.

5.3. Examination of the minimum required number of characters in the window and display time

Further, experiment about a display time of 56 msec was performed with two new subjects, and a statistical study was performed on the data from all five sub jects. Here, based on the

「 で は み な さ ん は 、 そ う い う ふ う に 川 だ と 云 わ れ た り 、 乳 の 流 れ た あ と だ と 云 わ れ た り し て い た こ の ぼ ん や り と 白 い も の が ほ ん と う は 何 か ご 承 知 で す か 。」 先 生 は 、 黒 板 に 吊 し た 大 き な 黒 い 星 座 の 図 の 、 上 か ら 下 へ 白 く け ぶ っ た 銀 河 帯 の よ う な と こ ろ を 指 し な が ら 、 み ん な に 問 を か け ま し た 。 カ ム パ ネ ル ラ が 手 を あ げ ま し た 。 そ れ か ら 四 五 人 手 を あ げ ま し た 。 ジ ョ バ ン ニ も 手 を あ げ よ う と し て 、 急 い で そ の ま ま や め ま し た 。 た し か に あ れ が み ん な 星 だ と 、 い つ か 雑 誌 で 読 ん だ の で し た が 、 こ の ご ろ は ジ ョ バ ン ニ は ま る で 毎 日 教 室 で も ね む く 、 本 を 読 む ひ ま も 読 む 本 も な い の で 、 な ん だ か ど ん な こ と も よ く わ か ら な い と い う 気 持 ち が す る の で し た 。 と こ ろ が 先 生 は 早 く も そ れ を 見 附 け た の で し た 。「 ジ ョ バ ン ニ さ ん 。 あ な た は わ か っ て い る の で し ょ う 。」 ジ ョ バ ン ニ は 勢 よ く 立 ち あ が り ま し た が 、 立 っ て 見 る と も う は っ き り と そ れ を 答 え る こ と が で き な い の で し た 。 ザ ネ リ が 前 の 席 か ら ふ り か え っ て 、 ジ ョ バ ン ニ を 見 て く す っ と わ ら い ま し た 。 ジ ョ バ ン ニ は も う ど

Figure 9: Example of display image (Night on the Galactic Railway)

average reading time for a window width of 17 characters, we performed a t-test of the average reading times for other window widths at a significance level of 5%. Table 3 shows the results. The yellow cell in Table 3 is the p-value of the window width, which shows no significant difference from the average reading time of the 17-character window width. It shows that there is a significant difference between window widths of 3 characters and 5 characters, and it is clear that there is no significant difference when the window width is 7 characters or more. Comparing the p-values with those for window widths of 7 or more characters, it can be seen that there is a large difference between the 7-character and
Figure 10: Example during experiment
Figure 11: Comparison of average reading time at each display time

Table 3: Results of t-test of the average reading times for 17-character window width and other window widths (5%)

window width	3	5	7	9	11	13	15
p-Value	0.000299	0.008255	0.286812	0.801026	0.729294	0.941101	0.735377

9-character p-values, but they become almost constant at 9 or more characters.

According to the above results, it was shown in this experiment that reading can be performed in the same time required for normal reading without a visual field restriction only by displaying text in a window of 7 characters with a display time of 56 msec. The reason for the difference between our results and those of previous research is that while the previous research used sample texts extracted from a third grade, elementary school textbook, the present research used a text extracted from the Aozora Bunko (copyright-free Aozora library). Both texts were composed of the same level of kanji, hiragana, and katakana, but it is possible that the present study had slightly fewer kanji. It is extremely difficult to match the ratio among hiragana, katakana and kanji as well as the difficulty of the kanji, but doing so will be necessary to improve the accuracy of the experiment.

6. Conclusion

In recent years, the number of people reading e-books on smartphones and tablet terminals has been increasing. A major feature of these information terminals is that they can turn pages instantly, unlike conventional paper books. It has already been shown that this causes a difference in eye movement between e-books and paper books.

In this study, we conduct research on visual information processing during reading, and we believe that it is possible to develop a more efficient and easier to see method of displaying information on such terminals. In previous research, we identified problems with the use of windows in researching effective visual fields and developed a new visual information processing analyzer that overcomes them. Furthermore, experiments using the developed device showed that normal reading without any restriction of view was possible if images were displayed for 98 msec with a window width of 9 characters.

In this paper, we extended our previous research, and while the previous research only involved experiments with a display time of 98 msec, here we investigated the minimum display time required for reading. In this study, 18 experiments were performed to increase the variation of the display time and to collect data for three persons for each of six display times of 98 msec or less. As a result, it was found that normal reading, as if there were no window or visual field restriction, could not be performed with a display time of 42 msec or less, but that normal reading could be performed when sentences were displayed in a window of 7 characters at 56 msec. Additional subjects were added and the 56 msec display time was tested further, and this finding was statistically confirmed.

Although our previous research used only on a 98 msec display time because the main focus of that study was device development, in this experiment we investigated the lower threshold of the gaze time required for reading by changing the

display time. As mentioned in the experimental method, it is extremely difficult to select a subject who can maintain the accuracy of eye movement measurement at the character size level from the start to the end of the experiment, so this time we conducted an experiment using eight adult male subjects. We believe that advances in eye movement measuring devices will make it possible to acquire eye movements with greater accuracy with less dependence on the subject. We believe that it is necessary to further increase the number of subjects, add female subjects at the same time, and verify various age groups.

In the future, we would like to research visual information processing from additional angles, such as changing the composition ratio of hiragana, katakana, and kanji, the difficulty of the kanji, the length of the sentences, and the size of the characters. Furthermore, we think that this research not only proposes a display method on an electronic device, but also psychophysically can clarifies what kind of processing is performed in the brain and how long it takes for reading and character processing. We would like to develop it as an effective means to clarify information processing in the human brain in a non-invasive manner.

Durability of Recycled Aggregate Concrete

Naouaoui Khaoula[*], Azzeddine Bouyahyaoui, Toufik Cherradi

Mohammadia School of Engineers, Mohamed V University Agdal, Rabat, 10000, Morocco

A R T I C L E I N F O	A B S T R A C T
	Many countries all over the world are promoting the recycled aggregate concrete for its advantage to solve the problem of shortage of natural resources in aggregates as well as promoting the recycling of waste and the reuse of materials. Recycled aggregate concrete replaces natural concrete with various rates of restitution of natural aggregates into recycled aggregates. The choice of rate is essential in the quality of the finished concrete and depends on the mechanical and durability characteristics. Tests in the civil engineering laboratory of the Mohammadia School of Engineers - Rabat Morocco have shown that above a rate of 30%, the mechanical characteristics drop. The addition of adjuvants / side products helps to increase this rate and a concrete with a 50% restitution can be used instead of natural concrete. Our study, the subject of this document, aims to study the durability of this concrete for various percentages of restitution. The experimental tests focused on determining the porosity of hardened concrete. The results were between 13 and 14% for all of the restitution percentages. This study concluded that for ordinary constructions, this concrete meets the criteria of the Perfertial Approach for durability. For projects with special criteria, other more in-depth studies will have to be carried out.

1. Introduction

Durability of concrete is the ability of concrete to resist to various types of damage, maintaining its strength and appearance integrity for its service period of exposure to its surrounding environment. Compared with nature aggregate concrete (NAC), the durability of recycled aggregate concrete (RAC) is usually weaker than NAC due to the adhered- mortar on the recycled aggregates (RA). The durability tests include deformation (drying shrinkage), impermeability, chloride penetration resistance, carbonation resistance, frost resistance and alkali aggregate reaction.

The benchmarking of many studies has demonstrated that the impermeability of RAC decreases with an increase of the replacement ratio of RA. Due to the capillary channels in the concrete system, fine elements of the recycled aggregates affects the impermeability more that the coarse ones [1-6]. In another side, the increase of coarse recycled aggregates increases the water absorption of concrete by immersion and capillarity regardless of the quality of RA.

For the chloride penetration resistance, the studies prove that it is lower in the RAC compared to NAC [7]. However, it was found that when RA was prepared with a low water /cement (w/c) ratio, it exhibits better performance than NAC in a chloride environment, probably due to the presence of higher C-S-H gels in RAC, which assists in chloride binding [8]. The carbonation depth increases, as many other durability properties, with the increase of RA replacement ratio. Many studies focused on the influence of different parameters on the carbonation resistance. They found that the increase of RA content, w/c ratio, and adhered mortar have a strong negative effect on it, the increase of exposure time or pozzolanic materials have negative effect when the presence of super-plasticizers, the pre-treatment of RA and the use of innovated mixing method affect positively the carbonation resistance.

Concerning the weak frost resistance, the RAC is not recommended in a harsh environment. However, the RAC, with a w/c ratio below 0.5 and incorporating 5% air content, can still be used in unsaturated and moderate cold climates [9]. The reduction of the amount of mixing water and the water saturation of the samples or the incorporation of a proper amount of fly ash and an air-entraining agent can help to improve the frost resistance [9-12].

[*]Corresponding Author: NAOUAOUI Khaoula, Mohammadia School of Engineers, Mohamed V university agdal Rabat, naouaoui.khaoula@gmail.com

Many methods have been proposed to improve the durability of concrete based on recycled aggregates [13-16] such us removing the adhered mortar of RCA. The adhered mortar content in RCAs has an obvious impact on strength and durability of RAC. Due to the presence of the adhered mortar, RCAs have a higher permeability than the natural aggregates.

Another method proposed is the use of the Two-Stage Mixing Approach (TSMA). The technique used is to divide the mixing process into two parts and proportionally splits the required water into two, which are added at different times us shown in Figure 1 illustrating the difference between normal mixing approach and TSMA mixing procedures [17].
Figure 1: Mixing Procedures of the (i) Normal Mixing Approach and (ii) Two-Stage Mixing Approach

The Experimentation highlights that the deformation and permeability of RAC can be enhanced by adopting TSMA with up to 68.09% on shrinkage (with 100% RA substitution after 14 days of curing). The increase is up to 46.42% on creep (with 100% RA substitution after 14 days of curing), 35.41% on water permeability (with 100% RA substitution after 126 days of curing), 51.81% on air permeability (with 20% RA substitution after 56 days of curing) and 29.98% on chloride permeability (with 100% RA substitution after 126 days of curing).

The third improvement method proposed is to enhance the characteristics of RCA without removing adhered mortal by using physical and chemical methods. The main methods used are [18] the impregnation by a foreign chemical to block the open porosity of RCA or the Use of polyvinyl alcohol (PVA)-impregnated method to improve the resistance to chloride-ion penetration. We might also use materials as additives like pozzolanic materials (specially pulverized fly ash or ground granulated blast furnace slag) or water repellent to improve the cement matrix in RAC and enhance the durability by reducing the permeability of RAC. These techniques may have inconvenient like reducing the compressive strength of RAC [14, 15, 19, 20]. We can also adopt an accelerated carbonation technique to enhance the quality of RCA as well as the mechanical properties.

2. Compressive strength of recycled aggregate concrete: Overview of the experimental study

Recycled aggregate concrete is a large-scale concrete that has been used in several countries for years.

In Morocco, RCA is subject to several types of research in order to encourage its local use.

As part of the valuation of the RAC, a mechanical comparison was drawn up in order to highlight the technical possibility of replacing normal concrete with recycled aggregate concrete.

The study protocol is devised to three main parties: Study of the characteristics of recycled aggregates (water content, water absorption) in order to highlight the quality of the aggregates. The second step is the formulation of the RAC according to the Dreux-Gorisse method based on the desired characteristics in the concrete and on the particle size analysis of natural and recycled aggregates and finally the compressive strength experimental tests.

2.1. Water content (W %)

The water content is equal to the ratio of the mass of water contained in the sample to the mass; we can calculate it using the following relation:

$$W = 100 * \frac{M - M_S'}{M_S} \tag{1}$$

with

W: Water content

M: The mass of the sample

M's: The mass of the sample oven dried at 105 ° C to constant mass without prior washing.

M s: The mass of the sample washed on the 4 mm sieve and oven dried at 105 ° C to constant mass.

Table 1: Water content experimental results

Recycled aggregates 5-12.5			Recycled aggregates 12.5-31.5		
M (g)	M's (g)	M s (g)	M (g)	M's (g)	M s (g)
2000	197.6	1975.32	2000	1915	1963.8
W			W		
1.49%			4.32%		

The comparison between two recycled aggregates of two different classes: Recycled aggregates with particle size 5-12.5 and recycled aggregates with particle size 12.5-31.5 showed that the water content is greater for large aggregates. This is justified by the presence of several pores, which disappear during the fine crushing of the aggregates.

2.2. Water absorption rate (AB %)

Water absorption by definition is the quotient of the mass of a sample immersed in water for 24 hours at 20 ° C and atmospheric pressure, by its dry mass. It is determined according to the relation below:

$$A_b = 100 * \frac{M_a - M_S}{M_S} \tag{2}$$

where:

Ab: Water Absorption

Ms: The mass of the sample washed on the 4mm sieve and oven dried at 105 ° C to constant mass.

Ma: The mass of the sample immersed in water for 24 hours at 20 ° C at atmospheric pressure and carefully blotted with an absorbent cloth.

Table 2: Water absorption rate experimental results

Recycled aggregates 5-12.5		Recycled aggregates 12.5-31.5	
Ms (g)	Ma(g)	Ms(g)	Ma(g)
1975.32	2194.8	1963.8	2148.4
Ab		Ab	
11.11%		9.4%	

The comparison between the two recycled aggregates of two different classes has shown that the water absorption rate is higher for small aggregates. This is justified by the superiority of the contact surface.

2.3. Particle size analysis

The particle size analysis is the main experimental step to formulate the concrete and to compare the recycled aggregates with the natural ones, the results of the particle size analysis are as follows, and the graph represents the rate of cumulative sieves relative to each opening of the sieve. The sieves used are standards ranging from 0.08 to 31.5mm.

The four aggregates tested are: GR 5-12,5 relative to recycled aggregate with particle seize between 5 and 12,5 mm , GR 12.5-131.5 relative to recycled aggregate with particle seize between 12.5 and 31,5 mm, GN 5-12,5 relative to natural aggregate with particle seize between 5 and 12,5 mm GN 12.5-31.5relative to natural aggregate with particle seize between 12.5 and 31.5 mm.
Figure 2: Granular curve for natural and recycled aggregates used in experimental study.

The interpretation of the granular curves shows that:

• The backbone of GR5-12.5 and GN5-12.5 is almost identical, at the opening 10 mm for example the percentage of the cumulative sieve of GN5-12.5 is almost 50% and of GR5-12.5 is 60%.

• The distribution of the various sizes of GR12.5-31.5 and GN12.5-31.5 aggregates is different.

Table 3: Differences between GR2 and GN2 in term of size analysis.

Diameter of the standard sieve	Cumulated sieve %	
	GN12.5-31.5	GR12.5-31.5
5	0,00	0,60
12,5	3,77	6,64
16	5,76	35,10
20	21,81	70,35
25	70,87	91,41
31,5	100,00	99,13

This distribution is favorable for GR12.5-31.5, it allows having less voids and pores in our concrete, which compensate for the defects of the recycled aggregates.

Based on the particle size analysis, the formulation chosen using Dreux-Gorisse method is:

Table 4: Concrete formulation

Component	Volume (m³)	Mass (kg)
Water	0.19	190
Cement	0.29	350
Sand	0,17	472,85
Gravel 5-12.5	0,15	376,14
Gravel 12.5-31.5	0,2	537,3

2.4. Compression test of pre-established concrete specimens

Compressive strength is the main characteristic of concrete in the medium term; identification tests and comparisons were carried out in the civil engineering laboratory of the Mohammadia School of Engineers and were based on changes in the replacement rate. Natural aggregates with recycled aggregates by opting for 0, 20, 30, 50, 75 and 100% recycled aggregates.
Figure 3: Compression test experimental results

The results interpretation is focused on the results at 28 days, we notice that with the increase in the replacement rate the compression decreases whether it is short term. We also notice that beyond 30% replacement the decrease in the value of compression exceeds 10%.

The second stage of the tests consists of improving the quality of the concrete in order to broaden its field of use and increase the replacement rate.

The proposed solution is to add various types of admixture in order to see the effect on the compressive strength of the type of admixture and the percentage of restitution used.

Our protocol is fixed on the use of three adjuvants: Plasticizer: BV 40, Super-plasticizer: Tempo 10M and the new generation super-plasticizer: SFR. These products are from the SIKA brand produced by SIKA MAROC installed in BOUSKOURA - Casablanca.

The choice of these three types is justified by the fact that we wanted to determine the effect of the type of admixture on our concrete.

Table 5: Compression test experimental results with and without adjuvant

% of RA	Compressive strength at 28 days without adjuvant – MPa	Compressive strength at 28 days with adjuvant (Tempo 10 M- 1%) - MPa
25	23.52	24,3
50	18,05	21,45
75	17,7	20,47
100	15	19,65

Results show that adding admixture improves compressive strength.

A comparison between various types of adjuvant proves that the plasticizer and super-plasticizer give better results than the new generation super-plasticizer as shown in table 5.

Table 6: Compression test experimental results with different adjuvants

% of RA	Type of adjuvant	% of adjuvant	Compressive strength at 7 days - MPa	Compressive strength at 28 days-MPa
50	BV40	1%	19,87	22,63
	SFR		11,50	16,65
	Tempo 10 M		17,47	21,45

The interpretation of these results is that adding a fairly complicated and developed formulation full of additive does not interact well with our attached cement.

The choice of the percentage of replacement of the binder by adjuvant is essential in the expected results. For each adjuvant, a recommended range of use is specified on the technical sheet for each product.

Experimental tests alone are able to choose the optimum value.

In our case, 1% constitutes our value chosen as being equivalent to the maximum of the test results (table 7)

Table 7: Compression test experimental results with different percentage of the adjuvant

% of RA	% of adjuvant	Type of adjuvant	Compressive strength at 7 days - MPa	Compressive strength at 28 days- MPa
50%	0.5%	Tempo 10 M	14,35	19,9
	1%		17,47	21,45
	1.5%		12,87	16,03

3. Porosity and density of hardened concrete

The porosity test was carried out according to NF P18-459 [21]

The test protocol is as follows:

- Formulation of concrete according to the quality required in test format,

- Leave 28 days in order to carry out tests on hardened concrete at 28 days of service life,

- After 28 days, place the test piece in a vacuum apparatus at a P <25 mbar for at least 4 hours,

- Reconnect the container to the vacuum pump and gradually introduce the imbibition liquid (drinking water) so that after 15 min the test pieces are covered with approximately 20 mm of water and maintain this pressure for a minimum of 44 hours.

Figure 3: the test pieces placed in the vacuum apparatus for 24 hours

The test carried out according to standard NF P 18-459 aims to determine the densities and porosities of various samples with different percentages of recycled aggregates replacing natural aggregates.

The density will thus be

$$\rho_d = \frac{M_{sec}}{M_{air} - M_{eau}} \times \rho_{eau} \qquad (3)$$

And the porosity

$$£ = \frac{M_{air} - M_{sec}}{M_{air} - M_{eau}} \times 100 \qquad (4)$$

with

M_{eau}: The mass of the specimen inhibited in the suspension system of the hydrostatic balance.

M_{air}: The mass of the test tube measured immediately after removing it from the water and wiping quickly to remove surface water without removing water from the pores.

M_{sec} : The mass of the oven-dried test piece.

The tests were carried out in an approved laboratory as part of the durability study of concrete made from recycled aggregates. The protocol is illustrated below:

Figure 4: Procedure for calculating M_{eau}

The results of the tests are collated in the following tables:

Table 8: The density experimental results

	M_{sec}	M_{air}	M_{eau}	ρ_d	
100%	2322,2	2464,1	1444,8	2,278	2,277
	2318,7	2459,4	1442,5	2,280	
	2310,3	2450,7	1434,8	2,274	
75%	2324,5	2465,6	1430,1	2,244	2,244
	2298,4	2439,9	1415,8	2,244	
	2298,3	2434,8	1410,9	2,244	
50%	2263	2423	1240,5	1,913	1,920
	2271,6	2429,4	1247,7	1,922	
	2284,1	2440,8	1254,3	1,925	

Table 9: The porosity experimental results

	M_{sec}	M_{air}	M_{eau}	£	
100%	2322,2	2464,1	1444,8	13,921	13,859
	2318,7	2459,4	1442,5	13,836	
	2310,3	2450,7	1434,8	13,820	
75%	2324,5	2465,6	1430,1	13,626	13,591
	2298,4	2439,9	1415,8	13,817	
	2298,3	2434,8	1410,9	13,331	
50%	2263	2423	1240,5	13,530	13,36
	2271,6	2429,4	1247,7	13,353	
	2284,1	2440,8	1254,3	13,206	

3.1. Results interpretation

The density increases with the increase in the rate of restitution. This is justified by the difference between the density of natural aggregates around 2000kg / m³ and the density of recycled aggregates from reinforced concrete with a density of 2500kg / m³

- Porosity, too, changes with the increase of recycled aggregates. This is justified by the characteristics of the recycled aggregates which consist of a natural aggregate coated in old cement, all coated in cement.

In order to interpret the results of our concrete in relation to its performance in terms of durability, the summary table of indicators following the Performantial Approach is used, based on various sustainability guides. (Table 10)

The buildings are subdivided into five categories according to the required lifespan:

- < 30 years

- From 30 to 50 years old: Building

- From 50 to 100 years: Building and civil engineering works

- From 100 to 120 years: Major works

- > 120 years: So-called exceptional works

Our study will be based on the first three categories due to the primary choice of the types of projects targeted by our concrete, which can be summed up in ordinary construction: Building or landscaping.

Based on durability indicators following the Performantial Approach, the recycled aggregates concrete might be used for all constructions with a lifespan of less than 30 years and all constructions with a lifespan of 30 to 50 years (Building) except those in:

• Tidal zone
• Immersion in water containing chlorides
• High exposure to sea salts or de-icing, but not in direct contact with seawater

Table 10: Summary table of indicators following the Performantial Approach[22] (P: porosity)

50 -100 Building and civil engineering works Level 3	30- 50 Building Level 2	< 30 Level 1	Required life Construction category Requirement level		Environment type →	
P < 14	P < 16	P < 16	- Dry and very dry (RH <65%) - Permanently wet (including immersion in fresh water)		1	Corrosion induced by carbonation (e = 30 mm)
P < 14	P < 16	P < 16	Wet, rarely dry (RH> 80%)		2	
P < 12	P < 14	P < 15	Moderate humidity (65 <RH <80%)		3	
P < 12(5)	P < 14(4)	P < 16	Periods of humidity alternating with dry periods without chloride (de-icing salts, spray, etc.)		4	
P < 14	P < 15	P < 16	5.1 : low [Cl-]	Exposure to sea salts or de-icing, but not in direct contact with seawater	5	Chloride induced corrosion (e = 50 mm)
•P < 11	P < 11	P < 14	5.2 : high [Cl-]			
•P < 13	P < 13	P < 15	Immersion in water containing chlorides		6	
•P < 11	P < 11	P < 14	Tidal zone		7	

Added to this, the possible use of the concrete is constructions with a lifespan of 50 to 100 years (Building and Civil Engineering Works) under the following conditions:

- Low exposure to sea salts or de-icing, but not in direct contact with sea water

- Humid environment, rarely dry (RH> 80%)

- Dry and very dry environment (RH <65%)

- Permanently humid environment (including immersion in fresh water)

Depending on the durability indicators, to use the concrete is other types of construction other in-depth studies should carry out and improvement in the concrete quality should be made.

4. Conclusion

This article is part of a series of test protocols carried out as part of the study of the performance of recycled aggregate concrete.

The study began with a mechanical comparison of ordinary concrete with recycled aggregate concrete with various replacement rates. These tests allowed us to deduce that for a basic concrete (without additions), the maximum replacement rate to meet the development conditions is around 25-30%. Beyond this value, training improvements will need to be made. In this sense, the addition of various admixtures has enabled us to deduce that super-plasticizers improve the quality of our concrete for replacement rates of 30 to 50%. Other changes might been used as explained in many researches studies: Change in the E / C ration, restitution of aggregates on one class only, primary sorting of aggregates.

The next step, the subject of this article, was to study the durability of recycled aggregate concrete. This study proves us that, overall, our new formulation complies with regulations in terms of manageability indicators for basic constructions.

At this stage, in order to finalize our protocol, an overview with a technical-economical comparison must be made in order to conclude the technical and economic reliability of the proposed product.

Conflict of Interest

The authors declare no conflict of interest.

A B S T R A C T

University operational activities are a routine part of university operations and supervisory control and monitoring function. The low controlling and monitoring of operational activities can cause irrelevance in the teaching and learning process. A graduate may have a graduation document but has never attended the teaching and learning process. An official institution can issue this graduation document, but it is fake because no teaching-learning activity occurred. It happens because the data is easily being manipulated and changed in the current system. From the problem, this is what drives this research to be carried out. With the characteristics of distributed, secure, and traceable information, Blockchain will solve this problem. Based on a previous study, blockchain technology facilitates university operational activities so that it will solve the current problems. This research uses qualitative research methods. The research process starts with literature studies and forum group discussions conducted on nine universities in Indonesia (public and private universities). This study used the User-Centered Design Technique. This research focuses on the user, so the results possibly are applied. The research results prove that Blockchain technology can record student attendance as part of the graduation process's teaching and learning process. Blockchain's immutable, unchangeable, and distributed characteristics will ensure the student attendance record's validity in the teaching and learning process.

1. Introduction

The problem of graduation documents forgery has risen in various countries. Several previous studies have reported that graduation documents forgery requires a new solution, Blockchain technology uses to be a solution [1], [2]. Other research states that Blockchain technology uses record operation activity in a university to protect information [3], [4]. This research tried to simulate the use of Blockchain technology (multichain) [5] to record student attendance because Blockchain characteristics such as distributed [6], secure, and traceable

information [7], [8]. Blockchain will be a new solution to this problem [9], [10]. To prevent the falsification of graduation documents issued by the Institution (such as fake attendance report). The irregularity was found because several universities issue original graduation documents, but the graduate had never conducted academic activities [11]. The early research stated a similar issue regarding fake attendance [12].

Blockchain technology is expected to provide a solution to this problem. This qualitative research was conducted by involving 9 universities, private and public universities, to obtain input and validation of the simulation result. The technique used in the research is user-centered design (UCD) [13], [14]. By using the

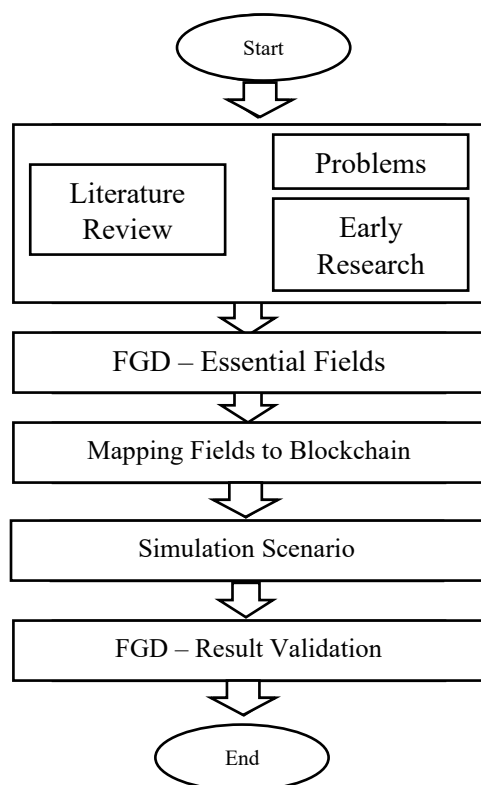
UCD technique, the research results will prioritize the user needs. This study aims to test blockchain technology for student attendance recording. The simulation results found blockchain technology can facilitate record student attendance during the lecture process, which is very important as a control and supervision function over university operations. The limitations of the existing system capabilities such as user easily to update the data. But with Blockchain technology, which can record data and not easily be manipulated and changed, even the data will always be immutable. After obtaining validation from 9 universities, the final result of this study stated that blockchain technology can be used for recording the attendance lists. This systematic writing of this paper starts with an abstract, introduction, literature, method, result and discussion and finally, the conclusion. The research stages can be seen in Figure 1 below.


Figure 1: Research Stages

Exhibit at Figure 1, the first research stage began with a literature review. This literature review found graduates who had graduation documents, but graduates were never found to be present in lectures. Another study found that Blockchain can handle this problem. The next step was to conduct FGDs with nine private and public universities to find necessary fields to support attendance records. After determining the fields, mapping is carried out to record student attendance into the blockchain (multichain) application and directly written into the multichain application (Blockchain). After that, a simulation was carried out and validated to 9 universities through FGD.

2. Literature Review

This session will describe some of the theories used in this study.

2.1. Multichain

Multichain is a platform created in 2015[5]. Multichain made for cryptocurrency. Multichain is a blockchain with private and permission types. The simulation carried out is limited to a laboratory at the university, but the simulation data are real data from the current system.

2.2. Blockchain for Education

Blockchain technology discovers in 2008 [15], and after a cryptographer in 2014 [16] combines smart content features into Blockchain technology. Many previous studies have stated that blockchain technology can be used to improve the process and activities in education, such as borrowing books or libraries [17], students loan [18], for graduation documents [19], [20], and others in education [1], [21]. From previous research, it can be said that Blockchain is not only for cryptocurrency but also for support operations in education.

2.3. Blockchain Characteristics

Blockchain Technology's characteristics help monitor lecture activities to minimize the occurrence of fake graduation documents, especially those issued by institutions that have the authority to issue documents. The characteristics of Blockchain are [6], [16]:

- Immutable, which means that information that has been recorded on the Blockchain will always be there and never deleted. In this case, attendance records that occur as a result of students coming to attend lectures will continue to be recorded forever and cannot be removed.
- Unchangeable, which means the information that has been recorded on the Blockchain cannot be changed or updated forever. In this case, the attendance that occurs as a result of students coming to attend lectures will continue to be recorded forever and cannot be updated.
- Secure, it means that all data in blockchain technology will be stored safely. In this case, blockchain technology (multichain) uses unidirectional encryption. When the transaction (absence transaction) is recorded, it is encrypted with the hashing method. Besides that, the transactions also follow the Merkle tree method hashing, and it does not only occur in a transaction but the entire transaction.
- Transparent means that all nodes on the registered network can see all activities or activities recorded on the Blockchain (all parties can see the transaction/absence transaction).
- Peer-to-Peer means absence transactions that occur on the Blockchain are done peer-to-peer, meaning there is no intermediary party at the transaction time. In this case, regarding attendance, attendance is directly given by the university to students.
- Distribute factor means that all absence transaction information recorded on the Blockchain will be distributed to all nodes on the same network.

2.4. Previous Research

Previous research searches have been carried out using Publish and Perish applications[22] at Scopus database, with keyword attendance in the title paper, with a range of 2015-2021, and found 1 article discussing student attendance. The problems presented are the same as the problems found, such as manipulating attendance being the problems found[12]—solution found by using IoT. However, manipulation on the database level possibly occurred.

3. Methodology

The methodology used in this research is the qualitative method. Some techniques used are literature studies and focus group discussions. The details of the activity can be seen in Figure 1. The research process initially started with a literature review. In this stage, two things were found, namely existing problems and previous research. The problem found at this stage is focusing on university operations for monitoring lecture activities with a student attendance system. Another finding states that blockchain technology facilitates operational lecture activities and can even be used to prevent fake diplomas.

The next step is determining the essential fields to be written on the Blockchain (multichain). Figure 4 shows the existing attendance report, from which the report can be described which fields will be used. It also shows the students list who attended face-to-face meetings and made class attendance in rooms 521 and 523 on October 23, 2017, with subject codes comp6049 and comp6045.

Mapping fields will be written on the Blockchain (multichain), after mapping the fields, the attendance scenario is created. After the scenario is complete, the simulation is carried out using multichain.

3.1 Simulation Testing

This study using simulation techniques. This simulation technique uses because this technique has similarities to the actual situation or is close to the actual situation. This technique is also very quick and inexpensive to perform and makes it easy to judge whether it is appropriate [23].

3.2 Simulation Stages

The first step in this research is to look at the attendance reports generated from the running system by taking several samples and then analyzing the current system's attendance report. Map the running system's fields based on the log report to the Blockchain (multichain) fields that will be used. Enter data into the Blockchain (multichain) based on the information in the current attendance log report. The final step is to show the Blockchain results (multichain) to the expert as part of the result validation.

Figure 4: Student Absence Log from Recent System

3.3 User-Centered Design (UCD)

This qualitative research study uses the User-Centered Design (UCD) approach. This technique is chosen to ensure the simulation results are more focused on the user (user) and industry [7]. The UCD technique creates simulation scenarios where user interaction occurs by communicating with experts in operational fields. For details, see figure 3.

4. Result and Discussion

This research using the simulation technique begins with data collection from the current system to record student attendance. Figure 4 shows the attendance log of the student's attendance, and the detail is students with the id "2101675432" attend courses with the code "COMP6049" and class code LC01 on October 23, 2017 (10/23/2017) present in class at 3: 24.24 in room ANG523 face to face "F2F".

From the attendance log report, Figure 4 is then simulated into the Blockchain (multichain) application. There is no customization on multichain used.

The lab configuration can be seen in Figure 5, which shows a node with the name chain1 and the multichain version 1.0.9 using the 10011 protocol.

Figure 5: Multichain Node

Figure 6: Multichain Addresses

The address configuration represents a university and student entity. In this case, the entity functions are to send assets that record attendance transactions that occur during the teaching and learning transaction.

The address configuration shows in Figure 6, which describes all entities' addresses for simulating attendance transactions.

After address configuration, the next configuration is asset formation. Assets represent courses, classrooms, and schedules in face-to-face mode (model).

Figure 7 explains the teaching and learning preparation (courses, classrooms, and the schedule) by the lecturer (KD_Lec), lecture schedule shift (15:20-17:00), and student classes.

Figure 8 shows the success of recording the program schedule, which is represented as an asset on the multichain.

Figure 7: Input Dashboard 1 – Comp 6049

Figure 8: Success Result Input

745

Figure 9 shows a simulation for filling the lecture schedule of COMP6065 course in classroom 521 on December 22, 2017, by KD_Lec (D3730) teachers with a face-to-face model and class LC01 student classes.

Figure 9: Input Dashboard 2 – COMP6065

Figure 10 illustrates the lecture schedule that has been successfully recorded on multichain (Blockchain) as assets. Figure 10 shows the number of students in the class so the assets can be sent to students present, while the attendance date follows the recording date on multichain.

COMP6049-ANG523-2017-10-23	1

Figure 12: Attendance Record in Multichain

The simulation results reported in this paper are not all transactions shown in Figure 5, but the simulation is carried out thoroughly. The simulation involves experts from 9 universities, and all universities agree that the student attendance recording transaction can be done on the Blockchain (Multichain).

This research will complement previous research were using Blockchain (multichain) to become a database in recording student attendance transactions will be more robust because student attendance records cannot be manipulated.

5. Conclusion, Limitation and Future Research

This research uses qualitative methods using several techniques, such as FGD with experts and literature reviews. The simulation results are carried out directly by comparing the existing system's attendance logs with multichain results.

This research produces a product that can be used to implement and become solutions in recording student attendance.

Other things that still need to be improved such as multichain configuration using only one node (single node), which should be at least 3 (three) nodes (best practice). Another thing is that there is no wallet created so that students cannot see the simulation's results. It can be used to be developed in future research.

Conflict of Interest

The authors declare no conflict of interest.

Comparation of Analytical Models and Review of Numerical Simulation Method for Blast Wave Overpressure Estimation after the Explosion

Alan Catovic[*], Elvedin Kljuno

Mechanical Engineering Faculty, Defense Technology Department, University of Sarajevo, Sarajevo, 71000, Bosnia and Herzegovina

ABSTRACT

A comparative analysis of formulas for blast wave overpressure is presented in the paper, and models were compared with available experimental data. The Kinney and Shin models show the best agreement with experimental data (Kingery-Bulmash) for free airburst, while for surface burst, Swisdak, Vanuci, and Jeon models predict test data most accurately. One of the novelties in the paper is introduction of new exponential and power functions for blast overpressure estimation, giving good agreement with experimental data. Also, several numerical simulations of free airburst explosions were performed to introduce methodology, and compare the data obtained with experimental data. A detailed description of the procedure for these simulations was provided – a contribution to numerical modeling of blast wave phenomena.

1. Introduction

There has been an increase in the research of explosive blast effects since numerous accidents (ie Beirut, 2020) happened, and terrorist attacks were carried out on civilians, with a large number of casualties during last decades. These include i.e. the bombing of US embassies (Ankara, 1958, Beirut, 1984), World Trade Center attack (New York, 2001), Mumbai attacks (2008), Mariott Hotel attack (Islamabad, 2008), Baghdad bombings (2016), Atatürk Airport attack in Turkey (2016), Nairobi hotel attack (Kenya, 2019), Jolo Cathedral bombings (Philippines, 2019), many attacks in Pakistan (Quetta, 2020) and also in larger area of Afganistan (lately Kabul, Kuz-Kunar, 2020) and many more.

An explosion presents violent release of energy. The detonation presents a rapid chemical reaction proceeding through the explosive charge at supersonic speed. The detonation wave converts explosive into a hot, dense, high-pressure gas, which is the source of powerful blast waves around explosion site (Figure 1).

Pressures at the Chapman-Jouguet point can go up to 400 kbar. Acceleration of the air particles (when the detonation is complete) beyond the face of the explosive is in order of 10^{11} g. Close to the face of the charge, at near-field scaled distance (where $Z=R/m^{1/3}$): $Z = 0,054$ m/kg$^{1/3}$, the maximal temperature is around 200 000 K. The temperature rises almost instantaneously with the shock front

arrival but the maximal temperature occurs at the expanding detonation products front [1].

In this paper, a comparison of analytical methods for blast wave overpressure is presented and compared to experimental data in Section 3. Also, numerical simulations of free airburst explosions were done in Ansys Autodyn for 1 kg, 10 kg, 10 T of TNT, and obtained data were compared with available empirical data, in Section 4. Section 5 presents conclusions.

2. Explosion types and blast wave parameters

There are two main groups of blast loads, regarding explosive confinement: unconfined (free air blast explosions), an air burst close to the ground, and surface burst) and confined (fully vented, partially confined, and fully confined). In free air spherical explosions, shock wave moves from the center of the explosion

[*]Corresponding Author: Alan Catovic, Email: catovic@mef.unsa.ba

and hits the target with no amplification. Hemispherical explosions are surface explosions where the detonation is close to the ground, and where the incident shockwave is strengthened due to reflections from the ground. As the blast wave propagate, Mach front (Figure 2) can be formed by superposition of the incident and reflected waves [2]. Confined explosion relates to detonation inside structures.
Figure 2: Free-air burst, air burst near ground and surface burst [2]

The pressure wave function in the air is schematicaly shown in Figure 3. There is a rapid rise from ambient pressure to a peak incident overpressure P_{so} which decays to the ambient value in time t_o (positive phase duration). The front arrives at a location in time t_A. Negative phase (duration t_{o-}) is characterized by underpressure P_{so-}. The incident impulse of the blast wave is the integrated area under the pressure-time curve (marked as i_s for the positive and i_{s-} for the negative phase) [2].
Figure 3: Free-field Pressure-Time variation [2]

In technical manuals [2], the overpressure exponential curve is often replaced by a linear curve. The negative phase is often ignored in structural calculations.

When the blast wave hits the surface, the reflected pressure value can be more than 20 times larger than the incident pressure value [3].

3. Prediction of blast wavefront parameters

A large number of studies were conducted in order to understand better blast effects after the explosion and the response of structures to blast loads. Empirical, semi-empirical, and numerical methods are mostly used for the prediction of blast effects.

Empirical methods are correlations with test data. The accuracy of empirical formula is usually lower for near-field explosions.

Semi-empirical methods are partly based on physical models. These methods rely also on experimental data and their accuracy is usually better than purely empirical methods. They are used in certain blast codes (programs)

Numerical (computational fluid dynamics, CFD) methods are usually the most accurate ones and are based on equations describing basic laws of continuum mechanics (conservation of mass, momentum, and energy). The physical behavior of materials is generaly described by constitutive equations [4].

Many programs such as BLASTX, CTH, SHAMRC, FEFLO, FOIL, DYNA3D, ALE3D, LS-DYNA, Air3D, CONWEP, AUTODYN, ABAQUS, 3D BLAST, SPEED have been developed to numericaly simulate the blast effects (Figure 4) and their load on structures.

Some of these programs (ie AUTODYN) can also be used to model the near-field explosion effects, in order to make new formulas for near-field air-blast estimations, and to update old formulas (ie. for reflection coefficients).
Figure 4: Simulations of shock wave in urban environment (AUTODYN and SPEED programs]
Figure 5: Positive phase parameters for spherical wave (TNT charges) from free-air bursts [4]
Figure 6: Positive phase parameters of hemispherical wave (TNT) from surface burst [4]

Reference [5] includes formulas for air bursts and surface bursts, for estimation of the values for incident and reflected pressures (and for other parameters as well). The positive phase pressures, impulses, durations, and other parameters of shock environment for free air and surface burst (for TNT) are given in Figs. 5 and 6 versus scaled distance Z (from Z=0,05 m/kg$^{1/3}$ to Z=40 m/kg$^{1/3}$).

According to Hopkinson-Cranz law, a dimensional scaled distance $Z = R/W^{1/3}$, where R is distance from the detonation point, and W is the mass of explosive charge (equivalent to TNT mass). The values of TNT equivalent mass factors can be found in papers and technical manuals.

Using diagrams, to obtain absolute value of particular parameter, their scaled value is multiplied by a $W^{1/3}$ to take the size of the explosive charge into calculation. Pressure and velocity are not scaled [5].

Calculations for surface burst are more straightforward than for airburst near the ground because of complex wave reflections in the latter case.

High-order polynomial equations functions made using regression analysis of test data [5] are used in the CONWEP.

In CONWEP (utilizes Kingery-Bulmash polynomials), following formula is used for defining P-t curve:

$$P(t) = P_{so}\left(1 - \frac{t - t_A}{t_o}\right)e^{-\left(\frac{A(t-t_A)}{t_o}\right)} \qquad (1)$$

Here A is decay coefficient, which can be calculated by curve fitting of experimental P(t) curve in positive phase [4]. Besides Eq (1), formulas of Flynn and Etheridge can be used for prediction of positive blast pressure profile.

Automated formulas for surface blast parameters can also be found in programs BECV4 and A.T. - Blast.

Table 1 below shows peak reflected overpressures P_r for surface burst (ie. in Figure 6) with different W-R (mass-distance) combinations. These values can be obtained using polynomial equations, or programs.

Table 1: Peak reflected overpressures P_r for surface burst

R (m)	Peak reflected overpressures (MPa)			
	100 kg	500 kg	1000 kg	2000 kg
1	165,8	354,5	464,5	602,9
2,5	34,2	89,4	130,8	188,4
5	6,65	24,8	39,5	60,2
10	0,85	4,25	8,15	14,7
15	0,27	1,25	2,53	5,01
20	0,14	0,54	1,06	2,13
25	0,09	0,29	0,55	1,08

Experiments have shown that human blast tolerance depends on magnitude of blast wave pressure and the shock duration. Tests showed that the lungs is the critical organ in injuries related to blast waves. The air bubbles release from damaged lung alveoli into the body vascular system accounts for most fatalities. The severe lung-haemorrhage occurs at pressure levels above 5,5 bar, while the lethality due to lung damage is for pressures 6,9 to 8,3 bar, Near

100 per cent deaths are confirmed for pressure levels 13,8 - 17,2 bar. Besides these primary effects of blast on humans, there are secondary (fragments from surrounding structures and buildings collapse), tertiary (blast wave and winds that can sweep people) and quaternary effects (other explosion-related injuries) [6].

Blast effects may damage structures by two main type of loading: diffraction and drag loading. Diffraction loading relates to loading the structure from all sides, where the blast overpressure is applied to sides of the object nearly simultaneously (i.e. on a building oriented towards explosion blast wave would arrive on the front sides and roof at nearly the same time). Ductile targets (i.e. made of metal) can be crushed. Brittle targets (i.e. made of concrete) will most likely shatter. The loading can be estimated from the peak overpressure [7].

Drag loading, related to dynamic pressure, is the force which acts on surfaces perpendicular to the pressure wave. The drag load is less than the diffraction loading, and it is applied for a longer time period. The drag load reverses direction, which can tear objects apart. Flexible targets are not damaged significantly by diffraction loading but can be prone to drag loading injuries. Objects not fixed can be thrown several meters away. Humans are quite vulnerable to this type of loading. Lightly protected equipment can also be damaged by drag loading [7].

Prediction formulas for blast loads on structures can be found in technical manuals.

Table 2 shows expected damage on structures loaded with the blast wave.

Table 2: Expected damage on objects loaded with blast wave [8]

Overpressure (kPa)	Expected damage
1,0 - 1,5	Window glass cracks
3,4 - 7,6	Minor damage in some buildings
7,6 - 12,4	Metal panels deformed
12,4 - 20	Concrete walls damaged
over 34,5	Wooden buildings demolished
27,6 - 48,3	Major damage to steel objects
41,4 - 62,1	Heavy damage to reinforced buildings
69 - 82,7	Probable demolition of most buildings

Blast overpressure is the most important parameter in blast effects modelling and many analytical relations can be found in the literature, most of them based on test data at different scaled distances and charge sizes.

The formulas for a free spherical airburst explosion can also be used for surface explosions by increasing the charge mass using the multiplication with a coefficient (reflection factor) 2η, where η takes into account energy used for deformation of the base material, with values ranging from 0,55 for water to 1 for steel.

The formulas for spherical airbursts and hemispherical surface burst blast wave pressure P_S, presented by several authors, are given in Tables 3 and 4.

Constants for polynomial formula by Kingery & Bulmash are omitted in Tables 3 and 4 because of space, but they can be found in their original paper [5]. Constants for formula by Jeon are also omitted from Table 4, and can be found in [9].

Table 3: Formulas for spherical airbursts blast wave pressure [10,11]

Author(s)	Formula for P_s (in MPa)	Applicability
Sadovskyi (1952)	$P_s = \dfrac{0,085}{Z} + \dfrac{0,3}{Z^2} + \dfrac{0,82}{Z^3}$ (2)	
Brode (1955)	$P_s = \dfrac{0,67}{Z^3} + 0,1$ (3)	$(1 < P_s)$
	$P_s = \dfrac{0,0975}{Z} + \dfrac{0,1455}{Z^2} + \dfrac{0,585}{Z^3} - 0,0019$ (4)	$(0,01 \le P_s \le 1)$
Naumyenko & Petroski (1956)	$P_s = \dfrac{1,050}{Z^3} - 0,0981$ (5)	$(Z \le 1)$
	$P_s = \dfrac{0,0745}{Z} + \dfrac{0,250}{Z^2} + \dfrac{0,637}{Z^3}$ (6)	$(1 < Z \le 15)$
Henrych & Major (1979)	$P_s = \dfrac{1,380}{Z} + \dfrac{0,543}{Z^2} - \dfrac{0,035}{Z^3} + \dfrac{0,000613}{Z^4}$ (7)	$(0,05 \le Z \le 0,3)$
	$P_s = \dfrac{0,607}{Z} - \dfrac{0,032}{Z^2} + \dfrac{0,209}{Z^3}$ (8)	$(0,3 < Z \le 1)$
	$P_s = \dfrac{0,0649}{Z} - \dfrac{0,397}{Z^2} + \dfrac{0,322}{Z^3}$ (9)	$(1 < Z \le 10)$
Held (1983)	$P_s = 2\dfrac{W^{2/3}}{R^2}$ (10)	
Kingery & Bulmash (1984)	$Y = C_0 + C_1 U + C^2 U^2 + ... + C_N U^N$ (11) (common logarithm of the pressure) $U = K_0 + K_1 \log(Z)$ (12) (C, K are constants, N is the polynomial order)	$Z \le 40,0$
Kinney & Graham (1985)	$P_s = \dfrac{808\left[1+\left(\frac{Z}{4,5}\right)^2\right]}{\sqrt{1+\left(\frac{Z}{0,048}\right)^2} \cdot \sqrt{1+\left(\frac{Z}{0,32}\right)^2} \cdot \sqrt{1+\left(\frac{Z}{1,35}\right)^2}}$ (13)	does not have limits on valid range
Mills (1987)	$P_s = \dfrac{1,772}{Z^3} - \dfrac{0.114}{Z^2} + \dfrac{0,108}{Z}$ (14)	
Hopkins-Brown & Bailey (1998)	$P_s = -1.245 + \dfrac{1,935}{Z} + \dfrac{0,2353}{Z^2} - \dfrac{0,01065}{Z^3}$ (15)	$(0,05 \le Z \le 1,15)$
	$P_s = \dfrac{0,0707}{Z} + \dfrac{0,3602}{Z^2} + \dfrac{0,4891}{Z^3}$ (16)	$(1,15 < Z \le 40)$
Gelfand & Silnikov (2004)	$P_s = 1700 \cdot e^{(-7,5 \cdot Z^{0,28})} + 0,0156$ (17)	$(0,1 \le Z < 8)$
	$P_s = 8000 \cdot e^{(-10,7 \cdot Z^{0,1})}$ (18)	$(8 \le Z)$
Bajić (2007)	$P_s = 0,102\dfrac{W^{1/3}}{R} + 0,436\dfrac{W^{2/3}}{R^2} + 1,4\dfrac{W}{R^3}$ (19)	
Shin (2015)	$Y = C_0 + C_1 U + C^2 U^2 + ... + C_N U^N$ (20) $U = K_0 + K_1 \log(Z)$ (21)	$0,0553 \le Z \le 40,0$

Table 4: Formulas for hemispherical surface burst blast wave pressure [10,11,12]

Author(s)	Formula for P_s (MPa)	Applicability
Newmark & Hansen (1961)	$P_s = 0,6784\dfrac{W}{R^3} + 0,294\sqrt{\dfrac{W}{R^3}}$ (22)	
Kingery & Bulmash (1984)	$Y = C_0 + C_1 U + C^2 U^2 + ... + C_N U^N$ (23) $U = K_0 + K_1 \log(Z)$ (24)	$Z \le 40,0$

Swisdak (1994)	$P_s = e^{(A_1 + B_1 \cdot \ln(Z) + C_1 \cdot \ln(Z)^2 + D_1 \cdot \ln(Z)^3 + E_1 \cdot \ln(Z)^4 + F_1 \cdot \ln(Z)^5 + G_1 \cdot \ln(Z)^6)} \cdot 10^{-3}$ (25) (A_1, B_1, C_1, D_1, E_1, F_1, G_1 are constants) (26)	$Z \leq 40,0$

Jeon (2017)	$P_s = 10^{(C_0 + C_1 \cdot \log(Z) + C_2 \cdot \log(Z)^2 + C_3 \cdot \log(Z)^3 + C_4 \cdot \log(Z)^4)}$ (30) (C_1, C_2, C_3, C_4 are constants) (31)	$Z \leq 40,0$
Vanucci (2017)	$P_s = e^{(0,14 - 1,49\ln(Z) - 0,08 \cdot \ln(Z)^2 - 0,62\sin(\ln(Z)))} \left(1 + \dfrac{1}{2e^{10Z}}\right)$ (32)	$Z \leq 40,0$

Figure 8: Positive blast wave incident overpressure values (vs scaled distance) for *surface* burst, obtained using formulas from different models, compared to experimental [5] curve (Kingery-Bulmash polynomials)

In this research, we conducted regression analysis (MatLab CF Tool) of test data [5] by using exponential and power functions, and for scaled distances range of $0,15 < Z < 40$. We propose exponential functions for surface burst wave pressure:

$$P_s = e^{(a_1 + b_1 \cdot \ln(Z) + c_1 \cdot \ln(Z)^2 + d_1 \cdot \ln(Z)^3 + e_1 \cdot \ln(Z)^4)} \quad \text{for } 0,15 < Z < 3 \quad (33)$$

$$P_s = e^{(a_2 + b_2 \cdot \ln(Z) + c_2 \cdot \ln(Z)^2 + d_2 \cdot \ln(Z)^3)} \quad \text{for } 3 < Z < 40 \quad (34)$$

Here, values of constants are: $a_1 = 0,3078$, $b_1 = -2,054$, $c_1 = -0,2916$, $d_1 = 0,06031$, $e_1 = 0,03571$, $a_2 = 0,906$, $b_2 = -3,514$, $c2 = 0,757$ and $d_2 = -0,08512$. Maximum relative difference between our formula (33) and test data [5] incident overpressure values is 3,3 % (Figure 9), and between formula (34) and test data values is 1,9 %. We propose, as a possible substitute equations, following power functions for hemispherical surface burst wave incident pressure, for different scaled distances:

$$P_s = 3,17 x^{-1,123} - 2,033 \quad \text{for } 0,15 < Z < 0,6 \quad (35)$$

$$P_s = 1,426 x^{-1,898} - 0,08057 \quad \text{for } 0,6 < Z < 2 \quad (36)$$

$$P_s = 1,448 x^{-2,371} + 0,01015 \quad \text{for } 2 < Z < 8 \quad (37)$$

$$P_s = 0,3396 x^{-1,366} + 0,0002888 \quad \text{for } 8 < Z < 40 \quad (38)$$

Maximum relative difference between formulas (35-38) and experimental data [5] for incident overpressure values is 3,4 % (Figure 9). Figure 9 presents comparison between our proposed

Figure 7: Positive blast wave incident overpressure values (vs. scaled distance) for *airburst*, obtained using formulas from different models, compared to experimental [5] curve (Kingery-Bulmash polynomials)

In this paper we made comparison of blast overpressures ($0,15 < Z < 10$) for airburst and surface (hemispherical) burst, using different models (presented in Table 3), and results are shown in Figs. 7 and 8. The experimental data [5] are included for reference as the widely approach for blast parameters prediction. Figure 7 shows most curves deviate from the test data for small scaled distances (ie for $Z < 0,4$). This may be since some of these equations (Brode, Mills) were developed for nuclear blast.

The Kinney (Eq. 13) and Shin (Eqs. 20 and 21) curves show the best agreement with Kingery-Bulmash data over the whole scaled distance. Figure 8 shows positive blast wave overpressure values for surface burst, obtained using formulas from different models (Table 4), compared to Kingery-Bulmash curve approximating test data.

Swisdak (Eqs. 25 and 26), Vanuci (Eq. 32), and Jeon (Eqs. 30 and 31) predict test data accurately, while other models struggle (i.e. Newmark model, used primarily for nuclear explosions, for scaled distances $Z < 0,4$).

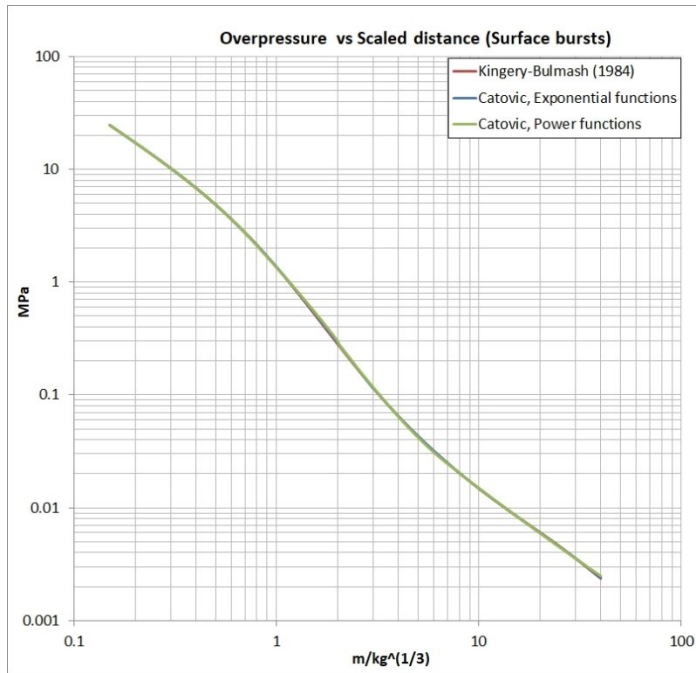
functions and test data [5]. As can be seen, our formulas (33-38) adequately predict incident overpressure values for hemispherical surface burst, for all values of scaled distance (Z < 40).


Figure 9: Positive blast wave incident overpressure values (vs. scaled distance) for surface burst, obtained using our models (formulas 33-38) compared to test [5] data (Kingery-Bulmash polynomials)

4. Numerical simulations

Numerical simulations of explosions were done in Ansys AUTODYN (version 2019), engineering software package that use finite difference, finite volume, and finite element techniques to solve a wide variety of non-linear problems in solid, fluid, and gas dynamics. This type of program is sometimes referred to as a hydrocode. The phenomena to be studied with such a program can be characterized as time-dependent with geometric nonlinearities (large strains and deformations) and material non-linearities (plasticity, failure, strain-hardening and softening, multiphase equations of state).

When simulating explosions, material properties can be selected from AUTODYN library (Table 5). Air uses Ideal gas equation of state, where the pressure P is related to the energy e (with adiabatic exponent γ) as:

$$P = (\gamma - 1)\rho e \qquad (39)$$

This form of an equation is useful for its simplicity and computation ease, where only the value of γ needs to be supplied.

For high explosives (i. e. TNT), there are different forms of equations of state (Ideal gas, Constant Beta, Wilkins, Becker-Kistiakowski-Wilson), but the one used in AUTODYN is Jones - Wilkins - Lee (JWL), in the following form:

$$p = A\left[1 - \left(\frac{\omega}{R_1 v}\right)\right] \cdot e^{-r_1 v} + B\left[1 - \left(\frac{\omega}{R_2 v}\right)\right] \cdot e^{-r_2 v} + \frac{\omega e}{v} \qquad (40)$$

The values of the constants A, R_1, B, R_2 and ω from Eq. (40) for some explosives have been estimated from experiments (cylinder test - expansion of a hollow metal cylinder filled with explosive), and are available in AUTODYN material library.

AUTODYN (1D, 2D, 3D) has been verified for use in blast effects estimation in many research papers.

In this research, we give an example of numerical simulation procedure of blast wave formation in the air after the detonation of 1 kg, 10 kg, and 10 T of TNT. Default values for the TNT and air equations of state were used, as well as other parameters specified in AUTODYN library (Table 5).

Table 5: Material properties of TNT and air in simulations (AUTODYN)

MATERIAL NAME: *TNT*	MATERIAL NAME: *AIR*
EQUATION OF STATE: JWL (det. products)	EQUATION OF STATE: Ideal Gas
Gamma: 1,35	Gamma: 1,4
Reference density (g/cm³): 1,63	Reference density (g/cm³): 1,225
Parameter A (kPa): 3,7377·10⁸	Pressure shift (kPa): 0
Parameter B (kPa): 3,7471·10⁶	Reference Temperature (K): 288,2
Parameter R_1: 4,15	Specific Heat (J/kgK): 717,59
Parameter R_2: 0,9	Thermal Conductivity (J/mKs): 0
Parameter ω: 0,35	
C-J Detonation velocity (m/s): 6,93·10³	
C-J Energy/unit volume (kJ/m³): 6,0·10⁶	
C-J Pressure (kPa): 2,1·10⁷	

Zones filled with the air were given initial energy of 2,068·10⁵ mJ/mm³ [13] to provide an ambient pressure of 101,3 kPa. A detonation point is located at the center of explosive (0,0,0) to start the explosion at time zero.

Gauge points (for pressure reading, Figure 10) were located at 0,5 m, 1 m, 2 m, 5 m from the detonation point of 1 kg TNT, 1m, 3 m, 6 m, 10 m for 10 kg TNT, and 3 m, 6 m and 9 m for 10 T simulation case.
Figure 10: Location od detonation point and gauge points along the mesh

In AUTODYN, the programs' Euler solver was used in a wedge-shaped grid (1D model) at the apex of which the explosive charge (TNT) was located. For a mass of 1 kg, the explosive radius was 52,7 mm, for 10 kg TNT this radius was 113,56 mm, for 10 T it was 1135,6 mm. Outflow transmitting boundary condition was used to eliminate the wave reflection [13]. In reference [13], cell size values of 3 mm were recommended as a compromise between simulation duration and accuracy, but the results are dependent on the mesh so we used a cell size of 1 mm for comparison with the test data. Reference [1] suggests cell size equal to 0,002 times the distance to the monitoring location on the reflecting surface provided results within 10% of the converged value for 0,0553 ⩽ Z < 40 m/kg^{1/3}. The reference [13] suggests quadratic viscosity values of 0,1 which we adopted in our simulations.

As a part of the mesh size sensibility study, we first numerically simulated the blast wave formation after the explosion, with three different mesh sizes (1 mm, 10 mm, and 20 mm, quadrilateral cell

size) for 10 kg TNT charge, as an example. Results can be seen in Table 6, and in Fig 11. Table 6 shows that for coarser grid (20 mm) results deviate substantially from experimental data comparing to finer mesh (1 mm).

Table 6: Mesh size sensibility study results for 10 kg of TNT

R (m)		P (MPa)		Rel. diff. (%)
		P$_{AUTODYN}$	P$_{EXP}$ [5]

	10	0,0345	0,0355	3,22

Figure 11 shows mesh size influence on shock wave form at a distance of 1m, after detonation of 10 kg TNT. The coarser the grid, the slower the rate of rise of pressure front and the flatter the curve shape. Peak overpressure values are different for different cell sizes (smaller cell sizes giving larger pressure values).
Figure 11: Mesh size influence on shock wave form at a distance of 1m, for 10 kg TNT explosive charge

Figure 12 shows the motion of a pressure wave along the mesh during simulation, for the case of 1 kg TNT.

During the simulation, AUTODYN shows rarefaction wave going toward detonation point (explosive charge). It reduces the pressures and density behind the front of the expanding detonation products.

This rarefaction wave, moving inward, is then reflected outward from the centre of the explosive forming, so called, secondary shock wave. Formation of a secondary shock wave, after the detonation of 10 kg explosive charge (TNT) can be seen in Figure 13.
Figure 12: Motion of a pressure wave along the mesh during simulation for 1 kg of TNT
Figure 13: Formation of secondary shock wave (visible close to detonation point on the left) after the explosion of 10 kg TNT charge

AUTODYN can also provide 3D view of mesh by rotation of initial mesh with 360°), as shown in Figure 14.
Figure 14: Rotation of initial mesh by 360°

Figure 15 illustrates the wave form P(t), obtained in simulations, at different distances from an explosion, for 1 kg and 10 kg TNT charges.

The second peak on the first (black) curve is likely caused by the blast wave reflection at the material interface (TNT/Air)

because of different acoustic impedances of these materials (it should be noted that this second peak is of little practical significance [13]).

We can see from Figure 15 that blast wave pressures drop significantly with distances in air.

Generally, when the blast wave moves through the atmosphere, pressures are rapidly decreased and have a brief existence span, (measured in milliseconds; as shown clearly in Figure 15).
Figure 15: P(t) curves obtained in AUTODYN for 1 kg and 10 kg of TNT at different distances

The results from numerical simulations for 1 kg, 10 kg, and 10 T of TNT explosive charge were compared with experimental data [5], and relative differences presented in Table 7.

Relative differences observed between simulation results and test data were smaller than 5,9 % for all cases for 1 kg TNT,

smaller than 4 % for 10 kg TNT, and less than 2,1 % for 10 T charge.

AUTODYN User's Manual reports of errors around 4% for peak incident overpresure between numerical simulations and test data.

Table 7: Comparison of blast wave overpressure values obtained in numerical simulation (1 mm cell sized mesh) with experimental data [5], for 1 kg, 10 kg, and 10 T of TNT at different distances

R (m)		P (MPa)		Rel. diff. (%)
		$P_{AUTODYN}$	P_{EXP} [5]	
1 kg TNT	0,5	3,6661	3,8848	*5,96*
	1	0,9897	0,9349	*5,86*
	2	0,1843	0,1947	*5,64*
	5	0,0318	0,0313	*1,59*
10 kg TNT	1	4,2715	4,4444	*4,05*
	3	0,4292	0,4420	*2,98*
	6	0,0919	0,0951	*3,48*
	10	0,0357	0,0355	*0,56*
10 T TNT	3	22,2757	22,6409	*1,64*
	6	9,8847	10,0005	*1,17*
	10	4,3524	4,4445	*2,12*

As can be seen from the results, AUTODYN can successfully model blast wave formation in the air after the detonation of high explosive. Results from these simulations can be remapped into 3D urban scenario simulation of explosion, which can be follow-up research.

5. Conclusions

In this paper we made a comparation of available formulas for blast wave overpressure. These formulas were compared with available empirical data [5]. The Kinney and Shin models showed the best agreement with experimental data for free airburst, while for surface burst, Swisdak, Vanuci, and Jeon models predicted test data most accurately.

Also, we performed a numerical simulation of airburst detonation after the explosion of TNT charge in Ansys AUTODYN, for the cases of 1 kg, 10 kg, and 10 T of TNT explosive charge, with a fine mesh (1mm), where obtained data were compared with experimental data (Kingery & Bulmash). Relative differences observed between simulation results and test data were smaller than 5,9 % for all cases for 1 kg TNT, smaller than 4 % for 10 kg TNT, and less than 2,1 % for 10 T charge. In this part, we also gave a detailed description of the procedure for these simulations as a valuable tool for blast wave phenomena investigation.

The novelty in the paper is that we introduced new exponential and power functions for surface blast overpressure estimation, with small relative differences compared to experimental data [5]. These formulas, with acceptable accuracy, are somewhat simpler than many of the formulas used for blast overpressure estimation, and can be implemented faster.

The following work in this field can be pointed towards complex geometry urban scenario blast effect modeling, where surface burst effects dominate, with complex reflections of shock wave present.

Conflict of Interest

The authors declare no conflict of interest.

A B S T R A C T

Blockchain technology has proven to be the best solution for digital data storage today, which is decentralized and interconnected via cryptography. Many consensus algorithms can be options for implementation. One of them is the PoA consensus algorithm, which is proven to provide high performance and fault tolerance. Blockchain has been implemented in many sectors, including the healthcare sector that has different characteristics of larger and more diverse record sizes. Implementing blockchain costs a lot of money. We used a blockchain network simulator as the best alternative in our research. The main problems with blockchain implementation are having a dynamic characteristic network and providing a blockchain system that is adaptive to network characteristics. Therefore, we propose a method to optimize the simulated PoA blockchain networks using Deep Deterministic Policy Gradients by adjusting the block size and block interval. The simulation results show an increase in effective transaction throughput of up to 9 TPS for AIH and 5 TPS for the APAC data models, and without affecting other important aspects of the blockchain.

1. Introduction

Currently blockchain technology is penetrating to all sectors in the world. One of which is the health sector, where a lot of data exchange and access restrictions are very sensitive and important. On the other hand, the characteristics of the data are also challenging because they are larger in size and heterogeneous. Another important factor is the interoperability of healthcare record, how to provide open access to read and write to the right party with the best scalability [1]. By applying blockchain technology to medical records, patients as data owners can better maintain and control their data as personal data, and health care professionals, institutions, and hospitals can exchange certain patient data as needed to facilitate analysis of patient health [2]. In short, blockchain has the potential to enhance PHR solutions that provide privacy and interoperability [3].

Research on blockchain began a long time ago, and many fields have adapted this technology. Initially in the financial sector known as cryptocurrency and more recently in the health care field [4]. Many approaches have been proposed for applying blockchain technology to health records. Most of which is focused on the distributed medical record ledger and provide a useful framework for safeguarding patient privacy. Apart from that, another aspect

that is also important in the consideration of ensuring the adoption of blockchain technology is the distribution and integration performance of health data among healthcare organizations [5].

Electronic Health Records (EHRs) adoption increased over time for all specialties [6]. As the adoption of EHRs increases, the possibility of failure to execute on the promise of shared health records also increasing, and this is a serious issue that needs to be addressed in EHR systems [7]. Wider adoption of electronic health records can significantly affect performance and allow a previously unknown level of violation of health data [3]. The privacy and security of medical records are the main concerns of patients. Some patients withhold information from their healthcare providers because of concerns about their privacy [8].

On the other hand, bitcoin as the first knowledge based in cryptocurrency only confirms with mean and median average throughput is between 3.3 and 7 transactions per seconds (TPS) [9]. Even in theory Bitcoin can handle transaction process with throughput up to 27 TPS (transactions per second) [10] with an average transaction size of 0.25 KB (kilobyte) [11]. That throughput is far from enough to handle health record transactions base on ORBDA (openEHR benchmark dataset), which size per transaction within 7.9 KB on average for the Authorization for Hospital Admission (AIH) XML data model and 12.4 KB on

average for the Authorization for High Complexity Procedures (APAC) XML data model [12]. In simple calculation, if we assume blockchain technology is adapted from bitcoin and the data has the same characteristic with ORBDA, we will only have transaction transfer speed around (7 * 250) = 1750 KB/s so the throughput with AIH XML data model only around 1750/7900 = 0.22 TPS and APAC XML data model had around 1750/12400 = 0.14 TPS. The blockchain needs optimization to handle PHR cases. Therefore, we propose DDPG to optimize the blockchain factor to be able to adjust to network conditions and maximize throughput.

2. Related Works

We present some related works with concern about optimize simulated PoA blockchain networks using healthcare data characteristics and optimization methods to adjust blockchain parameters in a way to handle dynamic network characteristics. Recently many research and development to implement blockchain technology into the health records sector. Here are some recent frameworks that use blockchain technology. Firstly, OmniPHR model [13] is a PHR model design that is distributed with the openEHR standard. It is using a blockchain but not integrated with the source of the blockchain. you can say it can't be changed with dynamic network characteristics. Secondly, FHIRChain Model [14], which is also uses a Blockchain-Base and uses the Office of the National Coordinator for Health Information Technology (ONC) according to its development needs, as well as security and interoperability issues with standards HL7, however, also does not mention the overall blockchain aspect and the associated optimization of the node from the blockchain used [12]. After all, we did not find research/or framework regarding optimizing blockchain in the health sector, and that would be a state of the art of this research.

Regarding related research blockchain optimizations, In 2019, Liu proposed an optimization for Blockchain-enabled in general proposed for the Industrial Internet of Things (IIoT) systems using Deep Reinforcement Learning, and she did not consider area/regional distribution, like where is the region of nodes, the block producers only scattering over a 1km-by-1km area [15]. In the real implementation of a blockchain network, it is demanded to be able to handle a very wide and unlimited network. In the same year, Liu also proposed optimization for blockchain-enabled Internet of Vehicle, the difference between the previews proposal is the security factor based on a number of validators instead of consensus selectors [16]. The process of both optimization studies showed significant improvement. Therefore, in this study, we tried to adopt the research methodology, using the data characteristics of health records with the ORBDA specification (openEHR benchmark dataset for performance assessment) with the same scale node distribution and same characteristics of the bitcoin network.

In 2019, Distributed Systems Group from Tokyo Institute of Technology developed an open-source system called SimBlock, to simulate a blockchain Network. This system suitable for use in blockchain network research [17]. Besides, SimBlock is very easy to configure and resembles the conditions with the characteristics of the blockchain network, so we decided to use this SimBlock as a simulator of a blockchain network in our research.

3. Proposed Simulated Blockchain System

This chapter will explain the blockchain system with parameters involved and can be optimized, and the design of an optimization model using the Deep Deterministic Policy Gradients.

3.1. Blockchain

The blockchain is an arrangement by the sequence of blocks, which holds a complete list of transaction records [18]. Blockchain is the core technology for Bitcoin, which was the first blockchain proposed from Nakamoto in 2008 rather than being implemented to the public in 2009 [19], Blockchain was wildly developed to be applied in all sectors such as financial services such as digital assets, remittances, online payments , Industry, etc. including the health sector, which is the focus of our research.

There are various types of transaction data from PHR, and openEHR is an open-source framework which is commonly used as a standard specification for PHR. For experiments in this study using ORBDA as a dataset. The ORBDA dataset is available in compositions, versioned compositions, and openEHR EHR representations in XML and JSON formats. In total, the dataset contains more than 150 million composition records. and consists of 2 data types namely AIH and APAC [12]. which we will use the characteristics of the transaction in the simulator.

3.2. Blockchain Network Simulator

Blockchain life cycle is a collection of dependent events, based on the consideration of block creation and message transmission(send/receive) as events, we consider SimBlock as a simulator of this research. SimBlock allows us to easily implement the neighbor's algorithm node selection. Given that block creation times are calculated from the probability of successful block creation, it is unnecessary to reproduce mines requiring large calculating power, and networks involving multiple nodes can be simulated. [17].

The SimBlock has an easy-to-modify configuration based on actual network characteristics. including: 1). number of nodes (N): in the simulation can set the number of nodes involved in the blockchain network (i.e., block producer / validator candidates) and assume (V) notation for number of block validator. 2). Block Size (S^B) : the average size of each block that the node will propose. 3). Block Interval (T^I) : Block generation interval targeted by the blockchain. 4). Regional distribution: the percentage distribution of nodes according to the specified region. 5). node computation (c): manage and randomize the compute capacity of the node, 4). upload / download speed: important factor of a network which is this simulator can be configure based on the origin and destination regions.

3.3. Proof-of-Authority (PoA)

Proof of Authority (PoA) is a one of consensus algorithms for permissioned blockchain that was superiority is due to performance increases with character to typical BFT algorithms. Because PoA has a lighter message exchange [20]. Another advantage of proof of authority is its power to validate blocks based on a person's actual identity thus making the system more secure and efficient, the blockchain which achieves high

throughput and low latency [20], [21]. PoA is basically proposed for private networks as part of the Ethereum ecosystem and is implemented in 2 types; Aura and Clique. In this experiment, we consider using PoA Clique with a node / validator identity as the sequence. The PoA Clique algorithm proceeds in an epoch that is identified by a sequence of committed blocks. A transition block is broadcast when a new epoch starts. It defines a set of authorities (i.e., their id) and can serve as a snapshot of the current blockchain by new authorities who need to synchronize [20].

a). Time 1   b). Time 2
Figure 1: Regulatory authorities could issue a block on Clique

Figure 1 shows two consecutive steps and how current leaders and authorities allowed proposed blocks change. There are number of validators $(V) = 10$ authorities, hence $V - (V/2 + 1) = 4$ authorities allowed to issue a block at each step, and one of them perform as a leader (V_1 in Time 1, V_2 in Time 2). In Figure 1 (a), the V_1 is the leader while V_2, V_3, and V_4 can propose blocks. In Figure 1 (b), V_1 are no longer allowed to issue a block (already in the previous step, so it has to wait $V/2 + 1$ steps or epoch, while V_2 is operate as a leader and V_5 is now authorized to issue a block [20].

3.4. Performance Analysis

Transactional throughput is key to measuring blockchain scalability that's why we need optimization to make it able to handle openEHR records, In addition to scalability we also need to keep other parameters. i.e. decentralization, security , and latency. Other parameters act as scalability constraints to overcome the four-way trade-off issue.

3.4.1. Scalability

Blockchain is literally an arrangement of linked blocks in which a block be composed of a transactions sequence. Scalability is the key to measuring the performance of the blockchain, scalability is measured using throughput (Transactions per Second), calculated from number of transactions in a certain time (second) that can be processed by the blockchain system. Transactional throughput represented by Ω (transactions per second, i.e. TPS) is depend directly on the variable block interval and block size, and the notation will be

$$\Omega(S^B, T^I) = \frac{\lfloor S^B/x \rfloor}{T^I} \tag{1}$$

Block interval is notated by T^I, block size is notated by S^B, and x is represents the mean of transaction size. we will use a variable block size or time interval can find a way to optimize the throughput on the blockchain network and it can be seen from Eq. (1) shows that increasing value of block size or reducing value of block interval between blocks can increase throughput. However,

the adjustment must also consider the network conditions, to maintain parameters such as decentralization, security, and latency, so that we cannot arbitrarily adjust the block interval and block size.

3.4.2. Decentralization

In the simulation we reproduced the actual environment of bitcoin blockchain. And in order to measure decentralization factor, we consider Gini coefficient, which is recommended to measure of income inequality in this case is wealth of validator. The decentralization factor comes from the inequality of validator nodes, in an equation derived from the number of authority processes on the blockchain. and each block at least has been authorized by $V/2 + 1$ validator. To identify the notation The set of nodes is denoted as $\Phi_S = \{z_1, z_2, .. z_N\}$, Meanwhile, to denote set of validators, $\Phi_D = \{z_{d_1}, z_{d_2}, ... z_{d_V}\}$, $\Phi_D \subseteq \Phi_S$ and V is number of validator.

$$G(Y) = \frac{\sum_{z_{d_i} \in \Phi_D} \sum_{z_{d_j} \in \Phi_D} |Y_{d_i} - Y_{d_j}|}{2 \sum_{z_{d_i} \in \Phi_D} \sum_{z_{d_j} \in \Phi_D} Y_{d_i}} = \frac{\sum_{z_{d_i} \in \Phi_D} \sum_{z_{d_j} \in \Phi_D} |Y_{d_i} - Y_{d_j}|}{2K \sum_{z_{d_i} \in \Phi_D} Y_{d_i}} \tag{2}$$

Note i, j is link connection between validators, first validator (z_{d_i}) and seconds validator (z_{d_j}) and validate block next. (Y) is number of validation distribution calculated from the number of times the validator validates a block. The value of the Gini coefficient is on a scale of 0 to 1, where 0 is the highest decentralization and 1 is the highest centralization. In other words, the closer the coefficient is to 0, the more decentralized validation is processed. On the other hand, and the closer to coefficient 1, the validation process becomes more centralized. To ensure a decentralized block validator/producer of the validation distribution factor, it must meet the requirements as notation below.

$$G(Y) \leq \eta_s \tag{3}$$

where η_s is decentralization threshold and $\eta_s \in [0,1]$.

3.4.3. Latency

In order to calculate blockchain latency, We evaluate the system with TTF, that is, the time to finality denoted by T^F, is measured by many seconds will take to receive reasonable assurance that transactions written on the blockchain are immutable. Note that transaction processing includes two phases, i.e., the time span from block creation to block creation and time for blocks to be validated and time to reach consensus on the generated blocks among validators, so the TTF for a transaction is obtained from adding the time of block issued (block interval T^I) with the amount of time for the block validation process to reach consensus, notated below.

$$T^F = T^I + T^C \tag{4}$$

where T^C represented latency of consensus, that is, the time span for a new block to be authenticated by the block validator.

Furthermore, we divide the validation process into two-stage, specifically sending messages and verifying messages (verifying Validator, verifying features.). Therefore, the formula of T^C is

$$T^C = T^D + T^V \tag{5}$$

T^D is the spanning time for sending message and T^V represented time of validation process. In order to set the optimal delay time we prepared the blockchain network scenario delay requirements, assuming a block must be issued and validated in a (ω) number of consecutive block intervals where ω is greater than 1 ($\omega > 1$). In particular, the time span for transaction completion must meet the following constraint,

$$T^F \leq \omega \times T^I \tag{6}$$

3.4.4. Security

The PoA Clique consensus algorithm that we propose in this study has a default security configuration, security can be guaranteed in all network conditions during $N/2 + 1$ signers to be honest signers. Thas a simple majority is all that is needed to run a secure network. To ensure the security of the blockchain system, each validator must not submit no more than 3 times in every epoch. if we assume B as a block t represent as an epoch containing a set of blockchain then set of block producer denoted by, $\Phi_B = \{ z_{b_1}, z_{b_2}, \ldots z_{b_K}\}$, $\Phi_B \subseteq \Phi_D$ with K notated of number block producer of each (t). then we can denoted by:

$$F_i^{(t)} = \sum_{z_{b_i} \in \Phi_B}^V |z_{b_i}| \tag{7}$$

where $F_i^{(t)}$ = Total number of block validators i propose a block in one epoch (t). Specifically, the node validator should not be as block producer more than 3 times in each epoch.

$$F_i^{(t)} \leq 3 \tag{8}$$

3.5. Performance Optimization

Blockchain system optimization challenges are facing dynamic and large-dimensional characteristics, in the form of transaction size and node features on the blockchain system (e.g. distribution, transfer rate, computing resources), we propose the DDPG algorithm. Below is an identification of action space, state space and reward functions.

3.5.1. State Space

The state space that we identified at the time of the decision / epoch t ($t = 1,2,3,..$) is a combination of the average transaction size (χ), the distribution of the validation process (υ), the computation power of node (c), and transmission rate, the speed of data exchange between each node ($R = R_{(i,j)}$), which is denoted as

$$S^{(t)} = [\chi, \upsilon, c, R] \tag{9}$$

3.5.2. Action Space

Action Space is a parameter that needs to be adjusted to optimize throughput, we identified several parameters including block size (S^B) and block interval (T^I) in the blockchain simulator that can be adjusted in order to adapt with the dynamic network characteristic of blockchain system, $A^{(t)}$ denoted as

$$A^{(t)} = \left[S^{B'}, T^{I'}\right] \tag{10}$$

where block size $S^B \in 1, 2 \ldots, S^{B'}$ is normalized value from S^B in Mb and block interval. $T^I \in 1, 2 \ldots, T^{I'}$ is normalized value from T^I in minutes .

3.5.3. Reward Function

The reward function is identified to ensure decentralization, security, and finality of the blockchain system while also maximizing transactional throughput based on the reward value given, the decisions issued on each epoch must meet the requirements as the notation below.

$$P1: \max_A Q(S, A)$$
$$C1: G(Y) \leq \eta_s$$
$$C2: T^F \leq \omega \times T^I \tag{11}$$
$$C3: F^v \leq 3$$

The decentralization factor of validators or block producer, distribution of validation tasks is guaranteed by C1 (Eq. (3)), Time finality (TFF) is ensured by C2 (Eq. (6)) and security factors secured by C3 (Eq. (8)), We denote reward function as $R\left(S^{(t)}, A^{(t)}\right)$.

$$R^{(t)}\left(S^{(t)}, A^{(t)}\right) =$$
$$\begin{cases} \frac{\lfloor S^B/\chi \rfloor}{T^I}, & if \; C1 - C3 \; are \; satisfied \\ 0, & otherwiase \end{cases} . \tag{12}$$

If one or more of the notations is unsatisfying, it defines the blockchain as having poor performance in security, latency, or decentralization, so the reward value given is 0 because this case addresses this invalid situation. respectively, so that the action value function Q (S, A) is denoted by

$$Q(S, A) = E\left[\sum_{t=0}^{\infty} \gamma^t R^{(t)}\left(S^{(t)}, A^{(t)}\right) \Big| S^{(0)} = S, A^{(0)} = A\right] \tag{13}$$

with the discount factor $\gamma \in [0,1]$ that reflects the tradeoff between the immediate and future rewards, For a deterministic policy $\mu : S \to A$ we can write the Bellman Equation as

$$Q\left(S^{(t)}, A^{(t)}\right) = E\left[R^{(t)}\left(S^{(t)}, A^{(t)}\right) + \gamma Q^{(\mu)}\left(S^{(t+1)}, A^{(t+1)}\right)\right] \tag{14}$$

The off-policy algorithms like Q-Learning use the greedy policy $\mu(S) = \arg \max_A Q (S, A)$. Function approximators parameterized by Q, which is optimized by reducing the loss function:

$$L(\theta^Q) = E\left[\left(Q\left(S^{(t)}, A'|\theta^Q\right) - y^{(t)}\right)^2\right] \tag{15}$$

where:

$$y^{(t)} = R^{(t)} + \gamma \max_{A'} Q\left(S^{(t+1)}, A'\right) \tag{16}$$

3.5.4. Deep Deterministic Policy Gradient (DDPG)

DDPG is an actor-critic algorithm based on Deterministic Policy Gradient [22], [23]. The DPG algorithm consists of a parameterized actor function $\mu(S|\theta^\mu)$ which specifies the policy at the current time by deterministically mapping states to a specific action [24]. The critic $Q (S, A)$ is learned using the Bellman equation the same way as in Q-learning. The actor is updated by applying the chain rule to the expected return from the start distribution J with respect to the actor parameters:

$$\nabla \theta^\mu J \approx E\left[\nabla_A Q\left(S^{(t)}, A^{(t)}|\theta^Q\right)\right] =$$
$$E\left[\nabla_{\theta^\mu} Q\left(S^{(t)}, A^{(t)}|\theta^Q\right) \nabla_{\theta^\mu} \mu\left(S^{(t)}|\theta^\mu\right)\right] \tag{17}$$

DDPG combines the merits from its predecessor algorithms to make it more robust and efficient in learning. The samples obtained from exploring sequentially in an environment are not independently and identically distributed so DDPG uses the idea from Deep Q-Networks (DQN) called replay buffer [24]. Finally, we present the proposed DRL-based framework in **Algorithm 1**.

Algorithm 1: Pseudocode of the DDPG optimization algorithm

---

for each decision epoch t **do :**

Optimization process

1) Select a random action ε, with probability otherwise $A^{((t))} = arg(max_A Q (S)^{(t)}, A^{(t)})$ re $Q(\bullet)$ is estimated by the main Q network;

2) Run simulator $A^{((t))}$ with adjusted block size and interval;

Update

1) Observe the reward $R^{((t))}$ and the next state $S^{((t+1))}$;

2) Store the experience $(S^{(t)}, A^{(t)}, R^{(t)}, S^{(t+1)})$ in replay buffer D;

3) Randomly sample a mini-batch of state transitions $(S^{(i)}, A^{(i)}, R^{(i)}, S^{(i+1)})$ from experience memory D;

4) Calculate the target Q-value from the target Q network by:

$$y^{(i)} = R^{(i)} + \gamma max_{A'} Q(S^{(i+1)}, A')$$

5) Update critic by minimizing the loss by

$$L (\theta^Q) = [Qh(S^{(i)}, A' | \theta^Q) - y^{(i)}]^2$$

6) Update the actor using the sampled policy gradient by

$$\nabla_\theta J \approx \nabla_A Q(S^{(i)}, A^{(i)} | \theta^Q) \nabla_{\theta^\mu} \mu(S^{(i)} | \theta^\mu)$$

7) Update the target networks

$$\theta^{Q'} \leftarrow \tau\theta^Q + (1 - \tau)\theta^{Q'}$$
$$\theta^{\mu'} \leftarrow \tau\theta^\mu + (1 - \tau)\theta^{\mu'}$$

6) Update the actor using the sampled policy gradient by

$$\nabla_{\theta^\mu} L \approx \nabla_{\theta^\mu} Q(S^{(i)}, A^{(i)} | \theta^Q) \nabla_{\theta^\mu} \mu(S^{(i)} | \theta^\mu)$$

end

---

4. Experiments

This chapter explains details of the experiment. It begins with preparing the simulation process, then reporting and discusses the result.

4.1. Simulation Process

In the simulation, we consider a simulate blockchain in 2 types of Health records data model 1). AIH XML data model. 2). APAC XML data model. With characteristics of transactions that generate random size by given mean and standard deviation. Mean of AIH XML type is 7.9 Kb and 12.4 Kb for APAC XML type, and 1.0 Kb for both of them standard deviation, The scenario will involve 600 nodes with 100 nodes as block producer and assume all block procedures are block validators. The DDPG optimization algorithm was implemented using the PyTorch library, with

python as a programming language. and the SimBlock developed by Tokyo Institute of Technology system as a blockchain network simulator, with Java as the programming language, which can be run via the bash command. For the platform, we are using PyTorch 0.4.1 with Python 3.7.3 on Ubuntu 18.04.3 LTS. The geographic nodes distributions as in Table 1.

Table 1: Bitcoin node distribution and network characteristic [17]

	Percent nodes geographical distributions (%)	Upload Bandwidth in average (bit per second)	Download Bandwidth in average (bit per second)
North America	33.16	19200000	52000000
Europe	49.98	20700000	40000000
South America	0.90	5800000	18000000
Asia Pacific	11.77	15700000	22800000
Japan	2.24	10200000	22800000
Australia	1.95	11300000	29900000

Performance comparison of the four schemes considered: 1) The scheme by adjusting the block size and block interval, dynamically adjusting the block interval and block size as the action state in the learning process. 2) Scheme with fixed block size and dynamic block interval, the block produced by the block producer is the same size (5MB) and the block interval can be adjusted as an action state in the learning process. 3) Scheme with fixed block interval and dynamic block size. the block issuance time span is set regularly (every 10 minutes). And only the block size is set in the action state in the learning process. 4) no optimization, which is no variable set as action state, so the block issued is always the same size 5MB and frequency issuing block is every 10 minutes.

4.2. Experimental Results

From the simulation obtain a good result, where the implementation of the DDPG algorithm brings improvement transactions throughput of the blockchain.

4.2.1. Decentralization

Figure 2 represents the decentralization of AIH data model and Figure 3 represents the decentralization of APAC data model. Both graphs visualize the decentralized performance of the simulated blockchain network. Where to measure the decentralization factor, we use the number of validation processes of each block validator, we use the Gini coefficient metric, to capture the generalized decentralized of validation task distribution. proven that in the Lorenz curve is gradually approaching the ideal decentralization (stripe) with a decrease in the threshold, then the blockchain gets more decentralized, so it can be interpreted that the Gini coefficient is considered as an effective metric to quantitatively measure a decentralized blockchain [16].
Figure 2: Lorenz curve of validation distribution of block validator with AIH data model
Figure 3: Lorenz curve, of validation distribution of block validator with APAC data model
Figure 4: Median throughput vs. rounding up block size with AIH data model
Figure 5: Median throughput vs. rounding up block interval with AIH data model

4.2.2. Baselines Performance

The correlation between block intervals and block size is very significant effect on throughput in AIH data models and can be shown in Figure 4 and 5.

The effect of the adjustment process in Simulation of Health records with AIH data model (Figure 4, Figure 5) showing significant correlations between transactional throughput with block size. Bigger block size, more likely it is to get a high throughput, but not guarantee the throughput will improve, and variable block intervals also have significant impact, the smaller the time interval proposed block, the more likely it is to get a high throughput. This correlation was also found in the blockchain health record simulation with the APAC data model depicted in Figure 6 and Figure 7.
Figure 6: Median throughput vs. rounding up block size with APAC data model
Figure 7: Median throughput vs. rounding up block interval with APAC data model

The effect of the adjustment process on block size and block interval on the transaction throughput is shown in Figures 4 - 7. We can see those graphs with 2 models AIH and APAC have the same pattern in the correlation between block size and throughput because the nodes validator can send and validate more transactions in one big block size but bigger block size needs more effort in sending a block into another node. Then, it can be seen that the Dynamic Block size and Block interval schemes achieve consistently higher throughput than other schemes with partially or completely fixed value parameters, because having a fixed value makes the system unable to adapt to network conditions. Meanwhile, it should be noted that fixed block size schemes perform better than fixed block interval schemes. A plausible explanation is in dealing with the situation of a low TTF threshold that a fixed block size scheme can be adjusted over the block interval. In addition, it makes sense when the results show that the

best performance of all schemes is a scheme whose block interval and block size can be adjusted according to network conditions, that reveals the advantages of a DDPG algorithm.

4.2.3. Throughput Performance

The simulation results show the performance of DDPG performance optimization scheme is presented in Figure 8 and Figure 9, the scheme we propose shows good convergence performance for both types of data models in AIH and APAC. At the beginning of the learning process, shows a very low throughput, and increases with increasing epoch, and reaches a stable state after about 750 episodes onwards. In addition, the proposed scheme can obtain the highest throughput results compared to other experiments with partially or completely fixed value parameters. The reasons behind these results are as follows: 1) In the DDPG Performance Optimization, the block interval and block size will be adjusted to optimize throughput adaptively based on network conditions; 2) For the proposed scheme with partially or completely fixed value parameters (block size / block interval), it fails to maximize throughput because the block interval or block size cannot adapt to dynamic networks.

In addition, based on the results of our research we also observe that the average TTF of a blockchain system decreases with an increase in the average source of computing power, and schemes with dynamic block size and block interval optimization require the lowest average TTF when compared with another partial optimized schema, or with a fixed block size and block interval scheme.
Figure 8: Convergence performance of different schemes with AIH data model
Figure 9: Convergence performance of different schemes with APAC data model

5. Conclusion

This paper presents the implementation of the DDPG algorithm performance optimization framework against the PoA Blockchain

Networks Simulation using Healthcare data characteristics in particular using the AIH and APAC data models, Scalability as the key to measuring blockchain networks can be increased effectively while ensuring other properties including decentralization, security, and latency. As we suggested, this research resulted in a framework combination of DRL based algorithm technic optimization and blockchain network characteristics of bitcoin in the simulator and applied with the healthcare data characteristics, the throughput of the blockchain was maximized by adjusting the block interval and block size based on the characteristics of the current network condition. The simulation results show that this framework can achieve maximum throughput than another experiment that has full or partial of the static parameter in blockchain system. The author realizes that this research still uses an emulator so, future work is in progress to consider adaptive in the real blockchain network and use types of Medical Records for blockchain.

Conflict of Interest

The authors declare no conflict of interest.

A B S T R A C T

This study builds the implementation of the traceability process by conducting simulation tests using business process simulations with the implementation of blockchain technology to track drugs. This research focus involved stakeholders, including the pharmaceutical industry, pharmaceutical wholesalers (distributors/wholesalers), health services (drug stores, hospitals), consumers. Simulation methods are used to describe the distribution and traceability of drugs. Finally, the research contribution in incorporating blockchain technology to supply chain management could potentially help in drug traceability. This study provides an overview of blockchain technology capabilities to find out which stakeholders and assets are transacted on the blockchain system. A decentralized Autonomous Organization is an approach to organizing data on the blockchain that defines all stakeholders identities associated with different addresses. This process can organize each address's transactions on a special blockchain platform in this study using multichain. Furthermore, transactions that have occurred cannot be updated or deleted. This simulation also illustrates some of the blockchain characteristics that must exist, among others, transparent, distributed, immutable, and peer to peer transactions. This contribution gives supply chain management, in particular on drug distribution, stronger control over distribution.

1. Introduction

Supply chain management (SCM) is a system management process that occurs to stakeholders (in general: suppliers, wholesalers, retailers, consumers) starting from the process of receiving raw materials from raw material suppliers to manufacturers, to distributing from distributors, retailers to consumers [1–4]. In SCM, distribution is the most important part to bridge every stakeholder in the SCM system. The distribution process supports the company's profitability process because it has a real impact on the related stakeholders' costs and experiences [5]. This distribution occurs throughout the industry, especially in the pharmaceutical industry [6, 7]. The distribution process occurs in the pharmaceutical industry distributing drugs from the pharmaceutical industry to wholesalers, wholesalers to hospitals or pharmacies, from pharmacies to end consumers (patients or communities) [8]. This distribution process has several problems that occur in the distribution of drugs, including a lot of data that must be identified, namely drug data,

stakeholders (industry, pharmaceutical wholesalers, health services (drug stores, hospitals), consumers). Data must be integrated to ensure the distribution process is good and correct, and the most important thing is drug data tracing/tracking. The drug distribution process requires a trace process to make it easy to find out that drugs sold in the market are free from suspected counterfeit drugs. The problems that occur in distribution can be solved with blockchain technology. This technology has a more secure platform, which supports auditable storage, data exchange, data integration, data that is easy to trace, distributed data, validated data [9, 10].

Many other kinds of research have developed this blockchain technology. One of its features is the ability to trace and trace data on circulating drugs and is believed to minimize counterfeit drugs [11–16]. In its development, the existing literature is an enormous challenge to prove the implementation of blockchain technology for drug tracking/tracing in the market. Apart from the literature, this study also conducted a forum discussion group (FGD) of the pharmaceutical industry, pharmaceutical wholesalers

(distributors/wholesalers). The results of the FGD, one of the most important processes of drug distribution and following the drug distribution model in general, experienced the problem of suspected counterfeit drugs circulating in the market, which was difficult to trace. Another thing from the FGD is that the Food and Drug Supervisory Agency will register the identity of a drug circulating in the market but (In Indonesian country is BPOM), which is a representative of government institutions as a supervisory body. These data are used as the basis for the available drug data and become part of the simulation test.

This study builds the implementation of the traceability process by conducting simulation tests using business process simulations with the implementation of blockchain technology to track drugs. This research's focus involved stakeholders, including the pharmaceutical industry, wholesalers (distributors/wholesalers), health services (drug stores, hospitals), consumers. A decentralized Autonomous Organization is an approach to organizing data on the blockchain that defines all stakeholders identities associated with different addresses. This process can organize each address's transactions on a special blockchain platform in this study using multichain. The purpose of the research is to understand the supply chain comprehensively, its advantages, and challenges. Finally, the research contribution in incorporating blockchain technology to SCM could potentially help in drug traceability. This contribution gives SCM, in particular, on drug distribution stronger control over distribution.

2. Literature review

2.1. Pharmaceutical Supply Chain Management

The 1990s saw the beginning of the supply chain. The supply chain begins with interrelated activities in the product transformation process. Product transformation starts from raw materials into finished goods, which are then distributed to consumers. With the increasingly complex development of the supply chain system, further management is needed to get maximum results. Supply chain management (SCM) is a system management process that occurs to stakeholders (in general: suppliers, wholesalers, retailers, consumers) starting from the process of receiving raw materials from raw material suppliers to manufacturers, to distributing from distributors, retailers to consumers [1–4]. SCM is implemented in many companies and industries in various fields, one of which is in the pharmaceutical industry.

Pharmaceutical Supply Chain Management (PSCM) is growing rapidly and plays an important role in the supply of drugs needed by various stakeholders [17–19]. This role ensures the drug distribution process from industry to consumers. This process occurs in the pharmaceutical supply chain, which consists of raw material suppliers, drug manufacturers, pharmaceutical wholesalers (wholesalers/distribution), health services (pharmacies, hospitals, health centers, and drug stores), and customers [8].

2.2. Blockchain

The history of blockchain was originally introduced by [20]. At first, it started with financial transactions or cryptocurrency, namely bitcoin. Blockchain technology development has

developed from the first version to the latest 3.0 version [21]. The development of version 3.0 of blockchain technology with smart contracts provides enhanced features of blockchain that can support various enterprise systems such as supply chain management [21] to improve the performance of a system that implements it.
Figure 1: Blockchain Pharmaceutical, Supply Chain Management [5]

2.3. Multichain Platform

Multichain is a platform with the application of blockchain technology [22]. Multichain can be applied in all systems in various industries or companies [22,23]. Multichain has a structure by having one node in its implementation [24]. In that one node will be able to have several addresses and several assets. The structure of multichain to the user interface can be access by the blockchain in multichain with API.

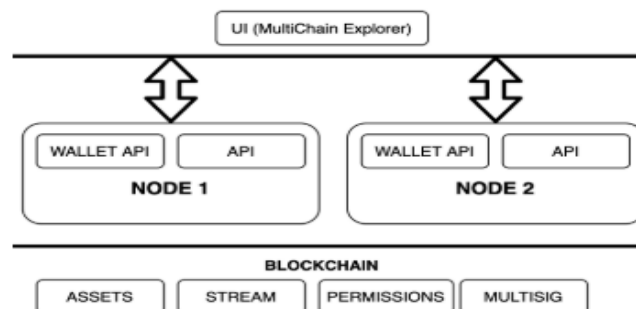
Blockchain with multichain consists of 3 layers, namely: layer blockchain is Assets, stream, permissions, multi-sig. This layer describes what can use in multichain, Layer Chain, and API. This layer describes the data from layer blockchain how to save or to can read from the next layer is layer UI (multichain explorer). This describes in figure 2.


Figure 2: Structure Multichain [22]

3. Methodology

In this study, we use the design science research methodology (DSRM) approach. This method is primarily used in information systems [25]. The steps are taken to identify the problem with a focus group discussion (FGD) with the pharmaceutical industry,

pharmaceutical distributors/wholesalers. Then proceed with developing the model and then carry out the validation process. In this study, validation is carried out to ensure that blockchain technology is able to track drugs circulating in the market in the PSCM system so that the model built can match its purpose. The business model that will be developed will be carried out with a business process simulation (BPS) approach. BPS is a method of business process management to improve business processes and develop new business models. This BPS approach can reduce the costs required and perform system simulations on real business processes. The results can be used for future development considerations [5].
Figure 3: Process Distribution Model with Blockchain [5]

The simulation testing model in this study is based on the business model in Figure 2, which is in accordance with the results of the FGD. The stages start from implementing the script, then the script testing, testing the results, and finally validating the test results. This test is implemented in the blockchain application shown in Figure 4.
Figure 4: Simulation Process Model

Blockchain technology experiments using the following device environments:

1. Server O/S   : Ubuntu Server version 18 LTS
2. Blockchain platform : Multichain
3. Node name   : Blockchain
4. Version   : 2.0.2
5. Protocol   : 10012
6. Database   : SQLite
7. Node Address   : Blockhain@xxx.xxx.163.25:2681
8. Language   : JSON, C++, Python

4. Analysis and discussion

In this study, a strategy is to map each entity involved in the PSCM business process with an address on the blockchain system and pharmacy drugs as an asset on the blockchain system. Mapping these addresses on the blockchain is the process of creating a Decentralized Autonomous Organization (DAO). DAO is an organization of everything that wants to be related to the blockchain system where the relevant stakeholders, the data that you want to store, use computer code and programs. Thus this organization has the ability to function independently without a

centrally regulated authority. DAO designed on a multichain platform can be seen as follows fig 5 and described in table 1.
Figure 5: Implementation DAO

Table 1: DAO implementation for different stakeholders

Stakeholder	Address
Government	1WUU5Tmzp5Wr9WTB3UFSm8JaPFk WqmYQ5wSNoH
Pharmaceutical	1N1Jcv3TsUSuYWkADUtNKVeigdrpU Kititqtab
Wholesaler	1TCZSt6D5vZ3e6vMiaSsMLZ39umwRG JVbj7U2Z
Health service (drug store)	177QbpjwmTeFRfkCdHmVkiZQH4Wn MhYUPRS7jf
Patient / End Consumer	1GKkwSFs92174KZef37DibNx5b8ee4W ix1vhZS

These structures have only one identity stakeholders represented by 32 characters from the hashing result or can be known as a pseudo name on the blockchain.

4.1. Business processes that are implemented in the simulation

In the business process testing simulation, starting from the wholesaler/distributor receiving a shipment of 10000 DBL9624502804A1 drug assets (unique drug labels) from the pharmaceutical industry, then the distributor sends 100 DBL9624502804A1 drug assets to drug stores. Then the final consumer buys 10 DBL9624502804A1 drugs as the final process. This test is carried out with a multichain blockchain approach. From the simulation testing process, it can be seen that the process of the blockchain script is mapped one by one in the model for each step, and the simulations carried out can be seen in Table 2.

Table 2: Implementing Business Process to Blockchain

No	Business Process	Script Blockchain asset
1	pharmaceutical industry registers drug production DBL9624502804A1 of 20000 pack/batch (this drug code)	Issue 10000 assets named "DBL9624502804A1" from Pharmaceutical (1N1Jcv3TsUSuYWkADUtNKVeigd rpUKititqtab) to Wholesaler

		(1TCZSt6D5vZ3e6vMiaSsMLZ39u mwRGJVbj7U2Z)
2	Wholesaler sends 100 packs of DBL9624502804A1 drug production to drugstores	Issue 100 assets named "DBL9624502804A1" from Wholesaler (1TCZSt6D5vZ3e6vMiaSsMLZ39u mwRGJVbj7U2Z) to the drug store (177QbpjwmTeFRfkCdHmVkiZQH4 WnMhYUPRS7jf)
3	Drugstores deliver 100 packs of DBL9624502804A1 drug production to consumers	Issue 10 assets named "DBL9624502804A1" from the drug store (177QbpjwmTeFRfkCdHmVkiZQH4 WnMhYUPRS7jf) to Konsumen (1GKkwSFs92174KZef37DibNx5b8 ee4Wix1vhZS)

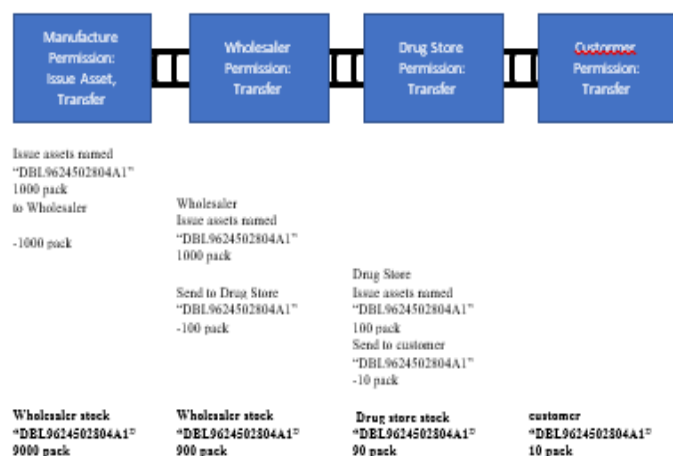
Figure 6: Implementing blockchain with a multichain platform


Figure 7: Blockchain transaction described in a block transaction

This business process maps to the blockchain system using a multichain platform where every process that is carried out will have one transaction, which is always recorded in a block. This process simulation shows that this platform can be appropriately used for the recording process of drug distribution.

Figure 8: Result tracing drug

4.2. Benefits of using blockchain in the pharmaceutical industry

Research an overview of the capabilities of the blockchain so that they can find out which stakeholders and assets are transacted on the blockchain system. Furthermore, transactions that have occurred cannot be updated or deleted. This simulation also illustrates some of the characteristics of the blockchain that must exist, among others, transparent, distributed, immutable, and peer to peer transactions.

This study implements peer to peer transactions that occur in related stakeholders in this system. With the results of technology simulation, testing with business processes serves to track drugs circulating in the market. This tracking also provides information on the final status of existing and circulating drug stocks in the market. The process of validating this simulation test results is carried out according to business processes that have been confirmed to domain experts such as the pharmaceutical industry and wholesalers.

4.3. Challenges of blockchain technology in the pharmaceutical industry

The challenge in this simulation process is that every data process that is published on the blockchain is in the form of a unique asset name (drug label name), and this process occurs sequentially to be validated on the blockchain system so it takes time and it is difficult to issue assets. The transaction can be many problem scalabilities.

5. Conclusion and Future Work

This study tested a business process simulation of the drug distribution process on the market from related stakeholders. This simulation explains how related stakeholders can interact with the blockchain system using DAO. With this, DAO initializes existing stakeholders with addresses that are formed using code and programming so that these stakeholders have a unique identity on the blockchain system. This study, using a multichain platform for simulation testing. This simulation test illustrates that the application of business processes in drug distribution can be implemented properly. So, that you can see the characteristics of the blockchain, including peer to peer (transactions that occur

directly with related stakeholders), cute (data cannot be changed because the transaction is hashing), and can be traced well to the drug distribution process.

This study is limited due to the pharmaceutical industry's lack of permission for various information related to the transaction process. The simulation testing system implements blockchain technology as it is by using multichain. The test process with this simulation has excellent results because it can describe the drug distribution business process that runs on blockchain technology using DAO. The next research will improve the blockchain technology infrastructure currently happening directly to multichain admin features. So that in the future, it is hoped that other support modifications can be made, such as a complete dashboard using API as integration with blockchain, implementable off-chain smart contracts, and direct development of business processes that occur in the pharmaceutical industry.

ARTICLE INFO	ABSTRACT
	Harmful algal blooms (HAB) or "Red tides" are organisms which produce toxins which are harmful to humans, fish, and other marine mammals. The said toxins come from dinoflagellates of genus Pyrodinium Bahamense var Compressum that cause Paralytic Shellfish Poisoning (PSP) and Dinophysis Caudata and Prorocentrum lima which results to Diarrhetic Shellfish Poisoning (DSP). In the coast of Western Samar, Philippines, there are reported occurrences of red tide toxins based on the laboratory result conducted by the Bureau of Fisheries and Aquatic Resources (BFAR) and the Local Government Unit (LGUs). HAB or Red tide has an impact on economy in terms of the loss of livelihood, sales, and exports, and also in terms of human life. This study developed a system that automatically detects the presence of red tide toxins and water quality parameters. Red Tide toxins and water quality parameters are determinant factors in detecting and forecasting the occurrence of HAB. In particular, the system utilizes a Surface Plasmon Resonance (SPR) and Water Quality parameter sensors used in detecting red-tide toxins and water quality. Data or information collected and generated by the system can be used for a faster, effective and efficient way of detecting and predicting the possible occurrence of HAB. Results positively indicate that the system performance can indeed be used as a Method in the detection and prediction of Harmful Algal Bloom. Specifically, for a time period of 80 minutes, 16 different sets of water parameters are captured and transmitted to the centralize system – making the system to be 100% functional as it is being set to operate in 5 minutes interval. Likewise, SPR bio toxin detection has a deviation rate of (+/-) 20%. Operational performance of the system is found to be 100%.

1. Introduction

Harmful algal blooms or HABs are organisms that produce toxins which are harmful to humans, fish, and other marine mammals. The said toxins come from Dinoflagellates of the genus Pyrodinium bahamense var compressum that is accountable for causing Paralytic Shellfish Poisoning (PSP) when ingested by mussels or oysters and also taken in by humans and for Diarrhetic Shellfish Poisoning (DSP) caused by the presence of Dinophysis caudata and Prorocentrum lima. In addition, this phenomenon has an enormous impact when it comes to economy since the production of supply of sea products, especially shellfish industry, is greatly affected.

There are over 4000 species algae (phytoplankton) and 2% (60 – 78 species) are known to produce toxins, and most of which are dinoflagellates. A proportion of these toxic dinoflagellates has a red-brown pigmentation-giving rise to the naming of algal blooms as 'red-tides', however, not all toxic algae are colored and incidents of poisoning have occurred in the absence of red blooms. Visible red tides may contain from 20,000 to 50,000 algal cells per l ml of seawater; however, concentrations as low as 200 cells per l ml may produce toxic shellfish [1].

In the coast of Western Samar, Philippines, there are reported occurrences of red tide toxins based on the laboratory result conducted by the Bureau of Fisheries and Aquatic Resources (BFAR) and the Local Government Unit (LGUs) from 2012 up to present. Based on their data, the most occurrence of red-tide was

in Irong-irong Bay, located in one of the costs of Samar Island, Philippines. It was followed by by Cambatutay Bay, Maqueda Bay, Villareal Bay of the same Island. The occurrence of this problem lasts for an average of 3 months with a longest recorded occurrence of 5 months for the past 5 years as indicated in 2016 Report of Bureau of Fishery and Aquatic Resources (BFAR).

On the contrary, various technologies were developed which are used in detecting HAB. One of these is the technology that utilizes fiber optic sensor in the detection of neurotoxin that causes harmful algal bloom. The technology makes use of the combination of absorption and reflection spectroscopy and the Principle Component Analysis (PCA) signal processing [2]. The process of sampling of the said technology starts with the gathering of contaminated water and put that sample on the device for analysis. But, there is no continuous monitoring mechanism on this part since there will be only testing of the sampled water if the user or researcher is on the site.

With this, the proposed system made use of ICT in achieving a real-time and low-cost monitoring of the different triggering factors of the occurrence of HAB. Specifically, a surface plasmon resonance multiplexer sensor and water quality parameter sensor was used coupled with that of the server-based monitoring software. Data gathered by the sensors were sent to a server-based program application. The same information are being stored in a cloud based services. Data captured and stored in a server based and cloud based application program will serve as a prime basis in the analysis and detection and prediction of HABs.

In particular, the study aims to develop an automated system that will capture the dynamics of the different parameters associated for the occurrence of HABs. Data captured in real-time basis will serve as inputs in the prediction. However, HABs prediction model based on the captured data by the developed system is not covered on this paper. Again, the intention of this study is to develop an automated mechanism that will detect the presence and dynamics of red-tide causing parameters.

2. Related Literature

The recurring occurrence of Harmful Algal Bloom in the coastal water of Samar, along with its adverse effect in human health and aquatic organisms necessitates the need to come-up an effective and efficient approaches, processes or technology that can be used to fast-tract the detection of the said phenomenon which is of paramount important. As such, several research and projects along on this area have been undertaken. On this, an analytical method has been developed for the quantitative analysis of marine biotoxins in shellfish – the main cause of the occurrence of harmful algal bloom.

One of such analytical method was made through the so called High Performance Liquid Chromatography (HPLC) with fluorescent detection using both pre-column oxidation as described in [3] and post column oxidation as described in [4]-[7]in addition to liquid chromatography tandem mass spectrometry. Similarly, HPLC with fluorescence detection in [8] have been utilized for the detection of Paralytic Shellfish Poisoning (SPS) toxins in algal and seawater samples with detection limits of nanograms per milliliter. Similarly, HPLC with fluorescence detection in [9] and LCMS/MS methods have been applied for the detection of the DSP toxins in

algal and seawater samples as described in [10]-[14]. Furthermore, the study of [15] describes a method incorporating HPLC with fluorescent detection of domoic acid with others using modified version as indicated in [16]-[18]. Indeed, the used of analytical method has been widely explored as evident to the number of researches undertaken as described previously; however, the said methods require skilled personnel and are labor intensive measuring only toxin group per method.

On the other hand, the study of [19], explored the used of near real-time ocean color data from the Sea-viewing Wide Field-of-view Sensor (SeaWiFS) to detect and trace HAB in Southwest Florida coastal water, its optical characteristics are influenced not only by phytoplankton and related particles, but also by the other substances, that vary independently of phytoplankton, notably inorganic particles in suspension and yellow substances. The results of the study showed that the SeaWiFS data provides an unprecedented tool for research and managers to study and monitor algal blooms in coastal environments. The existing study was also was not practical and expensive to be adopted by a rural area.

Accordingly, the study of [20], used the Early Warning Harmful Algae Bloom (HAB) Sensing System for use in Underwater Monitoring which utilizes Principal Component Analysis (PCA) to establish the complex linkages between ocean color, absorption and scattering, algae pigmentation and cell size, along the depth of bloom layers. The author proposed an optical fiber sensor based method of detecting the associated neurotoxins that cause Harmful Algal Blooms.

Another technology was developed by [21], a field deployable method that uses Surface Plasmon Resonance (SPR) and species-specific Peptide Nucleic Acid (PNA) probes to detect Alexandrium (a genus of dinoflagellate that is responsible for Paralytic Shellfish Poisoning at extremely low cell densities) rRNA. This instrument has been tested using synthetic nucleotide sequences designed to mimic two species of Alexandrium. The SPR is an optical detection method that measures the change in refractive index after binding (Hybridization) of a target to probe on a surface [22]. Changes in refractive index are measured in resonance units (RUs) [23] The samples are manually injected to the portable device, 100 uliters, and then starts to measure the sample.

The study of [24] developed a toolkit used rapid HABs detection and monitoring of maritime microalgae dubbed as Suitcase Lab. The toolkit enable rapid detection of specific microalgae associated with that of HABs as used in fields. In fact the toolkit can detect the presence of *A. catenella* – an HABs causing microorganism within the 2 hours of time sampling. Along with this, investigation and on micro phytoplankton community structure and abundance in two contrasted marine ecosystem has been explored in [25]. Results of such investigation indicates that the presence of such microorganism is prevalent in the commercially exploited environment.

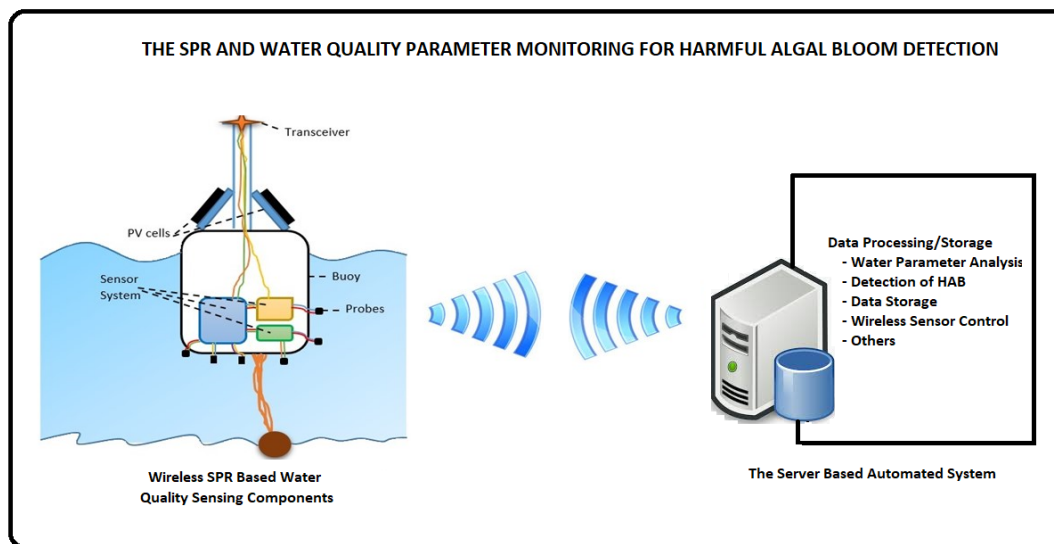
The existing study does not have continuous monitoring mechanism on this part since there will be only manual testing of the sampled water if the user or researcher is on the site. With our technology, the testing of sample procedure is automated and will


Figure 1: Developmental Model of the System

continuously be monitored depending on the necessary frequency of testing to be conducted.

Another method being explored in the detection of underwater biotoxins is the used of Surface Plasmon Resonance Technique described in [26]-[28]. Further, the study of [29] reported an situ SPR system using special optical fibers for measuring salinity of seawater using the determination of refractive index. The sensor was tested on a pelagic profiler and was successfully found to be functional. The study in [30] presented a similar optical fiber based SPR system for in situ measurement of reflective index and deployed it in 2013 in deep water.

3. System Development Model

A developmental research design approach following the Dynamic System Development Model (DSDM) has been adopted. DSDM is a project development concept consisting six phases as follows: (1) conceptualization, requirement and specification phase; (2) System Analysis Phase; (3) System Design – Hardware and Software Design phase; (4) Testing and Implementation Phase; and (5) Evaluation Phase.

In the conceptualization phase, benchmark information has been collected and analyzed. Benchmark information includes, but not limited to existing and similar technologies along water quality and harmful algal bloom detection; historical data on water quality and occurrence of harmful algal bloom in the specific site area; climate change and anthropogenic activities as causative factors to HAB occurrence; and other relevant information. This information becomes the basis in the formulation of the system conceptual model which is the outcome of the system analysis phase – the phase 2 of the DSDM. Figure 1 shows the conceptual model of the system.

In reference to the conceptual model shown in Figure 1, the operation and functional flow of the system has been developed following as one outcome of the system design process. The functional and operational flow indicated in Figure 2 shows the

graphical over-all workings of the proposed system. Figure 2 shows the detailed process, required and implied components – both hardware and software of the proposed system.

In particular, the system has been implemented utilizing the proposed backbone network articulated in [31] and [32]. The said network governs the communication and data transmission requirements of the sensing components s and that of the server-based automated system. Note that as indicated in Figure 1, detection of Harmful Algal Bloom via SPR, largely depends on the different water quality parameters that are being detected. The development model consist of two subsystems: (1) the wireless sensing component and (2) the server-based automated system.

The wireless sensing component consists of different sensors that detect the presence of HAB microorganisms in water and other water parameters such as the pH, turbidity, temperature, dissolved oxygen, and environmental parameters such as air temperature and humidity

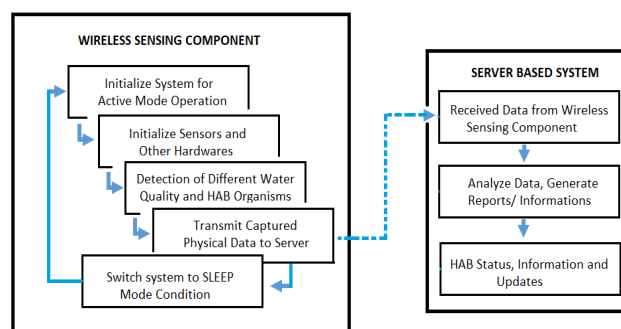
The server-based automated system received all the information from the wireless sensing components and performs analysis of all received data including the determination of the so-called Harmful Algal Bloom.


Figure 2: Operational and Functional Flow of the System
Figure 3: The Developed Wireless Sensors and SPR Based System

In particular, the Arduino uno, Xbee module, Spreeta Sensor, pH meter sensor, temperature sensor, humidity sensor, color - module, are used. Raspberry pie module. This hardware components form parts of the entire circuitry of the system. Further, a 5-watts solar panel is used to provide a 24/7 power supply to the wireless sensing component of the system. Note that a solar panel was specifically utilized in order to ensure a continuous power supply for the system and further ensure system continues operation.

The specific solar panel used was designed in conformity with the system required operational power where the current and voltage generated are auto-regulated. Voltage regulation was made possible with the use of LM317T and 1N4007 diode. In addition, considering the projected 24/7 operation of the system. Furthermore, the 1N4148 diode was also utilized to protect the LM317T and solar panel from reverse voltage generated by the battery. Reverse voltage is usually the main cause for the breakdown of the said component.

Figure 4: Water parameter sensor data

4. The SPR Based Harmful Algal Bloom System

4.1. The System Operation and Functional Flow

Figure 2 describes the operation and functions flow of the system. Once the system is on operational state condition – all sensors in the SPR based water quality monitoring automatically capture physical data and sends the same to the server-based automated system. Note that all sensors capture physical data and send the same to the central server for processing and analysis at

an interval of 4 hours. On this case, reports on the water quality and status of HAB are updated every after 4-hours period.

On the other hand, the server based system contains application and analytical software that performs the analysis of all received data. However, captured data by SPR sensors and water quality parameters sensor are collectively and comparatively analyze in order to determine the possible occurrence of HAB or if there is an existing occurrence of the same. Figure 2 shows the detailed operational and functional flow of the system.

4.2. System Development, Field Testing and Evaluation

Figure 3 shows the actual wireless sensing component of the system during deployment, testing and evaluation. Major electronics and circuits are enclosed in an air-tight box. A Polyvinyl Chloride (PVC) pipe was used as enclosure for probes that are submerged in the water. The same material was used as enclosure for environmental parameter sensors such as air humidity and temperature. Empty plastic bottles were used as buoy.

The system was deployed in Maqueda Bay Samar, Philippines. The buoy containing the wireless sensing component was stationed 50 meters off the shore of Maqueda Bay, where the server-side of the system was placed. The major focus of the field-testing is to determine the operation performance and functions of the system. For this particular purpose the sensing component was set to capture physical data and transmit the same to server-based component at an interval of 5 minutes.

Figure 4 depicts the captured physical water parameters being observed by the system as received by the server for a time period of 80 minutes. 16 different sets of collected data are received by the serve-based system on the said time period. The figure shows that when the air temperature decreases, air humidity increases.

These characteristics occurred from the received data set at 15:44 o'clock until the last received data set at 17:20 o'clock. In other words, the said results validates the general principle that as air temperature increases, air can hold more water molecules, and its relative humidity decreases. Thus, when temperatures drop, relative humidity increases. Note that there are two sets of temperature indicated on the figure – one is being represented in

Figure 5: SPR biosensor stability curve using the 0 ng/ml calibration standard

degree Fahrenheit and the other is represented in degree Celsius. Hence what is being referred on this particular discussion is the temperature represented in degree Fahrenheit. The degree Celsius represent the sea water temperature.

On the other-hand, the pH value of water does not significantly changes over the entire test and evaluation period. Figure 4 indicates that the pH water value ranges only from 5.61 to 5.66.

Moreover, the SPR sensor are actually multiplex biosensors that detects paralytic shellfish poisoning toxins, such as saxitoxin, okadaic acids and domoic acid. On this case, evaluation of the SPR sensors was based on biosensors response measured in RU monitored for a certain period of time. With this in order to ensure its operational and functional performance, test, monitoring and evaluation has been separately carried over an 8-week period. It is to be noted that, when the SPR biosensor is unstable, there would have been steady decrease in responses over time at each time point. However, from Figure 5, it can be seen that SPR sensors response time did not drop off significantly for any biotoxin, although fluctuation did occur having a (+/-) 20% deviation from system deployment until the end of experimental tests.

4.3. System Operational Performance

To further ensure the efficiency of the system operational performance. The system has been subjected to further evaluation by experts – emphasizing the extent of functionality of all components measured based on success or failure of operation over total number of test trials. Result of the said evaluation is shown in table 1. As reflected on table 1, the success of operation of all components is at 100%. The said results only implied that the develop system is indeed reliable once it would be adopted. In particular, the wireless sensing component of the system is programed to operate in two mode of operations – the ACTIVE mode and the SLEEP mode. The system is said to be in ACTIVE mode when it captures physical data and transmit the same to the central server. When the captured data are successfully transmitted, then the wireless sensing component switches to SLEEP mode and remains on that state for a period of 4-hours.

Furthermore, it can be seen in the figure that for over a 10 test trials of the different system components, no failure has been recorded. With the said result, the system operational capability can be considered as effective and efficient.

5. Conclusion and Recommendation

This study validates that real-time monitoring of sea-water quality parameters is feasible. These parameters include pH level, turbidity, temperature, dissolved oxygen, ambient air temperature and humidity among others. Also, the study was able to prove the capability and stability of the SPR biosensors as used in detecting paralytic shellfish poisoning toxins.

Thus, with the capability of the developed system to (1) monitor the real-time quality of sea water and (2) determine the presence of paralytic shellfish poisoning toxins in sea-water can be a good mechanism in the detection and prediction of the possible occurrence of Harmful Algal Bloom. Note that the HAB occurrence are correlated with that of water quality. Specifically, for a time period of 80 minutes, 16 different sets of water parameters are captured and transmitted to the centralize system – making the system to be 100% functional as it is being set to operate in 5 minutes interval. Likewise SPR biotoxin detection has a deviation rate of (+/-) 20%. Operational performance of the system is found to be 100%.

In conclusion, the developed system can be used as a mechanism to automate the detection and prediction of the possible occurrence of HAB. However, the need for the development of a comprehensive HAB prediction model software that will utilize the data captured by the develop system is recommended since the said is out-of-context of this study.

Table 1: Success and Failure of System Component Operations

Component and its Functions	Failure of Operation	Success Operation	No. of Test Trials	% of Success
The power supply and power system Acquisition of Sensor	0	10	10	100%
Node data for transmission	0	10	10	100%
pH level detection	0	10	10	100%
Water color detection	0	10	10	100%
Water Temperature detection	0	10	10	100%
Air temperature detection	0	10	10	100%
Reception/ Acquisition of sensors Data by Server Based system	0	10	10	100%
Analysis and Display of Sensor Data in Server	0	10	10	100%
Storage and retrieval of Data SPR multiplex sensors	0	10	10	100%
Average	**0**	**10**	**10**	**100%**

Mobile Application Design for Student Learning

Angelina, Weliati, Edwin Christian Jonatan Wardoyo, Sugiarto Hartono[*]

Information Systems Department, School of Information Systems, Bina Nusantara University, Jakarta, Indonesia 11480

A R T I C L E I N F O	A B S T R A C T
	The research objectives were to identify, analyze needs, as well as designing a mobile application for student online learning at PT. Ruang Raya Indonesia, particularly in the process of working on tasks assigned by the teacher. The methods used in this research are data collection method using Slovin theory, systems analysis by focusing on the current business processes, designing object-oriented systems (OOAD) method. The result is the design of mobile applications in the form of an application for students to be able to do the tasks assigned by the teacher, change private tutoring schedule, and view academic progress reports of the student during private tutoring. The Conclusion of this research is PT. Ruang Raya Indonesia requires a system that can provide students the information about student's private tutoring activity.

1. Introduction

PT. Ruang Raya Indonesia is a startup company engaged in educational technology. According to [1], the development of information and communication technology allows humans to exchange information in a short time without being limited by distance and time. As a result of globalization, there is free competition in the world of work, trade, and education. Advances in information and communication technology, especially in the field of education, have implications for how to use information and communication technology in the learning and teaching process as attractive as possible as a source of learning and improve the quality of education. Agreeing with Junaedi, [2] also argue that smartphones can be used for learning media, and one of the operating systems that can be run by smartphones is android. According to [3] smartphones have the impact of portability, namely practical and can be used to study anywhere and anytime.

According to [4], sometimes even though school teachers have taught well, students have the possibility of not understanding the material presented at school, so that additional material through tutoring may be needed by students to help students understand the material. In [5], the author revealed that private tutoring improves students' understanding of the subject matter, and has slightly better academic achievement than students who do not do private lessons.

Based on the percentage of APJII regarding the sector of internet service users, when viewed from the employment sector, the majority of the internet in Indonesia is used in the trade and service sector than in the 3rd place in education. The estimated increase in the number of smartphone users in Indonesia according to data quoted from [6] can reach 108 million users, taking into account this and also the opinions of users, all of these features will be developed on smartphones with the Android operating system. With this application, PT. Ruang Raya Indonesia has the hope of increasing student's interest in learning anywhere and anytime.

According to [7], there are 10 components that can be considered for an LMS, 2 of which are content development aimed at helping and also motivating students to learn, in this case, the teacher must be able to upload the teacher's notes. but the teacher also has to upload supporting material to increase student knowledge of certain materials. Apart from that students must be able to obtain supporting material, teachers must also be able to monitor student participation and development. The LMS must be able to record whether students take part in discussions or submit assignments.

Based on the results of data collection regarding the needs of users and stakeholders of the application at this time, it is found that the problems are both less supportive applications and lack of features to make users receive more information. Where current technology students feel uncomfortable with the current website because the page display is in the form of letters that can be very small and can be very large, writing that can overlap with other

*Corresponding Author: Sugiarto Hartono, shartono@binus.ac.id

writing and the layout of images that are not suitable so that it blocks other writing or images. The results of private lessons are not supported by documentation that can be seen directly by students. This results in a student not being able to know his academic progress while taking private lessons. The right place for doing assignments for students to do assignments given by private tutors. This allows students who take private lessons not to get enough enrichment assignments to improve students' academic abilities on the material taken. Then the private tutoring schedule that cannot be changed based on the situation at that time.

Seeing from all existing aspects, the application that is owned by PT. Ruang Raya can now be developed better to meet the needs of users. then it is proposed to do development that includes things such as acting classes, class history, online private tutor assignments, making student academic progress reports, making questions for student assignments, changing private teacher schedules.

The application developed aims to allow students to see a list of classes being taken by students and a list of classes that have been taken, allowing students to see the initial class plans taken and to view reports on academic progress during class, allowing students to change private tutoring schedules due to unpredictable obstacles, and allows students to do assignments given by private tutors and be able to see the value and discussion of this paper.

2. Research Method

In obtaining the data and information needed in this application design analysis, several methods are used as follows:

2.1. Data collection methodology

- Literature Review

Doing a literature study by looking at references from several books related to problems related to the problem, as well as looking for other references from the internet.

- Field Study

The first step will be observed. Where this observation is for data collection by observing directly about running business processes such as usage, and daily problems that occur with company applications.

The second step is to conduct interviews by holding direct questions and answers with related parties to obtain an overview of the ongoing business processes.

Then the third step is a questionnaire. This questionnaire was conducted using online distribution. Where the sample size taken is based on the Slovin formula. This questionnaire is distributed to students to obtain an overview of problems for the running system, to obtain student opinions on the application being developed, and to obtain information on the required features. Questions will be made open-ended and closed-ended questions, where closed questions are made and processed based on a Likert scale, that is, with questions measuring students' agreement and disagreement with a subject and have been arranged based on the need to obtain the required data and information.

2.2. Methods of Analysis and Application Design

The method used to develop applications is the Object-Oriented Analysis and Design (OOAD) method. The design stages are as follows:
Inception Phase
In this phase, determine the scope of the system to be designed and identify the system requirements. The focus in this stage is as follows:
- Identification and Analysis of Company and User Needs
- Observation of business processes and running applications
- Analyze the results of the questionnaire
- Determination of problems with the system and running application
- Recommended solutions on running systems and applications

All requirements obtained will be documented in the UML diagram as follows:
- Activity Diagram
- Use Case Diagram
- Domain Class Diagram
- Use Case Description
- State Machine Diagram

2.3. Elaboration Phase

In this phase, analysis and design of the system architecture is carried out, analysis of the system requirements is carried out in more depth and ensures that all user needs are identified. Documentation for Use Case Realization will be documented in the UML diagram used at this stage:
- User Interface
- Multilayer System Sequence Diagram
- Update Design Model Class Diagram
- Package Diagram

3. Result And Discussion

3.1. User Needs Analysis

Based on the user needs that have been obtained from the data collection process through questionnaires and interviews, it can be concluded that the needs of students who have not been met in the application are as follows:
Figure 1: Graphics of desirability of features in smartphones

Judging from the level of user needs, the features that are needed by users who are in the top three are doing assignments,

changing schedules, and viewing academic reports with a percentage of 15.3%. By looking at these priorities, these features are the top priority for the design to be made in advance to meet the needs of the user.
Figure 2: Graph of the operating system requirements on a smartphone

The development plan is made on the Android operating system because it sees the needs of the most selected users with a percentage of 71.1% so that development on the Android operating system becomes a development priority.

3.2. Problem Analysis

The problems faced in the current business process are as follows:

- Students who have taken private lessons can only be accessed on the official website where things that can be accessed are a list of active classes along with their details and class history. However, students feel uncomfortable with the current website because the appearance of the page is in the form of letters that can be very small and can be very large, the writing can overlap with other writing, and the layout of the images is not suitable so that it blocks other writing or images.
Figure 3: Fishbone Problem 1

- Currently, the results of private lessons are not supported by documentation that can be seen directly by students. This results in a student not being able to know his academic progress while taking private lessons.
Figure 4: Fishbone Problem 2

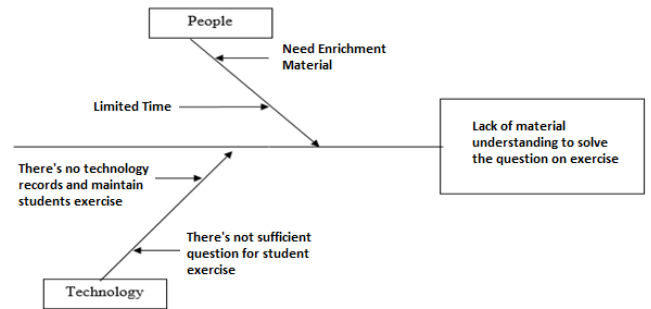
- There is no proper place for performing assignments for students to do assignments given from private tutors. This allows students who take private lessons not to get enough enrichment assignments to improve students' academic abilities on the material taken. Where time is limited and


Figure 5: Fishbone Problem 3
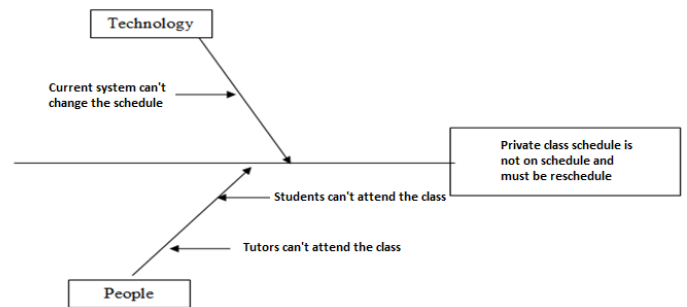

Figure 6: Fishbone Problem 4

4. Solutions

Proposals on Problems faced by PT. Ruang Raya Indonesia is as follows:

Table 1: Problem 1

Problem	Students who have taken private lessons can only be accessed on the official website. However, the page display is in the form of letters that can be very small and can be very large, text that can overlap with other writing, and the layout of the Figure is not suitable so that it blocks other text or figures.
Solution	Designed and built on mobile for this feature so students will be able to see the list by simply logging into the active class.
Reference	According to [5]: Strive for consistency, shortcuts to universal usability, offer informative feedback, design dialogue to generate closings, prevent errors, easy to reverse actions, support the internal focus of control, reduce short-term memory load
Features	- Students can see active Class - Students can view class history

Table 2: Problem 2

Problem	The results of private lessons are not supported by documentation that can be seen directly by students
Solution	Designed and made features to see student academic progress. This feature will be a place for students to see how their abilities are during class.
Reference	According to [5], all evaluation results must be reported to various interested parties, parents/guardians, school principals, supervisors, government, school partners, and the students themselves. This is intended so that the learning process, including the learning process and outcomes achieved by students and its development, can be known by various parties. The report on student learning progress is a means of communication between schools, students, and parents to develop and maintain a harmonious cooperative relationship between them. Broadly speaking, the purpose of reporting student learning outcomes is to provide accurate, clear information about the progress of student learning outcomes within a certain period, providing feedback for a student in knowing the strengths and weaknesses that give rise to motivation for learning outcomes, determine the progress of individual student learning outcomes in achieving competence.
Features	Students can view academic progress reports which consist of initial documentation reports, evaluation of sessions, evaluation reports

Table 3: Problem 3

Problem	Schedule that cannot be adjusted based on the conditions that occur
Solution	The features proposed are features of private tutoring schedule changes. This feature allows students or teachers to make changes to the private tutoring schedule that has been agreed upon in advance with the agreement of the two parties concerned. This feature is expected to help students or teachers to rearrange their private tutoring schedules so that private tutoring learning activities can run smoothly.
Reference	According to [5] states that "a schedule is defined as something that describes

where and when people and resources are at a time. Based on the Big Indonesian Dictionary, the schedule is the division of time-based on the work order arrangement plan. " Most people are familiar with lesson schedules presented as a table of days of the week and timeframes. It can be seen that each day is divided into periods. Each term has a list of courses being taught, by whom, and where. Schedules can be stated in several different ways, each student must have their schedule depending on the subject, as well as each teacher and room, all of these are different perspectives on the same schedule

Features	Student can reschedule

1. Application Design Result
- Use Case Diagram

Figure 7: Use Case Diagram

Activities that will be carried out in the application that are designed are doing assignments, viewing discussions - working on assignments, changing schedules, viewing reports, making reviews and ratings, changing reviews and ratings, viewing notifications (students), viewing discussions - active class (students), and see the discussion - history of class (students) where this activity will be carried out by students. Then make assignments, make initial documentation, make evaluation sessions, make evaluation reports, view notifications (teachers), see discussions (teachers), and decide on changes to private

tutoring schedules where this activity is carried out by the teacher. Furthermore, changing the initial documentation, changing the evaluation session, creating evaluation reports, changing assignments, and deleting tasks where this activity is carried out by the admin.

Figure 18: Making queestions-teacher

5. Conclusion

After analyzing the student application at PT Ruang Raya Indonesia, the following conclusions are obtained:

- PT. Ruang Raya Indonesia is a company that develops products and services in the field of educational technology. One of them is a mobile-based application with online chat features and can communicate and can ask questions that are not understood. However, the existing features still do not support students to interact more with mobile applications because there are very limited things students can do. With application development carried out, students will be able to interact more because students can see active classes taken, history of active classes that have been taken, work on assignments for student training, discussion of assignments that have been done, can change schedules, and can view reports - progress reports during private lessons.

- In the current running system, there are only a few features and features that do not meet user needs. As found there were no reports that could show the progress of students while taking private lessons. So it is proposed a development plan to view reports on academic progress. The report is filled in by private teachers in a special mobile-based application for teachers. In the teacher application, features are added to view the active class, make reports, make assignments, and make discussions which are used by the teacher as a basis for providing evaluation reports.

Based on the results of student application research at PT. Ruang Raya Indonesia, the advice that can be given to PT. Ruang Raya Indonesia is:

- To build an application design that has been made by PT. Ruang Raya Indonesia requires human resources who understand the use of Android Studio software.
- Make the features of the National Examination Practice Questions or tryouts so that students who need practice questions can carry out learning independently by working on questions from the question bank provided to prepare for future exams.
- Create a discussion forum so that students can have a community in the student application and can study groups online to explore existing material. With this forum students can also interact with each other with other students so that students who still have questions about a material can be assisted by other students in doing practice questions, learning modules and so on.
- Developing the search for private tutors because of the features to select and negotiate with the teacher directly regarding the teaching time schedule, and also the price per session for the total cost of teaching private tutors with students according to the existing private tutor ordering procedure.
- Make a learning video which contains a discussion of the material along with an explanation that students can understand. This video is useful for students to better understand the material by explaining it directly through the video.

Text Mining Techniques for Cyberbullying Detection: State of the Art

Reem Bayari[*], Ameur Bensefia

CISAM Division, Higher College of Technology, Abu Dhabi, 4102, UAE

A B S T R A C T

The dramatic growth of social media during the last years has been associated with the emergence of a new bullying types. Platforms such as Facebook, Twitter, YouTube, and others are now privileged ways to disseminate all kinds of information. Indeed, communicating through social media without revealing the real identity has emerged an ideal atmosphere for cyberbullying, where people can pour out their hatred. Therefore, become very urgent to find automated methods to detect cyberbullying through text mining techniques. So, many researchers have recently investigated various approaches, and the number of scientific studies about this topic is growing very rapidly. Nonetheless, the methods are used to classify the phenomenon and evaluation methods are still under discussion. Subsequently, comparing the results between the studies and identifying their performance is still difficult. Therefore, the current systematic review has been conducted with the aim of survey the researches and studies that have been conducted so far by the research community in the topic of cyberbullying classification based on text language. In order to direct future studies on the topic to a more consistent and compatible perspective on recent works, we undertook a deep review of evaluation methods, features, dataset size, language, and dataset source of the latest research in this field. We made a choice to focus more on techniques that adopted neural networks and machine learning algorithms. After conducting systematic searches and applying the inclusion criteria, 16 different studies were included. It was found that the best accuracy was achieved when a deep learning approach is used particularly CNN approach. It was found also that, SVM is the most common classifier in both Arabic and Latin languages and outperformed the other classifiers. Also, the most widely used feature is N-Gram especially bigram and trigram. Furthermore, results show that Twitter is the main source for the collected datasets, and there are no unified datasets. There is also a shortage of studies in Arabic texts for cyberbullying identification in contrast with English texts.

1. Introduction

Online social media is now a part of everyday life activity; without a digital footprint, it has become increasingly difficult to survive in this new age of digital media. Cyberbullying is defined as an electronic form of intentional harm and hate to someone and it's considered as a crime [1]. The work presented in [2] reports that cyberbullying had a major and long-term impact on the victims. Cyberbullying leaves both the abuser (predator) and the victim with mental and physical consequences. Different researchers [2], [3] have reported that victims attempted suicide due to many cyberbullying incidents, where they have been mentally abused by offensive and violent messages received from abusers. Numerous studies have shown that adolescents are the primary victims [3], [4]. Despite the regulations, presented in most of the countries, that protect and help bullying victims, there are still many people who suffer from this phenomenon. Indeed, if the victim or his family doesn't report the case of bullying, the victim will keep suffering, and the abuser will continue making other victims. Therefore, the early detection of bullying will help in finding an effective solution by protecting the targeted person and punishing the abuser. Measures to track and identify potentially harmful online behavior must therefore be implemented. Because of the large number of daily posts, and the huge amount of information that circulates through the different social media platforms, manual checking for all posts is just impossible.

Consequently, several studies focused on finding a way to autodetect the presence of cyberbullying quickly and effectively in order to avoid any serious consequences [5], [6].

In this paper, we present an exhaustive list of the most recent research dedicated to autodetecting cyberbullying by focusing mainly on machine learning, neuronal networks and deep learning techniques. We undertook a deep review of evaluation methods, features, dataset size, language, and dataset source of the latest research in this field. In the following section we give the reader a background of cyberbullying, followed by section 3 where we discuss and present the cyberbullying approaches based or website is denigrated.

To accomplish the primary objective of this study, we identified our research questions as follows:

- RQ1: Which dataset was mainly used for the classification of cyberbullying?

- RQ2: What was the size and language of the dataset?

- RQ3: What was the method of classification used? And which one has been used most?

- RQ4: What were the metrics of quality used?

- RQ5: Which approach proved the most effective?

- RQ6: Which features were the most frequently used with classifiers?

2. Research Method

The main stages of the review methodology (research strategy, quality evaluation criteria) were outlined in this section, as in Figure 1.

2.1. Data Sources

In January 2020, we started this study, and we included most studies from 2016 to 2019 and some studies before that. We used the following databases: IEEE, Science Direct, ACM.

2.2. Inclusion and exclusion criteria

The inclusion and exclusion criteria were developed in the selection criteria stage to ensure that the research included in this study was valuable and relevant and would lead us to our main objective.

Inclusion criteria

- Papers that are purely for the classification of cyberbullying in texts.

- Papers that used neural networks / machine learning in the classification.

- Papers that explained the model and its performance measures.

- Papers which mentioned the size and language of the dataset.

Exclusion criteria

- Papers not for text classification

- Papers that didn't mention the findings' accuracy.
- Paper had not been published in journal or conference
- Paper did not use neural networks / machine learning in the classification.
- Paper that didn't mention the size and language of the dataset.
Figure 1: Data Sources

2.3. Search strategy

We used the bellow keywords to collect all the previous studies:

- "Cyberbullying" and "classification" and "neural networks" and "text"

- "Cyberbullying" and "classification" and "deep learning" and "text"

- "Cyberbullying" and "detection" and "deep learning" and "text"

- "Cyberbullying" and "classification" and "machine learning"

- "Cyberbullying" and "categorization" and "text"

- "Cyberbullying" and "classification" and "text"

2.4. Quality assessment evaluation

In this part, we designed quality assessment questions to make a checklist for the research and ensure that it would satisfy the aim of this systematic review.

- Q1: Was the corpus (size and language) identified and described well?

- Q2: Were the text classification approach described clearly?

- Q3: Was the performance of the method identified clearly?

3. Cyberbullying Background

The template is used to format your paper and style the text. All margins, column widths, line spaces, and text fonts are prescribed; please do not alter them. You may note peculiarities.

For example, the head margin in this template measures proportionately more than is customary. This measurement and others are deliberate, using specifications that anticipate your paper as one part of the entire proceedings, and not as an independent document. Please do not revise any of the current designations.

Cyberbullying is defined as the use of communication technology and information such as messages, photographs or videos in order to spread aggressive actions with the intention of harming others [1]. Unlike, bullying, cyberbullying does not require the presence of the victim in the same place or near the bully's place [7].Therefore, it differs from traditional bullying that depends on direct abuse towards victims who could be children, adolescents, or women through physical aggression and intentional, visible behavior [8]. Due to the development of technology and the increase of using smart devices, cyberbullying has become more common and represent a real problem, nothing seems to be able to stop. This is because it is done via the Internet, which involves unknown distances and sources, that allow users to speak without restrictions and it is easy to repeat the aggressive actions at any time and could spread rapidly. Cyberbullying it's not a new problem, in 2005, [2], indicated that the correlation between bullying and psychological symptoms is a reality. These symptoms may compromise risk factors involved in psychopathology. The authors indicate that bullying causes violence, delinquency, depression, anxiety, self-destructive, identity and suicidal issues, and that such symptoms could lead to psychopathology. Cyberbullying's effects are profound and could have major and long-term effects compared to traditional bullying, especially for teenagers who present the largest proportion of victims. According to statistics of [3], [4], several victims of cyberbullying tried to commit suicide because of the, degrading, and violent texts that abusers sent to them .

3.1. Cyberbullying Categories

There are several categories of cyberbullying as stated in [9], [10].

- Flooding: Consists of the bully giving the same one regularly comments, nonsense comments, or even by clicking on the enter key, in order not to let the victim contribute to the conversation.
- Masquerade: includes logging in to bully in a forum, chat room, or software using the account name of another person in order to bully a victim or tarnish the image of the victim.
- Flaming (bashing): involves two or more users attacking each other on a personal level. The conversation consists of a heated, short lived argument, and there is bullying language in all of the users' posts.
- Trolling (baiting): is intentionally posting opinion agreeing with other posts in an emotionally loaded thread in order to provoke a war, even though the comments do not actually reflect the actual opinion of the poster.
- Harassment: resembles conventional bullying most closely with the assumed relationship of the bully and victim. This form of cyberbullying involves sending the victim repeatedly abusive messages over extended periods of time.
- Cyberstalking and cyberthreats: involve sending messages that include harm attacks, which are threatening or extremely aggressive, or include extortion.

- Denigration: this kind of bullying includes Writing obscene, negative, or false rumors of someone to others or sharing them on a public forum or chat room, or website.
- Outing: this kind of bullying includes posting confidential, personal, or embarrassing information in a public chat room or forum. This type of bullying is close to denigration but requires the abuser and the victim to have a close relationship with each other either online or in person.
- Exclusion: this type of cyberbullying occurred most frequently in chat rooms or conversations between young people and adolescents by ignoring the victim.

3.2. Cyberbullying prevention methods and limitations

Due to the extreme worldwide prevalence of cyberbullying and it's direct link with many negative psychological symptoms, researchers have studied the relationship of cyberbullying with several factors in order to help in cyberbullying prevention. The work presented in [11], found that supplying sympathy and strengthening the relationship between caregiver and adolescents affect positively in cyberbullying prevention. On the other hand , the work that represented in [12], reports that the improving of awareness on cyberbullying issues played an important role in cyberbullying prevention. In addition, some countries considered the cyberbullying as a crime. Therefore, they put the laws in dealing with anyone doing such a crime as well as encouraged people to report any case of bullying, as in UAE. This is all to try to prevent children and teens from engaging in cyberbullying as well as to assist cyber victims to deal with the adverse effects of cyberbullying. Although, methods and tools continue to enhanced in cyberbullying detection , the access restrictions on high-quality data limit the applicability of state-of-the-art techniques. Consequently, much of the recent research uses small, heterogeneous datasets, without a thorough evaluation of applicability [13].

3.3. Cyberbullying automatic detection methods

The effective solution to detect bullying in the posts over social media is to build machine-based automated systems. It's for categorizing information and producing reports where cyberbullying is detected so that with fewer losses all recorded incidents can be quickly sorted out and addressed. Different methods are used to detect cyberbullying such as machine learning techniques, Natural Language Processing (NLP), and Deep Learning (DL). Examples include in [14], several NLP models such as Bag of Words (BoW), Latent Semantic Analysis (LSA) and Latent Dirichlet Allotment (LDA) used to detect bullying in Social Networks. On the other hand , some of the autodetection methods were based on word embedding, which expands a list of predefined offensive terms and assigns different weights to obtain bullying and latent characteristics [15].

4. Cyberbullying Detection Approaches Language-based

In this section, we present the most relevant works conducted in cyberbullying detection. We organized them based on the selected language, either Arabic or Latin, and both the features and the classification used in both cases.

4.1. Detection in Arabic language

Alakrot et al in [6], investigated of using word-level and N-gram features with common pre-processing methods, including

extra normalization effect on the efficiency of a trained SVM classifier .This is to detect offensive comments. Authors created dataset of 15,050 comments by collecting comments about the famous Arabic people from the YouTube platform. The dataset is available for public.As a result the stemming with pre-processing enhanced the detection of offensive language in casual Arabic text. In addition, the use of N-gram features increased the classifier efficiency. Despite the combination of stemming and N-gram features showed a negative impact on precision and recall ,pre-processing with stemming and N-grams (1-5) achieved the best performance as highlighted in Table 1.

Authors in [16], authors represented the first study in utilizing deep learning in Arabic cyberbullying detection .They utilized the same dataset in [17], with little changes. Changes include removing all hyperlinks, un-Arabic characters and emoticons. The dataset was tokenized into words to remove all unneeded characters before building the model's layers. Word Embedding was created after that. The dataset is divided into 80% for training and 20% for testing, then they trained a Feed Forward Neural Network FFNN. Authors considered the final decision of the accuracy 93.33 percent with validation accuracy 94.27, for the seven-layer network. Although it achieved an accuracy 94.56% with the three hidden layers.

In [17], it is suggested a system for detecting cyberbullying in English and Arabic text. The only features included in the first stage were text (content of tweet) and language (English, Arabic). In the second stage, authors used an affective tweets package, specifically the TweetToSentiStrength Feature Vector filter. SentiStrength used for weighting the tweets, (2 to 5) for positive feelings and (-2 to -5) for negative feelings ,(1 , -1) for representing neutral feelings. The English lexicon files were used by SentiStrength where subsequently replaced by custom-built Arabic files including weighted profane words .Haidar et al, built two datasets. First one was obtained from Facebook which reached 0.98GB of size in order to verify the system. Second one was collected from twitter to train and test the system. The Arabic dataset was collected from different dialects Lebanon, Syria, Gulf Area and Egypt mainly, it contains 35273 unique tweets after removing all duplicates. Authors show that there is a difference between the "yes" precisions between the two classifiers. In terms of precision, SVM was much higher with "yes" class. However, the overall system precision was 93.4 for SVM, 90.1 for NB.

A study by [18], utilized a collection of predefined obscene words as seeds words to collect another list from a large set of 175 million tweets . These were used to create a list of obscene words to detect offensive language and hate speech. Authors then generated new list from 3,430 words by performing Log Odd Ratio (LOR) method on unigrams and bigrams features. Authors evaluated the detection of offensive language by using five methods which are (seeds Words (SW),SW+LOR (unigram),SW+ LOR (bigram), LOR (unigram), LOR (bigram). The highest precision achieved from using the list generated by LOR(unigram).Authors have made the dataset public for research as well as the list of obscene words and hashtags.

Table 1 provides a comparative summary between the different approaches in Arabic cyberbullying detection discussed above.

4.2. Detection in Latin language

In [19], authors used sentiment analysis to detect instances of bullying in the social network using Naïve Bays classifier (NB). Authors worked on a balanced dataset consisting of 5000 English tweets. Authors collected messages that contained one of these words "Gay," "Homo," "Dike," and "Queer". For training data, queer word used to classify the positive tweets while the presence of any of these terms "Gay," "Homo," "Dike" used to classify the negative tweets. As a result, NB classifier achieved accuracy 67.3%.

Table 1: Comparative summary between the different approaches in Arabic cyberbullying detection

Ref	Dataset Size	Language	Platform	Performance			Approach	Features
				Prec	**Rec**	**F1**		
[6]	15,050 comments	Arabic	YouTube	88%	77%	82%	SVM	N-grams (1-5), word-level
				83%	80%	81%		
[16]	4.913 records	Arabic	Twitter	Accuracy: 93.33 with Validation accuracy: 94.27			FFNN	Unspecified
	30.890 records							
[17]	Arabic 35273	Arabic, English	Twitter, Facebook	90.1	90.9	90.5	NB	Text Language, SentiStrength Lexicon
	English 91431			93.4	94.1	92.7	SVM	
[18]	288 words and phrases. 127 Hashtag, 3.430 word	Arabic	Twitter, Al-Jazeera	98%	41%	58%	SW, SW+LOR (unigram), SW+LOR (bigram), LOR (unigram), LOR (bigram)	Predefined list, Unigram, Bigram

Table 2: Comparative summary between the different approaches in Latin cyberbullying detection

Ref	Dataset Size	Language	Platform	Performance				Approach	Features
				Precession	Accuracy	Recall	F1		
[19]	5000 tweets	English	Twitter		67.3%			NB	Predefined list
[20]	1000 tweets 3.045 posts 20.921 questions and answers.	English	Twitter, FormSpring.me, YouTube	60-81%	69-73%	26-94%	4-74%	GHSOM	Syntactic Semantic Sentiment Social

[24]	25k tweets	English	Twitter	91%	--	90%	90%	logistic regression with L2 regularization	bigram, unigram, and trigram, syntactic structure sentiment lexicon, number of characters, words, and syllables in each tweet.
[15]	1762 tweets	English	Twitter	76.8		79.4	78.0	SVM	BOF, Latent Semantic Bullying

The authors in [20] , used an unsupervised approach for detecting cyberbully traces over social platforms. This is by utilizing Growing Hierarchical Self-Organizing Map. The suggested model is based on machine learning (decision tree C4.5, SVM, NB) as well as techniques derived from NLP (Natural Language Processing) such as semantic, syntactic features of textual sentences. Authors in this work tested the proposed model in three different datasets and platforms. The performance range for each classifier is covered in table 2.

The authors in [21], adopted a supervised approach for cyberbullying detection. Authors used different machine learning classifiers, TFIDF and sentiment analysis algorithms for features extraction. The classifications were evaluated on different n-gram language models. Authors found out, neural network with 3-grams achieved higher accuracy 92.8% compared to SVM with 4- grams that achieved 90.3%. Furthermore, NN exceeded other classifiers on the same dataset in another work. The dataset obtained from

Kaggle (Formspring.me) and consists of 1608 English instance conversations, labeled under two classes (Cyberbullying, non-Cyberbullying). Each class consists of 804 instances. The performance average rate for each classifier is highlighted in table 2.

A study by [22], authors adopted a supervised approach to the identification of bullying and harassment in posted messages in Turkish language. Authors used information gain and chi-square methods for features selection. Authors used the same labeled dataset. It was collected from Kaggle (Instagram and Twitter). Authors calculated the accuracy and running time for many machines learning classifiers, including SVM, Decision Tree (C4.5), Naïve Bayes Multinomial, and K Nearest Neighbors (KNN). Authors compared the accuracy of classifiers under different conditions, NBM classifier was the most efficient classifier before features selection is implemented, while IBk

achieved the most efficient when 500 features were selected. As shown in table two.

A study by [23] , authors used different methods of text classification to differentiate between hate ,profanity expressions, and other texts. In determining the baseline, authors used standard lexical characteristics and a linear SVM classifier. Authors applied a linear SVM classifier on three groups of features extracted surface n-grams, word skip-grams, and Brown clusters. The best accuracy (78%) achieved when authors used the character 4-gram model.

In [24], authors used a hate speech lexicon to collect tweets that containing hate speech keywords. It's used then to label a sample of these tweets under three categories (hate, offensive, normal) speech. Authors trained a multiclass classifier to distinguish these different categories. Authors used bigram, unigram, and trigram features as well as features for the number of characters, words, and syllables in each tweet. In addition, authors included binary and count indicators for hashtags, mentions, retweets, and URLs. Author then tested a variety of models; each model was tested by using 5-fold cross-validation. Authors found that the Logistic Regression and Linear SVM model outperformed other models. For the final model, logistic regression with L2 Regularization were used for the final model. The final model then trained by using the whole dataset to predict the label for each tweet. The best performance is highlighted in table 2.

In [15], authors introduced a novel learning method for cyberbullying recognition called Embedding Enhanced Bag-of-Words (EEBOW).EEBoW mixes BoW (Bag of Words) features, latent semantic features and bullying features .Bullying features are derived from word embedding, capturing the semantic details behind words. Authors reported that the EBoW model outperforms other comparable models, including Semantic-enhanced BOW (SEBOW), BoW, LDA(Latent Dirchilet Allocation), LSA(Latent Semantic Analysis) and BOW . The performance of best model (BoW) is highlighted in table two.

Table 2 provides a comparative summary between the different approaches in Latin cybe4rbullying detection as discussed above

5. Deep-Learning in Cyberbullying detection

Aauthors in [25] , proposed a novel algorithm to detect cyberbullying . The proposed algorithm is based on a convolution neural network (CNN) with semantics features by utilizing word embedding. It is to eliminate the needs for features extraction process. CNN-CB model consists of four layers: embedding, convolutional, max pooling and dense. Authors then applied the algorithm on dataset consist of about 39,000 English tweets .Authors then compared the accuracy result with the SVM classifier .Authors reported that the CNN-CB algorithm outperforms classical machine learning with accuracy 95 percent as shown in Table 3.

In [26], it is presented a novel approach to optimize Twitter cyberbullying detection based on deep learning (OCDD).The proposed approach eliminates the features extraction and selection phases . It's to preserve the semantics of words by replacing the tweet by a set of word vectors. Authors then fed it to a convolutional neural network (CNN) for classification phase along

with metaheuristic optimization a algorithm for parameter tuning. This is to find the optimal or near optimal values.

In [27], it is proposed an aggregate approach for the two deep learning models. The first one is character-level convolutional neural network (CNN). It's for capturing the low-level syntactic knowledge from the character series. The second is word-level (long-term recurrent convolutional networks) LRCN. It's to capture semantic high-level information from word sequence, complementing the CNN model. Authors used dataset contains in total 8,815 comments from Kaggle. Authors reported that the hybrid model's sensitivity and accuracy are 0.5932 and 0.7081, respectively. Also, the aggregated approach is significantly enhanced the performance as well as outperformed other machine learning methods in cyberbullying detection.

In [28], it is proposed a novel pronunciation-based neural network (PCNN) for cyberbullying detection .The proposed model is to overcome the misclassification that produced from using misspelled words. Authors phoneme text codes as interface for a coevolution neural network. This technique is to correct spelling errors which did not change the pronunciation. Authors then fed it to CNF in order to detect cyberbullying. Authors compared the performance of models using two datasets, collected from Twitter (1313 tweets) and Formspring.me (13,000 messages). Authors also solved the problem of datasets balance with different techniques in order to compare the result between balanced and imbalanced datasets. Authors compared PCNN performance with previous work and found PCNN outperform the other methods. Authors reported that PCNN performed better when it is applied on the Twitter dataset than Formspring.me dataset. In addition, PCNN and CNN Random model performed better than CNN with pre-trained.

6. Discussion

This section will present the results according to the language and method in three separate sections , following the same order of study that followed in section four.

6.1. Cyberbullying detection in Arabic language.

For Cyberbullying detection in Arabic language, the findings indicate that, SVM classifier is the most used classifier in the classification of Arabic text [6], [17]. Also, most of studies used Twitter platform as a source to collect the datasets[16]-[18]. For the surveyed papers, there was no unified dataset, and the maximum size of the dataset is 35273 tweets built by the writers in a study [17],and this size is small compared to the English dataset available. In addition, the results show that most common investigated feature is N-Grams particularly unigram and bigram [6], [18] . The common used method for measuring the accuracy are same to other languages (Precesion,Recall,F1). Furthermore, the highest accuracy achieved when authors used SVM classifier with Language SentiStrength Lexicon feature in [17] followed by NB classifier that is also investigated in the same study.Generally, it was found that deep learning algorithms have not been researched with the Arabic language as much as in English.

6.2. Cyberbullying detection in Latin language

The results of this analysis concluded that out of seven papers analyzed, the SVM classifier was tested five times, followed by the

NB classifier that was examined three times. Also, the most of the datasets are collected from Twitter platform , there is still no unified dataset and the maximum size of the dataset is 25k tweets in [24]. In addition, the results show that most common investigated feature is Bigram, Trigram. The commonly used methods for measuring the accuracy are same to other languages (Precession, Recall, F1).Also, the highest accuracy is archived by using SVM classifier that represented with bigram, trigram,4-gram features in [21].

6.3. Deep-Learning in Cyberbullying detection

After the deep systematic review, the results show that the CNN is the most common used method in the classification of cyberbullying. Also, CNN method had been investigated five times in different studies under different conditions . The results of review show also, that the most of datasets are collected from Twitter platform as well as there is no unified dataset and the maximum size of the dataset is 39,000 tweets, this is small to investigate the deep learning techniques. In addition for deep learning algorithms, the widely used approach for measuring the accuracy is the same for machine learning algorithms (Precession, Recall, F1). In addition, the highest accuracy is archived in [28] study when CNN is used, and outperformed the machine learning algorithms.

To conclude the result for both languages, the best accuracy was achieved when deep learning approaches were used particularly when CNN is applied in [28]. Also, deep learning algorithms were utilized more in the classification of cyberbullying in the English text, while machine learning used more with the Arabic text. Moreover, SVM is most common classifier in both Arabic and Latin languages and outperformed the other classifiers, it was examined seven times . Furthermore, N-Gram is the most widely used function for both Arabic and Latin languages with classifiers. The Twitter platform also primarily provides the origins of most of the datasets followed by FormSpring.me .

7. Conclusion

In this paper, we conducted an in-depth analysis of 16 studies on automatic cyberbullying detection methods based on text language. we undertook a deep review of evaluation methods, features, dataset size, language, and dataset source of the latest research in this field.We focused only on techniques that adopted neural network and machine learning algorithms. This is to direct future studies on this topic to a more consistent and compatible perspective on recent works, and to provide a practical and effective implementation for future systems. It was found that the best accuracy was achieved when a deep learning approach is used especially when CNN used. It was found also that, SVM is the most common classifier in both Arabic and Latin languages, and outperformed the other classifiers.Also, the most widely used feature is N-Gram especially bigram, trigram. In addition, Twitter is the main source for the collected datasets. Furthermore, there is no unified data sets. Although, cyberbullying prevention methods were adopted, largely, but most of the literature work aimed to enhance the detection by adding a new feature, as a number of features increased the process of features selection and extraction become more complicated. On the other hand, most of the work is

done to find automated English language solutions, although each language actually has different structures and rules. In addition, there is no standard dataset and list of bad words to be counted as being used in the cyberbullying detection efforts. Finding an effective solution to detect cyberbullying helps a lot in protecting the targeted person.

Conflict of Interest

The authors declare no conflict of interest.

Simulating COVID-19 Trajectory in the UAE and the Impact of Possible Intervention Scenarios

Abdulla M. Alsharhan*

Faculty of Engineering and IT, The British University in Dubai, Dubai, 345015, United Arab Emirates

A R T I C L E I N F O	A B S T R A C T
	This paper aims to simulate the current trajectory of the pandemic growth in the UAE; when it is likely to end and at what cost? It also examines the current and additional possible measures to contain the second wave of the pandemic. The method used is a simple Susceptible-Infected-Recovered (SIR) model called covid19_scenarios. The key finding suggests current intervention is 35 – 45% and effective, and based on keeping them, the pandemic curve in the UAE is expected to be flattened around the fourth quarter of 2022 with the maximum saved lives and lowest burden on the healthcare system. In contrast, it can end earlier at the end of the second quarter of 2021 but at a much higher fatality rate and a health system ready with 3,600 intensive care units. It also revealed that country closure has a minor impact, and severe and fatal cases will continue to appear even after vaccinating the whole community.

1. Introduction

On 16th January, a Chinese family arrived from Wuhan in the United Arab Emirates (UAE) to spend their holiday. One week later, the family headed to a local clinic after feeling unwell. Four family members, including the grandmother, mother, father, and a nine-year-old girl, were confirmed to have the virus [1]. The next day, on 30th January 2020, [2] confirmed COVID-19 outbreak as a Public Health Emergency of International Concern, and on 11th March declared COVID-19 as a pandemic.

In response, the UAE announced its National Disinfection Programme, whereby public facilities and transportation were disinfected daily from 26th March – 24th June 2020. After the quarantine, the UAE carried on specific interventions related to COVID-19, including preventing public gatherings and family visits, keeping physical distance, wearing masks and gloves, and not exceeding the limit of three passengers per vehicle for non-family members.

Policy-makers in the UAE made some noticeable primary efforts to contain the pandemic. Significant interventions included implementing distance learning and remote work, suspending prayer in all worship places, postponing sports events, closing shopping malls, maintaining distance at entertainment venues, and suspending visas, flights, and even the entry of GCC citizens [3]. On 24th June 2020, the National Emergency Crisis and Disaster

Management Authority announced the end of the National Disinfection Programme with immediate effect.

These efforts paid off when the rate of daily confirmed cases started declining, reaching the lowest recorded number of daily cases on 3rd August 2020. However, after some rules of social distancing were relaxed, the daily numbers started rising again, indicating a second wave of the pandemic. By 25th November, the National Emergency Crisis and Disaster Management Authority reported that 161,000 cases had been diagnosed in the UAE. While 93% have recovered, there are still 10,000 active cases and 500+ deaths.

Figure 1: Intervention impact on daily cases in the UAE (NCEMA 2020)

2. Literature Review

After carefully searching the major databases, two papers were located that discuss simulating COVID-19 in the UAE. The search

databases included WorldCat, Google Scholar, and CrossRef. The search keywords included terms such as "COVID-19" AND ("simulation" OR "simulating") AND ("UAE" OR "United Arab Emirates").

In [4], the authors tried to estimate the number of required beds for both acute and critical cases in the UAE in addition to the possible infection of healthcare personnel. The simulation also predicted the peak time and the total infections before and after non-pharmaceutical interventions.

Assuming the UAE population is 9,631,000. The simulation revealed that UAE would reach the highest at t = 56 at April 2020, where on the 26th of May, it will reach its peak at a 1.67 per cent infection rate of the total population, an equivalent to 165,360 infections. After that, it will decrease dramatically. The infection should disappear on the 100th day, around the 9th of July. However, although the actual figures from NCEMA match the peak prediction of the first wave, it did not match the total infection at that time, which appears to be around 30,000 confirmed cases only, which could suggest the effectiveness of the measures used by the policy-makers during that period.
Figure 2: Actual cumulative cases in the UAE as of the 26th of May, 2020 (Microsoft Bing.com)

This study also predicted that the maximum number of required beds would be 63,138 at t=66, which is equivalent to that of the 6th of June, 2020. While it is difficult to validate this assumption; the study did not mention how many of them are needed to be for intensive care unit (ICU) beds. The simulation also concluded the UAE transmission rate and the basic reproduction number on the period between the 21st of April to the 15th of May, 2020 to be R0 = 1.7768.

In [5], the authors simulated the dynamics of COVID-19 in the UAE based on fractional derivative modelling using Riesz wavelets. The parameters used in this study were calculated based on official published data of COVID-19 in the UAE, while the dynamic of the virus transmission was considered from other sources due to the fact that the dynamic of the virus transmission from a country to another does not change much. The total UAE population used in this study was 9.666 million, which is close to the previous study. The study did not mention a clear transmission rate or the basic reproduction number, but the transmissibility multiple used is ψp at (0.1).

However, as the UAE is preparing to get back to normal, little is known on how the new relaxed interventions will impact the spread of the pandemic. This study objective is to support the policy-makers by analysing the impact of going back to normal by the beginning of 2021. In order to simulate the desired outcomes, the following hypothesis will be tested:

A. The UAE is ready to go back to normal at the beginning of 2021.

B. The UAE can go back to normal, and the current healthcare system can handle all the cases.

C. Suspending entry to the UAE is necessary to contain and end the pandemic.

D. Extending the current intervention should be the new normal, as it is essential to decreasing severe, deadly cases.

E. Vertical Isolation (isolating young and senior citizens) is similar to the "doing nothing" scenario.

F. The vaccine will end the pandemic, and we can go back to normal life.

G. We still need to keep the current interventions, even if the community is vaccinated.

3. Methods

A simple Susceptible-Infected-Recovered (SIR) model was used to simulate the COVID-19 outbreaks in the UAE. The model is called "covid19_scenarios".

This model was selected because of its unique ability to blend real and simulated data. It is also already loaded with each country default parameters, including the UAE. It is simple to use and provide a web-based user-friendly interface that allows real-time data adjustment, which reflects the output immediately on the model. Besides, it has different categories for individuals exposed to the virus that are not yet infectious. In addition, severely sick individuals in need of hospitalisation, people in critical condition, and a fatal category. The tool that was utilised was a computational biology tool developed by [6]. The source code of this tool is freely available at github.com/neherlab/covid19_scenarios and the web-based version is also available at https://covid19-scenarios.org.

3.1. Basic Assumptions

- Individuals are infected by contact with infectious persons. Each individual causes, on average, R0 secondary infections while they are infectious.

- Infection rates could change based on seasonal variations.

- Individuals who are infected go into a state after a latency period. This development occurs in three different stages, which will ensure that the distribution of time spent in the exposed compartment matches real-life scenarios.

- Positive individuals either recover or progress to a severe case. The ratio of progressing to recovery to severe case depends on age.

- Severe positive cases are hospitalised in the Intensive Care Unit (ICU) (if beds are available), placed in an overflow compartment, or receive palliative care. At the same time, younger age groups are given priority access to the ICU.

- Individuals in the ICU either recover and are transferred to standard hospital rooms or die. Fatality rate depends on the age group and ICU admission availability.

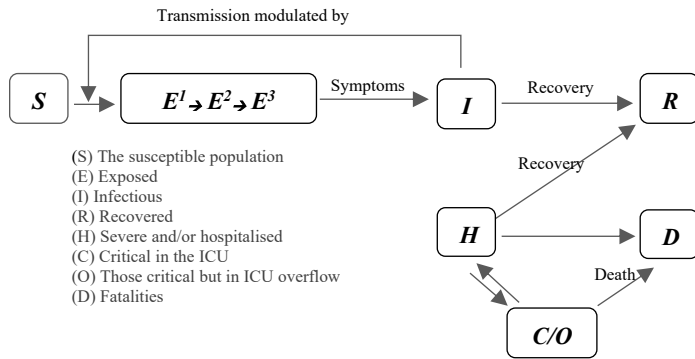
- Individuals in palliative care die, which could also represent death at home [6].


Figure 3: A schematic illustration of the underlying model

3.2. Parameters

The parameter values presented are based on the following assumptions:

Table 1: The UAE's Epidemiology and Population Parameters

Parameter	Value
Population [1]	9,935,374
Seroprevalence	8%
Initial number of cases	109,3962
Hospital Beds (est.) [2]	15,868
ICU/ICMU (est.) [3]	476
Imports per day [4]	22
Simulation time range	10th August 2020 – 31st December 2021
Number of Runs	15
Annual average R_0	0.89 – 1.16
Latency (days)	3
Infection period (day)	3
Seasonal forcing	1
Seasonal Peak	January
Hospital stay (days)	3
Intensive Care Unit (ICU) stay	14
Severity of ICU overflow	2

3.3. Basic assumptions about the UAE

1. According to [7], the current population of the UAE as of Tuesday 17th November 2020 is 9,935,374.

2. In reference to [8], the latest bed estimation goes back to 2013, since more recent numbers of beds are not provided. The total number of hospital beds in 2020 was estimated to be 15,868. Figure 2 shows the estimation is based on calculating the compound annual growth rate (CAGR) from 2013 (9,760 beds) to 2018 (13,811 beds), which is equivalent to 7.19%.

3. Intensive care units (ICU) were estimated with a common standard of 3% of the total hospital beds [6]. Therefore, the estimated ICU numbers are (3% x 15,868 = 476).
Figure 4: The total number of hospital beds in the UAE estimation

4. The latest available data about arrivals are not provided. The total number of passengers who arrived in the UAE in 2020 was estimated to be 15,868. Figure 3 shows that assumption is based on calculating the Compound Annual Growth Rate (CAGR) from 2011 (34 million passengers) to 2016 (58 million passengers) [8], which is equivalent to 7.19%. Then the growth rate was used to calculate the growth trajectory for 2017, 2018, 2019, and 2020. Since last February 2020, 59 airline companies stopped or reduced flights, and many countries, including the United States, Russia, Australia, and Italy, have introduced travel restrictions [9]. It is difficult to determine how much traffic is impacted by these interventions; therefore, we assumed international travel restrictions produce a 90% overall traffic reduction in the UAE, which result in an equivalent to 8 million (90 x 10% = 8).

5. The remaining data was based on the default setting of the model, which are based on the published epidemiological and clinical notes about each country, including the UAE.
Figure 5: Estimated number of passenger arrivals in the UAE

3.4. Age-dependent parameters

Table 2 shows the UAE age-dependent parameters. The second column shows the number of individuals who falls under each age group category. The next columns summarise the COVID-19 intensity based on epidemiological and clinical notes from China, Spain, Switzerland, and Italy. The "Confirmed" column shows the assumption of what fraction of the previous category will impact the next [6]. Both "Confirmed" and "Isolated" columns are editable and can be adjusted to test different hypotheses.

Table 2: The UAE age-dependent parameters

Age group	Age distribution	Confirmed % total	Severe % of confirmed	Palliative % of severe	Critical % of severe	Fatal % of critical	Fatal % of all infections	Isolated % total
0–9	1011712	5	1	0	5	10	0	0
10–19	842993	5	3	0	10	10	0	0
20–29	2149345	10	3	0	10	10	0	0
30–39	3169316	15	3	0	15	10	0.01	0
40–49	1608106	20	6	0	20	10	0.02	0
50–59	797911	20	10	0	25	20	0.1	0
60–69	242705	25	25	5	30	30	0.88	0
70–79	55883	30	35	10	25	40	2.1	0
80+	12431	40	50	20	15	40	5.2	0

4. Results and analysis

This section shows the results for several scenarios. The simulations represent major possible interventions that could be made by the policy-makers in the UAE. In this study, the parameters are based on data from the UAE.

4.1. Scenario (A): Going back to normal at the beginning of 2021

This scenario simulates the behaviour without any additional intervention, as it will be used as a baseline for comparison with all the other scenarios. To generate this scenario, the current intervention is assumed to provide 35% – 45% protection (Table 5). As per Figure 5, the estimated annual visitors are expected to be 10% of the usual annual visitors. At least 8 million passengers are expected to arrive in the UAE annually. If we are assuming the current airport interventions are effective and are dedicating 99% of the cases, then the community will only import about 0.1% undedicated positive cases annually. This is equivalent to 8,000 positive cases per year, or 22 positive daily cases on average (Table 3).
Figure 6: Scenario (A): Going back to normal at the beginning of 2021
Figure 7: Scenario (A): Distribution across age groups

Table 3: The UAE population parameters, baseline

Population parameter	Value
Age distribution for	UAE
Case counts for	UAE
Number of hospital beds	15868
Number of available ICU beds	476
Cases imported into the community per day	22
Number of cases at the start of the simulation	3000
Population size	9935374
Seroprevalence [%]	8.5

Table 4: The UAE epidemiology parameters, baseline

Epidemiology parameter	Value
Average time in regular ward [days]	3
Average time in ICU ward [days]	14
Infectious period [days]	3
Latency [days]	3
Increase in death rate when ICUs are overcrowded	2
Seasonal peak in transmissibility	January
R0 at the beginning of the outbreak	1.8–2.2
Seasonal variation in transmissibility	0

Table 5: The UAE Mitigation parameters baseline

Intervention name	From	To	Reduction of transmission
Current social distancing interventions	Aug 10 2020	Dec 31 2020	35% – 45%

With this scenario, a new peak should be expected during the second week of February 2021 resulting in the number of severe cases to reach 55.76k, with deaths totalling 5.68k. Moreover, 40% of the deaths are estimated to be among the $60 – 69$ age group. The curve will then flatten during the second week of June after most of the community has immunity against the virus and weekly cases will continue to fluctuate between $127 – 142$, and the total weekly deaths will be two. It is noticeable that there are four months of overflow in ICUs.

4.2. Scenario (B): Increasing the ICU up to no overflow is happening

In these scenarios (Figure 8), the number of ICUs is increased up to a level where there is no overflow. After several runs, the required ICU numbers are 3,800, eight times more than the current estimated available ICUs. This scenario shows that the total severe cases did not change than the baseline. However, the total death has decreased to 4.75k, which is 16% less than Scenario (1).
Figure 8: Scenario (B): Increasing the ICU units up to no overflow is happening
Figure 9: Distribution across age groups in scenario (C) shows decreased death rates in the 60 – 69 age group
Figure 10: Scenario (C): Vertical Isolation shows that severe cases have decreased by 32%, and the death rates have decreased by 61%

4.3. Scenario (C): Vertical Isolation

In this scenario (Figure 10), some age groups were isolated to examine how this intervention will affect the model. The isolated age groups are 0 – 9 and 60 – 69. However, since full isolation will not be possible due to family and community contact, the isolation rate was kept at 90%. The result of this scenario shows the total severe cases decreased by 32% to 37.85k of the baseline, and the total death has decreased by 61% to 2.19k of the baseline. The following chart (Figure 9) shows how Scenario (C) decreased death rates in the 60 – 69 age group.

4.4. Scenario (D): Airport closure

In this scenario (Figure 11), the impact of new cases imported to the community was examined. Simulating this scenario, the number of imported daily cases was assumed to be zero. Scenario (D) shows that the impact of this intervention was only less than 1% on the outcome as total severe cases have decreased by 0.3% to 55.59k of the baseline. At the same time, the total death cases have decreased by 0.9% to 5.63k of the baseline. However, it shows the pandemic will end by the middle of 2021, probably after achieving herd immunity.
Figure 11: Scenario (D): Airport closure

4.5. Scenario (E): Extending the current intervention

This scenario examines extending the current intervention taken by the policy-makers and the community of the UAE. In order to simulate the impact of these interventions, several runs were conducted to create a similar growth trajectory for the actual weekly cases. It was found the actual weekly growth, starting from the second wave (10th August 2020), matches a 35% – 45% reduction, which means the current intervention is reducing transmission by 35% – 45%. In this scenario, the same rate was continued for as long as it took to flatten the curve. The result shows the peak will be reached by the second week of March 2021. However, it will take the curve much longer to flatten, which

should decrease the pressure on the health care system, as there will be no ICU overflow, and therefore, no extra ICU units will be needed. The simulation assumes the curve can be flattened by the second week of October 2022, regarding severe cases and deaths. Scenario (E) shows that the number of severe cases has decreased dramatically, by 68.8%, to 17.4k of the baseline, and the total deaths have decreased, by 73.1%, to 1.53k of the baseline.
Figure 12: Scenario (E): Extending the Current Intervention
Figure 13: Scenario (F): Vaccinating the community

4.6. Scenario (F): Vaccinating the community

On 18th November 2020, [10] announced their COVID-19 vaccine to be 95% effective, beginning 28 days after the first dose. Many hope the vaccine will allow life to return to normal. The

scenario (F) simulation (Figure 13) assumes the entire community has been vaccinated against COVID-19. Therefore, all interventions are lifted at the beginning of 2021. The effectiveness of the vaccine was determined to be at 95%, meaning only 5% of the community could still be infected. The scenario, in this case, predicts the infection rate will reach its peak in the second week of February 2021, and a total of 501,000 people will have tested positive. However, most of these cases will be mild. This scenario shows that the total severe cases have decreased by 95% to 2.79k. In comparison, the total death cases have decreased by 96% to 228.5 of the baseline. The curve will be flattened in the third week of August 2021 at an average of 127 confirmed cases per week.

4.7. Scenario (G): Vaccinating the community and keeping the current interventions

In this scenario, we assume the whole community are vaccinated and have 95% immunity against the COVID-19. Nevertheless, the current interventions are still applied for as long as it takes to flatten the curve. The curve needed to be modelled for over three years. The outcome shows a 98.5% reduction in critical and death cases, with 910 critical cases and 82.5 death cases. The simulations also show the curve could be flattened in the second week of June 2022 at an average of 52k confirmed cases per week and 0 fatality rates afterwards.
Figure 14: Scenario (G): Vaccinating the community and keeping the current interventions

5. Discussion

5.1. (A) The UAE is ready to go back to normal at the beginning of 2021.

The simulation shows it is still too early to go back to normal at the beginning of 2021. The going back to normal life scenario (A) shows that another wave is expected to rise, reaching a peak in 45 days with more than 5,000 deaths to be expected, part of which is caused by intensive care units' capacity overflow.

5.2. (B) The UAE can go back to normal, and the current healthcare system can handle all the cases.

Scenario (B) examines how many ICU units are needed to prevent death by lack of ICU capacities. The simulation indicates there will be a need of 3,124 additional ICU units (total of 3,600). Furthermore, that will only decrease the fatality rate by 16%. However, the scenario (A) is likely to be the shortest scenario to flatten the curve (Q3 2021), but it comes with the highest fatality rate.

5.3. (C) Vertical Isolation (isolating young and senior citizens) is similar to the do-nothing scenario.

On the other hand, the vertical isolation scenario (C) seems to have a noticeable impact on the simulation outcome. It decreases death rates by 61%, and the severe cases by 31%. Therefore, it cannot be assumed it is similar to the do-nothing scenario.

5.4. (D) Suspending entry to the UAE is necessary to contain and end the pandemic.

One significant finding of these simulations is the minor impact of the airport closure scenario (D). As it turns out, it only has a less than 1% impact on the simulation outcomes, which indicate it is not an effective intervention and has an insignificant impact in the context of the UAE parameters.

5.5. (E) Extending the current intervention should be the new normal, as it is essential to decrease severe and death cases.

Keeping the current interventions scenario (E) is still highly effective, as it has decreased both severe and fatality rates by nearly 70%.

5.6. (F) The vaccine will end the pandemic, and we can go back to normal life.

The long-awaited vaccine for COVID-19. However, the outcome of this scenario shows around a 95% decrease in severe and death rates. However, the remaining 5% can result in an average of 2.79k severe cases and 127 deaths. A significant finding of scenario (F) suggests the importance of keeping some sort of intervention for some time, even after getting vaccinated.

5.7. (G) We still need to keep the current interventions, even if the community is vaccinated.

The final tested hypothesis in this study is vaccinating the community while keeping the current interventions (G). The outcome of this simulation shows little impact as it decreased severe and deadly cases by only an additional 3.5% (total of 98%).

As an alternative, a key takeaway of this study is that no matter what interventions are taken, at least 154 cases will still be expected on a weekly bases. This is even under the assumption that the airport intervention is 99.9% effective, airline movement is 10% of normal (Figure 3), and 100% of positive cases are isolated.

6. Conclusion

George Edward Pelham once said, "All models are wrong, but some are useful". We hope this study will bring some useful insights to policy-makers in the community of the UAE.

Based on the current trajectory of the pandemic growth, the current intervention suggests its effectiveness is 35-45%. The pandemic daily cases curve is expected to be flattened around the fourth quarter of 2022. Moreover, relaxing intervention and going back to normal earlier than expected will cost the UAE health system to be ready with an average of 3,600 intensive care units. This assumption is not counting the different federal Emirates measures nor vaccine availability as there is still not enough data about when it will be made available.

It is highly encouraged to use the COVID-19 scenario model to simulate different parameters in different geographical locations. This simulation provides some key insights that can confirm some commonly known hypotheses and disapprove others.

Conflict of Interest

The authors declare no conflict of interest.

A R T I C L E I N F O	A B S T R A C T
	This paper proposes a modeling framework (analytical modeling) for the case of fish cannery supply chain (FCSC) to optimize the environmental impact of the set of its processes; indeed, for our knowledge, there were few studies attempting to address this case study as a model of green supply chain. Implementation of the proposed model is done using first MCDM methods (AHP, TOPSIS) in order to select and classify processes and the corresponding environmental impact, as well as dealing with environmental analysis. Furthermore; a flowchart is proposed as an addition to improve the other processes in terms of reducing environmental impact, and the numerical resolution is carried out using the LINDO software. The proposed framework will guide researcher both as well as practitioners in establishing an optimal model for the green fish cannery supply chain (FCSC).

1. Introduction

In logistic field, most of researchers aim to meet the challenge of integrating new scientific data in terms of methods, software, managerial solution, to support supply decision making, furthermore environmental dimension is among the most attractive area of study to deal with. Nowadays, a set of supply chain (SC) models have been proposed in the literature, integrating the environmental dimension, using various modeling tools and methods [1]-[4]. Mainly; this paper proposes a modeling framework of the fish cannery supply chain (FCSC), by integrating the environmental constraints and it contributes in helping and assisting researchers, as well as practitioners to establish a global model of the green fish cannery supply chain (FCSC), where few articles seek to tackle modeling studies in this area of study, particularly as an industrial supply chain [5]-[7], followed by a numerical resolution using the LINGO software. The remainder of the paper starts with a relevant literature review, which typically tackle the cannery fish supply chain (FCSC), and the main keywords in section 2.

And subsequent to a detailed description of the case study in Section 3. The model formalization and discussion are addressed in Section 4. Section 5 provides the numerical resolution, while

Section 6 addresses the conclusion, limitations and future research direction.

2. Literature Review

2.1. Fish cannery supply chain

The Agri-food industry, in particular the fish cannery industry, is chosen as a case study. Generally, there are many kinds of fish, such as sardines and mackerel, which are among the most consumed fish in the Mediterranean region [8]; While in tropical and subtropical oceans, western and central pacific ocean (in particular Asian country) tuna is the most common cannery industry, Southeast Alaska and Puget Sound, Washington State, USA are known by salmon fish etc. One must bear in mind the time constraint since this industry is almost seasonal, operation is limited to about 3 months in a year for salmon [7], and up to 9 months/year for the other types. In this case study objectives are established as to demonstrate the applicability of the model whatever the purposes, and to visualize its added value on the one hand, by treating a case of an area rarely addressed in research as an industrial SC.

The environmental constraints or impact resulting from this type of industry is treated separately from its modeling. Among the most significant and widespread environmental impact of this

industry: water pollution, or wastewater [9]-[11], waste fish [7], most of research works that deal with this impact propose solutions to minimize it. On the other hand, fish processing waste has an interesting energy value. The increase of the aforementioned wastes as well as the increasing of the renewable energy market confirms that this waste could have a place as a future source of biofuels [12].

Furthermore; and for our knowledge, there is no standard model for this type of industry as a whole SC case study. In [6] the authors have dealt with the fish cannery industry, notably the case of tuna, under a model that encompasses multiple fishing fleets including canneries, in the form of scenarios by exploiting the future results of the world tuna fishery through a simple presentation: climate change effects, changes in global tuna demand, and changes in access to fishing areas. Also an optimization, mathematical model is reported by authors of [7], which aims to optimize food portion in packaging, actually the model is presented in a case study of a cannery portion of fish. We notice well that these two examples consist in treating this type of SC in the manner that the raw material is of exhaustible nature (in the biological way also), which strongly supports the scarcity of research works dealing with a global model of the green industrial SC (including all environmental impact), particularly the proposed case study.

2.2. MCDM method: AHP and TOPSIS

MCDM (Multi-Criteria Decision Making) gathers a set of sophisticated methodological tools to assist in decision making to cope with complex decisions. It is a powerful method for evaluating and ranking one or more customized solution from a set of options that consider multiple indicators, which are typically contradictory. In particular, it allows us to highlight conflicts within the metric indicators, to identify an effective and structured framework and, finally, to make the holistic trade-offs necessary to reach a decision"[13].

AHP (Analytic hierarchy process) method is among the MCDM tools, to hierarchize criteria in order to achieve a specific goal, where scores of all criteria are grouped into a unique aggregate score. In literature, there is a considerable amount of research work that has used the AHP method either to evaluate performance of the green SC [14], [15] and for ranking the key performance indicators [16], also for assessment of the sustainability of the SC [17], or for the risk assessment [18], [19], commonly AHP is well-known for supplier selection [20]-[22], also it's applied in reverse logistics.

TOPSIS (technique for order preference by similarity ideal solution) has been proposed for the first time by [23]. TOPSIS is an effective method to solve existing problems of multi-attribute decision making with finite alternatives. The concept of this method is to classify the alternatives by calculating the distance of each alternative in relation to the ideal solution and the ideal negative solution of the problems in order to determine the optimal alternative. These ideal and negative-ideal solutions are calculated in considering other alternatives [24].

Most of papers utilized both AHP followed by TOPSIS which is preferred in comparison, [25]. In [26], authors applied the robust Analytical Hierarchy Process (AHP)-Fuzzy and TOPSIS for the

evaluation and selection of contractors [27] the Fuzzy Analytical Hierarchy Process (FAHP) and (TOPSIS) is used to evaluate performance, and particularly in the selection of reverse logistics service [28]. In notably, this paper exclusively applies these two methods for the classification of processes and their environmental impacts.

In the following paragraph, a model of the (FCSC) is presented. Furthermore, the two methods: AHP and TOPSIS would be used, in order to classify the environmental impacts and the SC's processes.

3. Case study

This section presents a case study of the fish cannery industry, this option of industry is exclusively treated as a SC model in this paper in addition most of the research works focus on the biological aspect in studying this case study. Data is collected from 4 anonymous companies of the fish cannery industry in the same city in Morocco, preserving all the needed information, with the aim to establish a model of green (FCSC), which may help industrialists in this field, in the one hand, and researchers in the future, in the other hand, by providing a global framework of green SC modeling. Therefore, this type of industry is characterized by a set of activities from fish procurement to distribution.

After a five-month visit to the four companies, we have collected data related to each process of this SC, these processes may change in terms of appointment from one company to another, but the activities remain the same. Reception of raw materials from suppliers (different) and distribution of final product to a limited number of destinations (clients, retailers…). These companies use only Small fish species such as sardines. The set of processes is presented in fig.1 below, we opted for this organizational chart in order to highlight the objective of this paper, namely to meet the optimization of environmental constraints in SC modeling. Particularly, the fig.1 below shows the impact of waste water at all levels (till the process of cooling):
Figure 1: Fish canning industry supply chain (flow chart) [10]

3.1. Description

Hereafter a detailed description of the SC's characteristics, and the common elements between the four companies, all these data could be used in the resolution of the models, and to establish an action plan (improvement). In the next sections collected data are also used in AHP and TOPSIS (Water consumption, energy consumption, noise …).

Table 1: Case study data collection

Time sheet	- The delivery of final products and raw materials is done by a limited number of paths, and runs constantly 24h/24h -The plant works 8 hours a day, 6 days a week (8h/24h normal, 6d/7d)
Production site and platform	-Each company is composed of 2 production sites (only one site works when the total quantity doesn't exceed 8tonnes) -A physical systems for receiving the raw material from the logistics platform
Procurement	- Procurement of the fish quantity varies between 2 trucks to 4 trucks, each of which has a maximum capacity of 12 tonnes (minimum 4 tonnes).
Water and energy consumption	- The average monthly water consumption is 1400 m³ -Electrical energy(Total consumption per tonne): 86Kw/tonne
Processes	-10 processes (as shown in fig.1) only are taken into account
Raw materials	-Fish, brine and spices, oil, boxes, cartons, tomato sauce, detergents, coal, lead (for marking) -Total quantity of raw material (fish): [8tones, 48tonnes]

3.2. Material and Method

This type of SC promotes mathematical modeling, given the nature of its well-defined and flexible activities to model them mathematically. As evoked at the beginning of this paper, the analytical modeling has opted for, by proposing a mathematical model to an objective function which minimizes the environmental impacts, and helps in decision making, regarding the actions to be undertaken. For the mathematical model, only impacts whose parameters can be used in mathematical modeling are retained. In addition, for the identification of the significant impact, the TOPSIS method is used in order to hierarchize processes according to their criticality regarding environmental impacts as to classify

them from the worst alternative, also by further using the AHP method to classify the different environmental impacts and then using this ranking in TOPSIS method.

3.3. Identification of environmental Constraints

The environmental analysis presents a set of steps to be followed, to achieve a set of aspects, and significant impacts, of the different processes or activities of the SC. In addition the environmental analysis is required by ISO14001 standard, but it is indeed an optional direction. In this case study, we are interested in tackling, the most relevant significant impact regarding the critical activities or processes, and as we have previously mentioned, we opted for the AHP and TOPSIS methods which allows us to inherit the desired criteria, in a fuzzy environment to assist in the selection of processes and environmental impact.

Our main goal from AHP method is to classify criteria according to their criteria weight, the criteria adopted, according to the companies' experts of our case study, are the most relevant to prioritize in order to conduct a study of the most significant environmental impacts, namely: water consumption, energy consumption, noise, effluent discharge, air pollution, and then the ranking result are further used in TOPSIS, which is chosen to rate and compare processes alternatives in a fuzzy environment, to be taken into account in our modeling.
Figure 2: The structure of AHP method

3.4. AHP Method

A hierarchical structure is constructed using five criteria and four alternatives through the literature review and taking opinions from the four experts from each company. In order to achieve the main goal (namely: weight of the selected environmental impacts).

The pairwise comparison matrix determines the relative importance (table 2) of different attributes or criteria with respect to the goal, in table 3 below:

Table 2: Scale of relative importance

1	Equal importance
3	Moderate importance
5	strong importance
7	Very strong importance
9	Extreme importance
2,4,6,8	Intermediate value
1/3, 1/5, 1/7, 1/9	Value for inverse comparison

The normalized pair-wise matrix is elaborated in table 4. The new pair-wise matrix as shown below in table 5 is established by calculating the weighted sum value and each criterion weight with its rate:

Table 3: Pair-wise comparison matrix

	Water consumption	Energy consumption	Noise	Effluent discharge	Air pollution
Water consumption	1	1 /2	7	2	5
Energy consumption	2	1	5	2	5
Noise	1/7	1/5	1	1/5	1/3
Effluent discharge	1 /2	1 /2	5	1	3
Air pollution	1/5	1/5	3	1/3	1
Sum	3.84	2.4	21	5.53	14.33

Table 4: Normalized pair-wise matrix

	Water consumption	Energy consumption	Noise	Effluent discharge	Air pollution	Criteria weight
Water consumption	0.26	0.21	0.33	0.362	0.35	0.3024
Energy consumption	0.53	0.416	0.24	0.362	0.35	0.38
Noise	0.04	0.083	0.05	0.04	0.023	0.05
Effluent discharge	0.053	0.21	0.24	0.2	0.21	0.183
Air pollution	0.052	0.083	0.143	0.06	0.07	0.082
Sum	3.84	2.4	21	5.53	14.33	

Table 5: New pair-wise matrix (non-normalized)

	Water consumption	Energy consumption	Noise	Effluent discharge	Air pollution	Weighetd Sum Value	Criteria weight	Rate
Water consumption	0.302	0.19	0.35	0.366	0.41	1.62	0.3024	5.36
Energy consumption	0.604	0.38	0.25	0.366	0.41	2.01	0.38	5.29
Noise	0.043	0.08	0.05	0.0366	0.03	0.21	0.05	4.2
Effluent discharge	0.151	0.2	0.25	0.183	0.25	1.034	0.183	5.65
Air pollution	0.06	0.08	0.15	0.06	0.082	0.432	0.082	5.27

Table 6: Standard of RI

N	1	2	3	4	5	6	7	8	9	10
RI	0.00	0.00	0.58	0.90	1.12	1.24	1.32	1.41	1.45	1.49

The relative weights are given by the eigenvector (w) corresponding to the maximum eigenvalue (λmax), such as :

$$\lambda max = (5.36+5.29+4.2+5.65+5.27)/5 = 5.154$$

A consistency index (CI) is calculated. Equation (1) describes the formula for the coherence index. The consistency ratio (CR) is calculated. Indeed, the CR allows checking if the evaluations are

consistent or not. The CR can be determined by taking the ratio of the CI and the random index (RI).

Consistency index (C.I.)

$$(\lambda max - n)/(n-1)$$

$$C.I = (5.154-5)/(5-1) = 0.04$$

Consistency Ratio

C.I/ RI=0.04/1.12=0.034 <0.10 => so our matrix is **reasonably consistent**

Table 7 presents the result of criteria ranking:

3.5. TOPSIS Method

Define abbreviations and acronyms the first time they are used in the text, even after they have been defined in the abstract. Do not use abbreviations in the title or heads unless they are unavoidable. The TOPSIS method is used to classify (rate) processes according to the selected environmental impact, then to use them in the model formalization, for this case study only some environmental impacts are used in mathematical modeling, regarding priorities given by experts.

Table 7: Criteria ranking

Criteria	Criteria weights	Rank
Water consumption	0.3024	**2**
Energy consumption	0.38	**1**
Noise	0.05	**5**
Effluent discharge	0.183	**3**
Air pollution	0.082	**4**

Table 8: Selection of the best

	Attribute/criteria	Water consumption m3/tone	Energy consumption(l/tone; Kw/ton)	Noise	Effluent discharge	Air pollution
Alternatives	Transportation and reception	0,002	14,82	62	3	5
	Brine process	1,600	20	66	4	2
	Head and viscera removed process	0,71	12	64	5	2

	Canning	0,04	5	89	3	2
	Sauce filler	0,01	4,22	67	3	3
	Sealing PCC4	0,001	6,40	88	3	2
	Washing	0,48	6	89	4	2
	Sterilization	0,27	7	65	3	3
	Cooling process	0,003	16	64	2	4
	Packaging	0,001	6	62	4	2
	$\sqrt{\sum_{j=1}^{n} X_{ij}^2}$	3,7137	43,1524	255,0931	12,7671	10,5830

The transformation of units among various criteria into common measurable units to allow comparisons between criteria. Then, the normalized values of the alternatives are determined X_ij is the numerical score of alternative j on criterion i. The corresponding normalized value $\overline{X}_{ij}$ is defined as follows :

$$\overline{X}_{ij} \square \frac{x_{ij}}{\sqrt{\sum_{j=1}^{J} x_{ij}^2}} \text{ with: i=1,2, 3,....n and j=1,2, 3,....m ;}$$

Table 9: Non measurable criteria scale

Point scale	
Low	1
Below average	2
Average	3

Big	4
Very big	5

Vector normalization: $\overline{X}_{ij} = \frac{x_{ij}}{\sqrt{\sum_{j=1}^{n} x_{ij}^2}}$ (1)

The weighted normalized decision matrix vij can be calculated by multiplying the normalized evaluation matrix $\overline{X}_{ij}$ by its associated weight wi to obtain the result:

$$\text{vij} = \text{wi} * \overline{X}_{ij} \quad \text{with : i=1,2, 3,....n} \quad (2)$$

and j=1,2, 3,....m ;

$$\text{and } \sum_{i-1}^{n} w_i = 1 \quad (3)$$

Sealing PCC4	0,000081	0,056	0,017	0,043	0,015	0,024	0,261	0,914

Washing	0,039086	0,053	0,017	0,057	0,015	0,051	0,231	0,819
Sterilization	0,021986	0,062	0,013	0,043	0,023	0,037	0,240	0,867
Cooling process	0,000244	0,141	0,012	0,029	0,031	0,105	0,229	0,686
Packaging	0,000081	0,053	0,012	0,057	0,015	0,033	0,262	0,889
V_1^+	0,000081	0,037	0,012	0,029	0,015			
V_1^-	0,218228	0,196	0,018	0,072	0,039			

V_1^+ **Ideal best value**: correspond to the minimum value (because we are interested in minimizing impact)

V_1^- **Ideal worst value**: correspond to the maximum value (because we are not interested in maximizing impact)

Euclidean distance from ideal best and worst:

$$S_j^+ = \left[\sum_{j=1}^m \left(V_{ij} - V_j^+ \right)^2 \right]^{0.5} \quad (4)$$

$$S_j^- = \left[\sum_{j=1}^m \left(V_{ij} - V_j^- \right)^2 \right]^{0.5} \quad (5)$$

$$P_i = \frac{s_i^-}{s_i^+ + s_i^+} \quad (6)$$

For the P_j must be ranked in ascending order, as long as our goal is to classify the most activities that generate more environmental impacts. A set of alternatives can then be ranked in order of preference in descending order of P_i.

Table 12: Criteria (processes) ranking

Attribute/criteria	S_j^+	S_j^-	P_j	Rank
Transportation and reception	0,097	0,229	0,702	6
Brine process	0,193	0,094	0,329	2

Attribute/criteria	S_j^+	S_j^-	P_j	Rank
Head and viscera removed process	0,099	0,185	0,651	4
Washing	0,164	0,118	0,419	3
Baking	0,274	0,000	0,000	1
Canning	0,017	0,266	0,940	11
Sauce filler	0,016	0,271	0,943	12

Washing	0,051	0,231	0,819	7
Sterilization	0,037	0,240	0,867	8
Cooling process	0,105	0,229	0,686	5
Packaging	0,033	0,262	0,889	9

Based on the results of the TOPSIS method, "baking" is identified as the most critical process to be considered in the modeling. The table 13 below contains the set of significant aspect and related significant impacts, according to each selected process, this study is carried out, with the help of expert panel:

Table 13: Significant aspects and impacts

Activities	Aspects	Impacts
Baking	-Water consumption -Energy consumption(coal) -Emission of gaseous pollutants (greenhouse gases, CO2 ... etc.) -Noise - Liquids or solid wastes -Coal splinters	-Wastewater -Consumption of non-renewable energy -Noise pollution -Pollution of ambient air - Destruction of the ozone layer, and global warming - Flow towards the natural environment
Brine process	-Water consumption -Energy consumption(electricity) - Liquids or solid wastes -Accidental spills	-wastewater -Exhaustion of non-renewable energies -Pollution of ambient air
Washing	-Water consumption -Energy consumption (electricity) -Noise	-Wastewater (Water stress)and water pollution -Contamination of ground, and water surface. -Noise pollution -Exhaustion of non-renewable energies

Head and viscera removed process	- Liquids or solid wastes -The raw material splinters -Energy consumption (electricity) -Water consumption	- Contamination of ground, and water surface. -Exhaustion of non-renewable energies -Wastewater (Water stress)and water pollution
Cooling process	-Use of refrigerant gases -Air pollution -Energy consumption (electricity) -Water consumption -Noise	-Using the product generated from persistent waste in the environment. -Wastewater -Noise pollution -Exhaustion of non-renewable energies
Transportation reception	-Emission of gaseous pollutants (greenhouse gases, CO2 exhaust gases, etc.) -Consumption of fuels -Possibility of accidental dispersion -Atmospheric emissions due to fuel combustion	- Destruction of the ozone layer, and global warming -Exhaustion of non-renewable energies - Damage for people -Atmospheric pollution -Contamination of soil, surface water. -Pollution of ambient air
Sterilization	-Energy consumption (electricity) -Emission of gaseous pollutants (greenhouse gases, CO2 exhaust gases, etc.) -Noise -Water consumption	-Exhaustion of non-renewable energies -Destruction of the ozone layer, and global warming -Noise pollution -Wastewater
Sealing PCC4	-Energy consumption (electricity) -Possibility of accidental dispersion -Noise	-Exhaustion of non-renewable energies -Contamination of soil, surface water. -Noise pollution
Canning	-Energy consumption (electricity) -Noise - Liquids or solid wastes	-Exhaustion of non-renewable energies -Noise pollution - Contamination of ground, and water surface.
Sauce filler	-Energy consumption (electricity) -The raw material splinters -Noise	-Exhaustion of non-renewable energies -Contamination of ground -Noise pollution

4. The model Formalization

In the model formalization phase, and after selecting the method/tool to be applied, as well as the identification of the significant impacts, all the model elements are presented below:

Hypothesis and constraints

-Non-regularity of procurement

-Persistence of the raw material

Sets

J: Set of processes j of the SC.

I: Total energy consumption (type)

Parameters

- W_j : Water consumption in process j.

- d_j : Processing time of the quantity Qj of raw material (product) used in process j.

- $E_{e,j}$: Electrical energy consumption in process j.

- $E_{f,j}$: Energy (fuel) consumed in process j.

Decision Variables

- Q_j : Quantity of raw material (product) used in process j.

Data

- $E_{f,tot}$: Total energy (fuel oil) consumed (l/tone).

- $E_{e,tot}$: Total electrical energy consumed (kw/tone).

- W_{Tot} : Total quantity of water consumed (m3/tone).

- Q_{Tot} : Total amount of raw material per day.

-n_0 : The number of baking ovens available at the plant.

-Q_0 : Maximum amount of raw material to be baked in n0 oven.

-P_j: Percentage of water consumption of process water j.

- **D**: Total processing time of Qj from raw material to final product

Objective Function

For environmental impact of noise and effluent discharge, a set of actions is proposed to improve and to optimize theses impacts in Fig.3 below. Hereafter the objective function "(1)" that minimizes the environmental impact of the selected processes, by taking into account various variables as the quantity of raw material, etc.

NB: The environmental impact of water consumption, in transport and reception process, is excluded due to the negligible volume of water consumed during this process.

$$Max(z) = \sum_{j=1}^{n} Q_j d_j \qquad \text{With } j=1,2,\ldots6 \qquad (7)$$

Constraints

- Constraint of electrical energy consumption

$$\sum_{j=1}^{n} E_{e,j}\, Q_j \le E_{e,tot} Q_{Tot} \qquad (8)$$

- Constraint of maximum quantity to be processed in the baking process:

$$Q_j \le n_0 Q_0 \qquad (9)$$

- Water consumption percentage constraint for all processes j:

$$\sum_{j}^{n} P_j\, Q_j \le 100 \times Q_{Tot} \qquad (10)$$

- Water consumption constraint for all processes j :

$$\sum_{j}^{n} W_j\, Q_j \le W_{Tot} \times Q_{Tot} \qquad (11)$$

- Constraint of energy consumption of transport and baking processes (fuel oil):

$$\sum_{j=1}^{n} E_{f,j}\, Q_j \le E_{f,tot} Q_{Tot} \qquad (12)$$

- Constraint on the total quantity of raw material to be processed Qj:

$$\sum_{j}^{n} Q_j \le Q_{Tot} \qquad (13)$$

- Constraint of the total processing time from raw material Qj to finished product:

$$\sum_{j=1}^{n} d_j \le D \qquad (14)$$

The objective function (1) maximizes the amount Qj of raw material to be transformed during each of the six processes in order to minimize the energy consumed and the amount of water consumed. Constraints (2) and (6) ensure that the energy consumed by each process for the transformation of the quantity Qj of raw material versus the total energy consumed is satisfied. Constraint (3) limits the available backing capacity. Constraints (4), (5) determine respectively the percentage and quantity of water consumed for each process j. Constraints (7) and (8) determine respectively the total daily quantity and the processing time.

The proposed model is a mathematical linear programming model whose objective function is to minimize the following environmental impact: Energy and water consumption. All parameters, data and decision variables may be adjusted according to the studied SC; it is also conceivable to include other constraints. Indeed, the proposed model is quite streamlined and has not addressed all potential conditions or assumptions. The flow chart in fig.3 below is designed as an improvement action to monitor all environmental impacts, in particular noise, and effluents discharge. In the next section, a numerical resolution of this model is proposed.

5. Numerical resolution

The numerical resolution is performed using the LINGO software (from LINDO SYSTEM INC).Data: (for the transformation of the quantity QJ of the raw material.

Table 14: Numerical data of the studied supply chain

Processes	J	Processing time of one tone of raw material (min)	Energy (electric, fuel oil) consumed (kw/tone, l/tone)	% of water consumption	Water consumption (m³/tone)
Baking	1	67	22.22	0.3	2.68
Brine process	2	60	20	0.2	1.6
Washning	3	15	6	0.8	0.48
Head and viscera removed process	4	60	12	-	-
Cooling process	5	120	16	-	-
Transport and reception	6	10	14.84	-	-
Figure 3:flow chart for the monitoring of the environmental impacts

The objective function :

$$MAX=67*Q1+60*Q2+15*Q3+60*Q4+120*Q5+10*Q6 \quad (15)$$

Contraints :

$$20*Q2+6*Q3+12*Q4+16*Q5<=86; \quad (16)$$

$$Q1<=4.032; \quad (17)$$

$$0.3*Q1+0.2*Q2+0.08*Q3<=1*QTot; \quad (18)$$

$$2.68*Q1+1.6*Q2+0.48*Q3<=6.63; \quad (19)$$

$$22.22*Q6+14.84*Q1<=37; \quad (20)$$

$$Q1+Q2+Q3+Q4+Q5+Q6<=28; \quad (21)$$

The objective of this section is to present the application of our mathematical model, by proposing numerical examples. The problem is solved by LINGO 18, on a computer with 1.83 GHz and 2 GB RAM:

Global optimal solution found.

Objective value:	810.8794
Infeasibilities:	0.000000
Total solver iterations:	4
Elapsed runtime seconds:	1.16

For the values of Qj:

Variable	Value	Reduced Cost
Q1	2.473881	0.000000
Q5	5.375000	0.000000

We notice that the optimal quantity (to reduce water and energy consumption) of the raw material or semi-finished product in the baking process is: Q1=2.473881tone, for the duration of 67min, and for the cooling process Q5=5.375000 tone for the duration of 120 min (2h).

6. Conclusion

The research on green SC modeling has been flourishing, in recent years, but continues to require more and more in-depth research for future studies. Nevertheless, when it comes to academicians, and industrialists, the aim of achieving an optimal model of the green supply chain is very challenging to decide which methods or tools are suitable. On the one hand, this paper provides a theoretical contribution to the body of literature, to our knowledge, there is virtually no model of the (FCSC) that takes into account all environmental impacts. In the other hand, it has some managerial implications, the proposed model can be deployed by supply chain managers, as it demonstrated in the case of fish cannery, and also the result of implementation of this model on this case study can be exploited in other fields of application.

The paper starts with literature review of the main terminology such as the (FCSC). Next, it invests in a case study which is less often dealt with as a whole supply chain, namely the case of a fish cannery, where the paper further uses relevant methods in doing so, like AHP and TOPSIS.

Moreover, the proposed mathematical model aims to minimize the identified significant impacts, and as for some directions of future research, it would be interesting to deal with other software for the model resolution, even further to include the social and economic hypotheses in order to address the whole sustainable (FCSC) modeling. The proposed framework may also serve as a preliminary approach for modeling the green supply chains regardless of their nature.

This article presents an analytical model of a single-phase ferromagnetic core power inductor (reactor) based on a magnetic equivalent circuit (MEC). The MEC model consists of magnetomotive forces (MMFs) and reluctances for all flux paths: magnetic core and leakage flux paths. The MEC elements are found established on the characteristics of the ferromagnetic material and the reactor's dimensions. Then the inductances of the reactor are determined using the MEC for a group of Silicon Steel (Si-Fe) sheets, which are juxtaposed with the inductances obtained using the finite element analysis (FEA) method. This comparison corroborates the MEC presented here. Furthermore, for the unsaturated (linear) region of the B-H characteristics of the same sets of Si-Fe materials, the inductive reactance closed-form solution of the reactor is obtained as a function of the design parameters. As an application example of the presented analytical model, reactor design optimizations (single-objective and multi-objective) are formulated and solved based on the derived closed-form reactance expression resulting in a reactor not only optimized in reactance but also in terms of material use and size.

1   Introduction

This article augments the underlying work initially introduced in the 2019 North American Power Symposium (NAPS) [1].

Inductors (or the reactors in power engineering) are fundamental and most uncomplicated circuit elements that provide economical, sturdy, and efficient solutions to a spectrum of power system intricacies. The inductors have been used to limit fault and load current, compensate reactive powers, filter harmonics, damp the transients, and balance the loads, to mention a few applications in the electric power system. As a result of the significant expense and restricted usefulness for sufficient and optimal AC flow controls with FACTS devices, inductors are considered a superior alternative in power systems [2]. The use of reactors can be in conjunction with improving electric power quality, especially in the ever-changing contemporary power networks. The reactors can be connected either in series or parallel with the network based on a particular application. Contingent upon the voltage and power ratings, they can be either dry-type or oil-submerged sort. Usually, dry-type series reactors are made with air cores, and oil-immersed shunt types are made with ferromagnetic cores. Powdered core reactors, which are manufactured by the compression of the very fine particles of the magnetic materials, are preferred for high-reliability military and

space applications because they are robust against shocks, vibrations, and nuclear radiations. Also, flux containment is better in powdered core compared to the ferromagnetic cores [3]. A simple schematic of a single-phase $(1 - \Phi)$ ferromagnetic core reactor for use in power systems is shown in Figure 1.

The inductor is symmetrical with non-ferromagnetic (air) gaps in the center of the inner leg. Over the gaps, there is AC winding connecting to the AC circuit. The gaps are used to limit the magnetic flux in order to prevent reactor's saturation from the rated operating supply. The core of ferromagnetic reactors is made of a material with high permeability that acts as an excellent conductor for magnetic flux. The ferromagnetic core's ability to conduct and concentrate the magnetic flux flow and, consequently, the reactor's inductance is dictated by its permeability. The relationship between the flux flow in the ferromagnetic core and the current supply through the coils of an electromagnetic device (like the reactor) is nonlinear. The rate-of-change (ROC) of flux for the field strength shifts from moderate to rapid to low when the operating condition shifts from the inception to linear to the saturated region. Generally, magnetic power devices' operation is not recommended in the saturation region, where more increment in MMF supply produces a minuscule change in flux. The operation of such devices in the saturation region increases the magnetizing current, responsible for

increased losses and possible hazardous operating conditions. For some applications which work on the principle of the magnetic amplifier (MA), like continuously varying series reactor (CVSR) and fault current limiters (FCL), the inductance of the device is changed without any moving parts. The inductance variation is achieved with the help of DC bias supply by controlling the permeability and saturation of the ferromagnetic core as described in [2, 4]. The use of the laminated ferromagnetic core is the general practice to lower core losses; the ferromagnetic core in Figure 1 is shown as a solid rectangular core for simplicity only.Placing non-ferromagnetic gaps with magnetic properties similar to free space in the ferromagnetic core is also common. The effective permeability and the inductance of the device get reduced by such non-ferromagnetic gaps. However, the device's usable range of operation gets increased with dominant reluctance in the magnetic circuit. Likewise, the non-ferromagnetic gaps assume a crucial part in making the flux flow sensitivity lower to external conditions like temperature. The adequate selection of the air gap dimension is an essential job of the reactor designer because there is a need to struck an equilibrium between avoiding core saturation with a significant gap and imposed constraints to achieve the desired value of the inductance.
Figure 1: Ferromagnetic core reactor and its dimensions

FEA based methods are usually adopted for accurate parameter calculations and characterization of the electromagnetic devices. This numerical method can be tedious with a tremendous computational burden. It also lacks closed-form solutions. Therefore, it is not suitable for the repetitive design processes and dynamic analyses of magnetic power devices [5, 6]. In [7] and [8], the authors introduced the magnetic equivalent circuit (MEC) based method a long time ago. MEC is an alternative magnetic field modeling method for electromagnetic devices with a considerably reduced computational resources requirement. The MEC approach is based on the design inputs, material characteristics, and physical device geometry. It represents such devices with lumped magnetic circuit components: magnetomotive forces (MMFs) and reluctances. The MEC representation is considered coarser than the FEA but more acceptable than the electrical-equivalent lumped parameter models,

which are based on fundamental equations. Hence, MEC is considered a bargain between those approaches in terms of computational resource need and accuracy [9, 10]. MEC approach is based on the design inputs, material specifications, and geometry of the device. The inductance calculation of a device is straightforward with this approach. MEC has the ability to accommodate local saturation effects; however, because of the eddy current and skin effects, the MEC representation becomes challenging. A comprehensive understanding of the device in consideration and a significant engineering judgment is required to generate a reluctance network with spatial discretization [9]–[13].

A great deal of engineering time and experience can be avoided with the optimization-based design process, which can produce a better design with less engineering effort [14]. A reactor's design can involve many performance targets, some more important than others, with a set of constraints. With multi/many-objective design optimization, the feasible solution space might be discontinuous and non-convex. The evolutionary algorithms are typically chosen for such problems. A large number of design evaluations are necessary to produce a Pareto optimal front, and approximate analytical models make such computations efficient. In this article, the constrained single objective (SO) and multi-objective (MO) optimization design formulations, coupled with the detailed MEC-based analytical model that captures the reactor's electromagnetic behavior, are presented. These design examples signify the importance of computationally efficient and accurate analytical MEC models for the reactor's design optimization.

The article is structured as follows. Section 2 proposes an adequately precise yet simple MEC for a gapped ferromagnetic core reactor. The inclusion of the fringing fluxes in the MEC proposed in the previous section improves its accuracy. The methodology for the confirmation of the MEC model is presented in Section 3. The next section follows the methodology introduced with a case study for a set of Silicon Steel (Si-Fe) ferromagnetic materials. The design optimization examples are presented in Section 5, facilitated by the reactance expressions obtained from the validated MEC. Based on the proposed MEC, its validation, and optimization examples, conclusions are drawn in Section 6.

2 Magnetic Equivalent Circuit

The dimensions of the simple single-phase gapped ferromagnetic core reactor are shown in Figure 1. The gaps (air) in the core make the leakage flux not influential for the reactor's magnetostatic characterization. For this reason, an arbitrary winding configuration choice is made for this device. The reactor features two windows of width w_w and height h_w. w_o and w_c are the widths of the exterior and middle leg, respectively. The central leg has non-ferromagnetic gaps of elevation g which stretches d_c into the surface, which is the same throughout the reactor. Both top and bottom yokes have the same height of h_y.

Figure 2 represents one of the simplest possible MECs of the reactor. The reluctances (resembling resistors from electric circuits) in the proposed MEC are positioned to interpret the accurate reactor physical structure. Similarly, the MMF source position (resembling voltage source from the electric circuit) in the MEC indicates the

winding position in the reactor. The ferromagnetic core reluctances are denoted by $R_1 - R_7$, dependent on the magnetic flux through the corresponding elements. In MEC, these reluctance are shown to be a function of flux.
Figure 2: Magnetic equivalent circuit

However, the non-ferromagnetic air gap reluctance (R_8 in Figure 2) is fixed and does not depend on the corresponding flux. The MMF source in the middle leg of the proposed MEC is the product of the number of winding turns (N) and current supply through it (I), i.e., $F = NI$. In Figure 2, loop fluxes are represented by ϕ_1 and ϕ_2, making the inner leg branch flux to be ($\phi_1 - \phi_2$) in the specified direction.

For a representative branch k, the generalized reluctance is:

$$R_k = \frac{l_k}{A_k \mu} \tag{1}$$

In equation (1), A_k and l_k are cross-sectional area normal to the flux flow direction and length of branch element, respectively, and μ is the permeability (absolute) of the material used. The absolute permeability depends on the type of flux path, based on which the reluctances can be categorized into:

2.1 Core Piece Reluctance

The reluctances of ferromagnetic core pieces are intrinsically nonlinear. The reluctance of each ferromagnetic element in the MEC depends on the material property, physical geometry, and supply through the winding around the core. The core piece's absolute permeability can be demonstrated as a function of either flux density (B) or flux intensity (H). Considering the symmetry of the reactor, based on (1), the characteristic core piece reluctances can be written as:

$$R_1(\phi) = \frac{2w_w + w_o + w_c}{2d_c h_y \mu_B(\frac{\phi}{d_c h_y})} \tag{2a}$$

$$R_3(\phi) = \frac{h_y + h_w}{d_c w_o \mu_B(\frac{\phi}{d_c w_o})} \tag{2b}$$

$$R_7(\phi) = \frac{h_y + h_w - g}{d_c w_c \mu_B(\frac{\phi}{d_c w_c})} \tag{2c}$$

Also, $R_1(\phi) = R_2(\phi) = R_4(\phi) = R_5(\phi)$ and $R_3(\phi) = R_6(\phi)$. Each branch reluctance in (2) has absolute permeability represented as the functions of flux density through them. In [15], the author describes the process of finding these absolute permeabilities, which can be summarized by the following expressions.

$$\mu_B(B) = \mu_0 \frac{A(B)}{A(B) - 1} \tag{3}$$

where,

$$A(B) = \frac{\mu_r}{1 - \mu_r} + \sum_{k=1}^{K} \left\{ \alpha_k |B| + \frac{\alpha_k}{\beta_k} log \left(\frac{e^{-\beta_k \gamma_k} + e^{-\beta_k |B|}}{1 + e^{-\beta_k \gamma_k}} \right) \right\} \tag{4}$$

In equation (4), B represents the magnetic flux density; μ_r and μ_0 are the relative and absolute permeabilities, respectively. Here, anhysteretic characteristics are considered with the reactor operating in the linear region. Moreover, α, β, and γ are the permeability function parameters for select core materials.

An iterative numerical search is needed for each branch of the MEC corresponding to the core piece ferromagnetic components to find a value of reluctance, given some initial values for the flux density. Figure 3 shows the flowchart summarizing this iterative process. The absolute permeability calculation is the first step of the iterative process. For mesh circuit analysis, permeability as a function of flux density is preferred. Using the absolute permeability ($\mu \equiv \mu_B(B)$), the reluctance of each piece can be calculated using (1). In the next step, each branch is represented in the standard general form: a series combination of an MMF source and the reluctance. Based on the complete circuit element formation, mesh analysis is carried out to find the fluxes through each loop. Except for the first iteration, as indicated in the flowchart, the stopping criteria for the iterative process are the maximum number of iterations and branch flux relative error between consecutive iterations.

2.2 Air Gap Reluctance

In the MEC model of Figure 2, the reluctance R_8 is the air gap reluctance. It is a constant reluctance without any dependence on the flux passing through it. Following (1), the reluctance of the air gap is given by:

$$R_g = \frac{g}{d_w w_c \mu_0} \tag{5}$$

While getting reluctance in (5), it is assumed that the cross sectional flux flow between the top and bottom of the air gap is streamlined. However, there exists a portion of a flux that flows in the vicinity of the air-gap corners spreading in all directions,

which is known as the fringing flux. Because of this flux, the effective cross-sectional area of the air gap is increased, resulting in decreased air gap reluctance. The fringing fluxes should be incorporated into the air gap reluctance computation to make the MEC highly accurate.

Figure 3: Iterative non-linear reluctance calculation flowchart
Figure 4: Fringing permeance calculation

The Ampere's circuital law, which relates the current to the associated magnetic field, can be described by (6) representing the magnetic field intensity H(A/m) over a closed path c to be equivalent to the current enclosed by that path ($I_{enclosed}$.)

$$\oint_c H \cdot dl = I_{enclosed} \tag{6}$$

The fringing effect can be captured by applying Ampere's law for the uniformly flowing flux from surface node N_A to N_B along the expanse of the flux route shown in Figure 4 as:

$$H(g + \pi r) = F \tag{7}$$

In (7), H and $F(= NI)$ are the magnetic field strength (intensity) and the MMF source respectively. Based on the relationship with H, the magnetic flux density ($B = \mu H$) can be represented as:

$$B = \frac{\mu_0 F}{(g + \pi r)} \tag{8}$$

The surface integration of the flux density gives the flux coming out of surface node N_A, given by (9).

$$\phi = \int B dS = \int_0^{(h_w - g)/2} \frac{\mu_0 F}{(g + \pi r)} d_c dr \tag{9}$$

Also, the fringing flux incorporated with the designated path can be linked to fringing permeance (P_{fring}) and MMF source as:

$$\phi = P_{fring} F \tag{10}$$

From equations (9) and (10):

$$P_{fring} = \frac{\mu_0 d_c}{\pi} log \left\{ 1 + \frac{\pi(h_w - g)}{2g} \right\} \tag{11}$$

For the central leg with air gap, the depth and the width are the same; therefore, the total fringing permeance is four times the P_{fring}. Hence, the air gap reluctance can be given by:

$$R_{air-gap} = R_8 = R_g \| \frac{1}{(4P_{fring})} = \frac{R_g}{1 + 4R_g P_{fring}} \tag{12}$$

3 MEC Validation Methodology

A meshed circuit analysis based on Kirchhoff's laws from electric circuits can be adopted to solve the proposed MEC once each MEC element is determined. This analysis gives flux through each branch and loop of the MEC. The physical law of energy conversation holds for the MEC. Therefore, a balance between the energy generated by the MMF source(s) and energy dissipated into the reluctances always exists. The energy balance principle can be exploited to find the overall equivalent inductance of the inductor directly. From [16] the reactor's inductance is:

$$L_{MEC} = \frac{1}{I^2} \sum_{k=1}^{n} \phi_k^2 R_k \tag{13}$$

Here, $1 \leq k \leq n$ is the index representing each branch in the MEC with a total number of branches being n; while R_k and ϕ_k are the reluctance and flux through the branch k respectively. Furthermore, the winding coil has current I following through it.

By performing different analyses (magnetostatic/transient) using the software packages based on FEA can give the inductance of a reactor. A three-dimensional (3-D) model of an inductor with minimal error tolerance set up can compute the inductance (apparent/incremental) accurately in the FEA software package.

The proposed MEC of the reactor is verified by comparing the equivalent inductances obtained from MEC as described in (13) using MATLAB®[1], and the FEA based approach using ANSYS Maxwell®[2]. The following case study presents the comparative analysis.

4 Case Study

A contextual analysis for the affirmation of the presented analytical model is carried out in this section, followed by the closed-form reactance calculation based on the validated model.
Figure 5: Candidate ferromagnetic material characteristics

4.1 MEC Validation

A single-phase reactor considered for the MEC validation has the parameters, as shown in Table 1.

Table 1: Gapped core reactor parameters

Parameters	Symbol	Value
Window height	h_w (m)	0.374
Window width	w_w (m)	0.056
Leg width	$w_o = w_c$ (m)	0.076
Yoke/base height	h_y (m)	0.076
Core depth	d_c (m)	0.076
Number of turns	N	39
Rated current	i (A)	$25\sqrt{2}$

[1]https://www.mathworks.com/products/matlab.html
[2]https://www.ansys.com/products/electronics/ansys-maxwell

A set of magnetic core materials (Si-Fe) is considered with accompanying qualities (relative permeability, permeability function parameters, and maximum flux densities) extracted from [17]. The magnetic properties (B-H curves) for these materials generated according to [18] are shown in Figure 5. The two approaches described in the previous section are applied to calculate and compare the inductance of the reactor made up of each of the given materials.

For both linear and non-linear regions of the magnetization characteristics of Si-Fe, it is clear that the anhysteretic curve of Hiperco50 is considerably different from the others, as can be seen in Figure 5.

(a) Adaptive mesh plot   (b) Flux density plot
Figure 6: FEA simulation Results for Si-Fe Hiperco50 core

Figure 6 shows 3-D FEA results for the reactor with the Si-Fe Hiperco50 core with the parameters from Table 1. The adaptive meshing has been applied to the model to make the simulation more accurate. The figure also shows the flux density distribution throughout the core, and it can be seen that the middle leg has the highest flux density.

For every core materials from the group, the inductances using both approaches and relative error between them are summarized in Table 2. The errors are within 1% for each of the materials. This minimal range of errors across a group of Si-Fe materials confirms the accuracy of the proposed MEC.

Table 2: Inductance comparison

Si-Fe Materials	Inductance (mH)		% Error
	MEC	FEA	
M19	7.853	7.880	0.348
M36	7.905	7.871	-0.427
M43	7.910	7.935	0.310
M47	7.831	7.904	0.925
Hiperco50	8.012	8.081	0.850

4.2 Reactance Calculation

For a 60 *Hz* system, a single-phase inductor's reactance can be expressed as:

$$X_L = 120\pi L \tag{14}$$

where,

$$L = \frac{N^2}{\mathcal{R}_m} \tag{15}$$

here, $\mathcal{R}_m$ is the equivalent reluctance of the reactor. A circuit reduction on MEC can be applied to obtain it, as shown in Figure 7.

(a) Step I (b) Step II
Figure 7: MEC reduction

As the design of the reactor is symmetrical, a circuit simplification by the parallel combinations of the reluctances corresponding to the yoke and vertical leg transforms the MEC from Figure 2 to Figure 7a. Furthermore, the series reluctances in a single loop MEC in Figure 7a can be combined to achieve the simplest MEC as in Figure 7b. Accordingly:

$$\mathcal{R}_m = R_y(\phi) + 0.5R_l(\phi) + R_7(\phi) + R_8 \tag{16}$$

In Figure 7, $R_y \equiv \{R_1 = R_2 = R_4 = R_5\}$ and $R_l \equiv \{R_3 = R_6\}$. A further break down of (16) for a linear operation region (in the magnetization characteristic curve) returns:

$$\mathcal{R}_m = \frac{6.25 \times 10^5 g}{0.7854 d_c w_o + g d_c \log\left(-0.5708 + \frac{1.5708 h_w}{g}\right)}$$
$$+ \frac{X\left\{-h_y g + w_o(w_o + w_w)\right\} + Y h_y(h_y + h_w)}{d_c h_y w_o} \tag{17}$$

A symbolic mathematical computation program called MATHEMATICA®[3] has been used to obtain this simplified expression. For different core materials, the coefficients X and Y in (17) are summarized in Table 3.

---

Table 3: Reactance coefficients

Si-Fe Materials	Coefficients	
	X	Y
M19	44.324	66.486
M36	58.996	88.494
M43	51.342	77.012
M47	86.369	129.554
Hiperco50	36.473	54.710

5 Design Optimization

5.1 Single Objective Optimization

An example of a single objective optimization problem is set up using the expression for the reactance of the reactor. The use of minimal material for the core is the objective while complying with several design constraints. Here, it is assumed that the reactor core is made up of Si-Fe M36 material. The design constraints include the target reactance, flux density limits for each element of MEC ($n = 8$), and minimum and maximum limits for the design parameters. The design parameter vector (19) consists of all design parameters. Their ranges and the initial points are summarized in Table 4.

$$\begin{aligned}
\min_{\mathbf{X}} \quad & V = d_c\{2h_w w_o + w_c(h_w - g) + 2h_y(2w_w + 2w_o + w_c)\} \\
\text{s.t.} \quad & X_L = x_{design}, \\
& B_k \le B_{max}, \ \forall k \in n, \\
& \mathbf{x}_{min} \le \mathbf{x} \le \mathbf{x}_{max}
\end{aligned} \tag{18}$$

In (18), $B_{max} = 1.25\ T$ is the maximum flux density in the linear region of the B-H curve for Si-Fe M36, and $x_{design} = 2\ \Omega$.

Table 4: Domain of design parameters

Parameters	$\mathbf{x}_{min}$ (m)	$\mathbf{x}_{max}$ (m)	$\mathbf{x}_{initial}$ (m)
w_o	0.0762	0.1016	0.0889
w_w	0.0559	0.0762	0.0635
h_y	0.0762	0.1016	0.0889
h_w	0.3739	0.5080	0.4572
d_c	0.0762	0.1016	0.0889
g	0.0015	0.0023	0.0020
w_c	0.0762	0.1016	0.0889

$$\mathbf{x} = [w_o \quad w_w \quad h_y \quad h_w \quad d_c \quad g \quad w_c]^T \tag{19}$$

A non-linear solver called 'Knitro' with YALMIP toolbox from MATLAB® has been used to solve this non-linear optimization problem. Table 5 summarizes the optimization results.

Table 5: SO optimization results

Parameters	Value (m)	Parameters	Value (m)
w_w	0.0559	$w_o = w_c$	0.0762
h_y	0.0762	h_w	0.3739
g	2.286×10^{-3}	d_c	0.0762

The optimal (minimum) ferromagnetic core material volume is found to be $1.0452 \times 10^{-2} m^3$. An approximate 'back-of-the-envelope' calculation for the volumetric minimization of the reactor with some educated guess regarding the constraints verifies the presented results. The air-gap (g) is very sensitive towards the reactance and the flux density in the core; however, it has a minimal impact on the reactor's total ferromagnetic volume. Therefore, the constraint set $\mathbf{x}$ other than g can be guessed towards the minimum limit to get the minimum ferromagnetic volume. If $\mathbf{x}$ is chosen to be x_{min}, the ferromagnetic volume would be $1.0457 \times 10^{-3} m^3$.

The optimal ferromagnetic volumes for different Si-Fe materials are summarized in Figure 8. In the figure, the ferromagnetic volumes are very near each other; however, the price difference between the materials will impact material selection.
Figure 8: Optimal core volume comparison

5.2 Multi-Objective Optimization

Reactance is the most important characteristic of the ferromagnetic core inductor. In addition to the core material volume minimization, an additional objective of reactance maximization is introduced here. The multi-objective (MO) optimization searches a vast design space and is quite effective in finding optimal machine designs. An evolutionary population-based genetic algorithm [19] is implemented to solve a MO reactor optimization problem. A genetic algorithm (GA) can find multiple solutions from a population of solution candidates in one execution, which is not possible with classical optimization [14].

The goal of this design example is to come up with a single-phase power reactor design that has a reactance of at least X_{min}, and maximum ferromagnetic core flux density below B_{max}. It is desirable to minimize the reactor's ferromagnetic core material volume and maximize the reactance at the rated system conditions.

$$\min_{\mathbf{X}} \begin{bmatrix} V & \dfrac{1}{X_L} \end{bmatrix}$$
$$\text{s.t.} \quad X_L \geq X_{Lmin}, \tag{20}$$
$$B_m \leq B_{max},$$
$$\mathbf{x}_{min} \leq \mathbf{x} \leq \mathbf{x}_{max}$$

The ferromagnetic core material used in this optimization problem is the same material used for single objective optimization problem described in the previous section (Si-Fe M36). The optimal reactor would have a reactance of at least 1.5 Ω (X_{min}) and the flux density of the 1.25 T (B_{max}) so that the operation of the reactor is within the linear region of the characteristics curve of the selected core material for the rated supply. In 20, the flux density has been bounded only for the middle leg flux density because it is the dominant flux density region. The gapped middle leg flux density can be approximated by:

$$B_m = \frac{\phi_m}{A} = \frac{Ni}{\mathcal{R}_m A} \approx \frac{\mu_0 Ni}{g} \tag{21}$$

The parameter bounds are the same as in the previous section, given in Table 4. The free parameter vector is represented by (19). The symbols in parameter vector are as defined in Table 1. It is assumed that the window spaces are sufficient for the winding.

The fitness function for the MO optimization problem can be defined as:

$$f = \begin{cases} \varepsilon(\bar{c} - 1)[1 \quad 1]^T, & \bar{c} < 1 \\ \left[\frac{1}{V} \quad X_L\right]^T, & \bar{c} = 1 \end{cases} \tag{22}$$

In (22), ε–a small positive number (in order of 10^{-10})– does not have an influence on the optimization outcomes but is appropriate for the observation of the optimization progress.

And, $\bar{c}$ is the aggregate constraint of the MO problem, which is:

$$\bar{c} = \frac{1}{n_c} \sum_{i=1}^{n_c} c_i = \frac{c_1 + c_2}{2} \tag{23}$$

where, n_c is constraint number (here, $n_c = 2$). Once X_L and B_m have been evaluated using (14) and (21), constraint functions can be put together as (24):

$$c_1 = gte(X_L, X_{L_{min}}) \tag{24a}$$

$$c_2 = lte(B_m, B_{max}) \tag{24b}$$

where, $gte()$ and $lte()$ are greater-than-or-equal-to and less-than-or-equal-to functions, respectively. These functions are defined as:

$$lte(x, x_{max}) = \begin{cases} 1, & x \leq x_{max} \\ \frac{1}{1+x-x_{max}}, & x > x_{max} \end{cases} \tag{25a}$$

$$gte(x, x_{min}) = \begin{cases} 1, & x \geq x_{min} \\ \frac{1}{1+x_{min}-x}, & x < x_{min} \end{cases} \tag{25b}$$

The MO optimization is carried out using GOSET [20], a MATLAB-based genetic optimization toolbox. The optimization

has been performed with a population size of 1500 over 2000 generations with the specifications described by Table 6, and the parameter bounds given in Table 4.

Table 6: Genetic algorithm parameters

Parameters	w_o	w_w	h_y	h_w	d_c	g	w_c
Encoding	log	log	log	log	log	log	log
Chromosome	1	1	1	1	1	1	1

Table 7 summarizes the GA options carried out in the different steps of the MO optimization.

Table 7: Summary of GA options implemented

GA	Elitist nondominated sorting GA(NSGA-II) [21]
Selection	Tournament selection
Death	Random replacement
Gene repair	Hard limiting
Scaling	Offset scaling

Figure 9 represents the objective space at the end of the optimization, where each point represents the objectives of the corresponding design. The objective space plot is according to the fitness function definition. Therefore, reactance is plotted against the reciprocal of the ferromagnetic core material volume. The design points can be divided into nonviable, dominated, and nondominated design sets. The nonviable designs are near the origin and the negative axes of the objective space. The figure indicates the distinct design sets which are viable but dominated or nondominated.

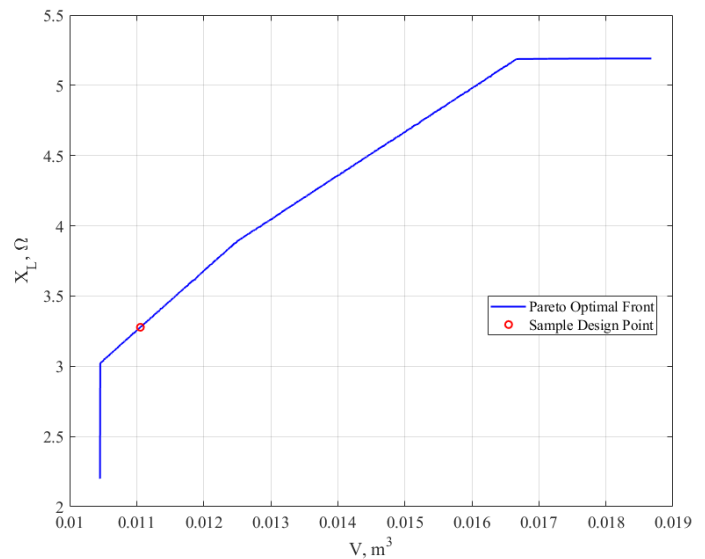
Figure 10 shows only the nondominated designs with the axes representing the reactance and the material volume. This plot clearly shows the tradeoff between the objectives. A sample design on the Pareto optimal front is also indicated. The parameters representing the sample design are summarized in Table 8.
Figure 9: Objective design space


Figure 10: Pareto frontier boundary

Table 8: Sample design results

Parameters	Values (m)	Parameters	Values (m)
w_o	0.085	w_w	0.05589
h_y	0.076233	h_w	0.3739
d_c	0.0762	g	0.001524
w_c	0.0762		

For the sample design, the ferromagnetic material volume is 0.011176 m^3, and the reactance of the inductor is 3.32 Ω. This reactance is above the minimum limit X_{Lmin}, and the flux density is found to be 1.137 T, which is less than the flux density limit B_{max}.

To check the validity of the sample design obtained above, a 3-D FEA model is created again with the parameters from Table 8. The magnetostatic analysis from FEA shows that the reactance of the sample design is 2.96 Ω, which is ≈ 12% off from the MO optimization results. It is a fairly good result considering the simplicity of the model used, and more accurate than a spreadsheet-based design typically used by manufacturers.

6 Conclusions

In this article, a systematic analytical representation was proposed for a 1-Φ ferromagnetic core air-gapped inductor based on MEC. For a set of Si-Fe materials for core, the proposed MEC was substantiated after collating the inductances obtained by using the 3-D FEA method. The minuscule error of the inductance values throughout the entire group of materials validated the proposed model. Furthermore, when the ferromagnetic core is in the unsaturated (linear) region of the operation, an inductor reactance expression was derived as a function of design parameters. To illustrate one of the applications of the suggested systematic model, both SO and MO optimization problems were formulated and solved. They prove the MEC's applicability for obtaining optimal reactor designs for a specific application and highlight its efficiency and importance.

The future work will include reactor design improvements with more complex models, including more detailed flux leakages, and analyses (loss and thermal), as well as data from tests on the physical device with comparison of computational and experimental results.

Conflict of Interest   The authors declare no conflict of interest.

Contingency Plan in the Supply Chain of Companies in the Retail Industry in the Face of the Impacts of COVID-19

Carlos Juventino Ruiz Montoya[*], José Luis Martínez Flores

UPAEP University, 21 sur 1103 Barrio de Santiago CP. Puebla, 72410, México

A R T I C L E I N F O	A B S T R A C T
	The main issue that is being presented in 2020 is the impact that all organizations are having due to the COVID-19 pandemic, and it is not for less given the global collapse that is occurring in all aspects. Many organizations have been affected by this catastrophe and in the face of an unforeseen scenario, the disruptions in the different supply chains have revealed the lack of some essential products for human consumption. *For organizations that are looking for alternatives of what to do and that are constantly analyzing how to reinvent their processes to mitigate the impacts of the pandemic and thus stay current during the contingency, they have before them the challenge of strengthening their supply chains, however It is difficult to think that the contagion of this virus that has brought the great powers of the planet to their knees, collapsing their productive, economic and especially health systems.* *This research aims to propose a model that allows the development of an action plan in the event of the COVID-19 contingency in the sector of companies classified as essential, such as the retail industry. It is not enough to have well-defined and structured processes, these must also be dynamic and interconnected to privilege the distribution of essential products and for this it is important to be clear about the pillars of supply chain management and the key elements that they proposed.* *Organizations must learn to protect their supply chains and to achieve it research offers a perspective on how to assess the level of risk of the processes of the retail industry and thus have identified the opportunities that will have to improve to build a resilient supply chain and strengthened.*

1. Introduction

Throughout time humanity has faced a significant number of disruptions that have affected from basic aspects such as the very survival or health of human beings to the complete collapse of the productive and economic systems, some of these disruptions have been caused for decisions related to the political and economic interests of man, such as the armed conflicts of the two world wars of the last century and that meant significant changes in the way of life of the affected countries, mainly those of the defeated side. Like the group of disruptions caused by the hand of man, there are other disruptions that have occurred and that have their origin in sometimes predictable behavior, but in many other unpredictable ones in nature, in both cases destructive, causing the loss of human lives and the destruction of assets and infrastructure for the proper functioning of business operations. In this group of natural disasters are hurricanes, earthquakes, tsunamis and fires, in addition to others, associated with diseases in humans that become epidemics and at a higher level of severity due to the size of the contagion, in the devastating effect of a pandemic.

Unfortunately, and due to this type of disruption, organizations are part of a side effect of what happens in the environment in which they find themselves. Each of these impacts and their post-mortem analysis are on an undesirable list of scenarios that have already occurred at the time, such as the SARS disease that occurred in Asia from 2002 to 2003, the tsunami in Indonesia in 2004, Hurricane Katrina that The United States struck in 2005, the 2009 - 2010 H1N1 influenza that occurred in Mexico, and currently the living pandemic of the COVID-19 coronavirus that started in China and is already spread around the world in 2020.

[*]Corresponding Author: Carlos Juventino Ruiz Montoya,
cjruizmontoya@hotmail.com

The historical account of disruptions that humanity has faced is wide and with a diversity of origins, however, regardless of their origin, they have something in common, a collapse of the different supply chains in the territory, region or country. where it occurs, causing to the companies a series of disorders in their supply operation from suppliers, in-house manufacturing and in the supply of goods to customers. Businesses with a more robust supply chain will enable them to be better prepared to responded more effectively to the effects of a disruption.

A service oriented organization must take care that the processes of its supply chain, in addition to being efficiently structured, have haracteristics of agility, adaptability and alignment to dynamically translate the needs that are being presented to the customer and can be respond satisfactorily in [1] the author explained the Triple A as a model that allows the supply chain to be adequately managed.

The supply chain management processes do not remain fixed over time, they have to be transformed according to the needs of the market and the sales point where the customer goes adapting to the purchasing trends of the consumer customer. Currently, from a commercial point of view in the retail industry, it is common to classify or have segmented the type of consumer that goes by store, this is a work of market intelligence, an emerging area in the modern design of organizations who have the need to know the sensitivity of how the market behaves, it is precisely this area that is responsible for doing this type of study to better define the commercial strategy to follow. In [2], the author explained the importance of having the commercial strategy integrated to the supply chain.

When talking about processes implicitly you have to consider two elements or vectors that converge on the subject, on the one hand, the capacity of the processes that in turn represent the potential designed to offer by the process, and on the other, the indicators of performance or kpi´s (key performance indicators) of the processes.

To measure the performance of the processes, they must have indicators or metrics that provide feedback to the system for which they were designed. The indicators must be focused on the measurement of the operational processes and offer deliverables on what happens at the border of each process, maintain a standard of behavior that constantly aspires to excellence in performance and that are also consistent with the strategy of the organization supply chain. If the importance of the Triple A Model was previously highlighted, in [3] the author complemented the model by highlighting the importance of top management's commitment to agility, flexibility, efficiency and service. Metrics should provide feedback to the organization on the elements that make up the established strategy.

With the evolution of the supply chain, accelerated mainly by the digital era and e-commerce, organizations have focused their actions to maintain an efficient customer service process by establishing strategies that allow them to stay current in a highly competitive environment, however the backyard that integrate the supply network, the management of optimal inventories for the preparation of orders looks vulnerable or simply exposed to the risks that every organization faces in the midst of a pandemic. In [4] the author described the importance of having identified supply

chain segmentation and regionalization as a way to mitigate risk. The stage during which this situation occurs generates high uncertainty where many organizations are not clear on how to act. In [5] the author explained the fact of having clear and defined processes to mitigate the effect of uncertainty and to have a clearer direction to follow by taking disruptive measures integrated in a mitigation strategy.

The purpose of this research is to offer a perspective on how to classify for a better assessment of the risk level of the retail supply chain. The classification is supported by four management pillars and these in turn integrate seven key elements that will be addressed in the proposed research methodology.

2. Literature review

When addressing the issue of disruptions that have occurred in the past, that are present today and that will surely continue to occur in the future, and that affect the environment where the basic daily activities of the world population are carried out, and therefore that of organizations, on this topic you can find a great diversity of research work and a multivariate approach or point of view, which depends on the type of research that the author wants to highlight or highlight. Just as these perspectives are mentioned in the different investigations carried out and that will be cited throughout the work, this investigation has as its main contribution to offer organizations an analysis, diagnosis and proposal of contingency actions against the disruptions caused by catastrophes natural as the pandemic that we are currently experiencing with COVID-19 and that affects the supply chains of companies considered or classified as essential as the retail industry, due to the impact they have on society in the supply of food and products of first necesity.

This research would not be a complete work if it does not leave a learning that generates value to the society in which companies develop and is not accompanied by a proposal for organizations on how they should be better prepared to face unplanned situations such as disruptions of this type.

Before continuing and delving into such a relevant topic today, it is important to start with a proposal to classify the disruptions that occur in organizations and in general in the society where we live, even before making such a classification it is important to be clear the definition of this, disruption is the sudden or sudden interruption of something that presents an expected behavior.

Having clarity of the definition, now if we can have a classification on the different types of disruption that exist, this classification is part of the research that has been integrated by different researchers who have contributed to their work on the subject. As described, a disruption has to do with an unexpected scenario and behavior that causes human beings, in addition to uncertainty, a forced change in their behaviors and behaviors such as work, consumption, coexistence, socialization, fun , among others. According to this description that contemplates a change in people's behavior patterns, we cannot expect something different to happen in labor and social organizations where people are the central elements that integrate them and give them life.

2.1. Classification of disruptions affecting the supply chain

By ordering ideas we can then say that when speaking of a disruption that affects organizations it is closely linked to an

unexpected situation or scenario and therefore can be classified into two types of disruptions, (1) those that are in a controlled environment and that in many occasions they obey technological innovations, and (2) those that arise due to an uncontrolled situation caused by disasters or natural catastrophes and even human-induced situations without even having dimensioned the impact that this will cause, such as terrorists acts. In [6], the author explained that whatever the origin that causes a disruption brings with it impacts on the supply chain. Annex 1 shows the classification of controlled disruptive events most relevant to the retail industry.

There is, as already mentioned, another group of disruptive events that are uncontrolled and that are also worth classifying in order to have a systemic perspective of the disruptive events facing humanity. In recent years we have seen these types of incidents that affect a large part of our planet and that lead us to reflect on how to manage properly and how to be prepared to when they happen, to mention some of these incidents and their impacts, how to imagine that the eruption of a volcano in Iceland would paralyze much of Europe's air movements and with it the interruption of the flow of goods, a series of forest fires in The United States and Australia would lead to the closure of companies dedicated to the assembly of by-products or components in the United States and, in the case of Australia, the closure of companies and the displacement of the workforce to other areas of the country, the bird flu that occurred in Asia and that caused millionaire losses to many companies affected by this situation and the sanitary fence that was implemented. The hurricanes and tsunamis that have occurred in different parts of the world have caused, in addition to human tragedies, the paralysis of factories and even the complete disappearance of companies dedicated to the manufacture of inputs within different supply chains. Disruptive events caused by uncontrolled situations can be seen in Annex 2.

The focus of this research is directed to this group of disruptions in uncontrolled environments and to be more specific, to the impacts of pandemics and epidemics in supply chains, in this case to the affectation that COVID-19 is causing in the international market and in the different supply chains that integrate it, in [6] the author explained in his conceptual framework of supply chain disruptions, about disruptions in the behavior of demand and disruptions in the supply of products.

2.2. COVID-19 and its impact on supply chains

The effect of a pandemic like that of COVID-19 is anteceded by what happened more than two decades ago with the aforementioned H5N1 avian influenza and a few years later with the H1N1 influenza that occurred between 2009 and 2010, however, the prolonged effect by COVID -19 is unmatched in terms of economic, social and loss of life impacts.

COVID-19 has come to present itself as an evil that the present generation had not faced, it has come as a script taken from a horror movie in all aspects, a segment of the apocalypse that illustrates what the future of the world will be like after observing how the health systems of entire nations have collapsed, of the economy and not to mention the psychosocial aspect that this disease is causing. Various authors describe the current scenario using analogies that refer to a combination of interrelated variables, on the one hand the probability that it will happen and the impact that

it can cause when it happens. In [7] the author metaphorically described such events as the COVID-19 pandemic as a "black swan" for humanity, in [8] the author described in reference to the same hypothesis the rarity of seeing a "black swan" and on the other hand the high impact it represents for humanity in this case the pandemic that is sweeping the whole world.

As a member of a leading transnational organization in the retail industry, just a few months ago, to be exact the beginning of 2020, we did not imagine in our annual strategic planning process of the company the threat of facing a scenario like the one that is being presented by the effect of COVID-19, it was not a topic, much less a stage that our organization and many others imagined.

After a few months of experiencing this global collapse, it is possible to make a count of learning that has favored the operational continuity of the organizations that have remained standing to continue being a profitable option for their clients and consumers. Among these learnings we can mention some in which the research will be deepened:

1) Have a structure robust enough for management, seeking efficiency both in the execution of local operational functions and in staff functions.
2) Have an interconnected network of suppliers for each distribution center, with a solid alternative of local supply.
3) Having human resources and protecting them from the environment so that what has been previously described can take place, even becoming the most important aspect for the organization to remain current. Protecting people becomes a priority for organizations.

These three lessons help organizations have more resilient supply chains in order to get this complicated stage on track, affecting their operational continuity. The motivation to carry out an investigation to carry out this investigation is to contribute knowledge and learning in situations such as the one being experienced.

2.3. An overview of the retail industry as an essential company in the days of COVID-19

The COVID-19 crisis has affected the economy through different factors related to the health of the population, the mandatory blockades and interruptions to trade, as well as a series of collateral effects such as the decisions that organizations forced by the situation have had to make and which are related to maintaining sources of employment. In [9], the author explained about emotional factors such as the pessimistic feeling of consumers and companies derived from high uncertainty and financial stress.

For companies classified as essential due to the role they play before society for offering food products and other types of food considered basic for human consumption, it is a challenge to keep their supply chain processes active in a complicated environment and where many companies that are part of the supply chain gradually lose productive capacity given the situation of the pandemic and with it the available inventories. It is here at this point where presented the situation many organizations reflect on the design, the priorities and the strategy that they have followed to develop the business and where the supply chain and the supply network that integrates it become relevant, such as previously

described, "leverage" in the factors of people, network of providers, above all the development of the premises and lastly the operational and staff structure that it provides. In [10], the author explained about the key aspect of developing collaborative strategies with suppliers and together adopting best practices that help to have a better performance in the supply chain.

The pandemic shows that it may be too simplistic to base decisions about production locations solely on economic factors and many companies may not fully appreciate their vulnerability to global shocks through their supply chain relationships and the costs this imposes. In [11], the author explains the importance of having future risk assessments of companies before they decide to relocate production or when reconsidering their location options.

There is a social commitment to the population and to the government authorities to keep the supply network in force so that the population is not affected by the lack of basic necessities. In a situation like COVID-19, a strategy must be adopted to adequately manage the shortage and make efforts to carry out emerging actions to ensure the supply of essential products. This work proposes scenarios in which organizations classified as essential, such as the retail industry, can adopt a model based on a continuity matrix in the face of the loss of capacity of the logistics network.

The value chain for food or perishable products offered in the retail industry becomes more relevant in a scenario such as the one currently presented in the COVID-19 contingency. In [12], the author described that the supply chain must be designed in such a way that production, transformation and distribution generate the expected value in the supply chain and therefore to the consumer.

3. A structured proposal for supply chain management based on a contingency plan against COVID-19

The proposal that is developed in this work incorporates the key elements to take care of for the operational continuity of the supply chain of companies in the retail industry. Adequate management through the proposed contingency matrix will not only allow operating with well-defined criteria for decision-making based on the changes that the supply chain is having in the different processes that comprise it, but will also help to maintain an organization communicated at all organizational levels about the intention of senior management in the face of the pandemic. The group of researchers who have worked on the development of the document have had the opportunity to carry out the implementation of the tool in the leading company in the market in convenience stores in Mexico.

Talking about COVID-19 today is talking about a diversity of topics that converge on a macro issue such as the global collapse due to the effects of the pandemic that we had to live in this 2020 and that will surely go beyond this year. It is common to see the large number of articles suggesting how to bring life in all aspects to a new normal.

3.1. Method of assessing the level of risk of the supply chain

Faced with the impacts of the pandemic, supply chains have collapsed to a greater or lesser extent throughout the world, the network of suppliers has been compromised and, in worst case scenarios, disarticulated. This level of exposure highlights the importance of having a mechanism for assessing the level of risk

in the supply chain. As part of the research carried out, a method of assessing the level of risk of the supply chain is being proposed. For this, it is important to start from a statement that the authors of this work make based on the experience and consultations made in the works of other researchers. As a starting point it is necessary to start with the definition of the key, operational and service processes.

3.2. Operational and service processes of the supply chain

The key processes that make up the operation of the supply chain become a distinctive seal that gives identity to the organization and marks the success or failure in achieving the value proposition to the end customer.

Focused on the case of the retail industry where companies participate in an environment with some volatility and where business strategies change from one day to the next or in extreme cases, from morning to night with various promotions simultaneously and with packages or commercial combos from different suppliers, the supply chain must be directly connected to the commercial strategy in order to make each of its processes focused on providing the service work. The companies that make up the retail industry are considered essential due to the impact on the supply of food to the community where they are located.

Following are the key processes in the supply chain of a distribution center serving a network of convenience stores:

1. Supply
2. Receipt of merchandise from suppliers
3. Storage of merchandise
4. Order management and replenishment planning
5. Assortment of orders
6. Preparation and consolidation of orders
7. Loading and boarding
8. Delivery of orders to the store

The key processes of a distribution center operation can be seen in Figure 1. In [13], the author described the supply chain processes in the SCOR Model with the objective of having a valid reference for the construction of a proposal that offers visibility and focus on having an efficiency analysis of the supply chain processes. In [14], the author explained the approach to supply chain efficiency and the integration of best practices. In [15], the author contributed to the SCOR Model the hierarchy of processes for decision making and supply chain management. Table 3 shows the relationship of the proposed processes with those classified in the SCOR Model. Table 3 shows the relationship of the proposed processes with those classified in the SCOR Model.

3.2.1. Supply

It is the process by which all merchandise supply activities are managed from the supplier to the distribution center or directly to the stores. The supply process aims to guarantee the supply of goods in a timely manner, in the quantity required for sale and with the quality that meets the parameters of each product for sale to consumer customers.

This process groups a series of activities considered strategic by a team that is constantly analyzing inventories, sales behavior, in close communication with the categories in which the product catalog is classified and finally with the marketing part. for proper planning of promotions.

Table 1: Comparative relationship of SCOR Model processes and operating processes of the retail industry.

SCOR Model processes		Retail industry supply chain operational processes
Plan Supply Chain	Plan Source	Supply - Receipt of merchandise
	Source Stocked Product	Storage of merchandise
	Plan Make	Order management
	Make to stock	Assortment of orders
		Preparation and consolidation of orders
	Plan Delivery	Loading and boarding
		Delivery of orders to the store

3.2.2. Receipt of merchandise

It is the reception of merchandise orders from suppliers, they obey an appointment planning agreed with suppliers and must be in accordance with procedures and policies on the requirements to be met in the proper handling of products that in some cases require certain parameters of refrigeration, humidity and security, such as the height of the platforms where the merchandise arrives.

3.2.3. Storage of merchandise

Within sequential flow of operations, it is the process in which the merchandise is located in a site within the area destined for storage. This process aims to create the appropriate conditions for the safekeeping and control of different goods. Each movement of merchandise from its storage location to another point, obeys a merchandise flow instruction to send said merchandise to an assortment location that can be refrigerated boxes, pieces or parts assortment.

3.2.4. Order management

It is an administrative process that is carried out with merchandise replacement tools at the store and is practically the equivalent of having a production program or planning of order fulfillment activities, ordered by priority based on the criticality of inventories. in shop. This process represents the intelligence center that drives the operations of the distribution center and through which resources are allocated to fulfill store orders.

3.2.5. Assortment of orders

It is the process in which operation personnel carry out order fulfillment activities. There are three different areas of order assortment which are:

1. Refrigerated product area: The assortment of orders is made in a plastic container and each piece is placed inside.

2. Product assortment per box area: The order assortment is for a higher unit of measure and is defined for products with high turnover or high displacement at the point of sale. To carry out this type of assortment, the Operator uses mobile equipment

to place all the merchandise that is supplied per box on a pallet.

3. Product assortment area by piece, blister or minor packaging: The assortment is carried out online by assortment by pieces and the Assortment Operator uses a plastic container to place all the pieces that appear in the order of order.

After an order is filled from any assortment area, there is an assurance reliability check thread, offering feedback to the assortment team on the quality of the task performed.

3.2.6. Preparation and consolidation of orders

Process by which the orders already filled, both boxes and dry parts and refrigerated parts are ordered by store. It is consolidated by store and in the order in which they will be loaded in the transport unit; as well as how the orders will be delivered by store according to routing, which requires room temperature and which requires refrigeration.

3.2.7. Loading and boarding

Process in which the orders are loaded in the transport units according to a routing sheet and delivery order, as well as the invoicing of each order. It is important to keep a sequential control of the load so that the Distribution Operator does not have setbacks in deliveries.

3.2.8. Delivery of orders to the store

It is the transportation process by which the merchandise is transported and delivered from the distribution center to the store. The Distribution Operator delivers to the customer under certain conditions that have to do with product handling conditions such as maintaining the cold chain for products that require it and the corresponding administrative and control documents that support the order. Annex 3 shows the capacities of each process, as well as the associated unit of measurement.

3.3. System of metrics or performance indicators of key processes

As the key processes of the distribution center have been defined, each process has an associated performance standard and metrics to evaluate it. Table 5 shows the metrics for each process under the efficiency approach. In the context of the supply chain, the integration of the objectives in its different levels is an important factor for the correct selection of the indicators, which will provide a broader view of the business. In [16], the author described the importance of having identified key performance indicators, through which a reference will be available at all times to assess the resilience of the processes when a disruption occurs.

Of course, there will be other indicators that have to do with the result of the business if what you want to see is the economic contribution; however, these are more common to see throughout the chain. They are also described in Annex 5.

In order to have a level of detail that allows a better management of goods, it is essential to have an administration by product categories. In [10], the author explained the importance of interconnecting merchandise categories for efficient management of supply chain processes. Figure 1 shows the supply chain from the supplier to the store, passing through the distribution center.

3.4. Key elements to successfully respond to the COVID-19 pandemic

During the research conducted, we had the opportunity to analyze different contributions from other researchers related to the key elements of the supply chain, which date back almost two decades. Without a framework for action that allows visibility of these key elements, it will be difficult to promote the improvement of supply chain performance. In [17], the author explained the importance for organizations of designing an operating model that facilitates the management of supply chain processes and identifying their restrictions, in addition to these elements. There are other researches that based on their studies make another proposal from a different perspective, where a classification is made according to the relevant aspects of supply chain resilience. In [18] the author presented a proposal to categorize resilience actions using four main categories: systems, process, control and recovery.
Figure 2: Key elements of the convenience store supply chain (source: self made)

The research proposal is contained in seven key elements, classified in turn into four supply chain management pillars comprising the proposed evaluation method, as shown in Figure 2. The key elements to consider in order to have A perspective and reference of the level of vulnerability of the supply chain to possible risks are grouped into four management pillars are described below:

- Operations: Refers to the group of activities that allow the continuity of the operation of the key processes. It includes the human resource, infrastructure and general facilities of the work unit.
- Supply: Includes the relationship and development of suppliers to guarantee the supply of goods from the supplier's facilities to the distribution center.
- Service: They are all the activities that allow the supply of goods from the distribution center to the store. The elements

that make up the service pillar are merchandise, distribution and stores.
- Communication: Refers to the strategy that the company intends to carry out to communicate its intention at all levels of the organization and even outside of it.

The key elements that, in turn, make up the supply chain management pillars and through which an evaluation of the level of response to the effects of a pandemic such as COVID-19 can be made are:

1. People

2. Facilities and infrastructure

3. Suppliers

4. Goods / Products

5. Stores / points of sale

6. Distribution / delivery to store

7. Communication

3.4.1. People

It comprises the most important resource at all levels of the supply chain, its well-being is a priority so that each of the supply chain processes can be carried out. Although it sounds like a very repeated cliche, "people are the most important thing" and they should know it and they should feel it, without a clear pronouncement from the organization of approach to people, it is difficult to advance in the other aspects.

Faced with a situation such as that of COVID-19, where the level of risk of contagion is present, there must be a consistency in the saying, in the being and in the doing from top management to the most basic positions in the structure. If there is no legitimate concern for the safety and health of people, there is no emotional bond that generates commitment.

3.4.2. Facilities and infrastructure

They are the assets of the organization necessary for the work units to be active. This element is closely related to human resources and must offer security and protection conditions so that personnel can carry out their activities without any distraction. It includes the industrial building or warehouse, the machinery and peripheral work equipment so that people can carry out their functions.

In the face of a pandemic like the one presented by COVID-19, maintaining the safety of the facilities becomes critical for the continuity of the operations of the companies that handle food and perishable products and that is why they are considered essential companies for society. Keeping the workplace pollution-free for employees represents a major challenge for companies and largely depends on the implementation of sanitation measures and / or protocols and strict compliance with government requirements for the preservation of hygiene standards.

3.4.3. Suppliers

It is the active network of suppliers that supply goods to the distribution centers or directly to the points of sale. It is important to have full knowledge of the conditions of each supplier in the

network, in [19], the author described the importance of having information from upstream suppliers several levels back. Companies that do not do so are less able to respond or estimate the potential impacts when a crisis erupts. Under the supply chain perspective, the objective is to maintain continuity in the supply of products in order to have them in a timely manner and in the quantity required in distribution centers and / or in stores or points of sale. A supply chain is as strong as is the capacity of alternative suppliers. Some researchers consider the supplier network as the benchmark to determine the level of resilience of the companies' supply chain, highlighting as a strategy the development of local suppliers to mitigate the risk of dependence on suppliers located outside their geographical area, of the country and even to the continent.

It should be borne in mind that in the face of a pandemic such as this one, companies must develop new supply alternatives, it is a fact that the companies that precede the chain will be affected in their operations.

3.4.4. Goods / products

Refers to the active catalog of items offered to the customer at the point of sale. When speaking of merchandise or articles, it is important to mention that the companies dedicated to the sale of basic necessities use for a better administration of these, a classification regularly called category. This classification consists of grouping the type of merchandise so that a group of people, regularly on a staff basis, can establish the marketing strategy that involves the relationship with suppliers, marketing, study of new developments and promotion plans. The categories together with the financial area determine the profit margin of each product to evaluate its performance, establishing for this purpose negotiations of costs and sale prices. In [20], the author explained the existence of algorithms or models that allow setting price points considering the market and the position as leader in the competition.

Faced with a situation such as COVID-19, organizations must be clear about the economic performance of each product, this will allow them to make better decisions about the profitability of the business and thus privilege the items that in their classification are considered essential for society but that are also profitable for the organization. In [21], the author explained the strategy of increasing inventories can be a measure to mitigate the risk posed by a disruption, however, it is reactive to an actual shortage; the strategy can include product substitution or back-up supply.

3.4.5. Stores / points of sale

These are the points of sale to the consumer customer or stores that the company has. They can be classified according to their location and format by the type of customer who regularly comes to buy. In [22], the author described that the complexity of the store as such lies in the number of stores in operation and the store formats it has with different sizes, catalog and price points.

The commercial and marketing team are the ones who carry out this classification of stores and thus be able to establish a catalog of products for each type of store. This classification of stores allows in addition to establishing a catalog of particular products, establishing the entire campaign of promotions, prices and launches, this differentiation is key to evaluating the performance of each store in its sales volume.

An example of differentiation in the classification of stores is the store that is located inside a high-density residential subdivision with the store that is located inside a hospital, it will be found that neither catalog of products for sale is the same and due to the location conditions, nor is the sale income.

3.4.6. Distribution or delivery to store

It is the transportation process by which the merchandise is delivered from the supplier or distribution center to the point of sale. The transport equipment used is conditioned for handling both merchandise that requires refrigeration and room temperature.

Under the store delivery conditions required in this contingency stage, the distribution personnel must have the necessary protective equipment to carry out the merchandise delivery tasks at the point of sale, as well as the sanitation measures for the units must be in accordance with certain regulatory measures for the handling of perishable product.

3.4.7. Communication

They are the means or mechanisms established by the organization to maintain timely and assertive communication at all levels of the organization, and even in the event of possible communication with the press and / or a statement to government authorities. Communication must at all times be reliable, truthful and above all timely about the organization's intentions in the face of the contingency it is facing.

There are different methodologies that help organizations to be prepared to face a contingency from the point of view of information management and what they want to communicate from a 360° perspective, as described above. We will mention that there is a methodology that helps coordinate and this is Incident Management and Crisis Resolution (IMCR), methodology developed in the United States.

3.5. Scenarios taken to a continuity actions matrix of COVID-19

Organizations are facing an unprecedented global crisis, human survival depends on essential elements during the pandemic and that can be met by properly utilizing key resources such as raw materials, employees and active logistics systems. In [23], the author described that the priority of nations during the pandemic is to save human lives, but shortages of essential commodities such as food, drugs, diagnostic equipment, clinical healing and personal protective equipment have made it difficult to fight the infection.

Having defined the priorities of nations and organizations to preserve the health of people as the most important priority, it remains for organizations to resolve the most important aspects to ensure the operational continuity of businesses, in [24], the author explained the importance of uncertainty management in the supply chain and how strategies can be established in inventory management. In [25], the author described that organizational leaders must urgently implement short-term strategies to be more resilient while making longer-term considerations that will reconfigure supply chains to protect against risks.

- Develop visibility of the entire value chain in primary, secondary and even tertiary players.

- Evaluate nearby options to shorten supply chains and increase proximity to customers.

- Take advantage of advanced manufacturing technologies to be more resistant. Another important point is to systematically evaluate the end-to-end value chain, to establish agile action plans.

Organizations are facing an unprecedented global crisis, and one approach that has not exactly been the most appropriate for supply chain management is to think about generating efficiencies and savings at the expense of eliminating slack or "margins of maneuver", such as operating with a diversity of suppliers for the same product, operating with safety inventories in the chain, etc., which in the face of a disruptive situation such as the COVID-19 pandemic leaves the organization exposed. In [26], the author explained that there has long been a focus on making the supply chain more efficient based on reducing costs, reducing inventories and increasing asset utilization, thus eliminating buffers and flexibility to absorb disruptions.

With the description of the key elements and their classification by management pillar, a continuity actions matrix can be integrated in a more practical way to evaluate possible scenarios and trigger actions focused on ensuring supply to stores.

In summary, after presenting the key elements for business continuity in companies classified as essential (and largely applicable to non-essentials as well), organizations will need to work on:

- Guarantee that people feel protected in a work environment that complies with the conditions and measures of control, sanitation and use of personal protective equipment that mitigates the risk of contagion, also keeping facilities and work tools under a protocol frequent cleaning. In [19], the author explained that employee welfare is paramount, and obviously people are a critical resource.

- Developing local suppliers for the supply of key merchandise, that implies redesigning the supply network to a great extent. If COVID-19 has revealed anything, it is the high level of risk represented by having a large number of suppliers in one place.

- Organizations should develop suppliers close to their main markets; this strategy will help mitigate the risk of centralized dependence, which can be maintained and alternatively explore other sources of supply. In [4], the author explained that another important factor to consider is that as transportation and other costs increase, global supply chains may be replaced by regional supply chains.

- Provide the service as far as the contingency allows and maintain the value proposition of the stores, without infringing the care of the workers and complying with the requirements established by the government agencies. As organizations considered essential, those products of first necessity for the population must be privileged and, on the other hand, they also represent a greater profitability for the organization, for this it is important that a detailed analysis of those products is made and that level is established with suppliers. priority in supply.

- Maintain communication at all levels of the organization about the decisions that the company is taking, from issues of personnel health and care of facilities}, to those that could be more critical as partial closure of operations and in in the worst case, the total closure of work units.

- For people, it is important to be informed about how the organization is facing the pandemic and what decisions are being made by senior management. To the extent that there is clear communication, the uncertainty will be combated and the staff will be focused on their care and the performance of their tasks.

- Assessing the level of risk in the supply chain is to have a preventive approach and it must be considered from the strategic planning process of organizations, that annual exercise that most organizations that describe themselves as preventive and that base their management under procedures and well-defined work systems, should consider in such planning an assessment of the risk level of their supply chain. Does this evaluation require an expense to be considered in the annual budget? The answer is yes, and excess spending due to not having an action plan to mitigate risks in the face of a disruptive event such as this pandemic may be much higher than the cost of a supply chain assessment.

- There will be many lessons learned from this disruption by COVID-19, even some organizations will not survive in order to capitalize on the learning it leaves. For the surviving companies it will be an opportunity to integrate the knowledge acquired and the recommendations that lead them to strengthen their processes and increase their resilience in the face of a disruptive event that submitted their performance and put their permanence at high risk.

The proposal made in this research is the COVID-19 business continuity matrix and is intended to provide a complete picture for organizations to evaluate the variables faced by organizations. In [27], the author described that robust strategies must be developed that integrate the purposes of reducing costs and improving customer satisfaction during and after a major disruption. In [28], the author described the importance of the design of the supply chain conceptual framework and the essential elements that have to do with resilience to disruptions that occur and supply chain resilience recovery policies. In [29], the author explained that the problem for top management of organizations is to choose a good strategy and quantify the benefits to develop a robust model for supply chain disruption analysis, for this it is important to identify and understand the overall behavior and intrinsic weaknesses of these systems and their components, especially in the face of negative events such as disruptions. In [30], the author presented that only a small minority of companies that invested in mapping and measuring the vulnerability of their supply chains are the best prepared to face this pandemic. Annex 5 shows the matrix of continuity actions to face the different impact scenarios of COVID-19.

3.6. Stabilization of the post-disruption operation

The stabilization stage of the operation is a continuation of the actions described in the continuity actions matrix as part of a plan where the regeneration or recovery of the resources of the supply

chain is taking place through the effect of the disruption has yielded. It is important to prepare a recovery plan and periodically review it by the management team so that the scenarios that require decision-making are updated. To the extent that there is an updated plan and communicated to the entire organization, the horizon will be visible when a total restoration of the organization and its supply chain will be presented and thus decisions can be made as to decide when to stop buying , when to stop transporting or when to stop producing, among other operations that have had to be implemented with an over cost justified by the disruption.

Another important aspect mentioned in the key elements is the communication that exists at all levels of the organization and which must be used to reach the collaborators with what they need to know, having a single source of information helps maintain the credibility of people when their health and that of their families is at stake.

Any action plan focused on treatment, solution or simply trying to coexist with a problematic situation, in this case a disruption of natural origin, must leave knowledge to organizations, considered essential or non-essential, if organizations do not learn from these lessons they will not have the opportunity to leave a legacy and an ABC of what was done as good practice to come out in front of a pandemic like that of COVID-19 and new managers, they will not be able to learn from those experiences to face the new challenges that they will surely have during their management when new disruptions arise.

Among the relevant contributions that integrate the research is a series of strategies that help stabilize operations and that focus on the objectives of identifying the level of risk in the supply chain, adequately managing resources and having an action plan to mitigate risks with suppliers and internal processes. In [31], the author explained that actions should be taken to improve internal capabilities, prepare inventory levels that meet projected sales and reserve logistical capacity.

4. Conclusions

The importance of having defined and structured processes for proper management of the supply chain offers a scenario that helps to better manage uncertainty and for this reason to mitigate disruptive environments that arise. Having performance metrics aligned to the strategy and capabilities of the processes help not to fall into the obsolescence of the supply chain. The processes and their metrics make it easier to be able to develop a proposal that allows evaluating the level of risk in the supply chain and consequently developing an emerging action plan for each scenario that presents a disruption of the magnitude of COVID-19.

Many organizations must be sensitive to the fact that the supply chain is a series of processes that have life and that must be evaluated periodically from the perspective of the level of risk to which they are exposed due to the dynamism of environmental variables. It will always be a successful and strategic alternative to diversify the sources of resources and related to this point, these types of decisions are what organizations must bear in mind when it comes to making decisions to pulverize the supply of goods from suppliers located in another region, in another country or even on another continent.

This research aims to offer a point of reference that allows evaluating the supply chain of organizations in the retail industry, from the perspective of the key elements raised throughout the work and that in the end is the main contribution that is made.

Finally, a supply chain oriented to service and to a value proposition committed to the customer allows creating a virtuous cycle to reinvent the increasingly resilient and anti-fragile supply chain. It is important to recognize that there are different investigations that focus on the management of disruptive stages in organizations, as well as these extremely valuable work carried out, there will be other future contributions that will come with new approaches and other variables to consider. Given this scenario, there is the commitment of those who collaborated in this scientific work to leave a documented learning for future generations of how to handle these disruptions, we will not be fulfilling a professional commitment, nor would our legacy be complete on how it was managed and left ahead of COVID-19.

Conflict of Interest

The authors declare no conflict of interest.

Annex 1. Main disruptive events in a controlled environment in the retail industry.

Disruption	Description
Technological effect / e-commerce	Definitely the disruptive element with the greatest impact in the last decade, those who dominate networks and online shopping have ample possibilities to position themselves in a highly competitive market. Today it is a must for organizations to be in the online market.
Proximity, time dedicated to home purchase and delivery	Another disruptive element associated with the first, the famous last mile represents for the consumer customer a key decision factor to carry out the purchase. Delivering merchandise at the consumer's door is a battle that is being waged every day today.
Specialty market and lifestyle	Not all stores have the same product catalog, for different reasons or circumstances, the store's commercial design may change to serve certain types of customers who come to or are in that market. A convenience store located in a popular sector should have a differentiation from a store located in a university.
Catalog of products and services	With the passage of time the convenience store has become a strong competitor for large supermarkets, let's say that the evolution of the "corner store" has become a convenience store that offers the consumer customer a wide catalog of products and services.
Perishable management	Bet on handling products that require refrigeration such as prepared food, meat and fruits and vegetables. Even a growing market that procures organic products claims a segment for this type of product.

Annex 2. Main disruptive events in an uncontrolled environment in the retail industry.

Disruption	Description
Natural disasters such as earthquakes, hurricanes, tsunamis, volcanic eruptions, fires, among others.	Natural events that happen suddenly in different locations in the world and that cause a collapse in the flow of goods and in the economic aspect. Although they may be areas that have identified the level of risk, this type of natural disaster cannot be forecast.
Pandemics / epidemics and other health issues involving a sanitary fence	Condition where the health of the population of a country or countries that have a commercial relationship is affected by the exchange of goods among themselves. The effect of a global pandemic has an impact on the flow of goods of all the countries that are interconnected for the transfer of goods and other types of resources.
Terrorist acts	Premeditated or intentional actions that aim to cause destabilization through inflicting damage to a specific place or society and that through chaos there is an expected size of affectation. In general, the disruptive event that it causes has to do with reinforcing security measures and trade blockades.
Socio-political and economic decline	Aggravation of the socio-political conditions of a country which causes a recession or deceleration in the economic development of the industry and in general for the population. This type of disruption can take time to appear at the maximum level of affectation and as it is a slow process, it also usually takes time to mitigate the level of maximum affectation.
Armed conflicts	Like the disruptions considered as deterioration of the social and political fabric and as a consequence an adverse economic impact, in many cases society ends up rising up in arms before an unacceptable government. This type of disruption often takes a long time to find a solution that manages to offer social and economic stability.

Annex 3. Operational and service processes of a retail industry supply chain.

Processes	Capacity	Unit of measurement	Description
Supply	Active code catalog	No. active codes	It is the catalog of active product codes.
	Active providers	No. of active providers	The number of active suppliers supplying merchandise.
	Supply service for criticality of merchandise and supplier	% service level	It is the level of supply service that can be measured according to the criticality by merchandise and by supplier.
Merchandise reception	Merchandise reception	Pallets	Pallets received from the supplier.
Storage merchandise	Case storage positions	Pallets	Number of positions for storing product pallets in cases.
	Case assortment positions	Pallets	Number of positions for product pallets that will be supplied by cases.
	Dry parts storage positions	Pallets	Number of positions for storing product pallets in boxes. Shares storage with group of cases.
	Dry pieces assortment positions	Assigned positions / lanes	Number of positions fed by cases and to be supplied by pieces.
	Refrigerated parts storage positions	Pallets	Number of positions for storing product pallets in refrigerated product cases.
	Refrigerated parts assortment positions	Assigned positions / lanes	Number of positions fed by boxes and to be supplied by refrigerated pieces.

Order management	Assortment of cases on shift	Cases	Capacity considered for planning and assigning tasks of assortment cases.
	Assortment of pieces dry pieces on shift	Pieces	Capacity considered for planning and assigning dry parts assortment tasks.
	Assortment of refrigerated parts on shift	Pieces	Capacity considered for planning and assigning chilled parts assortment tasks.
Assortment of orders	Assortment of cases on shift	Cases	Assortment capacity per shift of the assortment staff of boxes assortment.
	Assortment of dry pieces on shift	Pieces	Assortment capacity per shift of operating personnel for assorting dry parts.
	Assortment of refrigerated parts on shift	Pieces	Assortment capacity per shift of assorted operating personnel for refrigerated parts.
Preparation and consolidation of orders	Lowing of containers (pieces)	Containers	Number of drops for containers that were supplied by dry pieces.
	Preparation of pallets on duty	Pallets	Number of pallets prepared in the convergence of the assortment of dry pieces and cases.
Loading and boarding	Staying of prepared pallets	Pallets	Ability to safeguard assorted orders waiting to be loaded on the platform.
	Pallet load per hour	Pallets	Loading capacity to transport units associated with mobile equipment movements.
Delivery of orders to store	Transport fleet	No. of units	Transport units that make up the vehicle fleet.
	Gates	No. of loading gates	Number of platforms enabled for loading and unloading operations.

Annex 4. Key performance indicators of supply chain processes.

Processes	Indicator	Unit of measurement	Description
Supply	Inventory level in distribution center	Days	This indicator represents the level of merchandise inventory expressed in days in the distribution center and is a function of the volume of daily movement or transfer to stores. From the perspective of the Abasto process, it measures the effectiveness of planning the supply of suppliers to the center of distribution. Calculation: The inventory of the merchandise is divided by the value of its daily trip to stores.
	Lost sale	%	It is the percentage of merchandise that is not in inventory or not available for sale in the store and that has a daily sales behavior based on statistics. Calculation: The shortage of each merchandise is divided by the projected daily sale behavior of each merchandise.
	Inventory level in store	Days	This indicator represents the level of merchandise inventory expressed in days in the store and is based on the store's sales volume. From the perspective of the Abasto process, it measures the effectiveness of planning the supply from the distribution center to the store. Calculation: The inventory of the merchandise in the store is divided by the daily sale value of the store.
Merchandise reception	Compliance with supplier receipt program	%	Level of compliance with the appointment schedule established with providers. Calculation: The number of arrivals within the window is divided by the number of scheduled appointments.
	Fill rate providers	%	Level of compliance that is carried with suppliers on the requested merchandise. Calculation: The quantity of merchandise received is divided by the quantity of merchandise scheduled to be received.
Storage of merchandise	Inventory days in the distribution center	Days	This indicator represents the days inventory of merchandise in the distribution center, is based on the volume of daily trips to stores. Calculation: The inventory of the merchandise is divided by the value of its daily trip to stores.
	Product wastage	%	This indicator shows the decrease generated in the warehouse due to internal handling and product obsolescence. Calculation: The value of the lost merchandise is divided by the value of the total inventory of the distribution center.
	Inventory rotation	Cycles or number	This indicator measures the efficiency with which you have the ability to rotate inventory in the cedis. Calculation: It is the number of cycles or times that stocks were turned over during a period of time that can be monthly.
Order management	Product missing	%	This indicator shows products scheduled to be shipped to the store and not in the inventory available from the distribution center. Calculation: The total number of missing merchandise is divided by the number of merchandise scheduled to be shipped to the store.
	Cycle time	Hours	This indicator shows the cycle time of an order, it is also known as lead time. Calculation: It is the time elapsed since the store order is generated until the distribution center delivers it to the store.

Assortment of orders	Assortment productivity	Units / hr	Efficiency indicator that shows the use of resources for the productive tasks of operating personnel in each work area. Calculation: The volume supplied (pieces or boxes) is divided by operator per hour of work. There are three work areas and there may be different productivity units.
	Assortment error rate	%	Quality indicator that shows the reliability of the assortment of the productive groups. Calculation: Divide the number of errors in the operating staff assortment by the total assortment volume per operator.
Preparation and consolidation of orders	Productivity in preparation	Units / pallet	Indicator that shows the performance in the preparation and consolidation of the order prior to loading it on the platform. It is intended that the integration of orders, both for parts (plastic basket) and boxes, is of maximum density per palle. Calculation: Number of packages placed per pallet prepared.
Loading and boarding	Productivity under load	Units / truck	This efficiency indicator aims to measure the load capacity of packages in the transport unit. The aim is to make the most of the volume of the transport unit. Calculation: Number of packages loaded per transport unit.
	Unit charging time	Hours	This indicator measures the time the transport unit remains on the loading platform. The objective is for the unit to be released as soon as possible so that it begins its journey. Calculation: It is the elapsed time from when the transport unit is assigned to the platform until it is released to start the journey.
Delivery of orders to store	Compliance to delivery windows	%	This service indicator reflects arrivals within the expected time period or store delivery window. Calculation: The number of orders arriving within the assigned time window is divided by the total number of scheduled orders.
	Fill rate	%	Level of fulfillment of the delivered merchandise vs. the merchandise requested in the store order. Calculation: The quantity of merchandise delivered to the store is divided by the quantity of merchandise scheduled to be delivered.
	Cycle time deliveries	Hours	This indicator seeks to measure the time it takes for the transport unit on its order delivery route until it returns to the distribution center to start another cycle. Calculation: It is the elapsed time from when the unit is released to start an order delivery trip to stores until it returns to the distribution center.

Annex 5. Economics indicators of supply chain processes.

Processes	Indicator	Unit of measurement	Description
Group of processes inside the distribution center	Warehouse expense	$ / package	Represents the expense incurred in the warehouse operations considering the direct labor related to the operation.
	Wastage expense	$ / package	It is the expense attributable to the loss of product and inventory differences in the warehouse.
Entrega de pedidos a tienda	Distribution expense	$ / package	It is the expense of the distribution and delivery of merchandise to the store.
All processes in the supply chain	Total logistics expenditure	$ / package	It is the integral expense of all the key processes that make up the supply chain of the distribution center.

Annex 6. Continuity actions matrix of COVID-19.

Health phase	Risk level	Capacity level	Operatives		Supply		Service			Communication and diffusion
			People	**Facilities and infraestructure**	**Providers**	**Merchandise**	**Stores**	**Distribution / delivery to store**		**Communication**
Does no apply	0	Normal operation 100%	● 100% operational team ● Recruitment of personnel as a protection measure against possible damages due to loss of labor	● Review and evaluation of risks of manipulation of equipment and infrastructure ● Survey of vulnerable areas to contagion	● Identification of suppliers with risk of shortage ● Communication and risk mapping with strategic suppliers ● Explore alternative vendor alternatives	● Normal marketing plan ● Normal releases and promotions ● Local and regional promotions in the normal way	● 100% supply of stores ● Monitoring of stores closed due to contingencies	● Strengthening of the transport fleet (own and contracted) ● Routing planning with sequential time windows		● Activation of the Incident Management and Crisis Resolution Committee (MIRC)
1	1	Operation with emergenging actions 90% - 100%	● Assignment of personnel to the operational workforce by 10% ● Identification of areas that require working overtime ● Isolation for personnel classified as vulnerable group ● Activation of health filters to identify symptoms in the staff	● Installation of health and safety measures such as health filters ● Restriction of access to confined areas or without adequate ventilation ● Cancellation of meeting places that do not comply with the distance measures	● Establish a supply plan for items considered to be in high demand due to contingencies ● Establish prioritization strategy with merchandise categories (privilege suppliers of basic products) ● Activation of alternative providers and privilege regional alternatives	● Normal marketing plan ● Normal releases and promotions ● Local and regional promotions in the normal way ● Identification of the articles considered essential to prioritize their supply from suppliers	● 100% supply of stores ● Monitoring of stores closed due to contingencies ● Monitoring of rejection of deliveries to store by contingency			

2	2	Operational performance 70% - 90%	● Exploration and activation of operating schedules, working days and shift duration
			● Activation of shifts on non-working days
			● Keep staff from vulnerable groups in isolation
			● Maintain health filters to identify symptoms in staff
				● Installation of health and safety measures such as health filters
				● Restriction of access to confined areas or without adequate ventilation
				● Cancellation of meeting places that do not comply with the distance measures
				● Installation of physical barriers in work areas to avoid the risk of contagion
					● Generation of advance purchases for items classified as essential
					● Prioritization of supplier receipts
					● Consider the exchange of merchandise between distribution centers and stores (optimally distribute shortages)
					● Activation of alternative providers and privilege of regional alternatives
						● Adjusted marketing plan and according to merchandise availability
						● Prioritize the marketing of essential contingency items, such as food and perishables, cleaning and hygiene
						● Management with capacity planning, inventory replacement adjust purchases according to demand and capacity level of the distribution center
							● Monitoring of stores closed due to contingencies
							● 100% supply of stores
							● Monitoring of rejection of deliveries due to contingencies
							● Decrease in the frequency of delivery of orders to stores
							● Financial analysis that favors sending orders to the best-selling stores
								● Extension of distribution days
								● Modify daily delivery plan to a less frequent one
										● Establishment of the crisis action plan
										● Establishment of communication roles in the management team
										  - Towards the staff
										  - Towards the client
										  - Towards the General Directorate
										  - Towards authorities and government
										  - With the press and social media
										● Carry out a follow-up session to the operation and review each element of the contingency matrix

	3	Operational performance 50% - 70%	● Balancing of operating loads according to staff availability, activation of extra shifts according to availability ● Keep staff from vulnerable groups in isolation ● Staff working remotely (for those who apply the scheme) ● Strengthening of established health filters, identification of symptoms in personnel	● Installation of health and safety measures such as health filters, sanitizing mats, sanitization application with authorized cleaning fluids ● Restriction of access to confined areas or without adequate ventilation ● Cancellation of meeting places that do not comply with the distance measures ● Installation of physical barriers in work areas to avoid the risk of contagion	● Generation of advance purchases for items classified as essential ● Prioritization of the receipt of strategic merchandise suppliers ● Consider the exchange of merchandise between distribution centers and stores (optimally distribute shortages) ● Activation of alternative providers and privilege regional alternatives ● Daily communication on the operational continuity of suppliers based on the priority classification of their products ● Evaluate the collection of merchandise at the supplier's facilities	● Prioritize the marketing of essential contingency items, such as food and perishables, cleaning and hygiene ● Management with capacity planning, inventory replacement adjust purchases according to demand and capacity level of the distribution center ● Carry out financial analysis to privilege the articles that provide the greatest economic benefit to the organization. ● Exchange of merchandise between operating units and stores	● Validation of stores that remain open and capable of receiving merchandise ● Supply to stores classified as private based on sale ● Decrease in the frequency of delivery of orders to the store	● Extension of delivery days to store ● Balancing operators in deliveries 24 hours ● Decrease the frequency of delivery of orders to the store ● Perform dynamic routing with priority stores and ● Eliminate restriction of order delivery windows		
3	4	Operational performance 30% - 50%	● Balancing of operating loads according to staff availability, activation of extra shifts according to availability ● Keep staff from vulnerable groups in isolation ● Staff working remotely (for those who apply the scheme) ● Strengthening of established health filters, identification of symptoms in personnel				● Validation of stores that remain open and capable of receiving merchandise ● Monitoring of rejection of deliveries due to contingencies ● Supply of stores that remain open and classified as high sales ● Delivery of orders according to availability and receipt capacity			

Customer Behavior of Green Advertising: Confirmatory Factor Analysis

A R T I C L E I N F O	A B S T R A C T
	The implementation of green advertising is relatively low for credibility but has an impact on green customer behavior. Based on the phenomenon, the purpose of this study is to examine factors affecting green advertising development, which is based on experienced customers towards products and advertisements and environmental issues. This research focuses on customers to create an implementation model for green advertising among companies. The study was conducted through a survey of 215 customers in West Java (Indonesia) who experienced green advertising and bought environmental-friendly products. Data were collected through a quantitative questionnaire and processed with SmartPLS to test and evaluate Confirmatory Factor Analysis (CFA). In emphasizing the study results, a fit test of the research model and research hypotheses were also being carried out by valuing the KMO. Research findings show several dimensions involved in developing green advertising, such as experience, theme, message, claim, emotion, interaction, and impact. The dimensions of green advertising were plotted in the CFA model so that the priority scale from the implementation of green advertising measurement can be detected. Customers assume green advertising as advertising that takes environmental issues of "global warming," and this issue can adopt by companies in implementing the green marketing strategy.

1. Introduction

Customer behavior has led to environmental sustainability; it is assessed from the increasing level of customer awareness of companies' environmental-friendly products [1]. This phenomenon provides opportunities for companies to adopt environmental-based advertising [2]. Advertisement can influence a customer to choose environmental-friendly products. Environmental-based advertising activities which also known as green advertising, is a marketing strategy that tackle the issue of environmental sustainability and health impacts among users [3]. The implementations of green advertising become important because customers have started to care about the environment with various movements, such as "green consumerism" [4], whereby the activities put forward to customer behavior in consuming and recommending environmental-friendly products [5]. Green customer behavior becomes an essential part of the company's attention in implementing marketing strategy today [6]. The issue of "green product" has become a world issue; people's behavior is changing in every country to be more

concerned about the environment as an effort to face the issue of "global warming" [5]. The efforts made by creating environmental-friendly products and decreased the production of goods and services that use chemical materials [7]. The development of environmental issues occurs in several sustainability concepts, including the concept of green living, which is an effort to live a healthier life with the attention and the use of environmental-friendly products [8]–[10].

Green advertising is part of the green marketing strategy that companies used to create awareness of green products [11]. However, the credibility of green advertising is considered low by customer. This is because customer behavior towards advertising is influence by extensive propaganda of mass media [12]. Therefore, the study of customer behavior in assessing advertising is necessary because previous research has demonstrated that the attitudes towards advertising has provided opportunities for brand attitudes changes [7]. In Indonesia, the green advertising concept was started in 2004 and has been implemented by the government to educate the environmental issue, while companies used it for corporate image [13]. The consumer's perceived value of green

advertising focuses on 3R issue (reduce, reuse, recycle), no plastic day, and earth hour. The impacts of green advertising on green lifestyle and green products is still low, even though this issue is essential for companies to achieve green advertising implementation [14]. The essence of green advertising is a campaign on environmentally friendly products which support sustainability [15]. The concept of sustainability is undoubtedly considered necessary by various parties, such as the government, companies, and society [16]. The education of advertising seems to involve environmental issues in green advertising [17]. Green advertising appears to change customer behavior who cares about the environment. Indonesian government starts to implement the sustainability concept, which was started in 2012 through a regional regulation on Green Building in Jakarta [18]. As the government concern about the environment, it has become a part of green advertising which has been carried out by the government, to serve public service advertisements about the global warming issue [19]. The regulations issued by the government certainly have an impact on marketing strategy whereby companies tackle environmental issues through the concept of green advertising [20]. The characteristics of green advertising are difference with the advertising concept in general; because companies has a goal towards the image and reputation on social responsibility [21]. Hence, companies prioritize green advertising concept, not only for educating environmental-friendly products but also strengthening the company's image and reputation.

Realizing the importance on reviewing the implementation issue of green advertising in Indonesia and its impact on customer behavior, this study focuses on factor analysis that forms green advertising performance from a customer's perspective. This study intends to put forward the green advertising concept, so that it can be references by companies to campaign environmental issues, through symbols or images that are valuable to society towards sustainability concept.

2. Literature Review

2.1. Green Customer Behavior

Green customer behavior refers to customer behavior in using healthy, environmentally friendly products, and it can protect environmental sustainability [22]. Green customer behavior has a level of concern; the higher is the extraordinary impact on loyal behavior for all the environmental issues [23] and trying to recommend to others [24]. The customer's awareness of the environment prioritizes green products and campaigns for healthy lifestyles [25]. However, green customer behavior is not easy to develop [26]; it is influence by the internal situation of customers such as knowledge and self-awareness [27], and external situation of customers such as the environment [28]. Environmental factor has an important role [29] because it has greater level of interaction with customers.

2.2. Green Customer Behavior

Technological developments and environmental issues provide a new perspective for companies in marketing strategies through advertising media, by adopting green advertising, both offline and online [30]. Due to stiff competition, companies have started to find more creative advertising alternatives through unexpected places, unconventional methods, or unusual

communication delivery [31]. It seems clear that the company's efforts are to provide awareness through advertising media, which is easy to remember and provides value for customers and the company [32]. Green advertising is believed to be a strategy that also provides opportunities to increase company's value both from the viewpoint of the product and its image [33]. It considers that green advertising has a concept that is not much different from advertising in general. However, environmental issues provide other opportunities that can be interpreted by a customer today [7]. Media in green advertising is delivered online, like social media or the internet, and offline like newspapers or billboards [34]. The previous concept states that "green advertising are advertisements that promote products, services, ideas or organizations' ability to help or reduce environmental harm" [5]. There are two elements discussed in green advertising, namely education on products or services and a positive impact on the environment [1]. The implementation of green advertising for companies is considered successful if it can provide a company's environmental image. At the same time, customers are assessed through understanding and practicing green living [7].

Green advertising is genuinely delivered by companies or the government to increase customer awareness of the environment [20]. It is undoubtedly in line with government and companies' views, which is trying to deal with the issue of "global warming" and environmental sustainability [35]. Customer care is captured in a consistent attitude that considers good or bad towards a product in the environment to recommend it to others. It seems clear that green advertising is considered effective if it can influence customers' perceptions and customer behavior in the environment [17]. In the previous studies, it has been known that the impact of green advertising on customer behavior such as concern [5], perception [17], attitude [12] to company's image [36]. However, the essential green advertising concept is the consequence of growing customer awareness of the environment [20]. There are many green marketing strategy research indicated the impact of environmental knowledge and the awareness on customer behavior towards the environment [37]. Several media become customer's references in examining the concept of green advertising, such as television, website, media social, radio, newspaper or magazine, billboards, banner dan brochure [5]. However, each media certainly provides a different level of preference; it depends on the level of persuasion given. In the end, the concept of green advertising needs to meet three main criteria, namely explicit or implicit about the correlation between products and environment [12], promoting a green lifestyle with or without products [38], and it explains company image that cares to environment [20].

2.3. Measurements of Green Advertising

Green advertising's implementation contains two prominent elements; informational claims and effective claims [3]. Informational claims are related to the use of environmentally friendly products advertised, while effective claims are the experiences relate to the environment. Indeed, informational and effective claims provide a positive view of customers in assessing green products [12]. There are many criterias in assessing and evaluating green advertising; several previous studies have explained that there is no definite measure that can represent green advertising [3]. All criteria depend on the objectives of green

advertising and customer's goals that determine the success or the failure of advertising done [2], [5], [11]. Some experts' opinions explained the measurement of green advertising. Firstly, it starts with green impact, which is the importance of advertising media that takes to environmental issues into a biophysical environment, green lifestyle, and an image of environmental responsibility [21]. Secondly is a green message, where advertising is assumed necessary to give a clear message related to ecological, environmental sustainability, or nature-friendly messages [39]. The third is a green theme, where advertising needs to provide an attractive theme to be enjoyed by customers on green products that are pleasant, convincing, believable, favorable, and goods [12].

Fourthly is green emotions, where advertising can conveye the emotional values for customers in terms of environment-protection emotion [2], [40]. Customer emotion in advertising is related to moral emotion, social emotion, and ecological fear related to climate change [2]. The fifth is related to customer's experience; it is undoubtedly essential; it is related to the green experience. Advertising is assumed as necessary to provide an experience that is assessed from the perspective of knowledge, perceived comfort, and information obtained by customers [41]. Next is assessed from green interaction related to the level of interaction that customers will feel on advertising, such as appeal, issue proximity, and environmental consciousness [42]. Finally, the measurement based on the previous studies is assessed to green claims. This measure puts forward the recognition of environmental friendly products that can meet customers' expectations in terms of degradable, recycled, recyclable, ozone friendly [43].

3. Research Methodology

The research method was conducted by surveying customers who purchased environmentally friendly products through a set of questionnaires. Customer were chosen from products categories that is convenient to customers, such as food and beverages. Data were carried out through online questionnaire among customer in West Java Province. The answers had been determined through Likert Scale approach, from "1" for strongly disagree and "7" for strongly agree. The questionnaire was distributed within three months, from August to October 2020, with a target of 300 respondents. This research was also included in experimental research where the respondents were given a treatment, which was the knowledge related to green advertising at the beginning of the questionnaire to find out their views regarding green advertising in Indonesia.

The data from respondents were processed through the Confirmatory Factor Analysis (CFA) technique; it intended to find-out the factors that determine the creation (or development?) of green advertising proposed by the research model. Meanwhile, the analysis tools used were SmartPLS, considering the ease of analyzing CFA on data below 300. Based on the previous theory study, several elements would be studied in determining green advertising, such as green impact, green message, green theme, green emotion, green experience, green interaction, and green claim. Each dimension was measured by an indicator as shown in Figure 1. Data analysis stages were started from data tabulation, research model fit test, and rearch hypothesis test. Considering

that this research used the CFA approach, only a fit model test through Outer Model would be conducted. It was tested for convergent validity, composite reability, average variance extracted, and discriminant validity [44], [45]. Meanwhile, the research hypothesis test was conducted by evaluating the value of Kaiser-Mayer-Olkin Measure of Sampling Adequacy (KMO MSA), where it must be more than 0.5, and the value of Bartlett's Test of Sphericity (Sig.) was smaller than 0,05 [46]. The final objective of the analysis was to find the determinant factors to develop green advertising that provide customers' value of customers'concern for environmentally friendly products.

From previous research studies, it appeared that several measurements can be assessed from green advertising. However, all of them have one goal: to increase customer awareness of green advertising implementation. In this study, the measurements that have been tested,were green impact, green message, green theme, green emotion, green experience, green interaction, and green claim [2], [21], [39], [41], [43], [47]. The essence of some of these measurements provide the same opportunity as a determining factor in assessing green advertising; before the Confirmatory Factor Analysis (CFA) is carried out, the assumptions are conveyed in the form of research hypothesis based on the CFA model as follows.

Hypothesis 1 (H1) Green impact is a dimension that can developed green advertising.

Hypothesis 2 (H2) Green message is a dimension that can developed green advertising.

Hypothesis 3 (H3) Green theme is a dimension that can developed green advertising.

Hypothesis 4 (H4) Green emotion is a dimension that can developed green advertising.

Hypothesis 5 (H5) Green experience is a dimension that can developed green advertising.

Hypothesis 6 (H6) Green interaction is a dimension that can developed green advertising.

Hypothesis 7 (H7) Green claim is a dimension that can developed green advertising.

4. Result and Discussions

Confirmatory Factor Analysis (CFA) research relates to green advertising; it starts by distributing an online questionnaire for three months (August, September, October).

Data from the questionnaire spread to 215 respondents who filled in the data correctly, then data was tabulated, and the research model was tested through SmartPLS. Data analysis begins with the research instrument test, research hypothesis test, and analysis of Confirmatory Factor Analysis test result.

4.1. Validity and Reliability Test

Before conducting data analysis through CFA, validity, and reliability tests were examined. Considering that analysis is carried out through CFA, the tests are conducted only using the outer model test for convergent validity, composite reliability, average variance extracted, discriminant validity, and outer weight. If all the outer model test results are adequate, it is stated to be fit, and a CFA study can be carried out.
Figure 1: CFA Model

Convergent validity test is assessed by evaluating the correlation of outer loading results, which is more than 0.50 for the correlation. Furthermore, the discriminant validity test shows whether the measured variable has acceptable reliability. Discriminant validity has known through the evaluation of the composite reliability value, which must be above 0.8. The next test is the Average Variance Extracted (AVE) value, which is stated to be fair, and it fulfills the criteria when the value is more significant than 0.5. The next evaluation studied Cronbach's Alpha's value, which is one of the recommended discriminant validity measures to have a value above 0.7. The final test is carried out the outer weight, which is stated to fulfill the requirements if the outer weight value is above 0.20. The results of the first outer model test are summarized in Table 1, which

indicated that from all the previous tests, composite reliability, AVE, and discriminant validity are fulfill the requirements.

The second outer model test results which related to outer weight are summarized in Table 2, which evaluation of sample original value is above 0,20. It is stated to be fit, or it means that it fulfills the requirements. Finally, the results of the outer model test reviewed from convergent validity, where the results are summarized in Table 3 with all of the outer loading value are accepted because the correlation value is above 0.50. Based on all of the test results of the outer model, it can be stated that the research instrument can be accepted, and it can be analyzed further for CFA.

Tabel 1: Construct Validity and Reliability

	Cronbach's Alpha	rho_A	Composite Reliability	Average Variance Extracted (AVE)

4.2. Factor Analysis of Green Advertising

This research focuses on green advertising, which is assessed from several criteria, including green impact, green message, green theme, green emotion, green experience, green interaction, and green claim. Based on the result in Table 3, it showed that all outer-loading values are accepted; with the value above 0.70. Outer loading values explained the level of closeness between the indicator and its dimensions because the determining indicator is better when it close to 1. The result indicated that several factors supported the creation of dimensions on green advertising. The first dimension is green impact with a sequence of determinants, which starts from green lifestyle, environmental responsibility to the biophysical environment. The green impact is a dimension for green advertising and can motivate customers who accept advertising [48]. The first measurement, which becomes a customer's attention, is green lifestyle, where customers assume that green advertising is expected to provide a new lifestyle for healthier customers. The next dimension is green message;

several supporting indicators with a sequence are convincing, believable, pleasant, favorable, and goods. Green messages can be a dimension that forms green advertising; it considers that advertising is full of messages; customers will receive advertisements recipients [39]. Customers prioritize convincing message or giving confidence because the advertisement is trustworthy and not an imaginary advertisement. Another dimension that becomes the determining factor of green advertising is green theme with indicators formed from environmental, ecological sustainability, and nature friendly. A green theme is related to a theme in online or offline advertising, considering that a theme will stimulate customers to understand the meaning of advertising [12]. In this case, a green theme that becomes the primary concern of customers is environmental sustainability issue. This is because the themes have more impact on customers' understanding in conveying the advertisement.

The next dimension is green emotion, which is formed from several indicators, such as climate change, social, and moral.

Green emotion is considered as dimension that represent green advertising related to customers' emotional level when look at the advertisement. These emotions are positively natural-friendly, and aim to believe more in advertising behind green advertising [2]. Based on loading factor value survey, it has been revealed that the size of climate change is the most important indicator that can change customers' emotional value because green advertising relates indirectly to the issue of climate change. Green advertising lead to the assumption of customers involvement; which is stated in the green experience dimension [7]. Green experience is assessed from information, knowledge, and comfortable. Customers certainly hope that in assessing green advertising, they can improve their experience, and this experience is considered essential when it comes to the information they need. The next dimension that becomes the determining factor for green advertising is green interaction; it is formed by several indicators, such as appeal, environmental consciousness, and proximity issues. Green interaction is related to customers' interactions with the advertisements [42]; the outer loading appeal stated that it is the most influencing indicators. It means that green advertising will be able to invite interaction from customers if the advertisement is attractive. It is the reason why people said that to create content of green advertising is quite challenging because it requires special attention that relates to the environment. The last dimension is related to green claims, which consist of recycled, ozone friendly, recyclable, and degradable. It means that green claims relate to customers' recognition for the advertisements [43]. This recognition is considered as the most important recognition, because it need to ensure environmental-friendly product to be easy recycled.

A hypothesis test surely to tests the analysis results of determinants factors of green advertising; it was intended to emphasize that all the dimensions have been determined, and it can be a measurement for green advertising. The hypothesis test results are conducted by evaluating the value of KMO presented in Table 4. All "accepted" dimensions can be dimensions for green advertising. It considers that the value of KMO is above 0.5, and the value of Bartlett's Test of Sphericity (Sig.) is smaller than 0,05. Therefore, the result stated that the indicator factors which consist of green impact, green message, green theme, green emotion, green experience, green interaction, and green claim can develop green advertising.

4.3. Model of CFA Green Advertising

In the research finding of the analysis factor, there are seven dimensions of green advertising; green impact, green message, green theme, green emotion, green experience, green interaction, and green claim. However, these dimensions certainly have a different standard value informing to green advertising assessed by customers. Therefore, to determine the highest and lowest standard in green advertising, value extractions based on commonalities process [49] has been conducted, as illustrated in Figure 2.

Based on Figure 2, it is clear that the highest extraction value is green experience, and the lowest extraction value is green impact. The extraction value determines the impact's size of dimensions in determining green advertising. The findings show a composition of dimensions that can develop green advertising,

which is started from experience, theme, message, claim, emotion, and interaction to impact. The dimensions need to be conducted priority scale by companies if companies decided to adjust green marketing to green advertising. These research findings explain the importance of adjusting green advertising implementation as part of marketing strategy.
Figure 2: Model of Green Advertising

This study focuses on the behavior of customer who have purchased environmentally friendly products in Indonesia (West Java), which means that companies can utilise the model of green advertising (Figure 2) in promoting pure environmentally friendly products. All green advertising dimensions have meaningful content, so it would be better to develop green advertising. However, if the dimensions are to be reduced, it is advisable to start from the dimensions that have the lowest impact in developing green advertising. It means that the green advertising model's use of dimensions is adjusted to dimensional load in forming green advertising. The goal of green advertising can be achieved, namely product education that is friendly to the environment. The finding of this research can provide input for the government in advertising policies, for company in implementing green marketing and for society as customer who needs to get information related to a sustainable environment.

4.4. Customer Perceived of Green Advertising

Green advertising can give impacts on customer behavior by providing the assumptions and responses to environmental sustainability [1], [5]. In this case, customers of products and services offered by the company certainly need to understand the advantages and disadvantages of products they will choose, particularly for products that have a positive impact on the environment. Therefore, it is essential for company to implement green advertising. However, the implementation of green advertising needs to consider several dimensions which can develop the right customer's perception. In this study, a series of dimensions has been stated, namely: experience, theme, message, claim, emotion, and interaction. These findings are based on customers' assessment in evaluating green advertising received by them until now, and it refers to the evaluation on

environmentally friendly products. Based on green advertising results, it can be argued that a customer's experience of green products is controls by the customer perceived value of green advertising; the theme of the conveyed advertisement; the message of the conveyed advertisement; the advertisement claim which can change customer's confidence; customer emotion is positive after seeing the advertisements; customer interaction is optimistic after seeing the advertisements; and the impact of advertising which motivates to customers to live a healthy life.

The research findings depicted in Figure 2 can be implemented by companies to educate customer on environmentally friendly products and the government in educating the importance of environmental sustainability to society. However, the model of green advertising is not suitable when used in educating conventional products or is not purely environmentally friendly because the dimensions used in this study focused on green products and the selected consumers have an environmentally friendly concern. So it is necessary to consider green advertising that companies use is not only for environmental issues, but also for the products created. This research findings explained the importance of understanding customer behavior in supporting the implementation of marketing strategies; mainly, it takes environmental issues as green advertising. There is essential information for stakeholders such as the government, companies, and society in promoting green advertising.

5. Conclusions

This study aims to analyze the determining factors in deciding green advertising, in which there are several measurements have been presented by the previous studies. This study provides the appropriate measurement for green advertising which can be utilized to educate customers. Seven dimensions were tested in determining green advertising, namely: experience, theme, message, claim, emotion, interaction to impact. The implementation of green advertising has impacted customers' points of view; and it considered several customers' attention. Customers' attention means experience, which consist of information, knowledge, and comfort issues. A model of green advertising through Confirmatory Factor Analysis was developed in this research. Through this model, it can provide some input to the government in evaluating the policies to deal with "global warming" issues, as well as to companies in implementing green marketing.

This research, however, has certain limitations. It applied CFA based on each dimension and does not study the impact of green advertising implementation on customer behavior, for instance customer care. Therefore, future research should emphasizes on the utilization of exploratory factor analysis (EFA) and the impact of the study on customer behavior. In addition, this research does not examine the technology used in green advertising, so it is recommended that further research to examine the technical support in green advertising, taking into consideration that that the advertising model is utilizing electronic and digital media, which are related to the latest technology.

Addiction such as tobacco smoking affects the human brain and thus causes significant changes in the brainwaves. The changes in brain wave due to smoking can be identified by focusing on changes in electroencephalogram pattern, extracting different time-frequency domain features. In this aspect, a laboratory-based study has been presented in this paper, for assessing the brain signal changes due to the tobacco addiction. Four classifier models, namely, Logistic Regression (LR), K- Nearest Neighbor (KNN), Support Vector Machine (SVM) and Random Forest Classifier (RFC) were trained and tested for assessing the performance of the time domain, frequency domain and fusion of time-frequency domain features, with a five-fold cross-validation. Four different performance measures (sensitivity, specificity, accuracy, and area under the receiver operating characteristic curve) were used to measure the overall performance, and the results suggested that the classifiers based on time-frequency domain features perform the best while using combinedly. Using the utilized fusion of the time-frequency domain features, the classification models can identify the smoker group with an accuracy ranged from (86.5-91.3%), where the RFC shows the best accuracy of 91.3%, which is higher than the three other classifiers models.

1. Introduction

This paper is an extension of work originally presented in International Conference on Computer, Communication, Chemical, Materials and Electronic Engineering (IC4ME2) [1]. The presented paper [1] utilized electroencephalogram (EEG) for the diagnosis of tobacco smoking based on only one machine learning model (artificial neural network), where the current article is expanded further to validate the EEG based diagnosis using multiple machine learning models. Also, this paper examines the utility of the time domain and frequency domain, individually and their combination on the EEG based tobacco addiction diagnosis.

In this modern era of life science, research in the field of neuroscience and cognitive engineering is flourishing with technological evolution. Electroencephalogram (EEG) is being used in this sector to understand sophisticated conditions of the brain as this is sensitive and susceptible to any action, especially for drug addiction, for example, alcohol, morphine, heroin or Cannabis addictions. Different stages of drug addiction can be determined only through EEG analysis, and this is very much necessary in the treatment of drug addiction. Some drug elements, such as nicotine is found in nature (from Nicotiana tabacum and Nicotiana rustica). They also have good effects on health; for example, nicotine is being used in the treatment of cognitive disorder and depression. Its impact on the body depends on the way of its metabolism and absorption, such as P-450 pathway degrades several body parts. At a level, it strengthens/weaken other taken drugs. A review work has done to analyze the pros and cons of nicotine, where limitation they noted are the analysis of the complex way of changing cognitive function and host inflammatory response [2]. By analyzing the EEG response, the changing pattern can be determined easily. Drug elements like

tobacco, tar and nicotine affect on mood and behavior, which is controlled by human brain consisting of neurons [3].

2. Literature Review

A significant amount of public awareness against tobacco addiction have been conducted to date, but not all the public announcements were effective. To know the degree of effectiveness of public service announcement against smoking, a pilot study was conducted in Rome by collecting EEG, heart rate and galvanic skin response. Based on approach withdrawal, effort and emotional indexes, it was found that these parameters that show notable differences between effective and ineffective perception [4].

In addition to the public awareness, several studies have been conducted on identifying the physical and mental changes due to the smoking habit and potential treatments. An analysis was performed by [5], who had experimented on 21 male smokers. The authors had analyzed the EEG wave of the participants before and after the horizontal rotation treatment. They found that the treatment is beneficial in improving the EEG Alpha band, which reduces the smoking effect. An increment in alpha rhythm denotes higher relaxation and concentration ability of subjects [5]. Another study was conducted on 19 smoker participants. The functional magnetic resonance imaging (fMRI) and EEG analysis represented the effect of nicotine on the brain while doing oddball tasks, which is a response time task [6]. The study suggested that the integrated EEG-fMRI system is better identifying the brainwave changes due to smoking.

Though most of the studies has investigated the effect of tobacco smoking on the brain using the EEG, very few studies had done the differentiation of EEG characteristics using machine learning algorithms. In a study [7], the authors have done an experiment on 20 participants having 10 smokers and 10 non-smokers, to observe the changes in the EEG signal due to the smoking effect. The authors had used a Support Vector Machine (SVM) classifier based on Radial Basis Function (RBF) kernel and found that the the power spectral density (PSD) features performed better than the Fast Fourier Transform (FFT) features. Another study developed an EEG-based architecture to determine the effect of tobacco in the brainwaves, using 3 participants in a laboratory-based work [1].

The authors extracted time, frequency domain features from the EEG and showed that the frequency domain features, especially the power spectral density (PSD) and the Fast Fourier Transform (FFT) are most sensitive to the smoking condition than the time domain features for the smoker detection. The study showed promising results but utilized only one classifier (ANN) for the classification approach and only one performance measure (mean square error) for the assessment of the system [1]. However, considering the sensitivity and specificity metrics are most important for an EEG based detection system. As higher sensitivity with lower specificity leads to the higher false detection and the opposite trend causes the missing of a lot of positive states (in this case, smokers), a compromise between the two metrics is crucial.

This paper embodies a methodology for the diagnosis of tobacco smoking, based on the time-frequency analysis of the EEG signal. Also, the analysis was conducted to find efficient analyzing

model and feature. BIOPAC® system was used for data collection, and Acknowledge-4.1® package [8] was used for extracting features. Later, python 3.6.9 version was used in Google Colab platform for data analysis. Most importantly, four supervised classification models, namely, Logistic Regression, K- Nearest Neighbor (KNN), Support Vector Machine (SVM) and Random Forest Classifier (RFC) were trained and tested for evaluating the performance of each of the EEG rhythm, with a five-fold cross-validation. Moreover, four different performance measures (sensitivity, specificity, accuracy and area under the receiver operating characteristic curve) were utilized to examine the performance of the diagnosis system. The following part of this paper is organized as follows- a brief methodology, including experimental design and tools, then the result section with the findings. Last, the paper was concluded, followed by a short discussion on the outcomes.

3. Methodology

3.1. Experimental Design

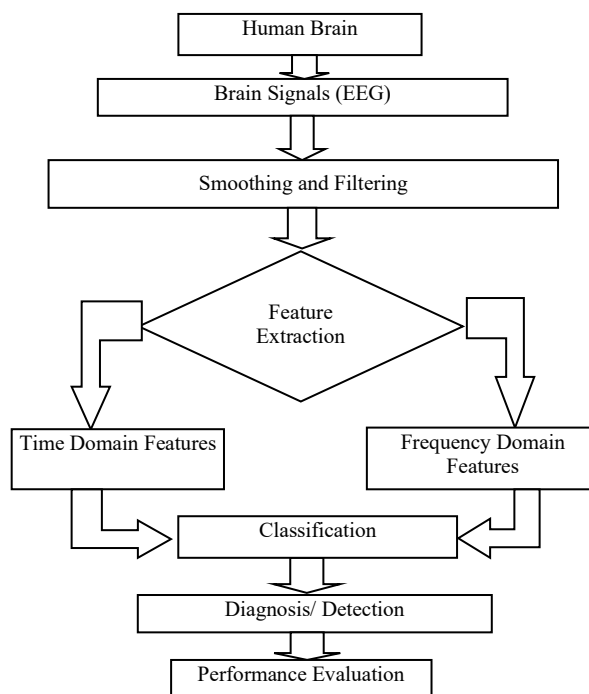
The methodology for building an electroencephalogram based tobacco addiction diagnosis system is shown in Figure 1. After selecting three participants, EEG were obtained by the BIOPAC® system. After that the removal of noise and artifacts were considered.


Figure 1: Block diagram for the proposed EEG based smokier / nonsmoker detection system

Afterwards, eight features were extracted for each domain, and the selected features were supplied towards the machine learning tools. Four different classification models, namely K-nearest neighbours (KNN), support vector machines (SVM), logistic regression (LR) and random forest classifier (RFC) models were developed in python 3.6.9 platform. The evaluation of the best classifier and domain was done by comparing their performance.

3.2. Experimental Equipment

3.2.1. Hardware tool

BIOPAC® MP 36 device was used at Biomedical Engineering lab, KUET for the experimentation purpose. The experimental setup is shown in Figure 2 [8].

3.2.2. Pre-processing and feature extraction software tool

Feature extraction was an important step in this study, which was done using the BIOPAC® student Lab Pro and Acqknowledge 4.1® software Google Colab research platform with the python 3.6.9 for developing the Machine learning-based classification models [9].

3.3. Participants

In total, three subjects participated in this experimental study, who were male, healthy and not suffering from psychological illness. The subjects were instructed to close their eyes while solving some simple arithmetic questions for 20 minutes. An interpreter used to ask the arithmetic question to the participants. In that respect, the brain response (EEG signal) is a result of cognitive event-related potential (ERP) type. A total of ten trials were taken for each subject. The cognitive event was selected because in that case, the participants can easily concentrate and in eye closed condition, there are no eye blinking/ EOG artefacts [9].

Electrodes placement was configured on the right central (C4), and the right occipital (O2) position as the regions are responsible for problem solving and cognitive function, respectively. It is to note that, the authors have selected the cognitive task from their experience from previous pilot studies where the cognitive task gives clear signals with less noise [10, 11].
Figure 2: Representational view while conducting the experiment in BME lab, KUET

3.4. Experimental Procedure

3.4.1. Signal Preprocessing

The primarily obtained EEG signals could have contained noise due to muscle movement, eye blinking and hand movement. Along with line frequency was 50 Hz. To pre-process raw EEG was gone through bandpass finite impulse response (FIR) filter with a range of 0.5 to 44 Hz, as it removes the non-linear trends of the signals. Later the signal was further smoothed, taking a moving average over a short period of the signal.

3.4.2. Feature Extraction

Various features were extracted in time and frequency domain, including standard deviation (STDDEV), maximum value (E_{max}),

skew (sk), kurtosis (k), power spectrum density (PSD) mean, PSD max, Fast Fourier Transform (FFT) mean, FFT max (total eight feature) were extracted for each subject using the Acknowledge 4.1® software. For feature extraction was done using a 5-second epoch length.

3.4.3. Feature Scaling

The time and frequency domain features, which were extracted from the EEG signal, have different range in their magnitude. As the machine learning models work with various features putting them in the same matrix, it is essential to put all the features in a same range, which is referred to as feature scaling. Two common types of feature scaling is done in preliminary data: standardization and normalization [12, 13]. MinMaxScaling was done in this study in python 3.6.9 platform, as a part of the normalization process. *MinMaxscaler()* function from *sklearn* library was used fo this purpose. Here the data is shrunk within a range between [-1,1].

$$x_{new} = \frac{x - x_{min}}{x_{max} - x_{min}} \tag{1}$$

The formula of min-max scaling can be given by equation (1). Here, x_{new} is the normalized value of a feature point x, within a range x_{min} and x_{max} [14].

3.5. Classification

For the diagnosis of tobacco smoking, classification is the main and last step, which is done through machine learning. Machine learning is the application of artificial intelligence, which provides a system capable of learning nature from a given data. There are three categories of Machine Learning models and applications, supervised learning, unsupervised learning, and reinforcement learning. Supervised learning is extensively used for the classification and regression problem [15]. Previous studies worked with EEG have used supervised learnings, especially K-Nearest Neighbour [16], Support Vector Machine [17], Random Forest Classifier [18] and Logistic Regression [19]. Based on the previous studies, these four classifiers were chosen for the data classification in this research.

3.5.1. Logistic Regression (LR)

Logistic regression is a supervised learning model, which works based on the linear method, and the predictions are made using a logistic or sigmoid function σ(t). The sigmoid function is 'S' patterned curve that takes a real number and maps within a range between 0 and 1. Equation (2) represents the sigmoid function.

$$\sigma(t) = \frac{e^t}{e^t + 1} = \frac{1}{1 + e^{-t}} \tag{2}$$

Considering two types of variables, dependent and independent, Logistic regression predicts the dependant variable based on the independent variable. The 'C parameter' was tuned here in the Logistic regression model to reduce overfitting [20,21].

3.5.2. K-nearest neighbours (KNN)

KNN is a supervised learning algorithm, and a non-parametric method where k nearest training examples in the feature space is taken as input and neighbours vote do the classification generally used for classification and regression. At the very starting point,

KNN read the value of K, type of distance D and test data; then it finds the K nearest neighbours D to the test data and thus sets the maximum label class of K to test data. The same process is gone through an iterative process named looping. In details, its algorithm initializes the value of K from 1 (setting as initial iteration value). After loading data, iteration from initial K =1 (generally) to the total number of training data point while distances specifically Euclidean distance between test data and each row of training data is measured and sorted in ascending order to get topmost k rows from the sorted array and the most frequent class is returned as the predicted class [22]. The value of K was tuned, and the k for best efficiency was chosen in the classifier model in this research to reduce overfitting.

3.5.3. Random Forest Classifier (RFC)

Ensemble learning models, such as Random forests are made of individual decision trees with a logic of group of weak learners to finally make a strong learner while the decision trees operate as divided or conquer. A class is predicted from every decision tree and a final class is predicted by model depending on their vote [22]. Two parameters were tuned in the RFC models in this study, namely, '*n_estimate*', which implies the number of trees in the forest and 'max-depth' which signifies the depth of each tree.

3.5.4. Support Vector Machines (SVM)

An SVM is a supervised learning algorithm, which aims to obtain a hyperplane classifying the data point (data points can be at any side of hyperplane) in feature dimensional space while depending on both linear and non-linear regression. Data points distance across to hyperplane are called support vector whose detection can exchange hyper plane's location [22]. The model used a Gaussian kernel for SVM classifier in this research due to the non-linear trend of the dataset. Two parameters- 'C' and 'gamma' was adjusted within a set of values using the grid search algorithm to reduce overfitting.

3.6. Performance Measures

3.6.1. Sensitivity or True Positive Rate (TPR)

True positive rate or Sensitivity is the proportion of the true positives (desired factor), which is correctly identified from the given test set [23]. The definition of sensitivity can be provided by equation (3), where TP = True Positive and FN = False Negative. In this study, sensitivity is the measure of the proportion of successfully identifying a smoker.

$$\text{Sensitivity} = \frac{TP}{TP+FN} \qquad (3)$$

3.6.2. Specificity or True Negative Rate (TNR)

True negative rate Specificity is the proportion of true negative (undesired factor) in which was correctly excluded from the given test sets [23]. The definition of specificity can be provided by equation (4), where TN = True Negative and FP = False Positive. In the case of this study, specificity is the measure correctly identifying a non-smoker. In this study, accuracy is the proportion of successful identification, either smoker or non-smoker.

$$\text{Specificity} = \frac{TN}{TN+FP} \qquad (4)$$

3.6.3. Accuracy

The overall accuracy is the proportion of true results (either true positive or true negative) in an experiment [23,24]. The definition of accuracy can be provided by equation (5), given that TP = True positive, TN= True Negative, FP= False Positive and FN = False Negative. In this study, accuracy is the proportion of the successful identification, either a specific person or not being that person.

$$\text{Accuracy} = \frac{TP+TN}{TP+TN+FP+FN} \qquad (5)$$

3.6.4. Area under the receiver operating characteristic (ROC) curve (AUC)

ROC is the plot of the sensitivity (true positive rate) against the (1- specificity) or false positive rate, where all the possible combination of TPR and FPR are plotted, showing the trade-off between them [23–25]. As sensitivity and specificity are two major parameters of performance measures, AUC under ROC always provides a compromise between them. Though there are few methods for validation, five-fold cross-validation was done in this study while evaluating the performance measures. The mean value and the standard deviation (SD) were noted, considering the five experimental validations. Thus, the mean sensitivity, specificity and AUC was calculated from the obtained confusion matrix.

4. Results

4.1. Data visualization (Box plot and violine plots)

Data visualization is an important part to observe the data arrangement. Given data points found from the selected features were plotted in box and violin plots to observe the range of each of the features. The following Figure 3 and Figure 4 shows that the time and frequency domain features are having a versatile variation in the range. Range of the difference features varies among themselves either in the time domain or in the frequency domain, and therefore, the feature scaling was performed.
Figure 3: Box Plot of part EEG data showing varying magnitude of differnt features

4.2. Classification Performance

All the features were scaled and were supplied towards the machine learning models after necessary parameter tuning. Four different performance measures were evaluated, namely, sensitivity or true positive rate (TPR), specificity or True negative rate (TNR), accuracy and area under the receiver operating characteristic (ROC) curve (AUC). The obtained results are listed in the Table 1.
Figure 4: Violine Plot of part EEG data showing varying magnitude of differnt features

Table 1: Performance measures (mean value) for EEG based smoker detection using four different classifiers, five-fold cross-validation

Domain	Performance Measures	LR	KNN	RFC	SVM
Time Domain	Sensitivity	58.9	56.07	63.6	53.1
	Specificity	55.2	57.54	61.3	55.3
	Accuracy	57.4	55.53	62.4	59
	AUC	53.7	54.04	65	60.1
Frequency Domain	Sensitivity	70.7	77.14	81.2	70.9
	Specificity	70.7	71.35	83.7	76.3
	Accuracy	76.1	73.75	82.9	72.9
	AUC	71.4	77.59	83.2	77.1
Time-Frequency Domain	Sensitivity	89.2	83.75	94.3	85
	Specificity	86.3	91.25	92.1	87.2
	Accuracy	**87.2**	**87.5**	**91.3**	**86.5**
	AUC	78.3	80.7	92	88.2
Figure 5: Performance measurement of time domain

4.2.1. Scenario-1: Classification using Time Domain Features

The following Figure 5 shows the plots of the performance measures (mean ± SD) obtained from the classification of smokers and non-smokers using the time domain features from four different classifiers, LR, KNN, SVM and RFC, respectively. The plots show that the gap between sensitivity and specificity is highest in LR (3.68%) and lowest in the case of KNN (1.44%). Overall, RFC gives an accuracy of 62.4%, which performs the best.

4.2.2. Scenario-2: Classification using Frequency Domain Features Domain

The following Figure 6 shows the plots of the performance measures (mean ± SD) obtained from the classification of subjects addicted to smoking using the frequency domain features from four different classifiers, LR, KNN, SVM and RFC, respectively. The plots show that the gap between sensitivity and specificity is higher in KNN (5.8%) and SVM (5.4%) and lowest in the case of LR (0.05%). Overall, RFC gives an accuracy of 82.9%, which performs the best.
