Editorial

Advances in Science, Technology and Engineering Systems Journal (ASTESJ) is an online-only journal dedicated to publishing significant advances covering all aspects of technology relevant to the physical science and engineering communities. The journal regularly publishes articles covering specific topics of interest.

Current Issue features key papers related to multidisciplinary domains involving complex system stemming from numerous disciplines; this is exactly how this journal differs from other interdisciplinary and multidisciplinary engineering journals. This issue contains 159 accepted papers related to computer engineering domain.

To evaluate and compare methods in computer vision, scientists must use a benchmark dataset and unified sets of measurements. The UCI-EGO dataset is a standard benchmark dataset for evaluating Hand Pose Estimation (HPE) on depth images. To build robotic arms that perform complex operations such as human hands, the poses of the human hand need to be accurately estimated and restored in 3D space. In this paper, we standardized the UCI-EGO dataset to evaluate 3D HPE from point cloud data of the complex scenes. We also propose a method for fine-tuning a set parameter to train the estimation model and evaluating 3D HPE from point cloud data based on 3D Convolutional Neural Networks (CNNs). The CNNs that we use to evaluated currently the most accurate in 3D HPE. The results of the 3D HPE from the point cloud data were evaluated in two branches: using the hand data segment and not using the hand data segment. The results show that the average of 3D joint errors of the 3D HPE is large on the UCI-EGO dataset (87.52mm) and that the error without using the hand data segment is many times higher than the estimated results when using the hand data segment (0.35ms). Besides, we also present the challenges of estimating 3D hand pose and the origin of the challenge when estimating real image dataset.

1 Introduction

In computer vision when evaluating and comparing the methods, the scientists must use a benchmark dataset and unified sets of measurements. The benchmark dataset usually includes training sets and testing sets/ validation set [1], this ratio is defined in the cross-validation parameter [2]. And these sets just include the annotation data of each sample. The UCI-EGO dataset has been published in [3] [1] and evaluated in many studies of HPE [4]–[6]. However, these ratings are evaluated in 2D space on the depth image. The UCI-EGO dataset provided the annotation data, each key point is represented by the structure (x, y, z), (x, y) are the coordinates on the depth image, z is the depth value of pixel which has the coordinates (x, y). However, the actual depth values of the annotation data are different from the depth data on the depth image. They are shown as Figure 2.

Nowadays, building robotic arms with hands that can perform many complex actions like human hands is an issue that needs research [7]. Since the human hands have many degrees of freedom (DOF), the complex actions can be performed. In order to build a robotic hand that can perform complex operations (Figure 3), first of all, it is necessary to restore and estimate the hand poses in the 3D space. Therefore, we continue to perform research on estimating human hand pose in the 3D space. In particular, estimating the hand pose on the data obtained from the EGOcentric VIsion (EGO-VI) sensor, contains many challenges such as missing, data loss, or obscuring.

Therefore, this paper includes the main contributions as follows:

- Standardizing the annotation data of the UCI-EGO dataset based on the depth value on the depth image. That means replacing the depth value of each point in the annotation data with the depth value of the corresponding point at that coordinate on the depth image, as illustrated in Figure 4. From this, using 3D hand pose annotation data to train the hand pose estimation model in the 3D space.

- Fine-tuning a set of parameters to train the hand pose estimation model in the 3D space based on the (V2V - V2V-PoseNet [8]) and evaluating the 3D HPE based on the most accurate 3D CNN (V2V). The estimation results are presented and

---

evaluated on the point cloud data. This is the same data as the real world.

Figure 2: The depth value of the first point in the hand skeleton of annotation data and depth image data.
Figure 3: Robot arm illustration follows the operation of human hands [7].

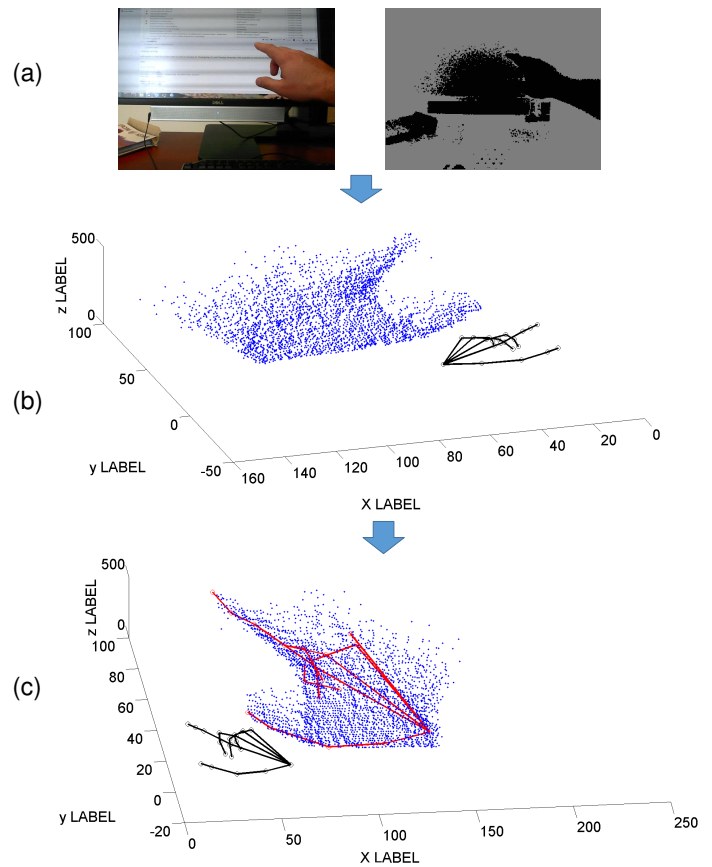
- Presenting and comparing some 3D HPE results on the full hand dataset and the dataset obtained from the EGO-VI sensor. Presenting some challenges of estimating hand pose in the 3D space when estimating on the data obtained from EGO-VI sensors.


Figure 4: Illustrating of standardized the UCI-EGO annotation data process. (a) is the RGB-D images; (b) is the annotation data of UCI-EGO (the blue points are the point cloud of hand, the black skeleton is the annotation of UCI-EGO dataset); (c) is the standardized the annotation of UCI-EGO.

During the research on recognizing the daily activities of the human hand based on data collected from the EGO-VI sensor. We only research within a limited range as follows: We are interested in the dataset obtained from the EGO-VI sensor, namely the UCI-EGO dataset studied in this paper; We are also interested in 3D CNN that use point cloud as the input because the point cloud data is real data similar to the real environment.

The organization of the paper is shown as follows: Section 1 first introduce the benchmark dataset, the existence problem of the UCI-EGO [3] dataset, and the 3D HPE problem, we also introduce the application of 3D HPE to build robotic arms. Section 2 presents studies on the benchmark datasets to evaluate 3D HPE and some results. Section 3 presents the standardization of the UCI-EGO dataset and 3D HPE in the point cloud data. Section 4 presents the results and some discussions of 3D HPE. Finally, there are some conclusions and the next research direction of the paper (Section 5).

2   Related Works

Evaluating on the benchmark datasets is an important step to confirm the correctness of the detection, recognition, and estimation model of computer vision. Currently, there are many datasets for evaluating 3D HPE. The datasets are listed in Tab. 6 of [9]. In this paper, we only reintroduce some of the datasets used to evaluate 3D

HPE and some results based on typical CNNs.

In [10], published MSRA dataset, [2]. It includes 76k depth images of nine subjects of the right hands are captured using Intel's Creative Interactive Gesture Camera. Each subject include 17 gestures captured and include about 500 frames with 21 3D annotation hand joints for each frame: wrist, index mcp(metacarpal bone), index pip(proximal phalanges), index dip(distal phalanges), index tip, middle mcp(metacarpal bone), middle pip(proximal phalanges), middle dip(distal phalanges), middle tip, ring mcp (metacarpal bone), ring pip(proximal phalanges), ring dip(distal phalanges), ring tip, little mcp(metacarpal bone), little pip(proximal phalanges), a little dip(distal phalanges), little tip, thumb mcp(metacarpal bone), thumb pip(proximal phalanges), thumb dip(distal phalanges), and thumb tip. The size of the captured image is 320×240 pixels. The camera's intrinsic parameters are also provided, i.e. principal point of the image is (160, 120) and the focal length is 241.42. This dataset only has depth images, especially the hand data that is segmented with environmental data. This is a benchmark dataset for the evaluation of 3D HPE, the results of the CNNs are shown in table 2 of [11].

In [12] [3], the author includes 72,757 frames of the training set captured from a single person and 8,252 frames of the testing set captured two different persons from three MS Kinect v1, i.e. a frontal view and two side views. Each frame is a couple of RGB-D images. This dataset provided 25-joints in the annotation data with 42 DOF. The authors used the Randomized Decision Forest (RDF) to train a binary classification model by this dataset. And then this classification segments each pixel that belongs to a hand or background in the depth image. 3D HPE results of the CNNs are shown in table 2 of [11].

In [13] [4], the author includes 22K frames for training and 1.6K frames for testing, they captured from the Intel's Creative Interactive Gesture Camera with 10 subjects to take 26 different poses. It also provides 3D annotation data with 16 hand joints: palm, thumb root, thumb mid, thumb tip, index root, index mid, index tip, middle root, middle mid, middle tip, ring root, ring mid, ring tip, pinky root, pinky mid, and pinky tip.

The above are the datasets collected from a fixed number of perspectives of the image sensors. In many real applications, the image sensors are mounted on the body to collect data from the environment. These datasets are named the "Egocentric" dataset. In [14], the author published the **UCI-EGO** dataset, in [15] the author published the **Graz16** dataset, in [16] the author published the **Dexter+Object** dataset, in [17] the author published the **First-Person Hand Action** (FHAD) dataset, in [18] the author published the **UCI-EGO-Syn** dataset, in [15] the author published the **CVAR** dataset. Most EGO-VI datasets contain challenges for 3D HPE as follows: The frames do not contain hands, and the hands are obscured by objects in the scene; Data of the fingers is obscured; Data of visible hand only data of palm. The percent of challenges in CVRA [15] and UCI-EGO-Syn [18] datasets are shown in Figure 5.
Figure 5: The percent of challenges in CVRA [15] and UCI-EGO-Syn [18] datasets.

In the past 5 years, many CNNs and related studies have been published for HPE. However, most of these studies were evaluated on the MSRA, NYU, ICVL datasets, the results are shown in table 2 of [11]. In this paper, we are interested in estimating 3D hand pose from the 3D annotation of hand skeleton data. The method we use is V2V, it has the input data of 3D annotation data and the point cloud data of hand. In [19], the author proposed 3D CNN for 3D HPE. This network projects 3D points of the hand following: x-direction, y-direction, z-direction. Synthesized in these three directions is encoded as 3D volumes storing the projective Directional Truncated Signed Distance Function (D-TSDF). Special, it only uses three 3D convolutional layers and three fully-connected layers to train the model. The estimated results have an average error of 9.58mm on the MSRA dataset.

In [20], the author proposed a deep regression network (SHPR-Net) for 3D HPE. This network consists of two components: A semantic segmentation network (SegNet) and the hand pose regression network (RegNet). The first component is used to segment the joints, the parts of the hand. That is, each part of the hand is segmented and labeled, RegNet is used to predict the 3D coordinates of the match corresponding to the segmented hand data areas. The estimated results have an average error of 10.78mm on the NYU dataset. In [21], the author proposed Hand PointNet to estimate 3D hand pose from the segmented hand on a depth image by using random decision forest [13], then convert to point cloud data using the Eq. 1. This method has improved the basic PointNet by using a hierarchical PointNet to generate the hierarchical feature extraction. Specifically, it uses three point set abstraction levels. Besides, In [22] and [23], the authors proposed the 3D DenseNet, Point-to-Point Net, respectively. The estimated error of result on the above methods is usually less than 10mm.

3 Standardized UCI-EGO Dataset and 3D HPE by V2V

3.1 *Standardized UCI-EGO Dataset*

As shown in Figure 4(b), the annotation data of the UCI-EGO dataset needs to be calibrated to meet the evaluation of 3D HPE in 3D space / on the point cloud data. Deviation in 3D annotation data of the hand pose is due to the 3D annotation data generated from the semi-automatic labeling tool. This issue is covered in Sec. 4.1 by UCI-EGO dataset introduction. This process is done as follows: The

---

[2]`https://www.dropbox.com/s/c91xvevra867m6t/cvpr15_MSRAHandGestureDB.zip?dl=0`.

[3]`https://jonathantompson.github.io/NYU_Hand_Pose_Dataset.htm`.

[4]`https://labicvl.github.io/hand.html`

coordinates of each keypoint $K(x, y, z)$ in the UCI-EGO annotation data, where (x, y) is the coordinate of K on the depth image, z is the depth value of K in the depth image [3]. In this paper, we replace the depth value of the K point in UCI-EGO [3] with the depth value of the point with coordinates (x, y) on the depth image. However, there are many cases of data loss or missing in the depth images, especially on the depth image sensors collected on previous depth sensors such as the Microsoft Kinect Version 1 [24]. We solve this problem by using the mean depth value of the k-neighbors of the K on the depth image, where $k = 3$, $d_K = mean(d_{K1}, d_{K2}, d_{K3})$.

After that, the coordinates (x, y) of the keypoint on the image combined with the depth value to generate one point (x_a, y_a, z_a) in 3D space / point cloud data [25] according to Eq. 1.

$$
\begin{aligned}
x_a &= \frac{(x - cx_d) * z}{f x_d} \\
y_a &= \frac{(y - cy_d) * z}{f y_d} \\
z_a &= z
\end{aligned}
\tag{1}
$$

where $f x_d, f y_d, cx_d$, and cy_d the intrinsics of the depth camera.

The results of the standardized annotation data are illustrated on the point cloud data of the hand as shown in Figure 4(c).

3.2 3D HPE by V2V

Based on the results of the 3D HPE of the 3D CNN on ICVL, NYU, MSRA datasets. The V2V [8] network has the best estimation result (average of 3D joints error is 6.28mm, 8.42mm, 7.49mm, respectively). Therefore, we used the V2V network to evaluate HPE on the UCI-EGO dataset. The execution process is shown below.
Figure 6: The hand data segmentation and 3D HPE based on 3D CNN (V2V) [8].

As shown in Figure 6 (left), the hand is in the complex scene, where the input data of V2V is the point cloud data of the segmented hand. Therefore, we propose a preprocessing step to segment the hand data with the environment and other objects.

We based on the annotation data on the keypoints of the hand skeleton frame on the depth image to crop a region container on the depth image with a rectangle that is bounding box of the keypoints on the depth image. We then find the maximum depth value of the keypoints M_d^h on the depth image. We rely on the context of capturing data from the EGO-VI sensor, the hand that is usually closest to the sensor. Therefore, the data near the hand that is large M_d^h is not part of the hand data.

As shown in Figure 6 (right), the input of the V2V method is 3D voxelized data. Thus, it reprojects each pixel of the depth map to the 3D space. After that, this space is discretized based on the pre-defined voxel size. V2V-PoseNet is based on the hourglass

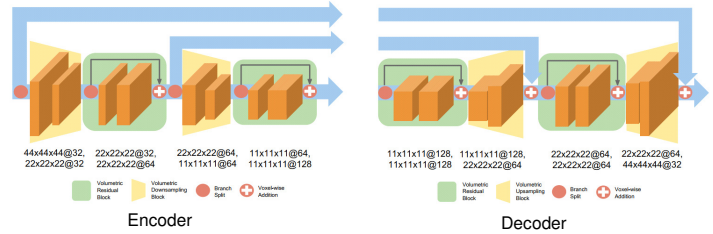
model [26] and is designed to be divided into four volumetric blocks. The first volumetric basic block includes a volumetric convolution, volumetric batch normalization, and the activation function. The location of the first volumetric basic block is in the first and last parts of the network. The second volumetric residual block extended from the 2D residual block in [27]. The third volumetric downsampling block is similar to the volumetric max-pooling layer. The last block is the volumetric upsampling block, which consists of a volumetric deconvolution layer, volumetric batch normalization layer, and the activation function.


Figure 7: Encoder and decoder phase in the network architecture of V2V-PoseNet [8].

Each phase of the V2V-PoseNet method in Figure 6 is shown in Figure 7. Each phase consists of four blocks as shown in Figure 7. Therein, the volumetric downsampling block reduces the feature map space while the volumetric residual bock increases the number of channels in the encoder phase. Otherwise, the volumetric upsampling block enlarges the feature map space. When upsampling, to compress the extracted features the network reduce the number of channels. To predict each keypoint of the hand in 3D space through two stages: encoder, decoder. They are connected by the voxel-wise. To supervise the per-voxel likelihood in the estimating process, V2V generates a 3D heatmap, wherein the mean of the Gaussian peak is positioned at the ground-truth joint location in Eq. 2.

$$
D_n^*(i, j, k) = exp\left(-\frac{(i - i_n)^2 + (j - j_n)^2 + (k - k_n)^2}{2\sigma^2}\right)
\tag{2}
$$

where n^{th} keypoint whose ground-truth 3D heatmap is denoted D_n^*, (i_n, j_n, k_n) is the ground-truth voxel coordinate of nth, and $\sigma = 1.7$ is the standard deviation of the Gaussian peak [8]. V2V also uses the mean square error as a loss function L in Eq. 3.

$$
L = \sum_{n=1}^{N} \sum_{i,j,k} \|D_n^*(i, j, k) - D_n(i, j, k)\|^2
\tag{3}
$$

where D_n^* and D_n are the ground-truth and estimated results for n^{th} keypoint, respectively, and the number of keypoints is denoted N.

4 Experimental Results

4.1 Dataset

In this paper, we are trained and tested on the UCI-EGO [14] dataset. It provides about 400 frames prepared the 3D annotation. 3D annotations of keypoints with 26 joint points are also provided. To

annotate this dataset for evaluating 3D HPE and hand tracking the authors developed a semi-automatic labeling tool. It can annotate the accurate partially occluded hands and fingers in the 3D space by using the techniques: A few 2D joints are first manually labeled in the image and have used to select the closest synthetic samples in the training set; After that, a full hand pose is generated combining the manual labeling and the selected 3D sample; This pose is manually refined, resulting to the selection of a new sample, and the creation of a new pose; This process is repeated until acceptable labeling is achieved. This dataset captured from a chest-mounted Intel Senz3D RGB-D camera/EGO-VI and capture 4 sequences, 2 for each subject (1 male and 1 female), as illustrated in Figure 8. The authors labeled the keypoints of any visible hand in both RGB and Depth images every 10 frames, as illustrated in Figure 9.

We perform experiments on PC with Core i5 processor - RAM 8G, 4GB GPU. Pre-processing steps were performed on Matlab, fine-tuning, and development process in Python language on Ubuntu 18.04.

Before performing 3D HPE from the point cloud data, we propose a pre-processing step to segment the hand from the complex scene data, as shown in Figure 14. The depth image contains the depth value of the hand data is the closest (the hand is closest to the sensor). From there we use a threshold d_{thres} which is the maximum depth value of the hand to segment the data of the hand and other data in the complex scene.

4.2 V2V Parameters

Like in the original study of V2V-PoseNet [8], this deep network is developed in the PyTorch framework. The zero-mean Gaussian distribution with $\sigma = 0.001$ is initialized to all weights. The learning rate is set 0.00025 and batch size is set 4. This is the maximum value that V2V can train the model on our computer. The size of input is $88 \times 88 \times 88$. This deep network also uses the optimizer method of Adam [28]. To standardize data for training, V2V rotates [-40, 40] degrees in XY space, scale [0.8, 1.2] in 3D space, and translate with the size of voxels [-8, 8] in 3D space. We trained the model for 15 epochs. Implementation details of V2V are shown in the link [5].

In the original V2V study [8], the model trained only for 10 epochs. Although, the depth data value on the MSRA dataset is from 0.3m-0.7m, while the depth data value on the UCI-EGO dataset is from 0.3-0.45m. In each epoch, we computed the total loss function of batch sizes by Eq. 4.

$$T_L = \sum_{j=1}^{N_p} L_j \qquad (4)$$

where $N_p = N_s / batch\_size$ is the batch size number of the training data, N_s is the sample number of the training data. L_j is the total loss function j^{th} of each batch size.

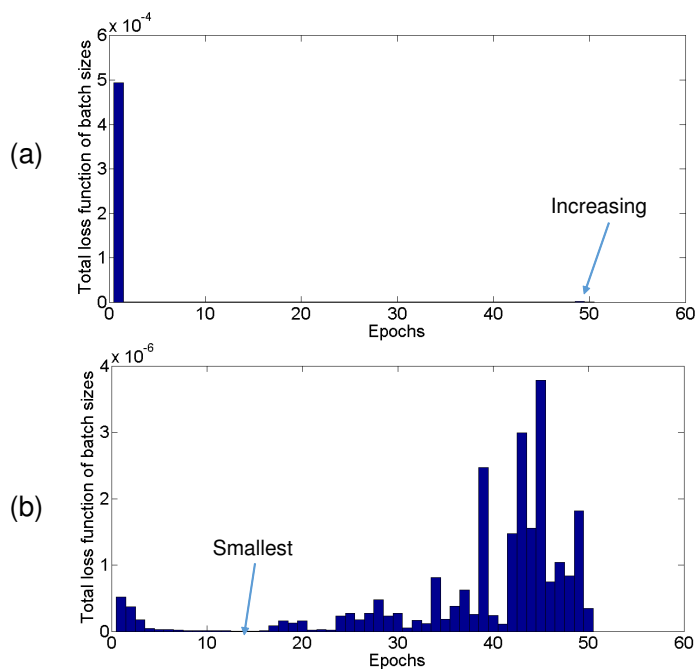
Figure 8: Illustration of hand grasping object in the UCI-EGO dataset [14].
Figure 9: Illustration of 2D hand pose ground truth on the RGB and depth images.


Figure 10: The total loss function of batch sizes at each epoch. (a) is the total loss function of batch sizes of training data when hand data is segmented on the depth image. (b) is the total loss function of batch sizes of validation data when hand data is segmented on the depth image.

We then compare the total loss function at each epoch. In a model with the smallest total loss function, that model is the best model for estimating the 3D hand pose. During training, we found that the total value of loss function up to the epoch 15th does not

decrease any more. We have trained the estimation model for 50 epochs, the total loss function of batch sizes at each epoch are shown in Figure 10. It can be seen that the value of the loss function decreases drastically and is about 10^{-11} at the epoch 10th. Specifically, on the validation data, there is the value of the smallest loss function at the epoch 10th as Figure 10(b). Therefore in this paper, we train only 15 epochs.

4.3 Evaluation Measure

As the evaluations of the previous 3D HPE method, we used the average 3D distance error (as shown in Eq. 5) to evaluate the results of the 3D HPE on the dataset.

$$\widehat{Err_a} = \frac{1}{Num_s} \sum_{n=1}^{Num_s} \frac{1}{21} \sum_{k=1}^{21} DIS(p_g, p_e) \qquad (5)$$

where $DIS(p_g, p_e)$ is the distance between a ground truth joint p_g and an estimated joint p_e; Num_s is the number of testing frames. In this paper, we evaluated the 21 joints of hand pose, illustrated in Figure 11.

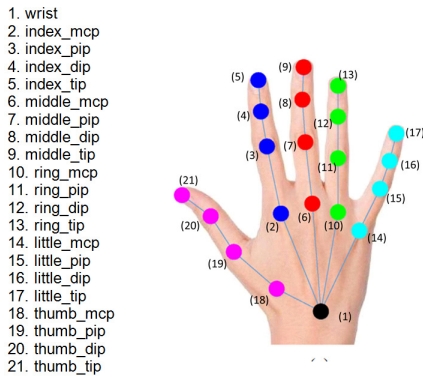
21. thumb_tip


Figure 11: Illustrating the hand joints of the UCI-EGO [14] dataset.

In this paper, we use the rate at 1:5, which means 80% for training and 20% for testing. This ratio is based on the division of [15](using 5-fold cross-validation for testing and training). This means the UCI-EGO dataset uses 283 samples for training and 71 samples for testing. Although, the UCI-EGO dataset provides 26 annotation points. However, we only use 21 annotation data points to evaluate the 3D HPE. The order of points is shown in Figure 11.

4.4 Results and Discussions

As the evaluation of 3D HPE results shown in Tab. 2 of [11], also use the 3D distance error (mm) to evaluate the estimation results on the UCI-EGO dataset. The average 3D distance error is shown in Table 1. The processing time of training process and 3D HPE process is shown in Figure 12. As figure 12, the processing time to train for 50 epochs is 1.472h and 0.442h, it is calculated by $(1m46s = 106s) * 50epochs = 1.472h$ and $(1m46s = 106s) * 15epochs = 0.442h$, respectively. The processing time for testing is shown in Table 2. It is calculated by $128ms/362samples$ and $137ms/362samples$, respectively.

(a) Processing time to train an epoch

(b) Processing time of testing

Table 2: The average of processing time of the V2V on the UCI-EGO dataset to estimate a 3D hand pose.

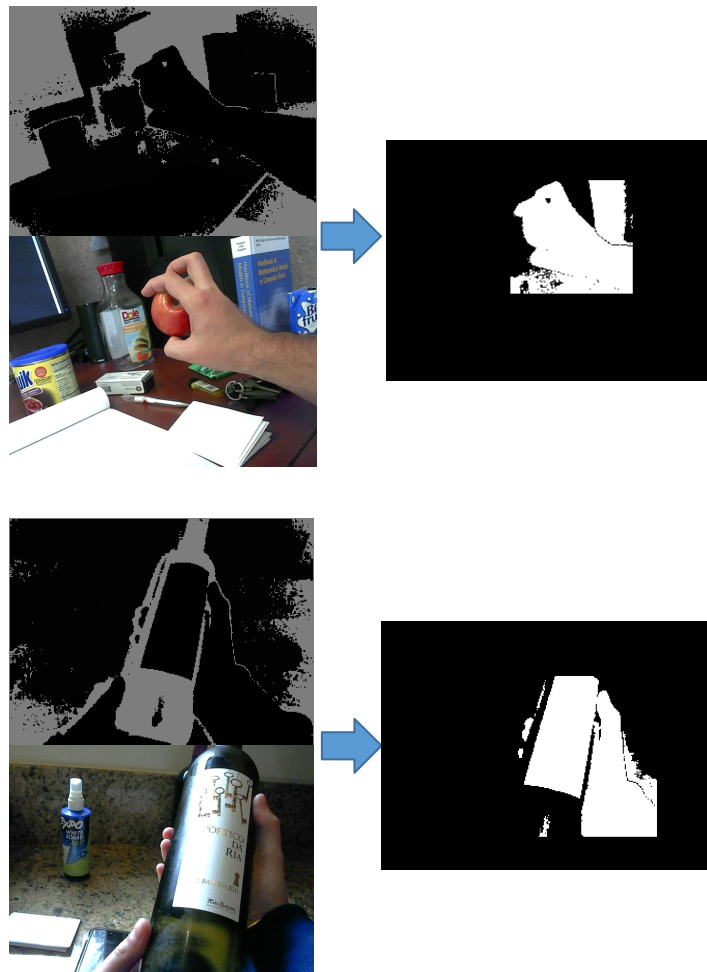
Measurement/ Method		V2V
Processing time (ms)/ hand	Hand segmentation	**0.35**
	No hand segmentation	0.38
Figure 14: Illustrating the data well segmented of hand in the complex scene.


Figure 15: Illustrating of the hand data and the objects in the UCI-EGO dataset.

From table 2 of research in [11] and Table 1, the error results of estimating the 3D hand pose on the EGO-VI dataset are much larger than those estimated on the obtained datasets from a fixed number of perspectives. The time of estimated hand joints when using V2V

is enormous, as shown in Table 2. This high estimate time due to carrying CNN using the input data is the point cloud data that is not reduced by number of points.

As Table 1 and Figure 13, the 3D HPE results when using the hand data segment are better when not using the hand data segment in the complex scenes. The error distribution when using the hand data segment concentrated in bins closer to 0.

Although when segmenting the hand data, the estimation results were better than when the hand was not segmented. However, the estimated results have not improved much. Since in the UCI-EGO dataset only about 9% of the hands are well segmented with other subject's data, as illustrated in Figure 14. The remaining about 90% of the hands are grasping objects like phone, book, spray bottle, bottle, ball, etc. Therefore, the hand data gets stuck with the data of the objects being handled, as illustrated in Figure 15.

Figure 16 shows the results of estimating 3D hand pose on the point cloud data in two methods: The segmented hand data (a) and no segmented hand data (b).
Figure 16: The results of the estimated 3D hand pose on the point cloud. (a) is the result of estimating the 3D hand pose in the 3D space on the segmented hand data; (b) is the result of estimating the 3D hand pose in the 3D space on hand data is not segmented. The blue points are the point cloud of hand and others object. The red skeleton is the ground truth of 3D hand pose, the black skeleton is the estimated 3D hand pose.

Based on the reading paper of [29], we find that the error of estimating the 3D hand pose on the UCI-EGO-Syn [18] dataset is high with: Hough [30], RDF [31], Deep Prior [32], PXC [33], Cascader [14], EGO.WS. [3]. The error distribution is from 35 to 100mm, as illustrated in Figure 18.

The UCI-EGO dataset has the hand data that performs grasping objects and is collected from an EGO-VI mounted on the person, the hand data is obscured, as shown in Figure 15. In particular, the data of the fingers is obscured. In this paper, we used V2V for estimating 21 joints of hand (3D hand pose), the input data of V2V is the coordinate of 21 joints in the 3D space of ground truth data, the output is also 21 joints, as illustrated in Figure 6. Therefore, the fields of the obscured fingers, the hand joints can still be estimated.

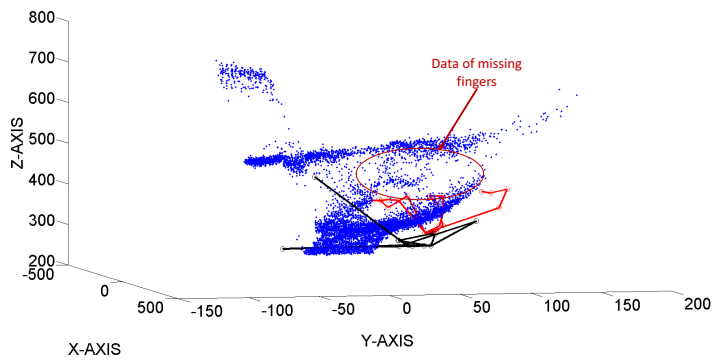
However, the point cloud data of the hand is much missing, the estimation results have large errors, as illustrated in Figure 17.


Figure 17: Illustrating of estimation results on the data with obscured fingers of Figure 9. The red skeleton is the ground truth of the 3D hand pose, the black skeleton is the estimated 3D hand pose.

During the research on 3D HPE, we found the challenges as follows:

- **_The high degree of freedom_**: In realistic/3D space human hand models have between 15 and 24 degrees of freedom [34]. From 21 joints there are about 63 coordinates of in the 3D space. To train such a large dimension vector requires a very strong model and very large learning data to train model.

- **_Data obscured_**: As shown above, the hand data is obscured making the hand's point cloud data missing. This makes the 3D HPE result from a high error value. This problem can be seen when comparing the results estimated on datasets with complete hand data (MSRA, ICVL, NYU) (table 2 of [11]) with the estimation results on the UCI-EGO-Syn [18] dataset (Figure 18). The quality of the depth images is also an issue affecting the 3D data / point cloud data. The depth images can be collected from a stereo camera or ToF (Time of Flight), this data still contains error noise.

- **_Hand size in the space_**: When moving in the 3D space to perform operations, the size of the hand is constantly changing. To train hand estimation models with different sizes, a large number of samples and strong models are required.

- **_3D hand pose annotation_**: The quality of the 3D HPE model depends on the training data. To prepare the training data requires an expensive system like in the FPHA (First-Person Hand Action) dataset [17], or use the estimated data through an estimation model like in the Ho-3D dataset [35].

5   Conclusion

To perform complex operations such as human hands then robot hand operations need to be built based on human hand operation. To do this, the poses of the human hand need to be accurately estimated and restored in 3D space. In this paper, we perform the standardization of the UCI-EGO dataset to evaluate 3D HPE. Simultaneously,

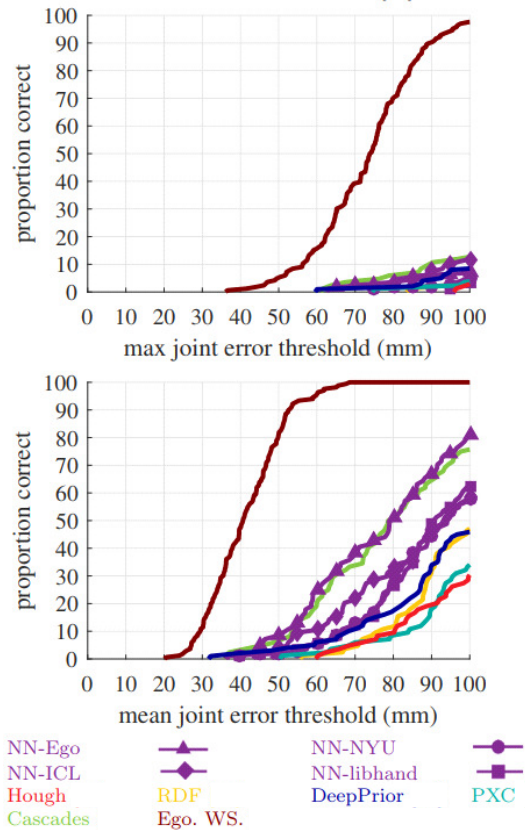
we retrained, evaluated 3D HPE, and presented the results on the point cloud data based on the V2V-PoseNet. The estimation results on the UCI-EGO dataset have been a large error and many challenging. The estimation results above also show that estimating 3D hand pose on the EGO-VI dataset is challenging and needs to be studied to improve the accuracy of 3D HPE.


Figure 18: Distribution of 3D joints error estimation [29] on the UCI-EGO-Syn [18] dataset.

A B S T R A C T

Graphene oxide (GO) was prepared by the modified Hummer's method, but the mass ratio of graphite to sodium nitrate (NaNO₃) was varied from 2:1, 1:1, and 1:2. The primary reason for the variation was to determine the optimum conditions that would afford more oxygen functional groups to improve the material for application in adsorption. The final products, termed GO$_{2:1}$, GO$_{1:1}$ and GO$_{1:2}$, were analyzed by several instrumental techniques. The layered structure of the GO sheet was established by transmission electron microscopy, while powder X-ray diffraction showed that the GO$_{2:1}$ material was more crystalline than either GO$_{1:1}$ or GO$_{1:2}$. Raman spectroscopy revealed the presence of a greater defect density in GO$_{2:1}$. The presence of oxygen functional groups was verified by Fourier transform infrared spectroscopy, and these were quantified by the Boehm titration method. Overall, GO$_{2:1}$ had a larger oxygen content than either GO$_{1:1}$ or GO$_{1:2}$, and a larger specific surface area. A preliminary study on the adsorption properties of the samples revealed that GO$_{2:1}$ exhibited the highest percentage removal for Cu^{2+} in aqueous solution. Thus, the preparation of graphene oxide with a smaller amount of NaNO₃ yielded a material with a greater oxygen content, which showed suitable properties for the adsorption of contaminants in wastewaters.

1. Introduction

Graphene is a 2D nanomaterial that consists of sp^2 hybridized carbon atoms arranged in a hexagonal pattern [1]. This ultra-thin material is crystalline and has several remarkable properties. It has an outstandingly high surface area (2630 m^2 g^{-1} for a one-atom-thick flat sheet of graphene) [2], electrical and thermal conductivities, electron transport capabilities, and excellent tensile strength. These exceptional features have created considerable research interest and industrial implementation in areas such as supercapacitors [3], hydrogen production [4], sensors [5], adsorption [6], and support fillers [7] for nanocomposites [8].

Graphene oxide (GO) comprises of a single sheet of graphite oxide and is prepared by the action of strong oxidizers on graphite [1, 9, 10]. GO can easily be exfoliated and dispersed in different solvents due to its hydrophilicity [11, 12]. The hydrophilic nature of GO enables it to be evenly distributed on a substrate in the form of thin films, which is important in the production of electronic devices [13]. The presence of oxygenic functional groups, including carbonyl, carboxylic, epoxide and hydroxyl groups, the

high surface area and hydrophilicity make GO flakes an excellent prospective sorbent material [14, 15]. These oxygen functional groups can complex with toxic metal cations through sharing of lone pairs of electrons. A large adsorption capacity is exhibited as a consequence of the large surface area of GO [16-18]. The hydrophilicity of oxidized graphite allows water to be absorbed into the layered structure, which further increases the gap between the layers to 1.15 nm [19], which allows for improved metal binding.

Graphene oxide is synthesised by using Hummer's method in which graphite is oxidized by reacting it with potassium permanganate and sodium nitrate in concentrated sulfuric acid [1]. Numerous reports describe the high adsorption capacity of GO for antibiotics [20, 21], heavy metals [15, 16], and dyes [21, 22]. Graphene oxide has been stated to possess an improved adsorption efficiency than other frequently used sorbent materials as a consequence of the number of O-containing moieties it possesses [14, 16]. Adsorption is the most cost-effective and resourceful procedure for the sequestration of pollutants from contaminated water [22-24]. This water remediation technique has been studied with a wide variety of adsorbent materials, including waste

biomass [25], peat moss [26], zeolites [27] and hydrogels [28], to name only a few.

Although many investigations on the preparation of graphene oxide have been published, there are no studies that discuss the preparation of GO that will afford more oxygen functional groups for the elimination of contaminants from wastewater [14, 16, 23]. Hence, the objectives of this work were to synthesize GO via a modified Hummers method; to establish the optimum synthesis conditions that would provide more oxygenic functional groups on GO, and to apply the most functionalised product for the removal of contaminants from wastewater. The products obtained were characterized by several methods which include transmission electron microscopy (TEM), scanning electron microscopy (SEM), powder X-ray diffraction (XRD), thermogravimetric analysis (TGA), Raman spectroscopy, Fourier transform infrared spectroscopy (FTIR), Brunauer-Emmett-Teller (BET) surface area analysis, Boehm titration, and elemental analysis.

2. Experimental

2.1. Materials

Analytical grade chemicals, including graphite powder (<20 μm, synthetic), sodium hydroxide (NaOH), potassium permanganate ($KMnO_4$), 98% sulphuric acid (H_2SO_4), 30% hydrogen peroxide (H_2O_2), 32% hydrochloric acid (HCl), copper metal and nitric acid (HNO_3), were utilized without further purification. They were obtained from Sigma-Aldrich (Pty) Ltd, South Africa. Milli-Q H_2O was from a Millipore Milli-Q Integral water purification system.

2.2. Synthesis of graphene oxide

Different variants of GO were synthesized according to the modified Hummer's method [1] by varying the mass ratio of graphite to sodium nitrate from 2:1, 1:1 and 1:2 respectively. The products obtained were named $GO_{2:1}$, $GO_{1:1}$, and $GO_{1:2}$ respectively. The preparation method was as previously described [29].

2.3. Characterization

The $GO_{2:1}$, $GO_{1:1}$ and $GO_{1:2}$, materials were analyzed to authenticate the homogeneity and structure of the products prepared. The morphology of the materials was investigated by scanning electron microscopy (SEM) (ZEISS Ultra PLUS) and structural information was obtained from transmission electron microscopy (JEOL, JEM 1010). X-ray diffractograms of the materials were measured with a Bruker Advance D8 spectrometer utilizing Cu Kα radiation at 40 mA and 45 kV. Raman spectra of the materials were recorded with a DeltaNu Advantage 532TM® Raman spectrometer with a Nd:YAG laser source and excitation at a wavelength of 532 nm. The thermal stability of the materials was determined in a nitrogen atmosphere with a PerkinElmer Simultaneous Thermal Analyser STA 6000 instrument. The samples were heated from ambient temperature to 1000 °C at a rate of 10 °C/min with a nitrogen flow rate of 50 mL/min. The textural properties of the samples were determined with a Micromeritics Tristar ASAP 3020 surface area and porosity analyser by using nitrogen gas as the adsorbent. The functional groups present were identified by FTIR with a PerkimElmer Spectrum RX1 spectrophotometer, using a pressed disc of each powder mixed

with KBr. Elemental analysis of the materials was performed with a Thermo Scientific CHNS/O LECO CHNS-932 elemental analyser. The Boehm titration method was used for quantifying the surface groups on the carbon materials as follows. The number of acidic functional groups on the surfaces of the GO samples were measured with base solutions of increasing strength known as reaction bases such as NaOH, Na_2CO_3, and $NaHCO_3$. To determine the acidic sites of the materials, 0.2 g of the samples were weighed separately into 20 mL aliquots of solutions of 0.1 mol dm^{-3} NaOH, 0.05 mol dm^{-3} Na_2CO_3, and 0.1 mol dm^{-3} $NaHCO_3$ and then agitated in a shaking water bath for 24 h. The solutions were filtered, and 5 mL of the filtrates were back-titrated against a standardized 0.05 mol dm^{-3} HCl solution. It is suggested that sodium hydroxide (NaOH) neutralizes the lactonic, phenolic and carboxylic groups, while sodium carbonate (Na_2CO_3) neutralizes the lactonic and carboxylic groups, and sodium bicarbonate ($NaHCO_3$) neutralizes the carboxylic groups. Thus, by difference, the quantity of each type of functional group can be determined.

2.4. Determination of adsorption capacity

A batch adsorption technique, with Cu^{2+} as the adsorbate, was used to determine the adsorption capacity of the GO materials. For this, a standard Cu^{2+} stock solution was prepared by dissolving 1.0 g of pure Cu metal into 10 mL of concentrated nitric acid (HNO_3). The stock solution was made up to a final volume of 1000 mL with deionized water. This solution was subsequently diluted to prepare working solutions of known concentrations.

A Metrohm 827 pH-meter was used for measuring the pH, and a Mettler AE 200 balance was used for weighing of samples.

The dependence of the adsorption of $GO_{1:1}$, $GO_{1:2}$ and $GO_{2:1}$ was determined by varying the adsorbent dose from 10 to 60 mg in contact with 20 mL of 20 mg dm^{-3} of Cu^{2+} solution at a pH of 5. The samples were agitated in a thermostated shaking water bath set at 25 °C for 5 h, and subsequently filtered through Whatman No. 1 filter paper. The filtrates were analysed for their Cu^{2+} content at a wavelength of 220.353 nm with a PerkinElmer Optima 5300 DV inductively coupled plasma-optical emission spectrometer (ICP-OES).

The adsorption efficiency, q_e (in mg g^{-1}), was estimated from (1):

$$q_{eq} = \frac{V}{m} \times \left(C_i - C_{eq} \right) \qquad (1)$$

where V is the volume (in dm^3) of the adsorbate solution, m is the mass of adsorbent (in mg), and C_i and C_{eq} are the initial and equilibrium concentration of adsorbate (in mg dm^{-3}) respectively. The percentage sequestration of Cu^{2+} was derived from (2).

$$\% \, adsorbed = \left(\frac{C_i - C_{eq}}{C_i} \right) \times 100 \qquad (2)$$

3. Results and discussion

In this work, different variants of GO (2:1, 1:1, 1:2) were synthesised via a modified Hummer's method. The GO samples were characterized by several techniques, and then tested for the adsorption capacity of a representative heavy metal cation contaminant, namely Cu^{2+}, in aqueous solution.

3.1. Morphology

The surface morphologies of the different GO samples were measured by SEM techniques. The SEM micrographs of GO$_{2:1}$, GO$_{1:1}$ and GO$_{1:2}$ are shown in Figure 1. In order to acquire these images, the GO samples were coated with a gold film fractured surface under liquid nitrogen. The surface morphology showed how the GO sheets are exfoliated for the different GO materials. The SEM micrographs show that the GO materials have a 2D sheet-like structure with a multiple lamellar layer structure that distinguishes the edges of the individual sheets. The GO sheets were thick, particularly at the edges, and this thickness arises from the O-functional groups introduced.
Figure 1: SEM images of GO samples: (a) GO$_{2:1}$, scale bar = 1 μm, (b) GO$_{1:1}$, scale bar = 1 μm, and (c) GO$_{1:2}$, scale bar = 1 μm

The TEM micrographs of the GO materials (Figure 2) revealed the anticipated layered structure of GO with a large sheet on top of the grids. The sheet resembles a transparent wrinkled, folded and silk-like veil due to the oxidation of graphite. This characteristic has been reported for the synthesis of GO by the modified Hummer's method regardless of the ratios of graphite to sodium nitrate [30]. The exfoliation of the graphite layer and introduction of defects on the GO layer is due to the introduction of oxygenic functional groups. From the TEM images, the level of transparency in the variants of GO might be as a result of the different ratios of graphite to sodium nitrate resulting in the intercalation of GO intermediates.
Figure 2: TEM images of GO samples: (a) GO$_{2:1}$, scale bar = 1000 nm (b) GO$_{1:1}$, scale bar = 1000 nm, and (c) GO$_{1:2}$, scale bar = 1000 nm

3.2. Crystallinity

The structural properties of the GO materials were examined by means of powder XRD. The diffractograms for GO$_{1:1}$, GO$_{1:2}$ and GO$_{2:1}$ are shown in Figure 3. There is a sharp diffraction peak for graphite at 2θ = 26.5° corresponding to a d-spacing of 0.34 nm of the graphite layers [31]. The characteristics of graphite at 42° disappeared after the oxidation process and a notable strong peak, for GO$_{2:1}$ at 2θ = 10.49°, GO$_{1:1}$ at 2θ = 10.47°, and GO$_{1:2}$ at 2θ = 10.48°, emerged. The increase in the interlayer spacing of GO to that of graphite arises from the introduction of O-containing functional groups, such as epoxide, hydroxyl, carboxylic and carbonyl groups, during the oxidative treatment [32]. The van der Waals interactions operative between the graphene sheets are weakened by the O-functional groups of GO and this increases the

distance between the sheets [33-35]. In the diffractogram for GO$_{2:1}$ a strong peak at 2θ = 43° is seen after oxidation indicating a random packing of the sheets [36]. The XRD results confirmed that the oxygenic functional groups were intercalated into the graphite interlayers.
Figure 3: Powder X-ray diffractograms for GO samples

Selected area electron diffraction (SAED) allows for a diffraction pattern to be obtained with a transmission electron microscope [37]. It can be used to find the d-spacing of the crystal planes and also to obtain information about the crystallinity of the samples. The brighter the spots, the more crystalline is the sample. The reciprocal of the radius of the SAED ring is the d-spacing of that ring, and the d-spacings for GO$_{1:1}$, GO$_{1:2}$ and GO$_{2:1}$ were determined as 0.2046, 0.1997 and 0.2131 nm respectively (Figure 4). From the SAED images, GO$_{2:1}$ was found to be the most crystalline of the three samples.
Figure 4: SAED patterns for (a) GO$_{1:1}$, (b) GO$_{1:2}$ and (c) GO$_{2:1}$

3.3. Graphitic and defective nature

Raman spectroscopy is an essential method for determining the defects, thermal conductivity, and strain in graphene and related materials [38]. The main aspects of the Raman spectra of graphitic C-based materials include the D and G bands, and their overtones. In the Raman spectra (Figure 5), the D bands of GO$_{1:1}$, GO$_{1:2}$ and GO$_{2:1}$ have very strong peaks at 1353, 1350 and 1347 cm^{-1} respectively. The D-peaks are associated with the vibration of sp^3 carbon atoms of defects that are randomly arranged on the GO sheets. The D-peak intensity together with a large peak width indicates significant structural disorder in the GO samples. The wavenumbers at 1595, 1593 and 1596 cm^{-1}, respectively, represent the G bands, which are related to the vibration of sp^2 C-atoms in the graphitic 2D hexagonal lattice. This gives rise to in-plane

optical vibrations that relate to the E_{2g} phonons from the bond stretching of the sp^2 carbon atoms in a graphitic 2D hexagonal lattice. The ratio of the areas under the D- and G-bands (I_D/I_G) is used to measure the graphitic nature of the sample. For these samples, the order of the I_D/I_G ratio is $GO_{2:1}$ (1.02) > $GO_{1:2}$ (0.97) > $GO_{1:1}$ (0.93). This result shows that $GO_{2:1}$ shows a greater defective density.
Figure 5: Raman spectra for GO samples
Figure 6: Thermograms of graphene oxide samples recorded in a N_2 atmosphere

3.4. Thermal stability

Thermal analysis was performed to assess the thermal stability of the $GO_{1:1}$, $GO_{1:2}$, and $GO_{2:1}$ sheets, since oxygen functional groups present in GO decompose on heating. Figures 6 and 7 depict the thermograms and derivative thermograms of the GO samples respectively. The first mass loss, that takes place at a temperature of 100 °C, is primarily due to the evaporation of adsorbed water that has interacted with the O-containing functional groups on GO [39, 40]. According to Dreyer *et al.* [41], the interaction of water with GO is by hydrogen bonding. The second mass loss arises from the pyrolysis of unstable O-containing functional groups such as carboxylic, hydroxyl and carbonyl groups to give CO_2, CO and H_2O [42, 43]. In $GO_{1:1}$, $GO_{1:2}$ and $GO_{2:1}$ this loss occurred at a temperature of 202, 212 and 216 °C respectively. The final mass loss at 614, 617 and 587 °C for $GO_{1:1}$, $GO_{1:2}$ and $GO_{2:1}$ respectively, shows that there is a reduction in the thermal stability of graphene oxide relative to graphite [44].

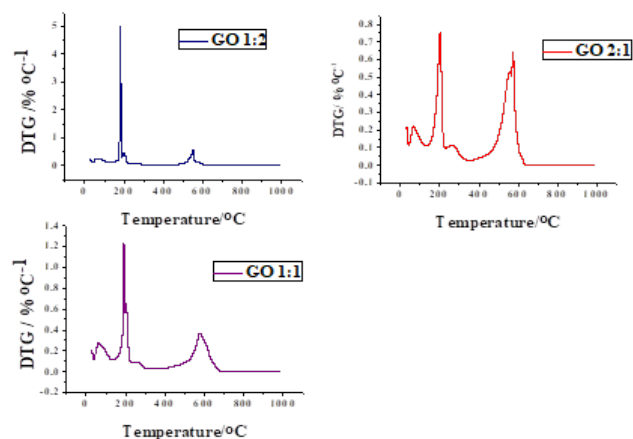
The derivative thermograms for the GO samples shown in Figure 7, revealed a small exothermic peak at 614, 617, and 587 °C. At 202, 212, and 216 °C, a larger exothermic peak is seen, and this is due to the loss of CO_2 and CO from the GO samples as a result of the decomposition of O-containing functional groups.


Figure 7: Derivative thermograms of graphene oxide samples

3.5. Textural properties

The BET method was used to determine the specific surface areas of the GO materials with N_2 as the adsorbed gas. In the first step, the materials were degassed at 120 K for 24 h. The results are shown in Table 1. The pores can be grouped into micro-, meso- or macro-pores, based on diameter. The results obtained for $GO_{2:1}$ (3.841 nm), $GO_{1:1}$ (7.350 nm) and $GO_{1:2}$ (19.861 nm) correspond to mesopores. The largest BET surface area was displayed by $GO_{2:1}$ (179.25 $m^2 \, g^{-1}$), followed by $GO_{1:1}$ (82.68 $m^2 \, g^{-1}$) and, lastly, by $GO_{1:2}$ (58.35 $m^2 \, g^{-1}$).

Table 1: Physical properties of the $GO_{2:1}$, $GO_{1:1}$ and $GO_{1:2}$ materials

Sample	Surface area/$m^2 \, g^{-1}$	Pore volume/$cm^3 \, g^{-1}$	Pore diameter/nm
$GO_{2:1}$	179.25	0.051	3.841
$GO_{1:1}$	82.68	0.054	7.350
$GO_{1:2}$	58.35	0.122	19.861
Figure 8: BET nitrogen adsorption-desorption isotherms

The N_2 adsorption-desorption isotherms for the GO samples are depicted in Figure 8. $GO_{1:1}$ and $GO_{1:2}$ exhibited type IV isotherms and type H3 hysteresis loops, signifying that the nanomaterials are mesoporous, as determined from the pore diameters. $GO_{2:1}$ also exhibited a type IV isotherm but has a H4 type of hysteresis loop. The type IV isotherm represents an adsorption isotherm with hysteresis related with capillary condensation in mesopores [45, 46]. The Barrett-Joyner-Halenda (BHJ) pore volumes of the samples are $GO_{1:1}$ (0.054 cm^3 g^{-1}), $GO_{1:2}$ (0.122 cm^3 g^{-1}) and $GO_{2:1}$ (0.051 cm^3 g^{-1}) (Figure 9).
Figure 9: The BHJ pore volumes of (a) $GO_{1:1}$, $GO_{1:2}$ and (b) $GO_{2:1}$

3.6. Nature of oxygen functional groups

FTIR spectrophotometric characterisation was conducted to explore the nature of the functional groups on the GO products and to confirm the formation of GO by chemical treatment of graphite (Figure 10). From the spectra of the GO samples, it is clear that large amounts of O-containing functional groups are present on the surfaces of the samples. The broad peak at 3430 cm^{-1} can be attributed to the free and associated O-H stretch arising from the presence of adsorbed water molecules and structural hydroxyl groups (–COH and –COOH) of GO [47]. The peak at 1728 cm^{-1} is assigned to the C=O groups. The peaks at 1626 cm^{-1} can be assigned to C=C groups that are due to the structure of the graphitic layer retained previously and after the oxidation process [48]. The peaks at 1220 and 1092 cm^{-1} are related to the C-O groups. From the results obtained, it is apparent that $GO_{2:1}$ shows the strongest and sharpest peaks in the C-O region, but these peaks are absent in the spectrum of $GO_{1:1}$ at 1220 cm^{-1}. The presence of C-O and C=O groups after the oxidation process confirms the successful functionalization of the samples, and the conversion of graphite into GO. This is in agreement with previous reports [49, 50]. Additionally, peaks at 1728 cm^{-1} due to the C=O stretch (COOH of carboxyl or carbonyl groups), at 1626 cm^{-1} due to the C=C stretch, and at 1092 cm^{-1} due to the C-O groups, appear in all the GO samples. Hence, there is evidence that GO was successfully synthesized, and the functional groups present on the surfaces of the GO sheets can furnish abundant adsorption sites, to increase the adsorption capacity for both organic and inorganic pollutants.

3.7. Elemental analysis

Elemental analysis was undertaken to ascertain the C, H and O elemental composition of the samples. From the results, it is apparent that $GO_{2:1}$ has the largest oxygen content of the three products (see Table 2). The oxygen content of $GO_{2:1}$ was 40.01%. Also, the C/O ratio for $GO_{2:1}$ is the smallest, also indicating the greater oxygen content. The H present in the GO products mainly arises from the presence of O-containing functional groups. The S is a residual impurity from H_2SO_4 used in the synthesis of the GO samples.
Figure 10: FTIR spectra of GO samples

Table 2: Elemental composition of GO samples

Material	C/%	H/%	S/%	O/%
$GO_{1:1}$	40.83	2.46	1.89	31.71
$GO_{1:2}$	42.35	2.59	1.97	32.02
$GO_{2:1}$	45.86	2.04	0.94	40.01

Table 3: Concentrations of acidic functional groups on the surfaces of $GO_{1:1}$, $GO_{1:2}$ and $GO_{2:1}$ as determined by the Boehm titration method

Sample	Base solution	Concentration neutralized/ mmol g^{-1}	Functional group	Concentration/ mmol g^{-1}
$GO_{1:1}$	NaOH	2.42	Phenolic	0.43
	Na_2CO_3	1.99	Lactonic	0.40
	$NaHCO_3$	1.59	Carboxylic	1.59
$GO_{1:2}$	NaOH	3.15	Phenolic	1.26
	Na_2CO_3	1.89	Lactonic	0.40
	$NaHCO_3$	1.49	Carboxylic	1.49
$GO_{2:1}$	NaOH	2.42	Phenolic	0.43
	Na_2CO_3	1.99	Lactonic	0.40
	$NaHCO_3$	1.59	Carboxylic	1.59

3.8. Quantity of acidic oxygen functional groups

The surface properties of the different GO materials were examined by using the Boehm titration method. The acidic properties of the GO variants are determined by the carboxylic, lactonic and phenolic functional groups (Table 3). These functional groups vary in their acidities and can be differentiated by neutralization with different basic solutions, namely, $NaHCO_3$, Na_2CO_3 and NaOH. The concentration of strong acid groups on $GO_{1:1}$, $GO_{1:2}$ and $GO_{2:1}$ was determined from the titre values of $NaHCO_3$, and that of strong and weak acidic functional groups was from that of Na_2CO_3 which gave 1.99, 1.89 and 1.99 mmol g^{-1} respectively. The concentration of weak acids was determined by the difference in the two titration values. The concentrations of the carboxylic acid groups were found to be 1.59, 1.49 and 1.59 mmol g^{-1} respectively. The overall concentration of the phenolic, and the strong and weak acidic functional groups was found from the

amount of NaOH neutralized. The total sum of the acidic functional groups on the $GO_{1:1}$, $GO_{1:2}$ and $GO_{2:1}$ surface was found to be 2.42, 3.15 and 2.42 mmol g^{-1} respectively. The phenolic functional group concentrations were determined from the difference in the three titration methods. From the results obtained, $GO_{1:1}$ and $GO_{2:1}$ are similar, whereas $GO_{1:2}$ contains significantly more phenolic groups than the other two samples. Therefore, the acidic surface functional groups of the samples are suitable for the uptake of cationic pollutants from aqueous solution. For each sample, the order of the number of acidic groups is carboxylic > phenolic > lactonic.

3.9. Adsorption properties

The effect of the adsorbent dose on the adsorption of Cu^{2+} from aqueous solution was determined by varying the mass of the GO samples from 10 to 60 mg at a constant temperature of 25 °C for 5 h. The results, shown in Figure 11, indicate that as the sorbent dose increases, the percentage of Cu^{2+} ions adsorbed onto the GO samples increases. An increase in the adsorbent dose with a higher percentage of adsorption arises from the increase in surface area and the availability of more binding sites for adsorption. The sorption of Cu^{2+} onto $GO_{1:1}$ was initially low compared with the other materials; this is possibly due to its surface area and the availability of active sites on the adsorbent surface. The other two adsorbents showed similar behaviour. Overall, the removal efficiency of the three adsorbents was high, but $GO_{2:1}$ showed the highest adsorption with a percentage removal of 59.7%.
Figure 11: Effect of adsorbent dose on the adsorption of Cu^{2+} onto $GO_{1:1}$, $GO_{1:2}$ and $GO_{2:1}$ [conditions: 20 mL of 20 mg dm^{-3} Cu^{2+}, pH 5.0, agitation speed of 150 rpm, equilibration time 5 h, temperature 25 °C]

4. Conclusion

In this paper, GO was effectively prepared by making use of a modified Hummer's method. In the synthesis, mass ratios of 1:1, 1:2 and 2:1 of graphite powder and $NaNO_3$ were used. This was done in order to determine if it would alter the number of oxygenic functional groups on GO. The elemental composition of the $GO_{2:1}$ material, synthesized with a 2:1 mass ratio of graphite powder to $NaNO_3$, showed the greatest oxygen content. As indicated by SAED analysis, the $GO_{2:1}$ sample was also more crystalline than the other two products. It also exhibited the largest surface area. However, the Boehm titration showed that of the three samples, $GO_{2:1}$ did not contain the greatest number of acidic O-containing functional groups. Oxygen-containing moieties improve the

hydrophilicity of GO so that it can form stable suspensions in aqueous media. The adsorption study revealed that the uptake of Cu^{2+} by $GO_{2:1}$ was greater than for the other two GO samples. Thus, the synthesis of graphene oxide with a smaller quantity of $NaNO_3$ offered a material with improved crystallinity, a larger surface area and a greater oxygen content, that showed enhanced adsorption properties. Therefore, this material was chosen for further use in the study of the uptake of both metal ions and dyes in aqueous solution.

Conflict of Interest

The authors declare no conflict of interest.

A B S T R A C T

The Internet of Things (IoT) is a technology that enables communication between everyday life using different sensor actuators that work together to identify, capture, and distribute critical data from the planet. Massive machines and devices are therefore linked and communicate with them. The use of resources in this area presents new challenges for this technology. The goal was to find a green IoT that focuses on energy efficiency and IoT efficiency. Green IoT is an energy-efficient way to reduce or eliminate the greenhouse effect of current applications. Radio Frequency Identification (RFID) is one of the Green IoT and Master IoT components that identifies a person or entity in a high-frequency electromagnetic spectrum when combining electromagnetic or electrostatic couplings. If the predictions are also correct, energy use issues arise as active battery-powered RFID detection needs to be addressed by incorporating new solutions for Green IoT technology. Past studies and assessments have attempted to evaluate RFID technology and its functions. Unfortunately, however, they concentrated on a single RFID view of technique and technology. This paper examines holistically and systematically the impact of RFID applications on green IoT, focusing on three categories: the challenges, environmental consequences, and the benefits of green IoT RFID applications. The impacts, performance and safety of RFID IoT applications have been carefully described. The benefits and examples of RFID applications, including their key advantages and disadvantages, are also discussed. Overall, this paper highlights the potential efforts of RFID to address existing Green IoT issues.

1   Introduction

Green power comes from natural sources such as sunlight, wind, rain, tides, plants, heat and algae as shown in Figure 1. These energy resources are renewable and naturally refilled to offer the most significant environmental benefit [1]. Conventional energy can be a valuable source of air pollution and emissions of greenhouse gases. The use of renewable energy helps to perform the following [2]:

1. Reduce the carbon footprint with purchased electricity.

2. Future price increases and volatility of electricity (individual products).

The purpose of green power is to find energy conservation measure in order to reduce energy consumption and increase the energy efficiency. Energy conservation means making use of less energy to accomplish work, namely reducing waste energy. Energy efficiency

has many advantages: reducing greenhouse gas emissions, declining energy demand and reducing our household and economic costs. Although the use of renewable energy technologies also improves this, increased energy usage is the simplest and often most efficient way to reduce fossil fuel use. There are enormous opportunities to enhance productivity in every sector of the economy, whether it be infrastructure, transportation, manufacturing or energy generation [3]. In reality, without Internet of Things (IoT), it isn't easy to imagine the future of renewable energies. Today sensor-based technology and data science enable wind farms and solar fields to be productive and automated. Green IoT technology programs should be taken into account because of the growing perception of environmental issues worldwide. The Greening IoT definition refers to innovations that make the IoT ecosystem healthier and environmentally pleasant through the use of facilities and storage that enables subscribers to capture, store, access, and handle different information.

Figure 1: Green Power Generation [1]

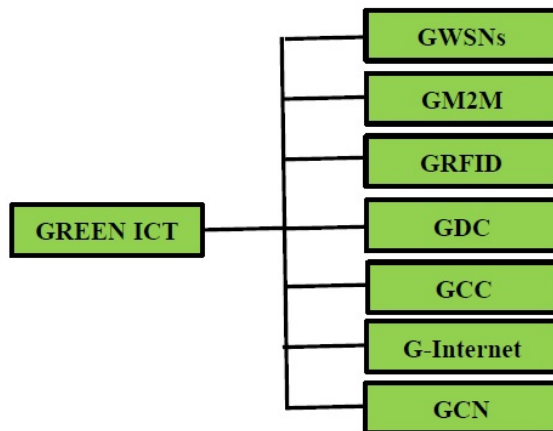
The technology that enables green IoTs is called information and communication technologies (ICTs) [4]. ICTs will cause climate change in the world because the rising application of ICT has used much more energy [5, 6]. The emphasis on sustainability for ICTs has been on data center optimization through infrastructure sharing techniques that improve energy efficiency, minimize CO_2 emissions and e-waste disposal [7]. Greening ICT enables green IoT technology which includes green wireless sensor networks (GWSNs), green machine-to-machine communication (GM2M), green RFID (GRFID), green data center (GDC), green cloud computing (GCC), green Internet (G-Internet), and green communication network (GCN) as shown in Figure 2. Greening ICT offers green IoT technologies. Green ICT innovations play a crucial role in green IoT and offer many benefits for society, including the reduction in energy used to develop, produce, and distribute ICT devices and equipment [8].


Figure 2: Green ICT technologies [8]

Green IoT consists of aspects of nature and exploitation. Green IoT focuses on reducing the use of IoT resources and CO_2 emissions, which are essential for creating an innovative and prosperous world of intelligent everything. As Figure 3 shows, the green IoT design elements apply to computer creation, energy conservation, communication protocols, and architectures for networking [9]. It is possible to use the IoT portion to remove CO_2 emissions, minimize pollution, and increase energy efficiency [10]. In networking, Green IoT aims to decide where the relay is located and how many nodes

meet budget constraints and energy saving [11]–[12]. For achieving green IoT, there are three principles, namely, design technologies, leverage technologies, and enabling technologies. Build technologies that apply to computers, communication protocols, network interfaces, and interconnections for energy efficiency. Leverage technology relates to reducing emissions of carbon and rising energy efficiency [13]. By reducing electricity, toxic emissions, use of resources, and pollution, green IoT has become more effective due to green ICT technologies. As a result, green IoT ensures the protection of natural resources, minimizes the effect of technology on the environment and human health, and dramatically reduces costs. In reality, therefore, green IoT focuses on green development, green usage, green design, and green disposal [14].

Figure 3: Green IoTs Environments [9]

RFID is a complementary solution to green IoT technology to save energy. RFID uses radio frequency to transmit, identify, classify and track data between readers and moving objects. It is fast and does not require a physical view or connection between the reader/scanner and the object to be inspected. The operating cost factor is deficient low and can use in many applications such as healthcare, manufacturing, inventory management, shipping, retail sales and home use [15]. RFID technology internal divided into two parts, namely RF communication; reader/tag protocols and middleware architecture, where RFID tag can be attached to almost anything such as items, cases or product palettes, high-value goods, vehicles, assets, livestock or personnel. RFID tags divided into two sits; which is a passive tag and an active tag. RFID middleware is RFID's software that exists between readers and enterprise/business applications. Middleware has several functions and plays an essential role in the operation and management of RFID systems. Middleware handles RFID readers and printers and communicates between these devices and business applications, as well as manage, filter, aggregate, and understand data derived from RFID tags [15]. RFID application used in manufacturing and processing for supervision, production of warehouse processing and fulfillment orders. In supply chain management, it should face in Inventory Tracking and Logistics management system. It also used in local controls for customer inventory and views; and automated checks with reverse logistics which benefit the environment. Whereas securities applied on access control, counterfeiting and theft control/prevention [16]. However, there is little discussion in the existing literature on RFID management in the environment. Is seen that ICT harms the environment [17], and RFID, as part of ICT, has gained a reputation

[18] as one of the leading computing technologies, using sufficient energy to impact the environment negatively [19].

The contributions of this paper are summarized as follows:

1. A detailed review of current and recent RFID literature on IoT, notably the Green IoT, in order to show that RFID can be part of the green IoT, not only for the benefit of the economy but also for the benefit of the organization, but also to improve responsible IT practice.

2. As this paper reviews the application of the Green IoT study proposed by RFID in recent years, it also outlines some of the early research related to this field.

Section 2 provides a summary of some IoT device RFID technologies. Section 3 Discussion about the security of RFID and addresses RFID implementation issues and environmental consequences in Section 4. In section 5, the benefit of greening IT. The future work of RFID in Green IoT is discussed in Section 6, and Section 7 outlines the study's findings.

2 Studying RFID Technology in IoT Application

The Internet of Things (IoT) intended to describe a range of technologies and research disciplines that enable global connectivity through the world's physical objects [20]. Activation technologies such as RFID, sensor networks, biometrics, and nanotechnologies are now widely used [21]. The IoT implemented in real implementations for different applications such as smart grid, e-health, and intelligent transport. RFID is a stand-alone technology used to enable various systems to perform functions based on object recognition, data recording, and different control objects [22]. The iconic RFID system consists of two parts: a tag (transmitter/receiver) and a reader (transmitter/receiver). The tag contains a chip attached to an object for detection and serves as an object identifier. Instead, RFID readers regularly exchange information with RFID tags using radio waves [23]. The main advantages of RFID technology are automatic object recognition, data acquisition and cost reduction in various activities [24]. The distributed RFID readers around the world are connecting to the Internet according to an appropriate routing protocol. Readers can then exchange information to identify, track, and monitor objects based on the tags they carry. Instead, IoT refers to virtual presentations in the IoT architecture, where identifiable objects are called "things". RFID is a prerequisite for the proper operation of an IoT system [25]. IoT is a global infrastructure that connects and ignores the distance between virtual and physical objects based on data usage and routing capabilities. The IoT architecture consists of three layers, namely the service or application layer, the network layer, and the perceptual layer, where the level of perception includes real-time information and the Internet of Things [26]. This layer uses sensors, wireless sensor networks, tags, RFID systems, cameras, GPS, smart terminals, EDIs, and creators to collect and display information about objects in the physical world. RFID tags, readers and application systems are composed of RFID systems. RFID systems are fast and effective for the electronic identification, control, and identification of different artifacts.

RFID uses wireless transmission to send a signal for an RFID tag that responded to a data collection reader linked to the host computer's data for analysis by a single ID code [27] RFID application functionality divided into three categories: control, tracking, and supervision. Monitoring concerns the current device status. For medical circumstances to be detected, irregular behavior and alarm must be an identifier. Tracking sees moving objects and provides a modeling sequence for every location of the data. Control refers to the evaluation and monitoring carried out without the awareness of the object [28]. RFID is used to prevent misplacement or to locate items quickly. One approach is to track the movement of objects in the database. For example, an RFID reader may attach to a door in a building between rooms. Thus, the location of the object can be determined by analyzing RFID reader recordings. It mainly used in supply chain management systems, item monitoring processes, and industrial process control. 3 Great advantages of identification of RFID supply chain properties as seen in the following Table 1 [29]. The use of RFID is also developing in manufacturing, agricultural management, health care management and tele-medicine, maritime operations, management of payment transactions, and others.

Table 1: 3 Great advantages of identification of RFID supply chain [29]

Item	Advantages
Increase the visibility of assets	RFID asset monitoring to increase inventory usability and visibility. This ensures that RFID tags can be read from all over the facility so that workers can easily display each item's location and value. Supplier chains can overcome issues created by bad management, misplaced components, tracking and manual process failures by increased transparency. Naturally, it can easily move things and make decisions about fly changes.
Improve employee productivity	RFID technology workers do not have to search for any items. No wasting time on tedious processes like scanning individual barcodes, finding the wrong tools and devices, and calculating inventory. This technology will increase the speed of sales of jobs and projects, lower labor and transportation costs, and improve the plant's overall productivity. Manufacturing and shipping products in unmanaged facilities are challenging and slow. By eliminating manual steps, human error and monitoring can avoid. Corrections can take a long time to improve inventory and asset visibility.
Reducing risk, theft and loss	RFID asset tracking to quickly and easily access inventory information and locations to track during items storing, distributing, or replenishing. With this type of visibility, there is little room for mistakes or mischief. Track each asset's movement in the facility to consider all items and pallets, minimizing costly risks and reducing misalignment's and losses. Struggle against counterfeiting and theft; Promote callbacks. It is imperative to avoid such errors as much as possible, since fixing these errors can lead to litigation, high fines, or loss of customers, as well as time and money. Full transparency and real-time information on inventory and assets increase profitability for significant organizational and productivity improvements.

2.1   Review Papers of RFID applications

This section discusses recent studies related to RFID applications in the IoT world.

1. In [30], building the Green Campus in IoT Architecture, RFID technology is used to detect students entering the lab. The system will read, and store data related to students or any-one entering the lab. Middleware acts as a connector between temperature sensors, air conditioners, RFID, and computers [31]. Each of these tools has its information. This information is used to determine the number of labs that should open to students, when the air conditioner needs to turn on, and finally, to monitor computer usage correctly [32]. The effectiveness of this system is when:

   - Laboratory management runs smoothly according to consumer demand.

   - The computer management mechanism can adequately monitor to save energy on laboratory equipment.

   - Energy-saving can do excellently when the air conditioner was only functioning when the laboratory temperature reached.

2. In [33], the System of global positioning and geographical information, RFID, general packet radio service and webcam combined into one device. The RFID reader in the camion reads both the customer and the bin details [34, 35]. This system improves waste management and decreases waste emissions resulting in ozone pollution [36].

3. Researchers in [37] introduced a new authentication strategy for home health applications using low-cost RFID tags. For systems where RFID tags need not be measured, only data stored for their storage sent. A tablet container has stored with the RFID tag inside the patient. The RFID reader receives the details when the patient recovers the [38] bag. In the RFID tag, the information is encrypted. Only valid ID tags and ID readers can decrypt the data decryption key – valid RFID tag ID and RFID reader, which generate the use key. Authentication between RFID tags and readers of RFID will combat several attacks, including tag-spoofing, reading readers. One of the benefits is that it reduces the likelihood of human error in data collection and that doctors can also provide reliable information on patients [39].

4. The environment, including the distribution system, has changed considerably in the past few years in [40]. With consumer demand changing, distribution structures are becoming increasingly centralized and globalized, and public changes such as deregulation, innovation and IT dissemination are moving forward. Simultaneously, there is a substantial demand for reducing CO_2 in logistics processes to solve global environmental problems. As a result, RFID (Supply Chain Management) technology was designed to use CO_2 reduction levels, deemed an impact identification object, to be identified and thought that improvement would be a criterion. To deploy an SCM with high efficiency, the information would be necessary, namely in real-time, which is a turning point for success

or loss. In this respect, the RFID tag can be a useful tool for automatically defining status by merely placing at the point of departure or arrival items, collapse containers and pallet vehicles using RFID technology. This process would help to understand conditions in real-time, such as the transportation of stocks and shipments [41]. They, therefore, expect RFID to be a practical tool rather than an existing barcode system and argue that the introduction of RFID is a new way to view the information in the SCM. The CO_2 reduction ratio is estimated by researchers as a function of transport expenses, with decreased labor costs, thus, reducing transport expenses. The amount of energy used, such as a roadway, is commensurate with transport weight (t) and distance (km). It means that transport costs and energy consumption are positively correlated. Since CO_2 is proportional to the amount of energy consumed, emissions of CO_2 may also decrease if power is reduced. The decreasing costs of transport can thus reduce CO_2 emissions, with a definite link between energy reduction and CO_2 emissions [42]. Consequently, the transport CO_2 emissions reduction rate was 3.2% as an effect of RFID introduction.

5. In [43], while metal fractures in the automotive industry have been a topic of productive study, plastic recycling in vehicles is poorly understood. It is now key to effective recycling of vehicles, due to legal requirements. Besides, the key problems faced are recognizing plastics and the technological standard of logistics activities, as well as scarce resources related to plastics. Therefore, authors in [44] introduce the RFID framework that automatically recognizes, register, distribute, and search for information during the product life-cycle. The research produces an efficient decision support solution (DSS) in a case study on automotive plastic recycling. DSS has applied during the life-cycle of the drug. It can be divided into three phases depending on the product life cycle management (PLM), initial life expectancy (BOL), life expectancy (MOL) and end-of-life (EOL) of the contemporary product [45]. BOL functions as product design, a manufacturer's preparation, and process management. MOL is used to assist with product repair, condition diagnosis, and prognosis. At the other hand, the classification of EOL has many meanings, including the duty to comply with economic benefits and legal requirements. The DSS method is as follows [46, 47]:

   - Throughout the BOL and MOL phases of the product life cycle, the flow of knowledge completely facilitated by knowledgeable systems such as CAD / CAM, Product Data Management (PDM) and other Knowledge Management systems used successfully in the Automotive Plastic Recycling industry.

   - Often the knowledge that comes to the consumer about the product is incomplete during the transfer process from MOL to EOL.

   - Data sources from MOL tell BOL that drug producers disrupted after product sales. The findings are typically based on BOL data, or limited but imperfect practical experience, based on full knowledge of past transactions.

Then, experiments used to produce missing information, but the cost of EOL operations increased significantly.

- RFID technology is then used to fill the knowledge gap and make product information reliable, accessible, timely, complete and available whenever needed during its life cycle. Different information can be collected and transmitted using RFID technology via MOL and EOL phases.

- Using the unique identifier stored in the RFID tag, EOL will obtain the information required to evaluate the recovery path from the product life-cycle information service. At the end of the support phase, the data collection unit is integrated to collect information from the stores using RFID technology.

6. Researchers in [48] provide the RecycleBank with the resources it requires to organize recycling activities for households, using RFID systems to allow municipalities to calculate the number of recycled materials per household. They have created a community-friendly approach with advanced, creative technology to tackle the rising cost of waste collection. Weight of recycled plastic turned into incentives for RecycleBank. Hundreds of local and national participants can award it. In collaboration with Texas Instruments, RecycleBank offers an RFID that adds low-frequency RFID tags with exact recycling containers and includes integrated RFID readers fitted to a counterbalancing system [49]. RFID tags developed and implemented for RecycleBank, stores Serial Number (referring to the name and address of the container owner), reads and data transmitted to the internal computer of the vehicle. The data collected are then transferred to the data collection and processing system of RecycleBank. Personal data (name, address, etc.) not scheduled for the tag. Only the recorded serial numbers are kept in the secure database of RecycleBank. The proprietary RFID tag stores provide unique advantages for waste and recycling applications with low-frequency technology as a weather-resistant, all-weather, secure solution that works in snowy, wet, or harsh environments throughout the world. Labels must be physically cute while preserving their technical characteristics over the life of the [50] container. The results are as follows:

- Within one week, the recycling rate in New Jersey, Cherry Hill City, increased by 135%. The average household recycled 12 pounds of recyclables before RecycleBank. Homes now earn an average of over 26 pounds each week.

- The city of Wilmington, Delaware, has been recycling in just six months from 0% to 37% using the RecycleBank programme.

- Elk City, New Jersey, averages 16 tons per week before RecycleBank of recyclable material. The municipality generates an average of 42 tons of recyclable material per week after the usage of RecycleBank, a rise of 136%.

7. The case study in [51] demonstrates a highly advanced waste electrical and electronic equipment reuse and recycling pro-

gram (WEEE). This center is named the Multi Life Cycle Center (MLC), using state-of-the-art advances in automation and IT to provide cost-effective and environmentally sustainable processes. WEEE is back to a valuable commodity [52]. IT and communicators, household appliances, electrical and mobile devices, toys, and recreational equipment are product categories subject to reuse. All other classes of items are stored and recycled. RFID technology is used for communication and organization, together with reverse logistics systems. This technology can be used as a monitoring device that transparentizes and prevents misuse of the WEEE stream. Furthermore, container level measurements are currently being tested, so that it can improve the collection route of the truck and prevent theft. A special reading station is located at the collection point to allow continuous monitoring to collect RFID information [53]. IoT is the link to the Internet of objects utilizing several information recognitions tools such as RFID, infrared sensors, global positioning systems, laser scanners and the identification of certain system information according to the accepted protocols. The computer is a large network. IoT can be used to define wisely, locate, map, control and manage to share information and communications [54]–[55]. Main IoT technologies, software, research and development technologies, external layers, network layers and device layers.Table 2 displays main perception layer technologies.

Table 2: Key technologies in the perceptive layer [53]

Key Technology	Performance Description	Application
RFID	Recognition and identification of objectives. Its purpose is to describe the object.	Application stage
Sensor	Sensitive organs, providing raw data.	The exploratory stage
Intelligent embedded technology	Intelligence is the target of IoT.	Experimental stage
Nanotechnology	Enables the interaction and connection of small objects and reduces system power consumption	Research stage

8. IoT requires finding, scanning, monitoring, and handling, and not just "connecting objects." As RFID is a "speaker" technology, RFID technology plays a vital role in critical technologies in the IoT layer of perception [56, 57]. RFID technology is, therefore, the first choice to establish a full system for IoT identification. EPC encoding, RFID EPC systems and EPC network systems are critical applications of RFID technology with RFID tags in the "IoT" EPC environment. In addition to handling individual objects, IoT encoding discovers objects at any time and enables coded requests, statistical tests, unique e-commerce categories and open information for objects. "One single-code entity." EPC encoding technology [58, 59] can best serve this need. The EPC RFID framework is a module for collecting codes automatically and shapes the EPC information network systems for local internet networks.

In the meantime, the global internet network is a platform for handling and flowing knowledge [60].

9. The goal of the analysis in [61] is to establish an overview of current RFID research from an IoT overview. The analysis includes passive UHF (860-960 MHz) devices (e.g. low battery) that can provide an effective sensor network to track human health and control the efficiency of the controlled environment [62, 63], with sufficient measurements and readings. Environmental sensors that calculate physical parameters such as temperature, humidity, and toxic substances may calculate the health of the environment and evaluate their human health relations [64]. Wearable and implantable labels offer more contextual knowledge about a person's in-room appearance, activity, contact with the individual, and innovative applications based around the body. Data on the health status of artificial organs can be produced [65]. When operating with special compounds or inter-linked with chips which include detection functions, passive RFID tags can detect changes in environmental chemical / physical parameters. Autonomous RFID tags are an important instrument for designing body-centric healthcare systems that are fully transparent to the consumer [66, 67] for touching and approaching the body. Most specifically, wearable passive UHF tags have long been technical tabus because of the significant power outages caused by human tissues. Previous body center network studies are mainly focused on active computers [68, 69]. Over the past five years, the development of commercially available low-power RFID (COTS) chips has changed gaming entirely, creating and testing of several prototypes of body-centered, sensitive, distance-readable tags compatible with remote-controlled monitoring [70, 71]. Since high electromagnetic losses characterize the human body, antenna power output is meager and the required reading distance for passive devices. The performance of the antenna power is deficient. This combination of wearable and ambient tags helps to track the situation of children, people with disabilities, and the elderly, identify human behaviors, and build passive RFID systems in a fully-passive manner [72, 73].

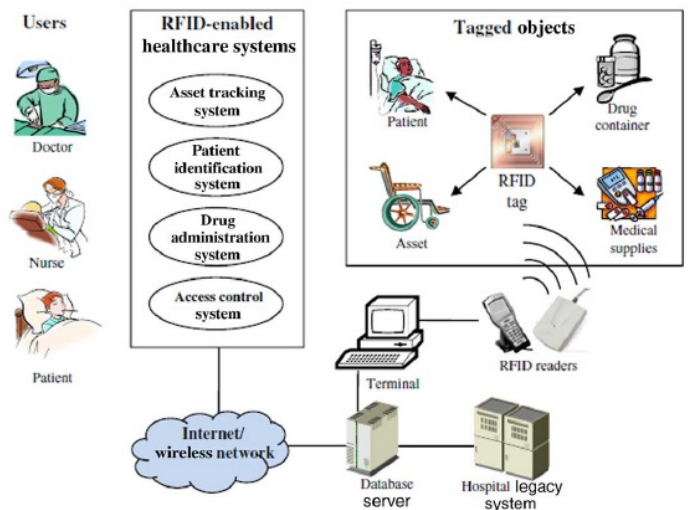
10. Researchers in [74], which explicitly addresses the safety criteria for RFID validation schemes, have submitted an authentication scheme based on elliptical curve cryptography (ECC) suitable for their protection and health care climate. The aircraft device Classify Friend or Foe (IFF) was the beginning of the RFID technology used during World War II. The benefits of RFID are that it is easy to use RFID tags, has read/write power, does not need long-distance RFID readers communication, and can simultaneously read multiple RFID tags [75]. RFID technology in the healthcare field is applied to the verification [76, 77], birth and patient recognition [78], medical treatment detection and confirmation [79], healthcare centers [80] and surgery sites [81]. A typical healthcare network with RFID technology [82], as shown in Figure 4. RFID authentication is one of the most critical measures to ensure secure communication inside the RFID system. However, there is a wide range of security features in the process of sending messages between RFID tags and RFID readers. Some researchers have established the safety criteria for secure RFID communication and reliable and effective authentication schemes when it is applied [83]. Mutual authentication between RFID tags, RFID readers, and servers are among the security requirements. Besides, before transmission, the confidentiality of sensitive information contained in the RFID tag must be encoded. The identity of the tag must also be protected for the protection of the owner [84]. The next requirement of protection is to validate the RFID authentication scheme during the life cycle of the RFID tag that gives alerts updating the confidential details that have shared during the implementation of the authentication scheme. It meant that the verification scheme would be invalid if the modified coordinate is lost. To ensure secure transfer [85], Transfer Protection requires an RFID authentication scheme. For certain RFID authentication systems, if the enemy successfully retrieves sensitive information from the RFID tag, it can detect the last position in the tag. It will severely breach the privacy of the user. As the RFID tag validation process is required, scalability, RFID authentication scheme must scale, an RFID device server must find the corresponding records in their database [86].


Figure 4: Typical RFID-based healthcare system [82]

As the number of RFID tags increases, the device does not scale if the workload of the search algorithm is significantly increased. RFID authentication processes must defend against multiple attacks, duplicate attacks, tag defense attacks, server spoofing attacks, mid-level attacks, cloning points, and others. Resistance to attacks to ensure the security of RFID communication [87]. The researchers found that the ability and memory of tag calculations were minimal when comparing the performance and safety aspects of the ECC-based RFID authentication schemes to determine whether ECC-based RFID validation schemes are adequate for practical applications. Cost measurements, communication costs, and storage requirements for practical applications are, therefore, important. The researchers investigated and found that most of the current ECC-based authentication scheme proposed

cannot comply with all safety requirements. To ensure secure contact, researchers will first build acceptable safety models for ECC-based RFID systems by using ECC-based techniques in RFID systems. They then developed an ECC-based RFID authentication system that protected security models securely.

11. IoT consists of an increasing number of interconnected smart devices that reduce hardware costs and architectural complexity, where communications occur at any time or anywhere. The reading of ultra-high frequency RFID tags is a cost-effective operation because of its technology and the reading system for these frequencies. The researcher proposes an architecture that reduces the cost of ultra-high frequency RFID reading equipment operating with cloud computing and micro-services in an infrastructure. Due to the scalability and management of large quantities of data that can be produced using ultra higher frequency RFID tags and the nature of the architecture linked to the theme of the research, the use of cloud and micro-computing was required [88]. To collect data and analyze the findings, the architecture proposed to address the research questions intended for the case study of this work has been created. After the RFID read tag has been detected by SparkFun Simultaneous RFID Reader — M6E Nanoboard, the Asset Micro-service must interact with the Read microservice to see if a similar physical object remains. This test takes place via the RFID tag area Electronic Product Code (EPC) present in the Asset microservice relational database and the Read microservice NoSQL database. Since the RFID tag EPC is a unique identifier, this is the only field needed to check whether an RFID tag is in the Asset Microservice database, identified by the SparkFun Simultaneous RFID Reader — M6E Nanoboard and registered in the Read microwave database. The monitoring microservice is used to view the collected data after telemetry information has been collected from the SparkFun Simultaneous RFID Reader — the M6E Nano Temperature, Position and Intermittent Connectivity Information through Microsoft Azure, the IoT Hub service. The result obtained from the case study as below:

- The board was able to read RFID tags with a distance of approximately 1 m and could read approximately 100 RFID tags per second only with its internal antenna. Having an external UHF antenna together with the board will improve the board's reading power. If the reading distance has a minimum value of the required project execution, the use of an external UHF antenna is needed.

- There were no charges for the software provided by Microsoft Azure. The non-cost is due to the use of all the free layer services. The cost will slowly increase as additional resource resources such as further computing, memory, or monitoring of other IoT boards increases.

3 Security of RFID

Some of the advantages of using an RFID device is that it performs tasks to classify, achieve efficiency and simplify its implementation automatically. Even these added benefits do not guarantee personal data protection. Therefore, when designing an RFID device, several criteria must be addressed to provide the highest degree of security. They are exchanged for the user or included in tags sent to the backend server. Data is private, accessible, and not modifiable (CIA). The safe maintenance and operation of the entire network A fully secure network continue to be a challenging challenge with numerous attacks and threats which that happen in various scenarios at the same time. RFID forgery: RFID can split into three groups by processing ability, which are simple tags, symmetrical key tags, and public-key tags. Basic tags are not encrypted and can be fooled easily. Supply chain and the operation of the travel industry are well established. To access or test product reliability [89], an attacker might write information to a primary black tag or change the data in a simple write tag. Many articles listed in the solution identified typical attacks which can occur on RFID systems during the investigation. Some of the most common attacks are shown below. In the literature, many steps and features have been suggested, including pseudorandom solutions, anonymous authentication schemes, symmetric and asymmetric cryptographic algorithms, and other hash-based systems. Several review studies related to the following security attacks are discussed in subsection 3.1.

1. Eavesdropping
   These attacks include eavesdropping on the network and recording examples of all interactions between the tag and the reader. The primary purpose of this attack is to collect data and use the information collected.

2. Denial of service
   Denial of service is the creation of a device that cannot use in an RFID system. An example of a use case for this attack is spam, which is sent to readers requesting a specific tag frequency to deactivate the reader.

3. Cloning
   The primary purpose of a clone attack is to spread RFID tags. Reverse engineering technology allows it to change and duplicate the label by extracting all the functions of the vehicle, precisely the secret key.

4. Tracking
   When detecting attacks, the tags voluntarily tied to a person, and their presence and movement are detected while the attacker's leader is inside the tag.

3.1 Security Review Studies

1. The IoT is the opportunity to have a means of distinguishing everyday objects and another way of interacting with each other. There is an extensive range of IoT technology domains like smart houses, smart cities, wearables, e-health, and others. Thus, tens and even hundreds of billions of devices are related. These machines would have intelligent capabilities for collecting, evaluating, and even making decisions without any human contact. Under these situations, protection is a supreme necessity, and authentication under particular

is of great importance given the harm that might result from a malicious, unauthenticated device in an IoT network [90]. This paper provides a general overview of the security issues and requirements in a layer-based approach in the IoT context. Instead, it offers an updated survey of the various IoT authentication schemes. It contrasts and analyzes the current authentication protocols through a multi-criteria framework, showing their advantages and disadvantages. The researchers found out the following:

- The authors proposed a lightweight RFID tag authentication protocol based on Physical Unclonable Functions (PUF) functions. There are three transactions in the protocol: tag identification, authentication, and update. The tag reader identifies the tag in the first transaction. The second transaction is a test where the reader and the tag verify each other's validity. The latest used key for the next check should be retained in the last transaction (Update).

- The authors have allowed the authentication and perceptibility of the IoT devices to secure the supply chain of connected devices through an RFID-based solution. The process of authentication consists of two steps: the verification of the connection between the tag and the IoT system and the tag perceptibility.

- The RFID reader is connected to the Internet in an IoT-RFID network to form an IoT end unit. On the other hand, it is linked via RFID communication protocols to the tagged objects. The tagged object is portable and transfers from a reader to another, so authentication is necessary to verify another identity. The device is vulnerable to security attacks, such as impersonation or clone attack, because of the absence of cryptographic features in RFID. The authors proposed an authentication protocol to be used with lightweight encryption algorithms in the case of IoT-RFID use.

- The authors suggested an offline authentication for PUF-based RFID-tags to prevent cloning attacks on the RFID tags. It combined security protocols for identification and digital signature. The tag generates a hidden key in authentication by questioning the PUF and gathering the answer. Such a reaction with the support data will create a certificate that will be stored inside the tag's ROM. First, the tag is authenticated by the verifier verifying the certificate validity. The authors proposed a PUF-based authentication scheme for the classic RFID tags to provide anonymous authentication for RFID systems. Then, they created an enhanced PUF noisy atmosphere scheme. The main downside of this scheme is not to re-feed the server with new Challenge-Response Pair (CRP) when the current pool is empty.

- The authors suggested a shared authentication scheme for IoT RFID-based applications in fifth generation of mobile networks (5G) by providing a cache to the user, storing the keys (used for authentication) for the tags recently visited, speeding up authentication, minimizing

computation costs and the storage security. On the other hand, the authors in [91] has been proposed authentication methods for heterogeneous networks which can be applied to RFID systems as well.

2. The detection of ultra-high frequency radio frequencies (UHF RFID) is becoming a central technology in the Internet of Things. It allows batteryless and wireless nodes to be deployed like sensors and actuators. Safety is a critical issue because of its possible transmission range is greater than 10 m, and the ability to hold sensitive information. For this reason, in 2014 the International Organization for Standardization released several UHF RFID crypto packages under the ISO-29167 standard. Nevertheless, no UHF RFID readers are currently available. In order to cope with the rapid growth of software-defined radios, "simple" and versatile readers are required. This paper illustrates a way to implement the decryption of ISO 29167-19 RAMON on a prototyping reader platform based on National Instruments PXIe chassis. PXIe programming is based on LABView. The first LABView implementation revealed that decryption only requires 51.3 s. It would mean being able to process just one tag per minute. Therefore, a prototyping platform intended to conduct practical experiments in the creation of new technology in UHF RFID systems is not suitable. Therefore, they prefer a different approach. The LabVIEW also acts as a platform and monitors the transceivers which are integrated. Nevertheless, a TCP/IP connection to a Java application is also provided. This Java code is decrypted. A TCP/IP link is used to return the decrypted plain message to LabVIEW and can be further processed [92]. The results are as follows:

- The average time spent with LabVIEW in tandem with the Java app is 2.2 ms, which improves the time-optimized approach to LabVIEW by 23,318 times. Within LabVIEW, the principal difficulty is that large numbers are difficult to deal with since they are widely used in encryption. The problem is not limited to the implementation of the RAMON method by outsourcing the calculation in a Java program. The approach can be used for any encryption method and for other processes in LabVIEW which handle large numbers. In this way, the RAMON encryption can be incorporated into the existing reader protocol and a fully working, easy to adapt reader can be obtained. Particularly for UHF RFID systems, it creates entirely new possibilities for rapid growth.

3. The medium of contact between the tag and the reader is vulnerable to multiple threats in conventional RFID systems, including denial of service, spoofing, and desynchronization. Therefore, the confidentiality and validity of the data transmitted can not be guaranteed. In this paper, the researcher proposes a new RFID authentication protocol based on a lightweight block cypher algorithm, SKINNY (short for LR-SAS), in order to solve these security problems. The 128-bit block size and key size n SKINNY encryption algorithm are being used to test the implementation in passive 96-bit

EPC-encoded radio frequency identification systems. The tag and the reader need to be mutually authenticated when implementing the LRSAS protocol, and the SKINNY algorithm encrypts the information used by the tag and the reader for mutual authentication. The key is already stored during the initialization process. This paper selects a SKINNY lightweight block cypher that has the advantages of low hardware power consumption and low computational complexity based on ensuring safe encryption. It can be used in Things terminal equipment's low-cost Internet [93]. The results are as follows:

- The protocol conceived in this paper uses one of the algorithms for SKINNY encryption and can accommodate 96-bit EPC encoding. In the encryption process, the calculation time for the round function used by the SKINNY encryption algorithm is shorter than the calculation for Hash, ECC, and Present encryption. However, the overhead measure also applies to low-cost RFID tags. Additionally, the tag's overhead storage is 3 L which significantly reduces the tag's storage capacity compared to other protocols, and reduces the complexity of the storage structure's logic gate design. Besides, the protocol has five information interactions in the mutual authentication of the tag and the user, and the total amount of data collected and transmitted is 6 L, which is relatively high, thereby ensuring the efficiency of the information interaction.

- Concerning the number of logic gates equivalent, multiple versions of SKINNY have varying numbers of logic gates equivalent. This protocol uses version SKINNY-128-128; the equivalent number of logical gates is 2391, less than 3K. It can also be used in low-cost tags. Furthermore, the number of equivalent logic gates for other protocols often allows specific security attacks to become vulnerable.

4 Challenges and environmental implication of RFID application

RFID is an exciting technology, but it does pose many technological problems and implications.

4.1 Challenges

The challenges of RFID technology applications in IoT were divided into seven: collision problems, privacy and security concerns, interference issues, miscellaneous challenges, technical issues, interoperability issues and energy efficiency.

4.1.1 Collision Problems

Electromagnetic interference can cause tags and readers to fail, leading to wrong choices. For tags and readers using the same radio frequency channel, multiple transmissions between the reader

and the tag can cause problems in a collision. To recognize multi-tag communication to promote the implementation of large-scale RFID systems, a secure and active collision avoidance protocol is required—a database tree protocol, a binary tree protocol, a split system protocol and others. Nevertheless, not all protocols produce the requisite efficiency as their identification efficiency is less than 50% commercial. For a new, better protocol will look for the best features of the detection protocol [94, 95].

4.1.2 Privacy and Security concerns

RFID authentication tags and security issues can affect people and organizations significantly. Tags are not properly secured and they considered an easy target to eavesdropping, DoS strike, analyze traffic and others. Besides, unauthorized readers can view multiple codes, which can breach privacy, without single access control. Predictable perceptions of tags can accompany secure tags. Traffic analysis attacks may jeopardize the privacy of the user. Appropriate confidentiality and protection protocols are needed for RFID systems given the associated costs. Extensive work is underway to define and incorporate cost-effective protection and privacy protections to improve RFID systems' reliability and usability. Several light-weight protocols have been proposed, but still have high costs and low protection and do not completely solve security issues. An excellent work section is available to develop ultra-light encryption protocols for low-cost RFID systems [96].

4.1.3 Interference Issues

Recently, a very high-frequency passive RFID (UHF) system has received much coverage. UHF RFID systems are widely agreed that many commercial applications, such as supply chain management will revolutionize UHF RFID systems. In the 860-960 MHz band more popular supply chain companies like Wal-Mart and Tesco will promote the use of UHF RFID systems in supply chains. However, with this distribution, dozens or hundreds of readers will work closely together and trigger to severe interference [97]. The UHF RFID interference has three types: tag interference, reader-to-multi-tag interference and reader-to-reader interference. The specifics of the intrusion issues are shown below.

1. Tag interference
   It happens when the reader simultaneously supplies power to several tags, and each signal reflects the reader. Owing to the dispersion of dispersed waves, readers cannot differentiate between individual IDs and marks. Anti-collision mechanisms, called binary trees and aloha, are therefore essential.

2. Reader-to-multi-tag interference
   It occurs when the mark is at the intersection of two or more reader requests, and the reader tries to interact with the tag simultaneously causing the tag to behave and interact unwantedly.

3. Reader-to-reader interference
   These are activated when a signal from one reader hits another and can also take place if the readers' surveys are not intersected. Interference between readers can cause serious

problems when using UHF RFID systems, as remote reader transmitted signals are so powerful that precise decoding of messages transmitted by neighbouring tags is prevented.

Active, semi-passive and passive RFID tags add comfort and prominence to RFID technology in our environment. Such tags are cheaper to produce and can be small enough to suit virtually any product. The type of RFID device works is shown below. Readers and tags focused on wireless two-way communication. The reader transmits a signal in passive RFID tags which induces a current in the tag to supply power to the transmitter of the tag. On the contrary, an active RFID device does not require an induced current to transmit its presence. Wireless communication may create a difference between RFID and other wireless technologies that are used in the workplace or data center since other RFID technologies often operate in the atmosphere and cause significant disruption [97]. Two classes ought to consider for new action. First, interruptions prevent data transmission properly and reduce the efficiency of one or more devices. Second, the danger of interpreting one signal from one device is that data from another is valid. The key cause of this disturbance is the environmental implications of use. This problem occurred in the past when the RFID tags placed on metal or liquid containers. The tag is inactive in both cases and refuses to respond to the reader. Recent advances allow these problems with proper antenna and tunnel design to tackled during the planning process. The UHF system may cause interference with the radiation of the power signal. Passive systems, on the other hand, are less vulnerable to intrusion than active systems with markers continually shifting. Crosstalk between RFID and WLAN or WPAN such as Bluetooth is another interference scenario when devices have a joint or an adjacent frequency band. Several cases of interference between wireless microphones and wireless endoscopy recorded in the medical field [98, 99].

1. Active and semi-passive RFID tags
   It uses an internal battery for the circuit. Active tags use an array to transmit radio waves to the reader, while semi-passive tags depend on the reader for transmitting power. Active and semi-passive tags reserved for expensive items capable of reading long distances, transmitting high frequencies from 850 to 950 MHz and reading more than 30.5 metres. If the label needs to read from a distance, an additional battery can increase the name range to more than 100 metres.
   It occurs when the mark is at the intersection of two or more reader requests, and the reader tries to interact with the tag simultaneously causing the tag to behave and interact unwantedly.

2. Passive RFID tags
   It entirely depends on the reader as strength. These tags are read and produced for use up to 20 feet (6 meters) and with disposable consumer goods.

4.1.4 Miscellaneous Challenges

Several other issues prevent RFID devices from spreading too. The key issue here is cost. The RFID tags are more expensive than the [100, 101] written stickers. A further issue is the complexity of

the RFID system. They are owing to their high-reliability readers, and labels are not on the market yet. Moreover, there is no guarantee of accurate recognition. The incorporation of RFID systems into the current network is another big problem needing a solution for using [102], large RFID systems. The designers need to know the approach to incorporate the new RFID system into the current network in a successful development phase.

4.1.5 Technological Issues

Implementation issues are most apparent and should be dealt with immediately. Some papers dealing with technological issues such as durability, precision, and contact with metals are still in the pilot process. For DHL, read speed accuracy is not 100%, because Tag interaction readers do not comply with defined specifications [97]. Even, it is not feasible to prohibit maximum use of short contact tags. The concept in citeb101 is to make sure that the people do not forget the process of activating RFID devices.

4.1.6 Interoperability Issues

If the RFID device is not working alone, but in conjunction with other electronic devices, the issue of information becomes apparent. For example, an RFID Smart Vareflyt system can operate independently, but will not work if it combined with an existing data system [100]. This question occurs when the real data is different from the reported data, does not change, or involves correction from other sources. On average, the accuracy rate in Nestle Italy's system is only 80-90% [99], due to the order output depending not only on the role of the RFID portion but also on the RFID system and the entire enterprise policy [99]. However, one of the hardest problems facing RFID technology is privacy and security. As corporations and public agencies continue to search for collaborations, sharing resources poses obstacles that involve sophisticated organizational solutions. The most challenging problem in the case of Smart Vareflyt is not just the issue of data incorporation at the knowledge level, but also the exchange of information and resources and the application of competition law to the level of the company [100].

4.1.7 Energy efficiency

The energy-efficient passive tag in the RFID device is a preferred option because it used without the need for an on-board energy source. The selection of passive tags is, however, limited compared to the active tag, which used on a broader scale. Nevertheless, the inactive energy efficiency tag is still an open research field that needs to be addressed [103]. As power usage decreased, energy efficiency improved. Several studies on power usage when using the RFID technology are discussed below .

1. The first large-scale backscatter communication system was developed by researchers in [104] for reflecting signal from an RF source to synthesize data packets, which are then decoded by a receiver. It has two significant drawbacks, and the backscatter must first organize the information so that the receiver can transmit it at a signal force less than -135 dBm and work efficiently in the event of robust external interference. Secondly, backscatter signals developed using

simple, affordable standard hardware, which makes it simpler to implement and improve the design needed instead of dedicated receivers for costly backscatter signals (e.g. RFID readers).

- The result shows that wireless power consumption, including Wi-Fi, BLE, ZigBee, Lora, and SigFox, consumes 10-50 mW of electricity, which is 3 to 4 magnitude orders higher than the system's energy consumption. Backscattering technologies, including RFID, passive Wi-Fi, and LoRa backscattering technologies, however, consume just $9.25\mu W$ for continuous frequency-modulated chirps generation and harmonic cancellation.

2. Researchers in [105] introduce an on-board digital temperature sensor with perovskite PV-RFID. This sensor can transmit temperature data wirelessly under sufficient lighting within a distance of up to 4 m. It is converted from light with perovskite PV into ICs and RF signals that used as contact links. The user acts as a portal to the Internet between these hundreds of nodes.

- According to the simulation performance, the overall energy consumption of the sensor depends on the sensor load (the number of sensor measurements per hour). For instance, a 20,000 / hour measurement requires approximately $20\mu W$ of power (calculated with a constant current of $6/muA$ in stand-by mode and $30\mu A$ in 8 mm a 1,5V input voltage each measurement).

3. Photovoltaics (PV) for use by researchers in [106] are the use of photovoltaics (PVs) to increase the energy available during the day, enhance read range and detection capability and add to integrated circuits (ICs) with minimum additional electronics.

- The researchers found that the IC's additional power not only enhances the ability to disperse the RF energy needed for additional tag areas but also enhances the ability to measure and transmit sensor data. This versatile sensor is also suitable for long-term detection embedding in 3D structures if the battery can not replace it. Thus, using PV-RFID can build wireless sensors that are autonomous, inexpensive, and reliable over a long-range. The frequency of PV-RFID measurements is about eight times that of traditional passive tags. By reading a wide area of PV-RFID tags with a limited number of readers and antennas, it lowers the network costs. The PV-RFID sensor additionally records 0.14 million measurements in 24 hours. It shows how sensors can monitor and transmit critical environmental data at low cost, without batteries.

4. PLoRa, an environmental backcast architecture that enables a remote wireless link for IoT devices without a battery, is available from the researchers. PLoRa uses the current LoRa transmission as a new signal, modulates the new signal

into the standard LoRa chirping signal, transfers the data to another LoRa channel received by a remote gateway, and adjusts this original signal [107].

- The results of experiments show that the prototype of the PCB-PLoRa tag backscatters an environmental broadcast of LoRa that is transmitted from a local LoRa node (20 cm) to an entrance up to 1.1 km away, with data accessible indoors or 284 bytes every 14 minutes. Simulate a lower power FPGA 28 nm prototype whose digital baseband processor delivers 220μW in power consumption.

4.2 Environmental Implication

RFID tags are used for managing product movement from factories to store in cartons and pallets. RFID has a great many useful applications for the world. RFID also has environmental drawbacks at the same time. The next topic will concentrate on ways and concerns that help create useful solutions and reduce possible impacts on the environment.

4.2.1 Reduced traffic using RFID

In order to pay for tolls, RFID congestion, and area pricing systems now deliver major environmental advantages. Automatic charging reduces downtime as well as braking and acceleration at the mail stop. Through the use of RFID repeaters on the New Jersey Turnpike tolls, 1.2 million gallons can save annually, air pollutant emissions decrease, and travel times decrease dramatically [101]. London has lowered the congestion level by 26%, nitrogen oxide, and particulates (PM-10) by 15%, and oil usage inside the congestion billing zone by 20% [102]. With the surface charging network introduced in Singapore since 1975, circulation has dropped by 45%. In 2006, the Stockholm scheme had reduced carbon dioxide emissions by 10 to 14% [108]. While it is very effective to reduce traffic, air pollution, and energy usage, plans for congestion charges are not common. The framework became popular after implementation [107].

4.2.2 RFID transponders on curbside waste and recycling bins

The waste truck fitted with an RFID reading panel. The device recognizes the bin when a truck gathers it. In 2001, a German public waste management firm surveyed RFID schemes, unimplemented containers, and productive waste collection routes through data that were exposed and evaluated. The RFID system implemented reported an average increase of 2.85%. In cities with invoices focused on waste numbers, non-recyclable waste decreased by 35% on average, and total waste decreased by 17% cent on average. Contains recycling and non-recycling stuff [109]. As a result, almost half of the overall waste reduction accounts for a 35% percent drop in the garbage disposal, and the other half is for recycling. This finding is consistent with the US surrender program, which reduces municipal waste by 25-35% for disposal [110].

4.2.3   RFID for information on the consumer environment

Item level RFID tags may provide information about different goods as well as generic products. That sort of knowledge can use to identify tainted beef, poultry, or fast food. Regulators, the foodservice industry, and regular customers are helpful with this [111]. At the same time, users will test how far they have transported, greenhouse gas emissions, allergens, and much more. Manufacturers and retailers have commodity carbon labels where a UK Tesco supermarket network sets carbon labels on each product sold, calculating the amount of greenhouse gas released during the manufacture, transport, and consumption of each product [112].

4.2.4   RFID for refurbishment and reuse

The RFID tag increases the efficacy of recycling as the UPC process enhances companies' productivity in the supply chain. For example, battery labels may make the sorting of cell types cheaper and more effective for recycling. Electronic equipment labels may connect to websites that show how to disassemble the device. Tags on hazardous goods, such as household chemicals, will define the material, how, and where to dispose of these [113]. Attributes on consumer goods make it easier to sell products online and are an extension of how UPCs used in the one-way supply chain where the majority of items sold today have UPCs. This code is intended for revenue estimation as well as for inventory control [114], distribution, consolidation, and managing. For RFID, instead of being discarded with it, it will leave the object's security code. The product code will allow many kinds of recycling opportunities. It may create systems that encourage recycling or punish improper disposal by recognizing when recyclable (or harmful or valuable) products placed into the garbage (or garbage can or trash can). Recycling opportunities, such as bottling, are not new, but an automated product-based solution will minimize costs and promote for innovation [115]. RFID systems provide a modest incentive for recyclable low-value goods and a significant incentive for high-value and high-risk goods. One sidewalk recycling company will handle specific items electronically for different goods, different markets, and various geographic areas [116].

Product codes can be applied both as UPC and RFID barcodes. When a large amount of device is picked up in a curb or code and put into a truck quickly, RFID could be preferred over bar code, as RFID can read from other devices at the same time. The benefits of recycling not deemed adequate to justify the expense of the product-level RFID tags. However, if RFID correlated with an item for other purposes, the side benefits of RFID processing can be significant [117]. The use of RFID for electronics replacement, roadside recycling, smart household waste disposal, the management of product deposits and returns in stores and recycling centers, and the collection of waste and recyclables in incinerators, landfills and resource recovery plants addressed in many different applications.

- RFID for Electronics Refurbishment
  Electronic recycling companies typically recognize multiple labels, computer models, printers, or mobile devices related to the most crucial element of the faulty parts market in their product instruction codes. The recycling industry, the product supplier, or the whole industry union RFID labels in products

may use these instructions to connect with databases where both parties may learn how to recycle papers. Will major component can have its RFID tag so that repairs can easily recognize parts and updates [113].

- Item-Level Curbside Recycling
  The use of RFID transponders has addressed in waste management and recycling containers. Through extending this kind of method, residual or recyclable material can detect at the item level. It opens up a whole variety of reward schemes. Incentives (rebates and fees) sent to the customer based on what put on the bin. Municipalities can also pay recyclable collectors extra fees to transport dangerous and challenging things to handle, such as mercury-containing fluorescent lamps, and recycled collectors can quickly sell their collections if they know what they have in-depth. This approach raises problems of a technological nature. The objects in the bin are one or two feet of the antenna for recycling vehicles, and probably other side and rear products which can absorb radio signals. Although RFID tags can be detected theoretically in products in recycling bins and empty bins can be ejected in lorries, this has not commercially demonstrated.

- Smart Trash Cans
  The RFID reader can read each object in the container for home recycling tanks. Drum items may either be sold online or published by traders. Consumers and businesses will automatically check for waste material and schedule recycling services. Online retailers check for the recycling containers, buy recyclable and reselling items, give back some of the consumer's income, and leave vital recycling services (paper, plastics, artistry, metal). Home intelligent trash will play mostly the same role as the item level curb set. Intelligent home trash can be technically pure but probably a more expensive alternative than the identification of congestion objects.

- In-Store Recyclables Collection
  RFID allows the storage in shop or recycling centers of recyclable items. Some retailers use recycled items already. Recycling Corporation Recycling Corporation (RBRC) provides electronics and electronic stores with batteries throughout the United States and Canada. For different computer producers Costco has a standard marketing and recycling plan [114]. Mobile telephone providers accept used telephones as well. Retailers often use UPC bar codes to handle returns. The use of product codes to provide customers with discounts using RFID tags is economical and straightforward. Like every other voucher or swap system, retailers may benefit from a discount plan. Selling machines can also accept recyclable goods and offer cash refunds or credits based on details on the product label.

- RFID at Materials Recovery Facilities
  To organize things in warehouses, incinerators, and dumps, using RFID readers. Modern materials recovery facilities include magnetic steel seams, aluminum vortex separators, and plastic seam infrared detectors. RFID devices can track small electronics and batteries. Previous studies have shown

that RFID-labeled items such as batteries, small electronics, and mobile devices can obtain at a much cheaper collection facility than recycled [113].

4.2.5 Environmental drawbacks of RFID

Many consumer goods include RFID tags, including food packaging. Over time, the number of tags produced and discarded increases. Usage of the global tag will reach 2 trillion a year [115]. Such marks end up in urban solid waste or systems for recycling paper, carton, metal, glass, and plastic. RFID tags typically include copper, aluminum, or silver antennas as well as integrated silicon circuits, adhesives, plastics [116]. In short, the use of RFID materials and removable tag properties allows the avoidance of problems that cannot be degraded or recycled as RFID tags can prevent the recycling of various products and other materials [117]. When carbon-based conductive ink used as a substrate antenna and bio-based plastic, most RFID tags can be biodegradable or ecologically friendly. However, silicone chips may have environmental effects, which at the development and not the stage of life are challenging to deal with reliably. The processing of silicon chips requires considerable energy and water and significant emissions of pollutants. A specific problem was the pollution of glass, steel, aluminum, paper, and plastics recycling, discussed in turn below.

- Glass Recycling
  Since silicon melts at speed other than glass, silicon RFID chips can pose problems for RFID tags attached to glass containers. If the silicon remains in the glass of the entire recycling line and the glass furnace, silicon beads can create in a new package. It is a potential weakness, especially for the media, and it shows that RFID tags used in the glass must be removed entirely or placed inside the lid and not on the glass itself [117].

- Steel Recycling
  RFID tags can contain approximately 20 mg of copper. On a regular 20 g steel box, this corresponds to a working copper concentration of 0.1%, and the steel copper content accumulates with continuous recycling. It is rising steel consistency. Therefore, RFID tags for steel goods should be entirely removable or made with copper-free antennas. RFID tags mounted on aluminum do not impact the recycling of steel. Inadvertent aluminum falls from tags removed during the exothermic reaction at very high steel temperatures [117].

- Aluminium Recycling
  Aluminum can be recycled with high-value many times. Flows of feed do not permit pollution. Pollutants shall be picked or removed by other means. RFID tags for aluminum items are either produced or made of eco-friendly materials.

- Paper Recycling
  RFID tags will join an old carboard container in the recycling facility. The National Aeronautical Research Committee (NCA) tests have shown that copper foil antennas are kept intact and can be easily captured and removed during the entire hydro pumping process. The silver ink antennas, however, contain 2 to 3 microns of silver particles. Pilot experiments

using labels containing around 16 mg of silver found that much of the silver in the dough remained. In certain cases, however, there was insufficient proof of rates exceeding the limits and regulations. Found in reverse water.

- Plastic Recycling
  The use of High-density polyethylene (HDPE) for milk bottles, washing machines, and other applications. Application of polyethylene terephthalate (PET) in bottles and other applications for soda and wine. Some of the most often recycled plastics are HDPE and PET. In general, RFID labels applied to substrates of PET. Thanks to the denser RFID tags than HDPE and their isolation during the first stage of the HDPE recycling process, RFID labels are anticipated to differentiate easily from HDPE bottles during the recycling process. However, it is a struggle to remove RFID tags from PET bottles. PET is more than one (1.2–1.4 g / cm3) in specific gravity, and both RFID and PET fragments immersed in water. As RFID tags typically performed in PET substrates, the mass difference between PET and RFID tags may not be sufficient using cyclonic separation. Every RFID tag used on PET bottles should also be designed to be easily removed, either by non-PET substrates or other methods.

- Towards RFID biodegradable systems
  However, most RFID tags can not be biodegraded. These include petrochemicals-based metal parts, plastics, or other materials. Smaller tags also make it hard to isolate and recycle different label components. Recent researchers have developed completely biodegradable tags, in particular for medical and feed supply chain applications [118].

4.2.6 Environmental Sustainability

While most case studies at various rates have achieved environmental sustainability, Walmart's case shows that the bigger the size, the higher the effect. A breakthrough in RFID implementation by Walmart that replaced the barcode system by Walmart decreased carbon footprint by 3.2% by allowing less product movement because of improved product visibility and handling and improved inventory management [116]. The TruckTag project is another new environmental protection program. RFID tags allow for automatic high-speed safety checks, reducing traffic jams, and improving air quality by reducing the lorry idle time [116].

4.2.7 Business Value

The average organization aims to reduce costs when introducing a green RFID scheme. The City of London School for Girls, with its RFID temperature sensor networks, will reduce the cost up to 80% compared to its wired networks and gain greater control over room temperature via RFID [117]. Using RFID to monitor temperature, Nestle can save up to 10% on energy-related costs, reduce harm, and boost efficiency. Although direct cost savings are legendary, indirect cost savings should also be acknowledged (such as loss-of-life insurance and increased quality). Many businesses use RFID for revenue generation. Recycle Bank, and Recycling Rewards offer recycling coupons to customers to launch a new business model and

promote more recycling families. Bank Recycle has raised its sales by collecting more recyclable products. The use of RFID saved over 318,000 trees and 21 million gallons of petroleum in the Recycle Tank [44].

4.2.8 Social Responsibility

Green RFID initiatives have an impact not only on the safety and sustainability of the ecosystem of business but also on environmental conservation, which adds value to customer-to-company relationships. It is because consumers know what they want in investment in the environment. Nestlé Italia uses an RFID-compliant management framework to support green ads and to boost brand identity successfully. Under public demand scrutiny, major businesses urgently have to meet their social obligations [99]. Through its smart truck initiative, DHL has minimized CO_2 emissions and fuel consumption by automating package scans to speed up driver handling of the parcels and idle periods to shorten the truck engines during delivery. In more environmentally aware businesses, the culture in which they work may have a positive effect. People and economies with their bank recycle point have raised more than one million dollars [97].

5 Benefit of Greening IT

Green technology is a concept that includes almost every type of practical use of technology to benefit the environment. Despite industrial technology advancing so far, its green predecessors are supposed to do the same. Many green technology examples include items that come under the given use of the subject, such as green chemistry, environmental monitoring, and others. Anything that fits the accepted concept of green technology will do one or two things. It is either to preserve or to help the ecosystem in any way. The words "environmental technology" or "clean technology" can also be used for this technology. Green tech's primary goal is to protect nature and help reverse the adverse effects humans have had on the planet [118]. Green technology enables us to turn our contaminants and waste from unnecessary by-products into a sustainable workforce that benefits humans and the environment. Green technology has some of the best recycling methods: turning waste into fertilizer. One of the most significant benefits of green technology is that it helps people recycle things like water and air. Green technology leads to emissions reduction and air purification for future generations. Above all, green technology has permitted people to save vast quantities of resources, dramatically reducing the remaining carbon footprint. Alternatives to systems that use a high volume of electricity and fuel are provided to the public at this very moment. The use of items such as electric vehicles and solar panels has become natural, daily, and the Planet could not be the best. It is highly recommended that people use environmentally friendly tools and appliances to help facilitate this energy saving. The ability to rejuvenate ecosystems that have suffered a great deal because of the effects of human carbon emissions and other factors is also a tremendous use of green technology. The use of this technology replants trees, replaces plants, and replaces entire habitats to their original glory. Besides, waste is collected and recycled, so that animals, which once existed, will now return to these destroyed habitats. It means a new beginning for many species worldwide [119].

Environmental concerns [120] again impact the IT industry's competitive landscape, and businesses with the expertise and vision to offer goods and services that tackle environmental problems profit from a competitive advantage. For example, when making transactions, leases, or contracting decisions, many consumers consider service provider registration and environmental initiatives. Companies face rising energy prices and could be subject to additional government taxes if they do not recognize the effect of environmental activities. Investors and customers are starting to seek more information about carbon emissions and environmental measures and business outcomes. Because of these issues, businesses start proving environmental efficiency, such as the Carbon Disclosure Project (https://www.cdp.net/en) an initiative that allows multinational companies to report their CO_2 emissions. The implementation of green IT practices gives companies and individuals economic and other benefits. IT operations increase energy efficiency, especially when electricity is costly and energy prices are increasing, through economically beneficial green initiatives. In a Sun Microsystems Australia survey, which included 1,500 responses from 758 Australian and New Zealand organizations, interviewed respondents said energy conservation and cost management were focused on environmentally sustainable environmental policies and environmental impacts. The primary reason for using the method shown in Figure 5 is that less is better said.
Figure 5: Reasons and benefits for using green IT practices[120]

Many businesses will concentrate on environmental conservation, energy usage, and cost control issues. The organization focuses on environmental protection through the frameworks for resolving business demands, legislation, and climate change. Business and institutional customers ask manufacturers to "relive" their goods and processes. For instance, businesses like Dell and Wal-Mart take actions that compel suppliers to follow environmental-friendly practices. People start evaluating the essence of the IT environment, and green IT will become a regular function in the next five years. The company provides a range of innovative green goods and services, generating new markets for companies.

6 Future Work of RFID in Green IoT

Green IoT's promising future will make our future world safer and greener, very high quality, socially and environmentally sustainable

and economically viable. Today, green communication and networking, green architecture, green IT and application infrastructure, energy-saving techniques, integrated RFIDs and networks, mobility and network management, the co-operation of homogenous and diverse networks, intelligent artefacts and green location all concentrate on exciting areas [121]. From two points of view, green IoT architecture can be applied to achieve outstanding performance and high quality. Identifying suitable techniques to improve QoS parameters (i.e. bandwidth, delay, and throughput) will make an effective and useful contribution to greener IoT. It would need to use less energy when it comes to greening IoT, searching for new resources, mitigating the adverse effects of IoT on human health, and disruption to the environment. Green IoT will then make a significant contribution to sustainable, intelligent, and green societies. Radio-frequency energy harvesting should be taken into account in order to achieve an energy balance to help green communication between IoT devices. Energy saving and CO_2 emission reduction is a major challenge for smart and green environment.

Logistics, Aero-ID, counterfeiting, supply chain control, spaces and much more will accelerate the growth of modern society and technology in the coming decades. Mobility, climate, safety, protection and energy, including medical, pharmaceutical and military applications, will become the leading technological drivers of the future, further growing the need for sustainability—wireless and electronic modules that are reliable, versatile, robust, low power and durable. Work on electronics and RFID seeks to develop versatile systems, based on organic/inorganic substrates and materials, to solve the limitations of ceramics and silicone in order to address these significant challenges. A challenge for potential applications is the convergence of elegant, lightweight, heterogeneous, versatile, environmentally sustainable, newer materials and cost-effective processes in a wide area. Continuous development and innovation involve a wide range of electrical components that can directly produce and incorporate from coils to affordable methods, mainly using organic electronics, along with work into a variety of electrical conductivity and semiconductor materials. Organic materials can be printed and modeled using several methods, each with its advantages and disadvantages, such as flexographic, width, offset, sorting, and injection. Based on these materials and techniques, primarily low-cost RFID transponders, different types of sensors, storage devices, photovoltaic cells, passive devices such as displays or batteries have tested active components such as diodes and transistors with the production of them. Though seen only in the low UHF (RF) range, the trend moves to higher speeds, resolutions and frequencies without compromising versatility, eco-friendliness and low costs. To address these problems includes a new approach to RFID and the design of electronic systems in terms of alternative materials, processes and functions. The researchers in [122] are proposing an innovative approach focused on developing a new low-cost inkjet printing platform with efficient diode integration for applications with optimized metallization traces and enhanced recognition capabilities. The method theoretically proposed can form the basis for the first generation of precise "smart" RFID devices.

More fields of research need to be explored to establish optimal and efficient Greening IoT solutions:

- Crewless aerial vehicles (UAVs), particularly in agriculture,

traffic, and surveillance, are required to replace many IoT devices, which will reduce power consumption and emissions. UAV is a promising technology that leads to low cost and efficient green IoT.

- Sensor data to the mobile cloud must be more useful. Sensor-cloud combines a network of wireless sensors and a mobile cloud. It is a hot and promising IoT greening technology. The device, service, WSN, and cloud management's energy efficacy can be examined through a green social network such as service (SNaaS).

- M2M connectivity plays a crucial role in reducing energy consumption and harmful emissions. In order to allow automated systems, smart machines must be smarter. In the event of traffic, computer automation delays must be reduced and intervention required and immediate.

7 Conclusion

IoT has an enormous influence on transforming our everyday lifestyle. IoT technology connects a large number of devices and items linked to the Internet around the world. The main concern is how data from these devices can be collected and analyzed effectively. RFID is one of the leading IoT tools, used for the identification and processing of information from IoT devices due to its cost and energy consumption characteristics. Studying this technology is therefore essential and paying attention to mitigating its adverse effects. This paper discusses and summarizes the latest RFID applications, including studies that have improved RFID applications in Green IoT efficiency. This paper also addressed the challenges and implications of green, IoT RFID applications. However, there are still some challenges to this field, such as sophistication, protection and lack of trust. These problems form a relevant research field for future study.

Conflict of Interest The authors declare no conflict of interest.

An Anonymity Preserving Framework for Associating Personally Identifying Information with a Digital Wallet

Qazi Mudassar Ilyas[*], Muhammad Mehboob Yasin

College of Computer Sciences and Information Technology, King Faisal University, Al Ahsa, 31982, Saudi Arabia

A R T I C L E I N F O	A B S T R A C T
	Growing adoption of cryptocurrencies by institutional investors coupled with recurring incidents of loss of access to digital wallets have resulted in emergence of custodial services for high net worth individuals and institutions. However, such services are not economically feasible for the wider community of crypto owners who are left with no recourse for recovery of lost funds. This paper proposes a framework, AFAP, for associating certain personally identifying information with a digital wallet so that a user may prove ownership of the said wallet. Thus, the owner is able to establish his/her claim over funds associated with such a wallet in case of loss of access to it. We show that the proposed scheme has no adverse effect on anonymity, privacy and forgetfulness of personal information of the wallet owner.

1. Introduction

Cryptocurrencies are gaining much traction in the mainstream economic activity because of their global and fully decentralized nature, promise of freedom from political influence, and peer to peer nature of transactions [1]. The blockchain does not carry any information pointing to the owner of a particular digital wallet. Further, the use of Hierarchical Deterministic (HD) wallets [2] makes it harder to even group individual transactions carried out by one individual. The pseudo-anonymity thus provided by blockchain is one of the major factors contributing to the popularity of digital currencies. However, a drawback of this characteristic is the inability to associate a digital wallet address with an individual in order to prove ownership of a lost digital wallet.

The value of Bitcoin, leader of the pack, recently climbed to an all-time high of USD 24,058 on CoinDesk Bitcoin Price Index beating the earlier high of USD 20,000 reached on December 2017 [3]. Several businesses have already embraced digital currencies, while governmental entities are also preparing to bring them into mainstream financial systems [4]. Hence, cryptocurrencies are on track to become an important part of all financial transactions in future. However, digital currencies are in their infancy and several issues need to be resolved before they can become part and parcel of a common individual's life [5].

The Achilles' heel of Cryptocurrencies is the fact that access to all funds owned by an individual is tied to a complex long number that is almost impossible to remember. Therefore, this complex number, known as private key of a digital wallet, needs to be stored safely. Also, the private key needs to be kept in a secure manner because anyone with knowledge of this number can use the funds stored in the respective wallet.

A private key can be lost owing to hardware or software failure, personal carelessness in safekeeping the keys, or in some cases even death of the owner. Several users have reported losing their private keys thus making their funds inaccessible to them. A survey reported that a significant fraction of respondents had experienced loss of Bitcoin keys at least once [6]. According to careful estimates, about 4 million Bitcoins had been lost till 2017 [7]. More recently, more than 100,000 individuals lost Bitcoins worth nearly USD 190 million owing to the death of the owner of a cryptocurrency exchange QuadrigaCX [8]. Since there is no inherent mechanism in the Bitcoin framework to recover lost keys, a lost private key simply means all Bitcoins associated with that key are lost forever. Hence, there is need for a mechanism to restore access to funds in case respective private keys become permanently inaccessible.

Since a mnemonic passphrase is easier to memorize or record as compared to a complex number, it is widely used by digital wallets to create the private key [9, 10]. Though, this improves the user experience, yet this does not absolve the user from

responsibility of storing her/his passphrase in a safe and secure manner. As in the case of loss of private keys, loss of a passphrase implies loss of access to the respective digital wallet. In the following, we address the problem of loss of access to a digital wallet which may be because of loss of a private key or loss of the corresponding mnemonic passphrase.

We propose a two-step solution to this problem. As the first step, the owner is afforded the ability to prove ownership of a lost wallet. Subsequently, either the funds stored in the lost wallet may be returned to the rightful owner or he/she may be suitably compensated. In this paper, a framework for proving ownership of a wallet is proposed, while the second step of solution is subject of future work. The proposed framework, "Anonymity Preserving Framework for Associating Personally Identifying Information (PII) with a Digital Wallet (AFAP)", can be used to associate the PII of owner with a digital wallet in a secure fashion while maintaining the same level of anonymity as provided by the current cryptocurrency ecosystem.

The proposed framework comprises three entities, namely CryptoRegistry, PII Associating Transaction (PAT) and PII Wallet. CryptoRegistry is a trusted long-lived entity that registers a given PII against a digital wallet by digitally signing this association and helps in validating the same when required to do so. A PII Associating Transaction (PAT) stores the aforementioned association on the blockchain by embedding the said CryptoRegistry signature in an outgoing transaction. A PII wallet is a specialized digital wallet that facilitates the registration and validation processes.

Rest of the paper is organized as follows. The next section summarizes the related works. The proposed framework is presented in Section 3 detailing key components and schemes for registration of a digital wallet and claiming its ownership. A case study is provided in Section 4 that shows feasibility of the proposed framework. The paper is concluded with the discussion and future work.

2. Related Work

The issue of loss of access to a digital wallet has gained attention of researchers owing to an increasing number of incidents resulting in loss of digital currency worth millions of dollars belonging to thousands of individuals [11,12]. The solutions proposed till date focus on safekeeping of digital wallets to ensure continued availability of private keys as and when needed. These solution approaches can be divided into two main categories, namely user-centric approaches that facilitate one in safekeeping of one's digital assets and custodial approaches that transfer the responsibility of safekeeping to a trusted third party.

User-centric approaches include cold storage, offline wallets and specialized hardware wallets. Cold storage refers to safely storing the private key of a digital wallet on an offline medium ranging from secondary storage to plain paper [13,14]. An offline wallet is an air-gapped device that can generate transactions for export to a hot wallet, thus providing an improved user experience.

A specialized hardware wallet incorporates Hardware Security Modules (HSM) to store the private keys in a protected area of microcontroller storage which cannot be accessed from outside the device [15]. As suggested in [16], one can derive two values from the private key and store one of these value on a remote server. Protection against brute force password attacks is provided by keeping the second value on the local machine. A shortcoming of this scheme is that one needs to remember password to retrieve the value from the server. Further, damage to the local machine can result in permanent loss of access to the key.

Though all aforementioned approaches provide varying levels of protection against loss of private keys, yet the possibility of damage to or loss of access to physical medium still exists, which will result in loss of access to the respective digital wallet.

Another class of solutions relies on Shamir's secret sharing scheme, as adapted by [17], based on semi-trusted social network comprising friends of an individual. However, such schemes are more suitable for corporate clients since social networks of individuals are quite fluid and cooperation of "friends" cannot be guaranteed for unforeseeable future.

In custodial approaches, such as a browser-based wallet, an online account is maintained with a service provider that is used for storing and retrieving digital assets; examples include CoinBase[*], Kraken[†] and BitStamp[‡]. However, several instances have been reported where many clients lost access to their digital assets owing to the service provider going out of business. For an exposè, the reader may refer to [18,19]. To overcome this issue, clients are usually facilitated to backup their private keys as an assurance against the possibility of the service provider ceasing to exist. Although these online services relieve the owner from the responsibility of safekeeping digital assets, they are exposed to a multitude of vulnerabilities such as internal or external theft and cyber-attacks. Recently, specialized custodial service providers have also emerged that claim improved security against aforementioned vulnerabilities by utilizing air-gapped devices and employing higher standards of security. Two of the well-known examples of such service providers are Fidelity Digital Assets[§] and Ledger Vault[**]. However, these services have high associated costs and thus are suitable only for institutional clients or high net-worth individuals. It needs to be emphasized that privacy and anonymity are obviously compromised in all custodial services as digital assets in custody need to be associated with identity of respective owners.

One may conclude that none of the solutions proposed so far gives absolute guarantee against loss of access to a digital wallet while maintaining privacy and anonymity. Another perspective is to accept the occurrence of such eventuality as an inherent weakness of the blockchain technology and devise mechanisms to handle such situations. One such mechanism may be to prove ownership of a lost digital wallet and claim compensation for unspent amount stored in that wallet.

Various initiatives have been proposed for using blockchain to prove existence or ownership of a digital asset at a certain point in

[§] https://www.fidelitydigitalassets.com/
[**] https://www.ledger.com

time. For example, the online service named "Proof of Existence" [20] stores cryptographic hash of a digital document on blockchain that can be used to prove that the said document existed at a particular point in time. Further, integrity of the document is also established. Additionally, various schemes, referred to as Colored Coins [21], exploit the immutable characteristic of blockchain technology to store real world asset manipulation information on the blockchain [22, 23]. In [24] a DNS like naming system is proposed that associates human-readable names with respective internet resources by storing mapping information on the blockchain. In all such schemes, non-financial data is made part of the blockchain by embedding it into script of an OP_RETURN output; a special output of a blockchain transaction [25]. We also exploit the said scripting feature of OP_RETURN output to associate PII with a digital wallet by storing requisite metadata on the blockchain. The details of the proposed framework follow.

3. Proposed Framework

In order to overcome the wallet ownership issue, one may associate some Personally Identifying Information (PII), such as national ID, driving license or passport number with the digital wallet using the aforementioned output script of a transaction. In the following, we first introduce some obvious extensions of the use of aforementioned scripting feature for storing PII on the blockchain and point out that anonymity and privacy of the wallet owner may be compromised by using such simple schemes. We then present our framework to associate PII with a digital wallet and show that it preserves anonymity and privacy of the wallet owner.

3.1. Simple schemes for storing PII on blockchain

In this section, we present three ways of storing PII on blockchain to associate ownership of a digital wallet in the order of increasing complexity.

3.1.1. Plaintext PII

In this scheme, the owner of a digital wallet constructs a transaction and embeds his/her PII in one of the output scripts. This transaction is then sent on the network for processing. Since output script of a transaction can only be created by the originating digital wallet and cannot be tampered with after the transaction has been broadcast, the said information is irrevocably tied to the corresponding digital wallet. The wallet owner may record ID of the said transaction (TxID) for future reference. Once this transaction is confirmed, it becomes part of the blockchain, thus permanently associating PII with the issuing wallet.

In case of losing access to the private key of a digital wallet, henceforth referred to as a lost wallet, blockchain will be scanned to extract the aforementioned transaction using TxID and identify the rightful owner of the issuing wallet from the embedded PII. This scheme may be used to serve as a basic naming system for digital wallets akin to BitAlias [26] and OneName [27] etc. However, this scheme violates one of the basic principles of blockchain technologies, namely, ensuring anonymity of parties to a transaction. Therefore, this way of associating PII with a wallet may not be of general appeal.

3.1.2. Encrypted PII

To preserve anonymity of the wallet owner, one may create a public-private key pair and encrypt the PII with this public key before embedding it into the script. Now, to prove ownership of a digital wallet, one needs to locate the corresponding transaction on the blockchain and decrypt the PII using the respective private key. This requires the corresponding private key to be readily accessible when needed. This problem is akin to safely storing the private key, of the digital wallet, itself. Hence, this scheme does not reduce the responsibility of the wallet owner in safeguarding a private key.

An alternate way to relieve the owner of this added responsibility is to use pubic key of a well-known entity, such as a coin exchange, for encrypting the PII. Now, one needs to approach the said entity for decrypting the PII in order to establish one's claim of ownership. Though a wallet owner is absolved from responsibility of safekeeping any private keys, this scheme suffers from two drawbacks.

Firstly, the well-known entity may not be aware of such use of its public key. Also, it is not bound to maintain all its public private key pairs for foreseeable future. Therefore, it may not be in possession of the required private key when approached. Hence, owner claim may not be substantiated based on the encrypted PII. Secondly, since public key is supposed to be widely available, the encrypted PII is prone to dictionary attack.

3.1.3. Hashed PII

This method requires PII to be hashed using a well-known hashing algorithm and the resulting hash to be embedded in the script of a transaction in blockchain. To establish the claim of ownership, one may create hash of one's PII and validate it against the hash recovered from the respective transaction. In order to avoid dictionary attack, a sufficiently large random, commonly called salt, may be added to the PII. However, PII validation process now depends upon availability of the salt used. Therefore, the wallet owner is made to bear the responsibility of safekeeping the salt. Though, the salt may be in the form of hash of a memorable passphrase, the situation is reduced to a problem that is akin to safely storing the private key of a digital wallet.

3.2. An Anonymity Preserving Framework for Associating PII with a Digital Wallet

By now, the need has been established for a long-lived trusted third party with the responsibility of safekeeping the information required for proving association of a given PII with a digital wallet in an anonymous way. We call this entity a CryptoRegistry and propose a framework that preserves owner's anonymity and privacy as long as the CryptoRegistry is deemed trustworthy. We call this framework AFAP - An Anonymity Preserving Framework for Associating Personally Identifiable Information (PII) with a Digital Wallet.

The proposed AFAP framework comprises three components, namely a CryptoRegistry, a PII Associating Transaction (PAT) and a PII wallet. In the following, we give the details of each one of these components.

3.2.1. CryptoRegistry

We introduce the concept of a CryptoRegistry that is a trusted long-lived entity. A CryptoRegistry is required to perform the following functions:

- To provide an Application Programmer Interface (API) for registering the PII provided by a wallet owner

- To provide an API for making available the following information:

  - A public key $K_{Pub,CR}$

  - Registration fee, F_{CR}

  - A wallet address, W_{CR}

  - A sufficiently large random number, also known as salt, for defense against dictionary attack as discussed below, S_{CR}

  - A hashing algorithm along with its parameters, $\mathcal{H}$

  - Hash of (PII $\|$ S_{CR}), H_{ID}

  - Digital signature on PII, S_{CR}, F_{CR}, W_{CR}, $\mathcal{H}$ and H_{ID} using $K_{Priv,CR}$

  - The digital certificate to the effect that the said CryptoRegistry is owner of the respective public key, $K_{Pub,CR}$

It may be noted that the proposed scheme introduces a random salt to preserve anonymity since use of hash of PII alone may be linked to the original PII by brute force attack.

- To ensure availability of the PII, S_{CR}, $TxID_{PAT}$, and respective public-private key pair, once a PAT constructed by a PII wallet paying the fee F_{CR} to the wallet W_{CR} is confirmed on the blockchain. By virtue of its digital signature, the CryptoRegistry is bound to the PAT. As a trustee, the CryptoRegistry is also required to ensure confidentiality and security of information entrusted with it throughout its life time.

- To provide a list of PATs and corresponding digital wallet addresses associated with a given PII. It is to be noted that, in the interest of anonymity and privacy, the aforementioned information will only be provided to the rightful owner of PII or any authorized legal entity.

- Optionally, a CryptoRegistry may advertise special prefix to be used with OP_RETURN to facilitate searching a particular PAT on the blockchain.

3.2.2. PII Associating Transaction (PAT)

Generally a PII Associating Transaction (PAT) consists of three outputs. Firstly, an output transferring Registration fee F_{CR} to CryptoRegistry wallet W_{CR}. Secondly, an output transferring change to the wallet owner's change address. Thirdly, a zero valued output with OP code OP_RETURN and output script comprising the following information:

- Special prefix provided by the CryptoRegistry (if any)

- $\mathcal{H}$(PII $\|$ S_{CR}), H_{ID}

- Digital signature on PII, S_{CR} ,F_{CR}, W_{CR} and H_{ID} using $K_{Pub,CR}$

It is to be noted that since every Bitcoin transaction is tied to the originating wallet and cannot be tampered with after it has been confirmed, thus the above information, by virtue of being embedded in the transaction, becomes irrevocably tied to the corresponding digital wallet.

3.2.3. PII Wallet

PII wallet is a specialized digital wallet capable of constructing and verifying PAT transactions for associating itself with PII. For this purpose, it needs to communicate with a CryptoRegistry and perform a number of functions as detailed below:

- Accepting and storing PII of the wallet owner in a secure way

- Providing a list of available CryptoRegistries to the wallet owner

- Initiating the process for registration of given PII with the selected CryptoRegistry

- Accepting response from CtyptoRegistry comprising S_{CR}, F_{CR}, W_{CR}, H_{ID} , a hashing algorithm $\mathcal{H}$ and a digital certificate

- Verifying digital signature and hash value, H_{ID}

- Constructing PAT as described above and transmitting to the network

- Sending H_{ID} and transaction ID of PAT to CryptoRegistry after confirmation of PAT

- Periodically querying the said CryptoRegistry for confirmation of H_{ID} registration in its database

- When required, querying all CryptoRegistries for registration status of provided PII

- Displaying to the user a list of CryptoRegistries with whom provided PII is registered

3.2.4. Associating PII with a digital wallet

The sequence of steps for the purpose of registering a PII of the owner of a digital wallet is depicted in Figure 1.

The details of each step are as follows:

1. The user provides his/her PII to the wallet.

2. The wallet sends the provided PII for registration with the selected CryptoRegistry.

3. The CryptoRegistry selects a wallet (W_{CR}) for receiving registration fee (F_{CR}), chooses a random salt (S_{CR}) and calculates H_{ID} which is hash of PII concatenated with S_{CR}. It saves this information in its database for future reference with registration status as 'Not Confirmed'.

4. The CryptoRegistry sends PII, S_{CR}, F_{CR}, W_{CR} and H_{ID} , its signature on this information and its corresponding digital certificate to the PII wallet.

5. The wallet creates a PII Associating Transaction (PAT) using the received information and transmits it to the Bitcoin network.

6. The wallet periodically queries the blockchain for confirmation of PAT.

7. Once PAT is confirmed, the wallet notifies the CryptoRegistry of the confirmation by sending transaction ID of PAT (TxID$_{PAT}$) and H_{ID}

8. The CryptoRegistry queries the blockchain for confirmation of TxID$_{PAT}$

9. Upon confirmation, The CryptoRegistry updates PII registration status as 'Confirmed' and records corresponding TxID$_{PAT}$

10. The wallet periodically queries the CryptoRegistry for PII registration status

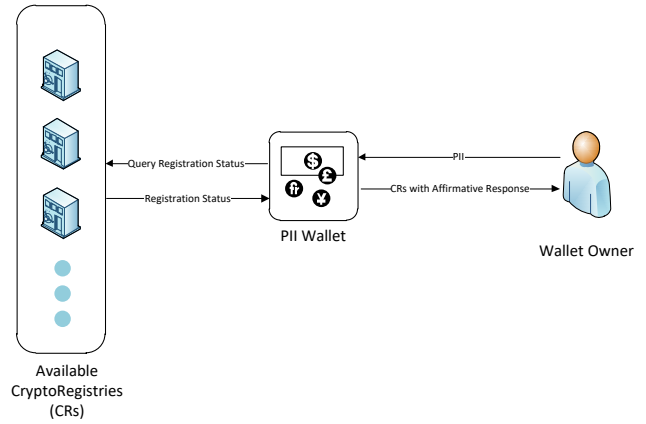
11. Upon confirmation, the wallet notifies the user that the provided PII has been successfully registered with the selected CryptoRegistry and records TxID$_{PAT}$ for future reference.


Figure 2: Claiming ownership of a lost wallet

The hash of given PII concatenated with salt is computed and matched against the one extracted from PAT. A successful match proves that the said PII was used to construct the PAT and that the wallet from which this PAT was broadcast is the wallet associated with the said PII. This way the ownership of the wallet, and any unspent funds associated with it, is established.

3.2.6. *Right to be forgotten*

One of the important principles incorporated into General Data Protection Regulation (GDPR) is a user's right to be forgotten (RtbF) allowing for retroactive erasure of all personal data. Considering the immutable nature of blockchain, it may appear that storing association of PII with a digital wallet may be in violation of the RtbF. However, the said right is safeguarded on two counts. Firstly, PII itself is not stored on the blockchain in any way, i.e., neither in plain text nor in encrypted form. Secondly, proving association of a particular PII with a digital wallet requires knowledge of the corresponding salt, which is a cryptographically strong random number. Hence, if the salt is forgotten, this association becomes unprovable. The right to forget this salt and any associated personal data can be exercised by the user with a request to CryptoRegistry. In [28], it has been shown that integration of such requirements into the current computing infrastructures is practically feasible.

4. Case study

In order to validate the proposed framework, a sample PAT was constructed by simulating interaction between a client and a typical CryptoRegistry as detailed below. The resulting transaction was successfully broadcast on Bitcoin Testnet. This was followed by simulating the situation of loss of this wallet. The lost wallet address was successfully retrieved from the blockchain by presenting only the PII. The following is the detail of interactions among the various components of the proposed AFAP framework.

4.1. PII Association with a digital wallet

The example client wishes to associate his PII "ABC1234567" with his digital wallet. The CryptoRegistry generates a salt, calculates hash of PII concatenated with this salt and returns the following information to the client along with his signature on the same:

CryptoRegistry Prefix = TESTPII

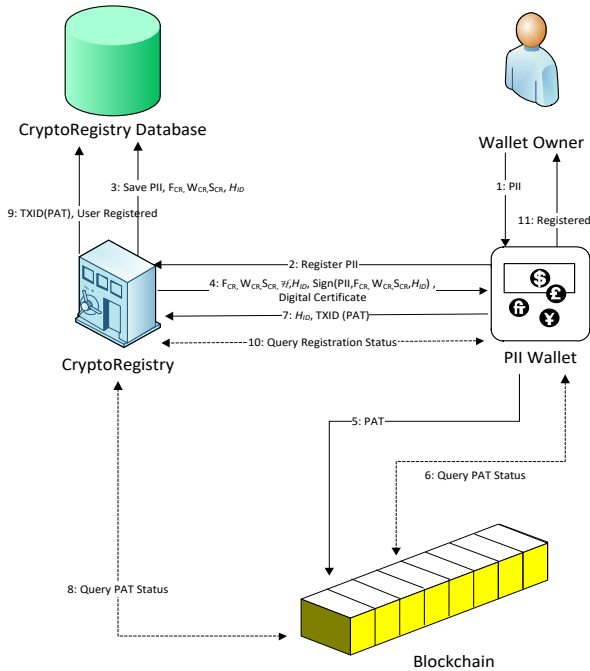
Salt: S_{CR} = 9586311452


Figure 1: PII Registration in AFAP Framework

3.2.5. *Claiming ownership of a lost PII Wallet*

In the event of loss of a PII wallet, a PII wallet is installed and its recovery mode is initiated. The following sequence of events may follow (see Figure 2).

- The user enters her/his PII used for querying the registration status of the lost wallet.

- The wallet queries all known CryptoRegistries one by one using the provided PII.

- PII wallet receives response from the CryptoRegistries and displays the list of CryptoRegistries with affirmative response.

In the interest of owner's anonymity, the CryptoRegistry shall not reveal any information other than whether the subject PII is registered with it or not. The said CryptoRegistry may now be approached by the owner to obtain the transaction ID of the corresponding PAT along with the salt.

SHA1 (PII || Salt): H_{ID} = d49cdc68c804114b402bbaa108d324a80a19e354

Registration Fee: F_{CR}= 5mBTC

Wallet address for receiving registration fee:

W_{CR} = mpvkKZ6ysUYEGZuXR1FYRCKzykvMmtovyv

Signature:

Sign(PII,F_{CR}, W_{CR},S_{CR},H_{ID}) = AAwPRuNFlPvKCaic12aFRLYXf9ZbytXjBowXeKZm0kGNE TcplSyEE268401jgS8=

The client constructs the PAT with three outputs. Firstly, paying registration fee to W_{CR}, secondly the change to be returned to itself and finally a null data transaction with the script comprising prefix, hash and signature of the CryptoRegistry. The resulting script is given below:

Script: TESTPIId49cdc68c804114b402bbaa108d324a80a19e354AAwP RuNFlPvKCaic12aFRLYXf9ZbytXjBowXeKZm0kGNETcplSy EE268401jgS8=

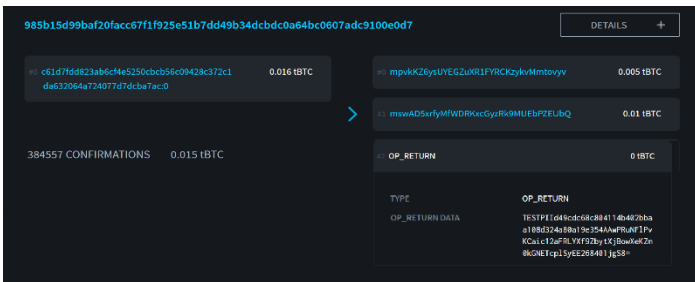
This example transaction was broadcast on Bitcoin Testnet and can be found with the transaction id "985b15d99baf20facc67f1f925e51b7dd49b34dcbdc0a64bc0607a dc9100e0d7". Figure 3 shows the details of the said transaction as depicted by Bitcoin Block Explorer.


Figure 3: Details of PAT as shown by Bitcoin Block Explorer

It may be noted that the CryptoRegistry is required to store the transaction ID of PAT and other associated information in its database, as depicted in Figure 1.

4.2. Claiming ownership of a digital wallet

Assuming the owner knows the transaction ID of PAT and the salt used to construct the script of PAT, firstly PAT may be retrieved from blockchain using transaction ID. Then, the PII association may be proven by calculating hash of PII concatenated with salt and validating it against the script of null data output of PAT.

Since the main purpose of the proposed AFAP framework is to relieve the wallet owner from maintaining access to the private key of a digital wallet in a secure, safe and anonymity preserving manner, the owner is not assumed to maintain transaction ID of PAT and the respective salt. In such a case, the owner may present her/his PII to the CryptoRegistry to confirm association of the said PII with a digital wallet.

5. Discussion

The proposed AFAP framework uses blockchain itself to store the association of the Personally Identifying Information (PII) of the owner with her/his digital wallet. The proposed framework requires a persistent entity, called CryptoRegistry, which is mandated to maintain record of transaction IDs of PII Associating Transactions (PATs) and associated information in a secure way. The proof of ownership of a digital wallet lies in hash of PII and a random number, called salt, stored in a PAT.

In case of loss of a digital wallet, the owner may query available CryptoRegistries to confirm registration of her/his PII against a PAT from their databases. Once a confirmation is received, the owner may prove her/his identity to the satisfaction of the respective CryptoRegistry in order to retrieve transaction ID of PAT and respective salt. The hash extracted from PAT validates the PII and ownership of legal claimant of the PII is established. The proposed scheme, therefore, depends on long term availability of the CryptoRegistry used to register a digital wallet. In the interest of anonymity and privacy of the wallet owner, the CryptoRegistry may require due legal process in identifying the claimant before releasing transaction ID of PAT and respective salt.

From the aforementioned requirements of a CryptoRegistry, one may draw parallel with crypto exchanges or custodial services as trusted third parties for safekeeping of users' crypto assets. However, it may be noted that in the latter case, clients' funds are stored in the wallets owned by the trusted third party functioning as a custodian. Thus a user may lose all his/her funds in the event of hacking or bankruptcy of the custodian. In contrast, in the event of bankruptcy of a CryptoRegistry, the hash values stored in respective PATs cannot be verified owing to unavailability of corresponding salts, whereas the user funds remain intact. A user may safeguard against this eventuality by choosing to register with multiple CryptoRegistries. Though, the cost of registration may discourage registration with multiple CryptoRegisteries, it is expected that existing crypto exchanges will offer CryptoRegistry services and they may waive off these fees to increase their customer base.

The proposed framework brings the cryptocurrency ecosystem a step closer to the conventional banking system where an account holder may prove ownership of funds after losing access to corresponding checkbook or card. It may be noted that the protection afforded to an individual by AFAP is stronger than that of traditional banks since the funds and proof of ownership are stored in an immutable blockchain and there is no risk akin to bankruptcy.

6. Future Work

Although a user may claim ownership of her/his lost funds in the above manner, the process for recovery/compensation may involve legal procedures. One possible way of compensating the owner of a lost wallet is to create a compensation fund for such eventualities. Alternatively, a special transaction to credit the required funds to claimant's new wallet akin to the mechanism proposed for managing deflation of cryptocurrencies by [29]. Further, similar to the expiration flag proposed by them, the old wallet needs to be flagged as invalid in a way that blocks any future access to it or funds associated with it.

Switching Capability of Air Insulated High Voltage Disconnectors by Active Add-On Features

Mariusz Rohmann[*], Dirk Schräder

Siemens Energy Global GmbH & Co. KG, SE GP T SP R&D TC ME, Research and Development, Berlin, 13629, Germany

A B S T R A C T

The need of add-on features (secondary contacts) for current paths of air insulated high voltage disconnectors switching capabilities (e.g. bus transfer switching) is introduced. The relevant product components for the switching capability and their functionality is described, which is giving boundary conditions for adding features necessary to achieve the switching capability. Possible features are discussed with necessary properties and performance. Those are separated in passive and active solutions, which are focused. Given solutions successfully applied, are explained and capabilities are shown based on experimental design and testing – where calculations and/or computational analysis are not shown (consequently no resulted data of such approaches), as those have not been used for the given solutions (the disconnector is still a low-cost product within industrial business circumstances, where invests for comprehensive design activities are unfortunately very limited). The testing of the solutions is covered with information for limited switching capability values and measures and/or further, partially theoretical, alternative solutions, for increased values. Also, the testing itself and possible laboratories with certain test execution opportunities and/or challenges is elaborated. The conclusion provides a market view, product users perspectives, in regards of the applicability for passive solutions and the need for active solutions.

1. Introduction

This paper is an extension of work originally reported in Proceedings of the International Conference on High Voltage Engineering and Technology (Central Power Research Institute, India) [1].

The standardized minimum switching capability of air insulated high voltage disconnectors (negligible currents of 0.5 A for rated voltages up to 420 kV as per IEC 62271-102) [2, 3] is frequently exceeded by three main applications:

- no-load conditions of transformers (inductive)

- long high voltage conductors (overhead lines, capacitive)

- bus-transfer cases within substations with more than one bus bar

The bus bar transfer case, being very common, is standardized by the IEC 62271-102, where the latest edition partially considers increased values (bus-transfer voltage and current) [2, 3].

A disconnector in its standard configuration will not be able to switch exceeded values. The damages on the contact system (contact erosion) would be too high to be still operational after such a switching case. The application of add-on features is necessary (secondary contact arrangements, like additional contact fingers), so that the contact system is protected and accordingly switching capabilities are achievable. Those add-on features are design as passive and/or active secondary contact arrangements [4-9].

The Main difference of the passive and active solutions is driven by the operational speed, where passive solutions are fully dependent on the current path design and active solutions are integrating semi or full independency of the current path design.

2. Current Path Operation

2.1. Current Path Types

The disconnector type determines the current path outlining (shape). The known types are groupable in inline disconnectors (the center break, the double side break, the side break, the V-type (based on center break or double side break disconnectors), the vertical break and the knee-type disconnector) and busbar

disconnectors (the vertical reach, the semi-pantograph and the pantograph disconnector).

For the inline disconnectors the current path operation occurs horizontally, and a common secondary contact arrangement solution can principally be achieved. For the busbar disconnectors the current path operation occurs vertically – a common secondary contact arrangement is not known to be achievable [4-9].

For the busbar disconnectors, the vertical reach and the semi-pantograph are likely to share a secondary contact solution with their familiars of the inline group (vertical break and knee-type respectively).

The pantograph disconnector is very unlikely to achieve a common secondary contact solution with one of the other mentioned disconnector types – its design principal of the current path is too distinctive.

2.2. Current Path Opening and Closing

Disconnectors are only operational under no-load conditions. The requirements for switching capability are given by residual currents, consequently main contact systems are designed for static current carrying capabilities [1-9].

In order to protect the main contact system (carrying rated continuous currents and short-circuit currents) it is necessary for any secondary contact arrangement to run ahead of the main contact system while the closing operation and to go behind the main contact system while the opening operation of the current path.

This is essential for the protection purpose, as the switching capability in any case results in arcing (lightning) and accordingly arc erosion resistance requirement. An optimized contact system in regards of the main purpose of carrying current will not be able to sustain such arcing erosion, where the main purpose of the secondary contact arrangement is this resistance but will not be suitable for carrying current continuously.

3. Secondary Contact Types

Where the main contact is optimized for low resistance (best current carrying capability while minimized losses, heating or hot spots) and longest lifetime, the secondary contact needs optimization for high resistance and a minimum lifetime (considering the IEC 62271-102 or specific market/customer requirements) [1-9].

Striving for this, the main contact needs:

- To be decoupled in switching operation conditions of the disconnector for being save from damages by arcing (lightning).
- A contact pressure suitable for the current carrying capability, but as small as possible for friction avoidance (no-load operations).
- A material choice suitable for the current carrying capability, but a surface supporting lowest friction (no-load operations).

Usually this results in silver plated copper fingers with applied springs to achieve the necessary contact pressure – being still one of the most economic solutions. Highly controlling the elasticity of the used copper may allow spring elimination but is likely to require silver-graphite-plating (increasing lubricating properties,

decreasing friction), which again is more costly due to the manufacturing process efforts.

The secondary contact needs:

- To be decoupled in normal operation conditions of the disconnector for being save from damages by rated continuous currents or short-circuit currents.
- A contact pressure suitable for the switching capability – residual currents need to be carried safely, so that arcing on the main contact cannot occur. Additionally, considering certain numbers of switching operation and occurring erosion, the chosen contact pressure needs to overcome accordingly outline changes (reduction) of the contacts (sacrificial contacts) - preventing jumping or bouncing effects of the secondary contact and any arc-back (reigniting) due to contact separation.
- A material choice suitable for the arc erosion resistance (residual currents)

In dependence of the secondary contact solution, the material choices vary significantly – again under economic aspects, so that any material usage is minimized as much as possible in regards of the used solution.

Used names for known solutions like arcing horn, guiding horn, bus-transfer device or filter-switching device are not used. Those are given mainly by the reasons for occurrence of the residual currents to be switched and are not reflecting the common task [1].

3.1. Passive Secondary Contacts

Passive solutions, depending fully on the operation speed of the disconnector, require materials with high arc erosion resistance. Material suitability is firstly indicated by a high melting point and a high tensile strength, nevertheless the tensile strength of a material is sometimes significantly reduced when heated (even far below the melting point). Tungsten, the element with the highest melting point of the periodic table of the elements, is a proven choice.

Market availability (raw material, alloys, machinability) and implied material costs is another important factor.

Finally, the resistance to corrosion and the conductibility is still of importance, so that mostly copper alloys will be used and respectively proportions needs to be defined. Further optimized material usage will be achieved by inlet applications and possible conductive connection methods need to be considered for the material choices, as well.

Reported application examples have been [1]:

- Passive add-on finger – a copper zirconium alloy finger with a copper tungsten alloy inlet and a copper tungsten alloy stud (high tungsten content – more than 3 quarters of the alloy experienced to be necessary of tungsten)

- Passive add-on needle – copper zirconium alloy crossbars with copper tungsten alloy inlets and 'tungsten needle'

The examples also successfully applied zirconium, which is another high-melting point element with a high enough tensile strength, also heated. Principally the noble metals are potential candidates: Ruthenium (Ru), Rhodium (Rh), Osmium (Os),

Iridium (Ir), Zirconium (Zr), Hafnium (Hf), Vanadium (V), Niobium (Nb), Tantalum (Ta), Chromium (Cr), Molybdenum (Mo), Tungsten (W), Rhenium (Re) and Technetium (Tc).

3.2. Semi-Active Secondary Contacts

Passive secondary contact may be enhanced by detailed design features for generating air flows advantageous for reducing the arcing time, so to increase the possible switching quantity or increase the switching capability.

For this, the air flow needs to be directed to one of the foot points of the arcing (inception point or arc origin), so that the separation or arc interruption will be facilitated. The enhancing effects are limited, but a significant advantage is the minimum weight effect for consideration of the mechanical behavior of the current path.

One successfully applied example is shown in figure 1, where a simple synthetic material could significantly increase the capability withstanding heating sufficiently.
Figure 1: Example of Air Flow Controlling Detailed Feature

The controlled air flow is not only forced into the right direction towards the arcing foot but is also determined for volume and speed by the given passage. As the success was experimental, the air flow details have not been measured, but the switching current was more than doubled (form 6 A to 15 A) at the same switching voltage (21 kV). The achieved switching current was limited by the used laboratory, so that the capability limit of the solution could not be determined.

The finger outline (knife type) allows a relatively long air flow controlling item and therefore passage, which is important for determining the speed of the used volume. The passage is generated as a cuboid-like channel between the detailed design feature and the secondary contact finger by the fixation solution of the feature on the finger. The applicability depends highly on the outline of the used secondary contact, so that the shown example is limited in its applicability accordingly.

Further it represents rare occasions, where the type test execution allowed contractually a limit testing (in this case limited by the laboratories capabilities). The usual situation, as valid for all other shown cases, is a design and testing as per standard and its required values to be fulfilled (mainly IEC 62271-102 [2] or specific customer requirements).

3.3. Active Secondary Contacts

Full active secondary contacts will be designed with elements storing kinematic energy, which is released when required and

provide the independent speed – classically those elements will be springs [5-9].

Figure 2 shows an example of such an active secondary contact. Compared to known passive contact systems it could be validated, that the switching capabilities are achievable with using only classical materials – the using of high-melting point materials or accordingly copper alloys was not necessary.
Figure 2: Active secondary contact system (double side break disconnector)

Figure 3 shows the same example of such an active secondary contact at a position of the closing operation, where the secondary contact is ahead of the main contact system. The copper sheet needs to run over the stainless-steel stud, so that the secondary contact goes behind the main contact system while the opening operation.
Figure 3: Feature Active secondary contact system in ahead-position

The spring is effectively applied only while the opening operation, so that the kinematic energy is specifically used for the demolition of the arc.

The intensity of the arc erosion while the closing operation is of much lower severity – as the arc arises, while the arcing distance decreases steadily. The arcing time is generally lower and the arc erosion stress on the foot points is less. In contrary, the erosion while the opening operation is of much higher severity – as the arc arises, while the arcing distance increases steadily until a high enough distance for insulation by air is achieved. In dependence on the arc intensity (voltage and current) the arcing time is

maximized in relation to the air gap necessary for demolition – exactly here the spring application comes into effect. Where passive solutions need to withstand this to full extend (only minimizable by dimensioning and eventually material elasticity), active solutions can significantly reduce the time independent speed. Of course, also active solutions require right dimensioning, as the used spring energy needs to fit to the allowed arcing time – achieved air gap at the time of arc ignition.

The spring application of active solutions does not require high-melting point material, which avoids the before mentioned challenges in regards of market availability. This allows again the usage of general core activities of disconnector designer and supplier concerning the current paths – plated copper / contact systems with spring applications.

Additionally, secondary contacts can be equipped with air flow controlling detailed feature. The shown example of figures 1 and 2 gives only little room for this.

3.4. Medium Voltage Switching Units

A further possibility for highest switching capabilities is given by the application of medium voltage switching units for active secondary contact systems. Those can be SF6 switching units or vacuum switching units, where the latter one is by far the preferred one as the first one is getting banned already in certain markets due to its negative environmental effects. Such a unit provides the advantage that in case of closing operations being kept open, no lightning occurs (because of the gap in the chamber of the unit). Important considerations of the application:

- Need for short-circuit resistivity in regards of the disconnector application
- Weight implications for the mechanical operation behavior of the current path – especially if applied to the moving part
- Potential requirement for complex kinematics for the operation of such units (tensioning and releasing unit internal spring applications)
- Protection of such units against environmental effects (e.g. rain or ice) with housings

The so far reported solutions (passive and active) are providing the big advantage against potential switching units application, that the weight implications is only low or eventually moderate and that the environmental protection coverage is mostly already given by the accordingly protection of the main contact system (or by simple and small size increase of the same).

The following earthing switch examples (figures 4 to 6) show known and successfully applied medium voltage switching units, which provide a technical basis being transferable to disconnectors.
Figure 4: Earthing Switch Application with SF6-Switching-Unit (switching capability beyond class B as per IEC 62271-102)
Figure 5: Earthing Switch Application with Vacuum-Switching-Unit and Arrester (switching capability requirement without lightning fulfilled)
Figure 6: Earthing Switch Application with Vacuum-Switching-Unit and Spark Gap (switching capability requirement without lightning fulfilled)

4. Values and Testing

In practice, as well as per IEC 62271-102, type test confirmations are possible and common [2,3].

Regarding passive secondary contacts a confirmation of the type test for the same type of disconnector is physically evident for increasing disconnector sizes (higher rated voltages), as the arm length of the current path increases and therefore the angular speed increases. This provides beneficial conditions for the secondary contact as the arcing time gets reduced the reference type test is safely applicable. The same is difficult for decreasing disconnectors sizes by reduced current path arm length and consequently reduced angular speed and increased arcing time. Even with the proven margin within a type test, the applicability is not secure. Such kind of confirmation challenges will be increased by changing the disconnector type.

For active secondary contacts the confirmation situation is much more convenient based on the independent speed. The applicability or validity of successful type tested active secondary contact is evident based on the positioning of the secondary contact elements for their function and in relation to the main contact system (protection purpose) in accordance to the reference type test. The disconnector operational speed is not relevant. This is another important advantage of active solutions.

4.1. Switching Capability Values

The reported solutions are classical solutions and followed the edition 1 of IEC 62271-102. Therefore, the switching capability target was usually set to a switching current of 1600A, the limit given with the rule for 80% of the rated continuous current. Further, the switching voltage was mostly set to 100V, as most of

the market requests have been served with accordingly rated voltages (up to 170kV as per edition 1 of IEC 62271-102, but often also for higher rated voltages based on customer acceptance). The reported example of an active solution followed this approach, as it was achieved before the release of edition 2 of the IEC 62271-102 [2,3].

Since edition 2 of IEC 62271-102 [2], the general limit of 1600A is only applicable for rated voltages <245kV. For rated voltages of ≥245kV and ≤550kV, the limit is set to 4000A, which is a significant increase in arcing intensity for the switching capability (even though the percentage approach was reduced to 60%). Further, the switching voltage required is not only based on ranges of the rated voltage, but additionally dependent on the rated continuous current [2, 3].

Following an approach to design a solution for covering a major part of the values with this given current scenario is very difficult, if not impossible with passive secondary contacts. Latest for rated voltages of 245kV and above this will require active secondary contacts, as those provide higher capabilities – beside the advantageous confirmability.

4.2. Test Circuits and Laboratories

Edition 1 of IEC 62271-102 requested a power factor of 0.15 for the test factor and certain conditions for the transient recovery voltages, where the edition to requires a power factor of 0.5 and skipped the part for the transient recovery voltages. On the maintenance for at least 3s after interruption of the power frequency recovery voltage is no change between the editions of IEC 62271-102 [2, 3].

In fact, this is reducing the arc intensity for the type test. However, first experiences indicate that this is far not enough for having passive secondary contacts capable to achieve the before mentioned approach on switching capability values [7-9].

Basically, high power laboratories are providing equipment for testing the switching capabilities of air insulated high voltage disconnectors. The following restrictive points for the test execution of disconnectors must be carefully aligned with such potential laboratories:

- Space constraints – as disconnector test objects easily lead to high installation space necessary, specifically with increasing rated voltage of the test object. Ground fixation can be a challenge regarding the typical outline of a disconnector, which is potentially unusual for the equipment tested in the concerned laboratory. The installation height is another specific aspect of a typical disconnector outline with potential high challenge for the concerned laboratory

- Where the switching current to be tested is generally unproblematic for high power test laboratories, the switching voltage to be tested has carefully to be checked with the laboratory. This is even more stressed regarding the required values for high rated continuous currents following the IEC 62271-102 edition 2 [2] (identifying a high voltage laboratory with capabilities for the switching currents to be tested is very unlikely).

- The time necessary for the test execution is an important factor, as well. As such tests are usually not the core business of accordingly laboratories, the necessary slot size by time

needs carefully to be aligned – the laboratory utilization, the throughput of test quantities, will be significantly impacted. The main determination of the overall test execution time is not mainly given by the quantity of operations to be done, but by the necessary time between to operations. This can be called cooling time and has to be determined by the disconnector designer/ supplier. Classically the focus was given by the avoidance of a motor overload (operating mechanism of the disconnector, automated test execution), which is with nowadays' motor performances not an issue. In fact, the focus needs to be given to the heating of the secondary contact – pre-heated secondary contact in view of subsequent operation. A maximum time gap between 2 operations is not regulated by standards and a realistic occurrence in the field will not be within minutes (maybe within days). For the before mentioned passive solutions a minimum time gap of 2 minutes was found to be enough (based on the high-melting point element tungsten). Considering 100 necessary operations (IEC 62271-102) [2], this ends up already to 3 hours, where setting, operation and frequent visual inspection has to be added, so that this part of the test execution easily need already a full day

Figure 7: Switching Capability Type Test Set-Up of a 245kV Center Break Disconnector with a Passive Add-On Finger Solution

Market demands represented in standards or resulting in new versions of standards are especially in the case of IEC globally driven. Based on this the possible design realization may be given already, but not generally. Usually it will be left to suppliers and customers to foster such realization, which will require consideration and alignment with testing facilities for realizations of accordingly type tests. The basis will be for the supplier, as well was for testing facilities, positive economic value adds. Potential volume, utilization and market prices will need to provide a

minimum basis for judging accordingly efforts. Partially even the requesting customers will join in a collaborative approach covering certain costs for realization (invests on disconnector supplier and/or tasting facility sides).

The switching capability testing for air insulated high voltage disconnectors could already be executed successfully with medium voltage high power laboratories (refer to figure 7). On first view this seems to be unusual but was possible since the above restrictive points have been servable.

5. Applicability Conclusion

As in every case of significant changes in standards and regulations there will be a transition period before the market will strictly insist. The established secondary contact solutions for the switching capability realization will therefore persist on the market for a certain period.

The market is already demanding steadily increased rated continuous currents, which is also reflected by the edition 2 of IEC 62271-102 [2], but not comprehensively. This is fostering the increased switching capabilities reflected in the edition 2 of IEC 62271-102 [2], but accordingly market demands run after the rated continuous current demands.

5.1. Passive Solutions

The shown examples are well suitable and proven especially for the rated voltage application <245kV, also in regards of the second edition of IEC 62271-102 [2]. Nevertheless, those solutions are at its limits and may exceed the given capabilities by semi-active detailed features. It requires the management of high-melting point elements for the design and the purchasing.

Consequently, it is reasonable that those passive secondary contact solutions will experience a replacement by simple active secondary contact solutions (e.g. the one reported above), as those allow increased switching capabilities and the avoidance of high-melting point elements.

5.2. Active Solutions

It is expected that active solutions will be the common solution in the feature based on the potentials given above – specifically in case of simple material usage and spring application, as reported above.

Considering the highest switching capability requirements as per edition 2 of IEC 62271-102 [2] – for the highest rated voltages and rated continuous currents – a strong demand for solutions integrating medium voltage switching units (chambers) is expected. Taking into account typical examples of bus-transfer disconnectors, like the pantograph disconnectors, and accordingly expected switching capabilities requirements as per IEC 62271-102 [2] or even above based on customer requirements, it is unlikely to be achievable with kinds of simple active solutions without compromising on functional reliability.

Vacuum chamber applications to the mating contact of pantograph disconnectors of 420kV rated voltage are under investigation and a final design achievement will need to be proven by type testing.

5.3. Earthing Switch Solutions

Earthing switches by its design and purpose must consider distinctive switching capabilities against disconnectors. Already accordingly standards are covering those switching capabilities reasonably distinctive [1-3].

Introduced earthing switch references with passive, active or active solutions considering medium voltage switching units are to be discussed separately. Basically, those known and successfully applied solutions are transferrable to disconnectors, but need specific considerations – e.g. the current path of an earthing switch is not having any duty of carrying rated continuous current, where this is one of the main duties of the current path of the disconnector (also this underlies exceptions for the earthing switch for certain applications) [1-9].

Conflict of Interest

The authors declare no conflict of interest.

Data sensitivity analysis using normalization techniques in decision making has an impact on preference values and rankings in the case of social assistance programs for student online. The distribution of assistance is disproportionate and not on target to potential recipients. This study aims to analyze data sensitivity from simple data normalization techniques and linear techniques in decision making. In particular, a simple data normalization technique is illustrated using Simple Additive Weighting (SAW), and a linear technique using the VIšekriterijumsko KOmpromisno Rangiranje (VIKOR) method. There are five criteria used, obtained from observation through measurements and a questionnaire from 400 students. The confusion matrix testing method is used to measure the value of data sensitivity, which includes precision, accuracy and error rate. The results of the study obtained data analysis sensitivity for each method shows that the distribution of normalized data in the selection of 10% (40 students) of positive target recipients, the sensitivity of the linear technique (Vikor method) is higher than the simple technique (SAW method). However, for the target of 15% (60 students) the simple method is higher. The results show that each data normalization technique for decision-making analysis has a different sensitivity value in terms of social assistance for target groups, although many studies suggest that certain methods may be better than others.

1. Introduction

Education World in the midst of a crisis due the Covid-19 pandemic causes UNICEF, WHO and IFRC [1] appeal that when the situation where the virus is spreading rapidly, schools must be closed and the education process must be continued through online learning activities using various media in "Prevention and Control of COVID-19 spreading in schools [1]". In response to this, the Indonesia Government issued a circular on the implementation of distance learning, through a Circular of the Minister of National Education regarding education policies during the Covid-19 emergency [2].

The closure of 217,270 schools and 4,670 higher education cause students: 25.5 million Primary Schools, 10.12 million junior high schools, 4.78 million senior high schools, 4.9million Vocational high school, 130 thousand children with disabilities schools and 8 million college-undergraduate students in higher education institutions must learn from home (LFH). However, to implement the policy is not as easy as expected. There are many things that make the implementation of online learning not optimal, the lack of facilities and technological literacy [3], the unpreparedness of educators for students [4], and there are several regions, certain areas that do not allow residents to use electricity (IT). In addition, the economic crisis caused by the pandemic has also become an emergency because it is in regard to community welfare issues.

The economic crisis problem has a significant impact on students in fulfilling internet needs for access to online learning, their parents cannot afford it and difficulties in providing more budget to buy internet data. Therefore, several Indonesia region government policies and educational institutions provide free internet data assistance to students to support the continuity of online learning.

The research study is motivated by the subjectivity in decision-making problems in the internet data assistance management to students. The distribution of data assistance is less than optimal and right on target to potential beneficiaries(student).

The normalized data technique according to research it is very important for the method of decision making, because the data

must be numerical and comparable to be combined into one score per alternative [5], The research revealed that normalization affects the results of the MADM method [6]. This study examines the popular effects of normalization procedures and shows that the empirical deformation of data caused by the use of normalization can influence the final choice [6], and Normalization Techniques for Analytical hierarchy process case study [7], about A state-of-the-art survey on the influence of normalization techniques in ranking for Improving the materials selection process in engineering design [8] and others. Therefore, it is the author's interest to apply and select appropriate normalization techniques and targeted handling in the distribution of internet data assistance programs.

In an effort to improve decision data analysis management, we propose a decision-making analysis method by providing a sensitivity study of decision-making methods in determining individual and group alternatives. We offer the SAW and Vikor analytical approach as a linear and simple method in preparing the decision matrix. In particularly. The study purpose was to provide an evaluation of the performance sensitivity of the VIšekriterijumsko KOmpromisno Rangiranje (VIKOR) and Simple Additive Weighting (SAW) methods in group decision making for ranking in internet data assistance programs. This study describes the results of the sensitivity analysis using the confusion matrix measurement approach to the sensitivity, which includes precision, accuracy, and error rate values.

The research contribution as a novelty in implementation and development extends to the use of decision-making analysis techniques and methods that affect preference assessments in handling cases of distribution of social assistance internet data packages for online learning.

2. Materials

2.1. An Overview Internet Data Assistance Program

One of the social assistance programs from the government and various universities and schools in Indonesia in dealing with the economic crisis of the community during the Covid-19 pandemic in the field of education is the distribution of internet data assistance to support students in learning online from home [9]. This program is managed by policymakers or stakeholders in an effort to maintain the continuity of learning activities. The object of a case study at a tertiary institution in East Kalimantan Province, Indonesia, especially for undergraduate students of the Informatics Department. Mulawarman University.

The initial activity was carried out by observation through collecting information about the needs for the amount of internet data usage, and the economic abilities of students. The results of the observations obtained five parameters which are used as criteria in decision making are; Use of Internet Data (C1), Subjects of Learning (C2), Credit Courses (C3), Economic Capability (C4) and Purchasing Power Data (C5). The description of student characteristics is shown in Table 1.

Table 1 presents the characteristics of student beneficiaries who are divided into 3 categories of beneficiaries who have the highest attributes of the benefit criteria or the maximum (C1, C2, C3), and the lowest in the cost or minimum attribute criteria (C4, C5), meaning that the main priority of the potential beneficiaries.

the benefits are those with high internet data usage, the number of courses and credits. Whereas for the low category are those (students) who are not targeted for assistance, this category has minimal internet data usage, few courses and credits, and has high economic capacity and data purchasing.

Table 1: Student Characteristics

Metrics	C1	C2	C3	C4	C5
Attribute	Max	Max	Max	Min	Min
Mean	749.21	7	20	2,133,113	237,000
Median	732.2	7	21	1,950,000	200,000
Mode	490.6	7	24	2,000,000	100,000
Std. Dev.	146.6	1.2	3.1	649,083.2	124,779.5
Min.	490.56	5	14	1,000,000	100,000
Max.	1,130.17	9	24	4,000,000	500,000
N	400	400	400	400	400

2.2. Sensitivity Analysis in Decision Making

The sensitivity of data analysis in decision making is influenced by many factors. This study discusses the sensitivity of normalized data analysis. In general, normalization in MCDM is a transformation process to obtain numerical input data and its comparison uses the same scale [7]-[10]. The normalization technique maps attributes (criteria) with different units of measurement to the same scale in the interval: 0-1.

The MADM methods determine how to attribute information is processed to arrive at a choice, reqsuiring comparisons between and between attributes, and involves appropriate explicit exchanges. Each decision matrix (decision table)in MCDM method has four main parts, i.e: (a) alternatives, (b) attributes, (c) weight or relative importance of each attribute, and (d) alternative performance measures with sets by attribute [11].

Several studies on the normalization matrix as in [8] examine the influence of normalization techniques in ranking: Improving the materials selection process in engineering design. Normalisation affects the results of MADM methods in [6] and [12]. Data normalisation techniques in decision making with TOPSIS method [5], Comparative analysis of normalization procedures in TOPSIS method: With an application to Turkish deposit banking market [13] and [14] etc. The linear normalization (LN) data sensitivity analysis we described it using the VIKOR method, and simple normalization (SN) data sensitivity was observed using SAW. The equations for the normalization method are presented in Table 2.

Table 2: The Normalization Equation for SN, LN, and VN

Attribute	Max	Min	
Simple (SN)	$r_{ij}\dfrac{a_{ij}}{a_j^{Max}}$	$r_{ij}\dfrac{a_{ij}-a_j^{Min}}{a_j^{Max}-a_j^{Min}}$	(1)
Linear (LN)	$r_{ij}\dfrac{a_j^{Min}}{a_j}$	$r_{ij}\dfrac{a_j^{Max}-a_{ij}}{a_j^{Max}-a_j^{Min}}$	(2)

3. Experimental Methods

3.1. Research Design

An overview of the research design is presented in Figure 1.
Figure 1: Research Design for Sensitivity Data Analysis Methods

3.2. Observation

Figure 1, the data collection method is through observation activities, namely data measurement to determine the amount of student internet data usage, and questionnaires to obtain information on the number of courses and credits, as well as the economic ability and purchasing power of students. Data collection was carried out at the peak of the Covid-19 pandemic. The results of activity observations form the basis for determining the criteria for mentoring.

The research observation population of 400 students is all students of the Department of Informatics at Mulawarman University who carry out online learning activities and become one of the alternative targets for internet data assistance.

3.3. Criteria Weighting Method

The criteria data for making decision assistance from the results of observation activities obtained five criteria for decision making; Use of Internet Data (C1), Learning Courses (C2), Credit Courses (C3), Economic Capability (C4) and data purchasing power (C5). The weighting method the criteria and attribute set used the Rank Sum weighting technique which refers to the research of Mats Danielson and L. Ekenberg [15] using the equation.

$$wi^{RS} = \frac{N+1-i}{\sum_{j=1}^{N}(N+1-j)} \qquad (3)$$

Denote the ranking number i among N items to rank, a larger weight is assigned to lower-ranking numbers [15]. Furthermore, from the calculation of equation (3), the criteria weight values are obtained and include the attributes shown in Table 3.

The attribute set for the criteria of Use of Internet Data (C1), Subjects of Learning (C2), Credit Courses (C3) are set to benefit

attributes (Max) with straight ranks and Economic Capability (C4) and Purchasing Power Data (C5) set Cost attribute (Min).

Table 3: The Criterion Weighting and Attribute

Criteria	Straight rank (rj)	Sum Rank weight (n − rj + 1)	Normalized weight	Attri-bute
C1	1	5-1+1= 5	0.333	Max
C2	2	5-2+1= 4	0.267	Max
C3	3	5-3+1= 3	0.200	Max
C4	4	5-4+1= 2	0.133	Min
C5	5	5-5+1=1	0.067	Min

3.4. Sensitivity Data Analysis Methods

The data analysis method for decision making applies the SAW method for Simple Normalization(SN) and VIKOR for Linear Normalization(LN). An overview of the flow of data analysis can be seen in Figure 2.
Figure 2: The Data Analysis Flow

The step-by-step sequence of the problem of multi-criteria decision making for data normalization analysis refers to [11], [16] is defined in Figure 2. Simple Normalization (SN) performance description is illustrated using the SAW method referring to [17], [18], the equation:

$$p_i = \sum_{j=1}^{m} w_j\, r_{ij} \qquad (4)$$

where p_i is the performance value or preference value of the alternative to - i; w_j denotes the weight of the jth criterion; r_{ij} is the normalized rank selected from the ith alternative against the j is criterion to be the equivalent unit.

Linear Normalization (LN) performance description is illustrated using the VIKOR method referring to [19] the equation:

$$Q_1 = v\left[\frac{(s_i - s^{max})}{(s^{max} - s^{min})}\right] + (1-v)\left[\frac{(r_i - r^{max})}{(r^{max} - r^{min})}\right] \qquad (5)$$

V is the weight ranging from 0-1 (generally 0.5). The value of v is the weight value of the strategy of the maximum group utility, while the value of 1 - *v* is the weight of individual regret. The smaller the VIKOR index value (Qi) the better the alternative solution.

3.5. Confusion Matrix

The confusion matrix is used to measure the performance of SN, LN and VN data normalization methods. In this test, the reference results of the 3 methods are compared with actual data, ie. alternative data which is the priority for internet data assistance, in the high category. In measuring the performance of these three methods, there are 4 (four) terms referring to [20] as a representation of the results of the performance process, ie. True Potential Positive Assitance (TPP), True Potential Negative (TPN), False Potential Positive (FPP) and False Potential Negative (FPN) [17]. Measurement values for sensitivity, accuracy, precision and misclassification (error rate) refer to [21], [22] as follows:

- $Sensitivity = \frac{TPP}{FPN+TPP} 100\%$ (6)

- $Accuracy = \frac{TPP+TPN}{TOTAL} 100\%$ (7)

- $Precision = \frac{TPP}{FPN+TPP} 100\%$ (8)

- $Error\ Rate = \frac{FPP + FPN}{TOTAL} 100\%$ (9)

4. Results and Discussion

4.1. Data Description Analysis

- Alternative data and criteria

The research data was obtained through observation activities in the form of measuring internet data during online learning (C1) and filling out questionnaire forms (C2, C3, C4, C5), which were obtained from 400 undergraduate students Informatics Dept, as an alternative in decision making or potential beneficiaries. Description of this data is shown in Table 4.

Table 4: description data analysis

Alts.	C1	C2	C3	C4	C5
A1	926.18	9	24	1,800,000	100,000
A2	690.96	9	23	1,850,000	100,000
A3	849.73	9	19	3,850,000	300,000
A4	1,002.07	9	23	1,350,000	100,000
A5	1,005.88	9	24	1,450,000	100,000
A↓	⋮	⋮	⋮	⋮	⋮
A399	1,002.31	9	23	1,200,000	100,000
A400	798.77	9	18	3,000,000	500,000
Avg.	749.21	7	20	2,133,113	237,000
Min.	490.560	5	14	1,000,000	100,000
Max.	1,130.17	9	24	4,000,000	500,000

Data analysis (datasheet) in Table 4, arranged in a decision matrix containing the value of each alternative A1 to A400, the average value for C1 is 749.21 MB, C2 averages 7 courses, for C3 averages 20 SKS for courses, C4 an average of IDR 2,133,113 and C5 an average of IDR 237,000. While the min-max value obtained

is 490,560 MB - 1,130,170 MB of internet data usage (C1), 5 - 9 number of courses (C2), 14-24 credits of courses (C3), IDR 1,000,000 - IDR 4,000. 000 economic capacity (C4), and IDR 100,000 - IDR 500,000 for C5.

4.2. Result: Normalization Data Analysis

- Result: Normalization Simple Data (SN)

Normalized data analysis for a simple technique using equation (1) calculating the min and max, the value of each alternative (A1 to A400) is obtained as shown in Table 5.

Table 5: Normalization Data SAW Method

Alts.	r_{1ij}(C1)	r_{2ij} (C2)	r_{3ij}(C3)	r_{4ij}(C4)	r_{5ij}(C5)
A1	0.819	1.0	1.0	0.555	1.0
A2	0.611	1.0	0.958	0.540	1.0
A3	0.751	1.0	0.791	0.259	0.33
A4	0.886	1.0	0.958	0.740	1.0
A5	0.890	1.0	1.0	0.689	1.0
A↓	⋮	⋮	⋮	⋮	⋮
A399	0.886	1.0	0.958	0.833	1.0
A400	0.706	1.0	0.7	0.333	0.2
Avg.	0.663	0.830	0.842	0.509	0.578
Min.	0.434	0.556	0.583	0.250	0.200
Max.	1.000	1.000	1.000	1.000	1.000

The calculation results (Table 5) of normalized data analysis using simple techniques, which are illustrated using the SAW method, the value of the simple technique is obtained with an average of 0.663 for C1 with a min value of 0.434 and a max value of 1.0. For C2, an average value of 0.830, C3 an average of 0.842 (min 0.583 - max 1.0), C4 an average of 0.509 (min 0.250 - max 1.0) and for C5 an average of 0.578 with a min 0.2 - 1.0.

- Result: Normalization Linear Data (LN)

Normalized data analysis for a linear technique using equation (1) calculating the min and max, the value of each alternative (A1 to A400) is obtained, as shown in Table 6.

Table 6: Normalization Data VIKOR method

Alts.	r_{1ij} (C1)	r_{2ij} (C2)	r_{3ij}(C3)	r_{4ij}(C4)	r_{5ij}(C5)
A1	0.681	1.000	1.000	0.733	1.000
A2	0.313	1.000	0.900	0.717	1.000
A3	0.562	1.000	0.500	0.050	0.500
A4	0.800	1.000	0.900	0.883	1.000
A5	0.806	1.000	1.000	0.850	1.000
A↓	⋮	⋮	⋮	⋮	⋮
A399	0.80	1.00	0.90	0.93	1.00
A400	0.48	1.00	0.40	0.33	0.00
Avg.	0.4044	0.6181	0.6213	0.6223	0.6575
Min.	0.000	0.000	0.000	0.000	0.000
Max.	1.000	1.000	1.000	1.000	1.000

The calculation results (Table 6) from normalized data analysis using a linear technique illustrated by the VIKOR method obtained a linear technique value with an average of 0.4044 for C1, for C2 an average value 0.6181, C3 was 0.6213, C4 was average. 0.6223

and for C5 the average is 0.6575. While the min and max values for each data criterion are at 0.0 - 1.0. Furthermore, the visualization of the data spread for simple and linear normalized data technique is shown in Figure 3.
Figure 3: Scatter-chart Data Normalization SAW-VIKOR

Figure 3 presents a simple technique data spread visualization showing the central area of the spread data for C1 range of 0.434 to 1.0. Meanwhile, the linear technique shows a distribution area of 0.0 to 1.0

4.3. Preference and Ranking

- The preference value

The preference value (P) for SAW method according to (3), for VIKOR using (4). The calculation results for each alternative (A) are shown in Table 7.

Table 7: Preference Value SAW and VIKOR

Alts.	Simple Norm.	Linear Norm.
	SAW	VIKOR
A1	0.880576	0.918040
A2	0.800864	0.827270
A3	0.732474	0.752377
A4	0.919317	0.942831
A5	0.921962	0.953826
A6	0.973333	1.000000
A7	0.789162	0.844602
A8	0.849240	0.885965
A9	0.816799	0.875406
A10	0.874123	0.908853
A11	0.936147	0.964779
A12	0.925985	0.960283
A↓	⋮	⋮
A399	0.931733	0.947088
A400	0.710034	0.725979

Table 7 is the preference value of the simple normalization data (SAW) and linear (VIKOR) calculation of 400 alternatives, which is the final result of the assessment of the criteria and weighting values of students who are prospective recipients of internet data social assistance. Furthermore, the visualization of the spread of

preference data from the SAW and VIKOR methods is shown in Figure 4.
Figure 4: Chart Preference Value SAW and VIKOR Method

Figure 4 shows a graph of the spread data preferences from the SAW method in the area 0.5408 - 0.9921 and the VIKOR method in the 0.0 - 1.0 area.

- Ranking

The calculation results of preferences are then sorted from largest to smallest, where the largest alternative preference value is the best alternative from the data which is the chosen alternative, while the alternative with the lowest preference value is the worst of the alternatives as shown in Table 8.

Table 8: Ranking SAW and VIKOR Method

SAW Method				VIKOR Method			
Rank	Alts.	Rank	Alts.	Rank	Alts.	Rank	Alts.
1st	A304	21st	A399	1st	A6	21st	A389
2nd	A375	22nd	A12	2nd	A395	22nd	A357
3rd	A292	23rd	A37	3rd	A304	23rd	A5
4th	A6	24th	A373	4th	A391	24th	A37
5th	A209	25th	A357	5th	A30	25th	A396
6th	A395	26th	A396	6th	A375	26th	A16
7th	A124	27th	A5	7th	A136	27th	A399
8th	A142	28th	A4	8th	A164	28th	A205
9th	A30	29th	A205	9th	A243	29th	A373
10th	A391	30th	A16	10th	A365	30th	A4
11th	A136	31st	A20	11th	A142	31st	A1
12th	A164	32nd	A1	12th	A292	32nd	A20
13th	A243	33rd	A10	13th	A75	33rd	A29
14th	A365	34th	A13	14th	A209	34th	A10
15th	A75	35th	A110	15th	A124	35th	A13
16th	A327	36th	A29	16th	A11	36th	A110
17th	A41	37th	A8	17th	A331	37th	A8
18th	A331	38th	A173	18th	A41	38th	A189
19th	A11	39th	A42	19th	A12	39th	A9
20th	A389	40th	A189	20th	A327	40th	A22

Table 8, there are 40 alternative ranking preference results from the two methods (SAW and VIKOR). Each method produces a different ranking of values, the SAW method produces an

alternative A304 with a preference value of 0.9921 in the first order A375, in the second-order A292, in the third order, and so on. Then, the results of the ranking preference Vikor method obtained the first alternative A6, A395 in the second, A304 third, and so on (see Table 8 and Figure 5).
Figure 5: The Ranking of SAW vs VIKOR method

The difference in the value of the two individual ranking decision-making methods is due to differences in the normalization data analysis method, where the SAW method applies the Simple Normalization (SN) method, and the VIKOR method uses the Linear Normalization (LN) even though the weighting of the criteria is equally important and the weight is straight.

4.4. Confusion Matrix: Sensitivity Data Analysis

Sensitivity data analysis uses a confusion matrix to determine the sensitivity, accuracy, precision, and misclassification of ranking values using actual data as an internal validation of the performance of each method. The test scenario is carried out by dividing the percentage of alternative aid targets by the target number of 10%, 15%, 20% and 25% (40 alt; 60 alt; 80 alt; and 100 alt.) potential recipients of social assistance and the sensitivity of decision-making methods regarding the target alternative groups.

Table 9: Actual Data vs SAW and VIKOR Rank Methods

Order	Alts.	SAW method Ranking	SAW method Valid	VIKOR method Ranking	VIKOR method Valid

Table 9 is an example of testing actual data for 40 alternatives out of a total of 400 alternatives (10%) that were targeted for selecting the SAW and VIKOR methods. The results are compared to then measure the confusion matrix. The comparison results in Table 9 validate the data from the 2 ranking methods against the actual data, then perform performance calculations. Table 9 presents the method of performance results for the 10% target or 40 alternatives.

Table 10: The Confusion Matrix Decision Analysis for SAW Method

	N = 400	SAW Method	
		Predicted: NO	Predicted: YES
Actual Data	Actual: NO	TPN = 320	FPP = 40	360
	Actual: YES	FPN = 4	TPP = 36	40
		324	76	

From Table 10, the performance value for SAW method:

- Sensitivity using(6): → 36/40 = 0.9 = 90%

- Accuracy using(7): → (320 + 36) / 400 = 0.890 = 89,0%

- Precision using(8): → 36/(36+40) = 0.474 = 47,4%

- Error rate using(9): → (40+4)/400 = 0.110 = 11,0%

From Table 11, the performance value for Vikor method:

- Sensitivity using(6): → 37/40 = 0.925 = 92,5%

- Accuracy using(7): → (320 + 37) / 400 = 0.893 = 89,3%

- Precision using(8): → 37/(37+40) = 0.481 = 48,1%

- Error rate using(9): → (40+3)/400 = 0.108 = 10,8%

Table 11: The Confusion Matrix Decision Analysis for Vikor Method

		SAW Method		
N = 400		Predicted: NO	Predicted: YES	
Actual Data	Actual: NO	TPN = 320	FPP = 40	360
	Actual: YES	FPN = 3	TPP = 37	40
		323	77	

Table 12: The Summary Scenario Results: Method Performance vs Actual Data

Metric	SAW Method				VIKOR Method			
	10%	15%	20%	25%	10%	15%	20%	25%
Sensitivity	90.0	80.0	80.0	75.0	92.5	76.7	80.0	79.0
Accuracy	89.0	82.0	76.0	68.75	89.3	81.5	76.0	69.76
Precision	47.4	44.4	44.4	42.9	48.1	43.4	44.4	44.1
Error rate	11.0	18.0	24.0	31.25	10.75	18.5	24.0	30.25

The summary of the performance measurement data from the percentage set scenario for the target alternative group is shown in Table 12.
Figure 6: Sensitivity and Accuracy Methods – SAW vs VIKOR

Figure 6 shows a line-chart of the sensitivity and accuracy values of the SAW and VIKOR methods, the sensitivity in determining targets results in different performance values, at the 20% target (40 targets) the Vikor method is 1 alternative higher than SAW, meaning that Vikor's sensitivity value for target 40 people with a sensitivity of 0.925 or 92.5% while SAW was 90%. However, when the target was increased by 15%, (60 targets) the SAW method was more sensitive than VIKOR, with a ratio of 48:46 or about 80% SAW: 76.7% VIKOR. When the target is increased by 80 people (20%), both methods have the same performance value for each metric (sensitivity, accuracy, precision and error rate), SAW and VIKOR.

Figure 7 shows the error rate value has increased linearly and simultaneously with an average increase of 7 points. and the value of precision is influenced by the sensitivity value decreases. In

principle, both the SAW and VIKOR methods are included in the linear analysis model, and this result is influenced by the weighted value setting assigned to the criteria.
Figure 7: Precision and error rate value method SAW – VIKOR

4.5. Discussion

This work also demands sensitivity in examining the details of the data and must be careful to look at every detail of the values that exist. The two methods used have their own characteristics in terms of sensitivity in the analysis of social assistance program data. From the results of the analysis of the previous method shows fundamental differences, it becomes our important point when carrying out this work, the findings include:

The data normalization analysis process, the results obtained show the distribution of values in the SAW method (see: Figure 3) which explains that the results of data normalization are coherent (dependent) in the value range [0.4 - 1.0], while in the Vikor method, the results of data normalization are independent of the range [0.9–1.0]. This explains that the spread of the results of the integrated SAW analysis normalization shows fierce competition in the selection, and will also have a significant effect on the performance (preference) of the SAW method. The benefit is that it is suitable for use in the case of group selection (10%, 15%, 20%, 25%).

The process of analyzing the performance of the social assistance data sensitivity also shows differences in determining the selection of positive beneficiaries, the VIKOR method has a higher sensitivity value than the SAW method if the alternative target is chosen by 40 students (10%), this can be seen from a higher preference value (see Figure 6). However, under certain conditions or when the target recipient of social assistance is increased (target 15%), the performance gradually decreases, the SAW method is higher.

This is based on the results of observations caused by the distribution of the normalized values of VIKOR data in the distribution range of 0 to 1, and the distribution of data (preference values) of the SAW method is mostly centred in the lowest distribution area of 0.5408 to 0.9921. In other data analysis also

obtained the same performance value, namely when the target beneficiary target is increased (20% target), and the addition of the target 25% target (100 alt) shows that the performance of the VIKOR method increases linearly better than the performance of the SAW method. This means that the characteristics of these two methods are different and experience changes in preference values caused by the different value distribution of the two Normalized Data techniques. In addition, the important point of this study is the sensitivity value of normalized data techniques in the decision-making process based on the number of target alternatives for social assistance and the total alternatives.

5. Conclusion

Decision making related to social assistance for community welfare requires good management because a slight change or error in determining the analytical method approach has a significant impact on the results, this is explained from the work carried out showing the sensitivity of simple techniques and linear techniques for normalized data in decision making.

The results of this study are based on the characteristics obtained from the two methods providing conclusions for new research for the author to explore further, namely, there are differences in the final rating (preference) value of the target size, and this occurs because of the influence of the characteristics of the data distribution of each. normalized techniques, for cases with a target <10% Linear techniques illustrated using the VIKOR method have a high degree of accuracy compared to simple techniques illustrated using the SAW method. However, if the target number of social assistance recipients is in the range >10% to 15% (60 alt from 400 alt), then the SAW method has a good performance, and the results of these observations are due to the distribution of data focused on certain areas. (preference value) of simple techniques that affect performance. That is, the use of Linear Normalization data technique is very good for decision making cases with small targets because it produces the right ranking performance compared to simple data normalization techniques.

Conflict of Interest

The authors declare no conflict of interest related to this paper.

A B S T R A C T

This research aims to investigate the energy and power management of a battery-supercapacitors Hybrid Energy Storage System (HESS) for Electric vehicles (EVs). A bidirectional DC-DC converter, a battery and a set of supercapacitors were employed to construct the parallel semi-active architecture of HESS. Two strategies of Rule-Base Linear Quadratic Regulators (R-B LQRs) were proposed to manage the power flow in HESS to reduce the overall battery stress during high demand events. The supercapacitors supply the high load demand, while the battery supplies the low load demand. The HESS, EV and the proposed controllers were simulated in a MATLAB/Simulink environment. Three standard drive cycles, namely, Urban Dynamometer Driving Schedule UDDS, New York City Cycle NYCC and Japan1015 drive cycle, were implemented to validate the controller's responses. The results of the R-B LQR controllers were compared in terms number of possible drive cycles. According to the results achieved, the proposed hybridization achieves stable response of the HESS current over the drive cycles, effectively reducing the battery's size and extends its life-time.

1. Introduction

Nowadays, landed vehicles can be categorized in to three main types, namely, conventional vehicles, Electric Vehicles (EVs) and Hybrid Electric Vehicles (HEVs). Conventional vehicles with an internal combustion engine (ICE) are the most common type in today's market. In ICEs, chemical energy (e.g. ethanol, gasoline, diesel etc.) is converted into kinetic energy in a process has significant power losses. On the other hand, the EV is an alternative-design automobile that relies on battery power to provide the electricity to actuate the vehicle by an electrical motor. Furthermore, The HEV is powered by two types of energy sources, namely, ICE and electrical motor with ESS; it combine the benefits of high fuel economy and low harmful emissions. Due to the necessity to reduce air pollution and harmful vehicle emissions, significant research has been focused on developing HEVs and EVs. Energy storage systems pose a significant issue in stand-alone applications. Batteries offer a wide range of the clean energy. Furthermore, they have high energy density and low power density due to chemical processes to deliver and store energy [1]. However, the main drawbacks are low cycle-life, and long recharging times. In addition, the immediate response to sudden load changes in charging and discharging could potentially reduce

the battery's lifetime. There are several kinds of chemical batteries that are currently available in the market such as lead-acid, lithium-ion, nickel metal hydride (NiMH) and nickel cadmium (NiCad) [2]. The supercapacitor is another energy storage technology, and is either an electric double layer capacitor (EDLC) or a pseudo-capacitor. These differ in the ways they store energy and charge [3]. Compared to batteries, supercapacitors have relatively low specific energy density and high specific power density. The supercapacitors are used as auxiliary an energy storage device due to the dependence of terminal voltage on the state of charge. Nevertheless, various benefits can achieved when using the supercapacitors as an auxiliary power source [4]. The low value of the terminal voltage is a core limit of supercapacitors; 2.5 volts is the maximum terminal voltage that can be provided by a single supercapacitor unit. However, several supercapacitors are connected in series and in parallel to achieve the required operation voltage and energy capacity by powerful applications. Consequently, many researchers have attempted to improve the performance of the ESS by combining high power devices like supercapacitors or flywheels in parallel with batteries. The main purpose of the Hybrid Energy Storage System (HESS) is to extend the efficacy of each power source [5]. This work designs a semi-active HESS by engaging a battery in parallel form with supercapacitors through a DC-DC converter, with the aim of

increasing the merits of the two devices, and decrease their limitations [6].

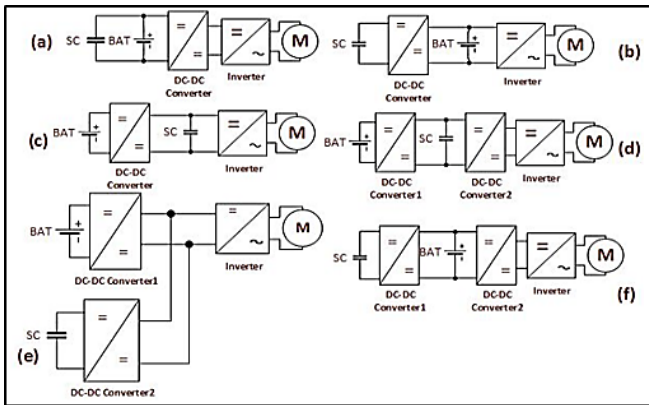
The essential challenge in the design of a HESS for EV is to manage the current flow between the supercapacitors and the battery. The advantages and disadvantages of many topologies of HESS have been reviewed extensively in the existing literature [7–9]. Furthermore, in the literature, the HESS used several types of bidirectional DC-DC converters. Figure 1 illustrates six different topologies of HESS. Figure 1(a) presents the simplest topology of a battery-supercapacitor system. Due to the direct connection, the battery and the supercapacitors voltage terminal remains the same, and the DC-DC converter is used to maintain the power flow. In this topology, the supercapacitor characteristics are limited. Furthermore, a full-sized DC-DC converter is needed to manage the delivered energy [10]. The configuration in Figure 1(b) is widely used in the literature [11, 12]. The bidirectional DC-DC converter was placed between the DC-Bus and the supercapacitors as an interface to manage the current flow in HESS. Reliability is the main feature of this topology, where the load current is not affected by the failure of the DC-DC converter. Figure 1(c) shows another configuration of a HESS. In this topology, the power flow of the battery was maintained within a safe range via the DC-DC converter. The supercapacitor operational range was limited, and it responded as an energy buffer [13]. The topologies represented in Figure 1(d, f) used two DC-DC converters to manage the power flow from the battery and supercapacitors, individually. These topologies require a full and medium sized DC-DC converter for every source. In addition, the loss, cost and weight are increased in this topology compared to the other topologies, in terms of the need for full-sized DC-DC converters [14, 15]. The scheme in Figure 1(e) uses a parallel connection of batteries and supercapacitors via two DC-DC converters separately, and suffers from the same constrains in Figure 1(d, f).


Figure 1: Most common HESS architectures [2].

On the other hand, many researches presented various models of bidirectional DC-DC converter designs for HESS [16,17]. The DC-DC converter was used to manage the current flow of HESS under transient and steady-state conditions. Many researches in the literature used different control algorithms to control the power flow of the HESS. In [17], the polynomial control strategy was used to manage the energy for two DC-DC converters, and the results are sufficient compared to the classical PI. Furthermore, recent studies focused on rule-based approaches such as fuzzy logic control [18] to manage the power flow in the HESS. The

accuracy in measurement noise and adaptation of fuzzy logic was used as an energy management strategy. However, human experience was implemented to design the membership function and fuzzy rule. Therefore, this cannot guarantee suitable control performance in unexpected conditions. In [19], the response of a non-linear model predictive controller was compared to a linear model predictive controller and rule-base control, based on the hybrid battery supercapacitors energy storage system for EV. In other work aiming to extend battery life-cycle, a rule-based controller of HESS was compared to a fuzzy controller, and the results show that in transient the controllers supplied the EV load current from the supercapacitor, while the battery supplied the load during the steady state [20]. In [21], the researchers tried to extend the driving cycle and decrease the size of the HESS by using multi-objective optimization. Three standard drive cycles were used to validate the proposed controller.

This research aims to design a control algorithm for HESS for an EV. Two control strategies of R-B LQR were proposed to be implemented as controllers in EV applications due to their simplicity to implement and short computation time compared with to optimization methods. The limit R-B LQR aims to limit the battery current to I_{b_max} while the share limit R-B LQR aims to limit the battery current to I_{b_max}, and share the load current between the battery and supercapacitor. Dual control layers were used in this work. The rule-based approach was used to obtain the desired supercapacitors current during the load demand. The LQR was used to control the DC-DC converter by manipulating the width of the duty cycle of PWM. In addition, the LQR controller can guarantee good close-loop behavior for the DC-DC converter, and it is relatively insensitive to external disturbances, since the controller feedback gain-vector has to be determined optimally [22, 23].

This paper is organized as follows. Section 2 discusses the HESS configuration. Section 3 discusses the modeling of the HESS and EV. Section 4 contains the proposed controller algorithm. The simulation results of the proposed controller are presented in Section 5. Section 6 concludes of this research.

2. System Configuration

In EV applications, a practical HESS should be light, highly reliable, and have fast response for load variation. Due to the previous reasons, the semi-active architecture in Figure 1(b) was selected to be implemented in this work. Figure 2 shows the semi-active topology of HESS in Matlab/Simulink. The model of the battery is connected directly to the model of the EV as a premier energy source, and the model of the supercapacitors is connected to the EV model through the bidirectional DC-DC converter model as an auxiliary energy source. Three different standard drive cycles, namely, UDDS, NYCC and Japan1015, were used to validate a performance of the proposed controllers.

The limit R-B LQR controller was designed to manage the current flow of the HESS by limiting the current of the battery to I_{b_max}. The supercapacitors supplied the peak load demand of the EV. Furthermore, the share limit R-B LQR controller was designed to manage the current flow of the HESS by limiting the current of the battery to I_{b_max}, and sharing the load current between the battery and the supercapacitors. The bidirectional DC-DC converter has two functions; it works as a boost converter during

the acceleration of the vehicle to discharge the supercapacitors energy, and also works as a buck converter during the deceleration to absolve and store the regenerative current. The maximum gain of the terminal voltage for the DC-DC converter was set as less than three, to increase the overall efficiency of the system [24].
Figure 2: The parallel semi-active architecture of HESS for EV.

3. The Modelling of the HESS System

In order to verify the proposed algorithm of the HESS for EV, an accurate model comprising the battery, supercapacitors, DC-DC converter and Electric Vehicle was required. Several different models of HESS components have been presented in the literature.

3.1. Model of the Battery

An equivalent circuit model is a common model that uses electrical components to model the behavior of the battery. There are many approaches to represent the electrical equivalent circuit model for the battery. The majority of these representations fall into three main classifications: Thevenin, impedance and runtime-based models [25–27] . Electrochemical batteries have a complex and nonlinear behavior during charging and discharging, depending on the battery's state-of-charge (SOC) and electrolyte temperature. For this reason, the researchers in [28] attempted to find a dynamic model that represents this nonlinearity. Furthermore, some researchers used the system identification technique to estimate the parameter values of the battery model [29]. Other researchers used the parameter estimation technique to obtain the parameter values for equivalent model of the battery [30]. Moreover, the thermal effect was considered in the battery models in these works.

The battery model can be found in the MATLAB/Simulink/SimPowerSystems library. This equivalent model contain a control voltage source and an internal resistance, as shown in Figure 3. The relationship between the time-varying parameters in the battery model is shown in Equation 1.

$$V_{bat}(t) = E_{bat}(t) - r_{bat}.i_{bat}(t) \qquad (1)$$

The battery current reduction ratio (BCRR) can be calculated by Equation 2 [31].

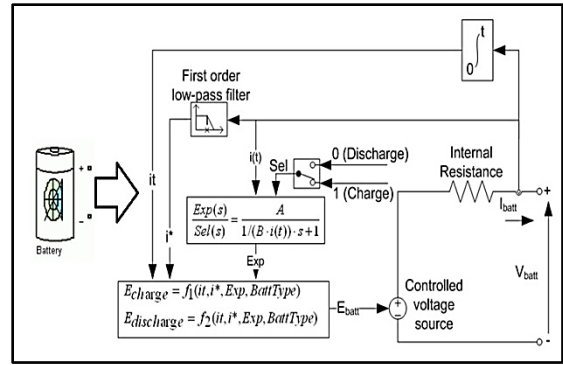
$$BCRR = \frac{\sqrt{\frac{1}{T}\int_0^T I_{bat}^2 dt}}{\sqrt{\frac{1}{T}\int_0^T I_t^2 dt}} \times 100 \qquad (2)$$


Figure 3: Equivalent model of the battery in SimPowerSystems library

3.2. Model of the Supercapacitors

Supercapacitors are commonly used in academia and in the automotive industry due to their high efficiency, low internal resistance, high power density, and long cycle-life. Equation 3 describes the behavior of the supercapacitor, which mathematically depends on the essential laws of a capacitor.

$$\begin{cases} i_{sc}(t) = -C_{sc}\frac{du_{sc}(t)}{dt} \\ V_{sc}(t) = u_{sc}(t) - r_{sc}i_{sc}(t) \end{cases} \qquad (3)$$

The design of the energy management system requires a model with good robustness and high precision, representing the dynamics behavior of the supercapacitor . The practical models proposed in [32] consists of three RC branches, and the parameters were determined from the terminal measurements of charging and discharging the supercapacitors. Other models that describe the behavior of supercapacitors are called dynamic models. The transient behavior of the supercapacitors is simulated by these models. The model parameters are identified through experimental tests, such as discharge and charge by the supercapacitor at constant current and electrochemical impedance spectroscopy in environmental constraints [33]. The supercapacitors model in MATLAB/Simulink/SimPowerSystems was used in this research.

3.3. Model of the DC-DC Converter

The model that describes the behavior of the DC-DC converter is important for designing the HESS controller, because the controller aims to control the bidirectional DC-DC converter to supply the required power from the supercapacitors. The terminal output voltage and output current of the bidirectional DC-DC converter were regulated by changing the width of the duty cycle of the PWM, which is applied to the IGBT of the bidirectional DC-DC converter. In this work, a solo layer of the bidirectional DC-DC converter was used to control the current flow of the supercapacitors in both directions. The boost converter was used to discharge, and the buck converter used to charge, the supercapacitors. Figure 4 represents the construction and main elements of the DC-DC converter [34].

The state-space average approach was used to model the bidirectional DC-DC converter. The nonlinear characteristics of the bidirectional DC-DC converter approximates to linear characteristics in the state-space average model. The OFF and ON status of the switching element was involved in the modeling of the DC-DC converter. The time averaging performance of the DC-DC converter is set as:

$$\dot{x} = [dA_{ON} + (1-d)A_{OFF}]X + [dB_{ON} + (1-d)B_{OFF}]V_{sc} \quad (4)$$

where:

$$\begin{cases} A_{on,off} = State\ matrices \\ B_{on,off} = Control\ matrices \\ d = the\ switching\ period \end{cases}$$
Figure 4: The main components of DC-DC converter

Figure 4, the control and state matrices of the bidirectional DC-DC converter in the OFF and ON conditions are represented as the following matrices:

$$X = [I_L \quad V_c]^T = state\ vector$$

$$A_{ON} = \begin{bmatrix} -\dfrac{r_L}{L} & 0 \\ 0 & \dfrac{-1}{C.(R+r_C)} \end{bmatrix}, \quad B_{ON} = \begin{bmatrix} \dfrac{1}{L} \\ 0 \end{bmatrix}$$

$$A'_{OFF} = \begin{bmatrix} \dfrac{-R.r_C - R.r_L - r_C.r_L}{L(R+r_C)} & -\dfrac{R}{L(R+r_C)} \\ \dfrac{R}{C(R_o+R_C)} & -\dfrac{1}{C(R_o+R_C)} \end{bmatrix}, \quad B_{OFF} = \begin{bmatrix} \dfrac{1}{L} \\ 0 \end{bmatrix}$$

$$\frac{d}{dt}\begin{bmatrix} i_L \\ V_c \end{bmatrix} = \begin{bmatrix} \dfrac{R.r_C.(d-1) - r_L(R+r_C)}{L(R+r_C)} & \dfrac{R.(d-1)}{L(R+r_C)} \\ \dfrac{R.(1-d)}{C(R+r_C)} & -\dfrac{1}{C(R+r_C)} \end{bmatrix}\begin{bmatrix} i_L \\ V_c \end{bmatrix} + \begin{bmatrix} \dfrac{1}{L} \\ 0 \end{bmatrix} V_{sc} \quad (5)$$

$$V_{co} = \begin{bmatrix} \dfrac{R.(d-1)}{(R+r_C)} & \dfrac{R}{(R+r_C)} \end{bmatrix}\begin{bmatrix} i_L \\ v_c \end{bmatrix} \quad (6)$$

$$\begin{cases} A_s = A = dA_{ON} + (1-d)A_{OFF} \\ B_d = (A_{ON} - A_{OFF})X - (B_{ON} - B_{OFF})V_{sc} \\ B_s = [B_d \quad B] \end{cases} \quad (7)$$

$$B_d = \begin{bmatrix} \dfrac{R.r_C}{L(R+r_C)}.i_L + \dfrac{R.r_C}{L(R+r_C)}.V_c \\ -\dfrac{R}{C.(R+r_C)}.i_L \end{bmatrix} \quad (8)$$

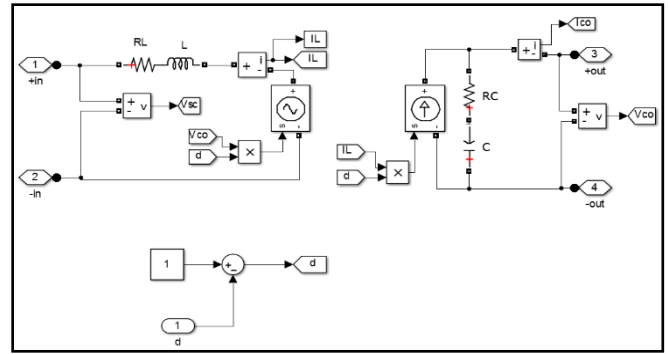
The parameters of the DC-DC converter were selected based on the hypotheses in [35]. The model of the DC-DC converter in Figure 4 was approximated by compensating the switching elements with an integration of controlled voltage and current sources, as represented in Figure. 5. This estimated model has good accuracy and reduces the overall simulation time [36]. Other methods were used to estimate the discrete function of the DC-DC converter in [37] by using the system identification technique.


Figure 5: Equivalent model of the bidirectional DC-DC converter

3.4. Electric Vehicle Model

To improve the energy consumption an accurate model representing the EV's behavior is needed. Many MATLAB/Simulink environment was used to develop few EV models by the researchers, whilst others depends on ADVISOR or equivalent software to analyze and compare the performance of a vast types of vehicles [29, 38–41]. In [4, 42] the dynamic system of the vehicles was defined clearly. The essential dynamics of the vehicles, the forces affecting the vehicles movement are acceleration force (F_{accel}), grading force (F_{grad}), rolling force (F_{roll}) and aerodynamic force (Faero) as shown in Equation 9. The motor drive were controlled the fuzzy logic control as in [43, 44].

where:

$$F_{accel} = M_v \times \frac{\partial v}{\partial t}$$

$$F_{grad} = M_v \times g \times Sin\theta$$

$$F_{roll} = \mu_{rr} \times M_v \times g \times cos\theta$$

$$F_{aero} = 0.5 \times \rho \times A_f \times C_d \times V^2$$

Table 1: The main coefficients of the EV model

Parameter	Value
$M_v \equiv$ Vehicle Mass [kg]	1325
$A_f \equiv$ Frontal area [m^2]	2.57
$C_d \equiv$ Drag coefficient	0.26
$\mu_{rr} \equiv$ rolling resistance	0.0048
Wheel radius [m]	0.3
$\rho \equiv$ Air density [kgm^{-3}]	1.29
$g \equiv$ Gravity acceleration [ms^{-2}]	9.8
$V \equiv$ Vehicle Speed [Kmh^{-1}]	Variable
$\theta \equiv$ Road angle [radian]	0

4. Rule-Based Linear Quadratic Regulator Control

The linear quadratic regulator (LQR) is a control technique that generates feedback gains. It is used to regulate the output of the system to achieve the optimal performance by controlling one state of the model. The cost function for a continuous-time linear control is defined as:

$$J(u) = \int_0^\infty (x^T Q x + u^T R u + 2x^T N u)dt \quad (10)$$

LQR returns the solution S of the associated Riccati Equation:

$$A^T S + SA - (SB + N)R^{-1}(B^T S + N^T) + Q = 0 \qquad (11)$$

The closed-loop Eigen values are defined as:

$$e = \text{eig}(A - B \times K) \qquad (12)$$

K is derived from S using:

$$K = R^{-1}(B^T S + N^T) \qquad (13)$$

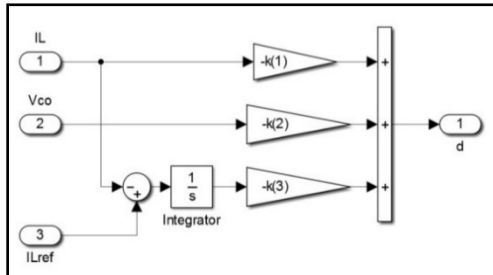
where R is a positive and Q is a symmetric positive definite matrix scalar. Furthermore, The LQR controller used a systematic procedure to calculate the state feedback control gain matrix. R and Q represent the weighted matrices which have a significant effect on the locations of the closed-loop poles [22]. The closed-loop response of the system changes depending on the values of the Q and R matrices. The weighting matrices can be obtained by using optimization methods. Investigating the optimal value of Q and R is beyond the scope of this research. Otherwise, the mathematical model of the DC-DC converter was used to design the controller of the switching elements of the DC-DC converter. The primary task of the rule-based control is to obtain the reference input current of the DC-DC converter, while the aim of the LQR is to obtain a desired duty cycle by the DC-DC converter. The LQR function in MATLAB was used to obtain the desired closed-loop feedback gains, while the steady-state errors were cancelled by adding an integration [45], as shown in Figure 6.


Figure 6: The feedback gains of the LQR controller
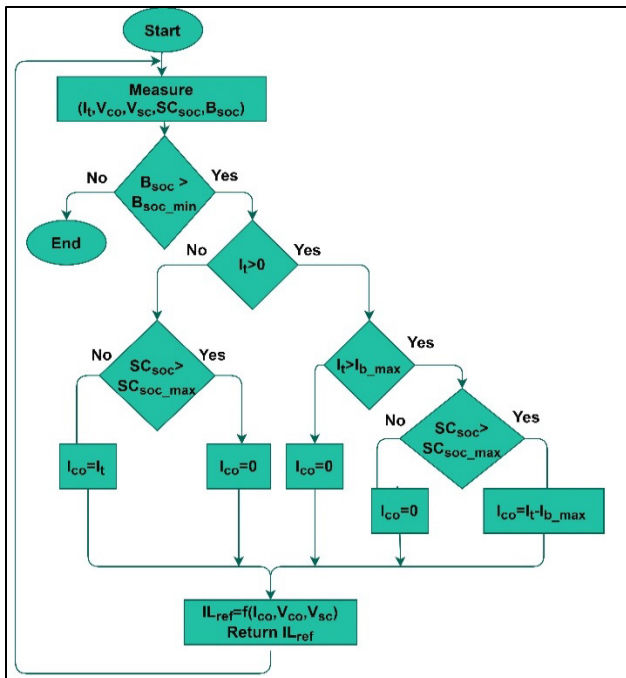

Figure 7: The flowchart of the limit R-B LQR controller

In this research, two strategies for the Rule-base LQR technique were designed to manage the power flow in the HESS. The limit R-B LQR was designed to limit the battery current to I_{b_max}, and supply the balance load current from the supercapacitors, when the total load current is more than I_{b_max}, and the state of charge for the supercapacitors more than 30%. On the other hand, the controller leads the supercapacitors to absorb the regenerative energy when the load current is negative and the state of charge of the supercapacitors is less than 95%. Furthermore, if the total load current is less than I_{b_max}, the controller supplies the total load current from the battery only. The flowchart in Figure 7 illustrates the algorithm of the proposed limit R-B LQR controller.

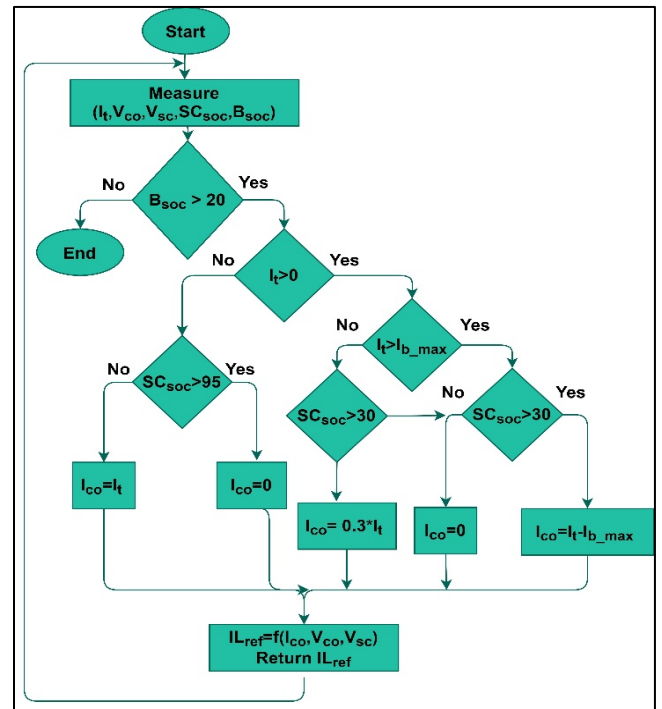
Moreover, the share limit R-B LQR was designed to limit the battery current to I_{b_max}, and supply 30% of the load current from the supercapacitors, when the total load current is positive and the state of charge for the supercapacitors is over 30%. The supercapacitors absorb the regenerative energy when the load current is negative and the state of charge of the supercapacitors is less than 95%. The flowchart in Figure 8 illustrates the algorithm of the proposed share limit R-B LQR controller.


Figure 8: The flowchart of the share limit R-B LQR controller

5. Simulation Results and Discussions

This work used MATLAB/Simulink to simulate the semi-active HESS model and the response of the proposed controllers. To validate the proposed limit R-B LQR and share limit R-B LQR for the EV, the dynamic responses of three standard drive cycles (i.e. UDDS, NYCC and Japan1015) were investigated. Figures 9a, 9b, and 9c illustrate the speed profiles for UDDS, NYCC and Japan1015 respectively.

The high peak and fast dynamic discharge and charge load in the EV application reduced the battery life-cycle. The proposed R-B LQR control strategies aim to reduce the battery stress and

extend the number of the repeated drive cycles. The battery and supercapacitors sizing optimizations are beyond the scope of this research. Figures 9b, 10b, and 11b demonstrate the total power demand of UDDS, NYCC and Japan1015 for the EV respectively. The battery's initial state of charge was 0.95, and the initial state of charge of the supercapacitors was 0.55. The definitive state of charge for the supercapacitors and battery of the HESS were taken at the termination of the single drive cycle.

(a)

(b)

(c)
Figure 9: The acceleration and deceleration Speed profile for: (a) UDDS, (b) NYCC, (c) Japan1015 drive cycle

The results of the proposed HESS were compared to the battery power of the battery alone system, to prove the effectiveness of the R-B LQR controllers for HESS in terms of reducing the battery peak current. The results of a limit R-B LQR and share limit R-B LQR were compared in terms of the number of the possible drive cycles. The proposed controllers was tested in three different drive cycles to validate the algorithm in a wide range of driver behaviors and driving environments. Figure 11 shows the limit R-B LQR response currents of HESS for the UDDS, NYCC and Japan1015 drive cycles. The battery power peak of HESS was limited compared to the battery power of the battery alone system. In the limit R-B LQR algorithm, the battery current supplied the low load current for the EV, and was limited by I_{b_max} 20A, while the supercapacitors supplied the high load current more than I_{b_max} 20A, and absorbed all the regenerative current during braking. The limitation of the battery current leads

to a reduction in the battery stress of the EV. This algorithm used the stored energy in the supercapacitors during the deceleration to enhance the battery in HESS of the EV.

(a)

(b)

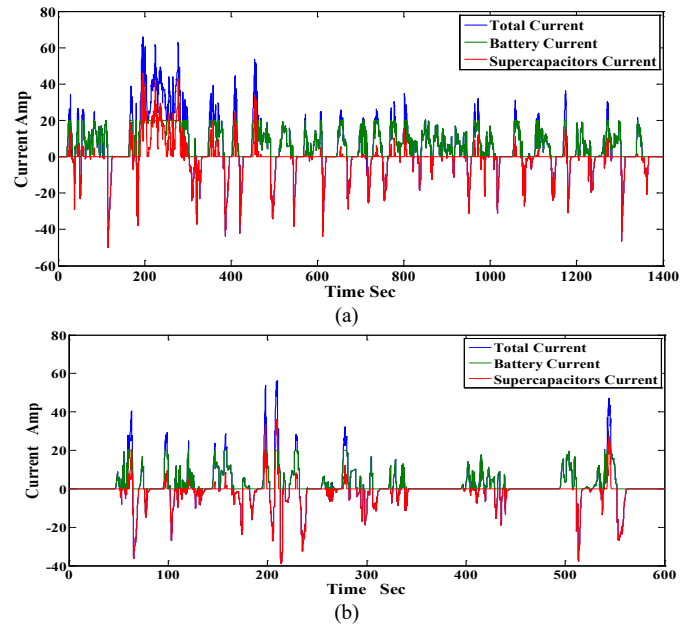
62


Figure 11: The limit R-B LQR HESS currents for: (a) UDDS, (b) NYCC, (c) Japan1015 drive cycle

On the other hand, Figure 12 shows the share limit R-B LQR response currents of HESS for the UDDS, NYCC and Japan1015 drive cycles. In the share limit R-B LQR algorithm, the battery and supercapacitors were shared to supply the load current for the EV and the battery current limited by I_{b_max} 20A. The battery supplied 70% from the load current, while the supercapacitor supplied 30% from the load current. Furthermore, the supercapacitors absorbed all the regenerative current during the deceleration and braking. The sharing load current and the limitation of the battery current lead to a reduction in the battery stress of the EV, and extended the number of possible cycles.
Figure 12: The share limit R-B LQR HESS currents for: (a) UDDS, (b) NYCC, (c) Japan1015 drive cycle

Equation 14 represents the calculation of energy consumption for the battery and supercapacitors.

$$\begin{cases} EnCo_b = \dfrac{SOC_b(0) - SOC_b(t)}{SOC_b(0)} \times 100 \\[2mm] EnCo_{sc} = \dfrac{SOC_{SC}(0) - SOC_{SC}(t)}{SOC_{SC}(0)} \times 100 \end{cases} \qquad (14)$$

Figure 13 illustrates the state of charge of the battery for the proposed controllers of HESS, and battery only for UDDS, NYCC and Japan1015 drive cycles. In the battery only scenario, the battery supplies the total load of the EV, and the energy consumption ($EnCo_b$) for UDDS, NYCC and Japan1015 drive cycle is 8.3%, 1.3% and 2.6% of the total stored energy of the battery respectively. In the limit R-B LQR controller of HESS, the energy consumption from the battery for UDDS, NYCC and Japan1015 drive cycles is 6.7%, 1.15% and 2.3% of the total stored energy of the battery respectively. Meanwhile, in the share limit R-B LQR controller of HESS, the energy consumption from the battery for UDDS, NYCC and Japan1015 drive cycles is 5.37%, 0.95% and 1.79% of the total stored energy of the battery respectively.
Figure 13: The battery stat of charge for: (a) UDDS (b) NYCC (c) Japan1015 drive cycle

The state of charge of supercapacitors increased during the operation, after absorbing the regenerative energy. In the limit R-B LQR controller of HESS, the energy earned in the supercapacitor

for UDDS, NYCC and Japan1015 drive cycle is 18%, 14.5% and 12.7% of the total stored energy of the supercapacitors respectively. In the share limit R-B LQR controller of HESS, the energy consumption in the supercapacitor for UDDS is 16.4% and the energy earned in the supercapacitor for NYCC and Japan1015 drive cycles is 9.1% and 0.0% of the total stored energy of the supercapacitors respectively. Figure 14 presents the state of charge of the supercapacitor for the proposed controllers of HESS, for the UDDS, NYCC and Japan1015 drive cycles.
Figure 14: The supercapacitors stat of charge for: (a) UDDS (b) NYCC (c) Japan1015 drive cycle

The design of the R-B LQR controllers achieved a wide range of operating zones for the supercapacitors. Moreover, the results of the supercapacitors state of charge proved that the supercapacitors work continuously during the drive cycles. Table 2 summarizes the state of charge of the battery and supercapacitors, the energy consumption of the battery and supercapacitors, and the number of possible cycles for the UDDS, NYCC and Japan1015 drive cycles. The results indicate that the share limit R-B LQR controller extended the n number of drive cycles compared to limit R-B LQR controller, with same battery size and supercapacitors.

The limitation of the proposed share limit R-B LQR algorithm is that the energy sharing percentage between the battery and supercapacitors is fixed to 30%, which leads to discharging the energy of the supercapacitors quickly in case the regenerative energy was limited. Future work will consider optimization

algorithms to obtain the optimal value of energy sharing between the battery and the supercapacitors.

Table 2: The Battery and supercapacitor state of charge for three different standard drive cycles

HESS		UDDS	NYCC	Japan1015
Battery Only	$SOC_b(0)$	0.95	0.95	0.95

6. Conclusion

This work proposed a control strategy for the battery-supercapacitors Hybrid Energy Storage System for an Electric vehicle. The state-space average model was used to analyze the dynamic behavior of the DC-DC converter. Two R-B LQR algorithms were proposed to manage the current flow in the HESS. The battery and supercapacitors responses was investigated with three different standard drive cycles, namely, UDDS, NYCC and Japan1015. The simulation results demonstrate that the limit R-B LQR has the ability to limit the battery current of HESS to I_{b_max}, in different types of drive cycles. Moreover, the proposed share limit R-B LQR was successful to limit the battery current and extend the number of possible drive cycles. The proposed algorithm enhanced the battery life-cycle and the stability of the energy storage devices, and effectively reduced battery sizes.

Modified Blockchain based Hardware Paradigm for Data Provenance in Academia

Devika K N*, Ramesh Bhakthavatchalu

Amrita School of Engineering, Department of Electronics and Communication, Amrita Vishwa Vidhyapeetham, Kollam, Kerala, 392025, India

A B S T R A C T

Educational organizations often need to distribute academic transcripts and certificates upon student's request since they are mandatory for admission into new scholarly programs including placement activities. Manual procedures involved with the transmission process of academic document is indeed a tedious task that results in substantial overhead. Thus the necessity for an autonomous electronic system for transfer of records among institutions is on the verge. This paper discuss and portray a hardware approach on the cryptographic elements of blockchain to impart data security and privacy that are found inadequate in its software counterpart.The novelty of this work relies on the design and implementation of a hardware equivalent structure for blockchain which could greatly alleviate the chances of various software attacks and security breach in existence. The solution proposed could cut down the waiting period of students to transmit their credentials and in addition provide a trustworthy verification platform to elude academic deceit. It can be integrated along with existing permission based blockchain framework to form a conjoined hardware-software architecture.

1   Introduction

Internet acquired it's admiration since 1990's, after which hard copy references and encyclopedias became ineffectual. During the initial times, internet was troublesome for the educators to adapt it into the academic domain. However, the field of education have progressed enormously over a short period of time. Online network had a great impact in the process of imparting knowledge and brought about a substantial revolution in the way people learn. Online learning platforms hold considerable amount of private documents and data related to students. These should be kept inaccessible to the third party user but at the same time should convey information to the concerned authorities to maintain data confidentiality. Currently India does not possess any law controlling data privacy or protection. Nevertheless, significant laws in India that serve data privacy are the Contract Act (India) 1872 and Information Technology Act, 2000. Presently, Blockchain comes out as the best solution to this scenario by forming an impregnable data repository and security from hacking. Cryptocurrency that turned out as the foremost noteworthy and the most inquiring wonders of the final century have Blockchain at its back end. Blockchain forms an ideal technology for storing and tracking scholarly documents. At present, all student credentials are stored as paper records or in a digital centralized directory which makes it accessible to third party.

Drawbacks of paper records include:

- Requires huge amount of storage space.

- Can easily be manipulated or misplaced by unauthorized individuals.

- Can be subjected to unexpected permanent destruction due to natural calamities like flood.

- Creation of paper records is itself a tedious task in terms of time span involved.

- There can be trust issues in relation to the accuracy and authenticity of data.

Centralized repositories that are considered as a reservoir of private data could be targeted by hackers leading to security breach.

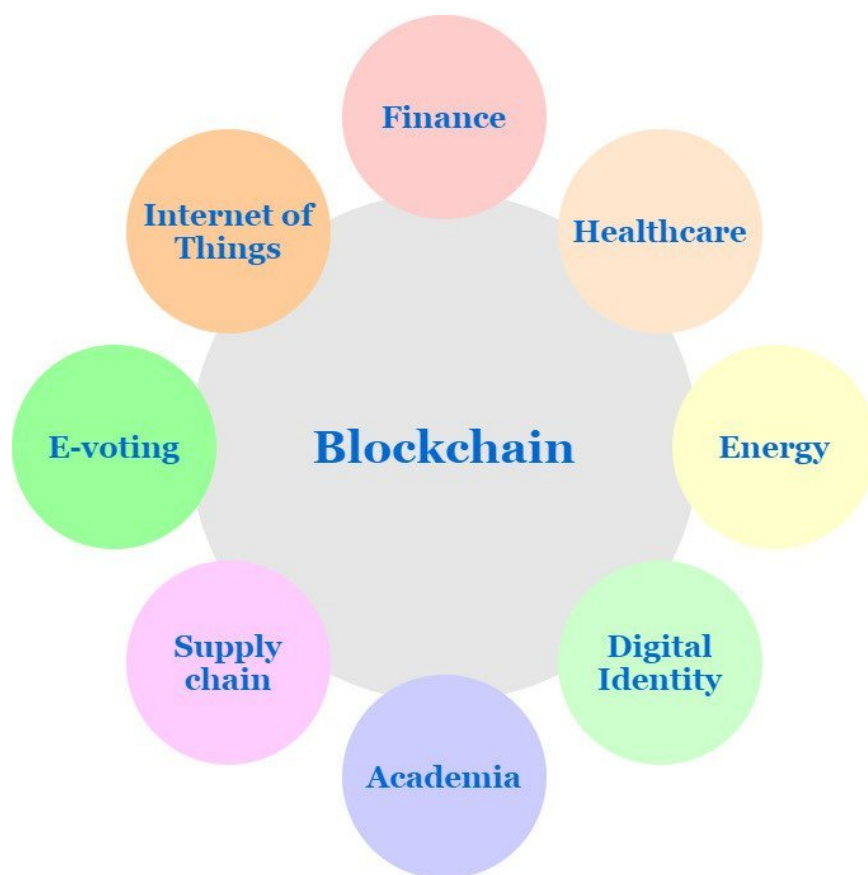

Figure 1: Applications of Blockchain technology

In a Blockchain, each participating entities called nodes are provided with a replica of the entire data communicated within the network. Thus it impedes the attempt to manipulate the contents imparting immutability. Data loss is prevented by avoiding centralization of information. In addition, it also provides the freedom to view information in public by any individual in case of Public Blockchain or only by the concerned participants for Private Blockchain. It prevents fraudulent individuals among teaching professionals who may provide fabricated certificates to highlight their experiences in academic field. Such untrustworthy officials questions the credibility of scholastic documents. Immutable property of the decentralized ledgers are utilized to guarantee the trustworthiness of the members involved through the submission of necessary credentials required.For placement purposes, it gives the freedom for the employers to directly access the records of students without involving colleges or universities. Presently, many universities around the globe have stepped into blockchain technology for tracing and screening academic transcripts.

Edublock is an innovative idea put forth by company called "Learning is earning" to collect the proof that a person have completed the required classes on his/her subject of study. This venture thus opens a wide range of opportunity to reform the sphere of education. All entities involved in the educational sector like students, professors, parents and other officials can be completely assured of the security provided by this emerging technology.

This paper provides a novel dimension to the world of blockchain by exploring the possibilities to design a dedicated hard-ware blockchain structure to securely store the academic information of students in Schools or Universities.

The remaining of the paper is organized as follows: Section II deliberate about the background research done on the innovative technology. Section III analyzes the benefits of Hardware cryptography over software cryptography. In Section IV, the technology behind blockchain is highlighted. Section V explains the proposed hardware approach to blockchain architecture. Section VI displays the results after synthesis and simulation in Hardware programming language. Section VII concludes the paper along with its future scope.

2 Background Research

Experts believe that blockchain application is never limited to bitcoin but uncover solutions in divergent fields as in voting, medicare, supply chain, energy industry, identity management and so on [1]. Figure 1 portrays different sectors in which blockchain is gaining significance. The paper work [2] does a survey on the application of blockchain technology in various industrial sectors. It in turn analyze the scope, advantages and threats of integrating this technical knowledge in industry.

In healthcare [3],[4], blockchain finds use in managing patient's information and in tracking medicines. It can resolve drug forgery to a great extent as all the data communication within the decentralized ledger are transparent and immutable that leads to tamper resistant

data. Participants involved comprises of medical experts, patients, insurance agencies, researchers etc. It enables interoperability of timely renewed medical profile of patients and in addition provides data protection, identity maintenance and transparency. Blockchain provides a framework for integrating medical transcripts of all patients among multiple healthcare expertise. It also enables patients to share their health details to medical experts through this platform [5]. Another work [6] discusses the usability of blockchain in healthcare domain to implement Adoptive Leader Election Algorithm (ALEA) for maintaining parallelism in accessing files.

Through distributed ledgers, blockchain certifies and reserves each execution in logistics industry that permits reduction in human flaws, time lag and management costs. In energy industry, blockchain uncover its utility in micro grid technology for power trading [7]. Thus it eliminates the necessity of a centralized controller for decision making and payment management [8], [9]. Blockchain can be applied to promote e-agriculture systems among farmers to improve farming process and provide improved productivity, food safety and reduced risks [10]. In food industry, it enhances food quality and trust by preventing food adulteration and reducing wastage of food [11]. This peer to peer technology put forward novel ideas for gamers through better containment on top of virtual assets in online entertainment platforms [12]. Aura network is an online gaming dais that utilizes it to sustain decentralization in games [13] and to assist the virtual world. It enables online streaming music platforms such as "spotify" to have direct transactions with the customers [14].

Stock market shareholders are currently experiencing tiresome proceedings due to the involvement of mediators and regulatory process which thereby delays the time taken for confirming transactions. In finance, blockchain permits decentralized stock exchanges and financial settlements completely, thus relieving the requirement of a negotiator and gearing up clearances [15], [16]. In e-voting , the voters are able to view the total votes taken for count through the transparent ledger mechanism assuring trustworthy and secular voting system [17]. Decentralization process in blockchain facilitates a person to create digital ID for identity verification on every online proceedings without relying on biometric systems or password [18]. This emerging science aids the dealers and consumers to differentiate between fabricated and original goods, thus impart trust into sale of goods.

In [19], the author presented a novel approach of creating Digital Twins (DT) using blockchain for ensuring immutable, reliable transactions and data availability. Smart contracts are utilized to manage and trace all proceedings involved in Digital Twin creation. They are virtual 3D representation of any real world object. Main objective of DT is to enhance manufacturing process and industrial operations of a system before its actual formation. In [20], the author investigates the pros and cons of applying blockchain to enlarge Industry 4.0. Industry 4.0 model propose the usage of significant technologies such as Augmented Reality (AR), Industrial Internet of Things (IIoT) that helps in free communication among numerous devices all over the industry and online network. Intensive research is done related to this ingenious automation for its utilization in Industry 4.0. Since the latter comprises of different entities such as customers, suppliers, manufacturers, operators and other IIoT nodes there arise trust issues with regard to each other.

Blockchain provides an interactive trusted platform for various smart technical clients [21]–[23] does a relative analysis regarding blockchain trade-offs, classification, details its architecture and also explore the challenges and future scope of this technology. [24] suggests authentication scheme based on blockchain that support user obscurity, inter mutual authenticity and security for multiple server platforms. Unlike other analogous strategies, this proposal offer centralized registration and introduce user revocation as added feature.

In addition to the above mentioned areas, there are numerous other fields where blockchain turn out to be beneficial for instance research sector that include both academia and industry. In [25], the author explains a solution that includes web interface to register and transfer record with permissioned blockchain framework functioning as the back end for verification purpose. Main aim of Academic Transcripts is to display a formal report of students performance [26]. It may take several days to certain months for the transfer of academic documents with the widely accepted paper approach due to processing and transmission time involved. Along with considerable time taken and chances for spoilage, there prevails the threat for fraudulent documents by deceitful intermediaries. Processing of paper transcripts amounts to huge expense related to the manual effort, proceeding time, delivery and conveyance fees. There exists 3rd party services for online document verification thereby avoiding manual procedures. Blockchain contribute in maintaining distributed and permanent list of records by educational institutions to assure authenticity of transcripts. Another effective method in [27] is despite recording the entire transactions, hash of the document that contain the hash list of all scholarly certificates is recorded in the ledger to be checked out by the receiver. Smart contracts are used in [28] along with Ethereum blockchain for managing identity and certificates.

When the current researchers focused more on the application of blockchain in miscellaneous sectors, hardly any analysis has been accomplished with regard to the implementation of blockchain technology. The proposed hardware prototype detailed in this work introduces a new outlook to the realization of blockchain architecture. Higher levels of security is offered by hardware cryptographic elements over software components since the latter are more susceptible to security attacks.

3 Hardware cryptography v/s Software cryptography

With the surge in the use of smart gadgets and as the attacks against confidential data in business and government sectors are enlarging, data security is gaining predominance among IT users and programmers. Recent progress in technology set forth many solutions for the above problem and it is up to the user to choose whether the solution should be hardware based or software based.

3.1 *Software encryption*

Currently software encryptions are more popular than hardware based solutions since they are easy to handle, upgrade and renew. Software programs are portable and accessible for every operating systems and devices. However, these encryptions provide protection

as long as the operating system on which it runs have high grade of security. If OS have any security blemish, the whole encryption would be compromised [29]. When a software program is executed in parallel with other operations in the environment, confidential information could be leaked through side channel attacks. Thus open platforms can recover the data on secret keys. Hackers can easily compromise software encoding by duplication of encrypted records and through frequent attempts of parallel breaking in different systems. Since software need frequent up-gradation they are more vulnerable to security attacks. There are many recovery options available to access data in spite of its failure.

In software cryptography, threats posed by side-channel attacks goes unnoticed. Side channels is a perceivable change as a result of ciphering which an attacker can sense and utilize to his favour. Predominance of side channels and its sensibility factor have increased the risk of hacking due to new features like advanced processors introduced in the host computers. In [30], the author discussed how data could be retrieved based on recent attacks that exploits timing of CPU cache, branch algorithm logic and correlation function.

3.1.1 *Software security threats*

Inefficiency of software to provide the required security is dependent on the following factors:

1. Limitation in security posed by OS
   Software security module are not standalone units. Therefore they rely on operating system of host computer for its functioning. Despite the complete security of the program, if OS is subjected to some defects such as memory leakage or trojan insertion then the whole system gets compromised. Safety of cryptographic software is directly related to OS security.

2. Random Access of Memory
   Another drawback of software implementation is the lack of dedicated memory. They entrust memory of host system to store private information. Sharing of system's memory with other operations concurrently will provide access to the contents inside memory for other applications thus confidentiality and privacy is threatened.

3. Code Integrity Issue
   Software codes stored in memory can easily be modified by a hacker through random access of cache. This could lead to impairment or data leakage. No system can detect software tampering thereby leaving integrity of codes at stake. No machines has been designed till date to identify or prevent manipulation of codes inside software. This increases the security concerns of software encryptions to a great extend.

4. Susceptibility to Reverse Engineering
   In Software domain it is much easier for an intruder to identify the functionality of a module by means of examining the instructions given in the code. This could jeopardize the design architecture before an attacker backing reverse engineering.

3.2 *Hardware encryption*

Most viable solution to protect drives that contains huge amounts of information in the fields of education, healthcare and finance are through hardware based encryptions. The contents within such devices will be protected even if these drives is taken and used in other systems owing to the effectiveness of hardware encryption keys. No encryption/decryption keys are stored inside systems memory and therefore less vulnerable to key attacks.

The recent surge in demand for power reduction in devices have motivated researchers to think about application specific hardware structures over generic processors. Computationally expensive and power hungry algorithms can be implemented using hardware methodology so as to match up with the present operational speed requisites. Application Specific Integrated Circuits (ASIC) showcase better efficiency in terms of speed, size and power but demands a huge non-recurring costs for prototyping. In these circumstances Field Programmable Gate Devices (FPGA) have superiority wherein they incorporate both hardware and programming on a single platform with low cost of application and reconfigurability in design. FPGA prototypes are designed using hardware description languages such as verilog or VHDL (Very Large Scale Integration Hardware Description Language) [31].

In hardware encryption, a customized processor handles the entire process of encryption, decryption and access to protect data [32]–[34]. Additional components are not required for encryption process as the device comprises of the required utilities. When a password is provided, processor employs random number generator to create encryption keys. It doesn't require additional software setup. Since the encryption solely runs on the dedicated hardware there is no forms of communication with the OS of the system. So the performance remains unaffected and is found to be much superior than software based solutions. Thus the hardware is basically protected from corruption, malicious software attacks and reverse engineering.

4 Blockchain Technology

Blockchain is an enlarging series of connected records called blocks secured through cryptographic algorithms. As per Gartner's prediction in 2017, market value of blockchain will emerge to about $176 billion by 2025 and can reach up to $3.1 trillion next to 2030. This emerging science can benefit different sectors and thus make possible a remarkable revolution form "Internet of Data" to "Internet of Value" and create a decentralized economic platform. Key features of this technology comprises of Decentralization, Data Authenticity, Transparency and Immutability [35].

The term "transactions" in this context refers to data framework that enables exchange of data or information of value among clients. Many such transactions are added up to form one block. Each block is linked with the other over one-way secure algorithms called hash functions [36]. Cryptographic hash forms the linking thread between current block and its predecessor.

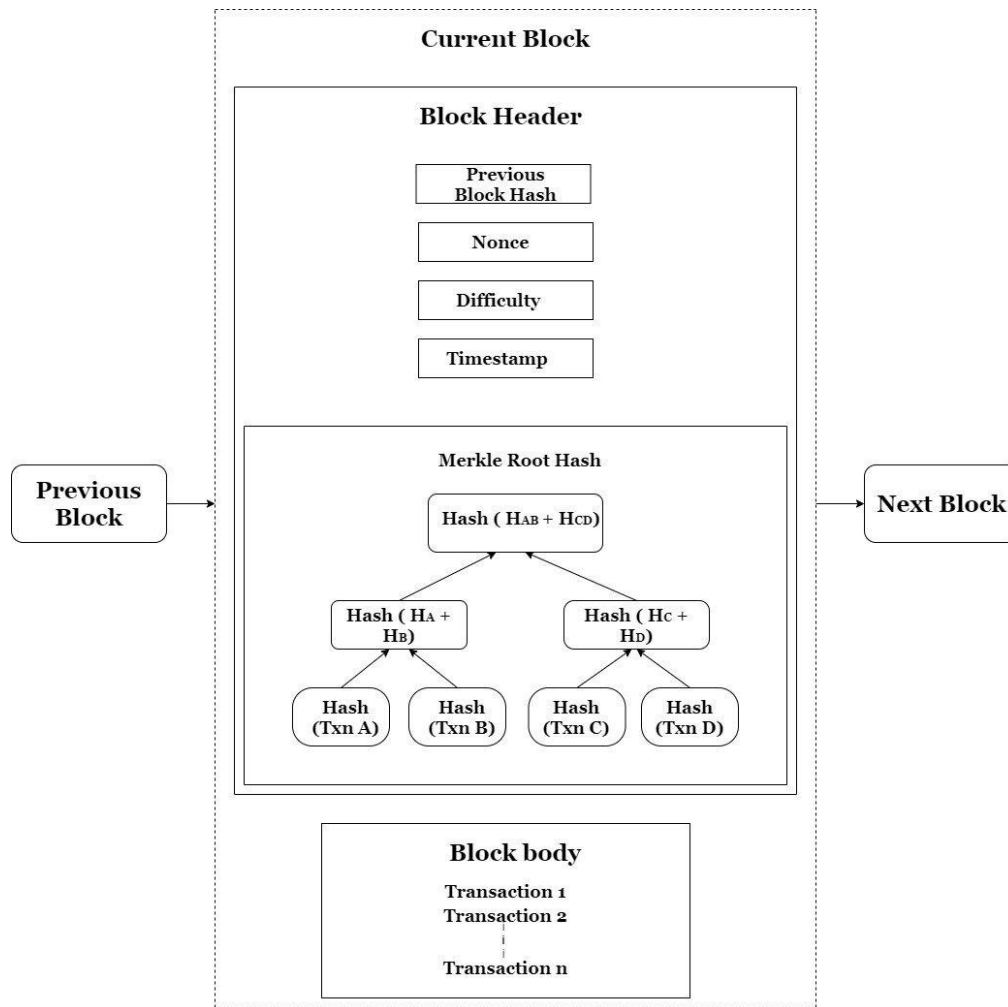
It enables a group of members within a network to share and store information related to transactions or events. Transactional records can be examined by the participants but none can alter or manipulate any of the validated data proceedings. This impart


Figure 2: Typical Blockchain Architecture

blockchain with immutability in regard to all events undergone in the network. Thus the shareholders even if not known to each other can trust themselves, arrive at an agreement, record them and form connected transactions in the form of chain. This technology can grant digital identities similar to passports or license for performing financial and other confidential tasks. Every transactions are approved by all individuals in the network before its linkage to the chain based on predefined criteria, thereby avoiding any possibility of repudiation. Figure 2 represents the typical Blockchain architecture.

4.1 Fundamentals of Blockchain

1. Block
   Block forms the principle constituent of the blockchain. Structure of a block consist of following elements:

   - Block Header
     It comprises of metadata related to block that includes hash of the previous block, difficulty, merkle root hash, nonce and timestamp. Merkle hash constitute the hash value of all transactions recorded in that particular block.

   - Block body
     It consist of all the transactions included in the block.

2. Hash functions
   Hashing is the technique to transform random sized input data to output of fixed size. Message Digest 5 (MD5) is extensively used for generating hash values of 128 bit length [37].

Table 1: Performance comparison of different hash algorithms

Hash function	Speed of operation	Security level	Hash size
SHA-1	Medium	High	160
SHA-3	Slower than SHA-1	High	256
SHA-256	Slower than SHA-1	Highest	256
MD5	Fastest	Lowest	128
SHA-512	Slower than SHA-256	Highest	512

The limitations of MD5 algorithm to create unique hash functions lead to the development of Secure Hash Algorithms(SHA).

At present various set of algorithms have been designed which includes SHA-1, SHA-2, SHA-3 and latest being SHA-256 and SHA-512. The execution time required by the above mentioned algorithms are furnished in [38] which gives an insight into the frequency of operation needed by each of the hashing methods. Most popular hash functions in usage is SHA-256 on account of its trade-off with respect to level of security and the bit length as shown in Table 1.

SHA-256 are one way hash functions that produce untampered 256 bit hash value [39], [40]. The string created after encrypting the block of information is irreversible. They are highly collision resistant since even a one-bit change in input reflects significant change in the output bits. Currently bitcoin utilizes SHA-256 for hashing blocks of data.

3. Consensus Algorithms
Consensus procedure in blockchain assures data consistency and enable all peers to reach on to common agreement in block creation[41]–[45]. In such a way reliability is attained and also empower trust among participants in a decentralized network. There exists different categories of consensus mechanisms as mentioned below:

- Proof of Work
  In Proof of Work(PoW) consensus process, a complex numerical puzzle needs to be solved by the participating node to mine the adjoining block. A good deal of computational power need to be spend by the mining node to find the solution to the puzzle. PoW is adopted by bitcoin for block formation.

- Proof of Stake
  In comparison to PoW, the holder with maximum share is given top priority for block creation in Proof of Stake (PoS). As the blocks get added the concerned shareholders get more assets as reward. This incentive provided encourages participation in PoS. Ethereum is found to utilize PoS to achieve consensus.

- Proof of Burn
  In Proof of Burn coins are burned by sending them to a random address, which will be nominated by the network. Through this burning process, the clients gain the authority to mine the blocks based on arbitrary selection procedure. More the coins are burned, greater is the probability to select the concerned node as miner. But as in PoW, the resources are wasted unnecessarily.

- Practical Byzantine Fault Tolerance
  The ability to arrive at an agreement between two communicating nodes in a decentralized network in the existence of malicious nodes is referred to as Byzantine Fault Tolerance. In Practical Byzantine Fault Tolerance (PBFT), the primary node is selected in a round robin fashion. This nodes creates the block upon receiving the request and broadcast it to all other nodes present in the network. Primary node reach to a decision based on majority voting so that data authenticity and integrity is assured. Each request is processed on getting support from two-third of the votes from the network. Thus this

consensus process function efficiently on the criteria that only one-third of the nodes are malicious in nature.New improved version of PBFT called Tendermint blockchain algorithm is proposed in [46].

Apart from the above discussed algorithms there are many other proofs such as Proof of Capacity, Proof of Space, Proof of Elapsed Time and so on. These consensus algorithms give an insight about their mode of execution and they are often used by experts in bitcoin. Blockchain application still may vary based on its utilization in other fields and the agreement process discussed in this section need to be modified related to the type of application.

4.2 Features of Blockchain

The Blockchain framework provide the following attributes that prove it to be a successfull platform for online data transfer [47], [48].

1. Data Integrity
   The decentralized connected network of blockchain guides students and teachers to apply, transfer and authenticate records. Entire process is automated, user friendly and openly accessible.

2. Data security
   Transparent ledger mechanism render safe and secure methods to transit, store and validate transcripts. Data is disclosed only to the destined receiver.

3. Flexibility
   Blockchain network is able to hold increasing number of colleges, institutions, students and documents. They are able to manage conversions and enhancements to record at the same time and thus maintains reliability.

4. Immutability
   The information once uploaded in the database can never be modified or updated. As a owner and also as a recipient of data, the participants can be confident on the provenance of the information.

5 Proposed Model for Hardware Blockchain

This research work discuss the hardware approach to blockchain architecture in order to safeguard and authenticate academic information in educational institutions. But the current blockchain structure has to be modified due to following limitations:

1. This work considers all subject marks attained by students on semester basis as the Academic record.The marks scored could be stored only after generating the block. So block needs to be created before storing the transactions.

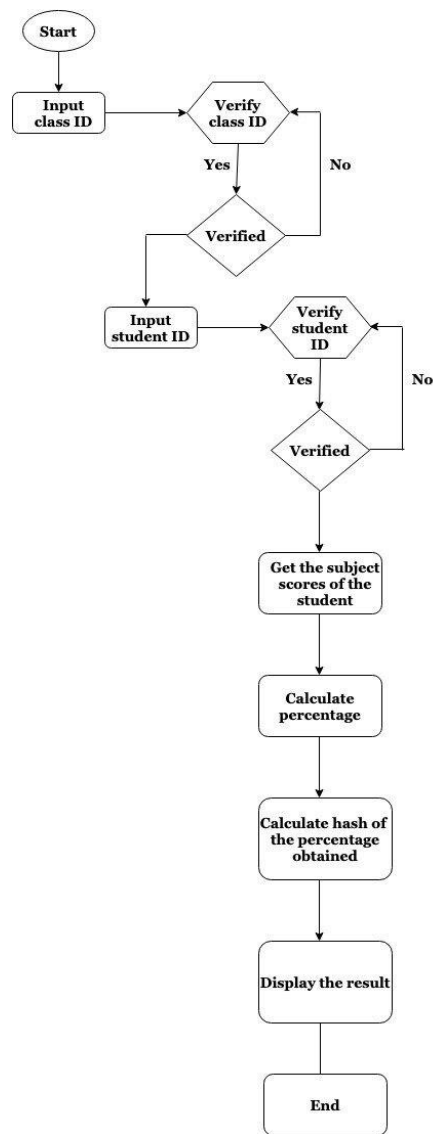
2. Ownership of a particular block belongs to a single authority. Further, it is imperative to create block without introducing


Figure 3: Flowchart of different operations performed within a single block

any computational complexity. Therefore consensus algorithms such as Proof of Work, Proof of Stake, or Proof of Burn are not significant in this context.

3. The proposed framework does data transmission only when the concerned students or teachers need to view and display their academic progress. Hence unlike the proofs detailed in the previous section that recursively repeat their execution, this system utilizes minimum resources saving energy, time and cost.

4. The suggested prototype assumes classroom as the block and the percentage of marks attained by each student that belongs to that class will act as a new "transaction". Typical consensus process are efficient for long transactions thereupon not acceptable for this application.

5. The officials authorized to enter the students credentials in the block repository are expected to do the same after thorough

content analysis and verification to prevent any typos or errors since the block contents once added remains immutable.

In view of the above limitations a different approach is introduced in the implemented design. The proposed hardware concepts are detailed here:

5.1   Formation of Block

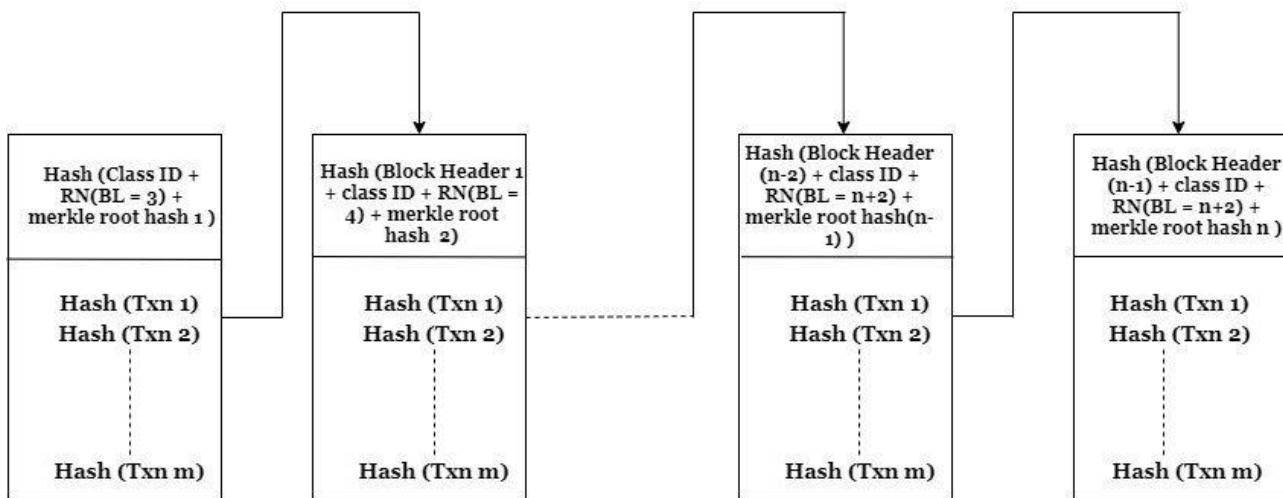
In Academia data could be recorded in the corresponding blocks only after its creation. Each block represents a class room. Class teacher and the students of the respective classes are assumed to be the authorized members of a block. Every class room is allotted with a unique identification number called Class ID. Each student in a class is provided with student registration number known as Student ID. Its is presumed that the class ID, student ID, and the subject marks attained by every students are stored in a dedicated memory within the concerned block. In this architecture every block in the chain consists of Block ID, Block Header, Previous Block
Figure 4: Block Formation in the blockchain


Figure 5: Block Securing Strategy

Hash and Merkle Root Hash. Figure 3 illustrates the flowchart of the different operations executed within a block.

1. Block ID creation

   Block ID refers to the unique number created for Block identification. It contains a random number that is generated by applying SHA-256 hashing algorithm on Class ID value. The Class advisor can enter the Class ID as the input and if it matches with the identification value assigned for the class, block ID will be created else the access is denied. Except the first block every other block have additional parameter called Block Header in the Block ID. Block ID formulas are as follows:

   $$Block\_1\_ID = hash(ClassID + RN(BL = 3)) \quad (1)$$

$$Block\_n\_ID = hash(ClassID+Block\_n-1\_Header+RN(BL = n+2)) \quad (2)$$

RN stands for Random Number
BL stands for Bit Length

2. Block body

   After the generation of Block ID, in the next phase the student can enter his/her Student ID. The student ID is verified with the original value already stored in the memory of block and if it is matched, the subject marks for the respective student is accessed and percentage is computed. Hash algorithm is applied to the unique value obtained after concatenating Student ID with the percentage scored. This results in a unique hash value which is displayed along with the percentage value as outputs.

3. Block Header

   Block header contains Merkle root hash of all transactions and Block ID. Block ID corresponds to the 256-bit hash value that distinguishes and identifies the block. Merkle root hash is obtained by hashing the sum of hashes of all the transactions conducted within the block. The "transactions" in this context refers to the percentage calculated for each student. Block Header is calculated based on the given equations:

$$Block\_1\_Header = hash(Block\_1\_ID+Merkle\_hash\_1) \quad (3)$$

$$Block\_n\_Header = hash(Block\_n-1\_ID + Merkle\_hash\_n) \quad (4)$$

4. Nonce and Difficulty

   First block is developed based on the unique class ID allocated to each class and a three bit random number. Hashing algorithm SHA-256 is imposed on these parameters to generate the hash for the block. Random Number is created by hashing the class ID and considering the last three bits from the LSB of the resultant hash. For the succeeding blocks, previous block hash, unique class ID and the random number are utilized. With the increase in the number of blocks, the bit size of the random number is also incremented. Random value assigned for hash generation determines the Nonce and difficulty. In this blockchain, block formation is confined only with the teachers who is entrusted with the class ID. Figure 4 shows how the blocks are formed within the blockchain.

5.2 Interconnection of Blocks

For ensuring additional security to the blocks created the following concept is applied:

- Block ID is the principle component that interlinks each block.

- Block Header of the current block consists of Block ID and merkle hash root of the commenced block. Every individual transactions that happened within a block are hashed separately using SHA-256 hash algorithm. These hash values are added on each time and once the entire transactions gets completed the resultant hash value is hashed once again to get the merkle root hash of the block.

- The block ID of the current block includes Class ID and random number that belongs to present block but block header of the previous block. Preceding block header contains block ID and merkle root hash of the previous block.

- Thus all the contents within each block gets interconnected with the other as the length of the chain increase.

- Therefore Nth block ID could be created only if the complete data is consistent from the first block to the preceding block with regard to data integrity and provenance.

- Interconnection of blocks thus assure added security since the contents within the block cannot be updated or manipulated as the hash values computed through SHA-256 are NP hard to find a solution. Figure 5 demonstrates the method adopted for securing blocks.

The main objective of blockchain hardware platform for storing academic database is to gain trust of the entities involved that includes students, teachers, parents, other higher officials who needs to validate the transcripts whenever required without the help of an external third party. Data security is ensured through block formation, block interconnection and hashing of contents. Other authorized educational organizations can access the blockchain database through creation of unique ID number followed by its verification by the authority in-charge (class advisors).

6 Synthesis and Simulation Results

The proposed hardware prototype for blockchain is designed in Hardware programming language Verilog. The functionality has been verified using Modelsim Simulator tool. The design is synthesized in Virtex 7 FPGA using Xilinx ISE design suite software tool.

The architecture designed can be programmed to include any number of blocks within the chain of blocks and is also flexible with respect to the number of transactions per block. As part of the research work, a miniature model of blockchain is considered that contains four blocks in the chain. Each block represents a class that comprises of 50 students. Four subjects pertaining to the current semester is stored within the blocks for estimating the Academic grade in percentage.

6.1 Simulation Results

Figure 6. displays the simulation results after percentage estimation for a particular student in Block 1. Inputs given were as follows:
Class ID = 20171
Student ID = 17002
Outputs obtained were :
Percentage = 82
Hash output of percentage for the student with ID 17002
= db3eee73beca217620ec21c37c0c07ccb0b65eddc1c9d9
a4382f7cd931696c7e
Block ID = d9bae266e5eb6914800a1894b8a5567290d63
efe7df89536892dafe4beb921a2
Block Header = df8c153e6682c3cb6c3330e804c3a44c983
246886ad888bc05832e57f177aaea
Merkle root hash = f3e886b34a03f33bf98d449f57d8cd562
fb1fb6f58f6c66ce3e985ee727900e5

6.2 Synthesis Results

The framework was designed to exist as different modules, synthesized separately and later integrated to form the entire architecture. The structure contained standalone modules for Block ID creation,
Figure 6: Simulation result after percentage estimation in block 1

Merkle hash computation, Block header creation and a Block module that includes the design for percentage computation. Table 2 shows the performance parameter summary for different design modules in the blockchain paradigm. In the table LUT-FF stands for Look Up Table and Flipflop pairs and IOB is the abbreviated form of Input-output buffers utilized by the design modules.

The entire system comprising of all the modules designed, functioned at an operational frequency of 95.138MHz. All modules were synthesized in xc7v1500t-2flg1761 device belonging to Virtex-7 FPGA family.

Table 2: Performance analysis of various blocks in the blockchain in Xilinx Virtex 7 FPGA

Design Modules	#Registers	#LUT-FF pairs	#IOBs	Speed (Mhz)
Merkle_hash_1	5804	4631	276	95.138
Block_1	6296	5528	569	95.235
Block_1_header	12269	9877	276	95.142

7   Conclusion and Future Scope

Credibility and authenticity of academic records are prerequisites to the reputation of academia and graduates. Unreliability of paper records and centralized electronic storage system demands the requirement of a distributed transparent platform to enable data sharing and communication. This scenario reveals the importance of Blockchain that offers a vital platform to implement an open access framework and attain interoperability. However the software elements in this technology are subjected to serious security threats that seems to put a downfall on the level of security provided by them in comparison to the hardware equivalents. This research work suggests a hardware approach that unfolds a new dimension to the architectural perspective of blockchain and helps the online experts that rely on this technology to overcome many vulnerabilities and challenges of an autonomous software application. In addition to Academic record maintenance, the proposed paradigm can be extended to higher levels that covers multiple domains and universities. Thus as an element of future work, the design find its application in University Management Scheme and Online Academic Systems so as to receive the complete details of the student performance.

Conflict of Interest   The authors declare no conflict of interest.

A R T I C L E I N F O	A B S T R A C T
	The objective of this study is to examine the current views of academics on issues and technology development in forensic accounting education. By applying the explanatory sequential mixed method, this study tries to acquire a better understanding of current perception regarding forensic accounting education. This study indicates that demand for forensic accounting services is expected to increase and offered as a separate courses at the graduate and undergraduate levels; respondent's perceived forensic accounting education as being relevant and beneficial to the business community, the accounting profession, and accounting students. Several technology tools and data analytics in investigation and analysis have been identified as important forensic accounting topics for curriculum developments. The limitation of this study is the small sample. A low response rate could be the result of this study containing bias so that it cannot be generalized, and most respondents are from accounting majors. These results are useful for universities in integrating forensic accounting education into their curriculum or redesigning their forensic accounting courses. The study shows the current view on forensic accounting education in Indonesia. Using an explanatory sequential mixed method is considered as a novelty of the present study.

1. Introduction

Nowadays, skill in forensic accounting becomes a requirement for the auditor to increase the probability of fraud detection [1]. If that so accounting profession need forensic accounting education? Some of the reasons for the importance of forensic accounting education today are because of the mass cases that occurred in the world such as Enron, WorldCom, and others. The other reason is the existence of new standards and changes in standards, beginning with the Sarbanes Oxley Act 2002 and changes to SAS 99. Both of these standards require auditors to detect fraud [2]. Changes in technology are also making forensic accounting more important because in the digital era, fraud not only occurred in financial statements but also cyber-crime, intellectual property (IP) fraud, piracy, forgery, and personal data [3]. When this financial fraud

combines with the use of computer and digital documents, fraud can falsify invoices or electronic money laundering. Consequently, electronic evidence of such crimes is found on personal computers (PCs) and company-owned mainframes, employee personal PCs, corporate networks, PDAs, diskettes, floppy disks, smart cards, and web servers on external networks [4]. Study shows that despite many cases involving fraud in large companies in the 2000s, only a few universities offer forensic accounting courses [5].

As far we know, there are many corruption cases in Indonesia, for example, Hambalang, a sting operation conducted by the Corruption Eradication Commission against several government officials. Also, in Indonesia, Insurance companies are now required by the Financial Service Authority to have fraud control and implementation anti-fraud strategies. This strategy includes prevention, detection, investigation, reporting, sanction, monitoring, evaluation, and follow-up. In line with the above

events, previous studies show that the demand for forensic accountant services is on the rise [5–7]. This demand was responded by various universities worldwide to offer programs or forensic accounting courses [5, 7–9]. Likewise, in Indonesia, many universities offer forensic accounting programs to meet high demand [10].

With the increasing number of universities offering forensic accounting education and the importance of knowledge about topics to support accounting students' future careers, this study examines academicians' opinions regarding forensic accounting education. These results can help academicians in developing or enhancing their curriculum choices in this field, helping students who are interested in career choices in choosing programs that can develop valuable expertise for the profession, and underline the importance of an interdisciplinary approach in forensic accounting education. In [11], the author said there are three reasons why should add a forensic curriculum. The first one is to prepare the students for their careers in accounting, the second is to improve the curriculum and the last one is for better employment opportunities. Using a mixed-method approach, this study describes forensic accounting education in Indonesia. It contributes to the forensic accounting curriculum and its results should be of concern to the accounting profession, academicians, and, in particular, to professional accountancy bodies, providing guidance that may influence how they approach or respond to this increasing demand for forensic accounting. This study aims to answer the following questions:

- What are educators' current views on forensic accounting?
- How do educators perceive obstacles in providing forensic accounting education?
- How do educators perceive important topics of forensic accounting?
- How do educators perceive various teaching methods in forensic accounting?

The next part reviews forensic accounting literature. This section discusses the literature review of forensic accounting, followed by a description of the research design to execute the study. Section 4 discusses the findings and results. The last section would be the conclusion and the implication of the findings, Limitation, and suggestion.

2. Literature Review

2.1. Perception of Forensic Accounting Education – Academicians

In the 2000s financial report scandals and frauds were widely published; hence, Barry Melancon - CEO of the American Institute of Certified Public Accountants – motivate academicians to teach students with "knowledge and skills to comprehend the essential attribute of fraud, identify factors indicating fraud, and obtain interview techniques [12]. The CEO stated that fraud, embezzlement, and other financial crimes that occur in the modern business environment makes the accounting and audit profession must have training and expertise to detect fraud [13]. These facts emphasize the need for courses specifically focusing on forensic accounting, assuming the audit course cannot provide sufficient training in fraud detection [5].

With this demand, it increases awareness of the importance of expertise in forensic accounting that can advance the ability to spot fraud [2, 14]. The Public Company Accounting Oversight Board (PCAOB) said that detecting fraud is a very important goal in auditing [1]. Research on the importance of forensic accounting education [5, 7–9, 15, 16]. These studies also suggest that forensic accounting education has evolved from initially limited to training in professional education for accountants to something currently offered as courses in several universities. Therefore, there is research that develops a guideline to serve the needs of academicians and practitioners, namely (1) to better understand the knowledge and expertise needed in the field of forensic accounting and (2) to assist academicians and professionals in developing appropriate subject matter and programs [15].

In [16], the author indicated that demand for forensic accounting services increases in the future and the Certified Fraud Examiner (CFE) practitioners chose to offer separate forensic accounting courses while academicians tended to integrate forensic accounting courses in accounting and auditing courses. Also, both groups stated that the accounting curriculum is not sufficient enough to fulfill the demand for forensic education and future accounting curriculum should add accounting forensic education. Their research also concluded that there were differences in perceptions between practitioners and academicians regarding the topics of forensic accounting. The most significant difference between both respondents is on the following topics: professional interview skills and legal aspects of interviews; and professional standards on forensic accounting. Both of the respondents believe that forensic accounting education has several benefits one of which is meeting the requirements for new regulations. However, several impediments like lack of faculty interest, lack of resources, and lack of flexibility in curriculum content mentioned as an obstacle in teaching the topic of forensic accounting by academics.

While the research of [7] signified the same thing that demand for forensic accounting services would increase in the future. Respondents prefer to integrate forensic accounting in accounting and audit courses. This is due to the challenges in terms of regulations, economics, social, ethics, and law faced by corporate that encourage an increase in demand for forensic accounting to create an accounting program to focus more on this field. As for learning techniques, the most important respondents choose from cases and books. The results of this study describe that there are different opinions between practitioners and academicians over 18 of the 49 subjects offered. But both of the respondents say that the majority of these topics are considered important. This study suggests that the topics offered in forensic accounting can be classified into three main sections in the forensic accounting module. the three main groups can be arranged as follows: the first part about basic fraud (such as types of fraud, fraud prevention, and deterrence programs and financial statement fraud), the second is related to corporate governance and legal aspects (earnings management, financial reporting process and analysis, white-collar and economic crimes, and criminology) and the latter focuses on topics related to careers in forensic accounting (expert

testimony and expert witness techniques, litigation consulting techniques). Meanwhile, the main setbacks to integrate forensic accounting into the accounting or auditing curriculum are the lack of financial resources, instructional materials, administrative support, and faculty interest.

In [5], the author studied survey academicians and practitioners regarding forensic accounting education. The results of his research showed that respondents preferred to offer forensic accounting in different subjects at the graduate or postgraduate level. Practitioners and academicians also have different perceptions about the topics taught and choose experiential learning as the most important learning techniques. Both of these professions agree that it is very important to teach forensic accounting courses in the accounting curriculum because this field experienced tremendous growth and the enormous interest of students. This research also shows that forensic accounting expertise will be very useful even though students do not take careers in forensic accounting. Respondents of this study also revealed that the lack of resources and the lack of qualified lecturers in teaching forensic accounting such as teaching topics on litigation, teachers must understand and have carried out this litigation process so that they do not only understand theoretical issues.

There is research on curriculum models and guidelines related to important topics that should be included in a forensic accounting course to meet the needs of students and companies [17]. In December 2003, a project funded by a grant from the National Institute of Justice at the West Virginia University Accounting Division was given to develop educational guidelines for academics, instructors, and students interested in fraud and forensic accounting. This project was implemented by forming a planning panel and Technical Working Group (TWG) that have expertise in this field. The results of the two-year project were curriculum models for fraud education and forensic accounting based on collaborative thinking among researchers, professional practitioners, and academicians to develop guidelines designed to help academics, universities, professors, course developers, and professionals. This TWG shows that the following main topics that must exist in the fraud and forensic accounting curriculum are criminology, fraud prevention, deterrence, detection, investigation, and remediation Forensic and litigation advisory services, including research and analysis, valuation of losses and damages, dispute investigation, and conflict resolution (including arbitration and mediation). This research can help universities, instructors, curriculum makers, and professional training to provide appropriate curriculum and topics in the field of forensic accounting, provide students with an initial understanding of fraud or forensic accounting, as material for reviewing audit courses, accounting so that the following forensic accounting practices. It also provides curriculum recommendations and course guides that can be used by users and finally provides training and development in the fields of fraud and forensic accounting for its users.

Research in [18], conducted a survey on CFE found several forensic accounting skills that were not taught in accounting programs such as interviewing and interrogation skills, sources of evidence, schemes of fraudulent financial reporting, criminology, computer/internet crime techniques, and expertise in human relations. This study shows that for a career in the field of forensic accounting must have technical skills and non-technical skills. Non-technical expertise includes ethics, collecting evidence, evaluation, documentation, and interviews as well as oral and written communication. This research provides suggestions for educators to help students learn both of these skills. Both of these skills are considered important for auditing financial statements properly. So when educators prepare their students with these two skills they can succeed in a career of fraud or forensic accounting.

2.2. Development of Forensic Accounting Education

During the period of accounting scandals that received considerable attention from around the world in the 2000s, there were still few forensic accounting educations available. Empirical evidence shows that in the very rapid development of forensic accounting, universities respond slowly to teach this topic to students [19]. In the next study, it was found that 21 universities were offering forensic accounting courses [7]. Then there was research on accounting education literature published in six journals for four years (2006-2009), showing that there is an increase in research related to the topic of fraud and forensic accounting, ethics, and professional responsibility [20]. Those studies recommended the content of forensic accounting embracing behavioral science [21], ethics and legal aspects [22], digital forensics [23], litigation consulting services [24].

Research in 2010 conducted a survey of 171 schools that were certified Association to Advance Collegiate Schools of Business (AACSB) to determine which universities offered forensic accounting and fraud checks [25]. The results indicated that only 4 of 171 schools offered degree programs for forensic accounting. While from 171, only 20 universities offered one forensic accounting course, and only 27 offered at least one fraud examination course. The research also shows that seven universities offer both forensic accounting courses and fraud checks.

In 2014, research was conducted on more than a thousand universities around the world, offering accounting programs to determine the extent to which forensic accounting education was taught [9]. Particularly, this survey involved 900 universities in the US and 186 universities in other countries. The study determined that 447 universities surveyed offered separate forensic accounting courses. Additionally, the study also found that 187 of the 1086 schools surveyed offered undergraduate and graduate special forensic accounting degrees, concentration, or specialization. Of course, the findings were a remarkable increase from previous research [25]. This study stated that this is strong and positive momentum in the development of forensic accounting education.

From previous studies, we know that forensic accounting education is developing rapidly throughout the world. The

demand for forensic accounting education is quite high. This is indicated by the number of universities that have begun providing forensic accounting courses. The availability of forensic accounting education is expected to be able to answer the challenges that the auditors today are expected to be more aggressive in finding fraud that occurs. Nowadays finding fraud is a must in the accounting profession. With the growing complexity of the business world, the development of technological challenges in finding and preventing fraud will be increasingly difficult. Forensic accounting expertise will be increasingly needed. Research shows that demand for forensic accounting services will increase in the future [5,6].

Research by [26] provides an overview of forensic accounting in the United Kingdom. Using questionnaires and in-depth interview methods try to explore perceptions of forensic accounting, profiles of people who work in this field, services offered, paramount expertise and knowledge needed, practitioners and academics respond to its development, and whether this should be considered a new profession. The results of this study show that accounting forensic is growing rapidly in the UK and its profession is dominated by qualified accountants, but in the last two years besides accountants who have taken part in this profession doubled. Forensic accounting is not a profession, according to this study naturally forensic accounting is a multidisciplinary science and it is very broad and deeper than any other profession that exists. Therefore, this field is too broad for someone to have all the knowledge, expertise, and do everything well.

Recently it shows that forensic accounting education is very important. With the rapid development of education, it is deemed necessary to research current forensic accounting education from an academician's perspective. This study surveyed to determine the latest views on various matters regarding forensic accounting education in academics.

3. Research Method

This study applies the Explanatory Sequential Mixed Methods Design [27]. This method includes two phases in which the researcher collects quantitative data in the first stage, analyzes the results, and then uses the results to plan (or built into) the qualitative phase. Quantitative results usually inform the types of the respondent that chosen for the qualitative step and the types of questions to be asked to them. The overall purpose of this design is for qualitative data to help explain in more detail the initial quantitative results.

- The researchers surveyed accounting academicians to answer questions about forensic accounting education sent online. This questionnaire focuses on the perceptions of accounting academicians regarding the development of forensic accounting, problems that become obstacles in the teaching of forensic accounting, important topics that must be taught in forensic accounting courses, and what are the best methods in learning forensic accounting. At the beginning of the

questionnaire collects demographic and background information for classification purposes. The validity of the questionnaire using Cronbach's alpha is 0,962. The questionnaire uses five Likert scales from 5 (very important or very agree) to 1 (very insignificant or strongly disagree).

- In the second stage, the researcher conducted interviews on the results obtained from the first stage. The results of this questionnaire are the basis of the material used to conduct interviews with respondents. Interviews were conducted with respondents who taught forensic accounting courses. The purpose of this interview is to collect detailed data on the development of forensic accounting, obstacles in teaching forensic accounting, important topics taught in forensic accounting courses, the best methods in the process of learning forensic accounting and the last respondents will be asked about anything they want to add in the curriculum of forensic accounting. Also by conducting interviews we can get a better understanding of the opinions of academics regarding forensic accounting education. Using member checking determines the accuracy or validity at this stage. Member checking is taking the result of a report or themes returned to the informant to test whether the informant feels that they are accurate [27]. Two respondents were selected to conduct interviews. The respondents have experience teaching accounting for more than 10 years. Respondents also have certification in forensic accounting so that they have a good understanding of the field of forensic accounting. Researchers also included responses to forensic accounting education in Indonesia from respondents who filled out questionnaires to further enrich the results of this study. Based on the description above, the model in this study is as follows.
Figure 1: Research Model

3.1. Research Sample

A total of 120 accounting lecturers were randomly selected to complete an online survey related to forensic accounting education. The reason for choosing this sample is because those who teach in the accounting department are considered to have an understanding and knowledge of forensic accounting. The response rate is 39%.

3.2. Data Analysis

Descriptive statistics are used to analyze the results collected through the interview stage. This data is processed using IBM SPSS 24.0. In the qualitative stage, the coding and thematic analysis are carried out by the Qualitative Software and Research (QSR) 12 Plus. The qualitative analysis includes (1) preparing transcribing interviews and writing memos; (2) start the coding

process; (3) developing themes based on code (4) Interrelating themes; (5) interpretation of themes [27].

4. Discussion and Analysis

The survey showed that the data processed was 47, which characteristics demographics of the respondents indicated that 25 were male and 22 were female with an average age of 42 years. The majority of the respondent's education level is educated master, which is 30 people or 64%. Then there is an educated Doctor level which is 17 people or 36%. While respondents who had certification in the forensic field (Certified Fraud Examiner and Certified Forensic Auditor) were 19%.

4.1. Development of Forensic Accounting

The findings of this study indicate that forensic accounting services will increase in the future both in terms of litigation support, expert information, and fraud examination. Requests for litigation support and expert witness increased by 89%, while 11% of respondents answered remained. Fraud examination services as much as 98% responded to increase while the remaining 2% answered decreasing. Other research results also show that the majority of these three services are increasing [5–7]. According to research [26], the expert witness has become an important service in the UK, even this service is at the top of the forensic accounting services. As we know that forensic accounting is developing very rapidly and this is followed by forensic accounting services that will continue to increase in the future. According to the informant on the development of forensic accounting:

"Services in this field have the potential to develop and forensic accounting competencies are needed, especially in finance and the public sector"

This statement confirms that the role of forensic accounting is important in finance and the public sector. Indonesia has many cases of corruption in the public sector, of course, competence in the field of forensic accounting can provide great added value to achieve good governance and in the prevention, detection, and investigation of fraud. However, forensic accounting services are very broad-ranging from business valuations to property cases in divorce [26]. The research of [26] also states that there are twelve services in forensic accounting. This means that forensic accounting has good prospects and opportunities to be developed in the future. But does not rule out the possibility of further forensic accounting services will continue to grow.

In academics itself, the development of forensic accounting also continues to occur. Respondents mentioned that at the university where she taught:

"The curriculum offered also continues to change. We invite an expert to advice on the forensic accounting curriculum".

This development is certainly very encouraging and forensic accounting has now penetrated other aspects such as social,

technological, psychological aspects, etc. With the development of technology, of course, there will always be continuous improvement in forensic accounting. Where a system will always be looked for weaknesses and as soon as that too there must be prevention and detection of acts of fraud that occur. Respondents said, "This is like a race between a thief and the police".

Next, the respondents were asked their opinion on how to integrate forensic accounting education in the curriculum. Table 1 shows that the majority of respondents (68%) chose to offer the topic of forensic accounting separately, as many as 30% chose to integrate it into accounting and audit courses while the rest chose not to offer (2%). Additionally, respondents were also asked for their opinion on whether forensic accounting education was offered at the level of Bachelor, Master, or both (Bachelor and Master education. Table 1 also shows that most respondents answered that forensic accounting education must be taught at both Bachelor's and Master's levels. While those who choose are taught at the Master level as much as 45%, the remaining 6% choose at the Bachelor level only.

Table 1: Perception of How Forensic Accounting Should Be Integrated and What Preferred Level

Integrated into Curriculum	Response (%)	Preferred level	Response (%)
Integrate throughout the accounting and audit course	14 (30%)	Bachelor	3 (6%)
Offered separate course	32 (68%)	Master	21 (45%)
Do Not Cover Forensic Accounting at all	1 (2%)	Bachelor and Master	23 (49%)

This result is conforming to the study of Kramer et al.'s (2017) which indicates that forensic accounting education is offered separately at the undergraduate and postgraduate educational levels. This result is different from research [7, 16]. In their research, it was stated that forensic accounting is better integrated into accounting and audit courses. This difference can be caused by the development of forensic accounting not only in accounting and auditing but also in multi-disciplines [5]. As we know nowadays the development of forensic accounting covers a variety of disciplines. Not only accounting and auditing, but also law, information technology. Even according to [26] behavioral sciences such as psychology, sociology, criminology, and anthropology can support the field of forensic accounting. The research of [26], who researched in the UK, showed that the forensic accounting profession from non-accounting has more than doubled for IT experts and experts in other fields in the last two years. But now according to respondents who work as lecturers said:

"at the Bachelor level the forensic accounting course is still an introduction, so to become an expert in this field is required the next level of masters and certification".

This means that formal education is quite important but there must be a need for certification in the field of forensic accounting.

This is following the current conditions in which forensic accounting has developed into a multi-disciplinary discipline so there is a need for certification that will greatly support this profession. Thus forensic accounting becomes an interesting science to keep on developing. Because as long as there is still fraud it is necessary to know how to detect and prevent this. For this reason, cooperation between various parties in Indonesia is needed to advance forensic accounting. There needs to be collaboration from academics and practitioners to do it. As conducted [17], which invited academics and practitioners in the field of forensic accounting to spend their time, ideas, and views on developing better education and training in fraud and forensic accounting. That way forensic accounting will develop in a better direction because the one who formulates education and training is the competent party in their field. The development of forensic accounting must move in line with the complexity of the case at this time. That way this profession will increasingly attract interest from students to work as forensic accountants.

4.2. Perception of Obstacles in Providing Forensic Accounting Education

Lecturers also asked their opinion about obstacles in providing forensic accounting education. Table 2 shows the mean and standard deviations of the responses of the respondents.

Table 2: Obstacles in Forensic Accounting Education

Obstacles	Mean	Standard Deviation
Lack of qualified lecturer	3,9362	0,8184
Lack of administrative and financial support	3,3617	1,1117
Lack of pedagogical materials	3,0426	0,9771
Lack of student interest	2,9149	1,0179
Lack of job opportunities	2,3617	0,8451
Lack of proper fit in accounting	2,2553	0,8715

According to the academicians, the main obstacle in forensic accounting is the lack of qualified lecturers, lack of administrative and financial support, and lack of pedagogic forensic accounting, which is indicated by the mean value higher than 3. The results are conforming to previous studies which mentioned these are the problems in forensic accounting education [5, 7, 16]. One respondent agreed that the obstacle in forensic accounting education was the lack of teachers. The respondent said, "The availability of teachers and practitioners is still limited". Further respondents also said the reasons for this obstacle were:

> *"Information update, to find out how fraudster does crime, what motivates it, etc. Usually, we always lag because updating is always a challenge for academics. Because teachers focus a lot on teaching, taking care of study programs, etc. Unless the research is focused there are no problems. Because there will always be a lot of reading. So sometimes the updates are only about the topic of teaching academics, even though forensic accounting is very broad in scope"*

Based on respondents' opinions, this was due to a lot of works such as teaching and becoming part of faculty management which was quite time-consuming. This is in line with the results of a survey which states that the lack of lecturer competencies is a major obstacle in forensic accounting education. The interview also mentioned that the scope of forensic accounting is very broad, this is following the statement that forensic accounting involves multiple disciplines making it difficult for teachers to follow their development. It takes a lot of reading material and of course, time is also needed. As a result, teachers only follow the development of the courses being taught.

Meanwhile, respondents disagree if a lack of student interest and job opportunities and lack of conformity with accounting are obstacles in forensic accounting education. This can be seen with a mean value of less than 3. Student interest and job opportunities in this field are very large. Even the research of [5], mentioned that the employment opportunities for forensic accounting are very numerous. Even if students do not choose a career in forensic accounting, the skills learned will make them better professionals whether it works as an auditor, manager, or consultant. If related to research [26], forensic accounting services in the UK are multiplying. This is proof that interest and job opportunities in the field of forensic accounting are very promising. Whereas for the suitability of forensic accounting with accounting is also not a major obstacle, indeed forensic accounting is multi-disciplinary, but the respondents consider that this is still following accounting and lecturers can teach forensic accounting in their department.

4.3. Important Topics in Forensic Accounting

Some important topics to be taught in forensic accounting. Whereas [18], in their research said that interviewing and interrogation skills, sources of evidence, schemes of fraudulent financial reporting, criminology, computer/internet crime techniques, and expertise in human relations are not taught in accounting programs. Another opinion states that there are no courses on criminology or psychology and what are the motives of fraud perpetrators in committing crimes in fraud and forensic accounting [21]. This research collects several important topics that must be taught in forensic accounting. Respondents were asked to give their opinions regarding 15 important topics in forensic accounting. The results are presented in Table 3, sorted by the highest to lowest mean values.

Table 3: Important Topics of Forensic Accounting

No.	Topic	Mean	Standard Deviation
1	Fraud detection methods	4,4681	0,6869
2	Fraud prevention and deterrence	4,4043	0,7120
3	Fraud investigation methods, including the organization and evaluation of evidence	4,3830	0,6774
4	Fraudulent financial statements and analysis	4,3830	0,6774
5	Corruption	4,3191	0,7255
6	Asset misappropriation	4,2979	0,7493
7	Digital forensics	4,2553	0,8462
8	Auditing	4,2128	0,7204

9	Criminology, the legal environment, and ethical issues	4,2128	0,8581
10	Forensic psychology, profiling, and the fraud mindset	4,2128	0,8059
11	Interviewing and interrogations	4,1915	0,7701
12	Data analytic software (e.g., IDEA, ACL, NVivo)	4,1277	0,7107
13	Valuation of losses and damages	4,1277	0,6794
14	Cyber-crime and security	4,1064	0,8656
15	Remediation and conflict resolution	4,0213	0,8206

Respondents stated that all of these are important topics in forensic accounting; this can be seen from the values of all the mean above 4. The results of the five highest rankings indicate that fraud detection methods, fraud prevention, and fraud, investigation methods, including organization and evaluation of evidence, fraudulent financial statements and analysis, and corruption. Of the five highest topics chosen by respondents, all indicated that there was a connection with accounting. This result is closely related to the expertise respondents of this study as academicians in accounting. Respondents stated that:

> *"Forensic accounting is taught in Bachelor Accounting as a compulsory subject. The basis of introductory forensic courses at least introduces to students that cheating may be done even by someone we trust. It is important for accounting and auditing courses as a basis for understanding forensic accounting".*

[5] research also shows that educators prefer topics related to accounting. The results of interviews with respondents also stated that accounting and auditing is a prerequisite skill for the student, which consistent with [17] indicating basic accounting, auditing knowledge, and skills that students should have when they are considering issues associated with fraud and forensic accounting. Furthermore, there is material about introductory forensic accounting that teaches the basics of fraud. Research [7,16] also show that fundamental fraud is the most important topic chosen by academics to be taught in forensic accounting education.

As for topics such as interviewing and interrogation, data analysis software (e.g., IDEA, ACL, NVIVO), valuation of losses and damages, cyber-crime and security, and remediation, and conflict resolution have smaller mean values, as these topics require special knowledge in forensic accounting. This supports the previous result stating that the obstacle in accounting education is the lack of competence of lecturers. This particular expertise certainly requires a teacher who has expertise in this field, this could be a practitioner who has a lot of experience in this field. The respondent said: "must continue to be developed through collaboration with the professional association of Forensic Accountants, Forensic Accountant practitioners, law enforcement". Of course, the collaboration will make forensic accounting develop quickly, academics will know what kind of demand is needed in the field of forensic accounting. So that students will be equipped with expertise following what is expected. That way topics about forensic accounting that require special expertise can be taught by people who are competent in

their fields. So the problem of obstacles regarding the limitations of teachers and the lack of qualified teachers will be overcome.

4.4. Various Teaching Methods in Forensic Accounting

In conducting the teaching-learning process it is certainly important regarding teaching techniques. Teachers must have teaching techniques that are adapted to the conditions of the students, which are more likely to succeed. Many teaching techniques will give different results from one technique to another. It could be that this technique will succeed at one time but at different conditions and times, it cannot work properly. In this research, respondents also gave their opinions regarding the importance of various teaching methods in forensic accounting. In this study, we provide twelve lists of teaching techniques taken from several previous studies. The results are presented in Table 4, which is sorted from highest to lowest.

Table 4: Various Teaching Methods in Forensic Accounting

No.	Methods	Mean	Standard Deviation
1	Case Studies	4.4894	0.6211
2	Digital Data Recovery (e.g. Data Recovery)	4.2979	0.6226
3	Computer Forensics Lab	4.2553	0.6746
4	Data Analytics Software (e.g. IDEA)	4.2340	0.6982
5	Guest lecturers	4.1702	0.7319
6	Role-playing	4.1064	0.6989
7	Field trips	4.0851	0.7754
8	Internships	4.0851	0.8554
9	Moot Court activities	4.0638	0.7634
10	Books	4.0638	0.5674
11	Student research project and presentation	4.0426	0.6580
12	Video	4.0213	0.7068

Based on the mean value shows that all methods of teaching forensic accounting are important. The results of the five highest techniques, according to academics are case studies, digital forensic software, computer forensic labs, data analysis software, and guest lectures. Respondent comments stated that:

> *"In my opinion, the best method is a case study. With case studies, we can find out the fraudsters cheat. So students know more about various kinds of cheating models, maybe one type of crime, but the mode is different. It will be easier for students to accept because the incident happened".*

From the interviews, respondents also chose case studies as the most important technique. Respondents said that with a case study, students could understand the case that occurred and know-how the perpetrator in committing fraud. Case studies help students with more fraud models and with various modus operandi on how to commit it.

Other respondents also stated that "this course should be taught with more practice so that students get a real experience". Forensic accounting will be better taught through practice so students can get an overview of this profession, what is done, and what is faced. However, there is one teaching technique that is also based on real-life experience but has a small mean value of

moot court activities. Moot court activities require teachers who have an understanding of the law. As the previous findings that one of the obstacles in forensic accounting is the less qualified lecturer. This can be overcome by collaborating with practitioners in the field of law or also with law faculties to teach it. With this students can understand the conditions of the trial or when providing expert statements.

5. Conclusion

This study attempts to find out the perceptions of academicians regarding the development of current forensic accounting education. This study also reveals more deeply about forensic accounting education through interviews with respondents. The findings in this study indicate that forensic accounting services will continue to increase in the future. Opinions from the lecturer show that forensic accounting education should be offered as separate topic and given to bachelor and master students. Then the main obstacle in forensic accounting education is the lack of lecturers who are competent in this field. While important topics, according to academics are closely related to accounting and the best teaching method is a case study.

From these results, it can be used as a suggestion for consideration in compiling a forensic accounting curriculum. Many requests for forensic accounting services can be seen as an opportunity to offer forensic accounting courses in the accounting department to be able to provide various skills needed by students who want a career in forensic accounting. This study also shows the importance of experienced practitioners in the field of forensic accounting and universities to work together to overcome shortcomings in the lack of qualified lecturers. So that students obtain materials and techniques that are following current forensic accounting practices. The importance is also that there is a collaboration between accounting parties in collaboration with other faculties in teaching other material not controlled by accounting majors such as law, psychology, social behavior, and information technology.

These results also indicate that academicians are more concerned with teaching techniques based on actual practice or real events and the importance of expertise in computer forensics. There must be teaching methods that lead to real practice so that students will understand the activities or work of a forensic accountant. Understanding more deeply about a case and focusing on technological developments in forensic accounting today is an important thing as an additional experience for students. Besides that, with the presence of a guest lecturer, students can learn profiles and can also take valuable lessons from the experience of the speakers.

This study also has limitations. A low response rate of this study could be the result of this study containing bias so that it cannot be generalized, and most respondents are from accounting majors. Important topics for forensic accounting only come from limited sources, there may be other topics that have not been included in this list. The scope of coverage examines in this study can be widened. Future studies can include the technological developments and expertise of computer forensics. This would enhance the understanding of academics and policymakers. Furthermore, it can add respondents from other departments such as law, psychology, and sociology, and information technology, which is expected to obtain more comprehensive perspectives regarding forensic accounting education.

Conflict of Interest

The authors declare no conflict of interest.

Learning Strategies and Academic Goals to Strengthen Competencies in Electronics and Digital Circuits in Engineering Students

Maritza Cabana-Caceres[1,*], Cristian Castro-Vargas[1], Laberiano Andrade-Arenas[1], Monica Romero-Valencia[1], Haydee Castro-Vargas[2]

[1]Faculty of Sciences and Engineering, Universidad de Ciencias y Humanidades, Lima, 27, Peru

[2]Faculty of Psychology, Federico Villareal National University, Lima, 15082, Peru

ITEM INFORMATION	SUMMARY
	The purpose of this article was to determine the incidence between learning strategies and academic goals in the competences of the curricular experience of electronics and digital circuits in engineering students of a private university in Lima, Peru. The objective was to explain how learning strategies and academic goals explain the behavior of engineering students of competencies in electronics and digital circuits. For this study, a sample of 89 students from the III cycle was used, to whom the ACRA test instruments were applied for the learning strategies of Román and Gallego (2001), the CMA academic goals test of Durán and Arias (2015) and a test to assess skills in electronics and digital circuits. According to the results obtained, it was shown that learning strategies and academic goals affect the skills of electronics and digital circuits in engineering students. By obtaining $x2 = 83.782$, ($p = .000 < 0.05$ and $Wald = 16.326$ showing that the proposed model is acceptable

1. Introduction

With globalization and the increasing ease of obtaining information, in Peru in most higher education institutions there is still a large gap in how to carry out an adequate learning strategy despite having the information at hand, regulatory bodies such as the National Superintendency of Higher Education SUNEDU [1] and the accreditation of the System of Evaluation, Accreditation and Certification of Educational Quality SINEACE [2] concerned about this, they try to implement norms so that educational institutions comply with basic quality standards, in this context, university education is in a process of educational reform to a model based on competencies, which they find it difficult to implement while maintaining the traditional teaching [3].

Thus at the national level, although access to university education and the level of skills as indicated is improving, there are still low levels of quality standards also at the international level, reflecting students with weak skills, low performance and insertion problems and job retention [4]. Several universities are still in the process of licensing and accreditation, so they are carrying out their curricular restructuring, to achieve a coherent curriculum to the institutional educational model, in an integrated manner according to the socio-economic, political, cultural

context, in the local scope. framework, regional and global [5]. In this sense, a student who does not exercise his skills acquired in the workplace becomes a stranger to his specialty, unable to continue developing his skills [6].

This situation is aggravated, because engineering careers require strong ICT skills, not only for students but also for teachers [7] who, when developing their classes with a curricular program that does not include ICT due to lack of training in the teaching staff and the low implementation of devices and laboratory equipment, it becomes a challenge [8]. In this sense, in a private university of Lima, in the course of electronics and digital circuits of the engineering faculty, passive students were observed in the development of the required competences, presenting deficiencies in the disciplinary knowledge of electronics and digital circuits , having fragmented learning. and not integrated into their professional training, losing interest in the subject, consequently, not being able to solve specialty problems when carrying out their pre-professional and / or work practices, which prevents them from successfully facing the demands of a dynamic real world. In this sense, it shows the need to implement and apply learning strategies and academic goals that address the indicated weaknesses, aimed at seeking the development of effective skills in electronics and digital circuits and in future engineering students that allows them

to exercise in a integrated. the significant learning acquired during their academic training stage at the university.

The need to implement and apply learning strategies and academic goals that address the identified weaknesses is shown, aimed at seeking the development of effective skills in electronics and digital circuits and in future engineering students that allows them to exercise in an integrated manner. The significant learning acquired during their academic training stage at the university.

For example, in Chile, it was found that learning goals and the attribution of academic success to effort have higher statistics. highlighted with respect to academic performance, this allows identifying and considering these dimensions in student support programs to promote academic achievement [9].

Also in Colombia, they obtained the existence of positive and significant correlations in study habits, learning strategies and academic performance, where the importance of using learning strategies as study habits to promote academic performance was highlighted, so both recommended creating intervention and support programs for strengthening in these areas [10].

The students from the Universidad Privada del Norte, Lima, were analyzed with a survey on the use of Arduino technology and a competency learning test. The research resulted in a significant correlation with a Spearman coefficient equal to 0.702 and a p value of 0.01, showing that the use of Arduino technology improves the development of students' skills in their learning [11].

Thus, in another private university of Lima, 96 students from the Faculty of Engineering were applied the instruments of the CMA Academic Goals questionnaire and Form 5 of Self-concept, determining from the results an r (96) = .205, p = .046 of the variables, with which it can be said that there is a relationship weak and significant positive between academic goals and self-concept, which means that high goals will be weakly related to high self-concept [12].

On the other hand, in a study of 290 students from the National University of San Marcos, it allowed to clarify the association between the learning strategies variables, motivation in relation to the explained variable of the study to predict the application of certain learning strategies, cognitive and metacognitive factors in students as indicators and decisive determinants to achieve reading comprehension [13].

The variables that we propose to study are expressed, the first study variable being learning strategies, there are different definitions, stating that it is a metacognitive, planned and conscious process of the subject in a given situation, influenced by the individual's perceptions to achieve optimal learning [14]. Given the above, it is reinforced that the strategies adopted by the students are sequentially concatenated and deliberately planned, in order to achieve the learning of the required task [15]. It can also be said that it is a process of sequence of decisions of the subject in a conscious and intentional state, in which the student deliberately decides and recovers knowledge, which requires the performance of a certain activity [16].

Another variable of study is the variable academic goals that is defined as the purposes proposed by the students, which guide their intentions and actions to obtain their achievements before certain

academic activities using the necessary resources. Likewise, it is indicated that they are the objectives that students want to achieve through planning, which will be their action to have a better understanding according to the complexity of the goal, for the solution of the academic activities to be developed [17].

Likewise, they are an integrated and organized pattern of thoughts and reasons that a management produces for a context of achievement, which includes the thoughts of competence, success, competitiveness, effort, errors and evaluation of its objectives to be fulfilled in the classroom [18] .

The last variable of studies competences of electronic and digital circuits, according to the Electronic Engineering curriculum with a major in Telecommunications of the Private University of Lima [19], mentions that the competences are the set of related knowledge, skills, attitudes and values with each other, in an integral way, that the student develops in the university to perform in academic activities and professional practice, in accordance with the standards of their specialty under the social, political, economic and labor context that governs it.

Posing the problem general research which is: What incidence exists between the learning strategies and the academic goals in the electronic and digital circuits competences in a Private University Lima, 2020? Regarding the specific problems, the following are established:

(a) What impact do the learning strategies and academic goals have on basic electronics and digital circuits in a Private University Lima, 2020? (b) What impact do the learning strategies and academic goals have on the electrical components of electronic and digital circuits in a Private University Lima, 2020? (c) What impact do the learning strategies and academic goals have on the hardware and digital circuits of the arduino electronics at the Universidad Privada Lima, 2020? (d) What impact do learning strategies and academic goals have on arduino electronics and digital circuits software at a Private University Lima, 2020?

For its part, the general objective set for this research is to determine the incidence between learning strategies and academic goals in the competencies of the subject of electronics and circuits in a private university Lima, Peru, and its specific objectives that are considered for the present investigation are: (a) establish the relationship between learning strategies and academic goals in basic electronics and digital circuits in a Private University Lima, 2020 (b) establish the relationship between learning strategies and academic goals in electrical components of electronics and digital circuits in a Private University of Lima, 2020 (c) establish the relationship between learning strategies and academic goals in arduino electronic hardware and digital circuits in a Private University of Lima, 2020 (d) establish the relationship between learning strategies and academic goals in arduino electronics and digital circuit software at a Private University Lima, 2020.

2. Methodology

The present investigation was of a quantitative approach because each stage proceeds to the next and the steps cannot be ignored, it is possible to define and limit them, in addition, it is known exactly where the problem begins, data collection was also carried out, to measure the variables learning strategies and skills

of electronics and digital circuits in numerical expressions and were analyzed with statistical methods.

2.1. Variables operationalization

For the learning strategies, 119 questions were used (see appendix), on a Likert scale, with 5 dimensions and a total of 9 indicators (Table 1).

Table 1: Operationalization of variable learning strategies

Dimensions	Indicators	Items	Scale	Levels or ranges
1. Acquisition	1.1 Attentional strategies	1 - 10	A: Never (1)	Low 119 - 277
	1.2 Repetition strategies	11 - 20		
2.Codification	2.1 Mnemonization strategies	21 - 42	B: Sometimes (2)	Moderate 278 - 437
	2.2 Processing strategies	43 - 63		
	2.3 Organizational strategies	64 - 66	C: Many times (3)	High 438 - 595
3.recovery	3.1 Search strategies	67 - 75		
	3.2 Response generation strategies	76 - 84	D: Always (4)	
4.Support	4.1 Metacognitive strategies	85-101		
	4.2 Socio-affective strategies	102-119		

Regarding academic goals, 16 questions were used, on a Likert scale, with 3 dimensions and a total of 8 indicators (Table 2). And for the electronic and digital circuits competences, 20 questions were measured, on a dichotomous scale, with 4 dimensions and 12 indicators in total (Table 3).

Table 2: Operationalization of the variable academic goals

Dimensions	Indicators	Items	Scale	Levels or ranges
1. Learning objectives	1.1. Problem solving	1-3	1: Strongly disagree	Low 16 - 37
	1.2. Progressive learning	4 – 7	2: disagree	
2. Achievement objectives	2.1. Academic achievement	8–9	3: Neither agree nor disagree	Moderate 38 - 59
	2.2. Professional achievement	10		
	2.3. Personal achievement	11	4: agree	High 60 - 80
3.Objectives of social reinforcement	3.1. Social recognition	12, 14	5: Strongly agree	
	3.2. Classroom stimulation	13, 16		
	3.3. Superior approval	15		

2.2. Population

A census population, composed of 89 students, from the third cycle of the engineering faculty of the University of Sciences and Humanities, 2020- I was studied.

2.3. Techniques, data collection instruments, validity and reliability

The instruments of the Roman and Gallegos Acra Test (see appendix) were applied to the students to evaluate the learning strategies, as well as the CMA questionnaire of Durán (2015) to evaluate their academic goals and finally a test was carried out to measure the competencies of electronics and digital circuits. The information collected was then transferred to a database in Excel and to the statistical program SPSS version 23, which will allow us to perform the data analysis.

Table 3: Operationalization of the variable competencies of electronic and digital circuits

Dimensions	Indicators	Items	Scale	Level ranges
1. Basic electronics	1.1. Identify the theoretical concepts of electricity.	1-2	Dichotomic 1: Right 0: Incorrect	In the beginning 00-10
	1.2. You have an idea of what electrical resistance is.	3		
	1.3 Define and develop basic exercises of electrical circuits	4 - 5		
2. Electrical components	2.1. Define the diode concept	7		In process 11 - 14
	2.2. Define the concept of transistor	6 - 8		
	2.3. Identify and solve circuits with diodes and transistors.	9 - 10		Achieved 15 - 18
3.Arduino hardware	3.1. Defines the theoretical concept of	11		
	3.2. Arduino general concepts details	12		Exceptional 19 - 20
	3.3. Identify the characteristics of the arduino board.	13 - 15		
4. Arduino software	4.1. Describe the general structure of a sketch.	16		
	4.2. Analyze instructions	17 - 18		
	4.3. Identify the serial communication with the arduino board	19 - 20		

The educational data mining technique is a tool that also allows data collection and analysis for subsequent decision-making, which is also suitable for evaluating groups of students, with the advantage of being able to cover a large number of data, as is the case of this investigation that has 119 questions for the study, for the case of the present investigation the data will be analyzed using SPSS.

Regarding the validation of the instruments, the content validity of the expert judgment was carried out and for the reliability a pilot test of a sample of 20 students of the electronics and digital circuits subject was used, the statistical values verified the reliability of instruments (Table 4).

Table 4: Reliability of the instrument

Variables	Statistics Reliability	Value	No. of elements
Learning strategies	Cronbach's alpha	0.857	119
Academic goals	Cronbach's alpha	0.851	16
Competences in electronics and digital circuits	Kuder-Richardson	0.8179	20

3. Results

The results obtained from the study are shown below.

3.1. Description of the learning strategies variable

Define abbreviations and acronyms the first time they are used in the text, even after they have been defined in the abstract. Do not use abbreviations in the title or headings unless they are unavoidable.

Table 5: Levels of variable learning strategies

		Frequency	Percentage
Valid	Low	26	29.3
	Moderate	48	53.9
	High	15	16.8
	Total	89	100
Figure 1: Levels of the learning strategies variable

Table 5 and Figure 1 show the percentage values of the learning strategies variable, of a total of 89 students. With the results obtained, it can be seen that the learning strategies tend to be moderate with 53.9%.

Table 6: Levels of dimensions of learning strategies

		Low	Moderate	High	Total
Acquisition	Frequency	15	54	20	89
	Percentage	16.8	60.7	22.5	100
Coding	Frequency	13	59	17	89
	Percentage	14.6	66.3	19.1	100
Recovery	Frequency	16	53	20	89
	Percentage	17.9	59.6	22.5	100
Support for	Frequency	18	49	22	89
	Percentage	20.2	55.1	24.7	100

3.2. Description of the dimensions of the learning strategies

Table 6 and figure 2 show the percentage values of the dimensions of the learning strategies, of a total of 89 students. From these results, it is estimated that the support dimension with more than 24% presents the best results compared to the other dimensions.
Figure 2: Levels of the dimensions of learning strategies

3.3. Description of variable academic goals

Table 7 and Figure 3 show the percentage values of the variable academic goals, of a total of 89 students. With the results obtained, it can be seen that the level of perception of academic goals has a trend of moderate level with more than 60%.

Table 7: Levels of variable academic goals

		Frequency	Percentage
Valid	Low	12	13.5
	Moderate	55	61.8
	High	22	24.7
	Total	89	100
Figure 3: Levels of the academic goals variable

3.4. Description of the dimensions of the academic goals

Table 8 and Figure 4 show the percentage values of the academic goals dimension of a total of 89 students. Based on these results, it is estimated that the achievement goals dimension presents better results with more than 30% compared to the other dimensions.

Table 8: Levels of the dimensions of academic goals

		Low	Moderate	High	Total
Learning goals	Frequency	fifteen	46	28	89
	Percentage	16.8	51.7	31.5	100
Achievement goals	Frequency	10	48	31	89
	Percentage	11.3	53.9	34.8	100
Objectives of social reinforcement	Frequency	15	45	29	89
	Percentage	16.7	50.7	32.6	100
Figure 4: Levels of the academic goals dimensions

3.5. Description of the electronic and digital circuits skills variable

Table 9 and Figure 5 show the percentage values of the variable dimensions of electronics and digital circuits, of a total of 89 students, which shows a trend of students at the level reached with less than 70%.
Figure 5: Dimension levels of electronic and digital circuits competencies

Table 9: Levels of electronic and digital circuits variable competencies

		Frequency	Percentage
Valid	In the beginning	5	5.6
	In process	11	12.4
	Accomplished	59	66.3
	Exceptional	14	15.7
	Total	89	100

3.6. Description of the competencies dimensions of electronics and digital circuits

Table 10 and Figure 6 show the percentage values of the dimensions of competencies in electronics and digital circuits, of a total of 89 students. From these results, it is estimated that the arduino software dimension has low outstanding results with less than 12% compared to the other dimensions.

Table 10: Dimensional Competency Levels for Electronic and Digital Circuits

		Initial	In process	Accomplished	In outgoing	Total
Basic electronic	Frequency	1	5	67	16	89
	Percentage	1.1	5.6	75.3	18.0	100
Electric components	Frequency	3	9	65	12	89
	Percentage	3.4	10.1	73.0	13.5	100
Arduino Hardware	Frequency	5	11	60	13	89
	Percentage	5.6	12.4	67.4	14.6	100
Arduino software	Frequency	8	14	57	10	89
	Percentage	9.0	15.7	64.0	11.3	100
Figure 6: Dimension levels of electronic and digital circuits competencies

3.7. Contrast of the general hypothesis

Ho: There is no incidence between learning strategies and academic goals in electronic skills and digital circuits in a Private University Lima, 2020.

HG: There is an incidence between learning strategies and academic goals in electronic skills and digital circuits in a Private University Lima, 2020.

Table 11: Model fit and likelihood ratio tests for the general hypothesis

Model fit information				
Model	Logarithm of probability - 2	Chi squared	gl	S.I.G
Interception only	286,034			
Final	202,251	83,782	36	, 000

Table 11 shows that the value x2 = 83.782, (p = .000 <0.05), indicates that the proposed model is acceptable. In this sense, the null hypothesis is rejected, with a probability of error less than 5%.

Table 12: Pseudo R squared of general hypothesis

Pseudo R squared	
Cox and Snell	, 610
Nagelkerke	, 630
McFadden	, 272

Table 13: Parameter estimates of the general hypothesis

	Estimate	S.I.G	Wald	95% interval trustworthy	
				Min	Max
[V3_ Competences of electronics and digital circuits = 1]	-9,224	, 000	25,904	-12,776	-5,672
[V3_ Competencies of electronics and digital circuits = 2]	-7,549	, 000	24,350	-10,547	-4,550
[V1_Learning strategies = 1]	-9,918	, 000	16,326	-14,728	-5.107
[V1_Learning strategies = 2]	-4,936	, 001	11,346	-7,808	-2,064
[V2_Academic Goals = 1]	-3,348	.014	6,053	-6,016	- .681
[V2_Academic Goals = 2]	-2,624	.038	4,311	-5.101	-. 147

Table 12 presents favorable values of pseudo R squared, which ensures a fit adequate of the proposed model to explain competencies in electronics and digital circuits. Similarly, it is stated that learning strategies is the variable that affects the most, since it presents a value of Wald = 16.326 and p = .000 <0.05 (Table 13).

3.8. Specific hypothesis test 1

Ho: There is no incidence between the learning strategies and the academic goals in the basic electronics of electronics and digital circuits in a Private University Lima, 2020.

H1: There is an incidence between the learning strategies and the academic goals in the basic electronics of electronics and digital circuits in a Private University Lima, 2020.

Table 14 shows that the value x2 = 61.281, (p = .005 <0.05), indicates that the proposed model is acceptable. In this sense, the null hypothesis is rejected with a probability of error less than 5%.

Table 14: Model fit and likelihood ratio tests for specific hypothesis 1

Model fit information

4. Discussion

With reference to the general objective set, satisfactory values of $x2 = 83.782$, (p = .000 <0.05), McFadden of 0.272, Nagelkerke of 63%, Cox and Snell of 61% and a Wald value of 16.326 were obtained. Indicating that the estimated model serves to explain the behavior of the dependent variable, being an adequate model, evidencing the rejection of the null hypothesis and admitting the incidence of learning strategies and academic goals in relation to the variable electronic competences and digital circuits. By virtue of this, they reaffirm the results obtained from the electronic and digital circuits competences with a tendency to be achieved with less than 70% of the engineering students of a Private University of Lima, 2020. In addition, The arduino software was estimated with more than 11% of the analyzed students presented low outstanding results compared to the other dimensions, which shows a profile of the student with deficiency in being able to develop skills in the description of a structure of the arduino software in the sktech. IDE, analysis of the arduino software instructions and achieve serial communication by connecting electronic devices to the arduino board, based on the data collected from the instrument application. On the other hand, the learning strategies show a moderate trend with more than 50% of the students, and it was evidenced that the support learning strategy presented the best results with a high level of more than 24% of

the students compared to the rest of your group, according to the Roman y Gallego ACRA test instrument (see appendix) applied. Likewise, the academic goals presented a moderate trend concentrating more than 60% of the students, being the achievement goal the one that presented the best results with more than 30% in the high level compared to the others in their group, according to the respondents to the the Durán CMA Test.

Similarly, the dependent variable of the research presented an incidence of 63% of variability with respect to the explanatory variables in students, which means that learning strategies and academic goals are important so that higher-level students can optimally develop your skills in electronics and digital. circuits for their good academic performance in a comprehensive and professional manner, in that sense they can successfully face the demands of the labor market, it should also be noted that the value of Wald showed that learning strategies have a greater explanatory force of incidence, so that these guide to a better development of the electronic and digital circuit competencies of the students compared to the academic goals, in addition,

With reference to the specific objectives, it was admitted that there is an incidence between learning strategies and academic goals in basic electronics, arduino hardware and software electrical circuits and arduino electronics digital circuits in Engineering students, Universidad Privada de Lima, 2020. No however, for basic electronics, in comparison with the other dimensions, satisfactory inferential values of $x2 = 61.281$, (p = .005 <0.05), Nagelkerke of 55.7% and Wald of 21.485 were obtained. This means that the learning strategies have a greater explanatory force of incidence for the basic electronic dimension compared to the other dimensions.

5. Conclusions

It was evidenced that the strategies of learning and academic goals affect the competences of electronic and digital circuits in engineering students, Universidad Privada Lima 2020. Due to acceptable values it was found of $x2 = 83.782$, (p = .000 <0.05) and Wald = 16.326 showing that the proposed model is plausible.

It was verified that the strategies of learning and academic goals affect basic electronics and digital circuits in Engineering students, Private University, 2020. Due to the favorable values obtained of $x2 = 61.281$, (p = .005 <0.05) and Wald = 21.485, which indicates that the proposed model is acceptable.

It was found that learning strategies and academic goals affect the electrical components of electronics and digital circuits in Engineering students, Private University, 2020. By favorable values of $x2 = 53.136$, (p = .033 <0.05) and Wald = 16.073, indicating that the proposed model is acceptable.

It was shown that the strategies of learning and academic objectives affect the hardware of Arduino electronics and digital circuits in Engineering students, Private University, 2020. Due to the value obtained from $x2 = 90.897$, (p = .000 <0.05) and Wald = 6.568, it which indicates that the proposed model is acceptable.

It is finally concluded that learning strategies and academic goals affect arduino electronics and digital circuits software in Engineering students, Private University, 2020. Due to the

acquired value of x2 = 64.208, (p = .003 <0.05) and Wald = 9.624, indicating that the proposed model is acceptable.

It was considered that there is an option that allows to dynamically cover a large volume of data, as well as flexible for educational environments, known as educational data mining [20].

6. Recommendations

It is recommended that the academic directors of the Private University establish institutional guidelines in their curricular plans for the implementation, incorporation and application of learning strategies and academic goals so that engineering students can effectively develop electronic and digital circuit skills, having significant learning.

The academic coordinator of engineering of the Private University is suggested to carry out activity programs for students of electronics and digital circuits in which topics of learning strategies and academic goals are developed in such a way that they can apply it in the subject and help them to develop. your core competencies in electronics, electrical components, arduino software, and arduino hardware.

It is proposed that the engineering professors of the Private University encourage their students of electronics and digital circuits in their pedagogical practices to use learning strategies, such as the acquisition, coding, retrieval and support of information, in the sense of raising skills and learning from the subject and achieve their academic goals.

New methods are recommended to better cover teaching strategies and thus avoid possible dropouts that may motivate students to drop out of college, such as an educational data mining option [21].

Appendix

ACRA TEST:

This test is divided into four scales: Acquisition of information: It helps the student to know how to acquire the necessary information for the study. Information coding: It informs about how the main and secondary ideas of a text should be differentiated. Information retrieval: It sets out the mechanisms necessary to retrieve previously stored information. Information support: What means and conditions will help improve the study.

Next, the student must take this test, which must be answered in the following way: The questions that are asked must be answered as follows:

If you NEVER or NEVER do what is asked, you must put A.
If the question is EVER done, put B.
If ENOUGH TIMES what is asked is done, put C.
If you ALWAYS do what you ask, you have to put D.

Scale I: Information Acquisition Strategy:	A	B	C	D
1. Before starting to study I read the index, or the summary, or the sections of the material to be learned.				
2. When I am going to study a material, I write down the important points that I have seen in a first cursory reading to more easily get an overview.				
3. When I begin to study a lesson, I read it all over the top first.				
4. As I study, I look for the meaning of unknown words, or of which I have doubts about their meaning.				
5. In books, notes or other material to learn, I underline in each paragraph the words, data or phrases that seem most important to me.				
6. I use signs (admirations, asterisks, drawings…), some of them only intelligible by me, to highlight those information in the texts that I consider especially important.				
7. I use pencils or pens of different colors to promote learning.				
8. I use the underlining to facilitate memorization.				
9. To discover and highlight the different parts of what is composes a long text, subdivided into several small by means of annotations, titles and epigraphs.				
10. I write down words or phrases by the author, which seem significant to me, in the margins of books, articles, notes, or on a separate page.				
11. During the study, I write or repeat the important or most difficult data to remember several times.				
12. When the content of a topic is dense and difficult I reread it slowly.				
13. I read aloud, more than once, the underlines, diagrams, etc…, made during the study.				
14. I repeat the lesson as if I were explaining it to a classmate who does not understand it.				
15. When I study I try to mentally summarize the most important things.				
16. To check what I am learning about a topic, I ask myself section by section.				

17. Even if I don't have to take an exam, I usually think and reflect on what I've read, studied, or heard from teachers.				
18. After analyzing a graphic or text drawing, I spend some time learning it and reproducing it without the book.				
19. I make them ask me the underlines, diagrams, etc. facts when studying a topic.				
20. When I am studying a lesson, to facilitate understanding, I rest, and then I review it to learn it better.				
Sum				
Multiply	X1	X2	X3	X4
Outcome

Percentile				
Scale Ii: Information Coding Strategy:	A	B	C	D
1. When I study, I make drawings, figures, graphs or vignettes to represent the relationships between fundamental ideas.				
2. To solve a problem, I begin by carefully recording the data and then try to represent it graphically.				
3. When I read, I differentiate important or main aspects and contents from accessories or secondary ones.				
4. I look for the "structure of the text", that is, the relationships already established between its contents.				
5. I rearrange or carry out, from a personal point of view, new relationships between the ideas contained in a topic.				
6. I relate or link the topic I am studying with others that I have studied or with the data or knowledge previously learned.				
7. I apply what I learn in some subjects to better understand the contents of others.				
8. I discuss, relate or compare with my colleagues the works, diagrams, summaries or topics that we have studied.				
9. I go to friends, teachers or family when I have doubts about the study topics or to exchange information.				
10. I complete the information in the textbook or class notes by going to other books, encyclopedias, articles, etc.				
11. I establish relationships between the knowledge that the study provides me and the experiences, events or anecdotes of my private and social life.				
12. I associate the information and data that I am learning with fantasies of my past or present life.				
13. When studying, I put my imagination into play, trying to see, like in a movie, what the subject suggests to me.				
14. I make comparisons by making metaphors with the issues I am learning (eg, the kidneys function as a filter).				
15. When the topics are very abstract, I try to look for something familiar (animal, plant, object or event) that resembles what I am learning.				
16. I carry out exercises, tests or small experiments, etc., as an application of what I have learned.				
17. I use what I learn, as much as possible, in my daily life.				
18. I try to find possible social applications in the content I study.				
19. I am interested in the application that the subjects I study may have to the labor fields that I know.				

20. I usually write down in the margins that what I am studying (or on a separate sheet) suggestions or doubts about what I am studying.				
21. During the teachers' explanations, I usually ask myself questions on the subject.				
22. Before the first reading, I ask myself questions whose answers I hope to find in the material I am going to study.				
Sum				

	A	B	C	D
23. When I study, I ask myself questions suggested by the topic, to which I try to answer.				
24. I usually take notes of the tutor's ideas, in the margins of the text I am studying or on the separate sheet, but in my own words.				
25. I try to learn the topics in my own words instead of memorizing them verbatim.				
26. I make critical annotations to the books and articles I read, either in the margins or on separate sheets.				
27. I arrive at new ideas or concepts starting from the data, facts or particular chaos that the text contains.				
28. I draw conclusions from the information contained in the topic I am studying.				
29. When studying, I group and classify the data according to my own criteria.				
30. I summarize the most important of each of the sections of a topic, the lesson or the notes.				
31. I make summaries of what was studied at the end of each topic.				
32. I prepare the summaries using the previously underlined words or phrases.				
33. I make diagrams of what I study.				
34. I build the diagrams using the underlined words or phrases from the summaries made.				
35. I order the information to be learned according to some logical criterion: cause-effect, problem-solution, etc.				
36. When the subject under study presents the information organized temporally (historical aspects), I learn it taking into account that temporal sequence.				
37. If I have to learn different steps to solve a problem, I use diagrams to help capture the information.				
38. During the study, or at the end, I design concept maps to relate the concepts of a topic.				
39. To develop concept maps, I rely on the underlined keywords.				
40. When I have to make comparisons or classifications, I use tables.				
41. When studying any subject, I use V-diagrams to solve the above.				
42. I spend some study time memorizing, above all, summaries, diagrams, concept maps, etc. that is, to memorize the importance of each subject.				
43. To fix data when studying, I usually use "tricks" to make that idea stick in my memory.				
Sum				
44. I construct "rhymes" or "fillers" to memorize lists of concepts.				
45. To memorize, I mentally place the data in places in a well-known space.				
46. I learn unfamiliar names or terms by developing a "keyword" that bridges the gap between the familiar name and the new one to remember.				
Sum

Scale Iii: Information Recovery Strategy	A	B	C	D
1. Before speaking or writing, I remember words and drawings that are related to the "main ideas" of the material studied.				
2. Before speaking or writing, I use keywords or phrases that help me differentiate the main and secondary ideas of what I study.				
3. When I have to present something orally or in writing, I remember drawings, images, etc. through which I elaborated the information during learning.				
4. Before responding to an exam, I remember those groupings of concepts (summaries, diagrams, etc.) made at the time of studying.				
5. For important questions, which are difficult for me to remember, I look for secondary data in order to be able to remember what is important.				
6. It helps me to remember what I have learned by evoking events, episodes or clues that occurred during class or at other learning moments.				
7. It helps me to remember other topics that are related to what I really want to remember.				
8. Putting myself in a mental and affective situation similar to that experienced during the teacher's explanation or at the time of study, makes it easier for me to remember important information.				
9. In order to better recover what I have learned, I take into account the corrections and observations that teachers make in exams, exercises or assignments.				
10. To remember information, I first look for it in my memory and then decide if it fits what I have been asked or want to answer.				
11. Before I start to speak or write, I think and mentally prepare what I am going to say or write.				
12. I try to express what I have learned in my own words instead of repeating literally or verbatim what the book or the teacher says.				
13. When answering an exam, before writing, first I remember, in any order, everything I can, then I order it and make an outline or script and finally develop it point by point.				
14. When I have to do a free writing on any subject, I write down the ideas that occur to me, then I order them and finally I write them.				
15. When carrying out an exercise or exam, I am concerned about its presentation, order, cleanliness, margins.				
16. Before doing a written assignment, I make an outline, script or program of the points to be discussed.				
Sum				

	A	B	C	D
17. When faced with a problem or difficulty, I first consider the data that I know before venturing to provide an intuitive solution.				
18. When I have to answer a topic for which I have no data, I generate an "approximate" answer relating what I already know about other topics.

18. I use personal resources to control my anxiety states when they prevent me from concentrating on the study.				
19. I imagine places, scenes or events in my life to calm me down and to focus on work.				
20. I know how to self-relax, self-talk, self-apply positive thoughts to be calm on exams.				
21. I tell myself that I can exceed my current performance level (expectations) in the various subjects.				
22. I try that in the place I study there is nothing that can distract me, such as people, noise, disorder, lack of light and ventilation, etc.				
23. When I have family conflicts, I try to resolve them sooner, if I can, to better concentrate on studying.				
24. If I am studying and am distracted by thoughts or fantasies, I fight them by imagining the negative effects of not having studied.				
25. At work, I am encouraged to exchange opinions with my colleagues, friends or family about the subjects I am studying.				

26. I am satisfied that my colleagues, teachers and family value my work positively.				
27. I avoid or resolve, through dialogue, conflicts that arise in personal relationships with colleagues, teachers or family members.				
28. To improve myself it stimulates me to know the achievements or successes of my colleagues.				
29. I encourage and help my classmates to be as successful as possible in their homework.				
30. I say words of encouragement to myself to stimulate and keep me on study assignments.				
31. I study to expand my knowledge, to know more, to be more expert.				
32. I make an effort in the studio to be proud of myself.				
33. I seek to have prestige among my colleagues, friends and family, standing out in studies.				
34. I study to get rewards in the short term and to achieve a comfortable social status in the future.				
35. I make an effort to study to avoid negative consequences, such as reprimands, upsets or other unpleasant situations in the family, etc.

A R T I C L E   I N F O

A B S T R A C T

A healthy watershed is important not only for the ecosystem but also for human socioeconomic activities. Therefore, a compatible assessment model is required to recognize watershed health. In Indonesia, the watershed health assessment is directed by the Ministry of Forestry regulation number 60/2014. A critic might be posed to this directive for not including the biotic aspects of the watershed. This research aims to assess the five watersheds in Lampung Province, Indonesia. Afterward, we develop a mathematical model using multiple linear regression analysis to identify influential indicators. In developing the model, we combined indicators in the Ministry of Forestry regulation number 60/2014 with the US-EPA directive to include the biotic indicators. To collect the data, we accessed secondary data officially launched by the authorities and did field observation if the secondary data is not available. Our assessment based on the Indonesian official regulation shows that 3 sub-watersheds are in unhealthy status while the rest can be categorized as healthy watershed. Furthermore, the mathematical model of the sub-watershed health assessment shows that the percentage of critical land and vegetation coverage plays an essential role in determining watershed health status. Besides, investment in the water-related infrastructure also significantly contributes to watershed health.

1. Introduction

A watershed is an ecosystem where living organisms, biophysical elements, and chemical substances are interlinked and dynamically interact [1]. This ecosystem also plays an essential role in the dynamics of materials and energy flows. Therefore, the watershed deterioration might bring negative impacts on many sectors within various scales [2]. The watershed also has hydrological functions to accommodate rainwater overflow and to maintain the water quality. Besides, a watershed also acts as a compound ecosystem engaging natural landscape, economic activities, and social development [3]. Considering their important functions, all components of the watershed, which are generally categorized as input (i.e., rainwater), output (i.e., river flow, pollutants, sediments), and process (i.e., human activities, vegetation, soil, climate, and topography), are supposed to be well managed to meet basic requirements of ecosystem stability as well as socio-economic development [4–6].

Watershed health assessment refers to structural and functional measurement. To specify, the structural measurement is related to the issues of biodiversity, organic and inorganic resources, and physical attributes. Meanwhile, the functional measurement refers to the issues of ecological processes such as hydrology cycle, nutrient cycle, and energy flow [7]. In the watershed ecosystem, the hydrological biophysics process naturally occurs. It becomes a place for socioeconomic activities. Up to this point, the hydrological biophysics process is a part of the hydrology cycle while socioeconomic activities cannot be separated from human intervention to the watershed and the surrounding environments [1]. Indeed, the natural mechanisms and human interventions are inter-correlated and bring impacts one to another [8]. Therefore, more attention should be paid on the issue of watershed health to sustain human socioeconomic activities. The other way around, the socio-economic activities taking place on the watershed environments should be carefully managed to ensure watershed health.

*Corresponding Author: Eva Rolia,✉ roliaeva@yahoo.com, ☏+6282373737372

Furthermore, various concepts are promoted to explore the issues of watershed health assessment. In [9], for instance, argued that the diversity in ecological and social structure and the ability to adapt with uncertainty are the key factors to maintain the mutual relationship between the watershed health and human activities taken place on the watershed environment. Thus, understanding the socio-ecological system is an essential approach to build sustainable and adaptive modern management [10]. Subsequently, various indicators have been developed around the globe to assess watershed health. For example, a report from the Lake Simcoe Region Conservation Authority (Canada) [11]used land, water, and social conditions as indicators to assess watershed health. Other indicators such as geological condition, groundwater, the quantity and quality of surface water, geomorphologic condition, aquatic system, cultural, natural recreation, and land use are indicators used to assess the watershed health in the Philippines [12]. Meanwhile, in Thailand, three main indicators namely climate and stream flow, stream water quality, soil erosion, and stream sediment are suggested as tools to do the watershed health assessment [13]. Besides geomorphologic and hydrological aspects, in China, living organism (e.g., flora, fauna, riparian vegetation) inhabiting the watershed are also counted in the watershed health assessment [14]while the United States refers its integrated evaluation of the watershed health assessment and protection on the condition of landscape, habitat, hydrology, geomorphology, water quality, and biology [15]. Furthermore, study in [16]considered the impact of climate variability on watershed health by analyzing the temporal and spatial variability of reliability, resilience, and vulnerability.

Indeed, indicators used in a certain location have respective benefits and drawbacks. Besides, they also depend on the local context. Indonesia, in particular, recognized two categories in determining the watershed health status. They are to be maintained and to be rehabilitated watershed. The assessment criteria are stated in the ministry of forestry regulation [17]to be a reference to develop watershed management planning and policy. The criteria are (1) land conditions; (2) the quality, quantity, and continuity of the water; (3) socio-economy and institutions; (4) water building investment; and (5) land use. In more detail, each criterion is broken down into several sub-criteria. To compare with other countries (e.g., the United States), the current indicators used in Indonesia do not include the biotic aspects of the watershed. Therefore, the determination of the watershed health status might be criticized since the existence of living organisms, either aquatic or terrestrial creatures, can be natural indicators to predict the quality of the water [18]. Another benefit to using biological indicators in the watershed health evaluation is that they also reflect physical and chemical characteristics of the water environment since the existence of living organisms are highly influenced by the physical and chemical environment [19], the more living organisms, the better water quality physically and chemically. Furthermore, macro-invertebrate and fish are usually used to indicate the river health because their disappearance represent environmental degradation either in local or regional scale [20].

Considering the importance of the biological indicators, we tried to add this aspect to the watershed health assessment in Indonesia. We took five watersheds in Lampung province, Indonesia as the case study areas. They are Sekampung, Seputih,

Semangka, Mesuji, and Tulang Bawang. To introduce, Lampung province is located on the south-end of Sumatera Island. The five watersheds respectively have characteristics. For instance, the Sekampung watershed is the area with a dense population since it passes big cities and the capital of the province. Meanwhile, the Seputih watershed stretched from the north to the east part of this province. The land use of this area is dominated by rice field and horticulture cultivation. Farming activities also dominantly appear in Tulang Bawang and Mesuji watersheds. Nevertheless, rubber and palm plantations are the most common farming activities in these areas. Lastly, the land use of the Semangka watershed, which is located on the west part of Lampung province, is dominated by forest. Besides, farming activities, which mostly cultivate coffee, pepper, and clove, also appear in this area.

Furthermore, the objective of this research is to do a health assessment for these five watersheds using the Indonesian directive [17]and add the biological indicators to the assessment. Thus, we combined the assessment procedures proposed by the ministry of forestry and the US-EPA. Therefore, we compared our analysis with the health status attached to each watershed and investigated whether the biological indicators might change the current status. Moreover, we investigated the relationship between indicators and weighed the most influential ones to develop the indicator model. We weighed indicators resulted from the modeling to determine the optimum value of the watershed health using the linear regression statistical model.

2. Materials and Methods

In conducting this study, we did both secondary and primary data collection. At the beginning stage, we collected the secondary data related to hydrology and land cover of the watersheds. We also identified institutions that are in charge of the respective watershed as well as socio-economic activities that took place on it. We utilized data officially launched by the government institutions to elaborate on those indicators, which are required by the assessment method directed by the ministry of forestry. Furthermore, we analyzed indicators required by the US-EPA assessment method i.e., landscape, biology, geomorphology, habitat, water quality, and hydrology. Information related to these issues is gathered from the secondary data and the primary data as well. After gathering information about the indicators above, we analyzed the relationship between indicators using the multiple linear regression analysis. This stage aimed to optimize the use of indicators to assess watershed health. Eventually, we formulated policy scenarios and simulated through qualitative analysis.

This research was started by collecting information related to the current health status of the five assessed watersheds. Referring to the regulation launched by the Ministry of Forestry, we collected the data on five criteria. They are (1) land conditions; (2) water conditions (quality, quantity, and continuity); (3) socioeconomic and institutions; (4) investment; and (5) land use. In more detail, each criterion is broken down into more specific sub-criteria. The Ministry of Forestry regulation number 60/2014 also provides the formulas as a guidance to calculate all indicators. Furthermore, this regulation also provides the classification for each criterion and a justification for weighing. Then, based on this weighing procedure, we assessed the health status of the seventeen sub-watersheds in

Lampung Province, Indonesia. In detail, the formula of the criteria, and the weighing system suggested by the Ministry of Forestry regulation number 60/2014 is presented in table 1.

Table 1: The Formula to Calculate Indicators Based on the Ministry of Forestry Regulation Number 60/2014 and the Scoring Justification

Indicators (Formula)	Remarks	Scoring Justification	
		Criteria	Score
Critical Land $CL = \dfrac{A_{CL}}{A_W} x100\%$	CL= Critical Land (%) A_{CL} = The area of the critical land (Hectares) A_W = The area of the watershed (Hectares)	CL≤5	0.50
		5<CL≤10	0.75
		10<CL≤15	1.00
		15<CL≤20	1.25
		CL>20	1.50
Vegetation Coverage $VC = \dfrac{A_{VC}}{A_W} x100\%$	VC= Vegetation Coverage (%) A_{VC}= The area of the vegetation coverage (Hectares) A_W = The area of the watershed (Hectares)	80<VC	0.50
		60<VC≤80	0.75
		40<VC≤60	1.00
		20<VC≤40	1.25
		VC≤20	1.50
Erosion Index $EI = \sum \dfrac{A_i}{A_W} x EI_I$; where $EI_i = \dfrac{PE_i}{TE_i}$	EI = Erosion Index Ai= The area of i-th segment Aw=The area of watershed EIi=Erosion index in i-th segment PE$_i$=Predictive erosion in i-th segment TE$_i$=Tolerable erosion in i-th segment	EI≤0.5	0.50
		0.5<EI≤1.0	0.75
		1.0<EI≤1.5	1.00
		1.5<EI≤2.0	1.25
		EI>2.0	1.50
Flow Regime Coefficient $FRC = \dfrac{Q_{max}}{Q_R}$; where $Q_R = 0.25 x Q_{av}$	Q$_{max}$=Daily quantity (in the highest quantity year) Q$_R$=Reliable quantity Q$_{av}$=Average quantity (within 10 years)	FRC≤5	0.50
		5<FRC≤10	0.75
		10<FRC≤15	1.00
		15<FRC≤20	1.25
		FRC>20	1.50
Annual Flow Coefficient $AFC = \dfrac{kQ_{an}}{RA_W}$	AFC=Annual Flow Coefficient k=Conversion factor =(365 x 86,400)/10 Q$_{an}$=Average annual quantity R=average annual rainfall A$_W$=the area of the watershed	AFC≤0.2	0.50
		0.2<AFC≤0.3	0.75
		0.3<AFC≤0.4	1.00
		0.4<AFC≤0.5	1.25
		AFC>20	1.50
Sediment Load $SL = kC_s Q_{an}$	SL=Sediment Load k=Conversion factor =(365 x 86.4) C$_s$=Sediment concentration (gram/Liter) Q$_{an}$=Average annual quantity	SL≤5	0.50
		5<SL≤10	0.75
		10<SL≤15	1.00
		15<SL≤20	1.25
		SL>20	1.50
Annual Flood Event	Data on the annual flood is officially launched by the government	Never	0.50
		Once in 5 years	0.75
		Once in 2 years	1.00
		Once in a year	1.25
		More than once in a year	1.50
Water Usage Index $WUI = \dfrac{WR_{tot}}{HH_{tot}}$	WUI=Water Usage Index WR$_{tot}$= Total water requirement HH$_{tot}$=Total numbers of households	WUI≤0.25	0.50
		0.25<WUI≤0.50	0.75
		0.50<WUI≤0.75	1.00
		0.75<WUI≤1.00	1.25
		WUI>1.00	1.50
Land Availability Index $LAI = \dfrac{A_f}{HH_f}$	LAI=Land Availability Index A$_f$=Area for farming activities HH$_f$=Numbers f households that are farmers	IKL>4	0.50
		2<IKL≤4	0.75
		1<IKL≤2	1.00
		0.5<IKL≤1	1.25
		IKL≤0.5	1.50
Population Welfare	PW=Population Welfare	PW≤5	0.50
		5<PW≤10	0.75
		10<PW≤20	1.00

$PW = \dfrac{HH_{pov}}{HH_{tot}} x100\%$	HH_{pov}=Numbers of households that are below poverty line living on the watershed area HH_{tot}=total numbers of households living on the watershed area	$20<PW\leq30$	1.25
		$PW>30$	1.50
Pro-conservation regulation	The data refer to availability of pro-conservation regulation in the local government located on the watershed	Available, widely applied	0.50
		Available, partly applied	0.75
		Available, no longer applied	1.00
		Unavailable	1.25
		Available, has not been applied	1.50
The existence of urban area	The data refers to the existence of urban areas and type of the city located on the watershed	No urban area	0.50
		Small city	0.75
		Medium sized city	1.00
		Big city	1.25
		Metropolitan	1.50
Investment on the water building	The data refers to the investment (expressed in billion Rupiahs) on water building e.g. dam, irrigation, etc.	$INV\leq15$	0.50
		$15<INV\leq30$	0.75
		$30<INV\leq45$	1.00
		$45<INV\leq60$	1.25
		$INV>60$	1.50
Conserved Area	Con A= Percentage of conservation area A_{veg}= The area of vegetation coverage in conservation area A_{con}= The total area of conservation in the watershed	Con A>70%	0.50
		45%<Con A≤70%	0.75
$ConA = \dfrac{A_{veg}}{A_{con}} \times 100\%$		30%<Con A≤45%	1.00
		15%<Con A≤30%	1.25
		Con A≤15%	1.50
Cultivated Area	Cul A=Percentage of cultivated area A_{25}=The area with the slope 0-25% A_{cul}=The total area of cultivation in the watershed	Cul A>70%	0.50
		45%<Cul A≤70%	0.75
$CulA = \dfrac{A_{25}}{A_{cul}} \times 100\%$		30%<Cul A≤45%	1.00
		15%<Cul A≤30%	1.25
		Cul A≤15%	1.50

Furthermore, we collected data required by the formulas to assess the health of the sub-watersheds. Afterwards, the accumulated score for each sub-water sheds was calculated to state the health status. This regulation defines a watershed is healthy when the total score is less than or equal to 100 and is unhealthy if the total score exceeds 100.

Moreover, we also assessed the watershed health by using the US-EPA assessment procedure which involves indicators such as habitat, hydrology, geomorphology, water quality, and biota. Since some indicators are not available in the Indonesian assessment system, we collected the data by direct observation. For example, habitat observation was carried out by tracing the rivers (about 200 meters long) to observe the riverbed substrate and disturbance factors surrounding the rivers and riparian. Besides, we calculated the geomorphology indicator based on the slope that is analyzed from the existing topographical data. To investigate the water quality, we utilized data from the environmental agency of the Lampung provincial government; the institution that is responsible for doing laboratory tests on the water quality.

Then, we developed a mathematical model representing the watershed health assessment. This predictive model aimed to investigate the relationship between independent variables and the dependent variable and the most influential indicators. We employed the multiple linear regression models following equation 1 and the numerical iteration is assisted by computer software (SPSS).

$$y_1 = \beta_0 + \beta_1 x_{1i} + \beta_2 x_{2i} + \beta_3 x_{3i} + \cdots + \beta_k x_{ki} + i \quad (1)$$

The y indicates the watershed health, which is the expected dependent variable while x1, x1, x2, and so forth are the indicators that act as inputs of independent variables. Based on the collected data, we developed four models. The first model represents the Ministry of Forestry regulation number 60/2014 and the second model represents the US-EPA directive. Then, the third and fourth models combine both assessment procedures. At the end of statistical procedures, we validated the watershed health equation models with the assessment based on the Ministry of Forestry regulation number 60/2014 following the criteria listed in table 1 as the reference. This validation resulted in the percentage of the margin of error that can reflect the suitability of the model and confirm the watershed health status.

3. Results

3.1. The description of the watershed

This research was taken place on five watersheds in Lampung Province located on the southern part of Sumatera

Island. Figure 1 is to illustrate the situation of the five watersheds and each characteristic.The figure shows that each watershed has a different size and most of them stretch across the city administrative borders. The red line indicates the border of each watershed. It can be seen Tulang Bawang watershed (the middle part) occupies the biggest area while the smallest one is Semangka watershed. Besides, different coloured spots show various activities taken place on the watersheds that are characterized by different types of land covering. The green areas indiate forests while the blue areas indicate paddy fields.biggest area while the smallest one is Semangka watershed. Besides, different coloured spots show various activities taken place on the watersheds that

are characterized by different types of land covering. The green areas indiate forests while the blue areas indicate paddy fields.Moreover, the red spots in the map shows the settlement areas. It can be seen that the existence of the forests in the case study area is still signifcant and the economic activities are dominated farming activities such as paddy fields, horticulture cultivation, and plantations. On the other hand, the mining activities also exist indicated by the dark brown spots.

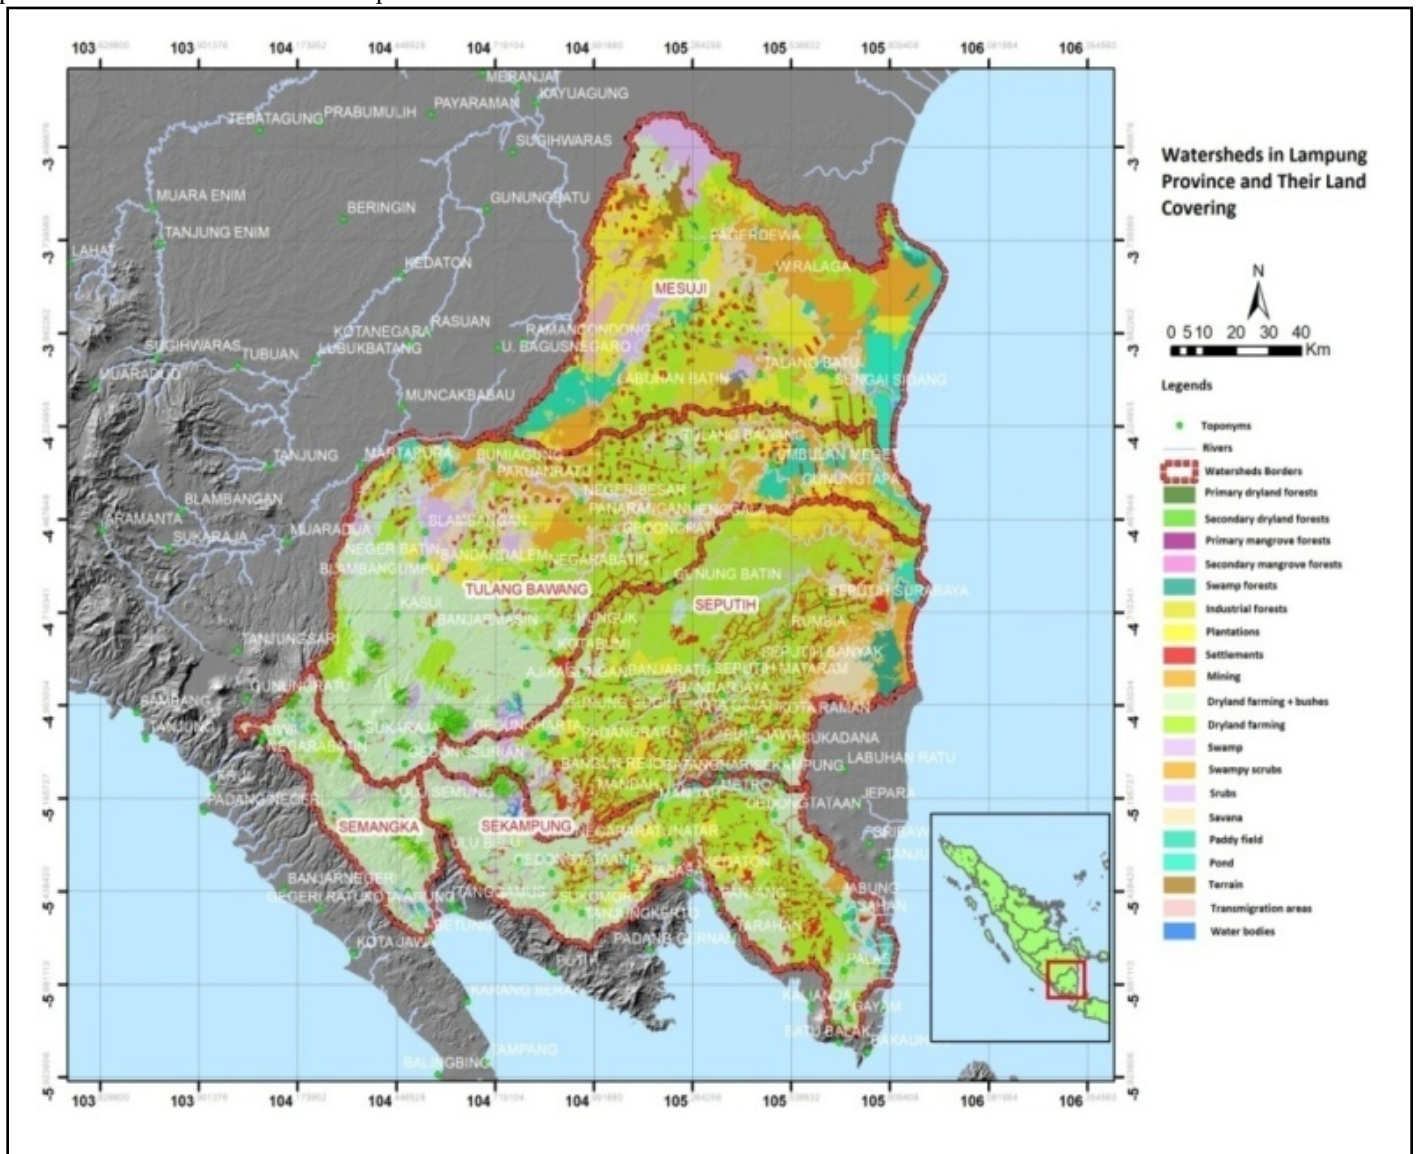
Furthermore, table 2 compares the watersheds size, the length of the main river, and the three most dominant land covering in each watershed.


Figure 1: The land covering map of the case study area

Table 2: The watersheds size and their most dominant land covering

Watershed	Area (Hectares)	The length of the main river (km)	Dominant land covering	
			Type of land covering	Percentage (%)

Figure 2: The sub-watershed clustering

Table 2 lists the three most dominant land covering the five observed watersheds. For all watersheds, the dryland farming is superior over other types of land covering with its respective portion. In the Semangka watershed, for instance, dryland farming shared 82.9% of the total area, which is the biggest percentage of land covering. Then, the percentage is followed by forest and swamp, which is respectively 6.5% and 5.7%. Similar with this watershed, the dryland farming is also the most dominant land covering in Sekampung, Tulang Bawang, and Seputih watershed, which is 73.8%, 60.0%, and 58.7% of the total area of each watershed. Although its percentage is not as superior as the other four watersheds', dryland farming still shares the highest percentage in the Mesuji watershed, which is 23.7% of the total area.

To organize the data collection and analysis, the five watersheds are divided into seventeen sub-watersheds and are codified as is illustrated in figure 2. Further, our data collection and analysis are referred to as this sub-watershed clustering and codification. To specify, we assessed five sub-watersheds in Sekampung watershed, six sub-watersheds in Seputih watersheds, and four sub-watersheds in Tulang Bawang sub-watersheds. For

Mesuji and Semangka watershed, respectively we took one sub-watershed.

3.2. *The watershed health assessment based on the Ministry of Forestry number 60/2014*

Referring to indicators and the formulas listed in table 1, we assessed the health status of the seventeen sub-watersheds. Firstly, we assessed the sub-watershed health based on the indicators of the land conditions. Critical land, vegetation coverage and erosion index are belonged to this indicator. Our analysis shows that the percentage of critical land varied, ranging from 0% to 33.6%, in all assessed watershed. The three highest percentages of the critical land appear in SMK-01 (33.6%), SK-01 (28.62%), and SM-03 (22.309%). Moreover, we scored the percentage based on the classification listed in table 1. The shifting in land use can probably be highlighted as the cause of the increasing trend of the critical land. For example, the land-use changes from the forest to the plantations in the upstream while in the middle areas and the downstream the land use mostly shift into settlements and commercial areas, which is in line with the population growth.

Other indicators of the land condition that we assessed are the vegetation coverage and erosion index. These elements are essential considering their importance to influence soil's physical and chemical characteristics and water flow. The data shows that there is a wide interval (from 0.005% to 89.838%) indicating a diverse situation of the vegetation coverage in the seventeen watersheds. The highest percentage of the vegetation coverage (89.838%) is in SK-01 while the lowest percentage (0.005%) is in SP-02. The higher percentage implicates on the lower score in the weighing procedure. Thus, the higher percentage of the vegetation coverage means the healthier watershed. In the case of erosion index, the calculation does not show a dramatic difference among all areas. The range of the erosion index is between 0.32% and 1.2% while the weight is within the interval 0.5 to 1.0. In general, based on the indicator of the erosion index, the assessed sub-watersheds have good conditions.

Furthermore, we continued the assessment on the indicator of the water quality, quantity, and continuity. We employed equations listed in table to calculate the assessment values using data recorded by the government institutions that are responsible for the watershed management in Lampung Province. We found that there is a variety among the sub-watersheds, but it is not as wide as in the land conditions. Thus, the sub-watersheds have a slight difference in the perspective of water quality, quantity, and continuity. The score of the respective indicator in the sub watersheds is illustrated in figure 3.
Figure 3: The score of the sub-watershed health assessment based on the quality, quantity, and continuity indicators

In the case of the Flow Regime Coefficient (FRC), which are represented by the blue bars, the highest score is in TR-02 (1.25) followed by TR-02 and SP-02 (1.25) while the result is dominated by the score 0.75. The uniform tendency also appears in the category of the Annual Flow Coefficient (AFC) that is represented by the yellow bars and the Sediment Load (SL) that is represented by the purple bars. On the other hand, more varied score appears in the category of the Annual Flow Event (AFE), which is illustrated by the green bars. In this category, SK-07 has the highest score (1.5) indicating that this sub-watershed has the most often annual flood event compared to other assessed sub-watersheds.

Subsequently, we summarized the sub-watershed health assessment on the socioeconomics and institution indicators. We found that the SK-01 sub-watershed has the lowest Land Availability Index (0.272 hectares/household) while the TB-02 sub-watershed has the highest LAI (9.946 hectares/households). However, it does not automatically implicate population welfare. The calculation shows that the watershed that has the highest LAI is not the most superior in the population welfare. Similarly, the lowest LAI does not implicate the most inferior in population

welfare. In the case of population welfare, the highest percentage is SK-06 sub-watershed (20.21%), which implicates on the highest weighing score (1.25). Meanwhile, other assessed sub-watersheds share the same weighing scores (1.0) even though their percentage of population welfare is varied from 10.64% to 19.19%. In the case of pro-conservation regulations, only the Sekampung watershed that has widely applied their local regulations those is pro-conservations while other watersheds have pro-conservation regulations but partly applied.

In the case of the investment indicators, the existence of urban areas and water-related infrastructure (e.g., dam, reservoir, irrigation, etc.) were assessed. We found that the seventeen sub-watersheds are dominated by the small cities and only the SK-05 has a medium-size city. Meanwhile, six sub-watersheds, which are SK-04, SK-06, SK-07, PB-02, TR-01, and TR-02, do not have urban areas. We also found that there is a wide disparity in the existence of the investment on the water-related infrastructure. The data shows the biggest investment, which is the biggest dam in Lampung Province, is located on the SK-07 (IDR 1000 billion). By contrast, the smallest investment (IDR 2 billion) is located on the SK-06.

Lastly, we did the health assessment for the seventeen sub-watersheds on the indictors of the land use. The land use is generally divided into two categories: the conserved and the cultivated areas. The conserved area is defined as the proportion of the vegetation-covered land to the dedicated conservation area. Meanwhile, the cultivated area is defined as the area with the slope 0 to 25%, which is considered as the area that could be cultivated. We calculated the respective areas based on satellite image analysis. We found that the biggest portion of the conserved area (75.49%) belongs to the SK-01 while other sub-watersheds have small percentages. Besides, the zero percentage might indicate that the dedicated conservation area is not available on the sub-watersheds. In the category of the cultivated area, the SK-05 has a hundred percent cultivated area implying that the whole areas have a slope less than 25%.

Table 3: The watershed health status and classification

Watershed	Sub-watershed	Code	Score	Health status	Classification
Sekampung	Sekampung 1	SK-01	111	Unhealthy	Rehabilitated
	Sekampung 4	SK-04	89.75	Healthy	Maintained
	Sekampung 5	SK-05	93.25	Healthy	Maintained
	Sekampung 6	SK-06	90	Healthy	Maintained
	Sekampung 7	SK-07	104	Unhealthy	Rehabilitated
Seputih	Seputih 1	SP-01	87.5	Healthy	Maintained
	Seputih 2	SP-02	86.25	Healthy	Maintained
	Seputih 3	SP-03	86.25	Healthy	Maintained
	Way Pengubuan 1	PB-01	88.75	Healthy	Maintained
	Way Pengubuan 2	PB-02	81.25	Healthy	Maintained
	Way Pegadungan 2	PG-02	90	Healthy	Maintained
Tulang Bawang	Tulang Bawang 1	TB-01	84.75	Healthy	Maintained
	Tulang Bawang 2	TB-02	84.75	Healthy	Maintained
	Terusan Nunyai 1	TR-01	79.75	Healthy	Maintained
	Terusan Nunyai 2	TR-02	93.5	Healthy	Maintained
Mesuji	Mesuji 3	SM-03	95.75	Healthy	Maintained
Semangka	Semangka 1	SMK-01	108.75	Unhealthy	Rehabilitated

In more detail, the assessment on the five indicators suggested by the Ministry of Forestry regulation number 60/2014 is tabulated in the Appendix A (Table A1, A2, A3, A4, and A5).

After conducting an assessment for all indicators, we compiled the scores and justify the watershed health status. If the total score exceeds one hundred, the sub-watershed health status is considered as unhealthy. Furthermore, the health status justification also implicates the watershed classification whether it should be maintained or rehabilitated. The analysis shows that most of the sub-watersheds are still in healthy condition. Only three out of seventeen sub-watersheds are considered unhealthy. In detail, the tabulation is presented in table 3.

3.3. Constructing a model for the watershed health assessment

After assessing the watershed health using the Ministry of Forestry regulation number 60/2014, we did a comparison with the US-EPA directive to validate the results and construct a model for the watershed classification. In general, the US-EPA directive defined five indicators i.e. landscape, hydrology, geomorphology, water quality, and biota observation. We used the same scoring procedure for the indicators that can be associated with the Ministry of Forestry regulation number 60/2014. For example, the landscape indicators can be associated with the vegetation coverage and the percentage of the conserved area. We also associated the hydrology indicators with the flow regime coefficient and annual flow coefficient while the geomorphology

indicators are associated with the critical land and the cultivated area. Nevertheless, the water quality and biota observation indicators are not accommodated by the Ministry of Forestry regulation number 60/2014. In this case, we did a field survey to collect the primary data if the data officially published by the authorities is not available.

To determine the water quality, we used the Water Quality Index (WQI) that considers nine parameters of water quality namely Dissolved Oxygen (DO), fecal coliform, pH, Biochemical Oxygen Demand (BOD), temperature, Nitrate, Phosphate,

turbidity, and suspended materials. We utilized the data published by the Environmental Agency of the Lampung Provincial Government. The data is based on the measurement conducted from April to November 2018. Moreover, the sub-watershed health status is justified using the US-EPA directive. In the case of biota observation, we did a field survey to observe the appearance of macroinvertebrates along the river. Then, the biota observation index is calculated to determine the level of pollution [21,22]. In detail, the sub-watershed health assessment on the water quality and biota observation is presented in table 4.

Table 4: The sub-watersheds health assessment on the water quality and biota observation indicators

Sub-watershed	Water quality index		Biota observation index	
	Score	Health status	Score	Pollution level
SK-01	55.33	Healthy	2.00	High
SK-04	58.00	Healthy	2.00	High
SK-05	56.25	Healthy	2.00	High
SK-06	55.00	Healthy	2.17	Moderate
SK-07	57.00	Healthy	2.00	High
SP-01	65.67	Healthy	2.00	High
SP-02	65.33	Healthy	2.00	High
SP-03	64.00	Healthy	2.00	High
PB-01	60.33	Healthy	2.33	Moderate
PB-02	60.67	Healthy	2.00	High
PG-02	56.33	Healthy	2.50	Moderate
TB-01	59.33	Healthy	2.10	Moderate
TB-02	66.00	Healthy	2.00	High
TR-01	55.67	Healthy	2.47	Moderate
TR-02	63.00	Healthy	2.23	Moderate
SM-03	46.00	Healthy	2.00	High
SMK-01	62.00	Healthy	2.00	High
Figure 3: The validation of the models with the actual calculation

Furthermore, we used the weighing scores to develop assessment modeling. We develop four modeling scenarios. The assessment modeling aimed to identify the relationship between indicators and the most influential ones. We employed multiple linear regression, which follows equation 1, to construct those three models. To compute, we used computer software namely SPSS (Statistical Package for Social Science). The scores acted as inputs of independent variables and the watershed health is the dependent variable that is desired after the model runs. These four equations represent the result of the computation.

$$y_1 = 159.121 + 0.18VC + 0.940SL - 65.948WUI - 74.567Reg + 11.158Inv \tag{2}$$

$$y_2 = 44.973 + 0.958CL - 0.507VC + 7.140AFC + 0.953Con + 0.372Cul \tag{3}$$

$$y_3 = 154.930 + 0.224VC - 43.327WUI - 66.802Reg + 8.930Inv \tag{4}$$

$$y_4 = 50.549 + 0.774CL + 7.084AFC + 11.687Inv + 10.653BOI \tag{5}$$

The equations show that each model has different influential indicators. In the first model (the Ministry of Forestry regulation) indicates vegetation coverage, sediment load, water usage index, pro-conservation regulation, and investment of the water-related infrastructure are the influential indicators determining the watershed health status. Similarly, the third model also has the same influential indicators except for the sediment load. Meanwhile, those indicators (except vegetation coverage) do not appear in the second model (the US-EPA directive). In this model, the percentage of critical land, annual flow coefficient, conserver area, and cultivated land are influential. Eventually, the fourth equation resulted in different influential indicators compared to

the first three. In this model, the percentage of the critical land, annual flow coefficient, investment, and biota observation index play the most essential roles.

To validate the models, we calculated the error percentage of each equation referring to the scoring and health status justification (table 3). The result is presented in figure 3. Figure 3 shows an insignificant difference between the result gained from the calculation and modeling. In general, iteration resulted in the margin of error around six percent or less except the TR-02 and the PB-02 in the third model (y_3). In this model, the margin of error respectively reaches 10.33% and 7.46%. The data insufficiency could probably be a major cause of this occurrence. Currently, the government agencies that involve watershed management have not recorded data required for the modeling. On the other hand, the primary data collected from the field survey did not suffice the requirement of the software iteration. Beyond this limitation, we have spent efforts to simplify the model using the available data.

4. Discussion

The main objective of watershed management is to maintain a healthy ecosystem. However, prioritization has to be taken due to various limitations. The watershed health assessment is one of the procedures to reveal the most urgent elements that require immediate measures. Indeed, the priority of watershed management is context-dependent and different from one entity to another. Therefore, a certain measure cannot be uniformly implemented for all regions. This research identified the health status of five watersheds, which are broken down into seventeen sub-watersheds, in Lampung Province, Indonesia. We mainly used the directive that is officially stated by the authority and added indicators that have not been accommodated by the current

directive. The mathematical models that resulted in this study can be utilized as a predictive tool for decision-makers to formulate the watershed management planning and required actions for necessary rehabilitation.

This study revealed that 3 sub-watersheds should be rehabilitated to increase their current carrying capacity. The sub-watersheds are Sekampung 1, Sekampung 7, and Semangka 1. This result implies an alarming situation regarding the sustainability of the sub-watersheds in supporting human activities. Meanwhile, the 14 sub-watersheds can be classified as the areas that should be maintained. It does not mean the sub-watersheds can be exploited without a proper management plan. Subsequently, the influential indicators resulted from mathematical modeling can be viewed as essential elements that contribute significantly to watershed health. Besides, it can be an input to set a prioritization strategy.

Furthermore, a watershed can also be seen as an entity requiring comprehensive and integrated planning to ensure sustainable resource utilization. To realize the comprehensive and integrated approach, a watershed is supposed to be considered as an inseparable entity involving various stakeholders and interests that sometimes cross over administrative borders. Therefore, the watershed management cannot be conducted partially for a certain sector or territory and institutional arrangement is highly required.

5. Conclusion

There are some conclusions can be highlighted from this study. First, three out of seventeen assessed sub-watersheds in Lampung Province, Indonesia can be categorized as unhealthy watershed based on the Ministry of Forestry regulation number 60/2014. This regulation suggested that the unhealthy watershed to be revitalized. Second, from the assessment using the US-EPA directive, the watershed health status of each assessed sub-watershed varies in accordance with the indicator. For instance, all sub-watersheds have healthy status from the water quality index indicator, but their biota observation index shows various pollution levels ranging from moderate to high. Third, the mathematical model of the watershed health assessment in this research can be utilized as a predictive tool to indicate the health status of the watersheds in the case study area. To compare with the assessment using the Ministry of Forestry regulation number 60/2014, the suggested equations have significant accuracy.

Conflict of Interest

The authors declare no conflict of interest.

A R T I C L E I N F O	A B S T R A C T
	In this paper are shown some new results on fixed point related to a $\varphi - \psi$ contractive map in JS – generalized metric spaces X. It proves that there exists a unique fixed point for a nonlinear map $f: X \rightarrow X$, using two altering distance functions. Furthermore, it gives some results which related to a couple of functions under some conditions in JS – generalized metric spaces. It provides a theorem where is shown that two maps $F, g: X \rightarrow X$ under a nonlinear contraction using ultra – altering distance functions ψ and φ, which are lower semi – continuous and continuous, respectively, have a coincidence point that is unique in X. In addition, there is proved if the maps F and g are weakly compatible then they have a fixed point which is unique in JS – generalized metric space. As applications, every theorem is illustrated by an example. The obtained theorems and corollaries extend some important results which are given in the references.

1. Introduction

The study of fixed point in metric space has an important role in Functional Analysis. It is developed in two directions during the years which are the improving contraction conditions and changing axioms of metric space with the intention to generalize fixed points results in this space. As a result, there are given many new spaces such as generalized metric space [1], cone metric space [2], rectangular metric space [3].

In [4], authors introduced the concept of JS – metric space. It generalizes well-known concepts of metric structures like metric spaces, b – metric spaces [5], metric - like spaces [6], etc. There are many articles which are worked on these spaces, like [7]-[10].

In [11], authors expanded the Banach contraction introducing the concept of weakly contractive function in Hilbert spaces.

Many authors have used these functions in many other spaces like [12]-[14].

In [15], authors provided some theorems related to fixed points of mappings in generalized metric spaces introducing the concept of altering distance functions.

In [16], authors generalized some theorems on fixed point for contractive functions of type Kannnan, Chatteria and Hardy – Rogers in generalized metric space.

This paper generalizes some important results on fixed point for weakly contractive functions and functions with altering distance between points, giving some new theorems on fixed point for $\varphi - \psi$ contractive functions in JS – generalized metric spaces.

Furthermore, it proves a theorem on common fixed points of two $\varphi - \psi$ contractive functions on JS – generalized metric spaces.

2. Preliminaries

Let X be a set which is not empty and D_{JS} be a non - negative function of cartesian product $X \times X$.

For each $\vartheta \in X$, let define the set

$$C(D_{JS}, X, \vartheta) = \{\{x_n\} \subset X: \lim_{n\to\infty} D_{JS}(x_n, \vartheta) = 0\}$$

Definition 2.1 [4] The map D_{JS} that satisfies the conditions:

(D_{JS_1}) $D_{JS}(x, \tilde{x}) = 0$ yields $x = \tilde{x}$

*Corresponding Author: Eriola Sila, Roliaerjola.liftaj@fshn.edu.al

(D_{JS_2}) $D_{JS}(x, \tilde{x}) = D_{JS}(\tilde{x}, x)$

(D_{JS_3}) There exists a constant $\rho > 0$, such that for $x_n \in C(D_{JS}, X, \vartheta)$, it yields

$$D_{JS}(x, \tilde{x}) \leq \rho \lim_{n \to +\infty} D_{JS}(x_n, \tilde{x})$$

for all $(x, \tilde{x}) \in X \times X$, is called JS – generalized metric.

The couple (X, D_{JS}) is called s JS – generalized metric pace.

In [4], authors showed that JS – generalized metric space are metric space, b – metric space, dislocated metric space, etc.

Remark 2.2 [4] As it can be seen in JS – generalized metric space, the map $D_{JS}(\tilde{x}, \tilde{x})$ maybe not zero.

Remark 2.3 [4] When the set $C(D_{JS}, X, \vartheta)$ does not contain any element for all $\vartheta \in X$, the couple (X, D_{JS}) is JS – generalized metric space satisfying only (D_{JS1}) and (D_{JS2}).

Definition 2.4 [16] Let (X, D_{JS}) be a JS – generalized metric space and $\{x_n\}_{n \in N}$ is in X and $\vartheta \in X$. If $\{x_n\}_{n \in N}$ is in $C(D_{JS}, X, \vartheta)$, it is called D_{JS} – convergent to $\vartheta \in X$.

Remark 2.5 [16] If a constant sequence is D_{JS} – convergent to $c \in X$ then $D_{JS}(c, c) = 0$.

Proposition 2.6 [16] A necessary and sufficient condition that the set $C(D_{JS}, X, \vartheta)$ is not empty is that $D_{JS}(\vartheta, \vartheta) = 0$

Proposition 2.7 [4] Let the pair (X, D_{JS}) be a JS - metric generalized space and $\{x_n\}_{n \in N}$ in X and $\vartheta, \bar{\vartheta} \in X$. If $\{x_n\}_{n \in N}$ is D_{JS} – convergent to ϑ and $\bar{\vartheta}$ then $\vartheta = \bar{\vartheta}$.

Definition 2.8 [16] The sequence $\{x_n\}_{n \in N}$ in a JS – generalized metric space (X, D_{JS}) is called D_{JS} – Cauchy if $D_{JS}(x_n, x_m)$ converges to 0 when m, n tent to $+\infty$.

Definition 2.9 [16] A JS – generalized metric space (X, D_{JS}) is named D_{JS}– complete if each D_{JS} – Cauchy sequence in X is D_{JS} – convergent in X.

Example 2.10 Take $X = [0, c]$ where $c \in R$ and D_{JS} be a non - negative function of cartesian product $X \times X$, where

$$D_{JS}(x, \tilde{x}) = \begin{cases} \max\{x, \tilde{x}\}, & (x, \tilde{x}) \neq (0,0) \\ \dfrac{x}{2}, & (x, 0) \\ \dfrac{\tilde{x}}{2}, & (0, \tilde{x}) \end{cases}$$

Since the map D_{JS} accomplishes (D_{JS_1}) and (D_{JS_2}) in trivially manner, it is a JS – generalized metric.

Consequently, it needs to verify that (D_{JS_3}) is satisfied only for $x \in X$ that $D_{JS}(x, x) = 0$. But $D_{JS}(x, x) = 0$ implies $x = 0$.

If $(x_n)_{n \in N} \subset X$ converges to 0 then $\lim_{n \to +\infty} D_{JS}(x_n, 0) = 0$.

Taking $n \in N$ and $\tilde{x} \in X$,

$$D_{JS}(x_n, \tilde{x}) = \begin{cases} \max\{x_n, \tilde{x}\}, & for\ x_n \neq 0 \\ \dfrac{\tilde{x}}{2}, & for\ x_n = 0 \end{cases}.$$

As a result, the inequality $\dfrac{\tilde{x}}{2} < D_{JS}(x_n, \tilde{x})$ is true.

From this, it yields $D_{JS}(0, \tilde{x}) = \dfrac{\tilde{x}}{2} < \lim_{n \to +\infty} \sup D_{JS}(x_n, \tilde{x})$.

So, (X, D_{JS}) is JS – generalized metric. However, it is not neither metric space nor dislocated metric space because it doesn't accomplish the third condition of their metric, for $x, \tilde{x} \in X - \{0\}$ and $x^* = 0$, because

$$D_{JS}(x, 0) + D_{JS}(0, \tilde{x}) = \frac{x}{2} + \frac{\tilde{x}}{2} < \max\{x, \tilde{x}\} = D_{JS}(x, \tilde{x}).$$

Definition 2.11 [15] The function $\psi: R^+ \to R^+$ that satisfies the conditions:

1. ψ is non-decreasing and continuous
2. $\psi(s) = 0$ if and only if $s = 0$.
3. $\psi(s) \geq Ms^\mu$, for every $s > 0$ where $M > 0, \mu > 0$ are constants

is called altering distance.

Definition 2.12 [15] A function $\psi: R^+ \to R^+$ that accomplishes the conditions:

1. ψ is non – decreasing
2. $\psi(s) > 0$ if $s > 0$ and $\psi(0) = 0$

is called ultra – altering distance.
The set of ultra-altering distances is denoted Ψ.

Let g, F two functions of X in itself.

Definition 2.13 [17] The point $\xi \in X$ which completes the equality $g(\xi) = F(\xi)$ is called coincidence point of g, F.

Definition 2.14 [18] The functions g, F that satisfy $gF\xi = Fg\xi$, for each ξ that is coincidence point of g and F, are called weakly compatible.

Definition 2.15 [18] The point $\xi \in X$, in which $\xi = F \xi = g \xi$, is called common fixed point of maps g, F.

Theorem 2.16 ([16], Corollary 5.5) Let f of set X in itself where (X, D_{JS}) is D_{JS} – generalized metric space which is complete and

$$D_{JS}(fx, f\tilde{x})$$

$$\leq \kappa max\{D_{JS}(x, \tilde{x}), D_{JS}(x, Tx), D_{JS}(\tilde{x}, T\tilde{x}), \frac{D_{JS}(x, f\tilde{x}) + D_{JS}(\tilde{x}, fx)}{2}\}$$

If there exists a $\varsigma \in X$ that $\delta(D_{JS}, f, \varsigma) < +\infty$, then the sequence $\{f^n \varsigma\}_{n \in N}$ D_{JS} – convergences to a point ϑ in X.

When $D_{JS}(\vartheta, f\vartheta) < +\infty$ then ϑ is fixed point of function f. Furthermore, for $\vartheta' \in X$ which is another fixed point of function f, such that $D_{JS}(\vartheta', f\vartheta') < +\infty$, it yields $\vartheta = \vartheta'$.

3. Main results

3.1. Fixed point results related to $\varphi - \psi$ contractions in JS – generalized metric spaces

Definitions 3.1.1 Define the set

$$\delta(D_{JS}, f, \varsigma) = \sup\{D_{JS}(f^l\varsigma, f^m\varsigma), l, m \geq 0\}$$

where $\varsigma \in X$.

Theorem 3.1.2 Let (X, D_{JS}) be JS – generalized metric space which is complete and $f: X \to X$ a function that satisfies the following condition:

$$\psi\left(D_{JS}(fx, f\tilde{x})\right) \leq \psi\left(M_{JS}(x, \tilde{x})\right) - \varphi(M_{JS}(x, \tilde{x})) \quad (3.1)$$

where

$$M_{JS}(x, \tilde{x}) = \text{maximum}\{D_{JS}(x, \tilde{x}), D_{JS}(x, fx), D_{JS}(\tilde{x}, f\tilde{x}),$$

$$D_{JS}(x, f\tilde{x}), D_{JS}(\tilde{x}, fx)\},$$

for every x and $\tilde{x}$ from X and φ, ψ from Ψ, where ψ is continuous and φ is lower semi – continuous.

If there exists a $\varsigma \in X$ that $\delta(D_{JS}, f, \varsigma) < +\infty$, then the sequence $\{f^n\varsigma\}_{n \in N}$ D_{JS} – convergences to a point ϑ in X.

When $D_{JS}(\vartheta, f\vartheta) < +\infty$ then ϑ is fixed point of function f. Furthermore, for $\vartheta' \in X$ which is another fixed point of function f, such that $D_{JS}(\vartheta', f\vartheta') < +\infty$, it yields $\vartheta = \vartheta'$.

Proof. Let take $\varsigma \in X$ that $\delta(D_{JS}, f, \varsigma) < +\infty$. Applicating (3.1) for $i, j, n \in N$, it yields

$$\psi\left(D_{JS}(f^{n+i}\varsigma, f^{n+j}\varsigma)\right)$$

$$\leq \psi\left(M_{JS}(f^{n+i-1}\varsigma, f^{n+j-1}\varsigma)\right) - \varphi\left(M_{JS}(f^{n+i-1}\varsigma, f^{n+j-1}\varsigma)\right)$$

$$\leq \psi\left(M_{JS}(f^{n+i-1}\varsigma, f^{n+j-1}\varsigma)\right) \quad (3.2)$$

$$M_{JS}(f^{n+i-1}\varsigma, f^{n+j-1}\varsigma)$$

$$= \text{maximum}\begin{cases} D_{JS}(f^{n+i-1}\varsigma, f^{n+j-1}\varsigma), D_{JS}(f^{n+i-1}\varsigma, f^{n+i}\varsigma), \\ D_{JS}(f^{n+j-1}\varsigma, f^{n+j}\varsigma), D_{JS}(f^{n+i-1}\varsigma, f^{n+j}\varsigma), \\ D_{JS}(f^{n+j-1}\varsigma, f^{n+i}\varsigma) \end{cases}$$

$$\leq \delta(D_{JS}, f, f^{n-1}\varsigma)$$

Consequently,

$$\psi\left(D_{JS}(f^{n+i}\varsigma, f^{n+j}\varsigma)\right) \leq \psi\left(M_{JS}(f^{n+i-1}\varsigma, f^{n+j-1}\varsigma)\right) \leq \psi\left(\delta(D_{JS}, f, f^{n-1}\varsigma)\right).$$

Using the non-decreasing monotony of ψ it results

$$D_{JS}(f^{n+i}\varsigma, f^{n+j}\varsigma) \leq M_{JS}(f^{n+i-1}\varsigma, f^{n+j-1}\varsigma) \leq \delta(D_{JS}, f, f^{n-1}\varsigma) \quad (3.3)$$

for every $i, j \in N, n \in N$.

$$\delta(D_{JS}, f, f^n\varsigma) = \sup\{D_{JS}(f^{n+i}\varsigma, f^{n+j}\varsigma), i, j \in N\}$$
$$\leq \delta(D_{JS}, f, f^{n-1}\varsigma).$$

As a result, the sequence $\{\delta(D_{JS}, f, f^n\varsigma)\}_{n \in N}$ is non – increasing and bounded.

Consequently, it D_{JS} – converges and $\lim_{n \to +\infty} \delta(D_{JS}, f, f^n\varsigma) = l \geq 0$.

In addition, from (3.3) the following inequality

$$\delta(D_{JS}, f, f^n\varsigma) \leq M_{JS}(f^{n+i-1}\varsigma, f^{n+j-1}\varsigma)$$

$$\leq \delta(D_{JS}, f, f^{n-1}\varsigma) \quad (3.4)$$

Taking the limit in (3.4) when $n \to +\infty$ and $i, j \in N$, it yields

$$\lim_{n \to +\infty} M_{JS}(f^{n+i-1}\varsigma, f^{n+j-1}\varsigma) = l \geq 0.$$

Furthermore, from

$$\delta(D_{JS}, f, f^n\varsigma) = \sup\{D_{JS}(f^{n+i}\varsigma, f^{n+j}\varsigma), i, j \in N\},$$

it implies:

for each natural number k, there exist $i(k)$ and $j(k)$ that the inequality

$$l - \frac{1}{k} < D_{JS}(f^{n+i(k)}\varsigma, f^{n+j(k)}\varsigma) \leq l \quad (3.5)$$

holds.

Taking the limit in (3.5) when $k \to +\infty$, it yields

$$\lim_{n \to \infty} D_{JS}(f^{n+i(k)}\varsigma, f^{n+j(k)}\varsigma) = l.$$

Furthermore, since φ is lower semi – continuous and ψ is continuous, taking the limit in

$$\psi\left(D_{JS}(f^{n+i(k)}\varsigma, f^{n+j(k)}\varsigma)\right)$$

$$\leq \psi\left(M_{JS}(f^{n+i(k)-1}\varsigma, f^{n+j(k)-1}\varsigma)\right)$$
$$- \varphi\left(M_{JS}(f^{n+i(k)-1}\varsigma, f^{n+j(k)-1}\varsigma)\right)$$

it implies $\psi(l) \leq \psi(l) - \varphi(l)$.

Consequently, $\varphi(l) = 0$. Since φ is in Ψ, it implies $l = 0$.

So

$$\lim_{n \to +\infty} \delta(D_{JS}, f, f^n\varsigma) = 0 \quad (3.6)$$

Since $\delta(D_{JS}, f, f^n \varsigma) = \sup\{D_{JS}(f^{n+i}\varsigma, f^{n+j}\varsigma), i, j \in N\}$, it is true that

$$0 \leq D_{JS}(f^{n+i}\varsigma, f^{n+j}\varsigma) \leq \delta(D_{JS}, f, f^n \varsigma),$$

for every $i, j \in N$.

Taking the limit when $i, j \to +\infty$, it implies

$$\lim_{i,j \to +\infty} D_{JS}(f^{n+i}\varsigma, f^{n+j}\varsigma) = 0 \qquad (3.7)$$

Since the sequence $\{f^n \varsigma\}_{n \in N}$ is $D_{JS} -$ Cauchy, there exists a point $\vartheta \in X$, that accomplishes:

$$\lim_{n \to +\infty} D_{JS}(f^n \varsigma, \vartheta) = 0 \qquad (3.8)$$

Let prove now that $f(\vartheta) = \vartheta$.

$$D_{JS}(f\vartheta, \vartheta) \leq \rho \lim_{n \to +\infty} D_{JS}(f\vartheta, f^{n+1}\varsigma)$$

Taking (3.1) for $x = \vartheta$ and $\tilde{x} = f^n \varsigma$, it implies

$$\psi(D_{JS}(f\vartheta, f^{n+1}\varsigma)) \leq \psi(M_{JS}(\vartheta, f^n\varsigma)) - \varphi\left(M_{JS}(\vartheta, f^n\varsigma)\right) \qquad (3.9)$$

where

$$M_{JS}(\vartheta, f^n\varsigma)$$
$$= \text{maximum}\{D_{JS}(\vartheta, f^n\varsigma), D_{JS}(\vartheta, f\vartheta), D_{JS}(f^n\varsigma, f^{n+1}\varsigma),$$
$$D_{JS}(\vartheta, f^{n+1}\varsigma), D_{JS}(f^n\varsigma, f\vartheta)\}$$

Taking limit in $M_{JS}(\vartheta, f^n\varsigma)$ when $n \to +\infty$ and from (3.7) and (3.8), it yields

$$\lim_{n \to +\infty} M_{JS}(\vartheta, f^n\varsigma) = \text{maximum}\{0, D_{JS}(\vartheta, f\vartheta), 0, 0, D_{JS}(\vartheta, f\vartheta)\}$$
$$= D_{JS}(\vartheta, f\vartheta)$$

Taking limit in (3.9) it implies

$$\psi(D_{JS}(f\vartheta, \vartheta)) \leq \psi(D_{JS}(\vartheta, f\vartheta)) - \varphi\left(D_{JS}(\vartheta, f\vartheta)\right)$$

Consequently $\varphi\left(D_{JS}(\vartheta, f\vartheta)\right) = 0$ and

$$D_{JS}(\vartheta, f\vartheta) = 0 \qquad (3.10)$$

From this, it yields $f\vartheta = \vartheta$.

If ϑ' is another point that $f\vartheta' = \vartheta'$ and $D_{JS}(\vartheta', \vartheta')$ is finite, then $D_{JS}(\vartheta', \vartheta') = 0$.

Indeed, applicating (3.1) for x and $\tilde{x}$ equal to ϑ', it yields
$$\psi(D_{JS}(\vartheta', \vartheta')) = \psi(D_{JS}(f\vartheta', f\vartheta'))$$

$$\leq \psi(M_{JS}(\vartheta', \vartheta')) - \varphi\left(M_{JS}(\vartheta', \vartheta')\right)$$

where

$$M_{JS}(\vartheta', \vartheta')$$
$$= \text{maximum}\{D_{JS}(\vartheta', \vartheta'), D_{JS}(\vartheta', f\vartheta'), D_{JS}(\vartheta', f\vartheta'),$$

$$D_{JS}(\vartheta', f\vartheta'), D_{JS}(\vartheta', f\vartheta')\} = D_{JS}(\vartheta', \vartheta')$$

As a result $\psi(D_{JS}(\vartheta', \vartheta')) \leq \psi(D_{JS}(\vartheta', \vartheta')) - \varphi\left(D_{JS}(\vartheta', \vartheta')\right)$,

which implies $\varphi\left(D_{JS}(\vartheta', \vartheta')\right) = 0$ and $D_{JS}(\vartheta', \vartheta') = 0$.

Furthermore, $D_{JS}(\vartheta, \vartheta) = 0$, because $f(\vartheta) = \vartheta$.

Due to the fact $D_{JS}(\vartheta, \vartheta') = D_{JS}(f\vartheta, f\vartheta')$, it yields

$$\psi(D_{JS}(f\vartheta, f\vartheta')) \leq \psi(M_{JS}(\vartheta, \vartheta')) - \varphi\left(M_{JS}(\vartheta, \vartheta')\right) \qquad (3.11)$$

where

$$M_{JS}(\vartheta, \vartheta') = \text{maximum}\{D_{JS}(\vartheta, \vartheta'), D_{JS}(\vartheta, f\vartheta), D_{JS}(\vartheta', f\vartheta'),$$

$$D_{JS}(\vartheta, f\vartheta'), D_{JS}(\vartheta', f\vartheta)\}$$
$$= \text{maximum}\{D_{JS}(\vartheta, \vartheta'), 0, 0, D_{JS}(\vartheta, \vartheta'), D_{JS}(\vartheta', \vartheta)\}$$
$$= D_{JS}(\vartheta, \vartheta')$$

From (3.11), it implies

$$\psi(D_{JS}(\vartheta, \vartheta')) \leq \psi(D_{JS}(\vartheta, \vartheta')) - \varphi\left(D_{JS}(\vartheta, \vartheta')\right).$$

As a result $\varphi\left(D_{JS}(\vartheta, \vartheta')\right) = 0$ and $D_{JS}(\vartheta, \vartheta') = 0$ and $\vartheta = \vartheta'$.

Remark 3.1.3 Theorem 3.1.2 generalizes Theorem 2.18 (Theorem 1.9) in [19].

Example 3.1.4 Let be $X = [0,1]$ and a non $-$ negative D_{JS} of $X \times X$, where

$$D_{JS}(x, y) = \begin{cases} \text{maximum } \{x, \tilde{x}\}, & x \neq 0, \tilde{x} \neq 0 \\ \frac{x}{2}, & x \in X, \tilde{x} = 0 \\ \frac{\tilde{x}}{2}, & x = 0, \tilde{x} \in X \end{cases}$$

(X, D_{JS}) is a $JS -$ generalized metric space as it is shown in Example 2.10.

Let $f: X \to X$ be a map such that $f(x) = \frac{x^2}{2(1+x)}$ and the functions $\varphi, \psi \in \Psi$, $\varphi(s) = \frac{s}{2}$, $\psi(t) = \frac{3s}{2}$.

For $x \neq \tilde{x}$ and $x \neq 0, \tilde{x} \neq 0$

$$D_{JS}(f(x), f(\tilde{x})) = \text{maximum}\left\{\frac{x^2}{2(1+x)}, \frac{\tilde{x}^2}{2(1+\tilde{x})}\right\}.$$

Taking $x < \tilde{x}$, $D_{JS}(f(x), f(\tilde{x})) = \frac{\tilde{x}^2}{2(1+\tilde{x})}$

$$M_{JS}(x, \tilde{x}) = \text{maximum}\{D_{JS}(x, \tilde{x}), D_{JS}(x, fx), D_{JS}(\tilde{x}, f\tilde{x}),$$

$$D_{JS}(x, f\tilde{x}), D_{JS}(\tilde{x}, fx)\},$$

$$D_{JS}(x, \tilde{x}) = \text{maximum}\{x, \tilde{x}\} = \tilde{x}, D_{JS}(x, f(x))$$

$$= \text{maximum}\left\{x, \frac{x^2}{2(1+x)}\right\} = x,$$

$$D(\tilde{x}, f(\tilde{x})) = D\left(\tilde{x}, \frac{\tilde{x}^2}{2(1+\tilde{x})}\right) = \tilde{x},$$

$$D_{JS}(x, f(\tilde{x})) = \text{maximum}\left\{x, \frac{\tilde{x}^2}{2(1+\tilde{x})}\right\} = \begin{cases} \frac{\tilde{x}^2}{2(1+\tilde{x})}, \\ x \end{cases}$$

$$D_{JS}(f(x), \tilde{x}) = \text{maximum}\left\{\tilde{x}, \frac{1}{2}\frac{x^2}{(1+x)}\right\} = \tilde{x}.$$

Case 1. If $D_{JS}(f(\tilde{x}), x) = \frac{1}{2}\frac{\tilde{x}^2}{(1+\tilde{x})}$, then

$$M_{JS}(x, \tilde{x}) = \text{maximum}\left\{\tilde{x}, x, \frac{1}{2}\frac{\tilde{x}^2}{(1+\tilde{x})}\right\}$$

$$= \text{maximum}\left\{\tilde{x}, \frac{1}{2}\frac{\tilde{x}^2}{(1+\tilde{x})}\right\} = \tilde{x}$$

$$\psi(D_{JS}(f(x), f(\tilde{x}))) = \psi\left(\frac{\tilde{x}^2}{2(1+\tilde{x})}\right) = \frac{3}{2}\frac{\tilde{x}^2}{2(1+\tilde{x})} = \frac{3\tilde{x}^2}{4(1+\tilde{x})}.$$

$$\psi\left(M_{JS}(x, \tilde{x})\right) - \varphi\left(M_{JS}(x, \tilde{x})\right) = \psi(\tilde{x}) - \varphi(\tilde{x}) = \frac{3\tilde{x}}{2} - \frac{\tilde{x}}{2} = \tilde{x}$$

Since $\frac{3}{4}\frac{\tilde{x}^2}{(1+\tilde{x})} < \tilde{x}$, the condition of Theorem 3.1.2 is accomplished.

Case 2. If $D(x, f(\tilde{x}))$ is x, then

$$M_{JS}(x, \tilde{x}) = \text{maximum}\{\tilde{x}, x\} = \tilde{x}$$

$$\psi(D_{JS}(f(x), f(\tilde{x}))) = \frac{3}{2}\frac{\tilde{x}^2}{2(1+\tilde{x})} = \frac{3\tilde{x}^2}{4(1+\tilde{x})}.$$

$$\psi(M(x, \tilde{x})) - \varphi(M(x, \tilde{x})) = \psi(\tilde{x}) - \varphi(\tilde{x}) = \frac{3\tilde{x}}{2} - \frac{\tilde{x}}{2} = \tilde{x}$$

Since $\frac{3}{4}\frac{\tilde{x}^2}{(1+\tilde{x})} < \tilde{x}$, the condition of Theorem 3.1.2 is completed.

Therefore, the function $f: X \to X$ has a fixed point which is 0.

Corollary 3.1.5. Let (X, D_{JS}) be a JS – generalized metric space which is complete and f a function of X in itself satisfying the condition

$$D_{JS}(fx, f\tilde{x}) \leq M_{JS}(x, \tilde{x}) - \varphi(M_{JS}(x, \tilde{x})),$$

where

$$M_{JS}(x, \tilde{x}) = \text{maximum}\begin{Bmatrix} D_{JS}(x, \tilde{x}), D_{JS}(x, fx), D_{JS}(\tilde{x}, f\tilde{x}), \\ D_{JS}(x, f\tilde{x}), D_{JS}(\tilde{x}, fx) \end{Bmatrix},$$

for every $x, \tilde{x} \in X$ and φ is from Ψ, and lower semi – continuous.

If there exists $\varsigma \in X$ that $\delta(D_{JS}, f, \varsigma) < +\infty$, then $\{f^n\varsigma\}_{n \in N}$ D_{JS} – convergences to a point ϑ in X.

When $D_{JS}(\vartheta, f\vartheta) < +\infty$ then ϑ is fixed point of function f. Furthermore, for $\vartheta' \in X$ which is another fixed point of function f, such that $D_{JS}(\vartheta', f\vartheta') < +\infty$, it yields $\vartheta = \vartheta'$.

Proof. Replacing $\psi(s) = s \in \Psi$ in above theorem, the proof is clear.

Corollary 3.1.6 Let (X, D_{JS}) be a JS – generalized metric space which is complete and f a function of X in itself satisfying the condition

$$D_{JS}(fx, f\tilde{x}) \leq \kappa M_{JS}(x, \tilde{x})$$

where

$$M_{JS}(x, \tilde{x}) = \text{maximum}\begin{Bmatrix} D_{JS}(x, \tilde{x}), D_{JS}(x, fx), D_{JS}(\tilde{x}, f\tilde{x}), \\ D_{JS}(x, f\tilde{x}), D_{JS}(\tilde{x}, fx) \end{Bmatrix},$$

for every $x, \tilde{x} \in X$ and $\kappa \in \ ]0,1[$.

If there exists $\varsigma \in X$ that $\delta(D_{JS}, f, \varsigma) < +\infty$, then $\{f^n\varsigma\}_{n \in N}$ D_{JS} – convergences to a point ϑ in X.

When $D_{JS}(\vartheta, f\vartheta) < +\infty$ then ϑ is fixed point of function f. Furthermore, for $\vartheta' \in X$ which is another fixed point of function f, such that $D_{JS}(\vartheta', f\vartheta') < +\infty$, it yields $\vartheta = \vartheta'$.

Proof. Taking $\psi(s) = s$ and $\varphi(s) = (1 - \kappa)s \in \Psi$ in inequality (3.1), the proof is clear.

Remark 3.1.7 Corollary 3.1.5 is a generalization of Theorem 2.16 which is the result of [16] as Corollary 5.5 and Corollary 3.8 in [20].

3.2. Common fixed point related to $\varphi - \psi$ contractive functions in JS – generalized metric space.

Theorem 3.2.1 Let (X, D_{JS}) a JS – generalized metric space which is complete and $F, g: X \to X$ such that FX is a subset of gX and the set gX is closed in X and

$$\psi(D_{JS}(Fx, F\tilde{x}) \leq \psi\left(M_{JS}(gx, g\tilde{x})\right) - \varphi(M_{JS}(gx, g\tilde{x})) \quad (3.12)$$

where

$$M_{JS}(gx, g\tilde{x}) =$$
$$\text{maximum}\{D_{JS}(gx, g\tilde{x}), D_{JS}(gx, Fx), D_{JS}(gy, F\tilde{x})\}$$

for x and $\tilde{x}$ in X and φ and ψ in Ψ, ψ is continuous and φ is lower semi – continuous.

If there exist $\varsigma \in X$ such that $\delta(D_{JS}, F, \varsigma) < +\infty$ and $\delta(D_{JS}, g, \varsigma) < +\infty$ then the sequence $\{\gamma_n\}_{n \in N} = \{g\varsigma_{n+1}\}_{n \in N} = \{F\varsigma_n\}_{n \in N}$, where $\gamma_1 = F\varsigma = g\varsigma_1$, D_{JS} – converges to a point ϑ in X.

If $\delta(D_{JS}, F, \vartheta) < +\infty$ and $\delta(D_{JS}, g, \vartheta) < +\infty$ then the maps F, g have a unique coincidence point in X.

Furthermore, they have a unique common fixed point in X,

if they are weakly compatible.

Proof. Let take $\varsigma \in X$ such that $\delta(D_{JS}, F, \varsigma) < +\infty$ and $\delta(D_{JS}, g, \varsigma) < +\infty$. For $\varsigma \in X$, due to $FX \subset gX$ then $F\varsigma \in gX$. Consequently, there exists $\varsigma_1 \in X, g\varsigma_1 = F\varsigma$.

Reasoning in the same manner for ς_1 and so on, there can be defined the sequences $\{\varsigma_n\}_{n\in N}$ and $\{\gamma_n\}_{n\in N}$ such that

$$\gamma_n = g\varsigma_{n+1} = F\varsigma_n \tag{3.13}$$

for $n = 0, 1, 2, \ldots$

If there exists any $n \in N$, such that $\gamma_n = \gamma_{n+1}$ then $g\varsigma_{n+1} = F\varsigma_n = \gamma_n = \gamma_{n+1} = F\varsigma_{n+1}$.

So, ς_{n+1} is the required point for g and F.

Let suppose now that the terms of $\{\gamma_n\}$ are diferent from each other.

Consequently,

$$D_{JS}(\gamma_n, \gamma_{n+1}) > 0. \tag{3.14}$$

$$\psi\left(D_{JS}(\gamma_n, \gamma_{n+1})\right) = \psi\left(D_{JS}(F\varsigma_n, F\varsigma_{n+1})\right)$$

$$\leq \psi\left(M_{JS}(g\varsigma_n, g\varsigma_{n+1})\right) - \varphi\left(M_{JS}(g\varsigma_n, g\varsigma_{n+1})\right) \tag{3.15}$$

where

$M_{JS}(g\varsigma_n, g\varsigma_{n+1})$
$= \text{maximum}\{D_{JS}(g\varsigma_n, g\varsigma_{n+1}), D_{JS}(g\varsigma_n, F\varsigma_n), D_{JS}(g\varsigma_{n+1}, F\varsigma_{n+1})\}$
$= \text{maximum}\{D_{JS}(g\varsigma_n, g\varsigma_{n+1}), D_{JS}(g\varsigma_n, g\varsigma_{n+1}), D_{JS}(g\varsigma_{n+1}, g\varsigma_{n+2})\}$
$= \text{maximum}\{D_{JS}(g\varsigma_n, g\varsigma_{n+1}), D_{JS}(g\varsigma_{n+1}, g\varsigma_{n+2})\}$
$= \text{maximum}\{D_{JS}(\gamma_{n-1}, \gamma_n), D_{JS}(\gamma_n, \gamma_{n+1})\}$

Case 1. $D_{JS}(g\varsigma_n, g\varsigma_{n+1}) = D_{JS}(\gamma_n, \gamma_{n+1})$, then replacing it in (3.15), it yields

$$\psi\left(D_{JS}(\gamma_n, \gamma_{n+1})\right) \leq \psi\left(D_{JS}(\gamma_n, \gamma_{n+1})\right) - \varphi\left(D_{JS}(\gamma_n, \gamma_{n+1})\right)$$

So $\varphi\left(D_{JS}(\gamma_n, \gamma_{n+1})\right) = 0$ and consequently $D_{JS}(\gamma_n, \gamma_{n+1}) = 0$, which is absurd due to (3.14).

Case 2. $M_{JS}(g\varsigma_n, g\varsigma_{n+1}) = D_{JS}(\gamma_{n-1}, \gamma_n)$ then replacing it in (3.15), it yields

$$\psi\left(D_{JS}(\gamma_n, \gamma_{n+1})\right) \leq \psi\left(D_{JS}(\gamma_n, \gamma_{n-1})\right) - \varphi\left(D_{JS}(\gamma_n, \gamma_{n-1})\right)$$

$$\leq \psi\left(D_{JS}(\gamma_n, \gamma_{n-1})\right) \tag{3.16}$$

Due to non-decreasing monotony of ψ, it implies

$$D_{JS}(\gamma_n, \gamma_{n+1}) \leq D_{JS}(\gamma_n, \gamma_{n-1}),$$

for all $n \in N$.

This shows that $\{D_{JS}(\gamma_n, \gamma_{n+1})\}_{n\in N}$ is non-increasing and lower bounded because $D_{JS}(\gamma_n, \gamma_{n+1}) \geq 0$.

Consequently, the sequence $\{D_{JS}(\gamma_n, \gamma_{n+1})\}_{n\in N}$ converges to $l \geq 0$, $\lim_{n\to+\infty} D_{JS}(\gamma_n, \gamma_{n+1}) = l$.

Taking the limit in (3.16) when $n \to +\infty$, it yields

$$\psi(l) \leq \psi(l) - \phi(l).$$

Consequently, $\varphi(l) = 0$ and $l = 0$.

So,

$$\lim_{n\to+\infty} D_{JS}(\gamma_n, \gamma_{n+1}) = 0 \tag{3.17}$$

Denote

$$c_k = \sup\{D_{JS}(\gamma_i, \gamma_j), i, j > k\} \tag{3.18}$$

c_k is finite for every $k \in N$ because $\delta(D_{JS}, F, \varsigma) < +\infty$ and $\delta(D_{JS}, g, \varsigma) < +\infty$.

Since the sequence $\{c_k\}_{k\in N}$ is non $-$ increasing, lower bounded from zero, it is convergent to a point ζ,

$$\lim_{k\to+\infty} c_k = \zeta \geq 0 \tag{3.19}$$

From (3.17), it yields:

for each $p \in N$, there exist $i_p, j_p > p$, such that

$$c_p - \frac{1}{p} < D_{JS}\left(\gamma_{i_p}, \gamma_{j_p}\right) < c_p \tag{3.20}$$

Taking limit in (3.20) when $p \to +\infty$ and using (3.19), it yields

$$\lim_{p\to+\infty} D_{JS}\left(\gamma_{i_p}, \gamma_{j_p}\right) = \zeta \tag{3.21}$$

Knowing that $D_{JS}\left(\gamma_{i_p}, \gamma_{j_p}\right) = D_{JS}\left(F\varsigma_{i_p-1}, F\varsigma_{j_p-1}\right)$, it implies

$$\psi\left(D_{JS}\left(\varsigma_{i_p}, \varsigma_{j_p}\right)\right) = \psi\left(D_{JS}\left(F\varsigma_{i_p-1}, F\varsigma_{j_p-1}\right)\right) \leq$$
$$\psi\left(M_{JS}\left(g\varsigma_{i_p-1}, g\varsigma_{j_p-1}\right)\right) - \varphi\left(M_{JS}\left(g\varsigma_{i_p-1}, g\varsigma_{j_p-1}\right)\right) \tag{3.22}$$

where

$M_{JS}\left(g\varsigma_{i_p-1}, g\varsigma_{j_p-1}\right)$
$= \text{maximum}\left\{\begin{array}{c} D_{JS}\left(g\varsigma_{i_p-1}, g\varsigma_{j_p-1}\right), D_{JS}\left(g\varsigma_{i_p-1}, F\varsigma_{i-1}\right), \\ D_{JS}\left(g\varsigma_{j_p-1}, F\varsigma_{j_p-1}\right) \end{array}\right\}$
$= \text{maximum}\left\{\begin{array}{c} D_{JS}\left(\gamma_{i_p-2}, \gamma_{j_p-2}\right), D_{JS}\left(\gamma_{i_p-2}, g\varsigma_{i_p-1}\right), \\ D_{JS}\left(\gamma_{j_p-2}, \varsigma_{j_p-1}\right) \end{array}\right\}$

From (3.17) and (3.19), it yields

$$\lim_{p\to+\infty} M_{JS}\left(g\varsigma_{i_p-1}, g\varsigma_{j_p-1}\right) = \text{maximum}\{\zeta, 0,0\} = \zeta$$

Taking the limit in (3.22) when $p \to +\infty$ and from (3.21), it implies

$$\psi(\zeta) \leq \psi(\zeta) - \varphi(\zeta)$$

Consequently, $\varphi(\zeta) = 0$ and $\zeta = 0$.

So,

$$\lim_{k \to +\infty} c_k = 0 \qquad (3.23)$$

From (3.18) and (3.23), it yields $\lim_{i,j \to +\infty} D_{JS}(\gamma_i, \gamma_j) = 0$, which means that the sequence $\{\gamma_n\}_{n \in N}$ is $D_{JS}-$ Cauchy in X.

Since $\gamma_n = g\varsigma_{n+1} = F\varsigma_n$, it yields $\{\gamma_n\}_{n \in N} \subset g(X)$. Since the set $g(X)$ is closed, there is $\vartheta \in gX$ such that $\lim_{n \to +\infty} \gamma_n = \vartheta$. Consequently, $\lim_{n \to +\infty} g\varsigma_{n+1} = \lim_{n \to +\infty} F\varsigma_n = \vartheta$.

Since $\vartheta \in gX$ then there is $\mu \in X$, $g\mu = \vartheta$.

The other step is to show that $F\mu = \vartheta$.

Knowing $D_{JS}(\vartheta, F\mu) \leq \lim_{n \to +\infty} D_{JS}(F\varsigma_n, F\mu)$ and applying $x = \varsigma_n$ and $\tilde{x} = \mu$ at (3.12), it implies

$$\psi\left(D_{JS}(F\varsigma_n, F\mu)\right) \leq \psi\left(M_{JS}(g\varsigma_n, g\mu)\right) - \varphi\left(M_{JS}(g\varsigma_n, g\mu)\right)$$
(3.24)

where

$$M_{JS}(g\varsigma_n, g\mu)$$
$$= \text{maximum}\{D_{JS}(g\varsigma_n, g\mu), D_{JS}(g\varsigma_n, F\varsigma_n), D_{JS}(g\mu, F\mu)\}$$
$$= \text{maximum }\{D_{JS}(g\varsigma_n, \vartheta), D_{JS}(g\varsigma_n, F\varsigma_n), D_{JS}(\vartheta, F\mu)\}$$

Since

$$\lim_{n \to +\infty} D_{JS}(g\varsigma_n, \vartheta) = 0$$

and

$$\lim_{n \to +\infty} D_{JS}(g\varsigma_n, F\varsigma_n) = \lim_{n \to +\infty} D_{JS}(\gamma_{n-1}, \gamma_n) = 0,$$

it implies $\lim_{n \to +\infty} M(g\varsigma_n, g\mu) = D_{JS}(\vartheta, F\mu)$.

Taking limit in (3.24) when $n \to +\infty$, it yields

$$\psi(D_{JS}(\vartheta, F\mu)) \leq \psi(\vartheta, F\mu) - \varphi(\vartheta, F\mu)$$

As a result $\varphi(\vartheta, F\mu) = 0$.

Consequently, $\vartheta = F\mu$.

The following step is to prove that ϑ is unique.

Suppose that there exists another point of coincidence $\vartheta' \neq \vartheta$ of g and F.

So, there exists $\mu_1 \in X$ which accomplishes $F\mu_1 = g\mu_1 = \vartheta'$

$$\psi\left(D_{JS}(\vartheta, \vartheta')\right) = \psi\left(D_{JS}(F\mu, F\mu_1)\right)$$

$$\leq \psi\left(M_{JS}(g\mu, g\mu_1)\right) - \varphi\left(M_{JS}(g\mu, g\mu_1)\right) \qquad (3.25)$$

For

$$M_{JS}(g\mu, g\mu_1)$$
$$= \text{maximum}\{D_{JS}(g\mu, g\mu_1), D_{JS}(g\mu, F\mu), D_{JS}(g\mu_1, F\mu_1)\}$$
$$= \text{maximum}\{D_{JS}(\vartheta, \vartheta'), D_{JS}(\vartheta, \vartheta), D_{JS}(\vartheta', \vartheta')\} \qquad (3.26)$$

$$D_{JS}(\vartheta, \vartheta) = D_{JS}(F\mu, F\mu)$$

$$\psi\left(D_{JS}(\vartheta, \vartheta)\right) = \psi\left(D_{JS}(F\mu, F\mu)\right)$$

$$\leq \psi\left(M_{JS}(g\mu, g\mu)\right) - \varphi\left(M_{JS}(g\mu, g\mu)\right) \qquad (3.27)$$

where

$$M_{JS}(g\mu, g\mu) =$$
$$\text{maximum}\{D_{JS}(g\mu, g\mu), D_{JS}(g\mu, F\mu), D_{JS}(g\mu, F\mu)\} =$$
$$\max\{D_{JS}(\vartheta, \vartheta), D_{JS}(\vartheta, \vartheta), D_{JS}(\vartheta, \vartheta)\} = D_{JS}(\vartheta, \vartheta)$$

Replacing $M_{JS}(g\mu, g\mu) = D_{JS}(\vartheta, \vartheta)$ in (3.27),

it implies

$$\psi\left(D_{JS}(\vartheta, \vartheta)\right) \leq \psi\left(D_{JS}(\vartheta, \vartheta)\right) - \varphi\left(D_{JS}(\vartheta, \vartheta)\right)$$

So, $\varphi\left(D_{JS}(\vartheta, \vartheta)\right) = 0$ and

$$D_{JS}(\vartheta, \vartheta) = 0 \qquad (3.28)$$

Using the same method, it can be proved that

$$D_{JS}(\vartheta', \vartheta') = 0 \qquad (3.29)$$

Replacing (3.28) and (3.29) in (3.26) and then in (3.25) it yields

$$M_{JS}(g\mu, g\mu_1) = D_{JS}(g\mu, g\mu_1) = D_{JS}(\vartheta, \vartheta')$$

$$\psi\left(D_{JS}(\vartheta, \vartheta')\right) \leq \psi\left(D_{JS}(\vartheta, \vartheta')\right) - \varphi\left(D_{JS}(\vartheta, \vartheta')\right)$$

From this, it implies $\varphi\left(D_{JS}(\vartheta, \vartheta')\right) = 0$ and $D_{JS}(\vartheta, \vartheta') = 0$. Consequently $\vartheta = \vartheta'$.

Furthermore, let prove that if g and F are weakly compatible then $F\vartheta = g\vartheta$.

From $D_{JS}(F\vartheta, \vartheta) = D_{JS}(F\vartheta, F\mu)$ and (3.12), it implies

$$\psi\left(D_{JS}(F\vartheta, \vartheta)\right) = \psi\left(D_{JS}(F\vartheta, F\mu)\right)$$

$$\leq \psi\left(M_{JS}(g\vartheta, g\mu)\right) - \varphi\left(M_{JS}(g\vartheta, g\mu)\right) \qquad (3.30)$$

$$M_{JS}(g\vartheta, g\mu)$$
$$= \text{maximum}\{D_{JS}(g\vartheta, g\mu), D_{JS}(g\vartheta, F\mu), D_{JS}(g\vartheta, F\mu)\}$$
$$= \text{maximum}\{D_{JS}(F\vartheta, \vartheta), D_{JS}(F\vartheta, F\vartheta), D_{JS}(\vartheta, \vartheta)\}$$

From (3.28), it is known that $D_{JS}(\vartheta, \vartheta) = 0$. Using the same method as in (3.28), it can be proved that $D_{JS}(F\vartheta, F\vartheta) = 0$.

Consequently, $M_{JS}(g\vartheta, g\mu) = D_{JS}(F\vartheta, \vartheta)$

Replacing this equality in (3.30), it implies

$$\psi\left(D_{JS}(F\vartheta, \vartheta)\right) \leq \psi\left(D_{JS}(F\vartheta, \vartheta)\right) - \varphi\left(D_{JS}(F\vartheta, \vartheta)\right)$$

From this $\varphi\left(D_{JS}(F\vartheta, \vartheta)\right) = 0$ and $D_{JS}(F\vartheta, \vartheta) = 0$.

So, $F\vartheta = \vartheta = g\vartheta$ and ϑ is unique.

Remark 3.2.2 Since JS – generalized metric spaces are metric spaces, b – metric spaces, dislocated metric spaces, partial metric spaces it implies that Theorem 3.2.1 is true in these spaces.

Example 3.2.3 Let be $X = [0, a]$, where $a \in R$ and D_{JS} the JS – generalized metric defined at Example 2.10 and the functions $\varphi, \psi \in \Psi$, $\varphi(s) = \frac{1}{5}s$, $\psi(s) = \frac{s}{2}$.

Let $g, F: X \to X$ two functions where $g(x) = \frac{x}{2}$ and $F(x) = \ln\left(1 + \frac{x}{4}\right)$.

The functions g, F complete the condition of Theorem 3.2.1.

Indeed,

$$D_{JS}(Fx, F\tilde{x}) = D_{JS}\left(\ln\left(1 + \frac{x}{4}\right), \ln\left(1 + \frac{\tilde{x}}{4}\right)\right)$$
$$= \text{maximum}\{\ln\left(1 + \frac{x}{4}\right), \ln\left(1 + \frac{\tilde{x}}{4}\right)\}$$

Since $x \neq \tilde{x}$, it is supposed that $x < \tilde{x}$ without restricting anything.

From monotony of logarithmic function

$$D_{JS}(Fx, F\tilde{x}) = D_{JS}\left(\ln\left(1 + \frac{x}{4}\right), \ln\left(1 + \frac{\tilde{x}}{4}\right)\right) = \ln\left(1 + \frac{\tilde{x}}{4}\right).$$

$M_{JS}(g(x), g(\tilde{x}))$
$$= \text{maximum}\{D_{JS}(g(x), g(\tilde{x})), D_{JS}(g(x), F(x)), D_{JS}(g(\tilde{x}), F(\tilde{x}))\}$$

$$D_{JS}(g(\tilde{x}), g(x)) = \text{maximum}\{g(\tilde{x}), g(x)\} = \frac{\tilde{x}}{2}$$

$$D_{JS}(F(x), g(x)) = \max\{F(x), g(x)\} = \frac{1}{2}x.$$

$$D_{JS}(F(\tilde{x}), g(\tilde{x})) = \max\{F(\tilde{x}), g(\tilde{x})\} = \frac{\tilde{x}}{2}$$

$$M_{JS}(g(x), g(\tilde{x})) = \frac{1}{2}\tilde{x}$$

$$\psi(D_{JS}(Fx, F\tilde{x})) = \psi(\ln\left(1 + \frac{1}{4}\tilde{x}\right)) < \psi\left(\frac{1}{4}\tilde{x}\right) = \frac{1}{8}\tilde{x}.$$

$$\psi\left(M_{JS}(gx, g\tilde{x})\right) - \varphi\left(M_{JS}(gx, g\tilde{x})\right) = \psi\left(\frac{\tilde{x}}{2}\right) - \varphi\left(\frac{\tilde{x}}{2}\right) = \frac{3\tilde{x}}{20}$$

Since

$$\psi\left(M_{JS}(gx, g\tilde{x})\right) - \varphi\left(M_{JS}(gx, g\tilde{x})\right) - \psi\left(D_{JS}(Fx, F\tilde{x})\right) >$$
$$\frac{3\tilde{x}}{20} - \frac{\tilde{x}}{8} = \frac{\tilde{x}}{40} > 0,$$

then g, F have a common fixed point 0.

Corollary 3.2.4 Let (X, D_{JS}) be a JS – generalized metric space which is complete and $g, F: X \to X$ such that gX is closed and FX is a subset of gX and

$$D_{JS}(Fx, F\tilde{x}) \leq M_{JS}(gx, g\tilde{x}) - \varphi(M_{JS}(gx, g\tilde{x})) \qquad (3.31)$$

where

$$M_{JS}(x, \tilde{x}) = \max\{D_{JS}(gx, g\tilde{x}), D_{JS}(gx, Fx), D_{JS}(g\tilde{x}, F\tilde{x})\}, \quad \text{for}$$
$x, \tilde{x}$ in X and φ in Ψ is lower semi – continuous.

If there exist $\varsigma \in X$ such that $\delta\left(D_{JS}, F, \varsigma\right) < +\infty$ and $\delta\left(D_{JS}, g, \varsigma\right) < +\infty$ then the sequence $\{\gamma_n\}_{n\in N} = \{g\varsigma_{n+1}\}_{n\in N} = \{F\varsigma_n\}_{n\in N}$, where $\gamma_1 = F\varsigma = g\varsigma_1$, D_{JS} – converges to a point ϑ in X.

If $\delta\left(D_{JS}, F, \vartheta\right) < +\infty$ and $\delta\left(D_{JS}, g, \vartheta\right) < +\infty$ then the maps F, g have a unique coincidence point in X.

Furthermore, they have a unique common fixed point in X,

if they are weakly compatible.

Proof. Taking $\psi(s) = s$ in (3.12), the corollary is true.

Corollary 3.2.5 Let (X, D_{JS}) be a JS – generalized metric space which is complete and $g, F: X \to X$ such that gX is closed set and FX is a subset of gX in X and

$$D_{JS}(Fx, F\tilde{x}) \leq \kappa \max\{D_{JS}(gx, g\tilde{x}), D_{JS}(gx, F\tilde{x}), D_{JS}(g\tilde{x}, Fx)\}$$

where $\kappa \in]0,1[$ for x and $\tilde{x} \in X$.

If there exist $\varsigma \in X$ such that $\delta\left(D_{JS}, F, \varsigma\right) < +\infty$ and $\delta\left(D_{JS}, g, \varsigma\right) < +\infty$ then the sequence $\{\gamma_n\}_{n\in N} = \{g\varsigma_{n+1}\}_{n\in N} = \{F\varsigma_n\}_{n\in N}$, where $\gamma_1 = F\varsigma = g\varsigma_1$, D_{JS} – converges to a point ϑ in X.

If $\delta\left(D_{JS}, F, \vartheta\right) < +\infty$ and $\delta\left(D_{JS}, g, \vartheta\right) < +\infty$ then the maps F, g have a unique coincidence point in X.

Furthermore, they have a unique common fixed point in X,

if they are weakly compatible.

Proof. Taking $\psi(s) = s$, $\varphi(s) = (1 - \kappa)s$ in (3.12), the corollary is true.

Corollary 3.2.6 Let (X, D_{JS}) be a JS – generalized metric space which is complete and $F, g: X \to X$ such that $FX \subset gX$ and gX is closed set in X and

$$D_{JS}(Fx, F\tilde{x}) \leq \kappa_1 D_{JS}(gx, g\tilde{x}) + \kappa_2 D_{JS}(gx, Fx) + \kappa_3 D_{JS}(g\tilde{x}, F\tilde{x})$$

where $0 < \kappa_1 + \kappa_2 + \kappa_3 < 1$, for x and $\tilde{x}$ from X.

If there exist $\varsigma \in X$ such that $\delta(D_{JS}, F, \varsigma) < +\infty$ and $\delta(D_{JS}, g, \varsigma) < +\infty$ then the sequence $\{\gamma_n\}_{n \in N} = \{g\varsigma_{n+1}\}_{n \in N} = \{F\varsigma_n\}_{n \in N}$, where $\gamma_1 = F\varsigma = g\varsigma_1$, D_{JS} – converges to a point ϑ in X.

If $\delta(D_{JS}, F, \vartheta) < +\infty$ and $\delta(D_{JS}, g, \vartheta) < +\infty$ then the maps F, g have a unique coincidence point in X.

Furthermore, they have a unique common fixed point in X,

if they are weakly compatible.

Proof. Taking $\kappa = \kappa_1 + \kappa_2 + \kappa_3$, $\kappa \in \left]0, \frac{1}{3}\right[$, it implies

$\kappa_1 D_{JS}(gx, g\tilde{x}) + \kappa_2 D_{JS}(gx, Fx) + \kappa_3 D_{JS}(g\tilde{x}, F\tilde{x}) \leq \kappa \left(D_{JS}(gx, g\tilde{x}) + D_{JS}(gx, Fx) + D_{JS}(g\tilde{x}, F\tilde{x}) \right) \leq \kappa \cdot 3 \cdot M_{JS}(gx, g\tilde{x})$.

Replacing $\varphi(s) = (1 - 3\kappa)s$ and $\psi(s) = s$ in (3.12), the corollary holds.

4. Conclusions

In this paper are given some theorems and corollaries on fixed points for weakly contractive functions and for contractive functions with altering distance between points in JS – generalized metric spaces. Furthermore, in it are proved some results related to common fixed points of two $\varphi - \psi$ contractive functions on JS – generalized metric spaces. Since JS – generalized metric spaces are metric spaces, b - metric spaces, dislocated metric spaces, partial metric spaces, it implies that all obtained results are true in above mentioned spaces. In additions, some important results given in this paper are generalizations of some known references. Concretely, Theorem 3.1.2 generalizes Theorem 1.9 in [19]. Corollary 3.1.5 is a generalization of Corollary 3.8 in [20] and Corollary 5.5 in [16].

A R T I C L E I N F O	A B S T R A C T
	Background: *Occupational injuries are an issue of huge significance in the United States. After a work injury, health care providers often utilize functional capacity evaluations to determine readiness of a patient to return to work. However, it can be difficult to determine if a patient is providing maximal "effort" during the evaluation. The aim of this study was to determine if the use of the Polylift could assist in recognizing when a subject reached maximal lift capacity of a manual lift from waist to shoulder. The Polylift is a computerized data collection instrument that measures velocity, acceleration, distance, time, and force during lifting activities.* ***Subjects:*** *42 healthy college students (20- males, 22- females) ages 20-27.* ***Methods:*** *Participants first performed repeated lifts from waist to shoulder until fatigue and the number of repetitions was noted. Using this information, Brzycki's 1 Repetition Maximum (1RM) formula was used to predict each subject's maximal load. Next, the Polylift recorded information during four lifts (25% of 1RM, 50% of 1RM, 75% of 1RM and 100% of 1RM).* ***Results:*** *The Polylift recorded a consistent, significant relationship between time and acceleration. As loads approached subjects 1RM, time required to lift the weight increased, and acceleration decreased in a predictable pattern.* ***Conclusion:*** *The Polylift assisted researchers in determining when a subject reached maximal lift capacity by demonstrating a significant decrease in acceleration and increase in time with progressively increasing loads.*

1. Introduction

Occupational injuries are an issue of huge significance in the United States. [1] reported that, "The medical and indirect costs of occupational injuries and illnesses are sizable, at least as large as the cost of cancer". Employers bear the burdens of absenteeism, loss of productivity, increased health care, disability, and workers compensation costs after an employee is injured [2]. Often, the employee requires subsequent rehabilitation and may eventually participate in a functional capacity evaluation [3], [4].

Physical therapists, athletic trainers, and exercise physiologists often play vital roles in the case management of patients with a work injuries. These practitioners often participate in evaluation and treatment of musculoskeletal disorders, assist in injury prevention, provide ergonomic education, perform functional capacity evaluations, prescribe conditioning exercises, and complete pre-work screening activities [5]. Operating in that capacity, these providers first identify and address risk factors along with utilizing gross objective measurements and observation to ascertain an individual's readiness to return to work, their ability to perform optimally on the job and most importantly assist in the prevention of re-injury.

A tool that practitioners often utilize within industrial medicine is the functional capacity evaluation (FCE). These evaluations are effective tools that are dynamic, comprehensive and mimic tasks such as lifting, carrying, reaching, squatting and gripping which are vital to effectively perform work functions [5], [6]. FCE's are comprised of bending and lifting activities that directly relate to musculoskeletal disorders. According to the U.S. Bureau of Labor and Statistics, injuries involving the musculoskeletal system accounted for thirty-one percent of the

[*]Corresponding Author: Jennifer Snell Ballard, jballard@hawks.huntingdon.edu

total cases reported in 2015 and are typically diagnosed as sprains or strains [7]. After a diagnosis is made and skilled therapy services are completed, a FCE is often performed utilizing equipment such as handheld dynamometer, Purdue pegboard, weights, step ladder, sled station, weight box and workstation equipped with shelves, heart rate monitor, sphygmomanometer and a stop watch which is assist in collecting measurements. During the evaluation, practitioners rely on both subjective information, objective measurements and clinical judgement to assess many of the musculoskeletal aspects of the test [8].

One of the more popular methods of the evaluation, the kinesiophysical method, involves practitioners determining maximal lifting capacity by observing altered lifting mechanics and use of accessory muscles, which does not involve objective measurements or validated equipment [3]. Experienced clinicians possess excellent clinical judgment and observation skills, and are often required to express an opinion as to whether the patient is providing their maximal effort during lifting activities. While patients have been known to manipulate FCE results by conscious and unconscious efforts, there are certain variables that cannot be manipulated. In particular, as maximal effort and maximal weight loads are achieved, the expected outcome is slower time to complete the lift, along with decreased velocity and acceleration. Up to this point, validated technology that can produce data to assist in deciphering if maximal effort has been produced has not existed. While indicators such as mechanical breakdown, postural breakdown, recruitment of accessory muscles, and heart rate may be used, the application of these indicators is to some degree subjective and thus subject to question. Technology of this nature could improve credibility of reports by providing tangible evidence to accompany sound clinical judgement during functional capacity evaluations. Objective measurements of this nature would reinforce evidence provided in medicolegal cases [8]. A machine such as the Polylift has the ability to provide such objective data and improve the reinforce the credibility of a functional capacity evaluation [8], [9].

The Polylift is a mechanized, data collection machine that is constructed to mimic a lifting workstation. The machine consists of an adjustable rack with shelves equipped with a control module and sensors to detect motion within the sagittal plane (see Figures 1, 2, and 3). The control module contains the necessary hardware and software, microcontroller and other components to collect data from the sensors. The microcontroller is based on a Real-Time Operating System that scans the logic and Inputs/Outputs approximately every 5 ms. The sensors utilize matched LED emitter / receiver pairs to capture the users lift movement and provide data related to the time at which the user both begins and completes the lift. The lifting box includes grasping handles on each side and an area inside to hold various configurations of weights. The machine comes equipped with an electronic device (such as an I-pad) which communicates with and stores data in a cloud database. The lifting box triggers the sensors to obtain data in real time related to the movement, position, orientation, velocity and acceleration of the box while a user is lifting. Users

can perform different combinations of lifts such as floor to waist, waist to shoulder and shoulder to overhead lifts. To collect data, the clinician first uses the computerized software application (located on the I-Pad) to identify which type of lift will be performed. Once the subject lifts the box, the lower LED emitter/receiver beam is triggered to start the timing of the lift and collecting data. When the upper LED emitter/receiver beam is triggered, the data collection ends for that lift and a time stamp is created. Information regarding the amount of time required to complete the lift, the average velocity and the average acceleration of the attempt is recorded by the computerized software application. The standing force plate also records the weight of the subject and provides data on the amount of foot pressure being placed through both feet throughout the lift. The electronic device (I-pad) collects data from lifts and can be used to perform one or more calculations, provide graphs of one or more lifts, and assist the health care practitioner in determining when maximal load is being reached. Data collected and displayed in the application of the I-pad electronic device includes the weight of the box and the weights therein, the distance of the lift from start to finish position, the time from start to finish of the lift, average velocity (in/s), average load applied to the force plate by the left foot and the right foot, and the foot disparity (%).

The goal of this study was to investigate the claims of the originators of the Polylift, who state that the machine is able to recognize that as the weight lifted by the participant increases, the velocity and acceleration of the lift decreases and the amount of time of the lift increases. In other words, as the weight that a subject lifts approaches their maximal lift capacity, researchers should note a significant increase in the time it takes to lift that load, with a subsequent decrease in velocity and acceleration. Note: the goal of this study was not to validate that the variables (time, velocity and acceleration) were being measured accurately by the machine. The Polylift is calibrated by an electrical engineer prior to use to ensure that those measurements are being accurately collected. The researcher's main goal was to determine whether the machine was able to recognize the time increase and velocity and acceleration decrease as the participant approaches maximal lift capacity. The benefit of the Polylift is its ability to assist in determining whether maximal "effort" and lift capacity is being reached by a participant. If the machine is able to recognize the natural increase in time and decrease in velocity and acceleration that occurs as a participant approaches maximal lift capacity, then the machine can be considered a helpful device in objectifying maximal lift "effort" during functional capacity evaluations. The claims regarding the Polylift would then be validated if it accurately, and significantly produced data that agreed with Newton's second law of motion (Force=mass x acceleration) indicated by a decrease in acceleration and increase in time with increasing load. Historically, health care practitioners have had to make judgement calls when determining whether patients were providing full effort during lifting activities. If the Polylift can objectify the normal relationship between time and velocity/acceleration during lifting activities, then practitioners will have a tool to mitigate the subjective aspect of the functional

capacity evaluation. In this study, researchers wanted to determine if the Polylift could recognize a consistent, significant difference (increase) in the amount of time required to complete lifts as the subject approached maximal lift capacity. Researchers also wanted to determine if there was a concurrent significant decrease in acceleration as subjects approached maximal load.

Figure 3: Illustration of a Subject Utilizing the Polylift During a Lift

2. Materials and Methods

To investigate the claims associated with the Polylift, two sets of data were collected. First, the participants' one repetition maximum (1RM) was determined to quantify "maximal lift capacity" in each subject in order to have a baseline for "maximal effort". Each participant performed repeated repetitions of a waist to shoulder lift at a submaximal level until they could no longer perform the lift with proper form. The number of repetitions performed was plugged into the Brzycki's One Repetition Maximum (1RM) formula [10]. The results were used to determine the participant's maximal lifting capacity. In the second portion of data collection, each participant performed a total of four waist to shoulder lifts. The weight of the first lift was 25% of the 1RM weight that was pre-determined. The second lift was 50%, the third lift was 75%, and the final lift was 100% of the pre-determined 1RM weight. The Polylift was utilized in this portion of the study to collect information regarding time, velocity and acceleration of each lift.

The subject sample was one of convenience drawn from healthy, uninjured college age students. Forty-two college students (20- Male, 22- Female), age 20 to 27 years old, volunteered to participate in this study. The exclusion criteria were as follows: any "yes" response noted on the Physical Activity Readiness Questionnaire (PAR-Q) [11], the presence of back pain within the last year, or any history of cardiac issues. Exclusion criteria was selected specifically to ensure the safety of the participants [12]. After clarity of the study's purpose and procedures were established, all participants signed an informed consent form. Subjects were informed that they were free to withdraw from the study or stop testing at any time. Participation length requirement was a single day of data collection. A baseline heart rate measurement was utilized prior to beginning data collection to maintain an objective measurement for the subject's safety, as well as serve as a baseline for continuing the second half of data collection.

2.1. Phase One Data Collection: One Repetition Maximum (1RM) Determination

A standardized lift from waist to shoulder was chosen to be performed for this study [13]. Waist to shoulder lifting is a
commonly utilized technique in many Functional Capacity Evaluations. Safe lifting guidelines provided by the Occupational Safety and Health Administration Technical Manual 7 were utilized as protocol along with correct demonstration from an investigator [14]. Each subject's 1RM prediction was calculated by using the submaximal repeated lift equation developed by Brzycki [10], [15]. Each subject's starting lift load was chosen by using a standardized maximum lift chart based on the subject's body weight [16]. All subjects were blind to the amount of weight placed inside the box. The starting waist position height was set at 35" from the floor, and the shoulder height at 55" from the floor [17], [18]. The subjects were instructed to perform the repeated lift as many times as possible with the same technique, speed, and form until fatigue [19], [20]. Prior to the investigation, operational definitions established by Gross et al. were observed by researchers in order to determine when maximal effort has been exceeded and when to safely stop the lift [8]. After completion of the repeated lift, the number of times each subject correctly performed the lift was inserted into Brzycki's 1RM formula {Load Lifted/ 1.0278 - (reps x 0.0278)} for calculation [10]. Subjects were then required to take a minimum of fifteen-minute rest break. Each subject's heart rate was re-measured to ensure that resting heart rate had returned to baseline level prior to beginning phase two of data collection.

2.2. Phase Two Data Collection: Polylift Data Collection

The second portion of data collection utilized a progressive resistance protocol along with the Polylift's ability to record the objective measurements time, acceleration, velocity, and distance. The progressive resistance protocol involved one waist to shoulder lift of each of the following loads: 25% of 1RM, 50% of 1RM, 75% of 1RM, and 100% of 1RM. The subjects were completely blind to their established 1RM and the amount of load used for each single trial. The subjects were instructed to lift the box as quickly but as safely as possible from waist height to shoulder height shelf. The Polylift's specialized data collection system was utilized, and the researchers carefully monitored to ensure that the subject maintained safe form and technique established with each lift. In between each trial, the subjects were allotted at least a one-minute rest break, as established by Matuszak et al. as sufficient time for recovery during 1RM testing [21].

3. Results

3.1. Descriptive Statistics

The criteria adopted to determine the 1RM produced results of subjects lifting between 12 and 65 pounds for 1-18 repetitions. Those results assisted in determining the computation of the subject's 1RM using the Brzycki formula. The resistance progression is demonstrated in Table 1 below.

In table 1, the data demonstrates the variable load lifted between subjects during Phase 1 data collection ranging from 12-65 lbs. for the initial calculation of 1RM using the Brzycki

formula. During Phase 2 of data collection, subjects lifted between 15.43-104.29 lbs. during the actual 1RM lift.

Table 1: Descriptive Statistics of Load Lifted by Test Subjects (n=42)

Variables	Range	Mean	Standard Deviation
Phase 1 Load lifted (lbs.)	12-65	38.262	15.800
Phase 1 Repetitions	1-18	7.929	4.319
Phase 2: 25% of 1RM (lbs)	3.86-26.07	12.394	6.095
Phase 2: 50% of 1RM (lbs)	4-52.14	24.700	12.331
Phase 3: 75% of 1RM (lbs)	11.57-78.21	37.182	18.285
Phase 4: 100% of 1RM (lbs)	15.43-104.29	49.577	24.382

Table 2: Mean Time & Acceleration during Trials of Progressive Resistance

Variable	Mean Time [s]	Standard deviation for time [s]	Mean acceleration [in/s²]	Standard Deviation for acceleration [in/s²]
25% of 1RM	0.342	0.117	245.104	196.385
50% of 1RM	0.354	0.086	185.567	79.557
75% of 1RM	0.416	0.100	132.909	52.687
100% of 1RM	0.548	0.204	85.607	41.080

In table 2, the data demonstrates the mean time and acceleration change with each stage of progression. The results of this study demonstrate how the mean time consistently increases with each stage of progression from 0.342 to 0.548 seconds. Therefore, the Polylift collected data that demonstrates that as the weight gets heavier, the test subject requires more time to successfully lift the weight. The results also demonstrate a decrease in acceleration with each stage of progression.

3.2. Pearson Product Moment Correlation

In this study, subjects varied greatly in their fitness levels and ability to lift heavy loads. Therefore, to perform a correlation, the load lifted was calculated as a percentage of each subject's body weight. A Pearson Product Moment Correlation was determined for each lift (25% of 1RM, 50% of 1RM, 75% of 1RM, and 100% of 1RM) for every subject and was compared to the velocity during each lift. Load lifted and velocity were found to be

moderately negatively correlated r(166)= -.283, p<.001. Figure 4 displays this relationship.
Figure 4: Velocity Correlated with Load Lifted (as % of body weight)

Table 3: Post-hoc Analysis Pairwise Comparisons for Time (LSD)

(I) Percent_1RM	(J) Percent_1RM	Mean Difference (I-J)	Std. Error	Sig.b	95% Confidence Interval for Differenceb	
					Lower Bound	Upper Bound
1	2	-.012	.013	.347	-.039	.014

	2	.062*	.011	.000	.039	.084
	4	-.131*	.026	.000	-.184	-.079
4	1	.206*	.027	.000	.150	.261
	2	.193*	.025	.000	.142	.245
	3	.131*	.026	.000	.079	.184

3.3. Repeated Measures ANOVA (Time)

A repeated measures ANOVA was also conducted to analyze the time needed to lift 25%, 50%, 75%, and 100% of a test subject's 1RM. There was a statistically significant effect on time across the four conditions, $F(3, 123)=40.874$, p<.001) with significance level set at p<.05. Post hoc analysis pairwise

comparisons utilizing LSD method further revealed that there were significant differences (p<0.01) in time between all conditions except for between 25% of 1RM and 50% of 1RM(p=0.347). Figure 5 displays this effect and Table 3 outlines results of post hoc analysis.
Figure 5: Time (seconds) Required at (1) 25%, (2) 50%, (3) 75%, and (4) 100% of 1RM (Repeated Measures ANOVA)

3.4. Repeated Measures ANOVA (Acceleration)

A second repeated measures ANOVA was conducted to examine the effects of acceleration at 25%, 50%, 75%, and 100% of 1RM. There was a statistically significant effect on acceleration across the four conditions, $F(3, 123)=21.811$ p<.001) with significance level set at p<.05. Post hoc analysis pairwise comparisons utilizing LSD method further revealed that there were significant differences in acceleration at 25%, 50%, 75%, and 100% of 1RM in all scenarios. Figure 6 displays this effect and Table 4 outlines results of post hoc analysis.

4. Discussion

The pattern of the results suggests that as the weight lifted by the participants increased, the acceleration of the lift decreased and the amount of time required for each lift increased. The variables of load lifted and velocity were significantly negatively correlated, demonstrating that as each participant lifted a higher percentage of their body weight, the velocity decreased. This correlation was present despite the fact that the subjects varied greatly in individual fitness levels and ability to lift heavy loads. There were significant differences in the amount of time for a participant to lift 25%, 50%, 75%, and 100% of their 1RM. In comparing each of these four conditions, there was a significant increase in time required to lift the weight in all conditions except for 25% and 50% of the 1RM. There were significant differences in the acceleration required to lift 25%, 50%, 75%, and 100% of the participant's 1RM. In comparing each of these four conditions, there was a significant decrease in acceleration between all four conditions.

A primary finding of this study is that the Polylift machine is able to recognize the variables of time and acceleration and display a consistent and significant relationship between these variables. As expected, when a person lifts a weight that is increasingly closer to their 1RM, the time required to lift this weight increases, and the acceleration of lifting this weight decreases. While this may be a well-known and understood fact, a device to measure and objectify this phenomena has not existed up to this point.

This study utilized established theories and validated calculations to assist in the investigation of claims related to the machine. Newton's second law of motion, which involves the variables of mass and acceleration during the production of force, was the basis of the hypothesized outcome. The formula Force = Mass x Acceleration establishes an inverse relationship between the variables such that an increase in the force required to move an object of a higher weight would result in a decrease in acceleration. Because lifting involves an object being moved through space with either submaximal or maximal force, the time to move the heavier object from one point to the other should increase as the load increases. Advantageously, all of the mentioned variables involved in the task of lifting are able to be collected by the Polylift, as demonstrated in this study.

Another calculation involved in the study was the validated Brzycki formula which is a commonly used tool to assess muscle strength. In order to generate force, strength is a vital factor to successfully perform a lift and cause change in acceleration. The formula provided baseline data of the 1RM for each subject, which was used to progress the resistance in the second phase of data collection. The Polylift demonstrated the ability to detect changes in the variables. In reviewing the results, it was significantly demonstrated that the Polylift is able to indicate maximal lift capacity by accurately demonstrating a consistent decrease in acceleration with increasing loads due to the diminishing ability to generate force. In particular, the load lifted at 25% of 1RM and 100% of 1RM demonstrated the Polylift's ability to detect a considerable difference in acceleration between both lifts.

It should be mentioned that there were some results during the 25% of 1RM lift that were not expected. When reviewed, these results produced slower acceleration rates when compared to the acceleration of the 50% 1RM lift. Researchers hypothesize that this can be attributed to the subject being cautious with the first trial after the completing submaximal lifts of a moderate weight in the initial data collection portion of the study. This occurrence brings to the forefront the many complex factors involved, especially the psychological aspect of lifting [22].

The data from this study suggests that the use of the Polylift to determine maximal lifting capacity will deliver measurable results indicated by the change in variables during the lifting procedure. The implications of these findings could be highly important as they can be applied during the functional capacity evaluation.

Limitations and Indications for Future Studies

Nacimento et al. determined that the Brzycki formula was most accurate when maximum repetitions ranged between 7-10 [23]. Our study included all results, with repetitions ranging between 1-18. This should be considered a limitation based on the premise that the repetitions sometimes went beyond the 7-10 range. Another limitation to be considered is the psychological aspect of performing the 1RM trials following repeated lifts during phase one data collection [24]. Many subject's acceleration and velocity measurements were inconsistent during the first single trial at 25% 1RM, likely because of the subject's expectation of a heavy load. A test trial with cueing for speed may be considered for future studies.

5. Conclusions

The significance of the results in this study demonstrate that the Polylift is able to indicate maximal lift capacity by accurately demonstrating a consistent decrease in acceleration with increasing loads due to the diminishing ability to generate force. Practitioners who are well versed in ergonomics and the area of human performance now have available to them a piece of equipment that provides objective measurements to assist in determining an individual's readiness to return to work. The use

of the Polylift during functional capacity evaluations and rehabilitation in general allows clinicians not to rely solely on their observational skills or subjective reports from the patient when full lifting capacity has been reached. The Polylift is able to reveal, through change in time and acceleration, if physical "effort" matches the expected outcomes. Conversely, if the machine does not identify an obvious increase in time with a decrease in acceleration, then the clinician can objectively assert that full "effort" and maximal lift capacity has not been demonstrated by the participant. The impact of this type of tool in functional capacity evaluations is significant and may be of great use to clinicians tasked with evaluating patients who have sustained industrial injuries. The Polylift assists in objectifying results and determining a patient's readiness to return to work.

Conflict of Interest

The authors of this study have no business and/or financial interests in the Polylift or other potential conflicts of interest to disclose regarding this research.

Downlink Indoor Coverage Performance of Unmanned Aerial Vehicle LTE Base Stations

A B S T R A C T

In this study, we study on the downlink indoor coverage performance of unmanned air vehicle (UAV) base stations. We consider a probabilistic expression for air-to-ground (ATG) path loss, and a deterministic one for additional indoor losses in order to provide a practical model. One of our important assumptions is that the UAV base station operates at the frequencies reserved for 4th Generation (4G) – Long Term Evaluation (LTE) based mission critical services in Turkey –around 2.6 GHz–. Therefore, we are able to neglect intercell interference issue, and we may rely on signal-to-noise ratio (SNR) for our coverage definition. We consider four different SNR requirement throughout our performance evaluation, and investigate the effect of UAV altitude and other related parameters on the radius of service area. We first observe that rural coverage performance is always better than urban conditions –this result is fully compatible with the fact that attenuation levels significantly arise in urban regions–. In addition, we show that increasing quality of service (QoS) requirement and/or using a more directive antenna unit decrease the coverage radius as they are expected. Thereupon, we conclude that it is possible to obtain the optimum altitude level –by employing the framework proposed here– in order to satisfy certain service criteria.

1   Introduction

In this paper, we extend one of our earlier studies presented in 27th Signal Processing and Communications Applications Conference (SIU) [1]. As we argue in [1], UAV base station idea seems to be a promising solution to provide cellular service for both the locations which cannot be covered by employing terrestrial networks and the times in which terrestrial networks may not be serving at all (e.g. natural disasters). In [2] and [3], earlier studies related to the UAV base station concept are summarized, and possible use cases are investigated. In addition, topics open for further studies are discussed in these publications as well. Among several other topics to discuss, modelling channel conditions of such a non-terrestrial network in a practical and also tractable way is an important requirement [4]–[11].

In [4, 5, 6], coverage performance of UAV networks is investigated for outdoor users, and the effect of UAV altitude on the coverage radius is discussed in detail. In the studies mentioned, ATG channel is modelled in two parts. First part corresponds to the free-space losses, and assumed to be a deterministic function which depends on the radiation distance. Second part basically aims the

losses in where man-made structures exist –urban environment–, and modelled as a Normal distributed random variable. In this paper, we follow this piecewise model to express the path loss related to ATG channel, and examine urban and rural conditions separately. The reason of the using deterministic approaches is that reliable characterization of the ATG propagation for large scale fading statistics. In addition, it is important to note that fast fading effect of the channel is ignored throughout this study.

Some earlier publications related to the topic utilize a practical UAV to form a testbed, and generate empirical channel models to figure out ATG propagation characteristics [9]–[11]. All three of those are funded by the same institution, and aims to model over-water, mountainous and near-urban environments, respectively. As the next step of this work, we also target to assemble a functional and realistic testbed.

Besides, some previous studies utilize stochastic processes to concentrate on outdoor coverage performance of UAV base stations [12, 13]. Authors of the former assume that both UAV and terrestrial base stations are deployed in an overlapping manner, and coordinate with each other to provide a continuous service. Such an overlapping structure of UAV and terrestrial base stations is not cov-

ered in the scope of this paper. The latter one considers only UAV base stations distributed according to a Poisson point process (PPP). Then, authors provide approximate expressions for both coverage ratio and average data rate. Here, we emphasize that we assume there exists only one UAV base station that operates on mission critical frequency bands, and therefore such stochastic processes are not required to model UAV base station density around. Yet, as a future concern, investigating networks consist of multiple UAV base stations is already scheduled.

Another significant aspect of this work is considering additional losses to serve indoor users. In literature, these indoor losses are generally studied for terrestrial networks rather than UAV ones [14]–[17]. In [14, 15], indoor losses are evaluated as a function of number of floors penetrated. Authors of [16, 17] offer a more complicated system model which accounts the number of internal/external walls and indoor propagation distance. Since only the latter one of these supports sub-6 GHz frequency bands, we follow the model proposed in [17]. Once we build a practical testbed, generating a novel indoor propagation model will be another important objective in our agenda.

Rest of this paper is organized as follows: Section 2 summarizes the system model that we employ, Section 3 proposes a parametric expression for indoor coverage ratio, Section 4 calculates coverage radius for several SNR demands, quality-of-service (QoS) requirements and antenna directivity levels, and finally Section 5 discusses the results obtained throughout our extensive simulations.

2   System Model

The aim of this study is to show that UAV base stations can be provide a fast and effective coverage in areas not covered by terrestrial networks or in emergency situations –by using frequency bands reserved for mission critical services–. Considering that UAV base station users are not exposed to interference, SNR is employed as performance criterion. The altitude range of UAV base station is accepted as 0.5-3 km. Maximum velocity of the UAV is 180 km/h. The movement of the UAV can be neglected because displacement on the air within the channel stationarity duration is too small compared to altitude of the UAV. Figure 1 shows an example of UAV base station layout.

The study assumes that UAV carries an outdoor base station which operates on Band 7 (2.6 GHz) which is defined by European Telecommunications Standards Institute (ETSI) as an LTE frequency band [18]. In this system model, UAV base station works on Single Input Single Output (SISO) mode and has single sector which is 120°.

2.1   Propagation Model and Antenna Gain

In the literature, the propagation model of UAV base stations is examined in two parts as free space loss and urban losses [5]. It is accepted that free space loss has a deterministic character and urban losses have a probabilistic one. The attenuation for cases with line of sight (LOS) and non line of sight (NLOS) are as follows:

$$PL_i = 20 \log \left(\frac{4\pi f_c d}{c} \right) + \lambda_i \quad \text{[dB]} \tag{1}$$

where f_c, d, c and λ_i, $i \in \{\text{LOS}, \text{NLOS}\}$ refers to carrier frequency, propagation distance, speed of light and urban losses respectively. In literature, these urban losses are considered to have a Normal distribution: $\lambda_{\text{LOS}} \sim \mathcal{N}(\mu_{\text{LOS}}, \sigma_{\text{LOS}}^2)$ and $\lambda_{\text{NLOS}} \sim \mathcal{N}(\mu_{\text{NLOS}}, \sigma_{\text{NLOS}}^2)$. μ_i and σ_i^2, $i \in \{\text{LOS}, \text{NLOS}\}$ express the mean and variance values of corresponding Normal distributions and numerical values can be calculated with respect to the propagation angle.
Figure 1: UAV base station coverage region.

The LOS and NLOS possibilities required to complete the propagation model are also functions of the propagation angle and denoted as follows:

$$\Pr\{\text{LOS}\} = \frac{1}{1 + a(-b(\theta - a))}$$
$$\Pr\{\text{NLOS}\} = 1 - \Pr\{\text{LOS}\} \tag{2}$$

Since calculating the constants a and b above is not in the scope of this study, numerical values are given in Chapter 4. The average loss of external environment obtained using Equations (1) and (2) can be expressed as follows:

$$PL_{\text{out}} = \sum_i PL_i \Pr\{i\} \quad \text{[dB]}$$
$$= 20 \log \left(\frac{4\pi f_c d}{c} \right)$$
$$+ \lambda_{\text{LOS}} \Pr\{\text{LOS}\} + \lambda_{\text{NLOS}} \Pr\{\text{NLOS}\} \quad \text{[dB]} \tag{3}$$

In addition, a model defined by ETSI is used to evaluate base station antenna gain [19]. According to this model, the antenna gain is given as a function of the beam angle:

$$G = G_{max} - \min \left[12 \left(\frac{\alpha}{\alpha_{3\text{dB}}} \right)^2, A_{max} \right] \quad \text{[dB]} \tag{4}$$

where $\alpha_{3\text{dB}}$, is the beam width corresponding to a 3 dB loss and its value basically determines the directivity of the antenna. Also, $G_{max} = 15$ dB and $A_{max} = 20$ dB represent the maximum antenna gain and the maximum attenuation, respectively. Variable of the expression above, namely beam angle is indeed a function of penetration angle: $\alpha = \pi/2 - \theta$.

2.2 Indoor Model

In literature, there exist studies which expresses indoor penetration (internal and external walls) and free space loss due to the indoor propagation by using empirical models [16, 17]. Within the model given in [17], total path loss for indoor users is given as follows:

$$PL_{\text{in}} = md_{in} + nL_{in} + kL_{out} \quad \text{[dB]} \tag{5}$$

where d_{in} and m denote the indoor propagation distance and the indoor path loss constant. n, L_{in}, k and L_{out} represent the number of penetrated internal walls, penetration loss of one internal wall, number of external walls penetrated and penetration loss of one external wall, respectively. The values of these parameters at the carrier frequency of 2.6 GHz are given as $m = 0.49$ [dB/m], $L_{in} = 4.9$ [db] and $L_{out} = 24.8$ [dB]. In this study, it was assumed that one external and one inner wall is penetrated to provide indoor coverage, and there is an indoor propagation distance of five meters. Therefore, the additional loss due to indoor coverage is calculated as $PL_{\text{in}} = 32.15$ dB.

2.3 Performance Criterion

As it is stated above, we assume that UAV base station utilizes the frequencies reserved for mission critical services. Thereby, we do not consider any interference effect, and employ SNR as our performance criterion. More precisely, we define the coverage incident by the probability of SNR is greater than a given threshold. By using (3), (4) and (5), SNR can be calculated as follows:

$$\text{SNR} = P_{tx} + G - PL_{\text{out}} - PL_{\text{in}} - P_N \quad \text{[dB]} \tag{6}$$

Here, P_{tx} ve P_N represent transmitted signal strength and noise power, respectively. We note that total noise power is basically given as a function of bandwidth (BW). In the following section, by using the system model given, the probability of indoor coverage of ATG communication systems will be expressed.

3 Probability of Indoor Coverage

Indoor coverage probability of a geographical location is defined as the probability of SNR exceeds a certain value. Corresponding expression is given as

$$\begin{aligned}\Pr\{c\} &= \Pr\{P_{rx} \geq s\} \\ &= \Pr\{PL_{\text{out}} \leq P_{tx} + G - PL_{\text{in}} - P_N - s\} \end{aligned} \tag{7}$$

where $s \in \{0.76, 4.7, 10.4, 15.9\}$ refer to the different SNR limits considered in this study. The reason for choosing values given is that these values are used in the literature as SNR levels to determine certain channel quality indices (CQIs) [20].

As given in (3), PL_{out} is basically the summation of the two different random variables with Normal distribution multiplied by two coefficients, namely Pr{LOS} and Pr{NLOS}. Thereupon, we conclude that PL_{out} is also a Normally distributed random variable

$$PL_{\text{out}} \sim \mathcal{N}(\mu_{PL}, \sigma_{PL}^2) \tag{8}$$

where μ_{PL} and σ_{PL}^2 represent the mean and variance parameters of the distribution, respectively. Numerical values of mean and variance can be calculated as follows:

$$\mu_{PL} = 20 \log\left(\frac{4\pi f_c d}{c}\right) + \mu_{\text{LOS}}\Pr\{\text{LOS}\} + \mu_{\text{NLOS}}\Pr\{\text{NLOS}\} \tag{9}$$

$$\sigma_{PL}^2 = \sigma_{\text{LOS}}^2(\Pr\{\text{LOS}\})^2 + \sigma_{\text{NLOS}}^2(\Pr\{\text{NLOS}\})^2 \tag{10}$$

Once we compute the distribution parameters in (9) and (10) –and according to the fact that outdoor path loss is modelled as a Gaussian random variable–, coverage probability given in (7) can be evaluated by using the tail probability which is defined as $\mathbb{Q}$ function [21]. Thus, (7) is given as

$$\Pr\{c\} = 1 - \mathbb{Q}\left(\frac{P_{tx} + G - PL_{\text{in}} - P_N - s - \mu_{PL}}{\sigma_{PL}}\right) \tag{11}$$

As a result of $\mathbb{Q}$ function exists in (11), it is not easy to express coverage probability in closed form. Yet, a fast, numerical solution exists. In the next section, we demonstrate our comprehensive simulation results in order to support our theoretical findings.

4 Numerical Analysis

In this section, we investigate the coverage radius for different SNR demands by utilizing the coverage expression above. The system parameters used in the simulations are: f_c = 2.6 GHz, P_{tx} = 46 dBm, α_{3dB} = 65°, BW = 10 MHz, P_N = −95 dB, a_{rural} = 4.88, a_{urban} = 9.61, b_{rural} = 0.43 and b_{urban} = 0.16. The center frequency and bandwidth of the base station are commonly used numerical values in LTE systems. Transmit power is maximum base station power value for given bandwidth standardised by ETSI [19]. Effective noise power is calculated according to formulation stated in [22]. 3dB beam width corresponds to 65° when UAV base station has 120° sector wide [19]. Other parameters used in simulations are empirical values from earlier researches.

In Figure 2a, we plot 90% coverage radius for an SNR requirement of 0.76 dB with respect to the UAV altitude. The first important observation obtained from the figure is that the coverage radius in the rural area is greater for the whole altitude interval. This result is intuitive since the channel conditions are rougher for urban areas. Another important result is that the coverage radius increases with increasing altitude. Therefore, in cases where the SNR requirement is as low as in this scenario, the highest feasible altitude value provides the best coverage radius.

In Figures 2b, 2c and 2d, the SNR requirements are chosen as 4.7 dB, 10.4 dB and 15.9 dB, respectively. The first major finding regarding to the figures is that the coverage radius is getting smaller with the increasing SNR requirement. As a matter of fact, in the highest SNR requirement scenario (Figure 2d), after the altitude of 2000 m in urban scenario and 2200 m in rural scenario, the coverage is completely lost. In addition, when the SNR requirement is high, the coverage radius becomes a concave function rather than a monotone increasing one. Therefore, it is seen that optimum altitude is not the greatest feasible value anymore.

(a) *s*=0.76 dB.

(b) *s* = 4.7 dB.
(c) *s*=10.4 dB.

(d) *s*=15.9 dB.

Figure 2: 90% coverage requirement, $\alpha_{3dB} = 65°$.

As seen in Figure 2c, the optimum altitude values for $s = 10.4$

dB in rural and urban scenarios are 2300 m and 2000 m, respectively. In the case of $s = 15.9$ dB (Figure 2d), the optimum altitude values decrease further and become 1200 m for rural scenario and 1100 m for urban scenario. Under the results achieved, we conclude that it is possible to obtain an optimum altitude value for providing a certain QoS through the largest service area.

Then, we increase the coverage ratio requirement to 99% to understand the effect of QoS expectation on coverage radius. In Figure 3, we observe that for each SNR level, coverage area gets slightly smaller with increasing coverage ratio requirement. This result is quite intuitive regarding to both theoretical coverage expression proposed in (11) and the general understanding of wireless communications. We also emphasize that maximum urban area radius that can be served with the largest SNR level decreases when we require a coverage ratio of 99%.

Finally, we analyze the effect of antenna directivity on the coverage radius. In Figure 4, we fix *s*=15.9 dB and consider a variable beam angle. For each configuration, it is observed that coverage radius enlarges with the increasing beam angle (decreasing directivity) whereas function characteristics do not change much. However, it is important to emphasize that a narrower coverage area would be preferred for certain mission critical services. In addition, for a multi-UAV base station network, narrow beams may be required to limit the intercell interference from time to time. Thereupon, a configurable directivity pattern seems to be a plus for UAV networks.

5   Conclusion

In this paper, we study on downlink indoor coverage performance of UAV base stations. According to the system model proposed, we accept SNR as the primary performance criterion. For the channel, we employ a two-staged model in which outdoor and indoor losses are assumed to be probabilistic and deterministic, respectively. Then, by employing the system model specified, we express the coverage ratio in terms of UAV altitude, cell radius and SNR requirement. In addition, to support our theoretical findings, we share our extensive simulation results. Throughout our simulations, we investigate the effect of UAV altitude, SNR and coverage ratio requirements, and antenna directivity on the coverage radius. According to our simulation results and observations, we conclude that it is possible to choose the UAV altitude level that optimizes the coverage radius. Finally, we note that we aim to build a practical test setup in order to build our own air-to-ground channel model to utilize in our future studies.

Conflict of Interest   The authors declare no conflict of interest.
(a) s=0.76 dB.
(b) $s = 4.7$ dB.
(c) s=10.4 dB.
(d) s=15.9 dB.

Figure 3: 99% coverage requirement, $\alpha_{3dB} = 65°$.
(a) $\alpha_{3dB} = 45°$.
(b) $\alpha_{3dB} = 55°$.

The objective of the metaheuristics, together with obtaining quality results in reasonable time, is to be able to control the exploration and exploitation balance within the iterative processes of these methodologies. Large combinatorial problems present ample search space, so Metaheuristics must efficiently explore this space; and exploits looking in the vicinity of good solutions previously located. The objective of any metaheuristic process is to achieve a "proper" balance between intensive local exploitation and global exploration. In these processes two extreme situations can occur, on the one hand an imbalance with a bias towards exploration, which produces a distributed search in the search space, but avoiding convergence, so the quality of the solutions will be low, the other case is the bias towards exploitation, which tends to converge prematurely in local optimals, impacting equally on the quality of the solutions. To make a correct balance of exploration and exploitation, it is necessary to be able to control adequately the parameters of the Metaheuristics, in order to infer in the movements taking advantage of the maximum capacity of these. Among the most widely used optimization techniques to solve large problems are metaheuristics, which allow us to obtain quality results in a short period of time. In order to facilitate the use of the tools provided by the metaheuristic optimization techniques, it is necessary to reduce the difficulties in their configuration. For this reason, the automatic control of parameters eliminates the difficult task of obtaining a correct configuration. In this work we implemented an autonomous component to the Intelligent Water Drops algorithm, which allows the control of some parameters dynamically during the execution of the algorithm, achieving a good exploration-exploitation balance of the search process. The correct functioning of the proposal is demonstrated by the Set Covering Problem, which is a classic problem present in the industry, along with this we have made an exhaustive comparison between the standard algorithm and the autonomous version that we propose, using the respective statistical tests. The proposal presents promising results, along with facilitating the implementation of these techniques to industry problems.

1 Introduction

This paper is an extension of work "An Adaptive Intelligent Water Drops Algorithm for Set Covering Problem", originally presented in 19th International Conference on Computational Science and Its Applications (ICCSA) [1].

The post-pandemic economic recovery brings with it a number of challenges for the industry, ranging from rethinking business models to making good use of every available resource. In this sense, optimization is an important tool to achieve the desired recovery [2]–[6].

There are various economic sectors where there are problems that need to be optimised such as the airport sector where, given the environmental restrictions, it is becoming increasingly difficult to build new airports and for this reason it is necessary to optimise each of the tasks of the current installations [7]–[9]. Another ex-

ample is the educational sector, in particular the universities where it is necessary to optimize the use of rooms and the curriculum of students [10, 11]. In summary, we can find a series of problems that can be treated through optimization techniques that have a positive impact on economic recovery.

In this sense the metaheuristics that are supervised heuristics [12], are a real option to give solution to the industrial optimization problems since their attraction is that they allow to deliver a high quality solution that can even be the optimal one in limited computation times. There is a great variety of metaheuristics which have been used to solve NP-Hard problems [13]–[16].

In general, metaheuristics have a great amount of parameters, which allow controlling the high and low level strategies of these, having direct relation with the performance of the techniques in the different problems [17], the optimal configuration of parameters constitutes in itself an optimization problem [18, 19]. The importance of a good parameter assignment to metaheuristic algorithms impacts on the quality of solutions, but on the other hand it is not possible to consider transversal parameters for all the problems to be solved, since the assignment of values depends directly on the problem and the instances to be solved [20].

The values that can assume the parameters can have a great amount of combinations, for that reason we can occupy different strategies to approach the optimal configuration of parameters, that according to the literature are divided in two great groups, off-line configuration and on-line control. The off-line configuration of parameters corresponds to the determination of the metaheuristic algorithm outside the run, that is, before its execution begins [21], while the on-line control dynamically updates the values of the algorithm during the execution [22].

Given the current context of using metaheuristic techniques to solve the problems of the industry, we must facilitate the use of these techniques to non-expert users, so the use of autonomous techniques for the control of parameters, is a great contribution to bring this type of tools to all users of the industry.

The present work, solves a classic problem of the real world, as it is it Set Convering Problem (SCP) [23], which has diverse applications in the industry, using metaheuristic techniques to solve problems of great dimension. We have used the metaheuristic technique Intelligent Water Drops (IWD), which is inspired by the physical behavior of water droplets in a river bed [24], Along with this, we have incorporated autonomous elements for the on-line control of its parameters, which has two main components, the first is the obtaining of external information on the problems to be solved, and the second is the obtaining of internal information on the behaviour of the algorithm. With this we can better combine the information of each problem to be solved, along with the internal behavior of the algorithm, which generates that our proposal is adapted to the various problems that are solved.

The work is structured in the following form, in Section 2 what has been done regarding parameter tuning is presented, in Section 3 the functioning of IWD is explained, while in Section 4 the adaptive implementation proposed for IWD is detailed, in Section 5 set covering problem is shown, in Section 6 the corresponding experiments and statistical analyses are presented, ending in Section 7 with the conclusions and future work.

2 Parameter Tuning

In this section we will review the various techniques of parameterization of algorithms in order to find a correct configuration.

The proper selection of parameter values for the algorithms is not an easy task and has an important impact. Usually a great deal of time is spent, using previous experiences and expert knowledge for the correct assignment of values which also constitutes a not easy task for non-expert users. In consideration of the latter, the ideal condition from the point of view of the non-expert user is that he or she should give general information about the problem and with the least possible interaction receive an adequate response (Fig. 1). This concept, called Autonomous Search, was proposed by [18], using indicators to determine the best strategy to use.
Figure 1: Autonomous Search.

The techniques for finding a good configuration for the parameters were initially grouped into two categories: offline configuration and online control. However, a new proposal is made in [21]: Simple Generate-Evaluate Methods, Iterative Generate-Evaluate Methods and High-Level Generate-Evaluate Methods.

2.1 Offline configuration

Finding a convenient parameter configuration previous to the execution of the algorithm is known as offline configuration.

This is primarily a trial and error process and can consume considerable time in research. The efficiency of this depends mainly on the insight and knowledge of the researcher or author of the algorithm. These processes are typically undocumented and are not reproducible, often driving to an unequal adjustment of different algorithms.

The following techniques exist within this group:

- F-race is an inspired method of racing algorithms in automatic learning, in particular, races in [25, 26]. This algorithm was presented in [27] and studied in detail in Birattari's PhD thesis [28]. The purpose of these methods is to iteratively evaluate a set of candidate configurations for a given set of instances. A set is removed when there is sufficient statistical evidence and there are survivors within the continuous race. This method is used after each evaluation of the candidate configurations, in which nonparametric Friedman two-way variance analysis [29] determines if there is evidence that at less than one of the configurations is significantly different

from the other ones. If the hypothesis is null and there is no difference, it is rejected; Friedman's subsequent tests are applied to remove these candidate configurations that are significantly worse than the best. This approach had been used by the ACO in [30].

- ParamILS was introduced by [31] as a versatile stochastic local search approach for automatic algorithm configuration. ParalILS includes methods to optimize the performance of an algorithmic, deterministic or stochastic object in a particular class of problems by switching a set of ordinal and/or categorical parameters. This proposal is based on an iterated local search algorithm that uses a combination of configurations chosen, a priori or at random, at initialization. The underlying idea of local search is an iterative "best first" method, which uses a variety of random movements to disturb the solution and avoid getting into local minima. The method always accepts configurations that improve or match the performance of the best configuration and restarts the search from a random configuration under a certain probability. The local search method moves through the search space by modifying only one parameter each time[32]. This approach has been used to configure ACO to solve transportation planning problems in [33].

- The other approach to optimization, focused on the sequential paradigm, includes improving the parameter initial values by the alternation of experimental design and the parameter recognition.

  In this paradigm, statistical significance takes a preponderant role, since each new experiment contributes with information about the performance of the parameters used, which are then referenced to the new stages.

  In the case of a parallel method, different experiments are formulated concurrently (all of them taking the same parameter nominal values); experiments are then carried out. The parameters are calculated and their suitability tested using the data obtained in all parallel experiments. If the data obtained from the parallel experiments are inadequate after the parameter estimation the procedure can be replicated [34, 35].

- In [36], the author used the graphic radial technique. The four basic metrics are employed for this method: worst case, best case, average case and average run-time. The region under the radar plot curve is obtained with these four metrics to set the best setting.

- The meta-optimization method was initially studied by [37] and is characterized by using an algorithm to optimize the parameters of another optimization algorithm, that is, there is an algorithm at a higher level that optimizes the parameters of a lower-level algorithm. This method has been used for covering problems in facility locations in [38], stand management in [39], and parameter selection in machine learning in [40].

2.2 Online configuration

One of the areas of research that has taken great strength in recent years is the online configuration, as it gives the algorithms the ability to adapt to the characteristics of a particular instance for better performance. For this online configuration to be useful, the exploration and exploitation phases must be clearly identified because the internal adjustments may be different for each of the phases. Thus, the online configuration can improve the results when the algorithms are used in situations very different from those that were built.

Different techniques exist, and the most simple is to define the parameter variation rules before executing the algorithm.
One possibility is the use of parameter adaptation, where the parameter modification scheme is defined for some behavior statistics of the algorithm.

- Absolute evidence: An example is the threshold of the distance between the solutions.

- Relative evidence: Considers that the relative difference in the performance with parameters of different values adapt to those with the best behavior.

2.3 Simple Generate-Evualate Methods

In this method the principle of generating and evaluating is used. Candidate configurations are occupied and then each of the parameters are evaluated to find the best configuration (Figure 2).
Figure 2: Simple Generate-Evualate Methods.

2.4 Iterative Generate-Evualate Methods

Unlike the first method, this one repeatedly performs the generation and evaluation steps. In this method the historical information allows to guide the generation, so that the search space for parameters is better explored and is more efficient in large search spaces (Figure 3).
Figure 3: Iterative Generate-Evaluate Methods.
Figure 4: High-Level Generate-Evualate Methods.

2.5 High-Level Generate-Evualate Methods

This approach generates candidate configurations to then evaluate them and select the best configuration. The idea is to generate a set of high quality configurations quickly using few computational resources and select the best one. The idea is to greatly reduce the resources used when exploring candidate configurations and use them to thoroughly evaluate these configurations (Figure 4).

3 Intelligent Water Drops Algorithm

During the year 2007 in [24] he presented the algorithm that is classified as constructive since it builds a solution from 0. Its inspiration is based on nature and corresponds to the displacement that water drops make through the flow of a river and its friction with the earth, considering that when a drop is moved from one point to another it displaces earth from the river bed making the friction less and less which makes the drops increase their speed and in turn incorporate part of the extracted earth.

In the Figure 5, we can see how the soil of the river behaves, on the one hand during the passage of the drop is removed soil from the bottom of the river and on the other hand is incorporated into the drop which directly influences the speed that is acquired, this is demonstrated in that two drops of similar size but with different speeds at the end of its movement are with different size because of the soil that is incorporated. This abstraction of the behavior of water drops in river soil, allows us to build diversified solutions at the beginning, while during the execution of the algorithm, these solutions converge to promising search spaces, which allows to intensify the search.
Figure 5: Water drop removing riverbed soil and adding to its own soil.

This algorithm has been used to solve mainly scheduling problems: Cooperative Search Path Optimization problem [41], Work Flow Scheduling Algorithm for Infrastructure as a Service (IaaS) cloud [42], Capacitated Vehicle Routing Problem [43], Trajectory Planning of Unmanned Combat Aerial Vehicle (UCAV) is a rather complicated Global Optimum Problem in UCAV Mission Planning [44], Method for Optimal Location and Sizing of Distributed Generation (DG) [45].

This algorithm has an initialization phase where both the static parameters number of drops, number of iterations, initial soil, initial speed and constants a_s, b_s, c_s, a_v, b_v, c_v are initialized and also the dynamic parameters Speed of drop k and soil value of drop k are initialized.

Then there is a construction phase where every drop builds a solution by visiting the nodes. The Eq. 1 is used to determine which node to visit:

$$p_i^k(j) = \frac{f(soil(i,j))}{\sum_{\forall l \notin VC^k} f(soil(i,l))} \quad (1)$$

where $soil(i,j)$ corresponds to the amount of soil between i and j and is calculated according to the following equation (Equation 2):

$$f(soil(i,j)) = \frac{1}{\varepsilon + g(soil(i,j))} \quad (2)$$

where ε is a small positive value to avoid division by zero.

The function g(soil(i,j) always obtains a positive soil value (Equation 3):

$$g(soil(i,j)) = \begin{cases} soil(i,j) & \text{if } \min_{\forall l \notin VC^k} soil(i,l) \geq 0, \\ soil(i,j) - \min_{\forall l \notin VC^k} soil(i,l) & \text{otherwise} \end{cases} \quad (3)$$

Once the drop has selected the new node, its velocity should be updated (equation 4):

$$vel^k(t+1) = vel^k(t) + \frac{a_v}{b_v + c_v \cdot soil^2(i,j)} \quad (4)$$

where a_v, b_v and c_v correspond to static parameters, and $soil(i,j)$ represents the amount of soil between i and j.

Next, it is necessary to update the soil after the step of the drop; for this, we use the following equation 5:

$$soil(i,j) = (1-\rho) \cdot soil(i,j) - \rho \cdot \Delta soil(i,j) \quad (5)$$

where ρ is a small positive value between 0 and 1, and $\Delta soil(i,j)$ is the amount of soil removed from paths i and j.

The value of $\Delta soil(i,j)$ is obtained with the following equation (6):

$$\Delta soil(i,j) = \frac{a_s}{b_s + c_s \cdot time(i,j : vel^k(t+1))} \quad (6)$$

where a_s, b_s and c_s are static parameters, and $time(i,j : vel^k(t+1))$ is calculated as follows (7):

$$time(i,j : vel^k(t+1)) = \frac{HUD(i,j)}{vel^k(t+1)} \quad (7)$$

where HUD is a heuristic that measures the degree of undesirability of the drop to jump from one node to another.

The Reinforcement phase is responsible for updating the global soil with the best drop of the iteration, and the following equation is used (8):

$$soil(i,j) = (1 + p_{iwd}) \cdot soil(i,j) - p_{iwd} \cdot \frac{1}{q(T^{IB})} \quad (8)$$

where p_{iwd} is a small positive value between 0 and 1, and $q(T^{IB})$ is the fitness value.

The best solution for each iteration is compared with the best global solution and updated according to the following equation (9):

$$T^{TB} = \begin{cases} T^{IB} & \text{if } q(T^{IB}) < q(T^{TB}) \\ T^{TB} & \text{otherwise} \end{cases} \quad (9)$$

Finally, the Termination phase is responsible for the completion of the algorithm process when the stop condition is met, which can be the number of iterations.

In 6 the original algorithm of the metaheuristics is shown.

Algorithm 1 Intelligent Water Drops Algorithm

{**Initialization phase**}

4 Adaptative Intelligent Water Drops

The configuration of initial parameters is a costly task, carried out by an expert user and performed prior to the execution of the algorithm. We can reduce the cost of this task based on the concepts from Autonomous Search [18], which obtains information from two different sources, internal, corresponding to the operation of the algorithm and external, corresponding to the problem we are solving. The use of these data sources allows us to compare the quality of the solution in the current iteration (f_{IB}) with the quality of the best found solution (f_{TB}).

The general scheme for obtaining information to guide the adjustment of parameters is presented in Figure 7.
Figure 7: Information required for the proposal.

The internal information source considers the performance of

the algorithm. In our proposal, we collect the number of iterations in which no improvement in the quality of the solutions is detected. The external information source comes from the data corresponding to the instance of the problem we are solving. We consider the number of columns and the density of the instance, which allows us to differentiate them. A weight is assigned to the columns of the instance that allows us to assign importance to them, multiplying it by the density, given in the Figure 8).

SET	Instance Set	m	n	Cost Range	Density	Optimum Solution

NRF	5	500	1000	[1,100]	20.00	Known

Figure 8: Standard description of the benchmark OR-library.

The algorithm has two initial parameters to which we assign values, these correspond to the Soil and Initial Speed ($Soil_{Initial}$ and $Velocity_{Initial}$ respectively).

In the first case we assign the value considering the number of columns of the instance and its density, which is done as follows:

To determine the first value we consider information of the instance considering on one hand the number of columns available and on the other hand the density that is presented. This value is obtained in the following way:

$$Soil_{Initial} = SoilInitial \cdot nColumn \cdot Density \qquad (10)$$

Where $Soil_{Initial} = 1$, $nColumn$ corresponds to the number of columns in the instance group and $Density$ corresponds to the percentage of nonzeros in the matrix.

$$Velocity_{Initial} = 15 \qquad (11)$$

For the case of the initial speed $Velocity_{Initial}$ the value is determined by a series of 10 previous executions of the original algorithm.

For the adaptation, in this work, it is considered the quality of the solution for which a weight is calculated that will allow us to update the local velocity, avoiding that the solution remains trapped in an optimal local. This percentage will be calculated by comparing the solution delivered in each iteration with the best solution obtained.

It has been experimentally determined that a low initial drop velocity impacts the convergence of solutions, making it more pronounced. This characteristic is taken into account in the parameter configuration.

Initial soil and velocity parameters update rule is given by the following equation:

$$Percentage = (f_{IB} \cdot 100)/f_{TB} \qquad (12)$$

where f_{IB} is the best solution obtained at the current iteration, and f_{TB} is the best global solution found.

$$Soil_{Initial} = Soil_{Initial} \cdot Percentage \qquad (13)$$

where $Soil_{Initial}$ is the available initial soil at the current iteration and *Percentage* is the percentage difference between f_{IB} and f_{TB}.

$$Velocity_{Initial} = Velocity_{Initial} \cdot Percentage \cdot \beta \qquad (14)$$

where $Velocity_{Initial}$ is the available initial velocity at current iteration and β is a random number in the interval [0, 1].

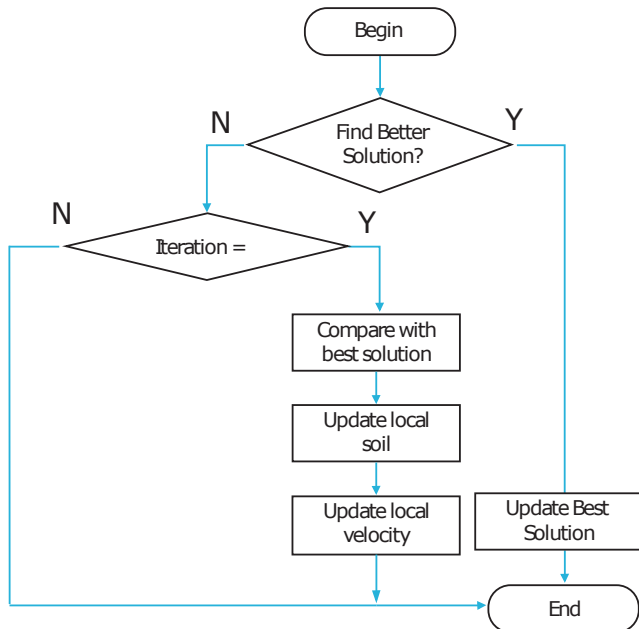
Figure 9 shows the proposed adaptation for the local soil parameter, aiming to improve the metaheuristic performance.


Figure 9: Parameter adaptation proposal.

At each iteration the improvement of the best solution found is evaluated. If an improvement is detected, the previous best solution found is replaced. Otherwise, a counter for not improved iterations is increased. An α value is set for the maximum number of iterations without improvement. If the counter is equal compared with the α parameter, the percentage difference of the current solution compared to the best solution is obtained and used to increase the local soil for the next iteration.

To obtain the value for the α parameter we perform 10 executions of the standard algorithm for each instance. The elapsed iteration number until a fitness improvement was evaluated. The analysis of this number allows us to determine the value for the α parameter to 5. A greater α value causes the fitness improvement probability to decrease, and the computation cost increases. The results of this analysis is shown in Figure 10, the column % represents the occurence percentage for each α, and *%Acum* column shows

the accumulated percentage for each α. Figure 11 shows the fitness change for two instances.

α	Occurrences	%	% Acum	α	Occurrences	%	% Acum
1	41	59%	59%	1	33	40%	40%

Figure 10: Experiments to determine the alpha value.

Graphic occurrences(%) V/S Accountant, Intance d1
Figure 11: Chart of fitness change based on the number of iterations.

After a series of tests, we show the convergence for different initial velocities in Figure 12. When the velocity is low, the convergence shows to be premature. For this case, the initial velocity was adjusted, multiplying it by a β value in range [0, 1].
Figure 12: Convergence chart of different velocities.

5   Problem to solve

SCP is defined as a binary matrix (A) of size m-rows and n-columns, where $a_{i,j} \in \{0, 1\}$ is the value of each cell in the matrix A; i and j are of the size m-rows and n-columns, respectively:

$$A = \begin{pmatrix} a_{1,1} & a_{1,2} & ... & a_{1,n} \\ a_{2,1} & a_{2,2} & ... & a_{2,n} \\ ... & ... & ... & ... \\ a_{m,1} & a_{m,2} & ... & a_{m,n} \end{pmatrix} \quad (15)$$

Defining column j satisfies a row i, if a_{ij} is equal to 1, which is a contrary case if a_{ij} is equal to 0. In addition, an associated cost $c \in C$ is incurred, where $C = \{c_1, c_2, ...c_n\}$, together with $i = 1, 2, ..., m$ and $j = 1, 2, ..., n$, which are the sets of rows and columns, respectively.

The problem has an objective of minimizing the cost of the subset $S \subseteq J$, with the constraint that all rows $i \in I$ are covered by at least one column $j \in J$. When column j is in the subset of solution S, this is equal to 1 and is 0 otherwise.

The SCP can be defined as follows:

$$\text{Min} \quad Z = \sum_{j=1}^{n} c_j x_j \quad (16)$$

Subject to

$$\sum_{j=1}^{n} a_{ij} x_j \geq 1 \quad \forall i \in I \quad (17)$$

$$x_j \in \{0, 1\} \quad \forall j \in J \quad (18)$$

6   Experiments

6.1   Benchmark Instances

In order to validate the proposed approach, the 9 sets of the Beasleys library were used, executing 55 instances that are known and that allow a finished experimental evaluation (Figure 8).

The proposed algorithm was built using Java Language and was executed on an Intel(R) Core(TM) i7-6700 CPU with a speed of 3.40 GHz, with 16GB of memory and using a 64-bit Windows 10 operating system.

6.2   Parameter Setting

As far as the configuration of the parameters used by this algorithm is concerned, IWD, as it is generally known, is a very difficult task that requires a great use of resources. Our approach takes care of working two of the most important parameters in IWD operation which are the initial soil and the initial speed, IntSoil and InitVelocity respectively. To verify the impact of these two parameters, a series of experiments with different values for the selected parameters were carried out. The idea is to adapt these two parameters dynamically in order to use the quality of the solution as an indicator of change. The action occurs if the best overall solution does not change after a defined number of iterations.

The parameters used for the different experiments are shown in the following Figure 13.

Parameter	Detail	Value
N	Amount of drops.	5000
$MAX\_ITERATION$	Number ofiterations.	50
$InitialSoil$	Initial soil value	1000
a_s	Soil parameter "a"	900000
b_s	Soil parameter "b"	0.01
c_s	Soil parameter "c"	1.0
$InitialVel$	Initial velocity value	15
a_v	Velocity parameter "a"	10.0
b_v	Velocity parameter "b"	0.01
c_v	Velocity parameter "c"	1.0

6.4 Statistical Analysis

Figure 24 shows a general scheme of the existing statistical techniques, where in this study the statistical analysis included the different tests:

- Kolmogorov-Smirnov-Lilliefors [46] is used to establish the independence of the samples.

- Wilcoxon's Signed Rank [47] is used to verify that the IWD algorithm with AD is better than the Standard IWD algorithm.

Both statistical tests considered a significance level of 0.05, so that values lower than 0.05 indicate that the null hypothesis cannot be assumed, i.e., H_0 is rejected.

Figure 25: Statistical Analysis Results.

When it is obtained that the data does not follow a normal distribution, the Wilcoxon-Mann-Whitney [47] test is applied. This test is applied to verify that the version with AD is better, where the hypotheses are as follows:

H_0 = Standard IWD algorithm $\geq$ IWD algorithm with AD
H_1 = Standard IWD algorithm $<$ IWD algorithm with AD

To obtain the p-values we use the programming language R, where obtaining a p-value < 0.05 implies rejecting H_0, and accepting H_1. The AD version is statistically better than the standard version, which extends to each instance of the benchmark (Figure 25. In addition, what is indicated by the statistical tests supports what has been obtained through verification by RPD.

The results of each instance can be seen graphically in the figure 26 to 30. IWD algorithm with AD has better results in all instances except for instances E and F.

difficulties in the configuration of parameters when implementing a metaheuristic in a real problem, a situation that will become increasingly common in the scenario of recovery from the economic crisis in post-pandemic times.
Figure 30: Instance F.1.

The adaptive element incorporated, obtains the necessary information to make decisions, based on external sources, coming from the problem and internal sources, typical of the normal functioning of the Intelligent Water Drops algorithm. With the correct combination of this information, it was possible to improve the balance of the exploration and exploitation of the search space of most of the solved instances, for Set Covering Problem, where the improvement was in average of 13.04%. In addition, the difference obtained by our adaptive proposal is significant in 77,78% of the compared instances, compared to the corresponding statistical comparisons.

The adaptive configuration is an interesting focus of future work, since there are a large number of static parameters that can be self-adjusting, in order to improve the performance of implementations, in order to decrease the influence of the off-line configuration in the performance when solving diverse instances. Along with this, it is necessary to replicate the implementation developed in this work, for other NP-Hard problems, validating the correct functioning of the incorporated adaptive components. Moreover, in the face of the growing line of research concerning the interaction between metaheuristics and machine learning techniques, a wide range of machine learning possibilities is presented in the decision making of the values to be taken by the adaptive parameters, adding to this, the option of choosing between different ways of calculating parameters according to internal and external information.

Conflict of Interest   The authors declare no conflict of interest.

7   Conclusion

In this work, we have presented an adaptive version of the Intelligent Water Drops algorithm, which is a tool that facilitates the use of metaheuristic techniques to non-expert users, reducing the

A B S T R A C T

In this work, a study of the process variation effects on the threshold voltage of a floating-gate device is proposed. The study demonstrates the sensitivity of the threshold voltage to five geometrical parameters including gate length, gate width, tunneling gate oxide thickness, bottom oxide-nitride-oxide oxide thickness, and nitride spacer thickness. This paper also proposed a detailed flow to fabricate the floating-gate device for CMOS 180nm process, which is used to design the floating-gate device for the study. This paper used the TCAD tools including Athena, Devedit3D, and Atlas for the simulations.

1 Introduction

The CMOS technology has been developing over the past many years thanks to its benefits like high integration density, low fabrication costs, and high operating speeds. In addition, many novel techniques of circuit design have been shown ranging from memories, analog mixed-signal, RFIC [1] -[7] to mm-Wave IC design [8], [9].

Meanwhile, there has been considerable development in the semiconductor memory field. This field is divided into two main branches which are volatile memories and non-volatile memories, and these types of memories are developing based on the CMOS technology [10], [11]. While the former lose data when the power supply is off, the latter can retain the stored information even after power is removed. Therefore, non-volatile memories are used in a very wide variety of products like cell phones, computers, and communication [12]. Thus, many researchers have focused on the study of this kind of memory. However, to study the memories, the

floating gate device needs to be investigated first since it is the core of the memories [13] –[15].

Focusing on designing a simulation model for the floating gate device, many parameters are studied under the process variation. There are two main methods to investigate the process variation effects. The first way is using the SPICE model. This is basically a fast method but the approach of this method lacks many conditions in the fabrication process like doping channel [16]. Therefore, the effects of the doping channel would not be studied. The other method is using the 3D-TCAD simulation for analyzing the geometrical parameters and the doping channel effects [17] -[19].

In this work, a detailed design flow and parameter values to fabricate the complete floating-gate device are proposed to investigate the structure and characteristics of the device. The process variation effects on the threshold voltage, which is a vital parameter of the device, are studied by using the TCAD simulation tools. Authors introduced the floating-gate device and presented ideas about how to study the process variation on threshold voltage in 180nm

floating-gate device in the "2019 19th International Symposium on Communications and Information Technologies (ISCIT)" [1] and the following paper is an extension of this work.

The remainder of this paper is organized as follows: Section II introduces an overview structure of the device in fabrication and the operation states also. Following this, the detailed flow and parameter values to fabricate a complete device are shown in section III. Next, section IV shows the analysis and discussion of the process variation results in the threshold voltage. This section also describes the simulation of operation states after fabricating. Finally, section V shows the conclusion.

2   Floating Gate Device

The floating-gate device is the core of almost modern non-volatile memories [20], [21]. With regards to fabrication, the device is recognized through the use of a "floating gate". The gate is completely surrounded by dielectrics [22]. A cross section of a device is given in Figure. 1. Being electrically isolated, the floating gate acts as the storing layer in the device. Therefore, the operation states of the device would be determined based on the status of the gate. More importantly, the insulator around the floating gate must be thick enough to prevent leakage of charges from the floating gate to the substrate when the power is off, and it also must be thin enough to allow the transfer of charges on and off the gate under appropriate bias configuration. Moreover, reducing the thickness of the insulator, especially the tunneling gate oxide thickness has been investigated to reduce the program/erase voltage and enhance the level of integration [13],[23].
Figure 1: Floating-gate device structure in fabrication

The floating-gate device has three operation states which are programming, erasing, and reading. Programming refers to putting electrons called Channel Hot Electrons on the floating gate. In contrast, removing the electrons from the gate to the substrate would be performed in the erasing process. The removing current is renowned for the Fowler-Nordheim Tunnel current. Reading is used to determine if the device is programmed or erased.

3   Floating Gate Fabrication & Simulation

This flow proposes using an additional Epitaxial grow layer which was not used in traditional CMOS processes. The growth of an epitaxial layer over the P-type substrate offers some advantages including improving the performance of this device as well as floating-gate integrated circuits, minimizing latch-up effects that a CMOS circuit

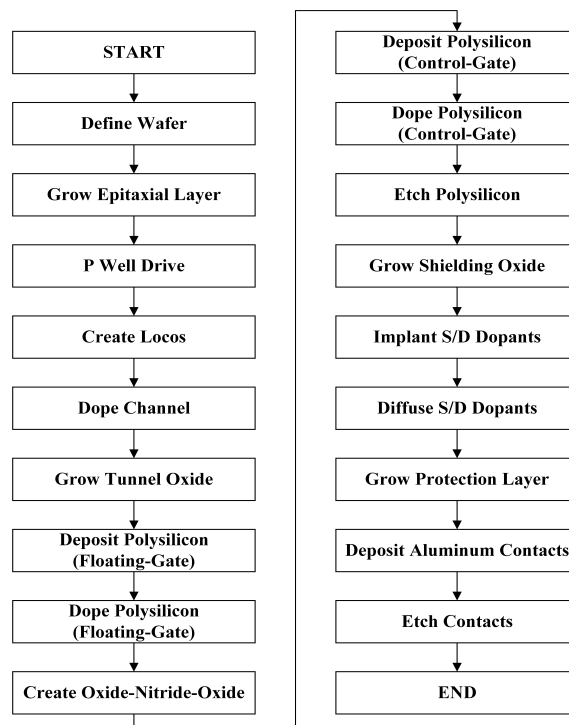
may undergo when powered up, and helping control the doping concentration of this device accurately [24].


Figure 2: Floating-gate device design flow chart

The main difference in terms of structure between the floating-gate device and CMOS device is that the former has an additional floating gate which is created by two steps (Deposit Polysilicon (Floating gate), Dope Polysilicon (Floating gate) in the flow. These figures below illustrate the main process simulations using TCAD based on the design flow chart presented above (Figure 3a-3h).

The fabrication process starts from creating P-substrate (initial surface thickness = 1μm) with Boron at a concentration of 1.0e14 cm^{-3} (Figure 3a). Next, a mesh is defined, and the density of the mesh is a trade-off between accuracy and simulation time. After the mesh and wafer definition, a 0.45μm thick Epitaxy layer with Arsenic at a concentration of 1.0e16 cm^{-3} is grown on the top to make device surface thickness increase to 1.45μm (Figure 3b). Then, a P well is implanted using Boron with a dose of 8e12 cm^{-3}. After that, the P well is also diffused with Nitro gas at 1200^0C for about 310 minutes (Figure 3c). Next, Locos and tunnel oxide layer are created (Figure 3d). Creating Locos is an important step in the fabrication of semiconductor devices for the purpose of isolating the operation of two devices on the same wafer, and Oxide is usually used for this isolation. The doping channel is created using Boron at 100KeV and a concentration of 2.5e12 cm^{-3} (Figure 3e). Figure 3f shows the device structure after Polysilicon (Floating gate) is deposited and doped. Figure 3g shows the device structure after Polysilicon (Control gate) is deposited and doped. The Floating gate, Control gate, Tunnel Oxide layer and Oxide-Nitride-Oxide layer which is between Floating gate and Control gate are etched. An oxide layer with a thickness of 0.1μm is deposited and etched on the top to protect the device by the next steps. The next step is to create Source and Drain gates with Arsenic at 50 KeV and a concentration of
Figure 3: The main process simulations with TCAD including in a) Definition wafer b) Grow Epitaxial layer c) P well drive d) After creating Locos and grow Gate oxide e) Dope channel f) Create Floating gate and dope polysilicon g) Create Control gate and dope polysilicon h) After implant and diffuse S/D dopants

7e12 cm^{-3} (Figure 3h). After growing the protection layer, the final step is to deposit and etch Aluminum contacts for Source and Drain gates. The detailed process flow to fabricate the device is presented in Figure 2.

In this work, we propose to use the Athena tool to simulate the process of fabrication and the Atlas tool for operation simulations of the device. The following table gives the default parameter values in designing.

Table 1: Description And Default Parameter Values

DESCRIPTION	VALUE [μm]
Thickness of oxide-nitride-oxide nitride	0.013
Thickness of nitride spacer	0.002
Thickness of bottom oxide-nitride-oxide oxide	0.01
Thickness of top oxide-nitride-oxide oxide	0.001
Thickness of tunneling gate oxide	0.02
Thickness of control gate	0.075
Thickness of floating gate	0.075
Length of control gate	0.18
Length of floating gate	0.18

The complete 2D and 3D structures of the device in this work are given in Fig. 4 and Fig. 5, respectively. Regarding the 3D structure, the one is designed by using the 2D structure and the Devedit3D tool.
Figure 4: The 2D floating-gate device structure

4   Process Variation Results

This section presents the threshold voltage results of the floating-gate device designed in the previous section before programming and after programming.

Initially, before programming, there are no charges which are stored on the floating gate. The drain current – threshold voltage curve is shown in Fig. 6. The threshold voltage of the device is 0.6V.
Figure 6: Threshold voltage of the device before programming process

After the programming process, the charges on the gate increase from 0C to around -3.5e-15C since the moving of electrons from the substrate. Meanwhile, the threshold voltage increases from 0.6V to approximately 6V. The charges on the gate and the threshold voltage in the programming process are given in Fig. 7 and Fig. 8, respectively. After that, the device is at the program state.

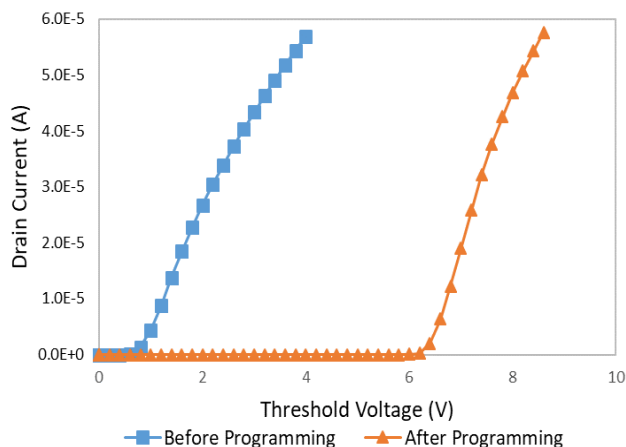
In contrast, as discussed in section II, the erasing process will remove all the negative charge on the floating gate which is generated from the programming process. Following this, the floating gate will have no charge, and the state of the device is as the initial (before programming state) or erasing state.
Figure 7: Floating gate charge in the programming process


Figure 8: Threshold voltage of the device after programming process

The study of process variation demonstrates the effect of the threshold voltage on different geometrical parameters. In general, what stands out from the study is that whereas the threshold voltage is more sensitive to the gate length, tunneling gate oxide thickness, and bottom oxide-nitride-oxide oxide thickness, the threshold voltage is less sensitive to the gate width and nitride spacer thickness. The details of the study are given as follows.

4.1 Vary in values of the gate length

The figure in this section demonstrates the effect of the gate length parameter on the threshold voltage, it is clear that the increase in this parameter tends to a considerable increase in the threshold voltage, climbing around 18.33%, from 6V to approximately 7.1V. Thus, in the fabrication process, this parameter should be controlled carefully.
Figure 9: Gate length variation effects

4.2 Vary in values of the gate width

The figure below illustrates the change of the threshold voltage when the width parameter changes from 0.4μm to 1.6μm. This parameter is defined as a variable varied in the z-axis of the Devedit3D tool. In general, what stands out from the graph is that the voltage is not

sensitive to this parameter. The threshold voltage remains stable at around 6V.
Figure 10: Gate width variation effects

4.3 Vary in values of the tunneling gate oxide thickness

The result is given in the graph in Fig. 11, it is clear that the change in tunneling gate oxide thickness results in a dramatic decrease in the threshold voltage when it varies from 20nm to 40nm. After programming, the voltage witnessed a drastic decrease, falling approximately 50% to about 3.2V. Hence, this is a very important parameter because the variation of the one causes a significant change in the operation of the device. With regard to the fabrication process, this parameter should be controlled carefully.
Figure 11: Tunneling gate oxide thickness variation effects

4.4 Vary in values of the bottom oxide-nitride-oxide oxide thickness

The graph in this section shows the results of the threshold voltage when the bottom oxide-nitride-oxide oxide thickness varied from 0.01μm to 0.03μm. Overall, it can be seen that the threshold voltage after programming experienced a considerable decrease of 23.33%, dropping from roughly 6V to approximately 4.6V. Thus, in the fabrication process, similar to the gate length and the tunneling gate

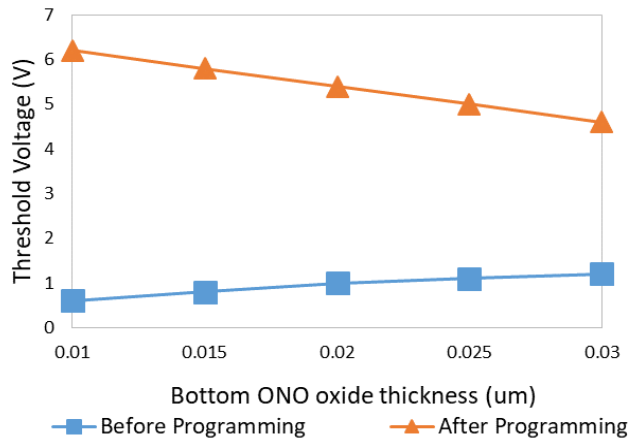
oxide thickness, this parameter should be observed carefully.


Figure 12: Bottom oxide-nitride-oxide oxide thickness variation effects

4.5 *Vary in values of the nitride spacer thickness*

The graph in the Fig. 13 presents the impact of the nitride spacer thickness parameter on the threshold voltage. It is clear that the impact of this parameter is very small. The threshold voltage after programming remaining between 5.9V and 6.1V throughout the study. Thus, the parameter would be controlled more easily than the others in the fabrication process.
Figure 13: Nitride spacer thickness variation effects

5 Conclusion

This work is successful in the study of the process variation effects on the performance of a floating-gate device. The tunneling gate oxide thickness, bottom oxide-nitride-oxide oxide thickness, and gate length were found out to be sensitive to the threshold voltage, especially the tunneling gate oxide thickness parameter caused 50% change in threshold voltage. The others are 18.33% and 23.33%, respectively. While the gate width, nitride spacer thickness turned out to be less sensitive. This paper also successful in proposing a detailed flow and the parameter values to fabricate the complete

floating-gate device based on CMOS 180nm process. The device which is designed by the flow worked as the expectation.

Conflict of Interest
The authors declare no conflict of interest.

There is a crisis in basic education during this pandemic which affected everyone worldwide, we see that teaching and learning have gone online which has effected student performance. Student's academic performance needs to be predicted to help an instructor identify struggling students more easily and giving teachers a proactive chance to come up with supplementary resources to learners to improve their chances of increasing their grades. Data is collected on KAGGLE and the study is focusing on student's engagement, how often they check their announcements, number of raised hands, number of accessed forum and number of accessed resources to predict student academic performance. Various machine learning models such as Support vector machine, Decision tree, Perceptron classifier, Logistic regression and Random forest classifier is used. From the results, it was proven that Support vector machine algorithm is most appropriate for predicting student academic performance. Support vector machine gives 70.8% prediction which is relatively higher than other algorithms.

1 Introduction

Student performance prediction is a crucial job due to the large volume of data in educational databases. A lot of data has become available describing student's online behaviour and student engagement [1]. Online data has been used by a great number of researchers. Online learning and teaching is making a significant impact on the fabric of basic education.

Predicting the performance of a student is a great concern to the basic education management. The scope of this paper is to identify the factors influencing the performance of students in different grades and to find out the best machine learning model to predicting student academic performance and helps to identify students with poor grades and then be evaluated and provided with new materials and methods to improve their results.

There is a crisis in basic education during this pandemic which affected everyone worldwide, we see that teaching and learning have gone online which has effected student performance/grades. Parents are now supposed to sign whether their children must attend traditional class or online classes due to this pandemic. Online

learning platforms is used to track student performance, provides unlimited access to online materials, organises online content in one location though many things that need to be learned do not add themselves to online learning. Many courses require the acquisition of soft skills, which cannot be easily learned or tested online.

They have been many attempts on predicting student academic performance using data collected from students activity logs and student demographic information. They have used several of data mining techniques. Decision trees were primarily used to find the predictor variables to the predicted variable and shows the targeted discrete value [2, 3]. Logistic Regression- was used to describe data and describe the relationship among the variables and Random forest was primarily used to maintain accuracy between the variable [4]–[5].

This research aim to predict student performance from data collected on student's activity logs on an online learning and student's demographic information. We want to find the accuracy of some classification models for predicting student academic performance. The major objectives of this study are:

---

*Corresponding Author: Ashwini Jadhav, The University of the Witwatersrand, Johannesburg, South Africa, Ashwini.Jadhav@wits.ac.za

- Finding the best classification model on student data set.

- Predict student academic performance using student's demographically data and student's online logging's data.

We would like to find out, does the online engagement have an influence on physical engagement? Does the parent association with the learners improve the learner's engagement?.

This study will be using various Machine Learning methods to predict student's academic performance. Five popular classification methods (Support vector machines, Decision trees and Perceptron classification, Logistic regression and Random forest) are built and compared to each other making use of their predictive accuracy on the given data samples to predict student academic performance. Data is collected on KAGGLE and we will be focusing on student's engagement, how often they check their announcements, number of raised hands, number of accessed forum and number of accessed resources to predict student success. The process of predicting student performance using online logging's data is performed using various data mining techniques. [6, 7].

This study proposes the following assumptions:

- Every student must have undergone some training on how to utilise online learning platform to predict correct results.

- Every student have an equal chance of receiving all course materials.

- If a student fails to submit an assessment or attend any forums it assumes the student has obtained 0% in that particular assessment.

2 Related Work

This chapter provides an overview of previous research on predicting student academic performance. This section illustrates other similar work-related to predicting student academic performance.

2.1 Data

Several researchers have used machine learning algorithms in predicting student's academic performance. 323 students doing undergraduate who enrol in dynamics in 4 consecutive semesters: in semester one there were 128 students, in semester two there were 58 students, in semester three there were 53 students and semester four there were 84 students [8]. Other authors have used undergraduate student's information from four different sources which included student's demographic data, course resources data, forums data and Sakai's grade book data [4].

Other authors have used electronic data from the universities to improve the quality of educational processes. They studied using machine learning techniques to study the performance of undergraduate students [9]. We also learnt that other researchers have conducted their study about the student academic performance in high schools and in Iran for bachelor degree students. They analysed data of 1100 learners where 500 where the high school students and 600 was that of the bachelor degree level [10].

2.2 Features

Several researchers have used student's demographic information and student online loggings data to predict student academic performance. The authors have done predictions for 4 class, 3 class and 2 class. The authors applied oversampling in other to balance the dataset and also used 3 different machine learning classifiers to predict student academic performance [8].

Several researchers collected data from student materials, assignments, tests, forums, and discussions on the online learning platform database to predict student success. Some researchers predicted student academic performance and they collected data from total login frequency on the system and a total number of attended forums [4].

2.3 Model

Various machine learning methods have been used by several researchers to predict student academic performance using student's demographic information and student online logging's data. Two machine learning algorithms were used which are Bayesian networks and Decision trees. The Decision trees was more accurate than Bayesian network by 3-12% [8].

Other authors have used C4.5 decision trees, Naïve bayes classifier, Random forests, neural networks and Meta-classifiers. After the analysis they found that C4.5 decision trees performed better [9]. The analysis shows that parent educational level, past examination results and gender has an impact on the presentation [11].

They also used decision trees and clustering data mining algorithms. They focused upon two type of student performance. They first predicted student academic performance at the end of the study programme [12]. Later predicted the student progressions and add them with the predicted results. The results shows good and bad performance of students and assists with identifying struggling students and giving teachers a proactive chance to come up with supplementary measures to improve their chances of passing. The decision trees gave out the best results [4].

3 Research Contribution

This study contributes to the current body on literature by predicting student academic performance and helps to identify students with poor grades can then be evaluated and provided with new materials and methods to improve their grades. Predicting students performance allow an instructor to spot non-engagement students based on their actions and activities from online learning platform. It also assists with identifying struggling students and giving teachers a proactive chance to come up with supplementary measures to improve their chances of passing during the course of their study programme.

From the literature that was reviewed various machine learning methods have been used by several researchers to predict student academic performance, they predicted student academic performance at the end of the study programme and they were unable able to detect which students may need immediate attention so that they lower the chances of them failing.

Table 1: Related Works.

Authors	Features	Models	Accuracy
Shaobo Huang and Ning Fang in (2012)	323 students doing undergraduate who enrol in dynamics in 4 consecutive semesters	Decision trees and Bayesian networks	The decision trees consistently 3 - 12% more accurate than the Bayesian network.
M. Lauria et al (2012)	Used undergraduate student's data	Logistic regression, support vector machines and C4.5 decision trees	Support vector machines and the logistic regression gave out higher
Oskouei Askari et al (2014)	Total number of 1100 and 500 where the high school students and 600 was that of the bachelor degree level	C4.5 decision trees, Naïve bayes classifier, Random forests, neural networks and Meta-classifiers	The best prediction was found using the C4.5 decision trees.
Raheela Asif et al (2017)	Used electronic data from the universities to improve the quality of educational processes.	Decision trees and clustering.	The decision trees gave out the best results.

4   Research Methodology

This chapter presents the methods that is proposed in this study to predict performance of students using student's demographical information and student's online logging's data.

4.1   Research design

Based on the literature the study proposed using data mining techniques to find whether the total spent time on online learning affect the student's performance and how have learning management system features affect the student performance.

4.2   Data description:

The data set consists a total of 480 records and 16 features. We found that there are 3 major categories of features: first being student demographic information such as student nationality and student gender. Secondly being student academic information such as student grade, student section and student educational stage. Thirdly being student behavioural information such as number of access resources, number of raised hands in class and school satisfaction.

The data set consists a total of 305 males and 175 females where 179 are from Kuwait, 28 are from Palestine, 172 are from Jordan, 22 are from Iraq, 17 are from Lebanon, 12 are from Tunis, 11 are from Saudi Arabia, 9 are from Egypt, 6 are from USA, 7 are from Syria, 6 are from Iran, 6 are from Libya, 4 are from Morocco and 1 is from Venezuela.

The data set is collected in two academic semesters, on first semester they were 245 student records and 235 student records on semester two.

The data set also covers the features of the school attendance days. There are two categories based on their number of absence days. We found that there were 289 students their absence days were under 7 days and 191 students were absent for more than 7 days.

Finally, the data set also contains parent's participation on their children academic process. There are two categories: first being the parent answering survey and secondly being parent school satisfaction. We found that 270 parents managed to answer the survey and 210 parents did not answer the survey. We also found that 292 parents are happy and satisfied with the school and 188 parents are not satisfied.

4.3   Classification field

There are three numerical intervals of student grades. The first interval is for students who obtained a failing percentage (L), the interval includes values from 0% to 69%. The second interval is for students who obtained low passing percentage (M), the interval includes values from 70% to 89%. Lastly is for students who got high passing percentage (H), the interval includes values from 90% to 100%.

4.4   Methods

Predictive Models: Five popular classification methods (Decision trees and Perceptron classification and Support vector machines, Logistic regression and Random forest) are built and compared to each other making use of their predictive accuracy on the given data samples. Brief description of the predictive models that will be used in this study.

Support Vector Machines: Support vector machines (SVMs) [13] helps in detecting the outliers on the data set and it also perform classification. SVMs are set of supervised learning methods. SVMs used kernel trick to modify data and use the modified data to find the difference between the possible end results. SVM finds the optimal solution by computing on each feature by using partial differentiation after employing the Lagrange multiplier [14]. The model decreases convolution of the training data consequential subset of support vectors.

Table 2: This table depicts the student related variables and their description.

Data Field	Description
Gender	The student's gender.
Nationality	The student's nationality
Place of Birth	The student's country of birth.
Stage ID	Educational level student belongs to (Elementary, Middle, or High School
Grade ID	The grade year of the student.
Section ID	The classroom the student is in.
Topic	The topic of the course.
Semester	The semester of the school year. (F for Fall, S for Spring)
Relation	The parent responsible for student.
raised hands	How many times the student raises his/her hand on classroom
Visited Resources	How many times the student visits a course content
Announcements View	How many times the student checks the new announcements
Discussion	How many times the student participate on discussion groups
Parent Answering Survey	Parent answered the surveys which are provided from school or not
Parent School Satisfaction	Whether or not the parents were satisfied. "Good" or "Bad". Oddly this was not null for parents who did not answer the survey. It is unclear how this value was filled in.
Student Absence Days	Whether or not a student was absent for more than 7 days
Class	Our classification field. 'L' is for students who got a failing percentage (Less than 69%), 'M' for students who got a low passing grade (Between 70% and 89%), and 'H' for students who achieved high marks in their course (90% to 100%)

Given a data set containing a training set of N data points, $\{x_k, y_k\}_{k=1}^{N}$ and input data, which is an n-dimensional data vector $(x\_k\epsilon R^{\wedge}N)$ and output, which is the one-dimensional vector space $(y\_k\epsilon r)$; SVM create the classifier as shown below in this equation:

$$y(x) = sign\left[\sum_{k=1}^{N} \alpha_k y_k \Psi(x, x_k) + b \right]$$

where α_k are positive real constants and b is a real constant.

Decision trees (DTs): In this study Decision trees is used to find the predictor variables to the predicted variable and shows the targeted discrete value. "Decision trees uses variable values to create a structure that has nodes and edges" [15]. A DT has internal nodes and leaves, rectangles represents nodes and ovals represents leaves. Data set features are represented by the internal node and it contain two or more child. The value of these features is found at the branches. Each leaf contains a classification label [16].

Decision trees are established from a training set. A tree is called the hierarchy and a node is called segment. The entire data set is contained at the original segment called the node of the tree. The branches are formed by the node with its successors that created it and the leaves are final nodes. The decision is made on each leaf and it is applied to all the observations in the leaf. The decision is the predicted value.

Perceptron classification: The Perceptron classifier [17] is a set of supervised learning, the classification field of a sample can be predicted using Perceptron classifier. Perceptron classifier accept numerous input and if the number of inputs is more than the specified condition, it does not return the output, it output the massage

for corrections. In the Perceptron algorithm features on the data set are taken as inputs and it is represented by x1, x2, x3, x4,...,xn where features value is indicated by x and the total occurrences is represented by n.

The required features to be trained is stored as input in the first layer. Now the total inputs and weights will be multiplied and add their outcome. The weights are the values obtained through the training of the model and are denoted by w1, w2, w3,..,wn. The output function will be shifted by the bias value and this value will later be presented to the activation function then the output value is obtained after receiving the value on the last step.

Logistic regression (LR): Logistic regression describe the association among variables and it was used to predict student academic performance by estimating the probability of an event occurring [18]. It also shows the probability of two categories by fitting the explanatory variables and log odds to model using this equation.

$$log(\frac{(P(Y = 1|X))}{1 - P(Y = 1|X)}) = \beta_0 + \beta_1 X_1 +, ..., \beta_N X_N$$

where $Y=(0,1)$ is the binary variable; 1 if it is higher than the reference level and 0 if not, $X = (X_1, ..., X_n)$ are n explanatory variables and $\beta = (\beta_0, ...\beta_n)$ are the estimated regression coefficient.

Random forest (RF): Random forest uses begging method to generate trees in which its prediction is more accurate than that of any individual tree [19]. Random forest was also used to avoid over fitting on the training set and limiting errors due to bias hence yield accurate and useful results. RF can handle outliers and noise in the data and gains high classification accuracy. RF generate numerous decision trees in the training phase and output class labels [20]. RF
Figure 1: This figure depicts the proportion of student academic performance of the classification field.

is used in this study since it is permissible to less over-fitting and it has proofed to be good classification results previously.

RF is a theoretical framework grounded on mixture of decision trees; $\{T_1X, ..., T_BX\}$. The ensemble produces B outputs $\{\check{Y}_1 = T_1(X), ..., \check{Y}_B = T_B(X)$, where $\check{Y}_b, b = 1, ..., B$ is the predicted grades by the bth tree. Output of all trees are aggregated to produce one final prediction $\check{Y}$, which is the class predicted by majority of trees.

4.5   Analysis

The data set consist a total of 480 records. Machine learning algorithms are applied to predict student academic performance and we found that Support vector machine algorithm is best suited to predict student academic performance. We achieve a total accuracy of 70.8% which shows the potential accuracy of Support Vector Machine technique, followed by Random forest with 69.7% accuracy, Logistic regression with 67.7% accuracy, Perceptron with 64.5% and lastly Decision tree with 46.8%.

5   Results and Discussion

5.1   Pre-processing

Typically in machine learning before processing and running a test on a data set, it is necessary to prepare the data and select the targeted attribute. Selecting attributes requires putting all the matching combination of attributes in the data set in order to find which combination is suitable in predicting student academic performance.

Our goal with pre-processing was to change our numerical fields that have a value like Grade ID to a numerical only value in a way that we preserve that distance in a meaningful way. We also assign our three classes to numerical outcomes with a preserved distance and set setting L = -1, M = 0, and H = 1. We chose to preserve the distance between the categorical values and scale our numerical fields so that they would be more meaningful when compared together.

The five machine learning models are used to evaluate the student's academic performance and to check which model best predict

student performance.

5.2   Data visualisation

The data set consist a total of 480 records. In this study, the purpose of selecting an attributes was to find the attributes that contain numerical data, attributes that contain categorical data and classification label. Our goal with data visualisation is to get an idea of the shape of the data set and to see if we can easily identify any possible outliers and also look to see if any of data is unclear or redundant.

5.3   Summary of results

In the previous section, student academic performance was discussed and how it will be evaluated. In this section we discuss the performance of five machine learning models that was specified in section 4. First of all, we performed data visualisation after performing data pre-processing by generating simple plots of data distributions to get an idea of the shape of the data set and then 5 main machine learning techniques was evaluated and also describe the variables contained on the data set. The evaluation was done on the full data set that consist of 480 features [21].

From the results, it was proven that Support vector machine algorithm is most suitable in predicting the performance of students. SVM is relative higher than other algorithms and it has 70.8% prediction accuracy, followed by Random forest with 69.7% accuracy, Logistic regression with 67.7% accuracy, Perceptron with 64.5% and lastly Decision tree with 46.8%. We found the overall percentage of passing rate using class variable. There were 26.46% students who got a failing percent (less than 69%), 43.96% students who got a low passing grades (between 70% and 89%) and 29.58% who achieved high marks in their course (90% to 100%).

Student absence days seems to have a strong correlation with class variable. Very few students who missed more than 7 days managed to achieve high marks and very few students who missed less than 7 days failed their course. From grade 2 to grade 12 we found that grade 5, 9, and grade 10 have very few counts. No 5th grade students pass and no 9th grade students achieve high marks.

In figure 4, the bar plot shows the accuracy of five popular
Figure 2: This figure depicts the grade the student is in and it also shows the average student performance for each grade.

machine learning models that is used to evaluate the student performance. The legend of the plot indicate that blue colour is Support vector machine, Yellow colour indicate Logistic regression, orange colour indicate Decision tree, light blue indicate Random forest and grey colour indicate Perceptron classifier.

Support vector machine has performed well when compared to other machine models. 78.75% instances was correctly classified and 21.25% instances was incorrectly classified. Another way of representing accuracy of the machine learning models that are in figure 4 is through confusion matrices. Table 3 describe how each algorithm has performed.

The graphical representation of receiver operating characteristic curve shows the performance of our best classification model, Support vector machine at all classification thresholds [22]. The ROC curve figure 5, figure 6 and figure 7 shows the classification performance of our best classifiers which is Support vector machine. There are three numerical intervals of student grades (low, medium and high). As can be seen from figure 5, figure 6 and figure 7. The ROC curve occupies the upper left corner, which means the classifier (SVM) used in this paper indicate a better performance and the prediction of positive value is specific in some degree, with AUC of 86%.

6 Conclusion and Future work

Companies and educational institutions uses learning management systems to create and manage lessons, courses, quizzes and other training materials [23]. Student's success needs to be predicted to help an instructor identify academic performance and helps with identifying struggling students more easily and giving teachers a proactive chance to come up with supplementary resources to learners to improve their chances of increasing their grades. It may be difficult for students to learn virtually than in a traditional class hence the student's performance vary due to difference methods of delivering the course materials [24].

Various machine learning models were used to predict student success using the learning management system. Each model indicate different percentage of accuracy when is tested with different features that are associated in an online learning platforms [25].

Student's performance was evaluated by five machine learning techniques which is Perceptron classifier, Support vector machine and Decision trees, Logistic regression and Random forest. Support vector machine ends up handling the data the best with 70.8% accuracy. The obtained results shows that the student absence days influence student academic performance on the other hand student class grades is not influencing student academic performance.

We aim to extend the study by collecting more additional features such as encouraging and motivational strategies taken by facilitators and teachers and considering more materials available for students in an E-learning platforms. We will also consider features such as psychological factors available which affect student's performance. We also intent to use more interesting and detailed data set to predict student academic performance in our future studies.

A B S T R A C T

Healthy lifestyles were proposed to improve the health status of the university population, they are a set of behaviors that are reflected according to the type of situation and behavior of each person who performs it during the period of their training, the inappropriate lifestyles provides many problems, which are non-communicable diseases that manifest in the health status of each individual, which most of the time students choose to consume less nutritious foods and they are not healthy and affect their health; inadequate lifestyles do not provide good academic performance and also generate a bad psycho-emotional state. The objective of the study is to determine the Lifestyle in nursing students at a university in North Lima, 2019. As results, regarding the Lifestyle in nursing students at a university in North Lima; 51.5% have healthy lifestyle and 48.5% have an unhealthy lifestyle. Regarding the dimensions, interpersonal relationships predominate 73.8% have an unhealthy lifestyle followed by stress management, 65.8% have an unhealthy lifestyle, responsibility for health, 63.3% have a lifestyle unhealthy, Physical activity dimension, 60.8% have an unhealthy lifestyle, spiritual growth, 48.8% have an unhealthy lifestyle, healthy nutrition, 29, 5% have an unhealthy lifestyle; it is important to know those results to make decisions.

1. Introduction

In the Republic of Ireland in September 2016 they have shown that university life transition has a negative effect on student lifestyles, resulting in weight gain, increased physical inactivity and stress [1]. University students go through a variation of changes in their mental, physical, social, and economic lives during their university life [2].

The university stage is characterized by a tendency to engage in a variety of unhealthy behaviors [3]. Evidences suggest that nursing students do not engage in healthy lifestyles such negative behaviors lead nursing students to become overweight and obese, as well as other risks such as smoking, alcohol consumption, drugs, an insufficient diet and poor physical activity [4], [5].

According to the research, it has carried out a technical reform that aims to educate the entire community, regarding issues related to nutrition, promoting healthy practices for a proper life and to prevent diseases such as anemia and chronic malnutrition,

as well same regarding overweight, obesity, diabetes, cardiovascular disease, high blood pressure and cancer. This technical document aims to promote the functions of exhaustive care and health promotion in the university population [6].

Unhealthy habits are factors that predominate in university students. According to studies, it is evident that they do not perform physical activity; they do not complete their sleep hours; they eat fast food [7], the negative effects are evident when they reach the adult stage, which causes health problems in older life The evidence shows that regular physical activity helps maintain good health styles and prevents diseases such as hypertension, obesity, metabolic syndrome, heart disease, diabetes, osteoporosis, some types of cancer, and produces significant benefits at the psychosocial level [8]. In this university stage, a sum of difficulties are manifested, likewise this type of qualities is linked to inappropriate health behavior; therefore, it should be noted that it is significant to determine certain health behaviors that are inadequate and have a much higher risk of suffering from non-communicable diseases [9].

In Peru in 2018, more than 50% of the disease burden is associated with non-communicable diseases, which affect all age groups. Tobacco use, harmful use of alcohol, unhealthy diet, infrequent physical activity. Approximately 62 million people have Type 2 Diabetes. Cancer is the second leading cause of death. In 2018, it caused 1.3 million deaths, and 3.7 million new cases. Tobacco kills 7 million people each year. 62% of adults are overweight or obese. The epidemic disturbs adolescent and young children since between 20% and 25% are affected by being overweight or obese [10].

In [11], the authors showed the sample of 829 university students included 504 (60.8%) Chinese and 325 (39.2%) international students. The Chinese students had higher scores in general healthy lifestyles and the scales showed low levels in physiological and social health. Gender was associated with psychological health in both groups. Smoking was a predictor of psychological health in both groups and of social health in the international group.

In [12], the authors showed that 47% of the study participants had a moderate-level lifestyle. Regarding musculoskeletal symptoms, the most frequent were reported in the back (88,33%), knees (83,33%) and thighs (71%). Furthermore, Pearson's correlation analysis revealed significant negative correlations between eating habits and musculoskeletal symptoms and interpersonal relationships, while a significant positive correlation was found between nutrition and stress management.

In [13], the authors presented a study carried out in Turkey, showed that in nursing students there were various factors such as financial problems (70.3% of moderate income level; inadequate) and the characteristics cultural factors that may have contributed to the decrease in physical activity observed in this study; therefore it should be noted that it is significant to determine certain health behaviors that are inadequate and have a much higher risk of suffering from non-communicable diseases.

The objective of the study is to determine the Lifestyle in nursing students at a university in North Lima, 2019. This research work will be developed to improve the lifestyle of university students to reduce the risks of acquiring different diseases due to bad lifestyles in university students at a university of north lima. In this study, we suggest that we should continue to emphasize the promotion of a healthy lifestyle in nursing students; in the university stage, an important role must be fulfilled, such as prevention and health promotion; this effort must be involved with other professionals to have more significant results in the benefit of the health of the university population, they are encouraged to raise awareness.

The instrument to be used is the Health Promoting Lifestyle Profile II (HPLP-II) developed by Pender Walker and Sechrist, in 1987 and translated into Spanish in 1995, consisting of 52 items divided into six dimensions: health responsibility that is the comprising an active notion of responsibility for one's own comfort. It implies maintaining an adequate interest in one's own health, educating oneself about health [14].

All the data will be addressed to a Microsoft Excel 2013 program, then it will be sent into the SPSS24 program.

To compile the information, articles were reviewed in all the scientific databases that exist internationally and nationally, it was possible to indicate that there are a large number of articles that address the health problem with respect to a healthy lifestyle, information is evidenced found in articles, therefore, this study seeks to increase the knowledge of each of the students. The subject is important since applying it in practice would bring many benefits for the human being.

This work is structured as follows: In section II, the steps to carry out the survey are explained, how the population and sample were acquired, type of study, inclusion and exclusion criteria, analysis of variables, data collection, place and application of instruments. In section III, the results acquired according to the surveys carried out in the study are presented, through the elaboration of tables and bars. In section IV, the discussions that show the interpretation of results obtained in the research work compared to another research will be presented. Finally, in section V, the conclusions of the research work will be shown according to the results found, what measures should be taken about them.

2. Methodology

2.1. Population

There are 400 students from the first to the tenth cycle of the nursing faculty. Day and night shift.

Table 1: Number of Students from day and night shift

Study semester	Total of Students	Percentage
Semester 1	60	15.0
Semester 2	45	11.3
Semester 3	42	10.5
Semester 4	33	8.3
Semester 5	41	10.3
Semester 6	39	9.8
Semester 7	30	7.5
Semester 8	32	8.0
Semester 9	41	10.3
Semester 10	37	9.3

2.2. Inclusion criteria

- Nursing students from 1st to 10th semester.
- Nursing students who have signed the informed consent.

2.3. Exclusion Criteria

- Nursing students who do not want to participate in research.
- Nursing students who have not signed the informed consent.

2.4. Type of study

The present investigation is of a quantitative approach, its non-experimental, descriptive, and transversal design. To start with the

data collection, the necessary coordination was carried out in the Faculty of Nursing to obtain authorization for access to the classrooms of the institution [15].

2.5. Application of the instrument

The survey and the instrument used is The HPLP (Health Promoting Life Profile II) created by. Walker S., Sechrist K., Pender N. Kerr M., published in Spanish in 1995, is made up of 52 items and distributed in six dimensions, responsibility in health (9 items), physical activity (8 items), nutrition (9 items), spiritual growth (9 items), interpersonal relationships (9 items) and stress management (8 items), also a standard scale is used Likert where the punctuation varies from 1 to 4, where "1 = never", "2 = sometime", "3 = often" and "4 = usually", giving a final score of 52 to 208, ranging from " 52 to 130" is an unhealthy lifestyle and "131 to 208" is a healthy lifestyle, the higher the score the higher the healthy lifestyle the student will present [16].

2.6. Place and application of the instrument

The instrument was applied at the Universidad de Ciencias y Humanidades in Los Olivos. A permission was requested from the nursing faculty to have access to the classrooms. For this, an enrollment in the ethics committee was made for the approval of the instrument to apply.

After approval, permission was requested from teachers who teach in the classrooms to provide 15-minute access to students to fill out the questionnaire. We had some difficulties with some teachers because they made us wait until the end of their class to give us the space, and others to wait for the break to be able to enter.

Figure 1: Delivering surveys to the students at a University of North Lima

As shown in Figure 1, they were given instructions on how to complete the questionnaire. To use exclusively a pencil to mark a single alternative in the question to avoid smearing.

Figure 2: Developing the surveys by the students at a University of North Lima

As shown in Figure 2, the students carefully concentrated on reading the questionnaire; some students did not understand the questions they did not interpret it in the health field.

The doubts they had about the questions were explained to the students and they were reminded that their answer must be sincere, and the development is individual, not group to get good results.

Figure 3: Collecting student surveys.

As shown in Figure 3, it is verified that the entire questionnaire is filled out. If a question doesn't have an answer, it is returned to the participant to complete so that the questionnaire is valid to be typing to the SPSS to find questions, also if there is missing answer, the survey is eliminated.

The nursing personnel is fundamental for the health study of the university students since it offers them Psycho-emotional support for the social well-being of the university students; because many are unaware of healthy lifestyles or do not practice them and lead a routine life and acquire non-communicable diseases.

3. Results

After obtaining the surveys, the data was synthesized and statistical tables were generated for a better understanding of them, as shown in Table I.

Table 1: Sociodemographic lifestyle data in nursing students from a university of north lima, 2019 (n = 400).

Participant Information	Total	
	N	%
Total	400	100
Sex		
Female	342	85,5
Male	58	14,5
Marital Status		
Single	262	65,5
Married	54	13,5
Widowed	5	1,3
Cohabitant	56	14,0
Divorced	23	5,8
Type of Family		

Nuclear	191	47,8
Extended	43	10,8
Amplified	55	13,8
Single parent	63	15,8
Reconstituted	23	5,8
Family equivalent	25	6,3
Occupancy Condition		
Study	142	35,5
Study and work	258	64,5
Degree of Study		
Secondary	170	42,5
University	156	39,0
Technical	74	18,5
Primary Education	3	0,8

In Table 1, it has the sociodemographic data of the study participants, there were 400 participating nursing students. The minimum age was 18 years old; the maximum age was 49 years old, the mean being 24.83 years old.
Figure 4: Lifestyle in nursing students at a university in North Lima, 2019 (N = 400)

Regarding sex, the female sex predominated with 342 students representing 85.5%, followed by the male sex with 58 students representing 14.5%. Regarding marital status, the single person predominates with 262 (65.5%) cases, followed by Cohabitant with 56 (14%) cases, married with 54 (13.5%) cases, divorced with 23 (5.8%) cases, and finally widowers with 5 (1.3%) cases.

Regarding the type of family, nuclear families predominate with 191 (47,8%) cases, followed by the single parent with 63 (15, 8%) cases, amplified with 55 (13,8%) cases, extended with 43 (10,8%) cases, family equivalent with 25 (6,3%) cases and finally reconstituted 23 (5,8%) cases.

Regarding the occupation status of nursing students, 258 study and work (64,5%) cases and only 142 with (35, 5%) cases study.

Regarding the degree of study, 238 students representing 59.5% have secondary education, 117 students representing 29.3% have technical education, 42 students representing 10.5% have university education and finally 3 students representing 0.8% have primary education.

In Figure 4, the lifestyle in nursing students from a university in Lima Norte, it can see that 206 students represent 51.5% have a healthy lifestyle and 194 students that represent 48.5% have an unhealthy lifestyle.
Figure 5: Lifestyle in relation to gender of nursing students from a University of Lima Norte, 2019 (N = 400).

Figure 5 shows the lifestyle in relation to gender of nursing students from a university in North Lima, where 169 (49.4%) who are female have an unhealthy lifestyle, 173 (50.6%) have a healthy lifestyle, 25 (43.1%) who are male have an unhealthy lifestyle and 33 (56.9%) have a healthy lifestyle.
Figure 6: Lifestyle according to its general dimensions that the instrument contains according to a study in nursing students from a university in North Lima, 2019 (N = 400).

In Figure 6, Lifestyle in its dimension health responsibility, in nursing students from a university in Lima Norte, it can see that 253 students represent 63, 3%, have an unhealthy lifestyle and 147

students represent 36.8%, have a healthy lifestyle. In the physical activity dimension, in nursing students from a university in North Lima, it can see that 243 students represent 60.8%, have an unhealthy lifestyle and 157 students represent 39.3%, have a healthy lifestyle. In the healthy nutrition dimension, in nursing students from a university in North Lima, it can see that 282 students represent 70.5%, have a healthy lifestyle and 118 students represent 29.5%, have an unhealthy lifestyle. In the growth dimension spiritual, in nursing students from a university in Lima Norte, it can see that 205 students represent 51.3%, have a healthy lifestyle and 195 students represent 48.8%, have an unhealthy lifestyle. In the interpersonal relationships dimension predominates 295 students representing 73.8%, have a healthy lifestyle. In the stress management dimension, in nursing students from a university in Lima Norte, it can see that 263 students represent 65.8%, have an unhealthy lifestyle and 137 students represent 34.3%, have a healthy lifestyle.

4. Discussion

The research work confirms the unhealthy lifestyles in university students based on the articles reviewed in [12] to their study carried out on university students from Iran Shiraz where bad interpersonal relationships were evidenced in the students and based on [11] to their study carried out, low results were evidenced regarding its dimensions; according to [13] to their carried out in Turkey, students have a sedentary life and do not carry out physical activity.

In the study carried out on students from a North Lima university in terms of dimensions, it was clearly shown that a large number of students who do not have good interpersonal relationships with their peers are not responsible for their health; they do not have good stress management and do not carry out physical activity. It leads to a sedentary life. Likewise, in [5], argue that students do not have a good lifestyle and that factors such as tobacco and alcohol show an inappropriate lifestyle.

This type of studies can be applied in other university centers to help the teaching for students and also train teachers so that they can implement educational programs such as physical exercise, stress control, improving lifestyles involves commitment and will.

Promoting lifestyles is a little difficult since students do not put into practice; they always make excuses for not doing it, that's why, this research work is presented to provide guidance on the situation that university students are in.

5. Conclusion

To conclude in this regarding lifestyle, it is projected from the promotion of the health of the university students, in order to contribute to the universities so that they include programs to have an adequate healthy diet, physical activity, etc.

It is concluded that the university population is made aware of the benefits of irregular practices of physical activities that improve the lifestyle.

It is concluded that counseling is provided to university students to develop educational intervention protocols in relation to healthy life habits.

Conflicts of Interest

The authors declare no conflict of interest.

A B S T R A C T

The use of wireless sensor networks (WSN) can be a valuable contribution in disaster situations or life-threatening exploration. Using wireless mobile robots, it is possible to explore vast areas without human intervention. However, the wireless network coverage that can keep mobile robots connected to the base station / gateway is a major limitation. With this in mind it was created a prototype of an extensible WSN using mobile robot nodes that cooperate amongst themselves. The strategy adopted in this project proposes using three types of nodes: master node, static node, and robot node. Three different algorithms were also developed and proposed: Received Signal Strength Indication (RSSI) Request; Automovement; Robot Cooperation and Response to Static Node. The performance evaluation of the prototype was carried out using a real-world testbed with each developed algorithm. The results achieved were very promising to continue the evolution of the prototype.

1. Introduction

This paper is an extension of work originally presented in conference *2020 15th Iberian Conference on Information Systems and Technologies* (CISTI 2020) [1].

Wireless Sensor Networks (WSNs) are composed by small nodes spread in an area of interest to measure environmental conditions such as temperature, sound, humidity, although they have many other uses [2]. Each node can be seen as a small computer, having processing, sensing and communication capabilities. The nodes connect to each other wirelessly and can cooperate in collecting information and routing it to an end user [3].

The need for extensible WSNs is tied with monitoring situations that require the deployment of a WSN. Situations such as forest fires or fires is large buildings [4], determining the extent of damage of earthquakes [5], nuclear disasters as in Fukushima, Japan, rescue operations, exploratory operations, mapping flooded caves, battlefield reconnaissance or planetary exploration [6]. In some of these situations it is possible for a human operator to deploy the nodes of the WSN. But in disaster situations, or any

situation where human life could be endangered, it is necessary to use alternative methods of deployment, such as the use of mobile robots.

With this purpose in mind a testbed was used, which serves as a prototype for a WSN. The testbed used was composed of three different types of nodes: master, robot and static nodes. The master node is used so an end user can receive information from the network and send commands to any node. The static nodes serve as intermediate relays that connect the master node and the robot nodes. The robot nodes serve to extend the network, having mobility besides communication capabilities. The objective of this project is to create an extensible wireless network, using intermediate static nodes that connect a gateway to a moving robot node.

This document is organized as follows. Section I introduces WSNs and the goal of the project, Section II gives a review of related literature, with examples of similarly deployed WSNs. Section III describes the testbed and the libraries used for programming the nodes. Section IV describes the algorithms developed. Section V describes four scenarios used to evaluate the performance of the testbed with the described algorithms and the

169

results achieved. Section VI discusses these results and Section VII concludes the report and proposes future avenues of exploration.

2. Related Work

There has been prior work on the problem of "as-you-go" or impromptu deployment of a WSN. In [4] and [7] are proposed algorithms for "as-you-go" deployment, in which an agent, human or robot, measures link quality at equally spaced intervals and makes placement decisions, while only moving forward along a line.

Some works consider a purely autonomous deployment of a WSN by mobile robots. In [6] is explored autonomous deployment of a WSN with the goal of human detection, in case of disaster situations, in which mobile robots perform simultaneous localization and mapping. In [5] mobile robots carry sensor nodes and measure the RSSI, to know when to deploy sensor nodes to ensure communication or restore the network.

Many of the proposed systems measure link quality, using communication metrics like RSSI or Packet Reception Ratio, and decide when to deploy a new relay when the metric satisfies predefined rules. In [8] such a system is used for dynamic deployment of a WSN through a breadcrumb system for firefighters. A breadcrumb dispenser is worn by firefighters and a link estimator uses the previous mentioned metrics to decide when to deploy breadcrumbs.

Works such as [9] also make use of mobile robots to deploy a WSN but focus on how these robots can help with problems such as coverage holes or collection of redundant sensors. They achieve this by using permanent grid-based deployment, with cluster concepts to reduce packets used in creating and maintaining the grid structure. Furthermore, they consider the communication range to be at least twice of the sensing range.

Cooperation between multiple agents is seen as an important problem to be explored. In [4] and [7] it is pointed the need for algorithms where two or more robots cooperate to deploy a WSN. While [6] calls for field test using two mobile robots and to address the communication issues that arise from coordination between multiple robots. These and more issues of multi-robot systems, such as reduction in network traffic, routing approaches and sensor data processing are pointed as areas that need appropriate operational methods by [5]. The study of communication metrics, such as RSSI, in various environments, to allow setting different parameters that could optimize the system, is called for by [8].

In the present study the aim is to use the communication metric of RSSI to know when a new node should be deployed and integrate this metric with cooperation between two mobile robot nodes. The RSSI metric has been used in studies such [10], [11] and [12] to locate the robot nodes, triangulating the robot node and static nodes for navigation and helping the robot node avoid obstacles and reach a goal. But these approaches require that the static nodes be placed before the robot node starts its action, and to locate the robot need a lot of deployed static nodes. The proposal presented in this paper gives a different approach to this problematic by promoting the static nodes deployment using

mobile robots. The RSSI value was used to decide the positions to deploy static nodes.

3. Wireless Sensor Network Robot Path Construction Proposal

The goal of this project was to build a prototype of autonomous WSN deployment by a mobile robot. In light of literature requests, it was decided to consider two mobile robots and develop algorithms that ensure the coordination between them as the WSN is deployed. In order to build an extensible network, it is necessary for the robots not only to cooperate each other but also respond to the deployment of static nodes. Using static nodes allows to maintain communication between mobile robots and gateway even when the mobile robots leave the network coverage area of gateway.

In this section firstly will be described the hardware used to create the testbed, namely the master node, robot nodes and static nodes. Then will be described the libraries and methods used to achieve the WSN behavior and obtain a communication metric from each node, the RSSI. The RSSI metric was considered due to the limited resources of the hardware platform used.
Figure 1: Photo of Master Node connected to a laptop.

3.1. Hardware Description

As mentioned before three types of nodes were used: a master node, static nodes and robot nodes. Master node and static nodes are composed by D1 mini pro boards with a wireless antenna Wi-Fi ESP8266, and a power supply. In the case of the master node the power supply was the PC it was connected to, in the case of static nodes a power banks were used.

Figure 1 is a photo of the master node used, connected to a laptop where the end user could send commands and received information from the network. Figure 2 is a photo of a static node used, which served the purpose of acting as a relay and extending the network.

The robot nodes were two wheeled mobile robots composed by a NodeMCU 1.0 board also with an ESP8266 module, a L293 Motor Driver Shield, two rubber wheels with Micro DC geared motors and a power bank, that served as a power supply. The

robots are completely similar in terms of hardware with just small differences in how the boards were mounted as can be seen in Figure 3 and Figure 4, which are photos of the first and second Robot Nodes used respectively.

Figure 2: Photo of a Static Node.
Figure 3: Photo of the first Robot Node used.
Figure 4: Photo of the second Robot Node used.

All the boards in each node were programmed using the Arduino programming language and respective Arduino IDE. The Arduino programming language makes use of two functions that are always present: setup and loop. Setup runs once when the board is connected to an energy supply. Loop runs continually after the setup, as long the board is connected to an energy supply. Future mentions to setup and loop, while explaining the code, refer to these two functions. The robots need to perform several tasks periodically, such as measuring the RSSI or moving. To achieve this behavior the Task Scheduler library was used.

3.2. Wireless Sensor Network Implementation

To manage creation of the wireless sensor network and communication between nodes the *painlessMesh* library was used [13]. This library uses the esp8266 hardware present in the boards to create a mesh network. The *painlessMesh* library does not use the Arduino WiFi libraries, due to performance problems, but the native esp8266 libraries [13]. The library allows us to make the nodes to communicate with each other, in a prototype of a WSN, without concern about how to structure or manage the network. The great advantage of using this library is that any operational nodes will automatically self-organize into a functional mesh network.

The messages between nodes are all JSON objects, which makes them human readable and facilitates integration with frontends and other applications. The mesh does not use or create a TCP/IP network, rather each node is identified by a 32bit chipId obtained through the esp8266 native SDK. As a result, every node will have a unique id, that can be used to communicate specifically to that node. Broadcast messages to all nodes in the mesh are also possible [13].

Some functions of the library are used in the setup of every node, namely init, which initializes the mesh, and the functions that set up callbacks, such as *onReceive(&receivedCallback)* and *onNewConnection(&newConnectionCallback)*. The functions given as arguments: *receivedCallback* and *newConnectionCallback*, are present in every node as well. They execute when a message is received by the node and when a new node connected to the network, respectively.

Other functions used at setup are *setRoot* for the master node and *setContainsRoot*, for all others. The purpose of these is to avoid the creation of submeshes during mesh formation. It makes sure all nodes know the gateway is the master node and a node once connected to the master node will not disconnect. This is necessary because of a limitation during mesh formation, namely that each node can only connect to another one node at any given moment. Because of this, nodes will try to randomly connect and disconnect until a full mesh is formed. This solution works but may create submeshes. The functions above aim to solve this problem. Another consequence of the "each node can only connect to one other node at a time" will be that usually only node of the mesh will be available to connect to other nodes.

A library function used in the loop of every node is the function update, which runs maintenance tasks and is required for the mesh to work. In the master node it is also used the *subConnectionJson* function, which allows to print the mesh topology in JSON format. All nodes use the *sendSingle* and

sendBroacast functions. The former allows to send a message to a node using its chipId, the latter sends a message to all nodes in the mesh.

Task Scheduler

The Task Scheduler library allows for periodic task execution. It is possible to specify execution period, in milliseconds or microseconds, and number of iterations, be they finite or infinite. The reason for needing to use this library is that the boards used cannot launch several threads at a time, hence cannot multitask with recurring to external libraries.

It works by first creating a scheduler using the Scheduler class. Then creating tasks using the Task class, and specifying the execution period, number of iterations and the actual function that will define the task behavior. Then at setup each task is added to the scheduler. From there on it is possible to enable or disable tasks as required [14]. The two main tasks used by the robot nodes are the RSSI Task and the Moving Robot Task.

The RSSI Task's main purpose is to measure the RSSI value. It will always do this if the scan for Wi-Fi networks is successful. Then depending on flags active it might just send this value to the master node or check if this value is lesser or equal to the RSSI threshold. If it is smaller, meaning more negative because the RSSI value is usually a negative integer, then it will send the RSSI value to the master node along with a request to place a new node. If the RSSI value is not smaller the robot can move further, and so it will call the appropriate movement function, disable the RSSI task and enable the Robot Moving task.

The Robot Moving Task's main purpose is to time the movement of the robot and send the RSSI value to the master node once a movement is finished. It is also used to create the robot node auto movement, as will be explained below.

The RSSI value is the most important metric in the prototype because it is based on it that the robot nodes will decide when a new node should be placed. Therefore, it regulates the extension of the WSN. It will also be used later both in the cooperation between robot nodes and in their response to deployment of new static nodes.

RSSI Request

It is useful to measure the value of the RSSI to understand how it changes, particularly due to growing distance from the master node. With this purpose in mind was created a way to simply have the master node send a request to a robot node and have the robot measure the RSSI and send its value back to the master node, to be printed and made available to the user.

The laptop connected master node expects user info from the serial monitor of the Arduino IDE. If the input received is the, case insensitive, string "RSSI" it will send a RSSI Request to all nodes. This request is simply a message that will prompt each node to enable the RSSI Task, which will make it measure the RSSI value, and then send this value back to the master node. The master node will print the value and an identifier of the node that sent it. Algorithm 1 represents the algorithm behind RSSI requests.

In terms of number of messages exchanged within the network, they are at least $2 * (n - 1)$, where n is the total number of nodes in the network. The reason for this number is that the master node will send a broadcast message upon being prompted by the user with an RSSI Request, so it will send a message to all nodes except itself, $n - 1$. Every node will then measure the RSSI and respond to the master node, so this number is doubled. Depending on the extension of the network this number will increase because the message may need to hop between nodes before reaching the master node.

Algorithm 1: RSSI Request

Result: The Master Node will print the RSSI values for all nodes in the network in its serial monitor

Initialization;

while *Master Node on* **do**
    Expects user input;
    if *User input = RSSI* **then**
        Send RSSI
        Request;
        Nodes send
        RSSI values;
        Print RSSI
        values;
    end
end

---

4. Testbed Deployment

With the testbed ready it is possible to start developing algorithms that will create us a prototype for an autonomous, extensible WSN. With this in mind, firstly it is necessary to develop ways of having the robot node move on its own and request new nodes for the network once a RSSI threshold is hit, which was called *AutoMOV*. Furthermore, ways of having two robot nodes cooperate with each other, to further extend the WSN, were developed, which was called *RCoop*. Finally, there was a need to develop ways for the robot nodes to know when a new static node was deployed and respond accordingly, extending the network if possible, which was called *ReStatic*. In this section the aim is to present each of these algorithms and explain how they were implemented using the testbed.

4.1. Automovement Algorithm (AutoMOV)

In the first implementation of the WSN prototype the robot node moved by commands sent from the master node by user input. But the goal was autonomous movement and deployment of an extensible WSN. To achieve this the robot nodes need to move autonomously, not prompted by user input, so an algorithm for robot node automovement was developed, hereinafter referred to as *AutoMOV*. All movement at this point occurs along a line.

An auto movement request is made if the Master Node catches a string that starts with 'A' or 'M'. This calls the function *AutoMOVRequest*. This function will print if the request is to start auto movement (A) or to stop auto movement and go back to manual (M). It will also send the given string to the robot node by method *sendMessage*. The method *sendMessage* uses the communication functions from the Painless Mesh library,

sendSingle or *sendBroadcast*, but with arguments to choose between them.

The robot node responds to this *sendMessage* with the callback routine *receivedCallback*. In the case of 'A' it will turn the movement type to 'F', which will make the robot move forward, this is the case because all movement occurs along a line at this point. Later it should decide the movement type based on sensor information.

It will also activate an *AutoMOV* flag and enable the RSSI Task. In the case of 'M' it turns off the *AutoMOV* flag and stops movement.

Algorithm 2: Automovement (*AutoMOV*)

Result: Robot Node performs discrete movement until it hits its RSSI Threshold
Initialization;
while *Master Node on* **do**
    Master Node expects input
    if *User input = M* **do**
        AutoMOV Stop Request;
        Robot Node stops;
    else if *User input = A* **do**
        AutoMOV Start Request;
        while *Current RSSI <= RSSI Threshol*d **do**
            Robot moves;
        end
    end
end

The RSSI Task will then be responsible for making the robot always move unless the current RSSI is equal or below the threshold, which would make *AutoMOV* stop and the robot node to send a request to the master node, for placement a new static node. Otherwise it enables the Moving Robot Task. This last task has an extra 'if', to deal with auto movement, that basically says: if one movement was completed and the *AutoMOV* flag is on, then it will enable the RSSI Task again. This creates a loop between the two tasks. Algorithm 2 represents the algorithm behind *AutoMOV* requests.

4.2. Robot Cooperation Algorithm (RCoop)

Coordination between multiple robots, cooperating in deployment or exploration, is seen as an important concern by current WSN literature [3-6]. With this purpose in mind there is a necessity for algorithms that allow multiple robots to cooperate and for field tests involving more than one robot [4][6][7].

The goal then was to develop an algorithm that allows two robots to cooperate in a prototype of WSN deployment based on communication metrics, namely the RSSI. Hereinafter this algorithm will be referred as *RCoop*.

The two robot nodes were named Robot One (R1) and Robot Two (R2) to help differentiate between them. The only real distinction between robot nodes is that R1 will be the first to move. All movement described occurs along a line.

R1 will be sent a signal from the user and start movement. Each robot movement is time limited to ten seconds. After these ten seconds of movement it will measure the RSSI and based on

this value decide to stop or move again. While the RSSI is above a certain threshold it will continue to perform discrete ten second movements. If the RSSI is found below the threshold it will stop, ask for the deployment of a static node and send a message to R2. Deployment of static nodes is done by human agents at this point. The reaction of robot nodes to the deployment of static nodes will discussed later. Here the main concern is about how the robots can cooperate.

R2 after receiving the message from R1 will know the first robot has reached the RSSI threshold and so commence its own movement. The message sent by R1 basically functions as R1 'calling' R2. R2 will mimic the behavior of R1 and move until it has reached the RSSI threshold. When R2 reaches the threshold, it will send a message to R1. This will prompt R1 to update its own threshold and start moving again. The goal here is to extend the network as much as possible using the two robot nodes.

The way this works in terms of code is that R1 will first be sent an *AutoMOV* request by the master node. It will normally follow *AutoMOV* until the threshold is reached. When it reaches the threshold, it will call *AutoMOVRequest*, which will send a message to R2. R2 will expect a message with this format via the callback routine *receivedCallback* and will activate its own *AutoMOV* because of it. R2 will then perform *AutoMOV*, as explained above, until it reaches its threshold. When at the threshold will send a message to R1 via *sendMessage*, informing it R2 is at the threshold. R1 will then decrement the *rssiThreshold* variable and turn its *AutoMOV* own again, and so move further until it reaches the new threshold value. Algorithm 3 represents the algorithm that deals with robot cooperation (*RCoop*).

Algorithm 3: Robot Cooperation (*RCoop*)

Result: The two robots will extend the network
Initialization;
R1 *AutoMOV*;
if *R1 RSSI <= RSSI Threshold* **do**
    R2 *AutoMOV*;
    if *R2 RSSI <= RSSI Threshold* **do**
        R1 expands Threshold;
        R1 *AutoMOV*;
    end
end

4.3. Response to Static Nodes Algorithm (ReStatic)

The other thing that is required to attain the goal of having an extensible WSN is that the network responds autonomously to the deployment of static nodes. To elicit this behavior, a communication metric is used again, the RSSI.

When a static node is placed it connects to the network normally, then it will measure its RSSI. It will send this value to the mobile robots connected. Then each robot will use this value to decide whether it should start movement or not. This decision is based on if the difference between its own RSSI and the static node RSSI is lesser than the value of the RSSI threshold. If the difference between RSSIs is lesser than the threshold then it means the static node is closer to the master node and hence the network can be safely extended, so the robot will move.

But if a new node connects it usually will connect as a subnode to the nodes already there, so how to solve this problem? The answer was to force a reorganization of the network. If the robot concludes by the above described method that the static node is closer to the master node then, before it initiates movement, it will reset its own board. The result of this is that when the robot reconnects to the network it will now be a subnode of the newest static node in the network topology. The value of the robot's threshold is saved in the master node, via a message sent by the robot before it resets. When the robot node reconnects the master node sends this value to the robot again, the later will update its threshold and reinitiate movement.

In terms of code this is achieved by using the RSSI Task in the static nodes as well. It will activate and measure the RSSI value as soon as the static node is turned on. Then it will send this value to the master node which will in turn send it to the robot nodes, via *sendMessage*. As usual the way to prompt behavior in a certain node, the node is made to expect a string formatted a certain way, via the *receivedCallback*, and if that string is received the desired behavior occurs. So, in that same way, when the robot nodes received the value of RSSI prefixed with the string "(mesh node)" they will first extract the RSSI value from that string. Then, they will check if the deployed static node can be considered closer to the master node, calculating if the difference between their RSSI value and the RSSI value of the static node is greater than their RSSI threshold (*currentRSSI - meshRssi > rssiThreshold*). If so, the robot node will expand its threshold and send it to the master node. The master node will save this value and send a message back to the robot node signaling the robot can now restart, with the purpose explained above. The robot node will then restart by esp8266 native function, *ESP.restart*, which will restart the board. The master node will expect a robot node connection via the *newConnectionCallback*, which is a callback routine that executes each time a new node connects the network. In case there is a saved RSSI threshold value for the robot node that connected then it will send this value to the robot that just connected. The robot will use this value to update its threshold and turn the *AutoMOV* on, thus extending the network. Algorithm 4 represents the response to static nodes algorithm described above. This algorithm will be known as *ReStatic*.

Algorithm 4: Response to Static Nodes (*ReStatic*)

Result: Robot Nodes extend network if possible
Initialization;
Static Node Deployed;
Send RSSI to Robot Nodes;
if *RSSI – Static RSSI > Threshold* **do**
  Expands Threshold and save it;
  Robot Node reset;
  Robot Node receives threshold;
  Robot Node *AutoMOV*;
end

---

5. Performance Evaluation

It was then time to put the algorithms to test to verify if the intended behavior of an extensible WSN could be achieved, take measurements, find potential faults or avenues for improvement. For these purposes four scenarios were developed, each progressively testing each one of the developed algorithms, first

separately, then in conjunction. As the presented work is still in its initial proposal, some RSSI issues were considered out of the scope. All demonstration scenarios considered an open space area with no obstacles and, as much as possible, a linear variation of RSSI.

The measurements were conducted in an open space indoor area. The master node was connected to a laptop via the USB port and will collect RSSI data. The laptop is placed on a wooden support that measures 31 cm in height. Time and distance are collected by the testers, while RSSI values are registered by the master node.

Firstly, it was important to study the variation of RSSI based on the distance between a robot node and a master node. This would serve to understand how it naturally variates without accounting for any robot node movement and illustrate the relationship between distance and the RSSI value. It makes use of and proves the functionality of the RSSI Request.

The robot node was placed at several distances of separation to the master node, always one meter apart from 0m to 13m. At each distance, the user would elicit the RSSI value through RSSI Request. After collecting ten samples at that distance of separation an RSSI average was calculated. Figure 5 shows the RSSI averages for the various distances of separation to the master node.
Figure 5: Robot Node RSSI variation with distance from the Master Node.

5.1. Scenario 1: One Robot Node

This first scenario intends to verify how much it was possible to extend the network simply using two nodes: the master node and a robot node. It will also illustrate the functionality of the robot node *AutoMOV* algorithm.

The robot node is place on the floor at a 0 meters distance from the master node. It will be sent a signal from the master node which will start the *AutoMOV*. Then, the robot node will perform discrete 10 second movements along a line while measuring the RSSI. When its current RSSI value is below a certain threshold it will stop and request the placement of a new static node. Figure 6 represents the end state for this scenario.
Figure 6: End state for Scenario 1 composed of Master Node and a Robot Node.

After ten trials an average of the values of time since *AutoMOV* started till robot node stoppage, distance traversed by robot node and last RSSI recorded is calculated. Table 1 holds the recorded values for this first testing using a robot node.

Table 1: Averages of time, distance and RSSI for 1 Master Node 1 Robot Node.

Time	54''
Distance	4m 83cm
RSSI	-68 dB

5.2. Scenario 2: Two Robot Nodes

The second scenario intends to extend the WSN using two robot nodes. This scenario uses two robot nodes and the master node and is meant to demonstrate the functioning of the *RCoop* algorithm.

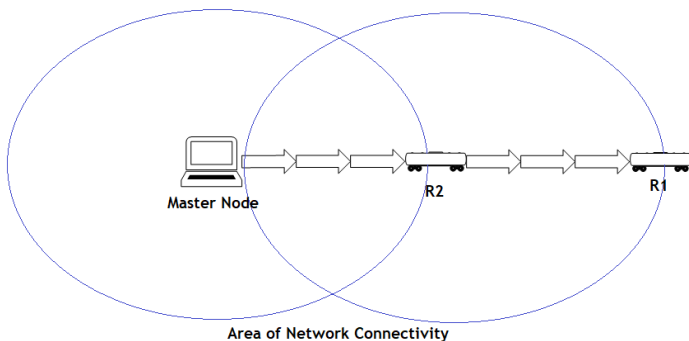
Both robot nodes are placed next to one another at a 0m distance from the master node. Then the user enters 'A' into the serial monitor of the master node in the Arduino IDE. This is the signal that will set the *AutoMOV* of robot node named R1 on. All other network extending behavior is autonomous. Figure 7 represents the end state for this scenario.


Figure 7: End state for Scenario 2 composed of Master Node and two Robot Nodes.

The last RSSI values of both R1 and R2 are recorded by the master node. The distance of both robot nodes to the master node after both robot nodes stop is recorded. The duration from the time the signal is sent until both robot nodes stop is also recorded. After ten trials an average of RSSI, distance and time was calculated.

Table 2 holds the recorded values for this first test with the two robot nodes.

Table 2: Averages of time, distances and RSSIs for 1 Master Node, 2 Robot Nodes.

Time	3' 01''
R1 Distance	7m 12cm
R2 Distance	5m 11cm
R1 RSSI	-71 dB
R2 RSSI	-64 dB

5.3. Scenario 3: One Robot Node, One Static Node

This third scenario intends to extend the WSN, by guaranteeing the robot nodes will respond to the deployment of new static nodes. So, it serves to test the functionality of the *ReStatic* algorithm. It does so by using the master node, one static node and only one robot node.

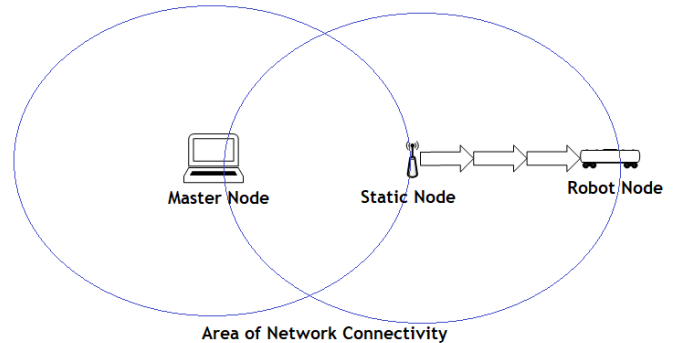
The robot node will be placed at a 0m distance from the master node. Robot node *AutoMOV* will be turned on by user input and then it will move until it reaches its RSSI threshold. Then, a static node will be place at this threshold. The robot node will respond to this placement autonomously and move again till it reaches a new threshold, extending the network. Figure 8 represents the end state for this scenario.


Figure 8: End state for Scenario 3 composed of Master Node, a Static Node and a Robot Node.

The last RSSI value before robot node stoppage is recorded by the master node. Time until robot node stoppage and maximum distance from static node are recorded by human users. After ten trails an average of these values is calculated. Table 3 holds the values for this first test that uses a static node.

Table 3: Averages of time, distance and RSSI for 1 Master Node, 1 Robot Nodes, 1 Static Node.

Time	3' 40''
Distance	7m 1cm
RSSI	-73 dB

5.4. Scenario 4: Two Robot Nodes, One Static Node

Finally, the fourth scenario allies the *RCoop* algorithms and the static node response algorithm. For this last scenario a master node, two robot nodes and one static were used.
Figure 9: End state for Scenario 4 composed of Master Node, a Static Node and two Robot Nodes.

The procedure is similar to the two robot nodes test except that a static node is place at the R2 threshold when both robot nodes and stopped. So, both robot nodes are placed at 0m distance from the master node. A signal is sent to R1 by the user from the master node. Then, robot node *AutoMOV* and *RCoop* occur autonomously. Finally, a static node is placed at the R2 threshold and the robots will identify it and move again to new thresholds. Figure 9 represents the end state for this scenario.

The last RSSI values before robot node stoppage for both robot nodes are recorded by the master node. The time from signal sent to R1 till the network stops extending is recorded by a tester. Final distances of each robot node to the master node are also recorded by a tester. After ten trials an average of RSSIs, distances and time was calculated. Table 4 holds the values for this final test that incorporates all the node types: master node, robot node and static node.

Table 4: Averages of time, distances and RSSIs for 1 Master Node, 2 Robot Nodes, 1 Static Node.

Time	4' 33''
R1 Distance	11m 50cm
R2 Distance	6m 76cm
R1 RSSI	-82 dB
R2 RSSI	-71 dB

6. Discussion

First, it is important to have an idea of how to expect the RSSI to change with growing distance from the master node, this is the purpose of the RSSI – distance test. It is expectable that RSSI value decreases with distance from the master node, seeing as at 0m the RSSI value is -34dB and at 13m distance the RSSI is -84m. But this variation is not linear, so it must be assumed that there are other factors contributing to RSSI change besides distance.

Distance reached by the robot nodes is a key factor in knowing if the purpose of the algorithms was fulfilled and the WSN is extending. If only the number of nodes used is considered, it is expected the distance from the master node will increase with the increase in the number of nodes used, as the WSN can extend itself further. In this case the one robot test would give us the least distance, with just one node used, and the two robot nodes and one static node test would give us the furthest distance, with three nodes used. Figure 10 shows us the distances obtained according to the numbers of nodes used. It is then

verified that the network is extending itself through the programmed behavior of the robot nodes.

Time was considered of less importance at this point in testing. Still it is noted a big increase, going from an average 54 seconds with one node to 4 minutes 33 seconds with three nodes. The way of reorganizing the mesh network, by resetting a robot node when a suitable static node is detected, should be reviewed. The current solution causes a lot of overhead.

Using a communication metric such as the RSSI gives rise to some problems. First off, must be said that when considering the RSSI threshold as the point where a robot node should stop and request a static node, this is a virtual limit. It is not exploring the actual hardware limit of the communication module, the wireless antenna Wi-Fi ESP8266. Explorations on RSSI variations using ESP8266 modules have used distances of up to 140m between a station and an AP and still reach acceptable values for RSSI [15]. These experiments were performed outdoors whereas the ones here were indoors, but they give an idea of the distances that could be reached if the limits of the hardware were explored. The aim here however was to develop algorithms that could generate the intended behavior on the prototype, namely the creation of an extensible WSN. Although it is legitimate to consider that testing the present proposal at the hardware limits would be interesting and closer to a live deployment scenario.
Figure 10: Variation of distance from the Master Node with number of nodes used in the WSN.

Finally, it is important to consider how the problems in expanding the RSSI threshold to make the robot nodes move further. Firstly, there is a need to find a better way to judge the distance of the static nodes when deployed. Deployment of several static nodes in proximity, or the same static node disconnecting from the network and then connecting again, might impress false information on the robot node, prompting it several times to move further. Secondly, saving the current threshold of the robot nodes in the master node when it resets could be problematic if the robot node disconnects from the network more than one time. This problem also arises from the method of reorganizing the network through resets of robot nodes. Even as it stands there might be a better way for the robot node to judge its threshold from the network topology and its own RSSI measurements, instead of receiving it from the master node.

7. Conclusion and Future Work

WSNs are ever more prevalent in modern living. Many applications, such as in disaster situations, require impromptu deployment of a WSN. Therefore, it is important to explore ways of WSN deployment. The usage of mobile robots to aid in this development is also important because it avoids the necessity of human agents. Coordination between mobile robots is essential in deployment and exploration tasks.

With this in mind a prototype of a WSN aimed at creating an extensible wireless network and proved it possible, within certain assumptions, using cooperation between mobile robots and responsiveness to the deployment of static nodes.

As for future work it should be interesting to test the solution proposed here with the actual hardware limits of the ESP8266 wireless module. Also, there is a need to develop a better way to manage network connections, even if that means foregoing the *painlessMesh* library and using the native ESP8266 SDK. Within the solution here, a better way to manage the RSSI thresholds of the robot nodes might also be a good avenue for new developments. Testing the WSN prototype with sensors able to capture environmental data would also prove interesting and open new avenues of exploring, such as how to effectively route sensing data.

Conflict of Interest

The authors declare no conflict of interest.

A B S T R A C T

Empathy in the care of the patient by the nursing students is important because it allows having the capacity of response towards the patient, this study aimed to determine the level of empathy in nursing students who attend in clinical practices of the Universidad de Ciencias y Humanidades. This is a cross-sectional study, with a population of 289 nursing students who answered a questionnaire and the Jefferson medical empathy scale. 210 participants (72.7%) had a medium level of empathy, 74 participants (25.6%) with a high level of empathy and 5 participants (1.7%) with a low level of empathy. Regarding the empathy dimensions, the high level in the perspective taking dimension predominated with 81.7%, followed by the average level of the capacity dimension to put oneself in the patient's place with 59.9% and the compassionate care dimension predominated in the low level with a percentage of 45%. An improvement program is required in terms of professional training so that nursing students can carry out compassionate care when performing their clinical practices.

1. Introduction

Empathy in patient care for nursing students is a cognitive attribute that implies the ability to understand pain, suffering and the patient's perspective, it is the ability to stablish this understanding and the intention to help [1].

Nursing students must be empathetic and this is governed based on their behavior, this will be influenced in the well-being of themselves and also of the patient [2].

Empathy depends on the personality and functional characteristics of the nurse so that the nursing student has a good performance in their study plan [3]. Therefore, there are numerous exploration methods that have been designed in educational programs to improve empathy [4]. In addition, empathy is attributed to factors that influence the nursing student such as interpersonal relationships, self-esteem, communication, and self-efficacy [5].

In [6], the authors explain a study carried out in Spain, it was found that technological advance acts on empathy in nursing

professionals, leading to a lack of interest in interaction with patients.

In [7], the authors presented a study carried out in Venezuela, it was observed in the results that 90.1% of the nursing students were women and those who obtained a higher score in level of empathy.

In [8], the authors described a study carried out in Canada, they stated in their results that the instructional and practice sessions increased students' self-awareness about prejudices and interest in learning empathy through video tag feedback.

This study is important since it will give relevant and real data about empathy as students go in their academic plan and, observe if they can have an empathetic attitude when they carry out their activities in the clinical practical field.

The following research work is structured as follows: In section II, the development of the data collection process of each nursing student will be presented, as well as the guidelines to consider so that they are within the research work. In section III, the results will show the level of empathy that nursing students

178

will present according to the specified dimensions of the instrument in the measurement of the variable. In section IV, it presents the discussions of the research work, in section V, the conclusions and in section VI the recommendations as well as the future work that is intended to come with the research work.

2. Methodology

2.1. Materials and Methods

In this part, the type and design of the research will be developed, as well as the population and sample that will be carried out in the research work, the inclusion and exclusion criteria in detail and finally the technique and the instrument of collection of data.

2.2. Research type and Design

It is a study with a quantitative approach, a non-experimental, descriptive and cross-sectional design [9].

2.3. Population

The population was 289 nursing students from the Universidad de Ciencias y Humanidades.

2.3.1. Inclusion Criteria

Nursing students who are in the third semester until the eighth semester and who have signed the informed consent that was evaluated and approved by the ethics committee of the Universidad de Ciencias y Humanidades.

2.4. Technique and Instrument

In the study, the data collection instrument Escala de Empatía Médica de Jefferson (EEMJ) from Hojat Mohammandreza was applied, which has been demonstrated to be useful in assessing level of empathy in nursing students.

The JSE instrument is a shortened and derived tool of the Escala de Empatía Médica de Jefferson, which consists of 20 questions developed in parallel in more than 85 countries and translated into 56 languages.

To measure empathy, the instrument Escala de Empatía Médica de Jefferson (EEMJ) from Hojat Mohammandreza, which includes 20 items grouped in 3 dimensions, will be used: perspective taking, compassionate care and ability to put oneself in the patient's place where they are governed by the high, medium, and low levels according to the instrument manual. The answers will have two significant frames for each of the items, if it disagrees it is 0 and if there is agreement it is valued at 7, with a variation score of 20 to 140. Between 20 to 60 refers to low empathy, of 61 to 100 refers to medium empathy and 101 to 140 refers to high empathy [10].

2.5. Place and Application of the Instrument

The questionnaire was carried out in two consecutive schedules, morning, and night at the same time as the nursing students who practice at the university, the questionnaire was taken to the nursing students with an approximate time of 15

minutes each selected semester (III semester to VIII semester according to inclusion criteria) in the research work, concluding with good satisfaction when collecting the questionnaires as the students provided support to carry out the research work.

The data collection was processed through the survey of nursing students, the data was carried out in a data matrix that will be designed in the statistical program SPSS (Statistical Package for the Social Sciences) in its version 24.0, in which it will allow a better data processing to make statistical tables and graphs so that they can then be described and interpreted in results and discussions, respectively.

It is important to emphasize the presence of medical personnel at the time of completing the student questionnaire, since most of them presented signs of having a health problem.

3. Results

Regarding empathy in nursing students who carry out pre-professional practices at the Universidad de Ciencias y Humanidades it can see that 210 participants represent 72.7% with a medium level of empathy, followed by 74 participants who represent 25.6% with a high level of empathy and 5 participants representing 1.7% with a low level of empathy.

Table 1: Level of Empathy in Nursing Students attending Clinical Practices of the Universidad de Ciencias y Humanidades, 2019 (N = 289)

Empathy					
		Fre que ncy	Perce ntage	Valid percenta ge	Accumul ated percenta ge
V a li d	Low	5	1,7	1,7	1,7
	Mediu m	210	72,7	72,7	74,4
	High	74	25,6	25,6	100,0
	Total	289	100,0	100,0	

These results indicate that the students present a medium empathy, because many of them possess skills that would demonstrate high empathy, however, they have the difficulty of expressing or manifesting what another person may experience, in which they cannot to be developed without having the adequate knowledge, for this, they seek solutions either at an academic or practical level in which they can complement that space, in order to be able to develop their skills and have the greatest capacity for evaluation in what another person may experience.

In the Figure 1 shown, the results regarding the dimensions of empathy are evidenced according to the data based on the research instrument:

In Figure 1, it can see the empathy according to its dimensions, in nursing students who attend clinical practices of the Universidad de Ciencias y Humanidades, where the dimension most affected was the compassionate care where 130 students representing 45% have low empathy. This dimension has been the most affected, although it is true it is related to patient care, however, it has been proven that the same patients

attribute that their care is not adequate, that they are not provided with compassionate care, for the Nursing students, this dimension assumes an important role due to the fact that the students are in full training, that compassionate care is very important, for this, education at an academic or practical level, it is necessary to distinguish a very important role on compassion, due to this fundamental role is being lost in nursing students due to the lack of interventions on understanding compassionate care for the patient.
Figure 1: Empathy according to its dimensions, in nursing students attending clinical practices at the Universidad de Ciencias y Humanidades, 2019 (N = 289).

Table 2: Empathy in relation to the Semester of study of Nursing Students who attend in clinical practices of the Universidad de Ciencias y Humanidades, 2019 (N = 289)

			Empathy			Total
			Low	Medium	High	
STUDY SEMESTER	III	Count	0	61	16	77
	SEMESTER	% within the Semester	0,0%	79,2%	20,8%	100,0%
	IV	Count	3	25	9	37
	SEMESTER	% within the Semester	8,1%	67,6%	24,3%	100,0%
	V	Count	0	47	10	57
	SEMESTER	% within the Semester	0,0%	82,5%	17,5%	100,0%
	VI	Count	0	34	16	50
	SEMESTER	% within the Semester	0,0%	68,0%	32,0%	100,0%
	VII	Count	1	28	9	38
	SEMESTER	% within the Semester	2,6%	73,7%	23,7%	100,0%
	VIII	Count	1	15	14	30
	SEMESTER	% within the Semester	3,3%	50,0%	46,7%	100,0%
Total		Count	5	210	74	289
		% within the Semester	1,7%	72,7%	25,6%	100,0%
Chi-square tests						

	Value	gl	Asymptotic significance (bilateral)
Pearson's Chi-square	24,344[a]	10	,007
Likelihood ratio	22,625	10	,012
Linear by linear association	4,130	1	,042
N°. of valid cases	289		

a. 6 cells (33.3%) have expected a count less than 5. The minimum expected count is .52.

In Table II, empathy is related to the semester of study of nursing students, in which it was determined with the Pearson chi-square test (X^2), the level of significance of the test obtained a value of 0.52 (p> 0.05) (X^2 = 24.344; df = 10). Therefore, a hypothesis of association between variables is not rejected, thus proving that there is a relationship between empathy and the semester of study of nursing students.

4. Discussion

In this study, we raise the issue of empathy is raised from the point of view of professional nursing training, where the level of empathy in nursing students who attend clinical practices at the Universidad de Ciencias y Humanidades, 2019 is assessed.

Regarding the level of empathy in nursing students who attend clinical practices of the Universidad de Ciencias y Humanidades, 2019, the medium level predominated followed by the high and low. These results may be because students have difficulty being able to understand or feel what the other person is experiencing.

It should be noted that the previous research work on the Empathy study were of different sociodemographic characteristics, the study in [3], the author indicates that the results of empathy were given by the different characteristics such as sex, academic year, academic performance, where the female sex showed high levels of empathy. Where empathy can change as the student progresses in their study plan. In [7], the author mention that the decrease in empathy is influenced by the absence of good teachers, the increased pressure for activities, long hours of service and evaluations in students, can lead them away from feelings of human problems and have a lack of opportunities to manage their emotions. Given the aforementioned, the nursing student can be related to their emotions, although it is true that empathy is not only based on doing a good job but, the way that the emotions are going to be applied in this situation, it is very important to know that emotions have an important role in the students since they are in full formation and need the emotional maturity that allows them to perform humanized care, this means that it is not only enough to perform academically, because it would only enable their cognitive abilities, and to develop their emotional skills in a successful way, it is necessary to have training for it, so that the nursing students themselves carry out their humanized care at the time of carrying out their clinical practices.

Regarding the level of empathy in its dimension perspective taking in nursing students who attend clinical practices of the Universidad de Ciencias y Humanidades, 2019, the high level predominated followed by the medium and low. The perspective taking dimension refers to cognitive flexibility, understanding mood states, having good communication and interpersonal relationships with the patient. In [8], the author mentioned that students were concerned with learning about the process of conscious or consciously driven perspective taking and practicing self-awareness to help identify and then put aside biases and beliefs about health risk behaviors allowing better patient care. In [11], the authors indicate that empathy in a quality with great cognitive predominance, where understanding is more important. Since in this way, the patient's pain can be understood to show adequate communication and support, where the nurse-patient relationship will be strengthened. That is why having the ability to understand the patient's pain will be related to motivational factors in academic nursing training.

Regarding the level of empathy in its dimension compassionate care in nursing students who attend clinical practices at the Universidad de Ciencias y Humanidades, the low level prevailed followed by the medium and high levels, where this dimension was the most affected. The compassionate care dimension refers to the emotional states of others, literally feeling the person's pain. It originates from primitive parts of the brain that allow to feel quickly without thinking deeply. Compassion has global implications for nursing care. However, patients report that nurses do not provide compassionate care. Nursing education has been examined on the impact training can have on student compassion as there is a shortage of interventions aimed at teaching compassion to nursing students [12]. In [6], the authors mention the need for high empathic results, since emotional understanding is needed, listening to the patient's concerns so that it can alleviate its anguish thanks to the emotional expression of the nurse. That is why the study in [8], the authors indicated that the students said that it is important to listen to the stories of the patients, it was revealing as the stressors related to care and their impact on self-care. Patient feedback made it easier for students to better understand and take ownership of their risky health behavior.

Regarding the level of empathy in its dimension, ability to put yourself in the patient's place in nursing students who attend clinical practices of the Universidad de Ciencias y Humanidades, 2019, the medium level prevailed followed by the low and high. The dimension of putting yourself in the patient's place refers to feel not only how other people feel, but also to know what they need from you. It involves putting yourself in the other's shoes, examining issues from their perspective, trying to think and feel as the other would. Lack of communication produces a loss of

empathy and understanding between people, which translates into bad humor, fights, and an atmosphere of tension. Despite the burdens it has on the journey, it must not forget that others also have their own problems. Listening, dialoguing, understanding and helping are just some of the actions laden with value that can improve coexistence between people and allow to live in a more peaceful society [13].

Regarding the level of empathy in nursing students who attend clinical practices at the Universidad de Ciencias y Humanidades, 2019, studies carried out in [14], they concludes that women score significantly more than men in fantasy, empathic concern and personal discomfort.

In [15], the authors showed that women are more empathetic than men. This was attributed to an increased ability for perspective taking and compassionate attention, a situation that can be explained by social and biological factors. Among social factors, stereotypes attribute to women greater emotional sensitivity, concern for social aspects, a tendency to care for children and the elderly people, and greater ability to perceive feelings and non-verbal language.

In [7], they mentioned that the female sex has greater empathy than the male sex. This is due to the brain structure, where the nerve fibers between the two hemispheres perform better information transfer in communication and empathy, which occurs in the case of women. This would also explain the synchronization they have with the emotions expressed in non-verbal language with the patient.

The implementation of empathy education in the nursing professional training process brings good results. A systematic review in [16], titled "A systematic review of the effectiveness of empathy education for undergraduate nursing students," they indicate that in 23 studies of empathy education in undergraduate education in nursing, practical improvements in empathy were demonstrated. In all of them, interventions based on interview and experimental simulations were carried out, focusing on vulnerable patients.

5. Conclusions

It is concluded that the level of empathy in nursing students have been high, it could be specified that as students' progress academically, they tend to increase their empathy, depending on how the students can express themselves regarding their academic performance either theory or practical.

It is concluded that to have a high level of empathy, it is not only requires having a good academic ability, but also having a good ability to show emotions during clinical practices to provide self-confidence and gain the confidence of the patient during their care.

It is concluded that within the established dimensions of the research variable, in terms of the compassionate care dimension, an improvement program is required in terms of their professional training so that students can carry out compassionate care when performing their clinical practices.

As a future work, it is important to keep in mind that in universities there must be student nursing programs that allow them to benefit from their own empathic skills, so students could

choose to have more knowledge and, at the same time, express their emotions through methods that allow to feel safe and have confidence in themselves when performing their clinical practices so that they are able to resolve any situation in patient care.

6. Recommendations

Regarding empathy in nursing students who attend clinical practices of the Universidad de Ciencias y Humanidades, 2019, the medium level predominated, followed by the high and low. It is suggested to the university authorities that activities be established to encourage students to have a good comprehensive education, in which the student can be involved in various topics in which the student can develop socially.

Regarding the empathy dimensions in all of them, the high level prevailed in the perspective taking dimension, it is suggested to the university authorities that students be fostered capacities in which they can distinguish when carrying out their clinical practices.

Training with the knowledge that the students could get a positive interaction with the people who will provide their care, involving both the faculty and the health institutions in which they will carry out their clinical practices.

It is suggested that, in future studies, a relationship between other variables linked to empathy be involved or exist, so that this problem can be better understood.

It is suggested to develop studies with qualitative or mixed approaches to complement the understanding of empathy in nursing students.

Conflicts of Interest

The authors declare no conflict of interest.

A B S T R A C T

For many years, the most popular technique for Internet video streaming is hypertext transfer protocol-based adaptive streaming, known as HAS (HTTP Adaptive Streaming). However, a seamless viewing experience can not be just simply guaranteed by HAS only. In the management network, the adaptation of HAS copes with a huge challenge since client-driven schemes lead to unfair share of available bandwidth when multiple players request adaptive bitrates (i.e bandwidth) through a bottleneck network link. Each client's requesting to maximize its needed bandwidth leads to the competition of network resources. This causes great QoE (Quality of Experience) reduction in terms of main metrics for each player: fairness, efficiency, and stability. In this paper, we propose an integration scheme of bitrate adaptation and Software Defined Networking-based resource allocation that can improve the QoE of competing clients. Our experiments show that the proposed scheme increases at least 20% up to 124% in terms of QoE scores compared with some existing methods as well as gains smoother viewing experience than the solutions of the traditional Internet.

1 Introduction

Recently we have observed a huge volume of media content, especially high-definition videos over the Internet. According to the report from [1], video traffic is estimated to occupy around 82% of the overall Internet traffic by 2021. Although the quality of the Internet has been improved significantly thanks to the advanced technologies such as 4G, 5G and Fiber to the Home (FTTH), current technologies are not yet ready to provide sufficient Internet bandwidth for new multimedia types such as 360-degree Videos and 12K Videos. Those new types of multimedia cause an enormous portion of Internet traffic.

The quality of video streaming over the Internet have been enhanced by several approaches such as: Microsoft's Smooth Streaming, Real-time Transmission Protocol, Adobe's Adaptive Streaming, Apple's HTTP Live Streaming, and MPEG-DASH. Especially, with

MPEG-DASH, the vendor dependence on previously invented protocols were removed so as content providers can extend their services easily.

Based on this DASH standard emerged a number of solutions in which a source video is segmented into short segments of 2-10 seconds, each of which is encoded at a different bitrate resolution and level. During the playback, each client uses its bitrate adaptation logic to dynamically request and fetch desired encoded segments based on metrics such as average throughput and buffer occupancy. In the DASH technology, most of the current adaptive algorithms that decide the bitrate for the next downloaded segment are based on two parameters at the client side: throughput variation and buffer level. The buffer-based bitrate adaptation methods determine the bitrate mainly based on the characteristics of the buffer. These methods can also consider throughput, but the characteristics of the buffer are the preferred factors. Typically, buffers are divided into

multiple ranges, and for each of these ranges, different actions will be applied to determine the bitrate. Note that the specific buffer thresholds depend on the specific adaptation method. Typically, if the buffer level is high, the next segment will be selected with a higher bitrate than the current segment. If the buffer level is average, the selected bitrate will not be too different from the current bitrate. On the contrary, if the buffer level is low, the next segment will be selected with a low bitrate to avoid rebuffering and video freezes.

In addition, throughput-based methods are only based on estimated throughput to define a bitrate for the next segment. The main difference between these types of algorithms is the way for estimating throughput and how to utilize throughput. The simplest way to determine the throughput is based on the ratio of the given segment duration over the download time. The segment delivery time is determined from the time of sending a HTTP request to the time of receiving a HTTP response message that contains that segment.

On the other hand, Software-Defined Networking (SDN) [2] has emerged as a new networking paradigm in which a SDN Controller can make network management more flexibly by eliminating proprietary protocols from hardware vendors. With the network control plane implemented in software, rather than in firmware, network traffic can be managed more dynamically and at a more granular level. SDN switches/routers send and receive information to and from the SDN controller via southbound APIs; and the SDN controller relays information to the applications and business logic via northbound APIs. Within the scope of SDN, the OpenFlow Controller [3] is a type of SDN Controller that uses the OpenFlow protocol to configure SDN switches.

In any network exists always a popular issue called bottleneck link that could be congested when the amount of bandwidth demands go beyond the bottleneck link capacity. In case of bottleneck, video streams for each resource-sharing users could experience a remarkable decrease in perception of the video service, called Quality of Experience (QoE). Therefore, a method to solve the bottleneck problem in video streaming is neccesary.

To extend our previous work [4], in this work, we deploy a streaming architecture which make use of the MPEG-DASH technique and the SDN technology to solve the bottleneck problem. The scheme can increase the overall video quality for all users sharing the same bottleneck point. At the client's side, we develop a throughput-buffer based bitrate adaptation algorithm to utilize most of the available bandwidth in order to increase users' QoE. On the SDN controller, we establish a flow management mechanism which monitors the network to ensure fairness and avoid congestion when the network does not have sufficient bandwidth to serve new incoming stream requests. In the SDN controller, we develop the so-called Media Streaming Multiple Access (MSMA) module to monitor the network, detecting the number of ongoing streams, and deciding a fair share of bandwidth to all clients. Additionally, MSMA can also reallocate bandwidth or reject a new incoming request if no sufficient bandwidth is found; and thereby preventing congestion at the bottleneck point. The proposed adaptation and bandwidth allocation methods aim at the three following goals:

• *Efficiency*: all players joining the system can choose for themselves a level of video quality as high as possible.

• *Fairness*: When there are multiple clients accessing the bot-

tleneck link at the same time, all of the available network resources must be allocated as fairly as possible.

• *Stability*: Each player should avoid video stalling, unnecessary quality switches, which will adversely affect users' QoE.

The proposed solution not only allocates bandwidth fairly and adaptably on the network side, but also adaptive bitrate at the client side to improve video streaming quality. When there are many clients streaming on bottleneck link, the problem of sharing bandwidth for optimization is very important. There are three main approach groups: dividing bandwidth equally, dividing it by groups or choosing which user should be the one to share bandwidth with new coming users or new request of an existing user. Each solution has its own advantages and disadvantages. So, our proposed technique's limitation is to trade off a small QoE degradation of one or a small number of users sharing the bandwidth. However, the advantage of the proposal is to maximize the number of access clients while keeping QoE in a good shape.

The rest of this paper is organized as follows. Section 2 presents related work of typical bitrate adaptation algorithms and bandwidth allocation schemes. Section 3 provides information on throughput estimation and the proposed adaptation algorithm. Our proposed SDN-based dynamic resource allocation is described in Section 4 . A performance evaluation is presented in Section 5. Finally, conclusions and future directions are discussed in Section 6.

2 Related Work

HTTP Adaptive Streaming (HAS) has become the key solution for video streaming. There are a number of recent researches conducted to improve users' QoE in the context of multiple clients requesting for DASH service. As discussed in [5] and [6], the authors proposed a so-called Aggressive method in which a rate adaptation algorithm based on the estimated throughput is implemented where the last segment throughput is simply used as the estimated throughput. The quality level will increase or decrease depending entirely on estimated bandwidth. The Aggressive method is sensitive to cases where the bandwidth increases sharply in a short period of time and then abruptly decreases (short-term bitrate peaks). The client then requires a high-quality version, but the high bandwidth level does not last long enough to load the required segment. This may cause video freezing during playback. The Aggressive algorithm aims to use most of the available bandwidth for the streaming client by always adapting to the highest quality version of video segment that does not surpass the available bandwidth. By doing this, the expectation of streaming users is also met. In [7], [8] the authors proposed a buffer-based bitrate adaptation algorithm for HTTP video streaming, called BBA. BBA is based on the current playback buffer occupancy only by selecting bitrate heuristically without throughput estimation. The goal of BBA is avoiding stalling events and maximizing the average video quality by choosing the highest available bitrate level. However, this scheme shows many limitations such as QoE degradation in case of long-term bandwidth variations and slow bandwidth fluctuation, especially in case of bandwidth competition in a shared network. In the literature, there are some ABR (Adaptive Bitrate) algorithms that take into account both of the estimated throughput and current buffer occupancy to define the most suitable video version

for the next segment. In [9], [10], the authors propose a buffer-based bitrate adaptation algorithm for VBR (variable bitrate) videos. The study in [11] proposes a throughput-buffer based algorithm relying on the buffer target, the playback buffer filling level, and the current bandwidth to determine the next segment's version. Work [12] proposes a segment-aware rate adaptation algorithm (SARA), in which segment size variation, the estimated throughput and the current buffer occupancy are considered to predict precisely the time required to download the next segment. In SARA, the MPD file not only contains the average bit rate information of the segment but also the size of the segment. SARA has expanded and changed the structure of the MPD file to accomplish this. Estimated throughput is based on the measured throughputs in the past and divides the buffer into different levels to determine the bitrate. This assures to download the best possible representation of the video while avoiding video buffer starvation. However, SARA shows low performance and poor QoE in the context of bandwidth sharing competition.

In a shared network environment, with so many Internet services available, bandwidth resource always gets risk of becoming insufficient to the increasing number of users, despite the maturity of cutting edge technologies nowadays. Therefore, it is always a huge concern for researchers to deal with limited resource allocation in any networking circumstances. Most of the existing researches tend to increase the Quality of Experience of clients while optimizing the transmission capability. Now exist three solution categories to deal with the problem where many clients compete through a bottleneck point. The first category is to solve the issue of sharing video streaming services at the client side as mentioned in [13]–[15]. In [13], an algorithm is proposed to improve efficiency, fairness, and stability named FESTIVE by providing schemes to ensure a trade-off of these factors. FESTIVE is the first known client-side adaptive bitrate algorithm that is designed for the multiple client context specifically. FESTIVE contains three main components: a scheduler that determines the time of starting to download a segment, an algorithm that estimates the throughput based on all previous downloaded segments and a mechanism to select the bitrate of the next segment. However, with FESTIVE, when the number of users grows sharply in a competition, the system's stability could be reduced remarkably since the estimation of the bandwidth is too high, perhaps. In [14], a rate adaptation algorithm for HAS service is proposed based on a "probe-and-adapt" principle at the client side so-called PANDA. "Probe-and-adapt" is a kind of the additive increase and multiplicative decrease principle (AIMD) that is used in TCP. However Probe-and-adapt operates at the application layer and in a longer time scale. PANDA is a HAS client rate adaptation algorithm designed to provide high stability and fast responsiveness to bandwidth variations in the context of multiple HAS clients sharing the same bottleneck links. For detecting the available bandwidth, the network is probed by PANDA which additively increments its sending rate at each adaptation step and multiplicatively decreases its rate if a congestion is detected, in order to adapt its video bitrate accordingly. During the estimation of the available bandwidth, the PANDA probing mechanism tries to increase its sending rate, instead of transmitting auxiliary piggybacking traffic. PANDA also allows HAS clients to respond to bandwidth fluctuation quickly and to achieve stability. But PANDA does not consider the resource al-

location strategy in the context of multiple user negotiation. In [15], the streaming framework in VHS (VideoHomeShaper) is designed and implemented to evaluate performance in home's last access hop. In this study, the evaluation of QoE for competing clients takes into account some metrics such as Stability, utilization, and fairness. Overall, these researches mainly focus on adapting bit rate at the client side to improve the parameters that can affect user's QoE.

The second category focuses on the sever side. In this area, servers are normally considered as the only control point responsible for managing video transmission for all clients. The authors of [16] introduce a server-side adaptation scheme, which uses TCP to limit the video bit rate. A server-based traffic shaping solution is proposed in [17] to notably decrease such oscillations, at the expense of a small loss in bandwidth utilization. However, we can only be observe the actual bandwidth congestion problem at the network's side. Consequently, not too many clients might be able to handled by the server.

Finally, the category of in-network methods uses active bandwidth allocation to gain QoE fairness for multiple clients. Fair bandwidth allocation for players at a bottleneck link has been recently suggested by several work. Based on the SDN technology, [18] proposes traffic shaping techniques and do an analysis of ABR video streams when sharing resources through a congested link. In this method, all shared connections at the bottleneck point have the same throughput; and the total bandwidths assigned to requiring clients must not exceed the available bandwidth at the bottleneck. SDN-based traffic shaping in [18] can improve QoE for video streaming in terms of efficiency, fairness, and quality. The authors in [19] also consider the bandwidth sharing within a bottleneck link. However, in the network sharing model, the network sharing is calculated periodically, not in the per-request basis. In adaptive streaming, clients can require changing the bit rate at any time and the SDN controller must calculate the network sharing based on all of requests at the certain time. Authors in [20] proposed a system for increasing QoE of SVC-DASH clients based on SDN. The SDN architecture enables to select different streaming path to transfer different video layer flows between the server and the clients. But this paper does not consider the resource allocation strategy in the context of multiple user negotiation. In [21], the author proposed an OpenFlow-based QoE fairness framework (QFF). QFF manages the player statuses and allocates network resources dynamically to achieve the maximum user-level fairness for all clients that compete in a shared network. A proof-of-concept implementation is provided considering a small number of concurrent flows. However, only the fairness parameter of QoE is considered in this research. In [22], network-assisted strategies are considered to provide service differentiation to concurrent video flows such as the Bitrate Guidance approach (BG), the Bandwidth Reservation approach (BR), and the hybrid approach (BG+BR). A centralized Video Control Plane (VCP) is built to provide Video Quality Fairness (VQF) to concurrent video sessions that are sharing a common bottleneck. Work [23] argue that the network and clients shall collaborate to gain QoE fairness while video streams are encrypted. Placing cDVD in the greater context of QoE delivery methods is instructive. The resource-sharing clients only focus on fairness but not efficiency and stability. In [24], centralized and distributed architectures are proposed for collaboration between video service provider (VSP), network service provider

(NSP), and DASH clients to provide SDN-based NSP-managed or VSP-managed DASH services with quality-of-service (QoS) reserved network slices. The SDN controller computes the shortest-path route and bitrate for each client. This approach is to gain QoE fairness among heterogeneous DASH clients. However, again the resource-sharing clients only focus on fairness but not efficiency and stability. In [25], the author proposed an optimization model aiming at fairly sharing the bottleneck link while maximizing the client's perceived video quality. However, the work focuses only in bandwidth allocation and maximal link capacity of each client without considering how bit rate should be adapted to receive desired quality experience of the clients based on the real condition of the clients. Research [26] proposes a SDN-assisted adaptive streaming solution for tile-based contents using DASH to improve the user's quality of experience. The paper also summarizes the difference in immersive content streaming between SDN-based and traditional networks and introduce a SDN-based framework to support tile-based immersive content streaming. However, this paper does not consider the bandwidth allocation and bitrate adaptation problem. In [27] and [28], the author proposed a SDN based management architecture and dynamic resource allocation for HAS systems aiming to alleviate scalability and improve the QoE of each client. This architecture is in charge of allocating the network resources dynamically for each client depending on the client's QoE expectation. The same authors in [29] propose a SDN-based QoE-aware bandwidth broker for HTTP adaptive streams in an hybrid fiber coax (HFC) network, so-called Bandwidth Management Solution - BMS that dynamically chooses the respective bandwidth allocation decisions and the optimal joint representation in oder to meet the per-session and per-group QoE objectives. In [30], there is a network-driven video streaming architecture is built to design robust mechanisms for multiple players so as to achieve end-user QoE fairness. The SDN controller observes the environment state, computing the reward, and updating Q-value and taking the bandwidth allocation action by forwarding flow tables. However, the author considered how bandwidth should be shared to achieve fairness while QoE is taken into account from the perspective of receiving bit rate that is suitable to the link bandwidth. The work does not consider how QoE of each client can be acquired based on the client's real need in terms of bit rate at a certain moment QoE. In [31], a SDN-based model is built over the DASH protocol to improve the QoE whilst taking into account the variety of video parameters, devices and the network requirements. The proposed scheme comprises two phases: Machine Learning-based estimation phase of available resources, and adaptation and selection phase based on the results of the first phase. The goal of the approach is to have the best quality perceived video. The authors in [32] proposed a SDN-assisted solution to use the network management plan to reinforce policies for improving QoE of clients. However, again, this work does not consider the case of lack of network resource so multiple users need to negotiate for the network share in trade off with QoE. In [33], the authors present SAND/3 that is an SDN-Assisted QoE control for DASH over HTTP/3 for improving the QoE at the client side based on criteria such as buffer size, display size, type of device and subscription plan, and available memory. From the SDN network perspective, SDN tries to find a route for each requested connection from each client based on available resource. But this paper does not consider the resource allocation strategy in the context of multiple user negotiation.

Generally, SDN-based dynamic bandwidth allocation shows a good performance in improving video quality. However, the interaction between the network control and the client-side control in the context of multiple users sharing one bottleneck link has not been well investigated. Therefore, deploying solutions in a large-scale system is still a pending question.

3 Bitrate Adaptation Algorithm

Our proposed framework to the bottleneck problem is a integration of the bitrate adaptation algorithm at the client's side and the centralized SDN-based resource allocation, i.e. a cooperation between the network and video streaming applications. In the streaming network, a flow management mechanism called MSMA (Media Streaming Multiple Access) is proposed (discussed in Section 4.2).

In fact recently, there have been two widely-adopted types of algorithms at a MPEG-DASH Client, which belong to either the throughput-based group or buffer-based group. Therefore, we consider the context of multiple video-on-demand players, provided that the throughput-based adaptation algorithm called Aggressive [6] is deployed at each client.

Besides, we have also proposed a buffer based bitrate adaptation algorithm to determine a video quality level for the next segment. Compared to the throughput-based algorithms, buffer-based algorithms provide smoother bitrate curves in video-on-demand streaming. In the next subsections, the description of the throughput estimation and the proposed adaptation algorithm are presented.

Table 1: Symbols use in this paper

Symbol	Description
B_i	Current buffer level at segment i
B_e^{i+1}	Estimated buffer for segment $i + 1$
B_{max}	Maximum buffer size
N	Number of clients
I_{i+1}	The chosen version for the next segment
T_i	The throughput for the current segment
T_{i+1}^e	Estimated throughput for the next segment
r_i	Bitrate of client i
$r_i^{'}$	Bitrate of r_i after the SDN controller is recalculated
$R_{0,\dots,V-1}$	Bitrate of version 0, 1, $\dots$, V-1
R_{max}	Bitrate corresponds to the highest level of quality
RTT	Round Trip Time
SD	Segment Duration
V	Total number of video versions

3.1 Throughput Estimation

In simple terms, the bitrate adaptation mechanism adapts its requested bitrate based on the estimated throughput. Video segments are delivered from the server to the clients in sequence of consecutive HTTP request-response transactions. In general, throughput is obtained by dividing the data size by the delivery time. Knowing the actual amount of data delivered by a request-response transaction is

important. The segment throughput T_i^e for each delivered segment i is computed using the request-response duration (i.e. from the instant of sending the request to the instant of receiving the last byte of the response). Table 1 lists the symbols used in this paper.

A video version is chosen based on Equation (1). Bitrate R_j is selected as the maximum value not exceeding the product of the current estimated throughput T_{i+1}^e and safety margin μ (μ varies from 0.0 to 0.5). μ is defined to solve the instability of the Internet connection and delay caused by other streaming processes such as bitrate adaptation calculation and file decoding.

$$R_j \leq (1 - \mu) \times T_{i+1}^e \tag{1}$$

Next, we propose to estimate the next throughput based on two previous measured throughputs at the client side (as described in Equation (2)). In the Equation, γ is a dynamic constant range from [0, 1] that allows a client to adapt well with highly bandwidth fluctuations, especially with highly variable bandwidth since it is the main cause of video freezing. γ is usually set to be 0.5. When $\gamma = 1.0$, the estimated result will be exactly the same as the one of the aforementioned aggressive method.

$$T_{i+1}^e = \gamma \times T_i + (1 - \gamma) \times T_{i-1} \tag{2}$$

Algorithm 1: Proposed Bitrate Adaptation Algorithm

> **Input:** $T_i, R_n, B_i, RTT, SD, I_i, \Delta_B$;
> **Output:** I_{i+1} ;
> $T_{i+1}^e \leftarrow \gamma \times T_i + (1 - \gamma) \times T_{i-1}$;
> $I_{i+1} = 0$;
> **for** $j \leftarrow V - 1$ *to* 0 **do**
> $B_{i+1}^e \leftarrow B_i + SD - RTT - \frac{SD \times R_i}{T_{i+1}^e}$;
>   **if** $j > I_i$ *and* $B_{i+1}^e \geq B_i + \Delta_B$ **then**
> $I_{i+1} = j$;
>   *Break*;
>   **end**
>   **if** $j \leq I_i$ *and* $B_{i+1}^e \geq B_i - \Delta_B$ **then**
>   New request to controller;
> $I_{i+1} = j$;
>   *Break*;
>   **end**
> **end**

3.2 Proposed adaptation algorithm

In this paper, we design a new quality-selecting scheme based on the estimate buffer level so as to avoid video freezing. According to our previous work [34], we use Equation (3) to estimate the next buffer level, provided the client selects version j for segment i where SD is segment duration. RTT is the duration defined from the instant a client sends its request to the instant it receives a response and calculated by timestamps of the westward and eastward packets captured at the network card of the SDN controller. The westward packet is the request packet sent from a client to the controller and the eastward packet is the packet carrying information of calculated BW from the controller to that client.

The main goal of our solution is to choose a suitable quality level that can keep the buffer greater than the current buffer B_i to prevent stalling events. Our method details are shown in Algorithm 1. This algorithm is based on an estimated buffer to determine a new video version for the next segment.

In fact, increasing the quality version has a lower priority than keeping the quality version stable, and the quality should be reduced as little as possible through threshold Δ_B. The larger Δ_B , the less varied the video quality version, but the worse the connection adaptation. On the contrary, the smaller Δ_B, the better the connection adaptation, but more the stability is lacked. This parameter usually ranges from 0.25s to 2s. In this paper, we choose $\Delta_B = 1s$, since this figure is appropriate to trade off the issues above. When there is network fluctuation, a client shall reduce its quality version accordingly. In that case, the client will request the SDN controller to recalculate the bitrate, and sending this bitrate information to all clients that are having ongoing connections so that the quality version of all clients are kept as stably as possible.

$$B_{i+1}^e = B_i + SD - RTT - \frac{SD \times R_j}{T_{i+1}^e} \tag{3}$$

4 Proposed SDN-based Solution

4.1 Bandwidth Allocation Policy

Provided that N clients go through the same bottleneck with bandwidth capacity C. $BW_{i,t}$ is the amount of bandwidth allocated for client i at time t. The bandwidth allocation policy is to map the bitrate requested by each client to the actual bandwidth that could be granted to that client:

$$BW_{i,t} = f(r_{i,t}) \tag{4}$$

where $r_{i,t}$ is the bitrate that client i requests at time t. r_i is the bit rate the clients desire to have at the beginning. But BW_i is the actual bit rate that the clients will adapt to after being reconsidered by the SDN controller. In case the bandwidth resource is sufficient, all clients will have BW_i which are the same to r_i. In case network resource lacks, one or some r_i may be different from BW_i.

If the network resource (bottleneck link capacity) is sufficient for all requested bandwidths of each client, the clients will be allocated the same bandwidth as they request, i.e.:

$$BW_{i,t} = \frac{C}{N}, \forall i \in N, \forall t \tag{5}$$

However, in reality, HTTP networks are not ideal because clients frequently require bitrates that can be higher than the then-actually allocated bandwidth. As described in [35], [36], the bandwidth allocation policy for this non-ideal HTTP network condition is as follows:

> . if $r_i = r_j$ then $f_i(r) = f_j(r)$;
> . if $r_i > r_j$ then $f_i(r) > f_j(r)$;
> . $\frac{\partial f_i(r)}{\partial r_i} > 0$, $\frac{\partial f_i(r)}{\partial r_j} < 0$, where $i \neq j$;
> . $lim_{r_i \to \infty} f_i(r) < C, lim_{r_i \to 0} f_i(r) > 0$;
> . $f(.)$ is a function of r and value of f is independent of the client order.

In fact, requests do not come to the edge switch at the same time, therefore naturally, a solution to each request is thought appropriate.

When a request comes, the system calcualte to determine if it should accept the request, so as to ensure no congestion occured at the bottleneck point, causing the drop of quality of experience of all N clients.

In DASH, content provider encode videos at different quantity levels of different bit rates and then brake the videos into segments. That is the base to determine the minimum bandwidth needed by each client in order to obtain an uninterrupted video streaming. That minimum bandwidth is equal to the average bitrate of the video with the lowest quality level. This value is denoted as R_0.
Figure 1: Proposed architecture and operation for the bottleneck problem

4.2 Proposed fair bandwidth allocation solution (MSMA-0)

The proposed architecture is illustrated in Figure 1. As it can be seen, the Aggressive adaptation algorithm and the MSMA module are implemented in each client and the SDN controller respectively. The whole solution is called MSMA-0. In our proposed architecture, the edge switch (OFS - OpenFlow Switch) communicates to the SDN controller through 2 interfaces: a standard Northbound interface of Openflow that connects OFS and the SDN controller via TSL protocol; and a legacy network interface that connect the OFS and controller as 2 legacy network devices called Westbound interface. The operation of the proposed architecture is as follows:

• Phase 1: Negotiation of appropriate bit rates requested by each client

(1) Each client calculates its desired bit rates according to the bit rate adaptation algorithm implemented at client.

(2) Client sends that streaming request (i.e. desired bit rate) to the edge OFS switch. Then, the OFS encodes the request information in a $Packet - In$ message and sending it to the SDN controller via the Northbound interface (which is defined in OpenFlow protocol).

(3) The Controller, via the Northbound interface with the OFS edge switch, having already knowledge of link capacity of the network cards of the switch can calculate new BW values, then sending these new information to the clients via Westbound interface (as a legacy network device).

• Phase 2: Requesting the finally negotiated bit rate to the application server

After receiving information on BW from the SDN controller, the clients operate as follows:

(4) N ongoing clients send new requested BW_i to the application server via an open connection.The new client $(N + 1)$ sends a request to connect to the application server, the SDN controller will order the edge OFS to install a new flow entry to establish the connection between Client N+1 and the application server.

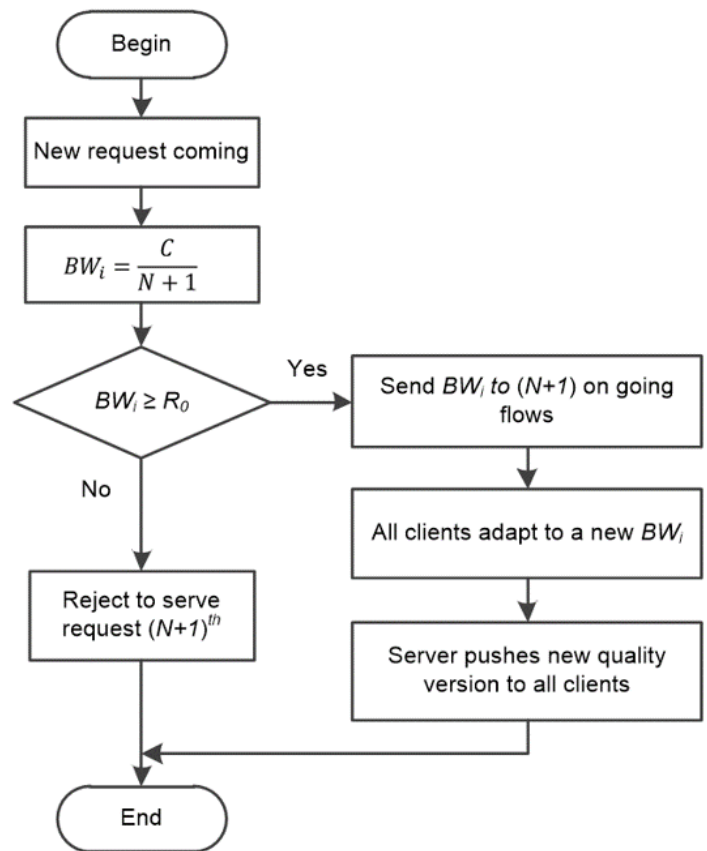
(5) Upon receiving the request on bit rate (i.e BW_{N+1}), the app server will push a video quality version segments accordingly to all streaming clients.


Figure 2: MSMA Flowchart

As the implication of its name, a network bottleneck causes a slow connection speed, limiting the experience of media streaming. Solving the aforementioned issue is the goal of our proposed MSMA algorithm. Figure 2 depicts the flowchart of MSMA deployment with the working principle described as follows:

1) Given that there are N ongoing clients requesting new quality versions for each segment, the average bandwidth BW_i distributed to $(N + 1)$ streams is recalculated by the MSMA module, according to the Equation (6) below:

$$BW_i = \frac{C}{N + 1} \qquad (6)$$

2) BW_i is then compared with the minimum acceptable bitrate R_0 by the SDN controller that then decides what action to take. Either one of these two actions depending on the result of the comparison will be carried out by the SDN controller.

3) A flow for the incoming stream is added by the SDN controller and BW_i is sent to all on going streams by the controller if $BW_i \geq R_0$ i.e. the bandwidth allocated to each client is higher than the one of the lowest quality version and is sufficient to stream that video version.

4) The incoming request is rejected to serve by the controller if $BW_i < R_0$ i.e. the bandwidth allocated to each client is insufficient to stream even the lowest quality version of the video.

Then after all, all streaming clients shall adapt to BW_i decided by the SDN controller. The clients then request the DASH server for the decided bitrate. The adaptation logic is described in the next section. TheDASH server pushes a new quality version to all streaming clients.

4.3 Proposed adaptive bandwidth allocation solution (MSMA-1)

In this work, we propose a new method (called MSMA-1) that combines a bit rate adaptation algorithm at the client side (i.e. Algorithm 1), with modul MSMA deployed in the SDN controller as Algorithm 2. The goal of MSMA-1 algorithm is trying to improve the Quality of Experience of each client on the streaming service by providing the bit rate that a client requires while trying to increase the number of clients that can access to the system within a limited resource.

At the network side, we allocate bandwidth dynamically (i.e. Algorithm 2) for all clients in order to maximize the number of clients that can be given an access to the network and minimize the number of clients who are requested to change their bitrate expectations (bitrate to satisfy the QoE criterion). Provided the system has N clients that have HTTP streaming over a bottleneck point. The capacity of the output link of the bottleneck point is assumed C (Mbps).

At the client side, each client deploys the bitrate adaptation algorithms proposed in Algorithm 1 to find out what is their bitrate expectation in order to achieve desired QoE. Actually, each bitrate is corresponding to a quality version defined by DASH and stored at the server.

In case, the sum of all requested bitrates r_i of N clients ($i = 1$ to N) is smaller or equal to capacity C, the SDN controller will request the DASH server to push the quality version desired by each client.

In case, the sum of all bitrates r_i ($i = 1$ to N) is larger than C, i.e:

$$\sum_{i=1}^{N} r_i > C \qquad (7)$$

then the SDN controller recalculates bandwidth allocated for each client. The SDN controller operates in the following criteria:

1. The SDN controller tries to keep the bitrates r_i required by the clients as stably as possible with the goal of meeting these clients' QoE requirement.

2. The SDN controller selects a client holding the highest rank, and taking a fraction of its required bandwidth to give to another client. In this manner, the network take a fraction of the network resource of this client but in return it will give

an access for an additional client (i.e. client $(N + 1)$). So, the goal of serving as many clients as possible is fulfilled.

In fact, as in the solution described in section 4.1, the link capacity C is divided equally to all $(N + 1)$ clients, therefore, all $(N + 1)$ clients suffer an undesirable QoE degradation since distributed resource may be lower than their requirements to achieve each client's satisfaction. Therefore, in this new proposed solution, the SDN controller, firstly, ranks all clients in a certain manner. Then the controller will set a policy to allocate resource to all clients by rank. Technically, this ranking function (or objective function) can be defined as a function of multiple objectives. Within the scope of this paper, we define the rank of client by Equation (8). Looking at the Equation (8) shows that the client that have a higher buffer level and a bitrate is likely to have the highest rank function. Therefore, this client will bring in some of the resources available for the new service. In addition, the choice of which client to share the resource will depend on for the two parameters which are bit rate r_i and buffer level B_i such that rank function is highest.

$$Rank(i) = f(B, r) = \alpha \times \frac{B_i}{B_{max}} + \beta \times \frac{r_i}{R_{max}} \qquad (8)$$

where α, β: non-negative weighting factors. And r_i is bitrate required by the ongoing client, B_i is current buffer level of client.

The set of $Rank(i)$ is arranged in the decreasing order according to the rank function value.

Details of the proposed solution are described in Algorithm 2. The details of this algorithm are explained as follows:

Firstly, the requested bitrate of a client who has the highest rank is recalculated to share the resource to other client. Provided the client with the highest rank is Client N. Then the bandwidths of client j and client N are reallocated as Equation (9) and (10) accordingly:

$$r'_j = \frac{r_j}{r_j + r_N} \times \Delta C \qquad (9)$$

$$r'_N = \frac{r_N}{r_j + r_N} \times \Delta C \qquad (10)$$

where r_N is the requested bitrate of client N who has the highest rank value and r_j is the requested bitrate of client who requests a new bitrate. r'_j and r'_N are the varied bitrates of r_j and r_N after the SDN controller recalculate bandwidth distribution. ΔC is the remaining bandwidth after reserving the bandwidth portion for all left clients that have not been shared it's resource. (i.e. all clients that retain their bitrates r_i). ΔC is defined by Equation (11).

$$\Delta C = C - \sum_{i=m}^{N} r_i \qquad (11)$$

where m is the number of clients who are sacrificed.

In case if the calculated bitrate of client j is smaller than the smallest acceptable quality version ($r_j < R_0$), continue to take the second highest bitrate requested by an ongoing client and redivide

proportionally for all 3 clients. The process continues until all N clients satisfy a bitrate $r_i \geq R_0$ $(i = 1 \div N)$.

Algorithm 2: . MSMA-1 algorithm

Input: r, C, Δ_C
Output: r
for $i \leftarrow$ *to* N **do**
  $r'_{N+1} = \frac{r_{N+1}}{\sum_{k=1}^{i} r_k + r_{N+1}} \times \Delta_C$;
  for $j \leftarrow 1$ *to* i **do**
    $r'_j = \frac{r_j}{\sum_{k=1}^{i} r_k + r_{N+1}} \times \Delta_C$;

5 Performance Evaluation

5.1 Experiment Setup

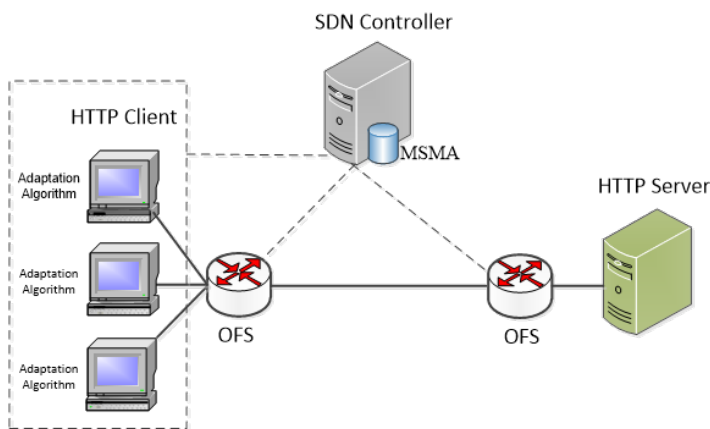
Bitmovin, a multimedia technology company providing services, which transcode digital video and audio to streaming formats using cloud computing, and streaming media players has developed and maintained a library named libdash [37]. In this paper, QtSamplePlayer is used as the media player of the streaming architecture. QtSamplePlayer is a Qt-based player recommended for the libdash library by Bitmovin. Videos pushed from the HTTP server to the clients are 2 types of videos: constant bit rate CBR and variable bit rate VBR. Besides, traffic from the clients to other devices (i.e. OFS switch and the SDN controller) is only control information on bit rate requests to adapt to required quality version.


Figure 3: Network topology used for experiment.

Figure 3 shows the network setup for performance evaluation. In our experiment, five machines are used to conduct the experiment: the media server, one machine for emulation of the streaming network including the SDN switches and the SDN controller - Floodlight [38], and 3 video streaming clients. One clients is implemented on a physical PC and all other machines are VMWare machines. Due to limited testbed resource, we just make a proof of concept with 3 clients. In the future, we will improve the testbed to scale up the experimental scenario. The network consists of two OpenFlow switches and a bottleneck link between them. An OFS is connected to the three client machines and the other OFS is connected to the media server ,in which MPD (Media Presentation Description) and video files are stored. The MPD file is an XML (Extensible Markup Language) file that represents the different quality levels of the media content and the individual segments of each quality level with Uniform Resource Locators (URLs). For this evaluation, Mininet [39] is used to create a realistic virtual network.

There are many different types of videos that can be used in evaluation simulations, but all of them focus on two types of video: variable bit variable (VBR) and constant bitrate video (CBR). In this paper, the experiment videos are two short movies named Elephants Dream [40] and Destiny [41] to represent the 2 aforementioned video types. In the Elephants Dream movie, the video is divided into 327 segments with the total duration of 654 seconds (i.e. 2 seconds per segment). This video is encoded in the VBR mode of 12 different versions corresponding to 12 different average bitrates. The version index, Quantization Parameter (QP), and the average bitrate of each version are listed in Table 2. The Destiny short file is a constant bitrate video (CBR) and is divided into 340 2-seconds-long segments of 16 quality levels of different bitrate (50, 100, 250, 400, 600, 800, 1000, 1200, 1600, 2000, 3000, 4000, 6000, 8000, 12000, 16000 Kbps).

Table 2: Version information of the VBR video

Version	QP	Average Bitrate (Kbps)
0	46	354
1	43	472
2	40	638
3	37	882
4	34	1234
5	31	1779
6	28	2588
7	25	3823
8	22	5613
9	19	8028
10	16	11156
11	13	15227

5.2 Experimental Scenarios

Six experiments are deployed to evaluate our proposed system:

• Experiment 1: The link capacity of the bottleneck is 10 Mbps, 7 Mbps and 4 Mbps. The controller uses the aforementioned method MSMA-0. Client 1 starts streaming 110 seconds (55 segments). After the first 110 seconds of Client 1, Client 2 starts streaming in 110 seconds and in the same way with Client 3.

• Experiment 2: The link capacity of the bottleneck is set at 10 Mbps, 7 Mbps and 4 Mbps. The controller uses the aforementioned MSMA-1 algorithm. Each of Client 1, Client 2 and Client 3 starts

streaming in 110 seconds, one after another.

• Experiment 3: The link capacity of the bottleneck is set at 10 Mbps, 7 Mbps and 4 Mbps. The Aggressive, SARA, BBA, PANDA algorithms are used. MSMA is not available. Each of Client 1, Client 2, and Client 3 starts streaming in 110 seconds, one after another.

• Experiment 4: The link capacity of the bottleneck is set at 10 Mbps, 7 Mbps and 4 Mbps. The SARA, BBA algorithms are used. The MSMA module is activated. Each of Client 1, Client 2, and Client 3 starts streaming in 110 seconds, one after another. This experiment simulates methods "SDN-based SARA" and "SDN-based BBA".

• Experiment 5: The link capacity of the bottleneck is set at 500 Kbps. The controller uses the MSMA modul. The clients request for the VBR video an independent time.

• Experiment 6: The link capacity of the bottleneck is 500 Kbps. The controller does not use the MSMA modul. The clients request for the VBR video at independent time.

We use the Aggressive method as the bitrate adaptation algorithm [6] with a safety margin $\mu = 0.2$.

We perform each of the five experiments in three times and record the average results for later comparison. The purpose of Experiment 1, Experiment 2, and Experiment 3 is to determine stability, efficiency, and fairness; The purpose of Experiment 4 and Experiment 5 is for checking the possibility of rejecting new requests when a congestion is possible.

With Experiment 5, since $R_0 = 354Kbps$, only the connection request of the first client will be accepted by the controller; and video with the minimum average bitrate will be streamed by the client. The evaluation results illustrates that the number of video freezes is 5 in case the segments contain a high bitrate compared to the representative bitrate (i.e. average bitrate). Our proposed system does not accept to provide services to requests from client 2 and client 3. Experiment 6 shows the scenario of a traditional network where the controller does not operate with the MSMA modul. In that scenario, the 3 requests from 3 clients are accepted in turn.

So, because the available bandwidth is not sufficient for all 3 clients sharing bandwidth and asking an acceptable bandwidth, all 3 clients are frozen immediately after being connected and also experience buffering most of the time during the whole course of their streaming section. This proves that at the circumstance of poor bandwidth, MSMA-0 is still able to serve the modest number of players, rather than the other methods where no user will be served.

5.3 Simulation Results and Discussion

To evaluate the performance of the proposed solution, we use three metrics of fairness, efficiency and stability as presented in [42] and [13] and a QoE metric. In the following subsections, these metrics will be described in detail.

5.3.1 Fairness, efficiency and stability metrics

In this subsection, the 3 metrics of stability, fairness, and efficiency are presented. In particular, the fairness score is measured by Equation (12)

$$Fairness = \frac{|\sum_{i=1}^{N} r_{i,t}|^2}{N\sum_{i=1}^{N} r_{i,t}^2} \quad (12)$$

where $r_{i,t}$ is the video bitrate allocated to client i at time t. The fairness score should be in the range of [0 to 1]. As the matter of fact, the closer to 1 the fairness score is, the fairer the system is.

The efficiency score of the bandwidth distribution is computed using Equation (13), where W is the available bandwidth of the shared connection. The closer to 1 the Efficiency score is, the better the system efficiency is.

$$Efficiency = \frac{|\sum_i r_{i,t}|}{W} \quad (13)$$

Equation (14) defines the stability score for client i at time t. This score is calculated based on the absolute amplitudes of the quality fluctuations (i.e. bitrate switches).

$$Stability = 1 - \frac{\sum_{d=0}^{k-1} |r_{i,t-d} - r_{i,t-d-1}| \times \omega(d)}{\sum_{d=1}^{k} r_{i,t-d} \times \omega(d)} \quad (14)$$

where: $\omega(d) = k - d$: weight function; and k: 20 seconds (10 segments) in this experiment. The closer to 1 the Stability score is, the more stable the system will be.

5.3.2 QoE Metric of Video Streaming

In this section, we first present parameters that have influences on the QoE of video streaming. Then, a QoE metric taking into account the parameters is provided. According to [43], the most important parameters are as follows:

Initial Delay (D_t): Initial Delay is computed as the duration from the point the first segment of a video is requested until the point the video is played out. For an effective video streaming system, the buffer time required for this parameter must be much smaller than the maximum client-side buffer level. According to [27], the initial delay should be less than 6 seconds.

$$D_t \ll B_{max} \quad (15)$$

Average Version Quality (AVQ): In the DASH system, the quality of the segments received at the client is variable. This parameter is defined as the average version of all the downloaded segments. Assume a video stream consists of K segments and each segment is encoded with V bit rate corresponding to V quality level, where v represents a specific quality level .

$$AVQ = f(i, v) = \frac{1}{K} \sum_{i=1}^{K} q_{i,v} \quad (16)$$

where $q_{i,v}$ is the quality value of the ith segment at the v quality session level, for example $q_{i,v_{max}}$ is the quality value of the ith segment with the highest quality level.

Number of Version Switch-downs (NVS): is the number of times that a downloaded segment has a lower bitrate than the previous segment. We can use this paremeter along with Average Video Quality to provide quantitative inferences of QoE. If video flows have similar Average Video Quality, a flow with the lower number

of Version Switch-downs will be perceived,by users, to be the better one .

$$NVS = \frac{1}{K-1} \sum_{i=1}^{k-1} |q_{i+1,v_{i+1}} - q_{i,v_i}| \qquad (17)$$

Number of Video Stalling (S_t): Video streaming will be stalled if the buffer at the client side is empty. In other words, if the playback buffer size is reduced to the minimal buffer level but has not downloaded the current segments, then a video stalling will occur. Number of Video Stalling can be calculated as the total number of stalls in a video playback time period.

$$S_t = \frac{1}{K} \sum_{i=1}^{K} S_i, \forall 0 \le B_i \le B_{min} \qquad (18)$$

To evaluate the performance of our bitrate adaptation scheme, we use an QoE metric based on the above parameters and also from the reference model provided by A. Bentaleb et al. [27] as follows:

$$QoE_i = \alpha_1 \times AVQ - \alpha_2 \times NVS - \alpha_3 \times S_t - \alpha_4 \times D_t \qquad (19)$$

Both S_t and D_t are in seconds. ($\sum_{n=1}^{4} \alpha_n = 1$) are non-negative tunable values and selected based on [13] to test in our experiments. We convert the QoE score to a normalized QoE (N-QoE) accordingly to Table 3 to represent a user's satisfaction MOS (mean opinion score) from 1 to 5.

Table 3: Normalized QoE

QoE_i	N-QoE	Quality
$QoE_i \le 1$	1	Bad
$1 < QoE_i \le 2$	2	Below Average
$2 < QoE_i \le 3$	3	Average
$3 < QoE_i \le 4$	4	Good
$QoE_i > 4$	5	Excellent

5.3.3   Performance Evaluation

In this section, we compare our proposals (MSMA-0 and MSMA-1) with the existing methods such as PANDA, BBA, SARA, Aggressive (called AGG), SDN-based SARA and SDN-based BBA. In which, the SDN-based BBA and SDN-based SARA methods are the BBA and SARA methods that are combined with the fair bandwidth allocation of the MSMA module. To understand more about the existing solutions, let us to highlight some main points of the existing methods:

1. AGG only based on the throughput of the previous segment to estimate the throughput for the next segment. This method has advantages in fast adaptability to the strongly fluctuating bandwidth conditions, but has disadvantages in the stable bandwidth conditions compared to other methods.

2. For SARA method, the bitrate adaptation algorithm of SARA is both throughput-based and buffer based to determine which quality level would be chosen. SARA has shown a number of advantages over the AGG algorithm as it is able to

maintain a higher quality level for longer time under stable bandwidth conditions because of having the segment capacity information, thus it could predict download time.

3. BBA is the buffer-based method only to select a version quality without estimating throughput.

4. PANDA uses "probe-and-adapt" to build the rate adaptation algorithm and fair-share bandwidth for players. This solution achieves good stability but the averrage video quality is not high. On the other hand, PANDA's resource allocation is in a distributed rather than centralized manner like our proposed one so fairness is not high.

The download rate (DLrate), buffer level, and selected versions of all the methods are shown in Figure 4 (with VBR video) and Figure 5 (with CBR video). In experiments for the 10 Mbps, 7 Mbps, and 4 Mbps cases, the results show similar performances in terms of version and download rate. Therefore we only count in the 4 Mbps case as the representative for this type of evaluation. As Figure 4 demonstrate, in case of using the SDN controller with MSMA-0 and MSMA-1, video versions of the client are stable during the whole course without requesting any new connection.

Especially, MSMA-0 is very stable, however this method has average video bitrate much lower than of MSMA-1. The other methods have relatively the same average video bitrate. For MSMA-1 and BBA, due to buffer preestimation, the buffer does not go to zero. This means that the video will not be stalled. Other methods have almost video stalling for some times. For MSMA-0, the buffer is dropped low in segments of 68-78. In PANDA, the video is interrupted from segment 60 to segment 78. In SARA, the average buffer is very low, and there are 2 video interruptions, one at around segment 110 and one from segment 174 to 198. In the Aggressive method, video quality is fluctuated continuously which can be annoying to viewers; and video is also stalled from segment 66 to segment 78. With the support in bandwidth sharing of the SDN controller, the SDN-based BBA and SDN-based SARA methods have better performance in comparison with the BBA and SARA, as described in Figure 4g and Figure 4h. As we can see, the SDN-based SARA method has more stable quality levels compared to SARA in the duration from segment 80 to 200. This is because the fair bandwidth allocation of the MSMA module incorporates the segment-aware rate adaptive algorithm of SARA when multiple clients access the system. With good buffer-based bitrate adaptation, SDN-based BBA as well as BBA can avoid video freezing.

As Figure 5 illustrates, the status of clients in the case of the CBR video is more stable than the one of the VBR case, since the segment sizes of the CBR video are quite similar while segment sizes of the VBR video are varied and unpredictable. Average version of SDN-based BBA is increased by about 3.2% compared to BBA. SDN-based SARA had similar average quality levels to SARA, but the variation in quality levels was significantly reduced. This is quite an important parameter in QoE evaluation.

For the performance evaluation, the time when all clients begin to stream at the same time is selected. It take 20 seconds (10 segments) to to calculate results of the performance. Figure 6 compares the performance of our proposed solutions (MSMA-0 and MSMA-1) with PANDA, BBA, SARA and AGG using the three

evaluation parameters: *Fairness*, *Efficiency* and *Stability*. For a more accurate evaluation, in this Figure 6, we get the average for all the three cases with the link capacities of 4 Mbps, 7 Mbps, and 10 Mbps. In real time, we set the mean value over three runs for 3 players. The results show that the fairness, efficiency, and stability obtained using the existing methods are much lower than those obtained using our proposed solution. However, due to the segment aware rate adaptation mechanism, in Figure 6a, the fairness between segments 4 and 7, SARA performs better than all of the others. This scheme uses all of the segment sizes, the estimated path bandwidth and current buffer occupancy to predict the amount of time needed to download the next segment. Therefore this method

guarantees the fairness for all players. Using the existing streaming solutions as PANDA, BBA, SARA and AGG, the fairness in these cases varies from 0.634 to 0.860 and has an average of 0.699, 0.723, 0.77 and 0.687, respectively. The experiment also shows that the proposed architecture has improved the fairness score significantly, with scores ranging from 0.791 to 0.863 that results in an average of 0.816 which is very high. The efficiency of bandwidth allocation in the current solutions also has a considerable deterioration with values from 0.488 to 0.761 (i.e. average of 0.654, 0.655, 0.602 and 0.604, respectively). Whilst the efficiency of MSMA-1 varies from 0.716 to 0.970 (i.e average of 0.830).

the 3 clients in all methods. It can be seen that the stability of our proposal is better than other schemes. Table 4 and Table 5 show the average fairness, efficiency and stability of the 3 clients in case of using the existing methods and our method. The shown results are taken from 20 seconds (i.e 10 segments) when all players are streaming at the same time.

For VBR video Elephants Dream, in the following summary list, the consecutive numbers represent the results for MSMA-0, PANDA, BBA, SARA and AGG, respectively.

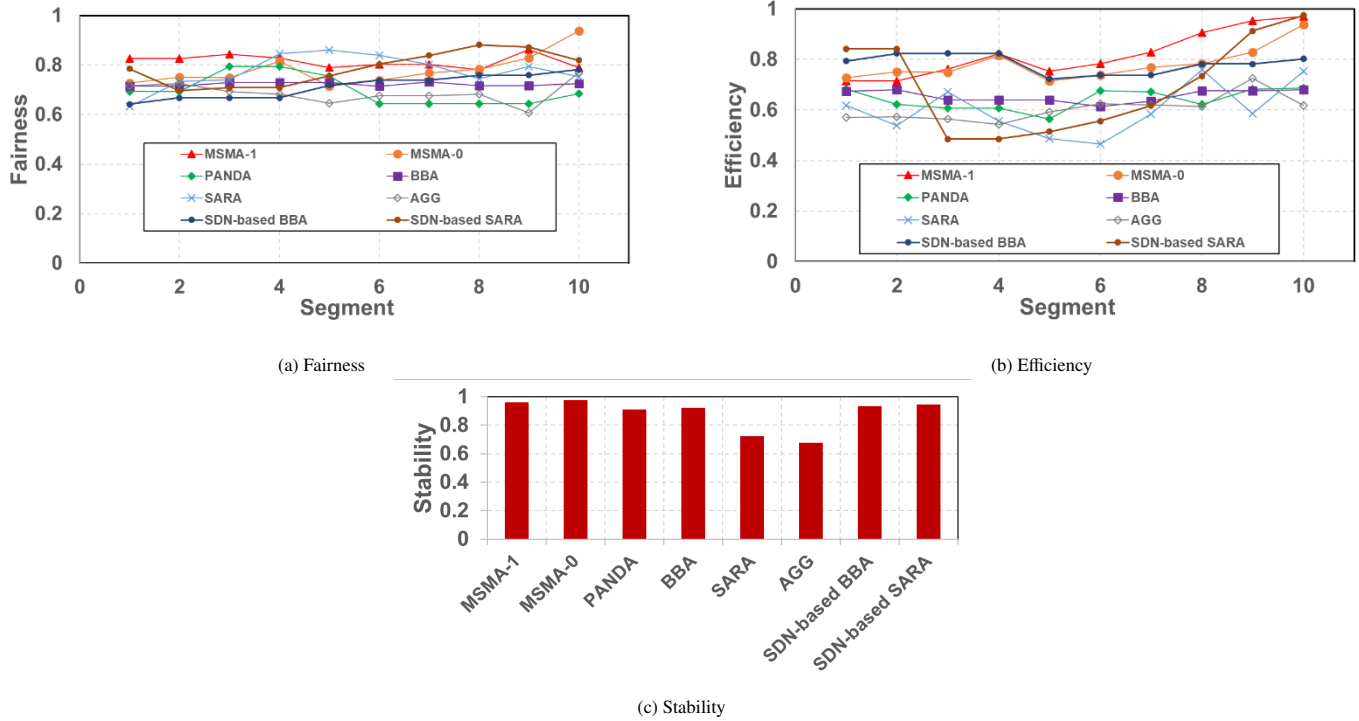
1) MSMA-1 outperforms the existing schemes in terms of fairness by an increase of 3.9%, 16.7%, 12.9%, 5.3% and 18.8%.

2) MSMA-1 improves bandwidth utilization in terms of efficiency by 3.3%, 26.9%, 26.7%, 37.8%, and 37.4%.

3) MSMA-1 increases the video stability by -1.5%, 5.6%, 4.6%, 33.1%, and 42.5%.

MSMA-1 improves two parameters: fairness and efficiency compared to MSMA-0. However, MSMA-0 has better stability than MSMA-1 because the clients in MSMA-1 are free to adapt their bitrates based on the throughput. And only when the throughput does not meet the requirements, the client will send the request to the controller. The SDN controller is then responsible for reallocating bandwidth to the clients accessing through that node, so that

(a) Fairness

(b) Efficiency


(c) Stability

Figure 6: Comparison average fairness, efficiency and stability of all methods

Table 4: Performance Comparison with VBR video

Metrics	MSMA-1	MSMA-0	PANDA	BBA	SARA	AGG	SDN-based BBA	SDN-based SARA
Fairness	0.816	0.785	0.699	0.723	0.775	0.687	0.714	0.807
Efficiency	0.830	0.781	0.654	0.655	0.602	0.604	0.783	0.697
Stability	0.962	0.977	0.911	0.920	0.723	0.675	0.933	0.945

the requesting clients receive the new bandwidth that can keep the most appropriate video version. As for MSMA-0, due to the use of the aggressive adaptive bitrate algorithm based on the bandwidth that has been divided evenly from the controller, it is still stable in choosing the bitrate or quality version of the next segment.

Similarly, with statistics in Table 5 (i.e. for CBR video "Destiny"), we can see that the two proposed methods (MSMA-1 and MSMA-0) outperform the rest. On another side, compared with traffic of the VBR video, traffic of the CBR video has higher Stability. The fairness of SDN-based BBA is almost similar to BBA, while the one of SDN-based SARA is slightly increased compared to SARA, by only 4%. SDN-based BBA effectively increases the bandwidth usage by 19.6% compared with BBA and SDN-based SARA increases by 15% compared to SARA. Thanks to the SDN-based fair bandwidth allocation, BBA and SARA have much better stability than the non-SDN solution.

Table 6 shows statistics from the experiments. As shown in the table, MSMA-1 outperforms the other methods. At first, with a reasonable throughput and buffer-based estimation mechanism, MSMA-1 is able to avoid stalling conditions whilst keeping the highest average value of buffer occupancy (i.e. 44.6s).

Secondly, MSMA-1, with the dynamic bandwidth allocation mechanism, can achieve the highest average bitrate of 2445.6 Kbps, which is an improvement of about 103.8%, 76%, 36.7%, 42.4% and 67.3% compared to MSMA-0, PANDA, BBA, SARA and AGG, respectively. Based on the QoE formula in Equation (19), the final QoE scores of MSMA-1 and MSMA-0 are calculated in comparison with 4 other solutions such as PANDA, BBA, SARA, AGG (Table 6). In fact, MSMA shows to achieve the highest QoE score compared to other competitors.

For the AGG algorithm, by requiring the highest bitrate according to the throughput without relying on the current buffer, the average video quality is low and the number of quality level switches-down is largest among all the methods. On the other hand, AGG also has the lowest QoE (i.e. 1.9).

SARA is the mixed throughput-buffer based algorithm, having the average video quality and QoE higher than AGG, but it is only medium compared to the other algorithms. BBA is the buffer-based algorithm, BBA successfully avoids stalling events which are very annoying to video viewers. The average bitrate of BBA is medium at only 1788.7 Kbps and its QoE stays at the good level (3.6).

With the estimation of the available bandwidth, a probing mech-

Table 5: Performance Comparison with CBR video

Metrics	MSMA-1	MSMA-0	PANDA	BBA	SARA	AGG	SDN-based BBA	SDN-based SARA
Fairness	0.971	0.965	0.764	0.713	0.716	0.873	0.932	0.917
Efficiency	0.879	0.796	0.904	0.665	0.726	0.708	0.812	0.803
Stability	0.975	0.957	0.931	0.949	0.826	0.703	0.941	0.955

Table 6: Quality Statistics of the solutions

Criteria	MSMA-1	MSMA-0	PANDA	BBA	SARA	AGG	SDN-based BBA	SDN-based SARA
Average Bitrate (kbps)	2445.6	1199.6	1389.5	1788.7	1717.4	1461.0	1812.3	1645.1
Average Buffer (s)	44.6	35.8	34.2	27.7	11.6	36.4	28.2	18.4
Number of Stalling	0	4	12	0	17	11	0	0
Average Version Index	6	4.5	5.1	5	5.2	5	5.4	5.1
Number of Version Switch-downs	21	3	7	17	20	40	16	15
N-QoE	4.25	3.6	3.54	3.55	2.8	1.9	3.96	3.74

anism is leveraged by PANDA to additively increase its sending rate, whilst decreasing sending rates multiplicatively, when congestion occurs. PANDA has a medium average bitrate at 1389.5 kbps and a relatively low number of switch-downs (7 times). The QoE score of PANDA also reaches 3.6.

For MSMA-0, the average bitrate is the lowest due to the use of the Aggressive bitrate adaptive algorithm on the client side, and MSMA makes its best to fairly allocate the bandwidth afor all clients. However, MSMA-0 has the lowest number of switch-downs (3 times). Besides QoE of MSMA-0 also reaches good quality (i.e. score of 3.6).

At the bottom lines, it's difficult to improve for all QoS parameters as well as the Quality of Experiment (QoE)- related parameters of video streaming. In fact, all of the proposed solutions need a tradeoff among these parameters to improve video streaming quality. However, our proposed solutions MSMA-0 and MSMA-1 have significantly improved average video quality, ensuring the highest average QoE compared to existing methods such as PANDA, BBA, SARA and AGG. Especially, MSMA-1 increases the QoE score by 18%, 20%, 20%, 51%, and 124% compare with MSMA-0, PANDA, BBA, SARA and Aggressive, respectively. As we can see, MSMA-0 does not SDN-based BBA and SDN-based SARA in terms of QoE, but our proposed MSMA-1 outperforms all compared methods.

Overall, our existing innovative algorithm is a combination of bitrate adaptation at the client side and resource allocation at the network side. The proposed rate adaptation method is to choose the best quality version on the current network condition and to avoid

video stalling events. At the SDN controller, the resource allocation handles fair and adaptive bandwidth sharing in order to maximize the number of access clients, while trying to minimize the number of clients who got QoE degraded.

6 Conclusion and Future Work

In this work, we have presented an integrated solution of centralized SDN-based resource allocation at the network side and bitrate adaptation at the client side to resolve the problem of multi clients streaming video through a bottleneck connection. This causes several problems such as low quality of service, congestion, delay, and especially quality of experience of users. The experiments show that our proposed solution outperforms the predecessors in terms of Quality of Experience.The proposed scheme ensures bandwidth fairness, efficiency and stability. Another contribution of our work is to ensure QoE of as many ongoing clients as possible. Additionally, the method can prevent congestion at bottleneck point when there is insufficient bandwidth by rejecting a new incoming request

Our future work will be building the whole SDN-based architecture to allocate network resources and to maximize QoE for each client, while avoiding scalability issues among many competing clients in a shared environment. Multiple heterogeneous scenarios with multiple SDN controllers and various clients will also be taken into account.

PrOMor: A Proposed Prototype of V2V and V2I for Crash Prevention in the Moroccan Case

Zakaria Sabir[*], Aouatif Amine

Ibn Tofail University, ILM Department, ENSA, Kenitra, 14000, Morocco

A B S T R A C T

Road safety has become an object of research and many research institutes have invested in this field because a lot of people die and many others are injured every year due to road accidents. The deployment of wireless communication technologies for vehicular networks can considerably improve road safety. It can enable new services such as traffic management, collision detection, and additional communication ease between moving vehicles. This paper presents a complete implementation of Vehicle to Vehicle (V2V) and Vehicle to Infrastructure (V2I) communications. Raspberry Pi boards, ultrasonic sensor, infrared obstacle detector, and line follower sensors are used in order to implement the complete prototype. The results show the usefulness of this road safety prototype named PrOMor (Prevention of Obstacles in Morocco). Based on these results, it can be concluded that the presented scenarios can be applied to the field of road safety related to the Moroccan case. This should reduce the number of accidents and save more human lives.

1   Introduction

This paper is an extension of work originally presented in the International Conference on Computational Intelligence and Knowledge Economy (ICCIKE) [1]. In the current work, the authors will deal with the whole vehicular communication system to address road safety issues, especially in the Moroccan case.

Since millions of people die every year and many more are injured because of car accidents, road safety has been gaining importance in recent years. Statistics [2] show that road traffic casualties in the world amount to 1.17 million per year. According to the World Health Organization (WHO), road accidents claimed the lives of 1.25 million people in 2013. In 2014, more than a million accidents occurred in Europe, killing 25 900 people and 1.4 million wounded. In 2017, 3,499 deaths were recorded on Moroccan roads, against 3,593 in 2016, a small decrease of 2.6% year-on-year. While statistics show a slight advance in road safety, they hide other, more disturbing realities[1]. These statistics are blatant, so the Ministry of Equipment, Transport, Logistics, and Water (METLE) thought to launch research projects in partnership with Moroccan universities and the National Center for Scientific and Technical Research (CNRST) in order to reduce the number of victims. This project based on the detection and the anticipation of the accidents aims to

help to reduce the accident rate using the V2V and V2I communications to detect obstacles and prevent the crash in the Moroccan case. According to the traffic accident statistics carried out by the METLE in 2016 [3], there were 80680 accidents caused by obstacles.

Today the road network in Morocco [4], whose routes are traditionally hierarchical in the main, collector, and service according to the function they fulfill for the network itself, is not in adequacy with its urban environment and the needs of the inhabitants and users. Thus, for example, very wide paths designed for cars can pass through neighborhoods endangering pedestrians who go there to shop, go to school or work, or simply go to the neighbor. It must be recognized that, particularly in dense urban areas, the lanes fulfill a multiplicity of functions that go beyond the simple role of channeling private vehicles (social functions, economic, leisure, etc.).

To put a stop to this massacre, in addition to legislative measures, digital technologies will play a major role. The automation/semi-automation of vehicles will limit the human error, responsible for the majority of road accidents. Manufacturers are working on connected vehicles that will be equipped with several sensors. They will be able to interpret their environment in a dynamic way to alert drivers of the various hazards which could be found on the road.

In this context, the main purpose of Intelligent Transportation

Systems (ITS) is to improve transportation safety, increase productivity, reduce traffic jams and reduce the number of accidents on our future roads, thanks to the use of advanced information technology. Nonetheless, the big challenge is to constitute an interdependent environment that merges all the technologies and can solve a variety of transportation problems. If the electronic, computing, and networking technologies are well integrated, the mobility will be more efficient, the roads will be safer and the impact on the environment will be minimized [5].

These systems will allow vehicles to communicate their relative positions, for example, to signal the presence of another vehicle in a blind spot. Mainly, it will be connected to various sensors inside the vehicle: stability, hazard warning lights, airbags, and other diagnostic tools. Therefore, a vehicle can automatically communicate to others the presence of a slippery roadway, if it is down or in an accident. The other drivers will then adjust their approach in the concerned area. The ITS will also help to know the position of emergency vehicles (ambulances, firefighters, police) on approach. Their only sirens today give little information on their provenance and direction. Civilian vehicles will then clear the way more efficiently using the ITS.

One of the most important components of ITS, which has been proposed to address challenges in the transportation surface is the connected vehicle system. It is a hopeful technology that uses wireless communication. In order to treat transportation problems, connected vehicle system will use Vehicle to Vehicle (V2V) and Vehicle to Infrastructure (V2I) communications [6] [7].

Different definitions have been given recently for a "connected" vehicle. A definition given at the 2013 Automotive News World Congress by IBM, identifies a connected vehicle as "a vehicle capable of seamless integration with multiple systems, connecting consumers to the digital world". More precise definitions include all the other connections of a modern vehicle: according to the US Department of Transportation (USDOT), "Connected vehicle applications provide connectivity between vehicles to prevent accidents, between vehicles and infrastructure, in order to generate safety, mobility and environmental benefits; between vehicles, infrastructure and wireless devices to provide continuous real-time connectivity to all users of the system" [8].

Different studies have already tried to develop prototypes of connected vehicles and systems that support V2V and V2I communications. But, as will be explained later, those systems were developed in foreign countries and cannot be applied in Morocco. Thus, the authors thought of a system that will fit the Moroccan case. This paper presents the implementation of a vehicular communication environment using both V2V and V2I technologies. This system is the first of its kind in Morocco. It requires a real test on real cars, but the authors carried out the tests on two robots only and it will be spread over a large number of cars in the real case, the used robots are based on Raspberry Pi-based mini cars kits, which were personalized by adding different features and other sensors in order to get to the target. The remainder of the paper is organized into four sections: Section 2 explain the proposed system. Experiments results will be presented and discussed in Section 3, while Section 4 concludes the paper.

2 Related works

This work is inspired by several prior studies that used various technologies on connected vehicle networks. A summary of related works is discussed in this section.

A recent work [9] explored the future beneficiaries of 5G and selected the conditions where 5G can make an effect. Particularly, three use-cases were considered: V2X (Vehicle-to-Everything Communication), Healthcare, and Drones. The authors investigated and emphasized some imperfections and failures of the current cellular topologies regarding the mentioned use-cases, then they determined how 5G will surmount those failures.

Kuramoto et al. [10] described the multi-class zone ITS communication scheme regarding short periodical communications and real-time for vehicle safety in intersections. In the proposed scheme, two types of areas around an intersection were designed, the nearest area and quasi-nearest area. In the first one, the communication of vehicles is done every 20 ms with a base station. While in the second one, vehicles make reservations for the communication for the first type and also communicate with the base station for safety. The required frequency bandwidth needed to realize the proposed design was shown in the simulation results.

A strategy of centralized and localized data congestion control is proposed in [11]. It uses RSUs (Road-Side Units) at intersections to control data congestion. It includes three entities for clustering messages, detecting congestion, and controlling data congestion. In order to detect data congestion in the channels, the strategy measures the channel usage. The messages are refined, assembled, and then grouped using algorithms of machine learning. Simulation results affirmed the efficacy of the proposed strategy in terms of improving the delay, packet loss ratio, and throughput.

Another system is presented in [12], it is an integrated vehicular system that uses an integrated V2I and V2V communication model improved with an information management system. The aim is the management, accumulation, and arrangement of context-aware information on driver location and traffic. The concept of smart roads is featured in the vehicular system. Significant information and all the risks related to the safety and detected by vehicles are managed by the infrastructure and adjusted to the driver's choices and the vehicle's context. The authors implemented the required software and used real hardware for infrastructure as well as a real vehicle to build the entire system.

Other authors [13] proposed to substitute the currently proposed standard (802.11p, DSRC/WAVE) to build an inter-vehicle communication system. They suggested using android smartphones along with Wi-Fi to replace the OBU (On-Board Unit) on consumer vehicles and to enable thereby V2I and V2V communications. The system is compatible with android devices with the 2.3 version and above. The users will then acquire an OBU that communicate with the nearby vehicles to broadcast an emergency alert or to warn about an accident. Experiment results showed the ease of use of the system, its efficiency, and its compatibility with Android devices.

Day et al. [14] checked out the performance of Het-Net (Heterogeneous Networks) consisting of LTE, DSRC, and Wi-Fi technologies for V2I and V2V communications. To enable Het-Net for vehicular communication applications, the authors developed an application layer handoff method. It was used to collect traffic

data and to warn about the collision. This research proved through the conducted field studies the usefulness of Het-Net in vehicular communications. Simulation experiments were run using a big number of connected vehicles including LTE and DSRC Het-Net scenarios. The results in terms of packet delivery error and latency from simulation were found to be identical to the field experiment results.

In this paper [15], the authors used data from the University of Michigan Safety Pilot Model Deployment project to analyze the performance of DSRC. They used selected road-side equipment and 1050 vehicles to evaluate the packet delivery ratio and the effective range of V2I communications. They have also studied the impact of some environmental factors like weather, trees, road elevation, buildings, and so on. The results are useful in the development of DSRC communication models and guiding future DSRC equipment placement.

Du et al. [16] used a distributed message delivery platform to develop a strategy. The aim is the creation of an effective and low-latency distributed message delivery system for connected vehicle applications. The strategy can transform the unstructured data into labeled topics for large consumers like data centers, mobile devices, and connected vehicles. The performance of the strategy was evaluated using a prototype and Apache Kafka, an open-source delivery system, and comparing its efficiency with the latency qualifications of connected vehicle applications. The experiments disclosed the correspondence of the measured latencies with USDOT (U.S. Department of Transportation) recommendation for connected vehicle applications.

In this paper, different from those studies, the proposed system considers employing vehicular communications in the Moroccan case. Authors have focused on the V2V and V2I communications since the conventional scheme can't be applied in Morocco. Taking into consideration the situation in Morocco and many other differences in comparison to other countries, a foreign system cannot work well for Morocco, the adjustment is required and many factors are to bear in mind. The architecture of Moroccan cities is different from other countries, in the big cities, for example, there are administrative regions, industrial regions, residential districts, the old medina, the new medina, etc. Other factors to take into consideration are culture and environment. The driver behavior and the usage of technology by the population need to be considered. Road conditions, alleys in one or two directions, signs boards, and narrow alleys also have to be considered.

The authors started with the realization using mini cars on a model and they have successfully achieved the goal. In the next step, they will move on to real scenarios with real cars in order to specify the necessary adjustments. The proposal represents also a contribution to the development of smart cities as there is already a trend for smart cities in Morocco. In June 2013, e-Madina was born in APEBI, the Moroccan federation of information technologies, telecommunications, and offshoring. e-Madina is a Smart Cities Cluster that works to make the city of Casablanca more attractive and more efficient using digital technologies and available material and immaterial resources. In March 2017, the government launched the "Cité Mohammed VI Tanger Tech" project, a smart city that will extend over 200 hectares within 10 years. Funding for the operation is estimated at $ 1 billion. Nearly 200 companies operating

in the automotive, aeronautic, textile, electronics, and machine tool industries will set up there.

To the best of their knowledge, authors believe this is the first paper that deals with vehicular communications in the Moroccan case, and this is one of the reasons that made this work chosen, accepted, and financed by the METLE and the CNRST.

3 Proposed system

Connected vehicles are able to revolutionize the current traveling style by creating a protected and interoperable wireless communications network, a system that involves several elements like cars, traffic lights, buses, and trains. Technologies of connected vehicles aim to address some serious challenges in the transportation fields, especially in environment, mobility, and safety.

The purpose of this work belongs to the last field, which is road safety, especially in the Moroccan case to solve the problems cited above, since the conventional scheme can't be applied in Morocco as it is as explained previously. Authors propose three safety scenarios which will be used to alert Moroccan drivers in different situations, in order to decrease the probability of road accidents and to stay away from collision scenes that repeatedly happen between vehicles and pedestrians, animals, trees, and such other objects. These scenarios are based on reel time information and use V2V and V2I modes. Roadside units and vehicles exchange information that will be very useful to anticipate a hazardous situation. This information is delivered to Moroccan drivers in order to help them avoid the danger presented in unstructured roads.

Taking into consideration the statistics presented in [3], the first scenario can notify a driver of a hard-braking vehicle in the path ahead. For example, three vehicles are traveling in the same lane (see Fig. 1 (a)); the driver of the third vehicle can't see the first vehicle because it's being blocked by the second one, which is located directly in front of him. Unexpectedly, the first vehicle slams on its brakes. Thanks to V2V communication, the third vehicle is able to provide a warning of the hard-braking vehicle ahead. This warning will help the driver to drive safely and avoid a potential crash, as can be seen in Fig. 1 (a).

The second and the third scenarios aim to notify a driver of a special traffic condition in the path ahead. Whenever a traffic event is detected (accident, traffic jam, pedestrian crossing the road, animal, road work...), the driver is advised to slow down, change the lane, and take another route. Using V2V communication, the warning notification is transferred by another vehicle ahead, which has previously detected the problem of the related traffic event. V2I communication also was used for the same purpose (see Fig. 1 (b)). In this case, the warning notification is transferred by the RSU placed on the border of the road instead. The location of the RSU depends on the number of accidents recorded in this area and given by the METLE Ministry.

The diagrams in Fig. 2 summarize the logical flow of the methodology in each car. In this scenario, V1 and V2 which are equipped with a Raspberry Pi ran on a straight path using line follower sensors. V1 keeps using the infrared sensor along the way in order to detect any obstacle before the destination. If V1 detects an obstacle, it will stop and send the data as an alert to V2. Similarly,

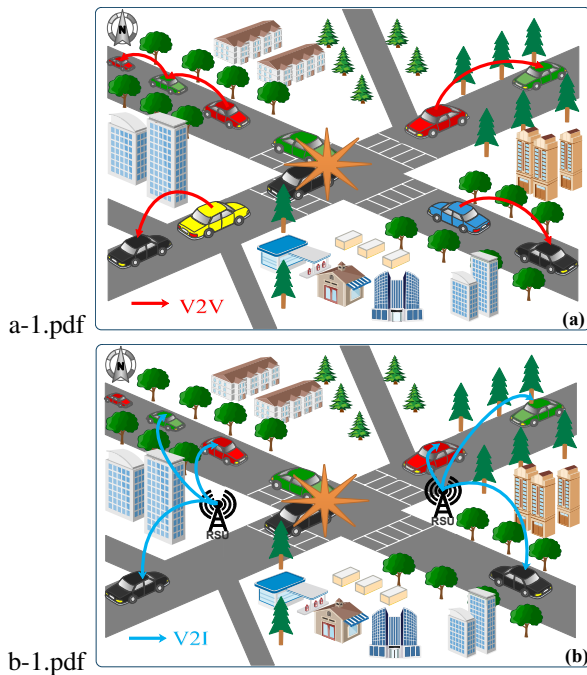
the latter continues on the path to the destination unless it receives an alert from V1. If so, it will stop and change the road to avoid the obstacle and get to the destination.


Figure 1: Operation of the system, (a) represents V2V mode and (b) represents V2I mode
Figure 2: Flowchart for V2V communication.

Reducing possible points of conflict between vehicles and with other users is a common practice of road safety. For this, it is necessary to act in particular on the geometry of the path and the management of the priorities, especially for the zones of intersection and crossing with the presence of different users. According

to the compendium of statistics of road traffic accidents [3], carried out in 2017 by the METLE, 14 998 accidents were recorded in the intersections. Thus, taking into account the statistics, the authors proposed the METLE concerning the locations of the RSUs concerning the areas likely to have accidents in the city of Kenitra (as can be seen in Fig. 3). The communication between these RSUs and also between these RSUs and the vehicles in the area can help to avoid the slowed traffic during a rush hour as shown in Fig.3.

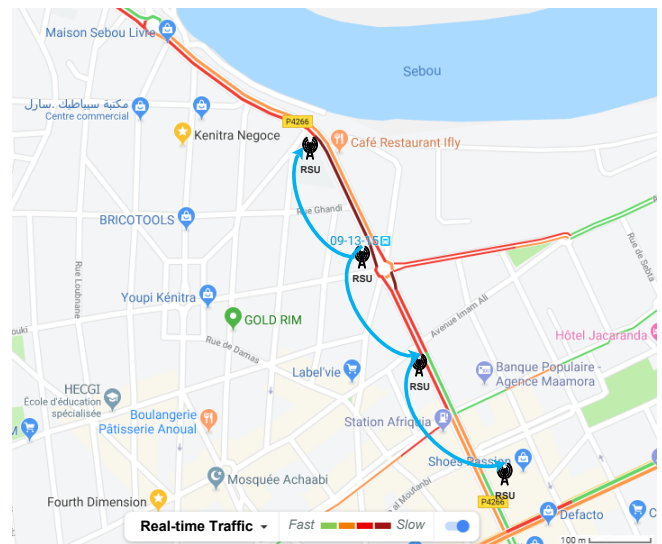
This communication can also help to avoid accidents in hazardous regions especially unstructured ones. A real case is shown in Fig. 4 where the area with diagonal lines was recently transformed into a roundabout, but it was not well adjusted to represent the roundabout. Therefore, someone who is a stranger to the city can take the road straight while it is forbidden. This can cause accidents in this area, as shown in figure 3.


Figure 3: The locations of the RSUs to help mitigate the congestion in Kenitra city
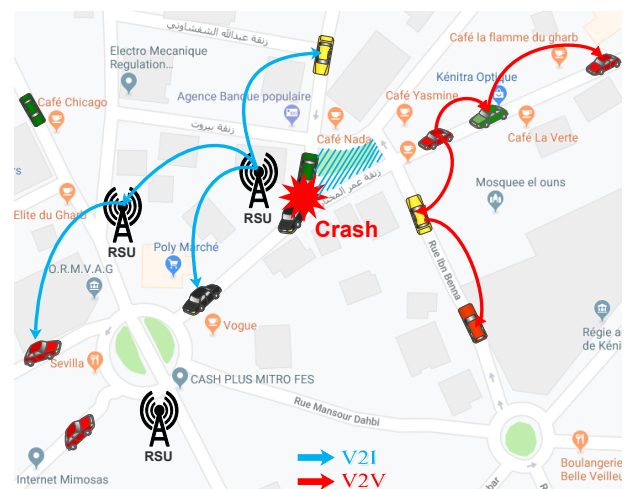

Figure 4: A Real case of an unstructured area in Kenitra city

In order to model the system, the authors proposed two algorithms. One on the client-side and the other on the server-side. Both algorithms start by importing the necessary modules and assigning

pins numbers. The next step is to create a socket so the two cars can communicate. After that, various methods used in the algorithms are defined :

- setup(): sets the setup of the system (variables, frequency, sensor modes . . .).
- setSpeed(): manipulates the speed of the vehicle and handles the error related to the trajectory.
- stop(): stops the motors of the vehicle.
- read_sensors(): reads the line follower sensors and stores a variable related to the error of the trajectory.

Algorithm 1 : Client-Side

```
 1: Import necessary modules
 2: Assign pins numbers
 3: Create a socket
 4: Define the setup method
 5: Define the setSpeed method
 6: Define the stop method
 7: Define the read_sensors method
 8: setup()
 9: while (true) do
10:     val ← IR_value
11:     if val = 1 then
12:         data ← "go"
13:         send data
14:         read_sensors()
15:         set_sensors()
16:     else
17:         stop()
18:         data ← "stop"
19:         send data
20: Close connection to the server
```

Algorithm 2 : Server-Side

```
 1: Import necessary modules
 2: Assign pins numbers
 3: Create a socket
 4: Bind address to socket
 5: Start TCP listener
 6: Accept TCP client connection
 7: Define the setup method
 8: Define the setSpeed method
 9: Define the stop method
10: Define the read_sensors method
11: setup()
12: while (true) do
13:     get data
14:     if data = "go" then
15:         read_sensors()
16:         set_sensors()
17:     else if data = "stop" then
18:         stop()
19: End server
```

[2]Sunfounder, https://www.sunfounder.com/learn/category/Smart-Video-Car-for-Raspberry-Pi.html/ (accessed Jul. 15, 2019)

An infinite loop is necessary to keep reading data from sensors, sending it by the client, and receiving it by the server. If the infrared sensor (located on the client side) detected an obstacle, the IR_value receives the value "0". The client sends then the data to the server which will stop immediately. Else, the IR_value remains in "1". The client sends then the data to the server which will continue the path to get to the destination. The proposed algorithms are presented in Algorithm 1 and 2.

Table 1 presents a comparison of the proposed system with other studies.

4 Experimentation

4.1 *Experimental setup*

In the validation step, the authors preferred to use prototypes in the tests before applying the system to real cars. The experiments were conducted using two mini cars from Sunfounder[2] (Fig. 5) to develop the prototype system. Each car has a Raspberry Pi 3 B+ with basic necessary configuration to enable communication and control movements and sensors. A third Raspberry Pi 3 B board was used to play the role of the RSU. The used boards consist of ARM Cortex-A53 quad-core, which is operating at 1.4 GHz for the model B+ and 1.2 GHz for the model B. They both have a memory of 1GB (RAM), 40GPIO, Audio jack, Ethernet port, Camera interface, HDMI port, Display interface, 4 USB port 2.0, and micro SD slot. The two devices are powered by 5V / 2.5A via a micro USB port. Raspbian was chosen as an operating system. It is installed and boots from the micro SD card.

Both the cars integrate Wi-Fi, so they are able to communicate within an ad hoc network while moving in the test zone. The movement of the cars is powered by the two rear wheels using a DC motor driver. The cars came also with a USB camera, a step-down DC-DC converter module, and a PCA9685-based servo controller. The camera is not used in the current prototype, but it is used to prevent pre-crash by detecting pedestrians in another part of the same project SAFEROAD [21].

Figure 5: Sunfounder mini car

Since the original car kit didn't come with all the hardware needed to run the tests, the authors used some other sensors to complete the prototype, as can be seen in ((a) and (b)) Fig. 6. Five line follower sensors were added below each car, so they help the car following the line (road), in addition to detectors that have the ability to sense the existence of an obstacle in the path.

Table 1: Comparison of the current work with other studies

Study	Communication Mode	Implementation	Tools	Scenario	Purpose	Special Case
[17]	V2V	Real Time	RPi; Ultrasonic sensors; Audible Alarm; GPS Sensor; RF Module	Blind Spot Detection	Improving Traffic Congestion	Not specified
[18]	V2V	Real Time	OsmAnd; Android Devices; GRCBox	Displaying location of relevant vehicles	Warning about emergency vehicles	Not specified

Figure 6: The prototypes, (a) Robot & (b) RSU

One infrared obstacle detector was used at the front of the first car, in addition to one ultrasonic sensor used in the RSU. The specifications of the sensors are given in Table 2.

Table 2: The specifications of the used sensors

Sensor name	Line Follower Sensor	Ultrasonic Sensor	Infrared Obstacle Detector
Reference	TCRT5000	HC-SR04	FC-51
Detection Distance	1 mm - 25 mm	2 cm - 4 m	2 cm - 30 cm, Angle: 35
Operating Voltage	5 V	5 V	3.3 - 5 V
Quantity	5	1	1

4.2 Results and discussion

The aim of the first and second scenarios was the dissemination of a warning message indicating the presence of an obstacle in the path ahead, using V2V communication. First, the authors tried to move the robots following a map (pre-programmed distances), but since the motors are not completely identical, they ran at different speeds. Consequently, the car couldn't move forward in a straight movement. For that reason, the authors added line follower sensors, to keep the car on the line (road).
Figure 7: (a) The first scenario (V2V communication): V2 stops, once receiving the alert from V1 indicating the presence of an obstacle. (b) The second scenario (V2V communication): V2 changes the road, once receiving the alert from V1 indicating the presence of an obstacle.

In the first scenario, V1 and V2 ran at the same time on a straight path, and an obstacle was placed just before the destination. V1 is equipped with an infrared sensor (see Fig. 6 (a)), which detect the obstacle. Once the obstacle is detected, V1, which plays the role of the client, stops immediately, and sends the data to the server (V2) as a warning notification, using the Wi-Fi interface. As soon as it receives the warning, V2 stops in its turn (Fig. 7 (a)). Receiving the notification depends on the range of the Wi-Fi (the maximum distance between the first and the second car).

Similarly, in the second scenario, V1 and V2 ran at the same time on a straight path, and an obstacle was placed just before the destination. The infrared sensor in V1 (the client) detects the obstacle and stops immediately. It sends then an alert to V2 (the server) to change the road in order to avoid the obstacle, and get to the

destination. Therefore, once V2 reaches the intersection, it changes the road taken by the first vehicle and chooses the safe road (Fig. 7 (b)).

For the third scenario, the intention was the sending of the warning message using V2I communication. For this purpose, a third Raspberry Pi board was used with an ultrasonic sensor to play the role of the roadside unit (RSU). In this case, one vehicle was put in the path, and the obstacle was placed on the road. The RSU senses the presence of the obstacle using the ultrasonic sensor (see (b) in Fig. 6). It uses then the Wi-Fi interface to send a warning to the vehicle presented in the zone. As soon as the vehicle reaches the intersection, it takes the safe road (Fig. 8).
Figure 8: The third scenario (V2I communication): once getting to the intersection, the vehicle will take the other road, thanks to the alert received from the RSU.

The realization can be applied in the real world, as can be seen in Fig. 4 which depicts an example of Kenitra city where the area mentioned is likely to have accidents. The presence of the RSUs in this zone can help to avoid accidents. The RSU detects the crash and sends the alert to the vehicles in the area and also to the nearby RSUs. Another type of obstacles that can be detected using RSUs is the slowed traffic, as it is illustrated in Fig. 3. The communication between the RSUs in the area can help Moroccan drivers to avoid the traffic jam by taking another road where the traffic is relatively fast.
Figure 9: Summary of the contribution to Moroccan roads.

As explained above, the application of the system in real life in Morocco can play an important role in addressing the issues of road safety. It can be used to serve to avoid accidents, as it can also be useful to avoid slowed traffic. Fig. 9 summarizes the contribution of the system in Moroccan roads. In the first direction, the RSU2 detects the crash and sends an alert to nearby vehicles using the Wi-Fi

interface. In the opposite way, the RSU1 detects the slowed traffic and sends a warning to the vehicles in the zone. The two RSUs can also communicate by sending information about the traffic in the two directions.

From Fig. 9 it can be seen that the crash was caused by a vehicle that took the lane in the opposite way. In order to resolve this kind of situation, the authors made another proposition to the METLE. They suggest building the new roads without a separation between the lanes of the opposite directions. Therefore, in the case of an accident or traffic jams, it will be possible to use a lane or more in the opposite direction to alleviate the traffic (see Fig. 10 and Fig. 11).

Figure 10: Road with separation between opposite lanes - Morocco

Figure 11: Road without separation between opposite lanes - Morocco

Due to V2I communication, the RSU will detect the obstacle (accident), send a warning to inform the nearby drivers and send also a notification to the traffic management center (direction of the roads or gendarmerie). Consequently, the center will change the light panels to indicate the use of additional lanes. The drivers will then keep the correct lane.
Figure 12: Avoiding Traffic Jams in Bangkok, Thailand by adding opposit lanes using the light panels

---

[3]https://www.shutterstock.com/video/clip-17081557-bangkok-thailand-june-2016–traffic-jam (accessed Oct. 01, 2019).

An example of Bangkok city[3] in Thailand is illustrated in Fig. 12. The road contains six lanes, but two of them were added in the opposite direction to mitigate the congestion. This is one of the propositions that can be made in the Moroccan case to solve rush hour problems, especially in big cities.

5   Conclusion

The main concern of the paper was to present an implementation of vehicular communications using both V2V and V2I technologies. The goal was to notify the driver at the right time so that he can take the navigation choice depending on the received alert. The tests were conducted using the Raspberry Pi 3 boards, model B and model B+, in addition to a specific number of sensors. Two mini cars were used to realize V2V communication by testing two different scenarios which worked well. Authors realized also the V2I communication which worked as well. In addition to that, they made proposals to the Ministry of transportation concerning the deployment of the RSUs and the management of traffic jams in Kenitra City. Based on the results, it can be concluded that these scenarios can be used in the field of road safety, related to the Moroccan case, to address the problems of transportation in kenitra city for example. This will decrease the number of accidents in Morocco and help save lives. As the current work may have some limitations that can be faced in real life, the authors intend in future research to conduct real experiments using two real vehicles. This will reveal all the limitations and lead to a complete system. Further research could bear from this work, such as the integration of cameras in this system in order to study different scenarios of accidents.

Conflict of Interest   The authors declare no conflict of interest.

The widespread team project method is more effective when used in conjunction with heuristic methods. The large number of heuristic methods and the variety of their descriptions create a problem to prepare students for the use of these methods. A method based on two areas of knowledge - heuristics and psychology - is proposed. The personality types of students STEM specialties according to Myers-Briggs are considered. An analysis of interaction of personality types from the point of view of application of heuristic methods is performed. The survey for percentage composition personality types of student STEM specialties was carried out and predominantly types of student STEM specialties was determine. Heuristic methods are consideration as sum of heuristic techniques and procedure. It is shown that many methods involve the same heuristic techniques and differ only in procedures. A generalized method has been developed that allows replacing most of the methods based on collective discussion. This method included five heuristic techniques: collective discussion, pause between the presentation of ideas and their criticism, random associations, analogy, expert evaluation, using a matrix. This method is mainly aimed at teaching students of STEM specialties. A project team is formed to use the method. The composition of this team includes a discussion group, a criticism group and a expert evaluation group. These groups are formed in accordance with the personal types of participants. The method includes an algorithm for team members to interact when using heuristic techniques and procedures.

1. Introduction

Research in the field of heuristics is carried out within a many scientific disciplines. Different approaches and terminology are used. In philosophical works, heuristics is understood as a science, the subject of which is the process of solving a problem in conditions of uncertainty. Another aspect of heuristics is the branch of the science of thinking. Different interpretation is related to pedagogy, so heuristics are often understood as a way of learning. The concept of heuristic is also widely used in cybernetics, where it is interpreted as a heuristic algorithm. Researchers estimate the number of existing heuristic methods in different ways - from several to hundreds. There is no unambiguous idea about the structure of the heuristic method. In different scientific disciplines, a set of principles, a set of steps, or a set of heuristic techniques are considered to constitute a method. First of all, heuristic methods aimed at enhancing the creative abilities of students and involving them in collective creativity are relevant for teaching. The number of such methods is quite large, but there are many common features in the structure of these methods. When it comes to collective creativity, the question of

performers immediately arises. How do personality differences between people affect their use of heuristic methods and how do these differences affect the organization of their interaction? This paper, that is an extension of work originally presented in International Conference on High Technology for Sustainable Development, is dedicated to solving this problem [1].

Consideration of the application of heuristic methods is associated with the personal differences of performers in two aspects: the effectiveness of the application of methods and teach students to use heuristic methods. Many heuristic methods are focused on collective creativity. Methods of this type are well suited for use in student learning. Heuristic methods are most widely used in teaching students studying the following specialties: science, technology, engineering and mathematics (STEM). When using heuristic methods formed by a group of students working together. The interaction of performers in such a group is well studied in project management. This kind of group of performers is called a project team. A large number of publications on psychology, management and education are devoted to organizing the work of the project team and the selection of performers. The project team can be organized for one seminar, or can work on a course project or diploma project during a semester or a year.

2. Review of heuristic methods

As methods of generating ideas used in teaching, the following are considered: Brainstorming, Method 6-3-5, C-Sketch, Gallery, Brainsketching. These methods differ in the form of communication: verbal - brainstorming; text - method 6-3-5; graphic - method C-Sketch; sketch, discussion and text - Gallery; sketch and text - Brainsketching [2]. In the 6-3-5 method, six participants write 3 ideas on a piece of paper in 5 minutes. Then they exchange their notes. This method resembles individual brainstorming in that each participant generates ideas individually, as well as electronic or online electronic brainstorming in which participants exchange ideas via e-mail. In Brainsketching, participants present their ideas in the form of sketches and then exchange them. As in the 6-3-5 method, the criticism of ideas is carried out without the participation of those who put forward the ideas. It is assumed that the graphical representation of ideas will help to find associations. In the Gallery method, the sketches created are discussed and selected together. In the C-Sketch method, the sketch is an imaginary construction. This method is targeted at mechanical engineers.

An experiment comparing Brainsketching and Brainstorming methods has been carried out. The experiment showed that during the Brainstorming process, the participants produced more ideas, and during Brainsketching, the ideas were more original. It is noted that Brainsketching is a type of Brainwriting. That is, the participants put forward ideas individually, as in the 6-3-5 method, only in the form of a sketch [3].

The methods can be divided into three groups [4]. Methods using graphic presentation of information: C-Sketch and Gallery. The methods of using the text include: Brainstorming, K-J Method, Checklists, Affinity Method, Storyboarding, Fishbone, and Method 6-3-5. In addition to the above two groups of methods, another group of Cross-representation methods is proposed [4].

In the Storyboarding method, the sketch is not static but is created in the presence of the discussion group members. The purpose of a sketch or series of sketches is to represent the origin and development of an idea. Affinity Methods operate with different types of information presentation: text, photo, sketch, etc. The group discussion task is sorting similar information into clusters. Affinity Method is, as many believe, a variation of the K-J method. In the Fishbone method, as a result of collective discussion, the factors are also grouped into clusters; only the grouping is visualized as a single diagram.

Cross-representation methods include Morphological analysis and Synectics [4]. Synectics uses collective discussion, the prohibition of criticism as in Brainstorming. Synectics encourages the use of analogies and introspection of the idea generation process. Morphological analysis requires the identification of a set of functions and a possible set of design solutions or physical principles. For this, the analogy of physical processes is widely used [5]. The comparison of possible combinations of properties and design solutions is performed using a matrix. Another name for the method is morphological matrix [5]. Note that the same method has different names Morphological analysis and Morphological matrix. The Affinity method is also called the Affinity Diagram; some researchers describe it as a separate method, others as another name for the K-J method. Brainwriting is an individualized brainstorming session and is very similar to the 6-3-5 method. The peculiarity of publications on heuristics is the use of different names of methods and different points of view on their classification, which is partly due to the authors' affiliation to different scientific disciplines, as well as different ways of presenting information by representatives of the humanities and engineering disciplines.

The comparison of the methods Brainwriting and S.C.A.M.P.E.R. was carried out [6]. In S.C.A.M.P.E.R. method the ideas are generated based on responses to prompts: Substitute, Combine, Modify, etc. The study did not obtain data that could indicate the superiority of one of the methods. It is noted that more creativity can be achieved if the participants are from different universities and different countries. This can be interpreted as a recommendation for using electronic Brainstorming.

The comparison of methods S.C.A.M.P. and TRIZ are performed; also data about Brainstorming was used [7]. It is noted that Brainstorming allows for more creative ideas, but S.C.A.M.P.E.R. and TRIZ provided ideas that could be implemented. Method TRIZ allowed getting more creative ideas than the S.C.A.M.P.E.R method. The S.C.A.M.P.E.R method is presented as intuitive in contrast to the logical TRIZ method.

It should be noted that TRIZ is aimed at solving inventive tasks, that is, it is focused at engineers. More precisely, the name is TRIZ methodology, not a method, since TRIZ contains a set of methods. Most of the TRIZ methods are not methods, but are recommendations for a mechanical engineer, for example: replace sliding friction with rolling friction or replace rectilinear motion with rotational. At the same time provides a method of analogy and decomposition.

A comparison of the methods used in the educational process is carried out; these methods include: Brainstorming, Method 6-3-5, Morphological matrix, Mind and Brain Mapping, Patent

Research, AIDA, Function Structure, House of Quality, Black Box, Decision, Matrix and Pugh Chart. The selection of methods raises questions - how and for what purposes these methods are used in the educational process [8]. The following design stages are highlighted: Task planning and clarification, Conceptual design, Embodiment design, Detailed design [9]. The advantages of the AIDA method are noted, which can be used both at the Task planning and clarification stage and at the Conceptual design stage. The possibility of using one AIDA method instead of using a number of methods is being considered: Brainstorming, Black Box, Morphological matrix, Decision Matrix and Pugh Chart [8]. Note that the feature of the AIDA method is the construction of an option graph, and then the established relationships are analyzed in the matrix. In this part, the method is similar to the Morphological matrix and Decision Matrix methods.

There are different ideas about the stages of the creative process and the stages of the engineering design process [10]. A large number of classifications have a lot in common. Most researchers indicate Analysis phase as the first stage or phase, and Generation phase as the second stage, which is also called Idea-finding, Generating ideas. Inspiration, Response generation. The third stage is the Evaluation phase, which is also called Looking Back, Solution-finding, Reinterpretation, Response validation. The fourth stage is Communication / implementation or Acceptance-finding, Developing an implementation plan [10].

Taking into account the division of the creative process into stages, it is possible to assess the applicability of various methods to these stages. Undoubtedly, of the above methods used in teaching for Generation phase, methods of collective creativity are suitable: Brainstorming, Method 6-3-5, S.C.A.M.P.E.R., Brainwriting, Brainsketching, C-Sketch и Gallery. The mind and brain map is suitable for use by a teacher. If it is used by students, it is transformed into methods with a graphical representation of the idea - Brainsketching, C-Sketch and Gallery.

The methods K-J Method, Checklists, Affinity Method, Storyboarding, Fishbone, AIDA are more suitable for the Evaluation phase, although they are also used in the second stage. The Morphological matrix and Decision Matrix methods are ideal for the third stage. In the fourth stage, Pugh Chart and Checklists can be used. Decision Matrix also has another name Decision support matrix (DSM) this method is aimed at solving engineering problems. The method DSM allows to establish the presence or absence of interactions between the nodes of the product. Based on the found interactions, elements are combined into a cluster [11]. Another method using a matrix is the Interaction Matrix method. This method also is aimed at identifying the interactions between structural elements and their systematization [12].

The TRIZ methodology contains a set of methods that are suitable for each stage of the design process. At the same time, the core of the method is also a matrix - a matrix of contradictions. The TRIZ method involves the formation of a matrix, in which the components and elements of the product are located horizontally, and functions or parameters — vertically. The contents of the matrix cells are a list of methods that can be used to resolve technical contradictions [13]. To this series of methods that use a matrix should be added - a Matrix Diagram (Quality Table). The matrix includes elements between which it is necessary to establish

the interaction. The values in the cells of the matrix indicate the presence and strength of the interaction [14].

3. Myers-Briggs personality types and creative process

The effectiveness of the application of heuristic methods largely depends on the selection of participants and the organization of their work. The selection of participants is especially important when the project team is being formed for a long time. The interaction of participants in the project team is described by the team role methodology. A team role is a description of a behaviour pattern that defines how one team member interacts with other team members when working to accomplish assigned tasks. In project management, the most widespread is the classification of team roles in accordance with [15]. Along with the Belbin typology, there are other typologies of team roles, including MTR-I Team Dynamics [16] and Margerison-McKenna [17]. In psychology, the typology of K. Jung and his followers is generally accepted. Thus, A. Augustinavichute proposed her original modification of K. Jung's typology, which was called "socionics" [18]. The most widely known indicator of the Myers-Briggs types (MBTI) [19]. The MBTI divides individual differences into four opposite pairs, leading to sixteen possible personality types. The sixteen types are usually designated by a four-letter abbreviation, the initial letters of each of their four preference types. For example: INTJ: Introversion (I), Intuition (N), Thinking (T), Judgment (J) or ESFP: Extraversion (E), Sensation (S), Feeling (F), Perception (P) [19, 20]. Likewise, from a combination of four letters, abbreviations of the remaining fourteen personality types are formed.

It is important to note that the role of an individual in the project team may not correspond to his innate individual differences as determined by the Myers-Briggs test. Work experience, acquired qualifications affect the role of the individual in the project team and the results of the MTR-i and Belbin tests. The personality type, in accordance with the Myers-Briggs typology, reflects the individual differences of a person, to a lesser extent dependent on external circumstances and experience, and to a greater extent - on the innate characteristics of the nervous system. Innate human abilities are important in terms of the spontaneous expression of ideas on which most heuristic methods are based. Therefore, this typology is most suitable for describing the heuristic abilities of project team members and their interaction in the collective generation of ideas, critical discussion and expert evaluation.

In the first place it is of interest the possible role of a certain type of students in the process of collective discussion. Apparently for electronic brainstorming it will be important to note that the intuitive interface is preferred [21]. It is also remarked that for extroverts, the response of other participants in the discussion is important in order to clarify the problem [21]. Participants who have the constructs N - Intuition and E - Extraversion [22] are useful for brainstorming. It is also indicated that it is advisable for students with a combination of ES constructs to be entrusted with case studies based on real facts. And students with a combination of IS constructs are preferable to be entrusted with a critical analysis of real facts and conclusions obtained by other students. In [23], personality types with a combination of IS constructs are characterized as a thoughtful realist, and the practical orientation

of their thinking is also noted; they are better at solving problems related to real life and based on real facts.

Students with a combination of IN constructs are distinguished by a critical analysis of new ideas, possibilities, and they can also formulate ideas expressed by other participants in the discussion [23]. Personality types with an IN combination are thoughtful innovators, they generate new ideas and penetrate deeply into the essence of the problem, they are most successful at generalizing facts in the form of a concept or theory [23]. The personal type EN shows itself best in new situations; it is an innovator, action-oriented and sees an opportunity to achieve success in challenges [22]. The same characteristic is given in EN [23], it pointed out that this personality type is suitable for joint execution of tasks, including joint generation of ideas during brainstorming.

In [24] give detailed characteristic NT - "Self analysis exercises and structured controversy are more likely to appeal to NTs, who focus on principles and abstractions". In [25] believes that "…NTJ, the type that tends to have the highest grades in engineering and is commonly drawn to engineering research". In [26] supported this characteristic ENTJ "they also have strategic ability, including reasoning, creative problem solving and strategic thinking". In [27] point out "…the student with the ENTJ personality types, it is preferable to choose for the role of a moderator".

The NP personality type likes to participate in brainstorming [21]. In [28] believes that "Sensitive-Thinking (ST) types preferred hard data and logical analysis in reaching decisions" and the "Intuitive-Thinking (IT) types preferred logic and to test several premises before coming to a decision". In [24] describes that "…NT and SJ individuals who tend to be more linear and serial, more structured, more rational and analytical, and more goal-oriented in their approach to problem solving." In [24] also describes personality types SP and SJ - "Role-playing and simulations are especially appreciated by SPs and SJs, who generally take a more practical approach to problem solving". For SP advisable it is an iterative process of determining a suitable decision through action. "SJs, care should be taken to proceed in a step-by-step, orderly manner, with ample time for consideration of all details at each step." In [25] add to the characterization of SP and SJ that "…students leave things to the last minute (SP), why some prefer a rigid schedule (SJ), why some are intellectual perfectionists (NT)".

In [26] gives characteristic ENFP as "get involved with the people with whom they work, and are very capable of and willing to reconsider plans when others offer input". For two types ISTJ and ENFP has been described problem-solving characteristics [21]. "In problem solving, ISTJ will want a clear idea of the problem (I) and attack it by looking for the facts (S) and by relying on a logical, impersonal (T), step-by-step approach in reaching conclusions" In [21] and [25] are expressed even more definitely "ISTJ engineering and technology stereotype". An important observation is made that ST and NT is cognitive pairs, they provide the exact opposite of the problem [25]. In [26] notes about ISTJ "meeting deadlines and budgets, ensuring productivity and accountability are strengths of ISTI personality".

ESTJ have a leadership qualities, they characteristics are authority and orientation to results [26]. In [18] supported this think, ESTJ is characteristic as administrator which "possess capability to assimilate large amount detailed information". It is noted that ESTJ is logical and rational; also he knows how to make decisions [18]. It is remarks that the set of INT and EST constructs corresponds to the developer using the heuristic TRIZ method [29]. In particular, ESTJ is suitable "determination of corresponding design principles and reviewing and understanding examples showing appropriate application" and INTP is suitable "abstraction to general TRIZ problem" [29].

4. The structure of heuristic methods

The presented overview of heuristic methods does not cover all existing methods. Consideration of only a part of the methods showed that the same method can have different names, such as Affinity Method and K-J method. Either they may differ a little, like Brainwriting and Electronic Brainstorming. The excretion of the characteristic features of methods or their structural units can significantly reduce the number of these methods. From our point of view, the basis of such an analysis can be the excretion of heuristic techniques and procedures from the composition of method. For example, Brainsketching and Method 6-3-5 use the technique of random association. These associations are called through various procedures in the Brainsketching, this is a sketch of another participant, and in the Method 6-3-5 and Brainwriting, these are notes made by another participant. Technique of random associations is used in methods: Brainwriting, Method of focal objects, Method of garlands of accidents and associations, S.C.A.M.P.E.R., Lateral thinking, etc.

The number of heuristic techniques is much less than the number of methods. And within one stage, only a few techniques are used. Let us consider the structure of the methods used in the "Generation phase" stage from the point of view of the applied heuristic techniques. Methods: Brainstorming, Brainwriting, Brainsketching C-Sketch, Gallery, Method 6-3-5, S.C.A.M.P.E.R. be sure to use the collective discussion technique. An important feature of the Brainstorming method is the use of the technique "Pause between the presentation of ideas and their criticism". This technique is also used in methods: Garlands of accidents and associations, Gallery and Lateral thinking. Many methods are based on the use a technique of analogy. These are the following methods: Synectics, Analogy, Empathy and S.C.A.M.P.E.R., which with their questions force the participants to look for similar solutions. In the K-J Method, information is sorted on the basis of analogy, although the use of random associations is also possible. In most methods, the final selection of ideas is done collectively. At the same time, the participants act as experts and their work can be organized on the basis of well-known expert evaluation procedures.

A powerful analysis tool is a heuristic technique «Use of matrix». In different versions, this technique is used by methods: Morphological analysis, DSM matrix, Interaction matrix, Matrix diagram, AIDA. First of all, the methods are selected that are suitable for use in the "Generation phase" stage, are widely known and contain, if possible, several heuristic techniques. These methods are summarized in the table to analyze their structures (Table 1).

Table 1: Structure of heuristic methods

Heuristic techniques / Heuristic methods	Collective discussion	Pause between the presentation of ideas and their criticism	Random associations	Analogy	Expert evaluation	Using a matrix

To develop a generalized heuristic method aimed at solving problems within the framework of the stage, we formulate a theorem.

Theorem: for each stage of the creative process one generalized heuristic method can be applied replacing all methods used for this stage if it includes all heuristic techniques used within this stage.

The generalized method for "Generation phase" stage includes the following heuristic techniques: collective discussion, pause between the presentation of ideas and their criticism, random associations, analogy, expert evaluation, use of matrix. The use of all these techniques in one method is mandatory. The order of using the techniques and the procedures applied in the method may be different depending on the branch of knowledge and the problems being solved. For example, the "Collective discussion" technique can be applied twice. Then one gets a variation of the brainstorming method - double brainstorming. The Brainsketching and Gallery methods use the "Random association" technique. These methods use different procedures to enhance creativity. In the Brainsketching method, participants can flip the image upside down, and in the Gallery method, they can observe the sketching process. The methods of the DSM matrix and the Matrix Diagram use the same heuristics "Using a matrix" and different procedures. In the DSM matrix, the procedure is to establish the presence or absence of an interaction between elements, and in the Matrix Diagram, the procedure is to assess the conformity of an element to certain requirements.

Let's point out the procedures typical for the methods used in teaching. These are procedures: selection of a moderator, selection of participants in a discussion group, selection of members of a group of critics, selection of members of the group of expert evaluation. Also, the procedures are - defining the rules of discussion and the method of forming an expert evaluation. Important procedures are the choice of the physical meaning of the columns and rows of the matrix and the rules for evaluating combinations of row and column elements.

Based on the analysis of heuristic techniques and procedures, it is possible to form an algorithm of the generalized method. This method must be suitable for use in education, also for design. That is, it should be a method of increasing creativity and at the same time a method suitable for use in the design process. The latter is important for students engineering specialties. To combine such an algorithm and data on the predisposition of students of different personality types to the use of heuristic techniques and procedures in the generalized method, it is important to establish what personality types are typical for students studying in STEM specialties.

5. Typical personality types of students STEM specialties

It is known that there are more introverts than extroverts among students studying STEM specialties. Thus, among students studying agricultural engineering, 83% have construct I, and only 17% have construct E [21]. In the ratio of the S and N constructs, there is no unambiguity: the construct S prevails in mechanical engineering (64 S%, 36% N), while for aerospace engineering the

construct N prevails. The most obvious is the predominance of the construct T over F and J over P [21].

It is claimed those students with the following personality types: ENTJ, INTJ, INTP, ESTJ, ISTJ, ESTP and ISTP, have the ability to work in engineering positions [30]. The personality type of ISTJ is especially highlighted, which is predominant among students of engineering specialties and makes up 26% of their total number [26]. Based on research carried out in [32], it is also stated that the personality type ISTJ occurs most often, the second most common is one of the following personality types ESTJ, INTP and INTJ. Testing of students according to typology (MBTI) was conducted in eight universities [21]. The percentage of students of a certain personality type is established, it is indicated in brackets. The study showed that personality types: ISTJ (16.46%), ESTJ (12.75%), ENTJ (9.43%), INTJ (9.43%), INTP (8.46%) and ENTP (7.43%), most often found among students studying STEM disciplines [21]. In total, personality types ISTJ, ESTJ, INTJ and INTP make up more than 50% of the students who passed the test, and personal types ESFP, ESFJ and ENFJ are less common among students of STEM specialties [31]. The most detailed study of the representation of certain personality types among students of STEM specialties is presented in [10]. First of all, we note that the most widespread personality type is ISTJ (16.9%), and the second place is occupied by INTJ (12.3%), which corresponds to the research data [32]; not much less than INTJ is represented by ENTP (11.8%); for other personality types the following data were received: ESTJ (9.2%), ISTP (7.7%) and INTP (7.2%) [10]. Thus, only four personality types out of sixteen ISTJs, INTJs, ENTPs and ESTJs account for 50.2% of the total number of students. The data of another survey [33] also revealed the prevalence of ISTJ (18.1%), and the second place in prevalence was taken by ESTJ (10.3%), as in [21]. Other personality types ranked in the following sequence: INTP (9.4%), INTJ (8.5%), ISTP (8.2%). It is noted that these five personality types make up more than half of the students [33]. It is noted that these five personality types account for more than half of the students [33]. Similar data were obtained in [32] - the following personality types are prevalent among students of STEM specialties: ISTJ, INTP, ESTJ, INTJ, ENTP, ENTJ and ISTP. Obviously, in further research, it is necessary to obtain data on the possibility of participation of precisely these personality types at different stages of heuristic search. According to the sources discussed above, the following personal types are typical for students STEM professions: ISTJ, ESTJ, ENTJ, INTJ, INTP и ENTP. It is also found that four personal types can account for more than half of the total. Three of them are ISTJ, ESTJ, INTJ, as the fourth, both INTP and ENTP are mentioned. For developing a heuristic method that uses personal types in a particular way, these facts are very important.

Therefore, a study of the distribution of personal types among students speciality "Mathematics and Physics" at the South Ukrainian National Pedagogical University named after K. D. Ushynsky (SUNPU) was carried out. The same test was performed for students speciality "Dynamics and durability of machines" Odessa National Polytechnic University (ONPU) in 2014-2016 years. In each semester, two academic groups numbering from 15 to 20 students were tested. The test was conducted twice, at the beginning and at the end of the semester. The coincidence of test results was observed in the range of 76–81%, which is within acceptable limits (75–90%) [34].

There were no students who refused to participate in the survey. But among the students of ONPU there were also those who did not take it seriously. Their questionnaires were not taken into account. Students of SUNPU treated the survey more scrupulously when the purpose of the survey was clarified - it was the selection of students into project team. They showed a great interest in testing, as it is directly related to their prospective teaching profession.

The distribution of personality types was calculated twice, first for all students, then separately, only for men majoring in "Dynamics and Durability of Machines" (ONPU), where the proportion of men is 87%, and only for women majoring in "Mathematics and Physics" "(SUNPU), where the share of women is 72%. The average value of data of the first and retesting were calculated. In that case, if the student equally corresponded to two personality types, for example, the constructs T and P scored the same number of points, then such people were taken into account twice, in each of the personality types. There were students who did not care about the test and gave mutually exclusive answers; such questionnaires were not taken into account in further calculations. The test results are summarised at Table 2.

Table 2: Personality types of ONPU and SUNPU students

Personality types	Students ONPU (%)	Students SUNPU (%)
ISTJ	22,1	18,1
INTP	11,9	15,5
ESTJ	11,7	14,7
INTJ	11,6	10,4
ENTP	7,8	8,4
ENTJ	5,3	4,4
ISTP	4,2	3,3
ENFP	2,0	2,5

ISTJ personality types are more common in ONPU, but INTP and ESTJ personality types are more common in SUNPU, as shown in Figure 1.
Figure 1: Percentage distribution of personality types

The relationship between personal types can be most clearly represented in the form of a pie chart in which the axes correspond to certain cognitive functions. The abscissa corresponds to the cognitive functions N and S. The construct N is located on the left, and the constructs S is located on the right along the abscissa. The

ordinate corresponds to the cognitive functions T and F. The construct T is placed below the abscissa, and the construct F above the abscissa is along the ordinate. The personality types within the inner circle are introverted; personality types outside the inner circle are extroverts. For each personality type, the average value of students of this type in ONPU and SUNPU was calculated: ISTJ (20.1), INTP (13.7), ESTJ (13.2). INTJ (11.0), ENTP (8.1), ENTJ (4.9), ISTP (3.8) and ENFP (2.3) (Figure 2).

The obtained average values of personality types were plotted on this pie chart. The size of the circle corresponds to the percentage of this personality type among all students.
Figure 2: Distribution of personality types relative to the pie chart depicting cognitive functions

The small number of students surveyed does not allow making any conclusions about gender differences. The repeated survey for women in ONPU and men in SUNPU gave an error higher than acceptable. We cannot fully rely on the absolute value of a particular personality type. Because when surveying 50 students, one incorrectly completed questionnaire gives an error of 2%. The data of students at six technical universities in the United States and Canada shows that only one university has the represented ENFP type among students [32]. For this reason, we excluded the ENFP personality type from further consideration because the data obtained correspond to one representative from two academic groups.

We obtained the following order of personal types by their prevalence: ISTJ, INTP, ESTJ, INTJ, ENTP, ENTJ and ISTP. The first is ISTJ, as in the sources [21, 26, 31]. The first six personal types are the same as in [21], but their order is different. The resulting distribution of personal types is close to [33]. In our study, the INTP (13.7%) is in second place and the ESTJ (13.2%) is in third place. the difference between them is within the margin of error. In [33] type personal ESTJ (10,3%) at the second location, and INTP (9,4%) for the third, but the difference between them is small. In [31], also the personal type ESTJ (10.9%) is in second place, and INTP (9.9%) is in third place and the difference between them is about 1% as in the article [33]. The first four personal types in our study make up 58%, which is also more than half of the total number as in sources [31, 33]. According to our data, more than 75% of students STEM specialties belong to the following personality types: ISTJ, INTP, ESTJ, INTJ, ENTP, ENTJ and ISTP. The personality types in the table are arranged in descending order, in accordance with the number of representatives of this type (Table). Refer that the most common personality types include types containing the construct T. These personality types have a predisposition to STEM professions. The only personality type between of those which contain a construct T and which is ranked among the common - this ESTP. This type is also not mentioned

among those common in papers [21, 33]. This is due to the fact that students of this type neglect the details and do not finish what they started. Equally represented are constructs Sensing (S) and Intuition (N).

6. The generalized method

The generalized method contains a heuristic technique *using a matrix*. Rows and columns of a matrix can be functions, units, a number of products with similar functions, design techniques, and so on. These recommendations are intended to solve engineering problems. The range of tasks solved by the technique *using a matrix* is much wider. It is proposed that the purpose of the technique *collective discussion* is to find ideas about the contents of the columns and rows of the matrix. After the first heuristic technique, there is a pause between the presentation of ideas and their criticism. In further, the criticism of the ideas put forward and their evaluation are providing. That is, the technique of *expert evaluation* is used. The semantic content of rows and columns is searched for by the technique of *analogy* and *random associations*. For example, for rows, the search is carried out by *analogy*, and for columns using *random associations*. If the search did not give satisfactory results, it is repeated, but the technique of *random associations* is already used for rows, and *analogy* for columns. The results are again *collectively discussed* and undergo *expert evaluation*. Based on the results of the heuristic analysis, the technique of *using a matrix* is applied - in this way the matrix is formed. Based on the results of the heuristic analysis, a technique *using a matrix* is applied – therefore the matrix is analyzed. Each cell of the matrix corresponds to a possible variant of a problem solution. These options are subject to *collective discussion* again. Then, *expert evaluation* and documenting of the results are performed.

The heuristic techniques and procedures described above require performers with a certain personal type. An effective *collective discussion* technique will not work if all participants are introverts. Extroverts with artistic abilities should not be entrusted with documenting matrix analysis results. The complete development of the method requires specifying the personality type in the performers for each of the techniques and procedures.

The ENTJ personality type has leadership qualities, strategic vision, logic, and therefore can be a moderator of the discussion. ESTJ - has organizational skills and the ability to keep track details of discussion. A student with the ENTJ personality type is selected as the moderator. If there was no such student in the group, then the student with the ESTJ personality type plays the role of the moderator. The moderator participates in the *collective discussion*.

Collective discussion is an extroverted process. Intuition is also important for generating ideas. In the process of collective discussion, there is a search for patterns, the construction of schemes and models, and a search for the relationship between known facts. It is important that the participants discard well-known dogmas, abandon stereotypes. Extroverted personality types (construct E) and intuitive personality types (construct N) take part in the *collective discussion*. Preference is given to personality types ENTJ, ENTP.

The logic is inherent by personality T. The personality NT is inventive, looking for regularities. The personality types INTJ and

INTP can generate ideas, however, they are introverts and the collective discussion is a problem for them. The personality type INTP is actively generating ideas; he has logic (T) and the ability to evaluate the logic of ideas expressed by other members of the team. The personality type INTJ is a researcher and has good intuition, but due to communication problems with others, he is not always possible to clearly express their ideas. The personality type INTP can be tactless and arrogant, which hinder a spontaneous expression of ideas. Based on the foregoing, the types of personality INTP perform the function of criticism.

The understanding an importance of the knowledge is inherent of a personality type TE. This quality, as well as extraversion, allows the personality type ESTJ to participate in the discussion, although ESTJ can consider the brainstorming ineffective. Based on the analysis of the above, students with personality types ENTJ, ENTP and INTJ are necessarily selected for the *discussion group*.

For the critical analysis of the proposed ideas, the following qualities are important: distrust, searching for flaws in everything, attention to detail, logicality. The critic is, without a doubt, an introvert type. The personality types ISTP, ISTJ, INTP, and INTJ are logical introverts. Critical analysis is the strong point of IS and IN. Sensitive-Thinking personality types ISTP and ISTJ prefer to focus on practical issues. These personality types prefer to carefully compare several options before making a final decision. In doing so, they rely on facts and logical analysis. Personality types INTP and INTJ are perfectionists that important for critics. Based on the foregoing, the students with the types of personality ISTP, INTP and ISTJ can function as critics.

Expert evaluation and critical analysis require similar personality types. Personality types ST and NT are a cognitive pair. For example, these are the ISTJ and INTJ personality types. They provide a different vision of the problem, this is important for the evaluation. The final decision on the meaning of rows and columns is made primarily by "experts" in the first place; these are representatives of the personality types ISTJ, and also ENTJ, ESTJ. The inclusion of personality types ENTJ and ESTJ in the number of experts is due to the fact that they led a collective discussion. The moderator can choose the final variant basing not only on his own opinion, but also on the opinion of other members of the team whose personal qualities he knows and appreciates. Therefore students with personality types ISTJ, INTJ, ESTJ and ENTJ can participate in the *expert evaluation*.

Note that the ENTJ and ENTP personality types have a good imagination and are useful when using the technique of random associations, and the INTJ personality type is endowed with perfect intuition. The ISTJ personality type is an ideal candidate for processing the results of the discussion and organizing them in the form of a morphological matrix of proposed solutions. The personal INTP type can do the job as well. It is also advisable to entrust the documentation of the final results obtained using the generalized method to the personal types of ISTJ and INTP.

If the proposed heuristic method does not work, a Feedback Group can be created. It is advisable to include representatives of each of the 16 personality types in this group, if students with such personal types are available. A group of students who performed a certain heuristic technique told the Feedback Group about their experience of participation, as well as problems that arose. After the discussion, all or part of the heuristic techniques are repeated.

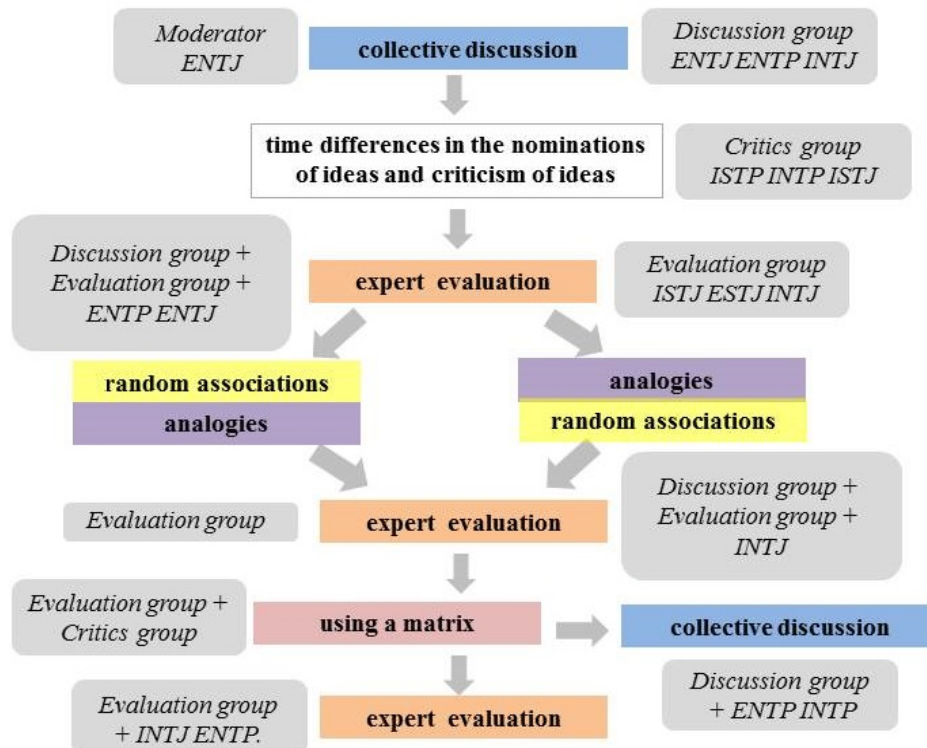
Consider the algorithm of the generalized heuristic method, taking into account the heuristic techniques and the content of the considered procedures (Figure 3).


Figure 3: The algorithm of generalized method

The first procedure is procedure for selecting a moderator. A student with personality types ENTJ is selected as moderator for the collective discussion group. If there are two representatives of this type, then the student with higher academic achievements is chosen as the moderator. If there are no representatives of this personality type, then ESTJ is chosen as the moderator. The project team should be divided into several parts: discussion group, critics group, evaluation group. The one student can be by participant of few groups.

The second procedure is procedure for selecting participants for the discussion group; these are personality types ENTJ, ENTP and INTJ.

The third procedure for selecting the participants of critics group is as follows - students with the ISTP, INTP and ISTJ personality types are selected as critics group.

The fourth procedure for selecting the participants of expert evaluation group: personality types ISTJ, ESTJ, and INTJ.

This is followed by the first heuristic technique - collective discussion. The collective discussion group consisted of five to ten people. Personality type ESTJ participated in discussions and idea generation provided he is a moderator. This personality type joins the discussion group also in the case of its small size.

The second heuristic technique is a pause between the presentation of ideas and their criticism. After a pause, the group of critics set to work. A group of critics is consisted of three to five people. The composition of the group can be increased so that all members of the project team can participate in the work. In small project teams with a lack of "critics", the ISTJ is served as a critic; they usually predominate numerically over representatives of other personality types. In this case, the INTP is joined the group of discussion and generation of ideas. Several members of the collective discussion group join the group of critics. First of all, this is the personal type of INTJ, Thus, a critical analysis is carried out both by the project team members who participated in the discussion and those who did not participate in the discussion; they represent a different point of view on the problem.

The third heuristic technique is expert evaluation. The group of experts should not be large. Not all participants with personality types ISTJ, ESTJ, ENTJ should be members of this group. This group primarily includes students with high academic achievement. Moderator is always included in this group.

The fifth procedure is the selection of groups for heuristic techniques of *analogy* and *random associations*. These groups are mainly formed from members of the discussion group and expert evaluation group. But members of the critics' group also participated, so almost all members of the project team participated in the two groups. Personality types of ENTJ and ENTP should be included in the group of *random associations*, and the group of *analogy* - personal type INTJ.

The fourth heuristic technique - *analogy* and the fifth heuristic technique - *random associations* were used in parallel and repeated if necessary.

The sixth heuristic technique is *expert evaluation*. The group can be updated. Other members of the personality types ISTJ, ESTJ and INTJ may be included in this group.

The seventh heuristic technique is the *using a matrix*. The matrix is formed based on the results of applying the previous heuristic techniques. For the technical work on the formation of the matrix, personality types ISTJ and INTP are involved. An *evaluation group* and a *critics group* analyze each cell of the matrix. Decisions that do not make sense and are not feasible under the given conditions are discarded. Promising solutions are brought up for discussion.

The eighth heuristic technique is a *collective discussion*. The discussion group can be expanded. You can add personality types with good logic - ENTP and INTP. Note that INTP was involved in the matrix developing.

The ninth heuristic technique is an *expert evaluation*. This is final heuristic technique and final evaluation. In this case, the evaluation group should be expanded to include representatives of *discussion group*: INTJ and ENTP. As a result of considering the options detailed in the process of collective discussion, one best is chosen.

Final procedure is a documenting the results. For this the personality types ISTJ and INTP. To do this, personality types INTJ and INTJ are involved.

7. Conclusion

The analysis of heuristic methods based on their structure is carried out. The heuristic methods which belong to the generation phase were considered. As part of the methods highlighted heuristic techniques and procedures. It is shown that two dozen methods belonging to the generation phase use only five heuristic methods. Many methods use the same heuristic technique and differ only in procedure. The theorem was formulated: for each stage of the creative process one generalized heuristic method can be applied replacing all methods used for this stage if it includes all heuristic techniques used within this stage.

The study of the personality type's distribution of students STEM specialties was carried out at the South Ukrainian National Pedagogical University named after K. D. Ushynsky (SUNPU) and Odessa National Polytechnic University (ONPU). The main part of students belongs to seven personality types. Data for SUNPU students on the percentage of each type to the total number of students: ISTJ (18.1), INTP (15.5), ESTJ (14.7). INTJ (10.4), ENTP (8.4), ENTJ (4.4), ISTP (3.3) and ENFP (2.5). Data for ONPU students on the percentage of each type to the total number of students: ISTJ (22.1), INTP (11.9), ESTJ (11.7). INTJ (11.6), ENTP (7.8), ENTJ (5.3), ISTP (4.2) and ENFP (2.0). The generalized method was developed. This method focused to teaching students STEM specialties. Method based on five heuristic techniques collective discussion, pause between the presentation of ideas and their criticism, random associations, analogy, expert evaluation, using a matrix. The heuristic process is considered from the point of view of the personality types of the participants. Personal types are considered in terms of how they are suitable for performing the indicated heuristic techniques. The recommendation about performers: moderator, discussion group, critics group, evaluation group, for each heuristic technique was developed.

Conflict of Interest

The authors declare no conflict of interest.

A R T I C L E I N F O	A B S T R A C T
	The Blockchain technologies enable decentralized networking consisting of large number of nodes. To determine the shared states and failures of all nodes in a fully distributed peer-to-peer system, the appropriate consensus algorithm needs to be selected for each Internet of Things system. In this paper, a novel hierarchical voting-based byzantine fault tolerance (HBFT) consensus algorithm is proposed. The proposed HBFT algorithm utilizes a typical PBFT algorithm hierarchically to guarantee low latency. The message complexity of HBFT shows that our proposed algorithm has better scalability. We also mathematically calculate the optimal number of groups based on the total number of nodes to determine the ratio of allowable faulty nodes per group. In addition, we analyze the reliability of byzantine fault tolerance to compare the reliability of group case with the reliability of non-group case. Finally, we introduce the methods of real-time Blockchain considering the service level agreement (SLA). The real-time processing performance of transactions is analyzed for the service level agreement (SLA).

1. Introduction

A Blockchain is a peer-to-peer distributed ledger , in which the process of transaction verification and recording is continuously executed [1, 2]. Participant nodes constantly verify a set of time-stamped transactions at a given time using a built-in consensus algorithm. The Blockchain technology improves reliability in addition to availability by storing and sharing data in a distributed manner. The use of Blockchain in Internet of Things (IoT) enables secure, decentralized networking for IoT data privacy and security [3]. Therefore, an efficient consensus algorithm is crucial to verify transactions and adjust interactions among IoT devices [4]. IoT data are validated through the consensus mechanism and then recorded securely in a distributed ledger.

This paper introduces a novel hierarchical voting-based byzantine fault tolerance (HBFT) consensus algorithm. The proposed HBFT algorithm operates the group level's consensus rather than the node level's consensus. It is to overcome limited scalability and high latency in a typical practical byzantine fault tolerance (PBFT) algorithm. Thus, the overall exchanging messages are significantly reduced even if the large number of nodes are participated in consensus operation. Despite the exponential growth in the number of nodes in the network, the scalability of HBFT is ensured compared with PBFT. Also, we calculate the optimal number of groups depending on the total number of nodes for grouping because the reliability can be affected by the number of groups. If faulty nodes are well distributed into groups, the probability of reaching consensus is higher even with an increased number of faulty nodes. Therefore, two cases are calculated to understand the influence on the number of faults per group.

However, since the participant nodes mutually verify and store the data, considerable number of computing resources are required, and concurrently the processing time decreases [5-8]. The same method of participant nodes (all nodes or certain nodes allowed to participate in Blockchain) has been used to process transactions on the Blockchain [9]; nevertheless, it is possible to apply the service level agreement (SLA) on Blockchain by determining the number of participant nodes according to the user's requirements. Therefore, we propose methods to control the number of participant nodes adaptively considering user requirements and computing environments. The transaction processing speed and throughput can be improved by using adaptive control method. Figure 1 is the diagram of real-time

Blockchain considering service level agreement(SLA). In this diagram, the reliability of a node with respect to time is periodically collected by the Blockchain monitor. It depends on the failure rate of a node determined intentional or unintentional faults. The Blockchain control also reads user requirements and Blockchain status. According to the user's request, a transaction is processed for generating a smart contract of Blockchain. The user can request reliability, maximum time and the cost for block generation. The reliability of a participant node can affect the reliability of the transaction processed.
Figure 1: Schematic of Real-time Blockchain considering Service Level Agreement(SLA)

The remainder of this paper is organized as follows. Section 2 overviews relevant background about various consensus algorithms. The details of HBFT algorithm are presented in Section 3. Here, how the HBFT algorithm differs from previous consensus mechanisms has been described. In Section 4, we analyze the reliability of byzantine fault tolerance, and present the algorithm of real-time block generation in Section 5. Finally, Section 6 concludes the contributions with future research perspectives and additional improvements.

2. Related Work

There are various consensus algorithms adopted by the popular Blockchain-based platforms such as *Bitcoin*, *Ethereum* and *Hyperledger Fabric*. In [10-11], the different advantages and disadvantages of each existing consensus algorithm are introduced. Bitcoin utilizes Proof of Work (PoW), which the high computational power is required to solve a cryptographic puzzle for mining operation. Proof of Stake (PoS) is designed to overcome the disadvantages of PoW algorithms. However, PoS suffers from a problem called Nothing at Stake because each participant can vote to both blocks. Also, Delegated Proof of Stake (DPoS) achieves consensus by delegates (called block producers) elected by nodes instead of participation by all nodes. Practical Byzantine Fault Tolerance (PBFT), implemented in *Hyperledger Fabric*, has

a primary node to manage the other nodes. Even if some untrusted nodes participate in the consensus operation, it is considered an agreement if more than 2⁄3 of the results are the same. Also, a variant of byzantine fault tolerance consensus algorithm called Delegated Byzantine Fault Tolerance (DBFT) [12, 13] is introduced for scalable participation. The randomly elected delegates (called bookkeeping nodes) of each group can only participate in the operation of the consensus process. Furthermore, PBFT is an permissioned protocol in which the identities of all nodes are exposed to the network [14]. Therefore, PBFT can be applied in permissioned platforms that enable autonomous, commercial, and financial application services in IoT environments. It is also suitable for applications that do not require tokens and incentives. That is why we developed a novel and efficient consensus algorithm based on PBFT for decentralized IoT.

3. Hierarchical voting-based Byzantine Fault Tolerance (HBFT) Consensus Algorithm to reduce System Resources

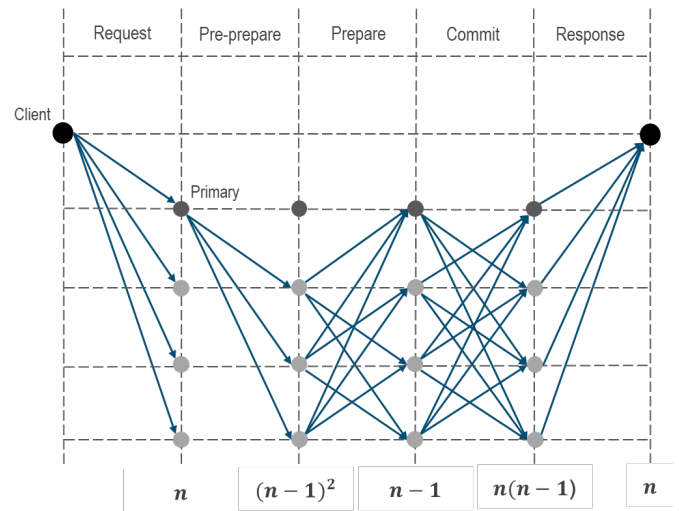
In this section, a novel hierarchical voting-based byzantine fault tolerance (HBFT) consensus algorithm is proposed. Also, we analyze the message complexity of the proposed novel consensus algorithm. Additionally, the best case and worst case are calculated to identify the influence on the number of faulty nodes per group in our proposed algorithm.


Figure 2: Flow Chart of PBFT

Practical Byzantine Fault Tolerance (PBFT) consensus algorithm has five processes for consensus processing [15-17]. Figure 2 shows the flow chart of PBFT. If the number of faulty nodes (f) is not more than $f = \lfloor (n - 1)/3 \rfloor$, a consensus can be reached. Even though faulty nodes participate in the network, PBFT consensus algorithm can prevent up to $n/3$ of faulty nodes since more than $2n/3$ nodes must be reliable nodes. The overall message complexity is $2n^2$ based on the messages generated in each process. In case of the PBFT algorithm supported by *HyperLedger Fabric*, the reliability of the consensus is improved because every node participates in the consensus process through the interactions with each other. However, the message complexity

increases exponentially as the number of participating nodes increase. Therefore, if the number of nodes increases, the problem of scalability can be generated by high network traffic and latency.

3.1. Proposed HBTF Consensus Algorithm for Scalability

Based on our previous researches [18, 19], the operation of HBFT consensus algorithm, which utilizes a typical PBFT algorithm hierarchically, is re-designed effectively. Our proposed HBFT consensus algorithm has two phases to validate transactions. The flow chart of HBFT is shown in Figure 3.
Figure 3: Flow Chart of HBFT

Firstly, the first phase start to request a verification about new transactions to all replica nodes. In the pre-prepare process, all nodes are randomly grouped into some groups and then, a primary node in each group is randomly selected to send a pre-prepare message to the other nodes. Each node compares a pre-prepare message with a request message. If the results match, a primary node responds a prepare message to the other nodes. In the commit process, each node reaches an agreement in the group depending on whether it received more than $2n/3g$ of prepare messages. Next, the second phase is executed in the same processes as the first phase to verify the voting results of each group. Finally, if more than $2g/3$ of prepare messages are received, the consensus is reached. Each primary node broadcasts the results to a client.

3.2. Message Complexity of HBFT Consensus Algorithm

The overall message complexity generated in each process of HBFT is $f(g) = 2g^2 - g + 2n^2/g - n$. The overall message complexity of HBFT is lower than that of PBFT by increasing the total number of participant nodes in Figure 4. Therefore, the processing overhead is significantly decreased. The lower latency and better scalability can be guaranteed because the overall overhead is reduced.
Figure 4: Overall Message Complexity Comparison between PBFT and HBFT

Additionally, we try to figure out the impact on the message complexity by increasing the number of groups in Figure 5. If the total number of nodes is 1000, the message complexity depends on the number of groups. The message complexity increases as the number of groups is too small or too large. Since the number of groups can affect the reliability of the agreement, the optimal number of groups according to total number of participant nodes needs to be calculated for facilitating efficient grouping. The optimal number of groups based on total number of nodes is calculated as follows. Eq. (1) is an equation for the overall message complexity of HBFT. By differentiating Eq. (1), we can achieve the number of groups with minimal message complexity. The optimal number of groups is given by Eq. (2). If the total number of nodes is 1000, the calculation result of Eq. (2) is about 79.45 as shown in Figure 5.

$$f(g) = 2g^2 - g + \frac{2n^2}{g} - n \qquad (1)$$

$$\rightarrow \quad f'(g) = 4g - 1 - \frac{2n^2}{g^2} = 0$$

$$g = \frac{1}{12}\left(1 + \sqrt[3]{1 + 432n^2 - \sqrt{432n^2(432n^2 + 2)}} + \sqrt[3]{1 + 432n^2 + \sqrt{432n^2(432n^2 + 2)}}\right) \qquad (2)$$

3.3. Fault Tolerance of HBFT Consensus Algorithm

In our proposed HBFT algorithm, consensus can be achieved to add a new block when the number of groups is more than two-thirds the total number of groups. Two cases are calculated to determine the influence on the number of faulty nodes per group. In the first case, the maximum number of allowable faults to reach consensus is calculated in (a). Additionally, a case where the consensus cannot be reached with the minimum number of faulty nodes is calculated in (b). When it is detected as a faulty node, a primary node is changed in the typical PBFT algorithm. Therefore, all primary nodes are assumed to be non-faulty nodes, similar to the PBFT algorithm. Additionally, we assume that the number of total groups is more than two, and the number of nodes per group

is at least four in our proposed HBFT algorithm for normal operation.
Figure 5: Message Complexity of HBFT depending on the Number of Groups

3.3.1. Best case: The maximum number of allowable faulty nodes in order to reach a consensus

One-third of total number of groups consists of faulty nodes and cannot reach a group consensus. The other two-thirds have only one-third faulty nodes in each group, leading to a group agreement. Consequently, the best case is that the number of faulty nodes is high; however, a consensus can be reached since faulty nodes are well distributed into groups. Eq. (3) shows the equation of the best case.

$$\left(\left\lfloor\frac{g}{3}\right\rfloor \times \left(\frac{n}{g}-1\right)\right) + \left(\left\lceil\frac{2g}{3}\right\rceil \times \left\lfloor\frac{n}{3g}\right\rfloor\right) \tag{3}$$

3.3.2. Worst case: A consensus cannot be reached with the minimum number of faulty nodes

If the number of faulty nodes in each group exceeds one-third, each group agreement fails. The worst case is in which the number of groups that do not attain group agreement exceeds one-third. As a result, even though the number of faulty nodes occupies a relatively small number, the consensus cannot be reached according to the ratio of faulty nodes per group. An equation of this worst case is described as follows.

$$\left(\left\lfloor\frac{g}{3}\right\rfloor + 1\right) \times \left(\left\lfloor\frac{n}{3g}\right\rfloor + 1\right) \tag{4}$$

Both equations are calculated to assess whether a consensus can be achieved according to the ratio of faulty nodes per group. The influence of the ratio of faulty nodes per group is shown in Figure 6. From these calculations, the number of allowable faulty nodes is up to approximately $5n/9 - g/3$ in the best case. In the worst case as already discussed, a consensus cannot be reached according to the ratio of faulty nodes per group. In both calculations, whether a consensus is reached or not is affected by the ratio of faulty nodes per group. Although the number of faulty nodes participating in consensus is high, a consensus can be reached depending on how all faulty nodes are well-distributed into groups as described in the best case. Finding the optimal ratio of faulty nodes per group to reach consensus in HBFT algorithm will be an important research area. In addition, it is required that the verification regarding the faulty nodes is executed at the beginning of consensus process. As a result, the number of

allowable faulty nodes can be low compared to PBFT algorithm depending on the ratio of faulty nodes per group in the worst case. On the contrary, the number of allowable faulty nodes can be more than that in the PFBT algorithm depending on the ratio of faulty nodes per group in the best case.
Figure 6: Influence on the Ratio of Faulty Nodes Per Group

4. Analysis of Reliability

We analyze the reliability of Blockchain operation in this section. It leads to the analyzing of the probability of normal operation in unit time. Assuming that the reliability of each participant node is equal to r, the calculations below are defined when n nodes participate in the processing a transaction. The reliability of the fail-stop faults can be calculated by the probability that at least one node is operating normally. A fail-stop means the occurrence of an unintentionally generated failure. It is assumed that a fail-stop at a node happens when a node is faulty.

$$1 - (1 - r)^n \tag{5}$$

In the case of the reliability for consensus, even if there are the fail-stop faults, the consensus can be reached if more than half of the number of nodes agree. Subsequently, the reliability of the byzantine faults can be calculated by the probability that less than half of faulty nodes are included on Blockchain as follows.

$$R(n, r) = 1 - \sum_{k=ceil\left(\frac{n}{2}\right)}^{n} {}_nC_k(1-r)^k r^{n-k} =$$

$$\sum_{k=0}^{ceil\left(\frac{n}{2}\right)-1} {}_nC_k(1-r)^k r^{n-k} \tag{6}$$

In the case of the reliability for consensus in byzantine faults, if less than one-third of faulty nodes are in the operation, the consensus is reached. The calculation is shown in Eq. (7)

$$R(n, r) = 1 - \sum_{k=ceil\left(\frac{2n}{3}\right)}^{n} {}_nC_k(1-r)^k r^{n-k} =$$

$$\sum_{k=0}^{ceil\left(\frac{2n}{3}\right)-1} {}_nC_k(1-r)^k r^{n-k} \tag{7}$$

In addition, the reliability of the byzantine faults in a hierarchical structure as in the proposed HBFT consensus algorithm can be defined as $R(g, R(n/g, r))$. It is assumed that the total number of nodes is n, and the number of nodes per a group is n/g. Additionally, when all nodes are divided into several groups for consensus, the number of groups is g. Therefore, the reliability of group is calculated as $R(n/g, r)$ based on the reliability of a node. In case of the reliability for consensus, even if there are the

byzantine faults, this same definition is applied. If the more than two-third the number of normal nodes are in the consensus operation, a consensus is reached to add a new block.

Assuming that the number of nodes is 400 and less than half the faulty nodes are included, the reliability based on that of each node is shown in Figure 7. Furthermore, if the number of groups is 20 with the total number of nodes, the reliability of hierarchical byzantine fault tolerance by grouping is shown in Figure 7. When the consensus operation executes hierarchically in the group level, the reliability of group case is similar or lower than the reliability of non-group case. Although the difference in the case of reliability of hierarchical byzantine fault tolerance is lower than in the case by the node's reliability, the message complexity is much better described in the Section 3.2; so it can be said that it is good to be grouped in the proposed algorithm. When the number of faulty nodes is less than one-third of the total nodes, the consensus operates hierarchically according to the reliability of each node.
Figure 7: Reliability in the Byzantine Fault
Figure 8: Reliability for Reaching Consensus in the Byzantine Fault

Figure 8 shows that the reliability of the consensus in the case of group level and in the case of non-group level consensus. Although the range with a little low reliability exists in the reliability of hierarchical byzantine fault tolerance for reaching consensus, there is no notable difference in the reliability of the overall ranges, similar to Figure 7. Even if the reliability of each node is different, or an incorrect answer is generated by an intentional failure or byzantine faults, the reliability can be calculated. In addition, even if the participant nodes have different conditions such as reliability, the possibility of cyber infringement, computing power, and data collection, it is possible to apply the proposed method of using Blockchain resources minimally according to various Blockchain configuration conditions and the user's requirements.

5. Real-time Performance Analysis using Block Generation Algorithm

Although the Blockchain has various advantages such as reliability, security, traceability and transparency, the excessive computing resources and communication bandwidths required to reach consensus and maintain consistency between duplicated ledgers are disadvantageous. Additionally, it is necessary to consider the reduction of the deadline meet ratio according to the laxity time for consensus in computing environments required real-time transaction processing. In this paper, the real-time processing performance of transactions is analyzed according to the redundancy of nodes. There are the applicable methods for maximizing real-time performance and satisfying user's requirements. The first method is real-time block generation algorithms. The second method is to use off-chain for reliable real-time performance although the reliability is decreased. A method to obtain the priority for block generation exists, as it pays more gas costs. Subsequently, the delay time is controlled by adjusting the number of nodes participating in consensus. In this section, we propose real-time block generation algorithm to adjust block generation according to the laxity time of the transaction. The two algorithms of block generation are compared in Figure 9 and Figure 10.

5.1. Algorithm of block generation at regular intervals (Conventional Blockchain)

Assuming that the time interval of block generation is T, the transaction arrival time is t, and the laxity time for block generation is D. When each block is generated at regular intervals, the deadline meet ratio, the average response time and the cost for block generation can be calculated as follows. A block is generated when a transaction arrives in the period D. Therefore, the deadline meet ratio is calculated as D/T. In Figure 9, if the period of D is greater than the period of T, a block is generated at any time within the period of block generation. The average response time is defined as $D/2$. The period D refers to the laxity time to wait for block generation. The cost for block generation in period of T is calculated as C_{block}/T. The graph of (a) algorithm for the cost is shown in Figure 10.

5.2. Algorithm of block generation by the shortest deadline of the arrived transactions (Real-time Blockchain)

If the transaction processing request arrives, and other transactions arrive at $1/f$ intervals, all blocks about the arrived transactions within the laxity time of the first requested block generation are generated. Therefore, all transactions in the laxity time are processed based on the laxity time of the initially arrived transaction. It is assumed that the arrival frequency of transaction is f, and a new transaction arrives at equal intervals. Then, the arrival time of a new transaction is $1/f$ (= P), and the block generation time of the new transaction can be calculated as $1/f$ (= P) + D. All transactions are always processed when the transactions arrive in the laxity time. Therefore, the deadline meet

ratio of (b) algorithm is 1 as shown in Figure 9. The average response time for block generation is calculated as $(P + D)/2$. The graph in Figure 10 shows the cost for block generation of (b) algorithm calculated as $C_{block}/P + D$.
Figure 9: Deadline Meet Ratio
Figure 10: Blockchain Generation Cost

6. Conclusion

We propose a novel HBFT consensus algorithm required for transaction generation to reduce the processing throughput and increase scalability in a typical PBFT algorithm. Since our proposed algorithm utilize PBFT algorithm hierarchically, the number of exchanging messages in the consensus processing is significantly reduced. It means that the HBFT consensus algorithm ensures the scalability even though large numbers of nodes are involved in the consensus process. Furthermore, we calculate the optimal number of groups to identify the influence on the overall message complexity depending on the number of groups. In addition, both the best and worst cases are calculated to determine the ratio of allowable faulty nodes per group. Additionally, the reliability of byzantine fault tolerance is analyzed to compare the reliability of group case with the reliability of non-group case. Finally, it is necessary to consider the reduction of the deadline meet ratio according to the laxity time for consensus in computing environments required real-time transaction processing. To compare with the conventional Blockchain algorithm to consider the service level agreement (SLA), the real-time processing performance of transactions is analyzed according to the redundancy of nodes. In the future work, we plan to demonstrate HBFT algorithm through simulations. Furthermore, we would also implement Blockchain-based application services to effectively manage the decentralized IoT data.

Sensorless Control and Corrected Error Commutation of the Brushless DC Motor

Anatoly Stepanov[*], Vitaly Enin

Department of Electrical and Industrial Electronics, Bauman Moscow State Technical University, Moscow, 105005, Russia

A R T I C L E I N F O	A B S T R A C T
	This paper presents a simple method for correcting the error of commutation windings for sensorless control of a brushless DC motor with a small inductance. Switching error analysis is performed based on the phase currents of the switched-off and switched-on phases. To correct the commutatiuon signals for the inverter, a speed-independent function is used, calculated from the back-EMF, by selecting its coefficients. The back-EMF is calculated for the system obtained by transformed a three-phase system to a two-phase one, which reduces the system dimension. An algorithm for start-up the motor with sensorless control based on the method of align and damping the rotor vibrations in a stable equilibrium position is proposed. The back-EMF is approximated by a function based on a piecewise linear function and an inscribed ellipse, for a more accurate description of the shape of the back-EMF. This approximation is used when simulation the motor. The simulation confirms the effectiveness of the proposed method for correcting the commutation error in the case of sensorless control of a low-power BLDC motor.

1. Introduction

This paper is an extension of conference report "Sensorless control of low-power brushless DC motor based on the use of back-EMF," presented in "2019 International Ural Conference on Electrical Power Engineering (UralCon 2019)" [1].

In the extended version of the paper, in comparison with the conference paper, a method for correcting error of commutation winding and the start-up procedure based on the alignment of the rotor position in the stable equilibrium position of brushless DC motor is proposed, which makes it possible to improve the reliability and quality of sensorless control.

The rectifier of the electrical motors, in particular the brushless DC motors (BLDC) are widely used in automation and control systems, as well as in orientation and navigation systems as a gyroscope drive [2 – 4]. Usually, the power of the BLDC windings is produced by a semiconductor inverter, whose transistors are switched by signals from sensors installed on the motor stator.

The use of rotor position sensors has disadvantages associated with an increase in the price of the electric drive, the accuracy of their installation, which leads to errors in determining the switching moments of the windings, unreliability of the sensors in difficult environmental conditions. To eliminate these

shortcomings, the methods of sensorless control of the BLDC motor have been developed.

In case of sensorless control, commutation signals are generated using back-EMF or flow, calculated from phase currents and voltages. The most widely used methods are those using back-EMF.

The most widely used methods of sensorless control based on the analysis of back-EMF are considered in [5-11]. If the neutral point of the motor is not available, the terminal voltage determines the moment when the back-EMF of the disconnected phase passes through zero (zero crossing point). Switching must be performed with a delay of 30 electrical degrees, after passing the back-EMF through zero. In [5], the least squares method is used to refine the switching points, but this does not guarantee accurate determination of the switching points, since the terminal voltage contains noise and pulses generated by the inverter. The implementation of these methods requires additional phase-shifting circuits, including a timer. The non-ideality of the back-EMF, the delay created by the low-frequency filter significantly reduces the reliability of these methods.

In [12, 13], a velocity-independent G-function calculated from the back-EMF is used to determine the commutation points. Commutation points are determined when the absolute value of this function exceeds a certain threshold value. The back-EMF contains noise and pulses generated by the inverter, which can lead

[*]Corresponding Author: Anatoly Stepanov, stepanov.bmstu@gmail.com

to erroneous determination of commutation points. The disadvantage of this method is also the ambiguity of choosing a threshold value.

To determine the commutation points in [14, 15], the third harmonic is used. This method requires creating a virtual third point. To form a neutral point, an additional electrical circuit is required, which is a disadvantage of this approach.

One of the problems with sensorless control is the problem of starting the motor and its operation at a low speed of rotation, in this case, the back-EMF of rotation is zero or very small. Then, determining the position of the rotor by the back-EMF of rotation is difficult or almost impossible.

In [16], when starting, the position of the rotor is initially set by the reaction of the current at magnetic saturation if the axis of the flow created by the current and the magnetic axis coincide. Only one current sensor is used. Then, after starting, the rotor is accelerated to the speed at which it is possible to switch to sensorless control of the winding switching. When the rotor position is aligned, oscilations occur in the vicinity of the equilibrium position, which reduces the reliability of this method.

Despite the large number of works on sensorless control, the problem of reliability and accuracy of determining the commutation points for the BLDC motor are relevant and require further research.

2. Mathematical model of brushless DC electric motor

Here we describe a mathematical model of a three-section electric BLDC motor. The power supply circuit of the windings of a three-section, brushless DC motor by an electronic commutator on field-effect transistors is given in Figure 1

The equations in the phase coordinates for the sections of BLDC motor with permanent magnets taking into account the mutual inductances of the sections have the form (the case of an implicit pole rotor is considered):

$$\begin{bmatrix} R_s & 0 & 0 \\ 0 & R_s & 0 \\ 0 & 0 & R_s \end{bmatrix}\begin{bmatrix} i_a \\ i_b \\ i_c \end{bmatrix} + \begin{bmatrix} L_s & -M_s & -M_s \\ -M_s & L_s & -M_s \\ -M_s & -M_s & L_s \end{bmatrix}\begin{bmatrix} \dfrac{di_a}{dt} \\ \dfrac{di_b}{dt} \\ \dfrac{di_c}{dt} \end{bmatrix} + \quad (1)$$

$$+\begin{bmatrix} e_a \\ e_b \\ e_c \end{bmatrix} = \begin{bmatrix} u_a - u_n \\ u_b - u_n \\ u_c - u_n \end{bmatrix},$$

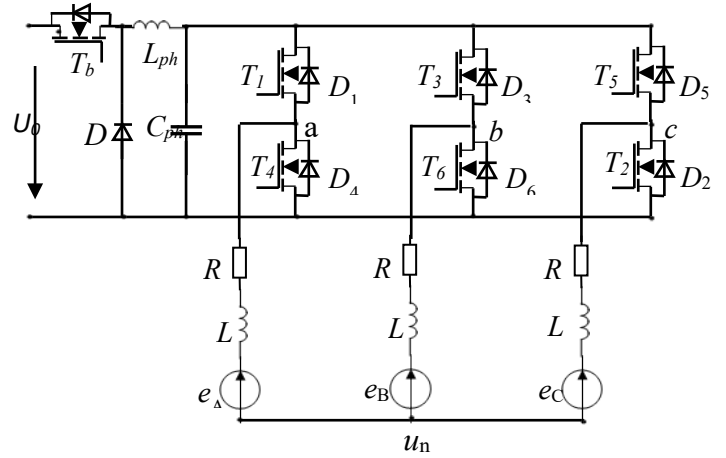
where R_s – active resistance of section stator winding; i_a, i_b, i_c – currents in the windings of the stator sections; L_s – inductance winding sections; M_s – mutual inductance of the windings of the sections; e_a, e_b, e_c – back-EMF of the stator windings; u_a, u_b, u_c – voltage applied to the windings of sections; u_n – neutral point voltage. In wye connection $i_a + i_b + i_c = 0$.


Figure 1: Three-section BDCM winding power supply circuit

Let us define the inductance of the stator along the longitudinal and transverse axes $L_d = L_q$ and the inductance L_0 for the zero sequence. The phase inductances of the windings of the sections in the rotating coordinate system d, q are defined as follows: $L_s = (L_0 + 2L_d)/3$; $M_s = (L_d - L_0)/3$.

Using the transformation (a particular form of the transformation matrix E. Clarke)

$$\begin{bmatrix} u_\alpha \\ u_\beta \end{bmatrix} = T \begin{bmatrix} u_a \\ u_b \\ u_c \end{bmatrix}, \quad (2)$$

when

$$T = \begin{bmatrix} \sqrt{2/3} & -1/\sqrt{6} & -1/\sqrt{6} \\ 0 & 1/\sqrt{2} & -1/\sqrt{2} \end{bmatrix}.$$

For the transformation matrix T, the following equality holds: $T^{-1} = T^t$ (T^t is the transposed matrix), $T T^{-1} = E$, E – unit matrix.

Transform (2) a three-phase system (1) to a two-phase system

$$\begin{bmatrix} R_s & 0 \\ 0 & R_s \end{bmatrix}\begin{bmatrix} i_\alpha \\ i_\beta \end{bmatrix} + \begin{bmatrix} L & 0 \\ 0 & L \end{bmatrix}\begin{bmatrix} \dfrac{di_\alpha}{dt} \\ \dfrac{di_\beta}{dt} \end{bmatrix} + \begin{bmatrix} e_\alpha \\ e_\beta \end{bmatrix} = \begin{bmatrix} u_{\alpha n} \\ u_{\beta n} \end{bmatrix}.$$

where $L = L_s + M_s$.

Using the transformation (2) we will express the back-EMF in the system α, β

$$e_\alpha = \frac{1}{\sqrt{6}}(e_a - e_b) - \frac{1}{\sqrt{6}}(e_c - e_a), \quad (3)$$

$$e_\beta = \frac{1}{\sqrt{2}}(e_b - e_c). \quad (4)$$

The back-EMF differences $e_{ab} = e_a - e_b$, $e_{bc} = e_b - e_c$, $e_{ca} = e_c - e_a$. They are calculated using equation (1). to calculate the back-

EMF according to (3),(4), it is not necessary to determine the voltage at the neutral point.

Back-EMF sections at a constant rotational speed vary according to the law $e_a(\theta) = k_e\omega_e\Phi'_a(\theta)$, $e_b(\theta) = k_e\omega_e\Phi'_b(\theta)$, $e_c(\theta) = k_e\omega_e\Phi'_c\theta)$, where $\omega_e = p\omega$, (ω – is the angle rotor speed, p – number of pairs of poles.

Trapezoidal function $d\Phi/d\theta$ (Φ is magnetic flux, θ electric angle) is approximated by piecewise linear function with inscribed ellipse [1]. This function $\Phi'(\theta)$ is used when simulation the BLDC motor.

Graphs of the functions $\Phi'_a(\theta)$, $\Phi'_b(\theta)$, $\Phi'_c\theta)$ for a three-phase and functions $\Phi'_\alpha\theta)$, $\Phi'_\beta\theta)$ for a two-phase system are shown in Figure 2, 3.
Figure 2: Trapezoidal functions $\Phi'_a(\theta)$, $\Phi'_b(\theta)$, $\Phi'_c\theta)$
Figure 3: Functions $\Phi'_\alpha\theta)$, $\Phi'_\beta\theta)$ in system α, β

3. Algorithm sensorless control BLDC motor in system α, β

The most widespread in practice is 120 degree commutation, in which the winding is connected to the source at an interval of

120⁰ electric degrees, then disconnected from the source at an interval of 60⁰ electric degrees.

For 120-degree commutation, the angles of switching on and off phases , the function value is selected, which determines the value of the back-EMF of the sections at the time of switching. The dependence of the back–EMF phase in relative units expressed using the function $\Phi'(\theta)$ is shown in Figure 3, from where it follows for 120 degree commutation $\Phi'(60°) = \Phi'(300°)$, $\Phi'(120°) = \Phi'(240°)$.

To determine the commutation points, the values of the back-EMF in system α, β calculated by the formula (3), (4) are used. The ratio of the back-EMF $e_\alpha(t)$, $e_\beta(t)$ is equal to the ratio $\Phi'_a(t)$, $\Phi'_b(t)$ and does not depend on the speed of rotation of the rotor. The values of the functions $\Phi'_\alpha(\theta)$, $\Phi'_\beta(\theta)$ for commutation angles are shown in table 1.

Table 1: The value of the function $\Phi_\alpha{}'(\theta)$, $\Phi_\beta{}'(\theta)$ at the points of commutation

θ_c	$\Phi'_\alpha(\theta_c)$	$\Phi'_\beta(\theta_c)$	$\Phi'_\alpha(\theta_c)/\Phi'_\beta(\theta_c)$
$\pi/3$	$C_1(1+\Phi'_b)$	$C_2(1+\Phi'_b)$	$1/\sqrt{3}$
$2\pi/3$	$-C_1(1+\Phi'_b)$	$C_2(1+\Phi'_b)$	$-1/\sqrt{3}$
π	$-2C_1(1+\Phi'_b)$	0	$-\infty$
$4\pi/3$	$-C_1(1+\Phi'_b)$	$-C_2(1+\Phi'_b)$	$1/\sqrt{3}$
$5\pi/3$	$C_1(1+\Phi'_b)$	$-C_2(1+\Phi'_b)$	$-1/\sqrt{3}$
2π	$2C_1(1+\Phi'_b)$	0	∞

In table $C_1 = 1/\sqrt{6}$, $C_2 = 1/\sqrt{2}$.

Let's introduce the functions $H_1(t)$, $H_2(t)$

$$H_1(t) = \frac{e_\alpha^2(t) + e_\beta^2(t)}{k_1 e_\alpha^2(t) - e_\beta^2(t)},$$

$$H_2(t) = \frac{e_\alpha^2(t)}{\left(k_2 + e_\beta(t)\right)^2}$$

Coefficients k_1 and k_2 in accordance with table 1 should be equal to $k_1=3$ and $k_2=0$. The function $H_1(t)$, $H_2(t)$ generates pulses at switching angles of 60, 120, 240, 300 electric degrees, and the function $H_2(t)$ at angles of 180 and 360 degrees. To determine points of commutation is set to the threshold value H_t. When the threshold value is exceeded ($|H_1(t)|> H_t$ or $|H_2(t)|> H_t$), the functions $H_1(t)$, $H_2(t)$ determine the commutation. The calculated back-EMF for voltage and current windings contains pulses generated by the inverter, which are smoothed by a low-frequency filter. As a result of this, a error commutation occurs. The accuracy of determining the points of commutation is also affected by the threshold value. The error of commutation can be corrected by changing the coefficients k_1, k_2. For example, for angle of commutation =240 degrees, an increase in k_1 (greater than 3) leads to a delay in the formation of the commutation signal, and when reducing k_1, the commutation signal is produced ahead of time. The estimation of the error of commutation is made by comparing the current at the time of switching off the section $i_{off}(t_c)$ and the

current at the time of switching on the section $i_{on}(t_c +\Delta t)$ (t_c – commutation of time, Δt – delay that takes into account the time of the transient process in the winding). The coefficients k_1 and k_2 are adjusted for the difference of these currents $di = i_{off}(t_c) - i_{on}(t_c +\Delta t)$.

When correcting the error commutation, the coefficient vectors $K_1 = [k_{11}, k_{12}, k_{13}, k_{14}, k_{15}, k_{16}]$, $K_2 = [k_{21}, k_{22}, k_{23}, k_{24}, k_{25}, k_{26}]$ whose initial values are set $K_1 = [3, 3, 3, 3, 3, 3]$, $K_2 = [0, 0, 0, 0, 0, 0]$. Each element of the vector corresponds to a point of commutation 0˚, 60˚, 120˚, 180˚, 240˚, 300˚. Parameters are also set Δt, di. After determining the time of commutation, the value di is determined and the corresponding coefficient is adjusted based on the table 2. The values of the coefficients restricted to values. After several cycles of switching the windings, the error is reduced.

Table 2. The calculation of the coefficients k_1, k_2 of the error commutation corrected

θ_c	$di>0$, $|di|>\Delta i$	$di<0$, $|di|>\Delta i$
$\pi/3$	$k_1=k_1-\Delta k$, $k_2=0$	$k_1=k_1+\Delta k$, $k_2=0$
$2\pi/3$	$k_1=k_1-\Delta k$, $k_2=0$	$k_1=k_1+\Delta k$, $k_2=0$
π	$k_1=3$, $k_2= k_2-\Delta k$ 0	$k_1=3$, $k_2=k_2+\Delta k$ 0
$4\pi/3$	$k_1=k_1+\Delta k$, $k_2=0$	$k_1=k_1-\Delta k$, $k_2=0$
$5\pi/3$	$k_1=k_1+\Delta k$, $k_2=0$	$k_1=k_1-\Delta k$, $k_2=0$
2π	$k_1=3$, $k_2= k2 +\Delta k$ 0	$k_1=3$, $k_2=k_2-\Delta k$ 0

For the model checking method was carried out for the model of the ideal typical signals $e_\alpha(t)$, $e_\beta(t)$, i_a, i_b, i_c . The results of the computational experiment are illustrated in Figure 4 for the angle of commutation 240 electrical degrees. The error of commutationon each cycle is reduced almost to zero.
Figure 4: Error of commutation

The functional diagram of sensorless control and error of commutation correction is shown in Figure 5.

The procedure for starting the BLDC motor includes two stages: the first process of aligning the rotor in the equilibrium position, the second of accelerating up the rotor from the stable equilibrium position to the speed at which it is possible to transit to sensorless control of switching the motor windings. When the rotor is started, the rotor of BLDC is stationary or rotates at a very low speed. It is almost impossible to estimate the position of the rotor by the back-EMF of rotation, which in this case is zero or small. When switching two of the phase, the position rotor of

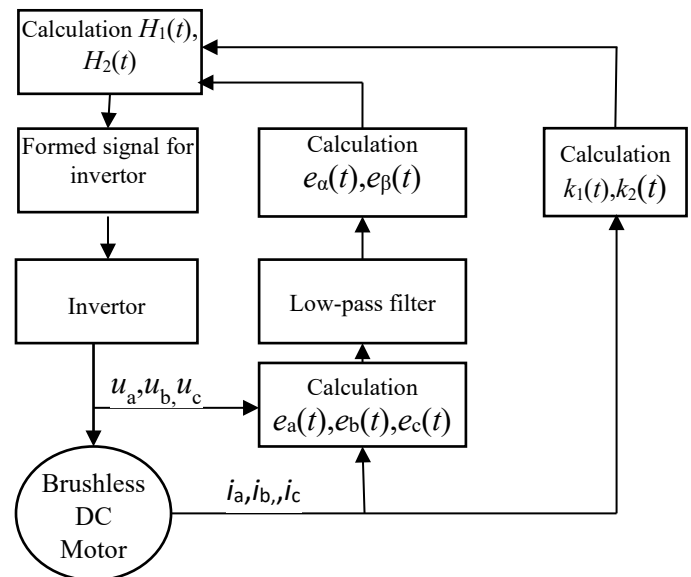
which is unknown, acquires acceleration and moves to a stable equilibrium position. With a small damping, oscilations occur in the vicinity of a stable equilibrium position. When moving in the direction of a stable equilibrium position, the rotor accelerates, and when moving from the equilibrium position, it is slowed down. If the damping is low, the kinetic energy acquired during rotor acceleration is approximately equal to the potential energy accumulated during braking. When the rotor speed is zero and the rotor starts moving in the direction to a stable equilibrium position. The acceleration square is approximately equal to the braking square.


Figure 5: The functional diagram of sensor-free control BLDC motor

Stable rotor equilibrium positions is depended on various load. The area of acceleration and braking depends on the magnitude of the voltage applied to the phases. Vibration damping when the rotor position is aligned is performed by reducing the acceleration square, which is performed by reduce of the voltage on the switching phases $u = U_r$. After passing a stable equilibrium position, the voltage on the phases increases $u = U_s$, which reduces the angle deviation from the equilibrium position. When the speed becomes zero, the voltage reduces $u = U_r$ (u – voltage of commutation phases). The acceleration square is reduced. The procedure is then repeated until the rotor position is aligned with the equilibrium position.

Let $S_a(\Delta\theta)$ be the acceleration area, and $S_b(\Delta\theta)$ be the deceleration area. For low damping, it must be performed $S_a(\Delta\theta) \approx S_b(\Delta\theta)$, $\Delta\theta = \theta - \theta_s$.

$$\Delta\theta(k+1) = (S_a)^{-1}[S_b(\Delta\theta(k))],$$

If the maping will be compressive if $|\Delta\theta(k+1)| < | \Delta\theta(k)|$, then the iterative process converges and $\Delta\theta$ tends to zero. The rotor position is aligned relative to the stable equilibrium position.

The moments of changing the voltage on the section are determined by changing the current of the section. After switching the winding, the current at the rotor acceleration initially decreases,

and then increases when passing the equilibrium position is equal to the initial one. At this point, the voltage increases $u = U_s$ and a new value of the initial current is set. The current during braking first increases, and then decreases and reaches the initial value, at which point the voltage decreases $u = U_r$. The process is then repeated until the rotor position is aligned (Figure 6).
Figure 6: Aligned position of rotor

4. Simulation results

To substantiate and study the effectiveness of the proposed sensorless control, start-up and corrected error of commutation method for a low-power brushless DC electric motor with permanent magnet was simulated.

The simulation was performed using the MATLAB&Simulink system and models of a three-phase brushless DC motor and a power semiconductor bridge commutator of the SimPowerSystems expansion. A motor is an electric machine with a three-section winding on the stator and a multi-pole rotor with permanent magnets. BLDC motor parameters are given:

Rated DC Voltage – 27 V;

Rated speed, n = 2000 r/min;

Number of poles, p = 4;

Phase resistance, R = 6 Ω;

Phase Inductance, L = 0.42 mH.

When starting the motor, the position of the rotor is not determined. If one connects two sections of the motor to a DC voltage source, the rotor begins to move to a stable equilibrium position (stable point). Let $u_a = U_0$, $u_c = 0$, phase "b" is disconnected from the source.

The proposed start-up procedure involves two steps for the transition to the sensorless control of BLDC motors. In the first step, the procedure is performed to align the rotor position and to calm down oscillation in a stable equilibrium position. At this step, a constant voltage of various values $U_r = 27$ V, $U_s = 50$ V was applied to the switching phases (phases a, c), which provided alignment of the rotor position and damping of vibrations around a stable equilibrium position. In the second step, a constant voltage was applied to the switching phases (phases b, c). After the speed set, there was a transition to sensorless control of commutation of the BLDC motor windings. Simulation of start-up and control of

commutation of the BLDC motor windings was performed using the MATLAB/Simulink system. For Figure 7 the simulation results are presented: the function $H(t)$. Function $H(t)$ is sum $H_1(t)$, $H_2(t)$. The results of modeling the motor start and transition to sensorless control are shown in Figure 8.
Figure 7: Function H(t)
Figure 8: Start-up fnd transition to the sensorless control
Figure 9: Corrected of phase current

To demonstrate the capabilities of the proposed method for correcting the commutation error, a simulation of BLDC motor with different speeds was performed. Error correction was performed by analyzing phase currents. Phase currents after error compensation are shown in Figure 9.

The table 3 shows the dynamics of the commutation error when it is compensated by the proposed method. At low speed=500 the initial commutation error was small. Initial commutation error was reduced to an error 0.12 electrically degree. At the speed of 1000, the initial error 3.5 electrically degree was also reduced by the correction method to 0.1 electrically degrees. At the nominal speed of rotation, the significant error of 14 elecctrically degree was reduced to 0.2 electrically degrees. These results confirm the possibility of reducing the compensation error in a simple corrected method.

Table 3: Error of commutation

t, s	$\Delta\theta$, deg (n=500 r/min)	$\Delta\theta$, deg (n=1000 r/min)	$\Delta\theta$, deg (n=2000 r/min)
0.01	1.25	3.5	13.9
0.05	0.96	1.9	10.8
0.1	0.81	1.6	5.2
0.15	0.54	1.35	3.7
0.2	0.56	1.08	2.1
0.25	0.45	0.54	1.6
0.3	0.12	0.1	0.2

5. Conclusion

The paper offers a simple method for correcting the commutation error in the case of sensorless control of a BLDC motor. A start-up procedure based on align the rotor position and damping its oscilations in a stable equilibrium position is proposed. This allows to accelerate the rotor and transient to sensorless control. The proposed method can increase the efficiency of sensorless control methods for BLDC motor with small inductive.

Conflict of Interest

The authors declare no conflict of interest.

ARTICLE INFO

ABSTRACT

Enrolment figures have been expanding in South African institutions of higher-learning, however, the expansion has not been accompanied by a proportional increase in the percentage of enrolled learners completing their degrees. In a recent undergraduate-cohort-studies report, the DHET highlight the low percentage of students completing their degrees in the allotted time, having remained between 25.7% and 32.2% for the academic years 2000 to 2017, that is, every year since 2000, more than 67% of the learners enrolled did not complete their degrees in minimum time. In this paper, we set up two prediction tasks aimed at the early-identification of learners that may need academic assistance in order to complete their studies in the allocated time. In the first task we employed six classification models to deduce a learner's end-of-year outcome from the first year of registration until qualifying in a three-year degree. The classification task was a success, with Random Forests attaining top predictive accuracy at 95.45% classifying the "final outcome" variable. In the second task we attempt to predict the time it is most likely to take a student to complete their degree based on enrolment observations. We complete this task by employing six classifiers again to deduce the distribution over four risk profiles set up to represent the length of time taken to graduate. This phase of the study provided three main contributions to the current body of work: (1) an interactive program that can calculate the posterior probability over a student's risk profile, (2) a comparison of the classifiers accuracy in deducing a learner's risk profile, and (3) a ranking of the employed features according to their contribution in correctly classifying the risk profile variable. Random Forests attained the top accuracy in this phase of experiments as well, with an accuracy of 83%.

1 Introduction

The benefits that can be drawn from institutions of higher-learning extend beyond the degree holder. A study conducted on the relationships between the quality of life, human capital, and universities, revealed that valuable consumption amenities that enhance an areas quality of life are positively correlated with both the local level of human capital (measured by proportion of degree holders in an area) and the number of institutions of higher-learning in a region [1].

The higher-education system is one of great benefit to enrolled-individuals, the economy, and society, however, an inefficient system with high dropout rates and low throughput rates carries harsh costs and consequences for the individual student as well as the society financing the cost of service delivery [2]. The South African

Human Science Research Council (HSRC) found that on average, 70% of the university drop-outs they surveyed came from families in the "low economic status civilian" category [3]. Students that belong in this category heavily depend on government study grants and subsidies to supplement the funding they receive from their parents or guardians. It is clear that student debt accumulation, or alternatively, costs to the government without a return on investment will be the outcome when these learners struggle and dropout. This was the case in 2005, where the national treasury reported R4.5 billion lost to student grants and subsidies that resulted in no graduates [3]. There is a student attrition problem in South Africa, as the expansion of enrolments has not come with a significant increase in the percentage of students completing their degrees [4].

Noting the value and possible severe-costs associated with in-

Table 1: This table introduces categories for the different features associated with student performance as discussed in Section 2. The features are divided into four groups, namely, "Socioeconomic Factors" (SEF), "Psycho-Social Factors" (PSF), "Pre & Intra-College Scores" (PICS), and "Individual Attributes" (IA). It is also important to take note of the colour coding scheme developed here for later reference to the four categories, [5](sic).

Socioeconomic Factors (SEF)	Psycho-Social Factors (PSF)	Pre & Intra-College Scores (PICS)	Individual Attributes (IA)
Family income	Academic self-efficacy	Mathematics	Age at first year
Parents education	Stress and time pressure	English	Work status
Head of house occupation	Class communication	Admission Point Score	Home language
Dwelling value	College activity participation	Accounting	Home province
Dwelling location (rural/urban)	Organization and attention to study	Economic studies	Home country
Financial support	Sense of loneliness	Statistics major	Interest in sports

stitutions of higher-learning, we see the clear need to explore the activities influencing student success or failure to solve the problem of student attrition and avoid the severe costs and consequences that it brings. Furthermore, we seek to develop advanced systems for the early-identification of vulnerable learners that may benefit from academic support systems.

In this research, we investigate the influence of biographical and enrolment observations on student success. This research was conducted through two published studies referred to as "phases of the current study" throughout this paper [5, 6]. In the first phase, we employ six machine learning models to predict three target variables that describe a learner's end-of-year outcome, namely, "first-year outcome", "second-year outcome", and "final outcome" [5]. The first phase of this research contributes to the current body of work by showing that various classification models can be used to predict a learner's end-of-year outcome from the first year of registration until qualifying in a three-year degree. We argue that if we can predict the academic trajectory of a student, early-assistance can be provided to students who may perform poor in the future, remediating their performance and promoting student success.

The second phase of this study involved the prediction of a "risk profile" variable, a variable that categorises the time taken by a student to graduate in a three-year degree by four values, namely: "no risk", where the student completes the degree in three years; "low risk", where the student completes the degree in more than three years; "medium risk", where the student fails/drops-out in less than three year; and "high risk", where the student takes more than three years to drop out [6]. We used six machine learning algorithms to predict the "risk profile" variable for a student based on biographical and enrolment observations. The second phase of this study contributes to the current body of related literature in three ways: (1) a comparison of six different classifiers in predicting the risk profile of a learner; (2) a ranking of the features employed according to their contribution when deducing the "risk profile"; and (3) an interactive program which uses Random forests classifier to deduce the distribution over a learner's risk profile. The contribution made by this research implies institutions of higher-learning can use machine learning techniques for the early-identification of learners that may benefit from academic assistance initiatives.

This paper continues with Section 2 which presents the background knowledge around the problem. We then introduce the

procedure and system of methods applied in Section 3, followed by the results in Section 4. The work is concluded on Section 5 and we close this study with ideas of future work in Section 6.

2 Related Work

Predicting student performance is a multifaceted task that cannot be easily completed using attributes discovered in student enrolment records alone [4]. We therefore, set-out to explore the various factors influencing student performance, aiming to discover and develop an efficient methodology for solving the problem set up in this research. We begin this chapter with the discussion and grouping of the factors influencing student performance, followed by a brief presentation of the conceptual framework adopted for feature selection in this research, and we close the chapter with a comparison of the various methods of predicting student performance.

2.1 Factors affecting student performance

The South African Department of Higher Education and Training (DHET) released a report with results that portray an increasing number of first-time-entering university students, from 98095 students in the year 2000 to over 150000 students in the 2017 academic year [7]. This significant increase brings the idea that the various attributes that describe a university student must be more varied now than ever before, as more learners from different regions are now enrolling for degrees. To accurately early-identify a member of a given group of learners as successful or unsuccessful in their studies, we must explore a wide range attributes that describe these students, so that our decision is informed.

2.1.1 Socio-Economic Observations Determining Student Success

To determine an individual or their family's measure of social and economic position in the population, we explore the category of socio-economic attributes as determinants of student success. Studies have shown that a correlation exists between socio-economic status and academic achievement, furthermore, traditional measures of socio-economic status have been revealed to usually correlate strong enough with academic achievement to account for variations
Figure 1: The graphical representation of the framework adopted to determine student success, [6](sic).

in a learner's performance [8]. A study of the determinants of student success also concludes that socio-economic factors contribute significantly when predicting a learner's performance [4]. The socio-economic attributes investigated in the literature we reviewed include; parents' education, dwelling value, family income, and parent/guardian's occupation. Family characteristics and financial support also form part of socio-economic factors revealed to explain student performance, specifically drop-out behaviour in university [2].

2.1.2 Psycho-Social Factors Affecting Student Performance

We seek to find more categories of factors that account for variations in a learner's academic performance. We therefore, explore the combined effects of a student's thoughts, social factors, and general behaviour at university on academic performance. Research conducted at a South African university found that to predict a learner's academic performance and adjustment to higher-education, psychosocial factor's such as; help-seeking attitude, workload, perceived stress, and self-esteem could be utilized as determinants [9].

Research on college students' performance utilized six psychosocial factors to predict first-year college student success [10]. The six psycho-social attributes used for prediction were; stress and time pressure levels, communication/participation in class, academic self-efficacy (a learner's belief in their ability to succeed academically), attention to study (measures time-management, planning, and scheduling behaviour), stress levels, and lastly, emotional satisfaction with academics. It was revealed that a strong correlation exists between the six psycho-social factors and a learner's GPA, these findings align with other related work [11]. A separate study also discovered that academic self-efficacy, student's optimism, commitment to schooling, and student health account for some of the variations in a student's performance, expectations and coping perceptions [12].

2.1.3 Factors Available For This Study

The review literature centred around factors affecting student performance revealed that a learner's mindset, social surrounding, and behaviour, explain significant variations in the performance of a

university learner. In this research, student biographical and enrolment observations such as, majors enrolled for, age, pre-college scores, province and country of origin, are available to build machine learning models for the prediction of academic performance. We continue this chapter by introducing the framework we adopted for the rationale behind predicting academic performance from biographical and enrolment observations.

2.2 Conceptual Framework

We use the conceptual framework depicted in Figure 1 as a logical basis to predict the academic performance of a learner from biographical and enrolment observations [13]. The framework develops three categories of attributes contributing to student attrition (dropout behaviour), namely, background attributes, individual attributes, and pre-college scores. The study reveals that these factors together influence a learner's goal and institutional commitment, which in turn contributes to the drop-out decision of a student via academic and social integration [13]. In this research, we partition background attributes further into socio-economic and psycho-social factors. Table 1 presents the grouping of features discovered to explain variations in academic performance during the review of related literature conducted in this section.

2.3 Methods For Predicting Student Performance

Various authors have already accurately predicted student performance utilizing machine learning. Table 2 compares the accuracies obtained in the various literature reviewed in this research. Acquiring the top accuracy position is a research based on the prediction of the success of a second-year student using an Artificial Neural Network (ANN) model [14]. The study uses individual attributes (IA), pre & intra-college scores, and socio-economic factors as predictors, these inputs are utilized for almost every result presented in the table [11, 17, 16].

3 Research Methodology

This research proposes an approach to the task of university-learner-performance prediction involving the prediction of a learner's end-

of-year outcome from the first year they register for a three-year degree until qualifying to graduate. We complete this task by employing six different machine learning algorithms to deduce the outcomes in the first, second, and final year of study in a South African university. This study extends further by attempting to predict a learner's risk-profile based on the time it will take the student to complete a three-year degree.

Table 2: The table compares the accuracy achieved by various authors using different machine-learning models to predict academic performance in each case. The table also illustrates for each case, the combination of features used as predictors, based on the feature categories developed in Table 1, [5] (sic).

Author(s)	Factors considered	Model used	Predictive Accuracy
Abu-Naser *et al.* (2015)[14]	IA, SEF, and PICS	Neural Networks	84.60%

Ramesh *et al.* (2013)[16]	IA, SEF, and PICS	Decision Trees (C4.5)	64.88%

In this section, we introduce the procedure and system of methods implemented for the purpose of this study. The study incorporates two phases and thus, we begin by giving a description of the two phases, followed by subsection 3.2 giving a description of the data-sets. We present the feature selection technique in subsection 3.3 and follow this by a brief description of the machine learning models we used, closing the section with methods of evaluating and validating our results.

3.1 Phases of the Study

This study was conducted in two phases. The first phase, named, "Preliminary Phase", involved generating preliminary results on a synthetic dataset. In this phase we employed six different machine learning models, namely, Decision tree (C4.5), Logistic Model Trees (LMT), Multinomial Logistic Regression, naïve Bayes, Sequential Minimal Optimization (SMO), and Random forests. The purpose of the first phase was to reveal that machine learning models can be utilized for the early prediction of a learner's end-of-year outcome from the first year of registration until qualifying in a three-year degree, based on biographical and enrolment observations.

The second phase of this study, named, "Post-preliminary Phase", involved the prediction of the distribution over several risk profiles that describe the time it will take for a university student to complete a three-year degree. This phase is performed on a real dataset which the synthetic dataset in the first phase was modelled to resemble. In this phase we employed six different machine learning models, namely, Decision tree (C4.5), Linear Logistic Regression, Support Vector Machines (SVM), naïve Bayes, and Random forests. This phase provides an interactive program which calculates the posterior probability over a learner's "risk profile" as the main contribution o this study, and a ranking of features through Information Gain Ranking (IGR), to determine the features most contributing to student performance.

3.2 Data Description and Pre-Processing

Two sets of data were utilized in this study. We therefore, split the description of the datasets, starting with Subsection 3.2.1 which gives the synthetic dataset description, and Subsection 3.2.2 giving a description of the real dataset.

3.2.1 The Synthetic Dataset Description

The dataset used for the preliminary phase of this study is a synthetic dataset generated using Bayesian Network. The dataset was adopted from a recent prediction modelling study aimed at improving student placement at a South African university [17]. In this dataset, conditional independence assumptions were implemented to portray the relationships that exist between enrolment, socioeconomic, and individual attributes found in student records.

Three target variables are investigated in the preliminary phase, namely, "First Year Outcome" (FYO), "Second Year Outcome" (SYO), and "Final Outcome" (FO). The SYO and FYO variables contain two similar possible values: "proceed", and "failed", were proceed is the outcome for a student who met the requirements to proceed to the next year of study, and failed implies the student failed to meet the minimum requirements to proceed. The FO variable also has two possible values: "qualified", and "failed", were qualified implies the learner met the minimum requirements to graduate in a three-year degree, and failed implies the student failed to meet the requirements to graduate.

Data pre-processing is a crucial step when employing machine learning models. The pre-processing task incorporates, data preparation, data cleaning, data normalization, and data reduction tasks [18]. The synthetic dataset originally contained 50 000 instances. Three random samples (without feature replacement or bias to uniform class) containing 2000 instances were drawn from the raw dataset and several experiments were conducted to make the samples more suitable for our machine learning models. The first set of experiments focused on the detection and removal of outliers or anomalies. This involved the evaluation of classification results from different machine learning classifiers in an attempt to detect and remove instances that display significant deviations from the majority patterns. The second set of experiments conducted aimed to prevent over-fitting. This was done by the implementation of Synthetic Minority Oversampling Technique (SMOTE) which enforced an equal number of training instances for each value in the class variable. The third set of experiments conducted in the preliminary phase is feature selection, where 20 features were selected from each sample based on Information Gain Ranking (IGR) criterion. Subsection 3.3 presents the set of features selected from each sample and a discussion of how we arrived at this set.

3.2.2 The Real Dataset Description

The real data utilized for this study is from a research-intensive university in South Africa. The dataset composes of enrolment and biographical observations of learners enrolled in the faculty of science at the university, from the year 2008 to the year 2018.

The target variable for the post-preliminary phase of this study is "Risk Profile", a nominal variable that tells us how long it will take for an enrolled student to complete a three-year degree at a

South African university. The risk-profile variable has four possible values, namely; "no risk", where the student completes their degree in 3 years (the minimum allotted time); "low risk", where the student completes the three-year degree in more than 3 years; "medium risk", where the student fails to complete the three-year degree before the end of three years (student drops-out in less than 3 years' time); and "high risk", where the student fails to complete the three-year degree after exceeding the 3-years period (student drops-out after exceeding the allotted time).

Since our aim is to perform an accurate classification task on the dataset, pre-processing procedures had to be carried out before training the chosen classifiers. We performed the same experiments as those performed on the synthetic dataset to detect and remove outliers. We then employed a sampling procedure similar to the one we implemented in the preliminary phase of this study. Along with applying SMOTE, a random sample (with no replacement of features or bias to uniform class) of 200 instances was drawn from the original dataset. In Subsection 3.3 we present the features selected and the procedure followed to select them.

Table 3: A table providing the various features selected for input into the employed classifiers. The table groups the features according to whether they were used for the prediction of the learner's first year outcome, second year outcome, or final year outcome. The colour shading gives the category which the feature selected belongs to according to Table 1, [5] (sic).

#	Feature	1st Year	2nd Year	Final Year
1	English Home Language	green

3.3 Feature Selection

In this subsection we present the methodology behind the features selected for both phases of the study. Subsection 3.2.1 provides the features we utilized to generate the preliminary results and Subsection 3.2.2 provides the features selected for the post-preliminary phase of the study.

3.3.1 Features for the Preliminary Phase

To select features for the purpose of predicting the three target variables investigated in this phase of the study we utilized Information Gain Ranking (IGR) criterion, which involves deducing the contribution of each feature when classifying an instance as a value of the class variable. Table 3 presents the features selected in all cases considered for the preliminary phase, based on the colour coding scheme developed in Table 1.

Feature selection was performed on each of the 3 samples drawn from the synthetic dataset. We investigated the contribution of 44 features using Information Gain (entropy). Through the entropy values and repeated experimentation with different sets of features, a total of 20 features were selected to predict the target variable in each of the three samples.

The features presented in Table 3 are not arranged according to IGR as there are significant differences in the entropy of most features across predicting the three target variables. The features selected align with our findings from the review of previous work, and more importantly, the conceptual framework we adopt in this research [13]. This is because for each target variable, there were features selected from each of the three investigated categories of features, namely, background (socio-economic) attributes, individual attributes, and pre-college scores.

3.3.2 Features for the second phase

To select features for the post-preliminary phase of this study, we continued utilizing IGR alongside the conceptual framework investigated in the related work section [13]. From the "individual attributes" category, the following features were selected; the National Benchmark Test (NBT) scores for academic literacy (NBTAL), quantitative literacy (NBTQL), and mathematical literacy (NBTMA). These scores give a measure of the individual learner's proficiency and ability to meet the demands of university-level work. To further determine an enrolled learner's professional career aspirations, we also considered the academic plan selected by the learner. The "plan code", "plan description", and "streamline" (Earth Science, Physical Science, Biological Science, or Mathematical Science) variables were selected for this task.

From the "background and family" category, the following features were selected; the home-country and province of the student, whether the school attended by the leaner is in the urban or rural areas, the quintile of the school attended, and the age of the learner at the first-year of registration. These variables combined give us a description of the learner's socio-economic status.

From the pre-college scores category, scores from the following subjects were considered; Mathematics major, Mathematics Literacy, Additional Mathematics, Physical Science, English Home Language, English First Additional Language, Computer studies, and Life Orientation. We note that in this phase of the study, we did not utilize college or university outcomes as inputs, these outcomes were only utilized in the prediction of target variables set up in the preliminary phase as indicated in Table 3. The features selected for the post-preliminary phase of this study are presented ranked according to entropy in Table 6.

3.4 Classification Models

This study composed of two phases, each involving a classification task. In total, we use nine off-the-shelf machine learning predictive models to perform the classification tasks in this research. The models used are: Random forests, naïve Bayes classifier, Decision tree (C4.5), Logistic Model Trees (LMT), Multinomial Logistic Regression, Linear Logistic Regression, Sequential Minimal Optimization (SMO), Support Vector Machines (SVMs), and the K-Star (K*) instance-based classifier. We continue this subsection by giving a brief description of the selected models.

Sequential Minimal Optimization: SMO is an algorithm derived for the improved (speed) training of Support Vector Machines. SVMs previously required that a large quadratic-programming problem be solved in their implementation. Traditional algorithms are slow when training SVMs, however, SMO completes the task much faster by breaking the large quadratic programming problem into a series of smaller problems which are then solved by analytical methods, avoiding the lengthy numerical optimization required. The SMO algorithm we use for the purpose of this study follows the original implementation [19].

Multinomial Logistic Regression: This model derives and extends from the binary logistic regression. It does so by allowing categories of the outcome variable to exceed two. This algorithm utilizes the Maximum Likelihood Estimation (MLE) to predict categorical placement or the probability of category membership on a dependent variable [20]. Multinomial Logistic Regression requires the careful detection and removal of outliers for accurate results, however, the model does not assume or require linearity, homoscedasticity, or normality [20]. An example of a four-category model of this nature, with one independent variable x_i can be given by: $\log(\frac{\pi_i^{(s)}}{\pi_i^{(0)}}) = \eta_0^{(s)} + \eta_1^{(s)} x_i$, s = 1,2,3,4. Where; $\eta_0^{(s)}$ and $\eta_1^{(s)}$ are the slope and intercept respectively, given the probability of category membership in "s" can be denoted by $\pi_i^{(s)}$, and the selected reference category by $\pi_i^{(0)}$. The Multinomial Logistic Regression implementation in this research follows the implementation by other authors before the current study [21, 22].

Naïve Bayes Classifier: The naïve Bayes model is a simplified example of Bayesian Networks. The model achieves learning with ease by assuming that features employed are all independent given the class variable.

The diagram (a) in Figure 2 is an illustration of the naïve Bayes model. This is because the features, $x_1,...,x_5$ are conditionally independent given the class variable, C. The naïve Bayes independence assumption can be stated as the distribution: $P(C|X) = \prod_{i=1}^{n} P(x_i|C)$, where $X = (x_1,...,x_n)$ is a feature vector and C is the class variable. In application, naïve Bayes often performs well when compared to more sophisticated classifiers, although it makes a generally poor assumption [23]. The naïve Bayes model implementation in this research follows other similar implementations in related studies explored; [24, 23].

K* Instance-Based Classifier: The K-Star algorithm classifies instances using training instances that are similar to them alongside a distance function that is based on entropy. The use of an entropy based function provides consistency in the classification of instances in our experiments that may be real-valued or symbolic. The K* implementation utilized for the purpose of this research followed the implementation by [25].

Support Vector Machines: The (SVMs) classification model separates classes of the training data with a hyper-plane. The test instances then get mapped on the same space with their prediction based on the side of the hyper-plane they belong after splitting. This task is performed by incorporating the training dataset into a binary linear classifier that is non-probabilistic. SVMs can be scaled through the one-versus-all partitioning, for various types of classification problems including high-dimensional and nonlinear classification tasks. The SVM model implementation in this research follows the implementation in other related work [26].

Linear Logistic Regression: The Linear Logistic Regression model utilizes additive logistic regression with simple regression functions as base learners of the algorithm [27]. The implementation of this model followed in this research follows that of related work conducted in the past [28, 29].

Decision Tree: This model uses a decision support system to build a classification function that predicts the value of a dependent variable given the values of independent variables, through tree-like graph decisions and their possible after-effect, including costs of resources, chance results, and utility [30]. There are different algorithms for generating decision trees; C4.5, Random forest, and LMT are the tree-models selected for the purpose of this research.

The C4.5 algorithm uses information gain to build a decision tree, selecting features based on entropy and utilizing the ID3 algorithm recursively to build the tree. We follow the original structure and implementation of the C4.5 algorithm in this study [31].

LMT builds a single tree from a combination of logistic regression models and a tree structure. This model accomplishes the combination by using the Classification and Regression Tree (CART) algorithm to prune after building the regression functions through the LogiBoost algorithm. The LMT method used in this study follows from the original implementation [28].

Random Forests are a combination of decision tree predictors dependent on the value of a random vector, where the value also governs the growth of each tree in the generated forest. This algorithm involves utilizing the training data to generate an ensemble of decision trees and allowing them to decide on the most-popular class. Implementing this technique has several advantages, including that, the procedure abides by the Law of Large Numbers to prevent over-fitting, it is relatively robust to noise or outliers in

Figure 2: The diagrams (a) to (d) illustrate various examples of a Bayesian network model. The arrows travelling between nodes represent conditional dependencies among the features $x_1, x_2,...,x_5, C$. Where C, represents the class variable and the models differ based on the existence of a statistical dependence between the predictors $(x_1,...,x_5)$ [18].

data, and the model achieves accuracy as good as similar techniques such as, Adaboost, Bagging, and Boosting, while still training faster than them [32]. The Random forest model implementation in this research is based on the original model [32].

3.5 Prediction and Evaluation

In this research, the dataset contains the dependent attribute and the values of the classes are known, we therefore have a classification task set up. This subsection provides the measures and techniques utilized to complete this task.

3.5.1 Evaluation and Validation

10-fold cross-validation procedure is applied to evaluate each model employed in this research. In this validation procedure, the training dataset is partitioned such that a portion (testing data) of it is not provided to the algorithm during training, but is used for the validation. The partition remaining for training is further split into 10 partitions (folds). Interchangeably, each of the 10-folds serve for validation while the remaining 9 are used for training until all 10-folds serve as the validation fold once.

3.5.2 Confusion Matrix

We use confusion matrices to illustrate classification outcomes. Table 4 provides an example of the format of a confusion matrix.

Table 4: This table depicts the structure of a confusion matrix. We denote "negative" and "positive" by -ve & +ve respectively. Where TP are the true positives (correctly classified positives), FP the false positives, FN are false negatives, and TN are the true negatives (correctly classified negatives).

	Predicted Class +ve	Predicted Class -ve
Actual Class +ve	TP	FP
Actual Class -ve	FN	TN

3.5.3 Accuracy

We extract precision and recall metrics from the confusion matrix in order to measure the accuracy of the employed machine learning models. "Precision" represents the correctly real-positive proportion of predicted positives, while "Recall" represents the correctly predicted proportion of the real positives. We calculate precision and recall as follows:

$$Precision = \frac{TP}{TP+FP} \tag{1}$$

$$Recall = \frac{TP}{TP+FN} \tag{2}$$

The accuracy follows directly, calculated as:

$$Accuracy = \frac{TP+TN}{TP+TN+FP+FN} \tag{3}$$

This representation of accuracy has been used in other related work [17], [33]. Other measures of accuracy explored include the Receiver Operating Characteristic (ROC) curve. This curve plots recall (the true positive rate) against the false positive rate (ratio between FP and the total number of negatives), and the area under the ROC reflects the probability that prediction is informed versus chance [34]. We desire the ROC-area to lie above 0.5, anything below 0.5 implies the prediction was guesswork and not informed. Another accuracy measure utilized is the F-beta measure (F1 score), which calculates a test accuracy as the weighted harmonic mean of precision and recall. The optimal value for the F-measure is 1 (indicating perfect precision and recall), and the worst value is 0.

4 Results and Discussion

This study was conducted in two phases. The first phase involved generating preliminary results on a synthetic data-set, while in the second phase, a similar set of experiments are performed on a real data-set, leading to conclusions and implications about the performance of the trained machine learning models in classifying the problem at hand, furthermore, the results drawn from the second phase provide a ranking of the employed features according to entropy, together with an interactive program which calculates the posterior probability over the students' risk profile so that support initiatives and programs can be focused on them.

4.1 Preliminary Results

This Subsection presents the results of six of the nine prediction models discussed in Section 3, namely; Decision tree (C4.5), Logistic Model Trees (LMT), naïve Bayes Classifier, Sequential Minimal Optimization (SMO), Multinomial Logistic Regression, and Random Forests. We present first the prediction outcomes through a table comparing predictive accuracy of the models as determined by Equation 3. This will be followed by an evaluation of the model's performance through F-measure and Receiver Operating Characteristic (ROC) curve.

4.1.1 Prediction Outcomes

Six different machine learning models were utilized to solve our classification problem. The predictive accuracy achieved by each model is recorded and presented in the Table 5.

Table 5: Predictive accuracy as calculated by Equation 3. After 10-fold cross-validation, all of the models utilized achieved an accuracy above 80%, with Random Forests achieving top accuracy in all three cases considered, [5](sic).

	Predictive Accuracy		
Model used	1st Year Outcome	2nd Year Outcome	Final Year Outcome
Random Forest	94.40%	93.70%	95.45%
LMT	91.90%	91.75%	93.15%
Decision Trees (J48)	87.55%	86.20%	91.45%
Multinomial Logistic	87.80%	86.20%	90.70%
SMO	87.25%	84.45%	89.20%
Naïve Bayes	83.95%	83.40%	84.40%

4.1.2 Model Performance Evaluation

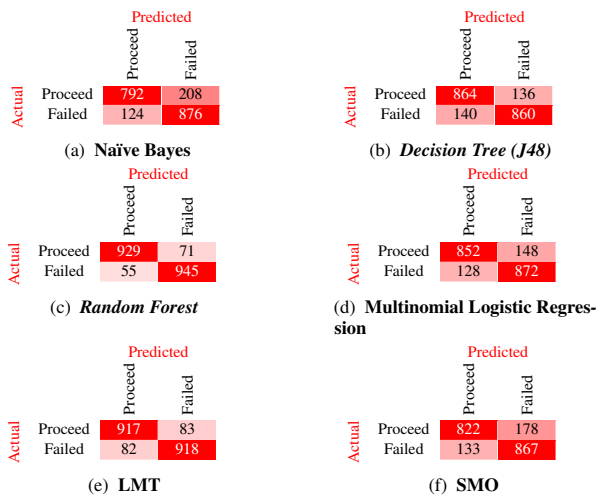
A study based on evaluating classification results argued for the use of Precision, Recall, F-Measure, and the ROC curve, as accurate measures of a machine learning model performance [34]. We utilize these measures to evaluate results presented by Figure 3, 4, and 5.
Figure 3: The set of confusion matrices resulting from the prediction of first-year outcome. Evaluation of the accuracy by class reveals that the weighted average of both precision and recall lies above 0.84 for all six models trained in our study. Further observations reveal that the f-measure of accuracy is more than 0.83 for all models, this value aligns with our accuracy as determined by Equation 3 in the Table 5. The test accuracy obtained in the table is further supported by the ROC curve obtained for all six models, as the weighted average of the ROC area for each model is more than 0.84 implying the models trained were making informed decisions in classifying the problem and not simply guessing.


Figure 4: The confusion matrices obtained when classifying the second-year outcome variable. When we evaluate the detailed accuracy by class for each model, we find that the weighted average of both precision and recall measures is above 0.83, furthermore, the f-measure of test accuracy aligns with our findings in Table 5 with a value of more than 0.83 for all six models considered. The ROC curve obtained for all six models also aligns with our accuracy as determined by f-measure of test accuracy and Equation 3, as the weighted average of the area under the ROC curve lies above 0.85 implying the models trained are not attaining the great predictive accuracy through guess-work, but they are making informed predictions.
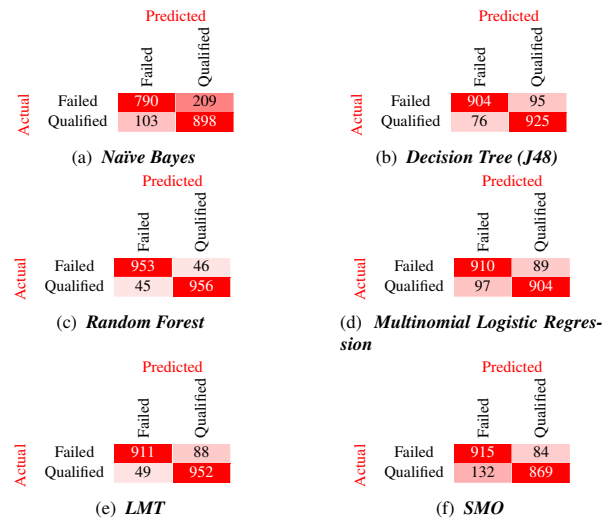

Figure 5: Confusion matrices obtained when classifying the third-year outcome variable with the six trained machine learning models. Evaluating the detailed accuracy by class results, we find that the weighted average of both precision and recall measures is more than 0.89 for all models except the naïve Bayes classifier which scored 0.85 for precision, and 0.84 for recall. The underperformance of the naïve Bayes model with respect to other trained classifiers can be explained by the naïve feature-independence assumption it makes. Results also show that the weighted average of the area under the ROC curve for each model is in alignment with our test accuracy measures, as it lies above 0.89, implying each model is making informed predications and not simply guessing the outcome.

4.2 Main Results (Post-preliminary)

The preliminary phase of this study revealed that we can utilize machine-learning models to accurately predict a learner's outcome from the first year of registration until qualifying in a three-year degree. The preliminary results confirmed our initial hypothesis but furthermore, revealed the kind of model we should utilize with such a wide variety of models available for use, but few fitted to the problem set up in this study. Evaluating the preliminary results, we note that Random Forests achieved top accuracy and performance as measured by all our model performance and accuracy evaluators, across all three test cases.

In this subsection, we present the results obtained when utilizing machine learning models to classify a learner into the four risk profiles ("No Risk", "Low Risk", "Medium Risk", and "High Risk") defined in Section 3, as the preliminary phase has confirmed this task can be completed. The classification problem set up in this phase is parallel to that in the prelim-phase in several ways, as the preliminary phase utilizes a synthetic data-set modelled to resemble the relationships that exist within the student enrolment data utilized for the second phase.

Subsection 4.2.1 presents the selection and ranking of features utilized, we follow this by a presentation of the classification outcomes and close the section with the presentation of an interactive program that can be utilized to calculate the posterior probability over a student's risk profile.

4.2.1 Selection and Ranking of features

We selected 20 features to predict the class variable. The features were selected using Information Gain Ranking (IGR) to deduce

the contribution of each feature in classifying the instances. The feature selection findings are illustrated through Table 6 with three columns below. The first column determines the rank of the features among the input set, the second column gives the amount of entropy attained by the feature, and the third column has the name of the feature associated with the ranking and entropy.

Table 6: A ranking through information gain (entropy) of the set of features selected to predict the student risk profile, ranked from the most contributing feature to the least contributing feature. The top seven features that are highlighted indicate an entropy greater than 0.1, [6] (sic).

Rank	Entropy	Feature Name
1	1.21960228	PlanCode
2	1.15086266	PlanDescription
3	0.59886383	Streamline
4	0.29582771	Year Started
5	0.20836689	AgeatFirstYear
6	0.18695721	SchoolQuintile
7	0.14234042	MathematicsMatricMajor
8	0.12166049	Homeprovince
9	0.06417526	isRuralorUrban
10	0.0568866	LifeOrientation
11	0.04978826	PhysicsChem
12	0.02780914	EnglishFirstLang
13	0.01253064	Homecountry
14	0.00550434	AdditionalMathematics
15	0.00000902	MathematicsMatricLit
16	< 0.00001	NBTAL
17	< 0.00001	NBTMA
18	< 0.00001	NBTQL
19	< 0.00001	ComputerStudies
20	< 0.00001	EnglishFirstAdditional

Figure 6: A graphical illustration of how the information gain (entropy) level varies across the chosen feature input set. The x-axis indicates the feature rank, and the y-axis indicates the information gain from utilizing the corresponding feature, [6] (sic).

The use of IGR also has implications on the contribution made by a feature relative to others within the chosen input set of fea-

tures. We investigate the behavior of entropy as you move between subsequent features and present the findings through a graphical illustration in Figure 6, showing the monotonically decreasing behavior of the entropy function plotted versus rank. We see that the loss in entropy between each subsequent point (feature rank) is logarithmically decreasing, furthermore, we highlight the same top seven features from the IGR Table 6.

The highlighted features on Figure 6 illustrates their relative importance in forecasting the success of a learner. We note that the set of factors most contributing to a learner's success includes, "the plan-code and plan description" (combined, these two variables give a precise description of what the student is studying), "streamline" (mathematical, life, or physical science), "the year started", "school quantile", "age at first-year", and "the student's matric mathematics score".

4.2.2 Classification Outcomes

This section presents the results obtained from the classification algorithms trained to predict the class variable (risk profile). Six of the nine classification procedures discussed in Section 3 were employed for the post-preliminary phase of the study: Decision trees (C4.5), naïve Bayes Classifier, Linear Logistic Regression model, Support Vector Machines (SVMs), K*, and Random Forests.

Figure 7 (a) – (f) illustrates the results of each trained classifier after 10-fold cross-validation. Evaluating the performance of each model relative to other models employed, we note that the Random forests classifier attains the highest accuracy (83%) of all the models trained for the post-preliminary phase. This result aligns with our findings from the preliminary phase of the study as Random forests attained the highest accuracy among the selected models for both phases of the study.

We note further that the SVM classification model was revealed to be the least suited for the problem set up in this study. At 52%, SVMs attained the lowest predictive accuracy in this study, furthermore, SVMs took the longest time to train. When discussing training and testing times, it is also important to note that the K-star model took the least time to implement in this study.

Overall, the classification task was a success, with five of the six models employed attaining a predictive accuracy above 75%. Noting that Random forests was the most accurate in predicting the class variable for both phases of this study, this section continues by providing a web application utilizing the Random forests classifier to predict the risk-profile of a learner based on enrolment and academic factors. Severity of misclassified instances was also evaluated and taken into account to determine Random forests as the most suited model for the task, for example, the 27% of "No Risk" instances incorrectly classified by SVM as "Medium Risk" is far more severe and misleading than the misclassification of 5% "No Risk" instances as "Medium Risk" by Random forests classifier.

4.2.3 Main Contribution of The Study

In this subsection we provide an interactive program which can calculate the posterior probability over a student's risk profile utilizing the Random forests model employed in Section 4.2.2. This automated system makes predictions about a student's risk of fail-

Predicted Risk

	No	Low	Med	High
No	171	20	9	0
Low	26	143	25	6
Med	17	22	145	16
High	2	7	16	175

(a) A confusion matrix resulting from the prediction of a student's "Risk Profile" utilizing the **C4.5** classification model. The **C4.5** algorithm achieved **79**% accuracy, furthermore, 634 instances were correctly classified and 166 instances were incorrectly classified by the model.

Predicted Risk

	No	Low	Med	High
No	159	24	11	6
Low	25	145	14	16
Med	14	21	124	41
High	6	7	12	175

(b) A confusion matrix detailing the performance of the **K*** classifier when predicting a student's "Risk Profile" (class variable). The lazy K-Star algorithm achieved **75**% accuracy, furthermore, 603 instances were correctly classified and 197 instances were incorrectly classified by the model.

Predicted Risk

	No	Low	Med	High
No	174	16	10	0
Low	31	142	22	5
Med	8	17	160	15
High	6	8	17	169

(c) A confusion matrix detailing the performance of the **naïve Bayes** classifier when predicting a student's "Risk Profile" (class variable). After 10-fold cross-validation the naïve Bayes classifier achieved **80**% accuracy, furthermore, 645 instances were correctly classified and 155 instances were incorrectly classified by the model.

Predicted Risk

	No	Low	Med	High
No	108	23	55	14
Low	38	80	65	17
Med	29	34	125	12
High	37	26	34	103

(d) A confusion matrix resulting from the prediction of a student's "Risk Profile" utilizing the **SVM** classification algorithm. The SVM algorithm achieved **52**% accuracy, furthermore, 416 instances were correctly classified and 384 instances were incorrectly classified by the model.

Predicted Risk

	No	Low	Med	High
No	174	17	9	0
Low	23	150	21	6
Med	6	15	161	18
High	5	4	14	177

(e) A confusion matrix resulting from the prediction of a student's "Risk Profile" utilizing **Random Forests** classifier. After 10-fold cross-validation the random forests model achieved **83**% accuracy, furthermore, 662 instances were correctly classified and 138 instances were incorrectly classified by the model.

Predicted Risk

	No	Low	Med	High
No	168	21	11	0
Low	37	138	19	6
Med	6	22	149	23
High	4	4	18	174

(f) A confusion Matrix detailing the performance of the **linear logistic regression** classifier when applied to a dataset of biographical and enrolment observations. The linear logistic regression model achieved **78**% accuracy, furthermore, 629 instances were correctly classified and 171 instances were incorrectly classified by the model.

Figure 7: A set of confusion matrices obtained when classifying the "Risk Profile" variable. We provide the accuracy of each classification model as determined by Equation (*****) along with a count of the correctly and incorrectly classified instances by each model, [6] (sic).

ure based on the conceptual framework developed in a "drop-out from higher education" study [13]. The conceptual framework connects dropout decision to categories of input features, namely, background (family) attributes, individual attributes, and pre-college scores. This framework is better depicted in the Figure 1 provided under the related work section.

The web application depicted in Figure 8 provides a practical tool which university student support programs can utilize for early detection of learners in need of academic support. We argue that the early detection and assistance of students at risk of failure is likely to lead to improved academic performance and eventually higher pass-rates, which translate to increased throughput rates.

The example depicted in Figure 8 illustrates the calculation of the risk profile of a learner based on biographical and enrolment observation. The program predicts the posterior distribution over the four "Risk Profiles", namely, "No Risk", "Medium Risk", "High Risk", and "Low Risk" using the Random forests classifier. The learner in the example is from an urban quantile 3 school in Kwazulu-Natal South Africa, furthermore, individual attributes are provided as follows; scores of 48%, 50%, and 55% for the quantitative, academic, and mathematical literacy National-Benchmark-

Tests (NBT) respectively. The learner also completed pre-college courses with scores of; 50% for both core Mathematics and Life Orientation, and 60% for English Home Language. The output presented at the bottom of Figure 8 illustrates that hypothetically the student is 10% likely to complete their degree in 3 years (No Risk), 50% likely to complete their degree in greater than 3 years (Low Risk), 35% likely to drop-out before the end of 3 years (Medium Risk), and 5% likely to drop-out in greater than 3 year (High Risk). With the output obtained, students support-program-coordinators can then decide what assistance will prove most beneficial to the student in the example as the learner posses a high chance of struggling to complete their degree in the allocated time (50% Low Risk).

5 Implications and Conclusions

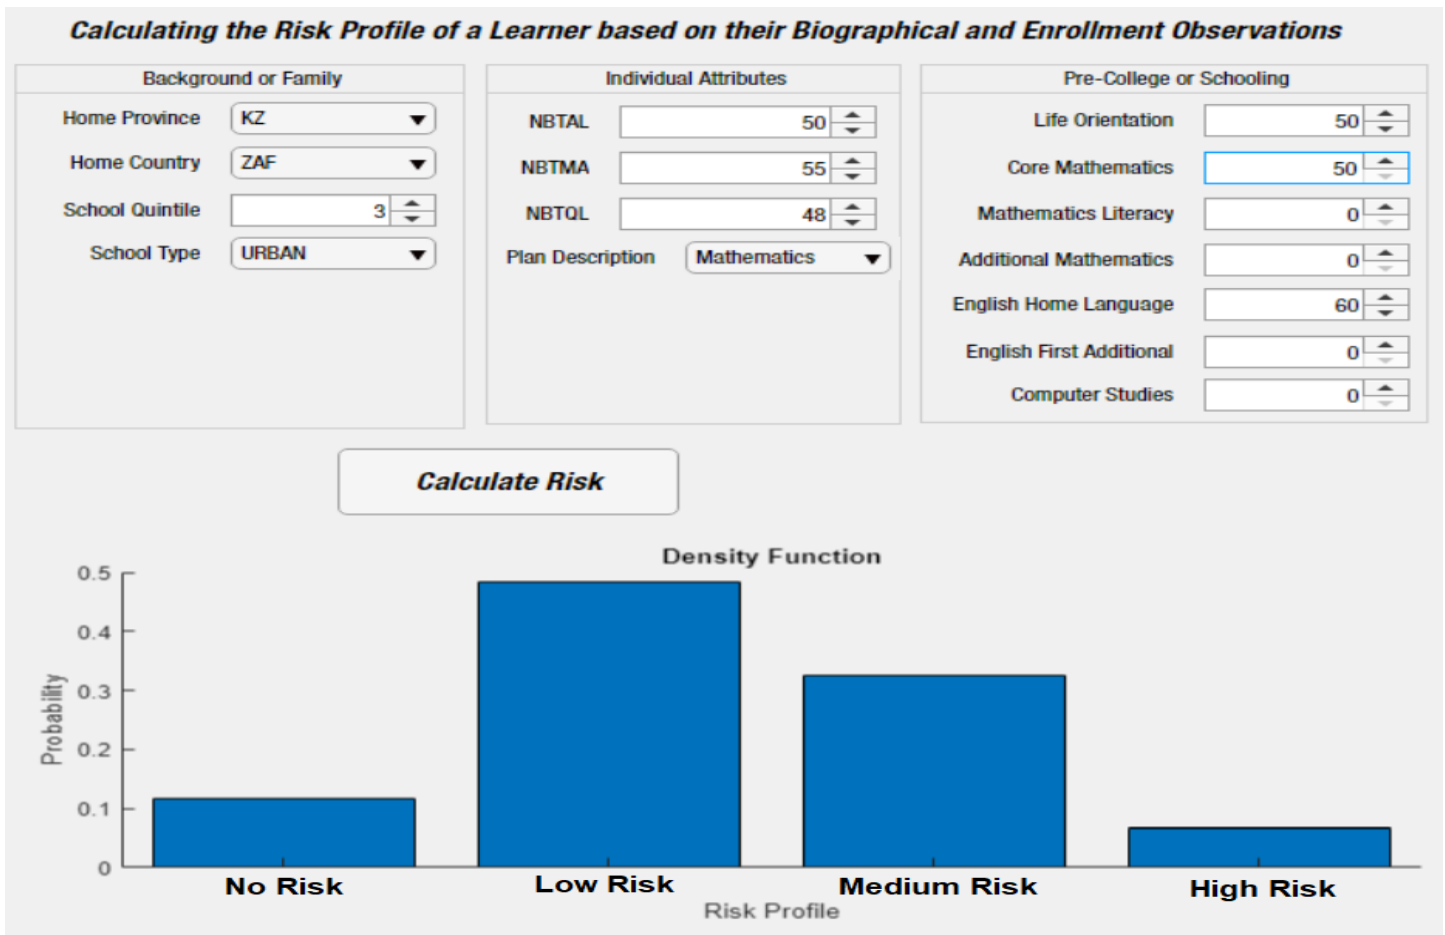
The expansion of enrolments in South African universities has not been accompanied by a proportional increase in the percentage of learners graduating. In this study, we took on the task of early prediction of a learner's academic trajectory, aiming at identifying those who may struggle in universities, so that proactive learner


Figure 8: The graphical user interface for the at-risk program, [6](sic).

remediation to promote success may be provided to them.

This paper contributes to the current body of knowledge firstly by introducing an approach involving the prediction of a learner's outcome from the first year of registration until qualifying in a three-year degree. We argue for the early prediction of a learner's entire academic trajectory with the aim to detect those who are likely to benefit from student academic support initiatives. We trained six machine learning models to predict first, second, and final year outcomes from a synthetic data-set. After 10-fold cross-validation this task was completed with great success as all six models attained an accuracy above 83%. Furthermore, an evaluation of the F-measure of accuracy and ROC-curve reveal that these models are making informed-accurate decisions and not simply guessing, therefore, leading to our second contribution involving a real data-set from a research-intensive university in South Africa.

The second contribution of this study is a ranking (through entropy) of features according to their contribution in correctly predicting a learner's "risk profile" (class variable). The ranking of features according to entropy reveals which features are stronger determinants of student success relative to others employed and, in this study, we highlight the seven top-ranked features, namely, "plan code", "plan description", "year started", "age at first year", "streamline", "school quantile", and "Matric Mathematics major".

The third and main contribution made by this study is an inter-active program which can predict the distribution over a learner's risk profile utilizing biographical and enrolment observations. The interactive program proposed in this paper can be utilized for early identification of university learners who are most likely to benefit from student support initiatives aimed at improving academic performance. The implication of this study is that university learners can be assisted early in their academic journey increasing their chances of success. Furthermore, the early detection and assistance of learners in need of academic support will result in an improved and enriched learning experience beyond what the student would have experienced if support initiatives were implemented after failure has been detected.

6 Future work

To continue with the work done in this paper, future work may involve: (a) incorporating into our models features from categories not considered such as the "psycho-social attributes category", (b) exploring what courses offered in university possess high failure rates and how good the set of features we employed predict success in these courses, or (c) approaching the problem from a different perspective by attempting to predict which courses are students likely to struggle completing so that support initiatives may be focused on the specific courses.

A B S T R A C T

Indoor positioning system (IPS) has become a high demand research field to be developed and has made considerable progress in recent years. Wi-Fi fingerprinting is the most promising technique that produces an acceptable result. However, despite the large amount of research that has been done using Wi-Fi fingerprinting, only a few Wi-Fi based IPS in the market can be said to be successful. Doing the research in a controlled environment and ignore the temporal signal changes may be the cause of such scenario. A long-term dataset was built to overcome this issue, yet the distance error of the state of the art was 2.48m. Therefore, we aim to reduce the distance error by combining two positioning algorithms which are Weighted k-Nearest Neighbor (WKNN) and Long-Short Term Memory (LSTM) using ensemble learning. The result shows that our ensemble method can reduce the localization error to 1.89m and improve the performance of the IPS by 23.7% when compared to the state of the art.

1   Introduction

Today, outdoor positioning is already a mature research field. An object with Global Navigation Satellite System (GNSS) service – such as Global Positioning System (GPS), GLONASS, Galileo, BeiDou – can be easily located with the help of satellite signal with high accuracy [1].

On the contrary, Indoor Positioning has not reached its maximum results and is on the focus of researchers recently. Satellite signals cannot be used for Indoor Positioning System (IPS) purposes due to too much signal attenuation in an indoor environment [2] that results in IPS with an accuracy of more than 100m [3]. IPS is very useful and has many functionalities in an environment like museum, department store, university, etc. Which is why IPS has become a high demand research field to be developed and has made considerable progress in recent years. Due to the absence of satellite in an indoor environment, researchers attempt to utilize other signals to be used in IPS such as Wi-Fi, Bluetooth, FM radio, RFID, ultrasound or sound, light, and magnetic field [4].

Wi-Fi signal has been the most popular and most used in developing IPS in recent years because it achieves high applicability in a complex indoor environment and does not require line-of-sight measurement of Access Points (APs) [4]. However, Wi-Fi also faces several problems when deployed in IPS. Wi-Fi is usually established

for communication purposes and rarely deployed with the ideal density and geometry for IPS [5]. The existing environment will need to deploy extra AP to create an ideal environment for IPS, which results in spending more money and makes it relatively expensive.

The most popular and promising approach in building an IPS is fingerprinting. This approach has two stage, offline phase and online phase. In the offline phase, the characteristics of several locations, called as Reference Point (RP), is measured. Then, a positioning algorithm will be used in online phase using the data collected during the offline phase. IPS with Fingerprinting approach can be viewed as a classification or regression problem. Many classification and regression algorithms like k-Nearest Neighbor (KNN), Weighted k-Nearest Neighbor (WKNN), Support Vector Machine (SVM), Multilayer Perceptron (MLP), Convolutional Neural Network (CNN), Recurrent Neural Network (RNN), and Long Short-Term Memory (LSTM) have been tested.

Combining the two, Wi-Fi fingerprinting has been the most popular technique for developing IPS. With dense Wi-Fi coverage in a well-surveyed environment, Wi-Fi fingerprinting can achieve acceptable accuracy, as shown in recent research [6]. Local Feature-based Deep Long Short-Term Memory (LF-DLSTM) was proposed and achieves localization performance with mean localization errors of 1.48m and 1.75m under the research lab and office environments, respectively.

However, to the best of our knowledge, only a few WiFi-based IPS in the market can be said to be successful. Although there are many methods that have been tested before, the accuracy in the real environment decreases. This may happen if the testing of the IPS was done in a specific, probably controlled environment. Therefore, the accuracy in the real environment may decrease significantly [7]. To overcome this issue, research in IPS needs to be done using a public dataset, therefore the environment cannot be controlled by the authors.

There are many public IPS dataset that can be obtained online such as [8] and [9]. However, these datasets were collected in one day only and do not take into account the changes in the temporal signal that inevitably occur in the real environment. This happens because the RSSI received from an AP might be different between one day and the next day, even if the location and environment is precisely the same [10]. Therefore, the accuracy in the real environment may drop significantly. To resolve the issue, dataset needs to be collected and updated periodically.

In this research, we use an IPS dataset that is published online which considers the temporal signal changes [7]. To the best of our knowledge, the best accuracy that has been done using this dataset was the research by Hsieh that used RNN to obtained a distance error of 2.48m [11]. To the best of our knowledge, the research employs RNN and LSTM separately and is applied directly to the dataset without any modification to prevent overfitting. However, the training data only contains fingerprint from 24 RP, while the testing data contains fingerprint from 106 RP. With much fewer reference points in the training data, the model tends to overfit.

This research aims to reduce the localization errors by applying methods to prevent overfitting in the LSTM model. We also provide a new way to reduce the localization errors further by combining two positioning algorithm which are WKNN and LSTM using ensemble learning.

2 Literature Review

2.1 Fingerprinting

Fingerprinting technique utilizes the signal characteristics of a specified location in a particular environment. It consists of an offline phase and an online phase. During the offline phase, a site survey is conducted on the environment. First, several location coordinates, referred to as Reference Points (RPs) will be chosen, which later each of them will be used to collect the RSSI from numerous access points. Multiple RSSI readings will be taken in each RPs. These collections of data consist of RPs and RSSI from multiple access points is usually known as radio map. During the online phase, a mobile unit observes RSSI measurements at a specific location and use an algorithm to associate the measurements with the radio map. The mobile unit is assumed to be collocated with an RP if the measurements made in the online phase and offline phase are similar.

Fingerprinting approaches can be viewed as a classification problem. The radio map collected during the offline phase is trained to obtain a model. Then, the position of the mobile unit will be estimated by putting the measurements taken into the model as a parameter. Classification algorithm such as K-Nearest Neighbor

(KNN), Weighted K-Nearest Neighbor (WKNN), Support Vector Machine (SVM), Naïve Bayes, Artificial Neural Network (ANN), Recurrent Neural Network (RNN), Long-Short Term Memory networks (LSTM) have been used.

In a traditional site survey where the surveyor collects the radio map by standing at RP and taking multiple measurements, it took 10 hours for two people to build a radio map consists of 150 RPs in a 281m^2 environment [12]. It can be concluded that, when using a site survey as a radio map collection method, the offline phase is time-consuming, labor-intensive, and cost-prohibitive.

Fingerprinting can produce a low localization error because unlike any other approach, fingerprinting relies on the characteristics of the environment itself. Fingerprinting allows obstacles like wall, furniture, and other static objects do not interfere with localization accuracy. However, this also works as a trade-off. If there are any changes in the environment, such as furniture and access points relocation, another site survey is needed.

Then, researchers tried to lessen the time taken to build a radio map. [13] introduced the Quick Radio Fingerprint Collection method (QRFC) that allows radio map to be created, simply by holding a smartphone while walking. QRFC makes the radio map collection become effortless, especially if there are extra volunteers. Even with lesser times, radio map built by QRFC has been proven gave the same results with a radio map created by a site survey, and even better.

The fingerprinting technique offers both accuracy and ubiquity. Access point location does not need to be known, and there is no Line of Sight (LOS) requirements. Usually, fingerprinting techniques produce an IPS with better localization accuracy, which makes it superior to other methods [14].

2.2 Weighted k-Nearest Neighbor (WKNN)

Weighted k-Nearest Neighbor (WKNN) is a modified version of k-Nearest Neighbor which is a supervised machine learning algorithm that can be used for classification and regression problems. KNN assumes the data in the same cluster is identical and has the same characteristic. It can be seen in Figure 1, that the data in the same cluster is adjacent one to another.
Figure 1: k-Nearest Neighbor

The similarity between two data points can be known from the distance between them. The distance can be calculated using several methods, the most basic and used one are the Euclidean distance (1). The smaller the distance, the more similar the data is.

$$d = \sqrt{\sum_{i=1}^{n}(q_i - p_i)^2} \qquad (1)$$

Euclidean distance is used to calculate the distance between the new data and the dataset. Where n is the number of access points that transmit RSSI, q_i is the RSSI measured on the RP from i^{th} access point, and p_i is the RSSI measured on the mobile unit from i^{th} access point.

A number of *k* data points with the smallest distance are considered as the nearest neighbor to the new data, which means they are similar to each other. The mode of the *k* labels will be considered as the label of the new data in a classification problem. In a regression problem, the mean of the *k* labels will be returned instead.

However, the hyperparameter *k* needs to be chosen carefully. If *k* is too large, the neighborhood may include too many data points from other classes, which leads to inaccuracy. However, KNN would be more sensitive to outliers if *k* is too small. Several experiments need to be done to decide the value of hyperparameter *k* in KNN.

To overcome existing problem in KNN, a weight is given to every *k* neighbors; thus, this algorithm is called weighted k-nearest neighbor. Any function can be used to determine the weight of every neighbor, usually called a kernel function. The bigger the distance gap between the new data and its neighbor, the smaller the weight is. Bigger weight means the data is more similar than other neighbors with a smaller weight. In this research, the kernel function is defined in (2).

$$w_i = \frac{1/d_i}{\sum_{j=1}^{k} 1/d_j} \qquad (2)$$

Where *k* is the total number of neighbors, d_i is the distance from the mobile unit to i^{th} neighbor, and w_i is the weight for i^{th} neighbor. Then, the position of the mobile unit can be estimated by assigning the weight to the RP coordinates using (3).

$$(x,y) = \sum_{i=1}^{k} w_i(x_i, y_i) \qquad (3)$$

Where w_i represent the weight for i^{th} neighbor, while x_i and y_i is the coordinates of the ith neighbor which are X and Y, respectively.

2.3 Long Short-Term Memory (LSTM)

Long Short-Term Memory (LSTM) was made to overcome the problems found in Recurrent Neural Network (RNN). It is well known that RNN suffers from the vanishing gradient problem during backpropagation, which makes it is hard to remember the importance of the data from earlier timesteps if the data sequence is long enough.

RNN layers are connected to each other, as shown in Figure 2. To obtain the output at time *t* (Y_t), RNN takes into account the input at time *t* (X_t) and the hidden state from the previous time step (h_{t-1}). The hidden state from previous time step (h_{t-1}) is passed to the current step (h_t) as an input, which holds the information of the previous time step. However, the gradient in the earlier layers in RNN usually shrinks as the sequence gets longer, and with a low gradient update rate, the layers stop learning. With the layers from

early timesteps stop learning, RNN will forget what it had seen when the sequence got longer, thus having a short-term memory.
Figure 2: Recurrent Neural Network

LSTM used the same flow as RNN, where the information from the previous time step is passed onto the current time step. The difference is LSTM has an internal mechanism called gates that can learn which data is essential or not. If the data is considered important, LSTM will keep the information. If it turns out that the data is not important, LSTM will forget the information. This internal mechanism in LSTM is called a cell state, which has various gates.

The cell state can be thought of as a "memory" in LSTM, where the cell state will carry information throughout the processing of the sequence. As the sequence goes, additional information will be added to the cell, and some will be removed from the cell state. The cell state consists of three gates: input gate, forget gate, and output gate. These gates determine which information will be stored, keep, and be omitted from the cell state. Two activation functions are used within the three gates, which are sigmoid and tanh, which can be written as (4) and (5), respectively.

$$\sigma(z) = \frac{1}{1 + e^{-z}} \qquad (4)$$

$$\tanh(z) = \frac{2}{1 + e^{-2z}} \qquad (5)$$

2.3.1 Forget Gate

Forget Gate decides which information to be kept or discarded. Both information from the previous hidden state and the current input will be passed into a sigmoid function. The forget gate can be described as (6).

$$f^t = \sigma(w^f[h^{t-1}, x^t] + b^f) \qquad (6)$$

The information is considered as unimportant if f^t is close to zero, and the cell state will discard the information. If f^t is close to 1, that means the information is important.

2.3.2 Input Gate

The input gate has a role in determining which information will be added to the hidden state from the current input. Besides the sigmoid activation function, the input gate also uses tanh activation function.

$$i^t = \sigma(w^f[h^{t-1}, x^t] + b^i) \qquad (7)$$

First, the previous hidden state will be passed along with current input into sigmoid functions, written in (7). Then, we pass the hidden state and current input into tanh function, written in (8), producing $\widetilde{C}^t$.

$$\widetilde{C}^t = tanh(w^c[h^{t-1}, x^t] + b^c) \tag{8}$$

Now, we can determine the current cell state by executing (9).

$$C^t = f^t C^{t-1} + i^t \widetilde{C}^t \tag{9}$$

2.3.3 Output Gate

The output gate is the one that produces a new hidden state to be passed to the next time step. Just like forget and input gate; first we passed the information from the previous hidden state along with current input into sigmoid function, written in (10)

$$o^t = \sigma(w^o[h^{(t-1)}, x^t] + b^o) \tag{10}$$

Then, the new hidden state to be passed into the next time step can be obtained by using (11).

$$h^t = o^t tanh(C^t) \tag{11}$$

2.4 Related Works

The most straightforward yet beneficial application of IPS can be found in [15]. The research provides a system to ease doctors and nurses in locating their patients, especially in emergencies. The system was built by deploying multiple BLE throughout the ceiling of the hospital for every 10m. By using the proximity technique, the nearest BLE will be chosen based on the RSSI, and the location of the BLE will be sent to the system server for location mapping. The user will be considered in the same room, or the same area with the nearest BLE detected. By using this algorithm, the system achieved 97.22% accuracy for location classification.

An IPS made using the multilateration technique can be seen in [16]. The research was performed in a furnished laboratory environment with 13.1m x 6.5m. A total of 6 Raspberry Pi3 was used to capture the signal from a mobile BLE that transmits two signals at each second. Linear Least Squares is a multilateration method and was used in the research with a localization errors up to 1.79m.

Meanwhile, [6] proposed an IPS based on Wi-Fi signal with Deep LSTM architecture, which is just a stack of LSTM. The data were preprocessed using the sliding window to reduce the noise effect on the RSSI, which produces a more robust representation of the RSSI with minimal loss of signal properties. Two LSTM layers were used with 30 and 40 hidden layers. Then, a fully connected layer with a size of 60 was used to transfer the outputs of the second LSTM layers. The architecture also implements one dropout layer to prevent overfitting that usually happened to deep networks. The experiment was carried in two environments, a research lab with 35.3m x 16m and an office with 55m x 50m. The result of DLSTM was compared to ANN, SVR, Extreme Machine Learning (ELM), WKNN, and Stacked Denoising Autoencoder (SDA). The result shows that the proposed algorithm outstands the other algorithm with a localization error of 1.48m and 1.75m under the research lab and the office, respectively.

Due to creating a fingerprint database took a long time, some researchers focus on creating a fingerprint database for indoor positioning research purposes, such as [17]. The dataset consisted of multiple buildings and multiple floors and is used by Jang, who proposed a convolution neural network (CNN) [18]. The network uses the Interquartile range (IQR) for feature scaling, a dropout layer, data balancing, and ensemble methods. The architecture consists of 3 identical CNN models, with each of them has a different filter. The research shows that the proposed algorithm outperforms the Deep Neural Network (DNN) architecture.

RNN and LSTM has been proved to be successful in detecting pedestrian trajectory in indoor environment [19], [20], which inspired Hsieh et al. to utilize RNN and LSTM in indoor positioning system [11]. The research used a public dataset, which is the one used in this research [7]. The model consists of input layer, RNN or LSTM layer, fully connected layer with 40 neurons, fully connected layer with 2 neurons, and output layer. The number of RNN or LSTM layers were adjusted to 1, 3, and 5. The result shows that the best accuracy can be achieved by employing 5-layer RNN with a distance error of 2.48m and 99.6% accuracy of floor prediction.

Several ensemble learning approach has been done in building Indoor Positioning System. A research by Li et al. provide an ensemble approach to fuse Differential Time Difference Of Arrival (DTDoA) with RSS value [21]. Some research provide a way to combine the results from several positioning algorithm such as KNN [22]–[24] and neural network [25]. Research by Hayashi divide the environment into several area and each area has its own positioning algorithm. The result from positioning algorithms from each area is combined to get the final prediction [26].

A simple application of IPS can be created using simple techniques such as using proximity to locate the mobile unit in a particular subarea. To determine the exact position of the mobile unit in a small to medium environment scale, trilateration or multilateration can be used. However, if the environment grows bigger into a multi-floor or even multi-building environment, using a fingerprint technique is recommended.

Ensemble approach has been proved to be successful in both classification and regression problem [24]. Previous research provide ways to combine the result several weak-learners to obtain the final prediction. To the best of our knowledge, this is the first research that uses an ensemble approach where the result from one positioning algorithm was taken as an input for the next positioning algorithm in the IPS field.

3 Methodology

3.1 Dataset

We used a dataset released online by Mendoza et al. [7] to verify our proposed method. According to the authors, the dataset has been standardized and ready to be used for indoor positioning research purposes. The dataset was collected in a library that consists of multiple bookshelves from two different floors (3rd and 5th) with total coverage of 308.4m^2. To overcome the problem that occurs because of temporal signal changes, the data were collected within 15 months, with 63.504 measurements in total.

Each measure in the dataset provides information such as exact position, RSSI readings, timestamps, and some identifiers. Four hundred forty-eight access points were used in the measurement. Access points were installed on both floor levels at approximately 2.65m from the ground.

To collect the fingerprint database, A trained person that is called as the subject was chosen. Multiple locations were chosen to create the radio map. The radio map consists of fingerprint data with the subject facing four different directions, which are forward, backward, left, and right. At the offline stage, the subject stood at the selected location and held Samsung Galaxy S3 with the right hand in front of his chest. The mobile phone was equipped with an application that collects the RSSI of the Wi-Fi and eases the collection process. The app gave an ordered list of locations for the subject and gave a specific direction for the subject has to face. Therefore, this application reduces the likelihood of the subject placing themselves in wrong positions.

The dataset has been split into training and testing dataset by the authors. The training dataset consists of 16.704 fingerprints from 24 different RP while the testing dataset consists of 46.800 fingerprints from 106 different RP. Each fingerprint consists of 448 RSSI readings from every AP. However, not all of them were detected. If an AP is not detected in a fingerprint, the value will be recorded as 100. In this research, the dataset is scaled using Min-Max Scaler which can be described in (12).

$$X_{scaled} = \frac{X - X_{min}}{X_{max} - X_{min}} \qquad (12)$$

where X is the original value of the feature, X_{max} and X_{min} is the highest and smallest value that exists in the feature, respectively.

3.2 Proposed Method

Several research [22]–[25] used an ensemble learning approach where the outcomes of several positioning algorithms are combined into one single output. In this study, we provide a different ensemble method which combines two positioning algorithms, namely WKNN and LSTM.

Since the result from WKNN will be used as an input in the LSTM model, we need to get the coordinates and floor prediction from WKNN. Each data in the testing dataset which contains RSSI values from 448 APs will be used as an input into WKNN to predict the coordinates and the floor level of the object. The data will be scaled using Min-Max Scaler to turn it into the range of 0-1 by using (12).

For every data in the testing dataset, WKNN will create a list containing all of its neighbors from the training dataset. To be precise, each testing data will have 16.704 neighbors in total. Every neighbor has its own distance from the testing data. The distance is measured using Euclidean Distance (1). The smaller the distance means the RSSI values between the testing data and the neighbor is similar to each other. If the RSSI values are similar, it can be assumed that the object positions are also similar. Therefore, it can be concluded that we can predict the coordinates and the floor level of the object by collecting several neighbors with similar characteristics (RSSI value).

A number of k neighbors with the smallest Euclidean Distance will be used to predict the coordinates and floor level of the object. The coordinates, both X and Y, is calculated using (3). Since the smaller the distance means the data is more similar, a neighbor with a smaller distance will have more weight. Thus, it has more impact in predicting the coordinates of the object. We select the floor level that occurs the most within the k neighbors as the floor level prediction of the object. Since we are using mode to predict the floor level, the number of neighbors must be odd. Hence, the configuration of hyperparameter k is set to an odd number in this research.

After the coordinates and floor level of the object has been predicted by WKNN, the result will be concatenated to the testing data to create a new dataset called WKNN dataset. WKNN dataset consists of RSSI values from 448 APs, predicted coordinates by WKNN, predicted floor level by WKNN, real coordinates, and real floor level.

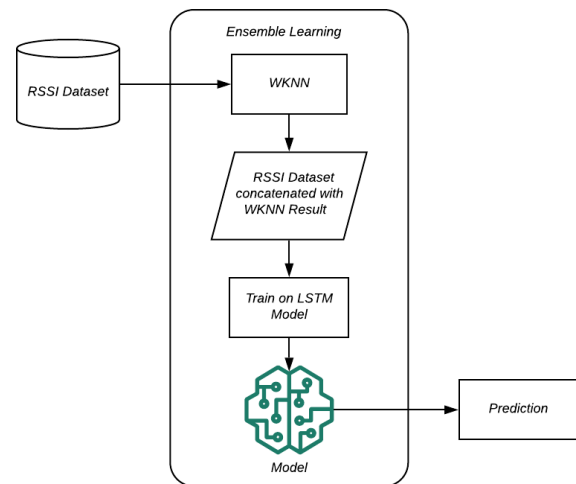
The WKNN dataset will be used to calculate the localization error and accuracy of the WKNN model, and it will also be used in LSTM architecture. Two architecture are proposed in this model since we are using regression to predict the coordinates and classification to predict the floor level of the object. Figure 3 shows the overall process of our ensemble method where the result from WKNN is combined with the original features and is used as an input to the LSTM model. To the best of our knowledge, this is the first study that uses this kind of ensemble learning approach in the IPS field.


Figure 3: Proposed Method

4 Experimental Design and Result

4.1 Experimental Design

Both regression and classification will be done in the experiment since the dataset contains data with multiple floors. The purpose of the regression model is to predict the coordinates of the object while the classification model predicts the level of the floor the object is on.

Three scenarios will be conducted in the experiment. The first scenario is to use only WKNN to predict the coordinates and the level of the floor of the object. The second scenario will use both the regression and classification model to predict the coordinates and the level of the floor of the object. The third scenario is similar to the second scenario. But in this scenario, the result from WKNN (coordinates or floor) will be added as an input for the model. Therefore, there will be 4 neural network architecture used in this experiment. All of the architecture is trained using k-fold cross validation to prevent overfitting. The number of folds used in this research is 5.

The neural network of the regression model can be seen in Figure 4. The input layer consists of 448 features which are the RSSI value for each AP. The features are fed to LSTM layer that consists of 448 neurons with tanh as its activation function. To prevent overfitting, a dropout layer is added in the LSTM layer with 0.5 dropout rate. Then, the result from LSTM layer will be fed into a fully connected layer that consists of 40 neurons with sigmoid as its activation function. Finally, the output layer consists of 2 neuron that represent the coordinates of the object. Linear activation function is used in the output layer. The model uses Adaptive Moment estimation (adam) as the optimizer and root mean squared error as the loss function. Ten epochs ere used to train the model with 5 training examples for each batch.

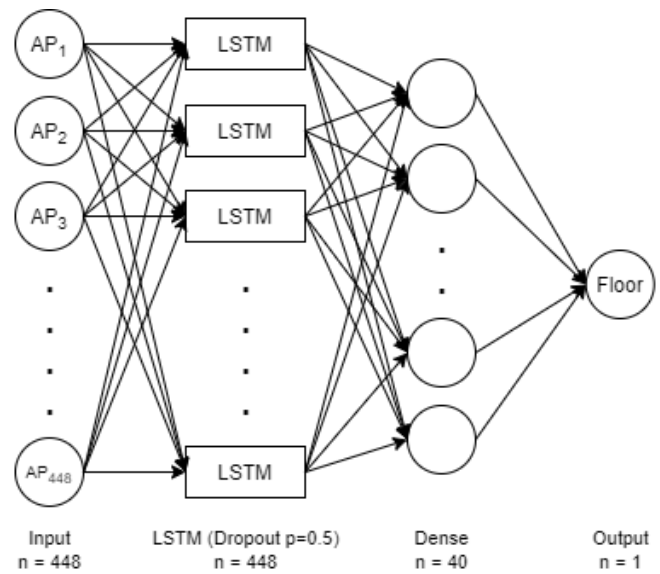
layer and LSTM layer since there are additional inputs which are the coordinates from WKNN.


Figure 5: LSTM Classification Architecture

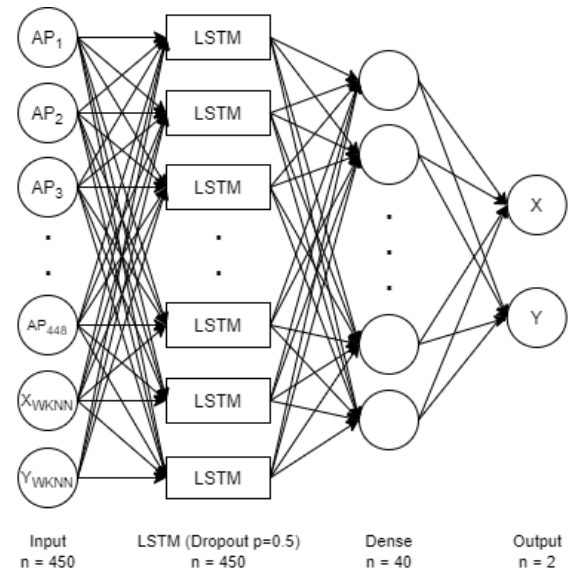
Figure 4: LSTM Regression Architecture


Figure 6: WKNN-LSTM Regression Architecture

The architecture of the classification model can be seen in Figure 5. The architecture is similar to the regression model. The difference resides in the output layer which only consists of one neuron that represents the floor level of the object. Instead of using the linear activation function, sigmoid is used as the activation function of the output layer. Binary cross-entropy is used as the loss function and accuracy as the metrics.

The architecture of the regression model for our proposed method (WKNN-LSTM) can be seen in Figure 6. All of the activation functions, optimizer, number of epochs, batch size of this architecture is the same as the one used in LSTM regression architecture. The only difference is the number of neurons in the input

The architecture for WKNN-LSTM classification model can be seen in Figure 7. Same as before, the architecture use the same settings with LSTM classification architecture and there will be one additional input which is the floor level prediction from WKNN.

4.2 Experimental Result

In the first scenario, we try out several WKNN model with a different values of hyperparameter k. The result of the first scenario can be seen in Table 1.

It can be seen that the distance error decreases as the hyperparameter k increase while the floor prediction accuracy does not

show any significant changes. The increase in performance is pretty significant between *k=5* and *k=13*. However, the performance gap between *k=13*, *k=21*, and *k=25* is not too big. Yet, as the hyperparameter *k* increases, the computational cost and time also increase. Therefore, hyperparameter *k* needs to be adjusted according to the user needs.
Figure 7: WKNN-LSTM Classification Architecture

Table 1: WKNN Results

Model	Distance Error (RMSE)	Floor Prediction Accuracy
$k = 5$	2.28m	99.75%
$k = 13$	2.17m	99.76%
$k = 21$	2.15m	99.77%
$k = 25$	2.14m	99.76%

The result of the second and third scenario can be seen in Table 2. The three hyperparameter *k* values in Table 1 will be applied in the third scenario for WKNN model to predict the coordinates and the floor level. We also compare the result from our experiment with the research by Hsieh [11].

Table 2: LSTM and WKNN-LSTM Results

Model	Distance Error (RMSE)	Floor Prediction Accuracy
RNN [11]	2.48	99.6%
LSTM [11]	2.57m	99.5%
Our LSTM	1.99m	99.8%
WKNN-LSTM ($k = 13$)	1.90m	99.85%
WKNN-LSTM ($k = 21$)	1.92m	99.87%
WKNN-LSTM ($k = 25$)	1.89m	99.86%

Our LSTM model can achieve distance error and accuracy of 1.99m and 99.8%, respectively. Both predictions are superior compared to WKNN model. However, when the result from WKNN is used as an additional input to LSTM, our model can achieve distance error and accuracy of 1.89m and 99.86%.

It can be seen that the LSTM model surpass the performance of WKNN model in predicting the coordinates and the floor level. Yet, the performance can increase even more if both of the model is combined using our ensemble approach.

5 Conclusion

In this research, we proposed a new way to reduce localization error by using ensemble learning. The ensemble consists of two positioning algorithms which are WKNN and LSTM. Aside from the original features which are RSSI values from all of the APs, the result from WKNN, either the coordinates or the floor level, are taken as an additional input for the LSTM model. The result shows that our ensemble approach can improve the performance of the IPS by 11.6% and 5% when compared to the performance of our WKNN and LSTM, respectively.

	To create a Virtual Reality (VR) system for Wing Chun's basic hand movement training, capturing, and classifying movement data is an important step. The main goal of this paper is to find the best possible method of classifying hand movement, particularly Wing Chun's basic hand movements, to be used in the VR training system. This paper uses Oculus Quest VR gear and Unreal Engine 4 to capture features of the movement such as location, rotation, angular acceleration, linear acceleration, angular velocity, and linear velocity. RapidMiner Studio is used to pre-process the captured data, apply algorithms, and optimize the generated model. Algorithms such as Support Vector Machine (SVM), Decision Tree, and k-Nearest Neighbor (kNN) are applied, optimized, and compared. By classifying 10 movements, the result shows that the optimized kNN algorithm obtained the highest averaged performance indicators: Accuracy of 99.94%, precision of 99.70%, recall of 99.70%, and specificity of 99.97%. The overall accuracy of the optimized kNN is 99.71%.

1. Introduction

Martial arts training is one of the preferable methods of physical exercise. It provides health & psychological benefits, such as preventing osteoporosis [1], reduces stress, depression, and increases mindfulness [2], and also has the potential to reduce aggressive behavior [3]. Basic movements of martial arts training such as stance and punches are usually done with the supervision of the instructor. However, instructors cannot always be there for one student, they must accompany other students as well. It could be a problem for new students who have just learned stances and punches. Repetitive movements without supervision could result in the students become unmotivated and stop their movement. Having the instructor to watch over them is helpful for the students to keep repeating the movement without stopping. There needs to be a method of training to make the students keep their excitement going during basic training when the instructor was not able to watch them. Watching video tutorials and reading books are some of the ways to improve the students' training experience, however, it lacks interactions and presence needed in martial arts training.

This is when Virtual Reality (VR) technology comes into play. It is mentioned by [4] that VR is typically defined in technical terms, meaning it is associated with technical hardware such as computer systems, head-mounted display (HMD), motion trackers, etc. VR itself can be simply defined as an environment that simulates the real world and is generated by a computer system in which users can then interact with by using motion trackers [5]. The trackers are used to collect data from the real environment and translate them to the virtual environment [6].

Due to its immersive capabilities, VR technology has been used in areas, such as architecture and landscape planning [7], dancing [8], military training [9], medical, such as stroke rehabilitation [10], and psychological treatment [11]. It has also been used for research in martial arts scope, even though there has not been much of them. The reason is that higher immersion and presence result in higher performance to the user [12].

A VR-based training simulation system could help in practicing the movement and motivates the user, due to its immersive capabilities [13]. To develop the system, capturing and classifying the hand movements is crucial, as being able to classify basic movement in Wing Chun is one of the basic training outcomes. This study uses Oculus Quest, a VR gear with a head-mounted display (HMD) and a pair of controllers. These controllers are used to capture hand movements. Variables such as time, location, rotation, angular acceleration, linear acceleration,

angular velocity, and linear velocity, were recorded and used as features for classification.

The purpose of this paper is to find the best possible method of classifying Wing Chun's basic hand movement to develop a VR-based training system. Since this paper uses Oculus Quest with a pair of hand controllers, hand movement data can be captured in the form of location in the world space. Not only that, other properties like rotation, angular acceleration, linear acceleration, angular velocity, and linear velocity can be captured as well. RapidMiner Studio [14], [15] is used to process the data, optimize models, and to analyze the result. This paper is presented as such: Section 1 is the introduction. In section 2, this paper outlines the studies and works that were related to motion and gesture recognition or classification. Section 3 outlines the method that is used in this paper. Section 4 shows the result and analysis of the study. Section 5 provides the conclusion of this paper based on the result and analysis. Section 6 provides discussions and further works that are possible to improve this paper.

2. Related Works

The study by [16] shows the approach is to segment or classify movement into distinct behaviors. The first approach is using Principal Component Analysis (PCA), which is based on the observation that simple motion exhibit lower dimensionality than complex motions. The motion is broken into frames, and each frame is represented as a point, which is the joint's location. It is based on dimensionality, in which a motion sequence with a single behavior should have a smaller dimensionality than the one with multiple behaviors. The second approach is using Probabilistic PCA. The Probabilistic PCA ignores the noises of motion, unlike PCA. The third approach is Gaussian Mixture Model (GMM), in which the entire sequence of motion is segmented whenever two consecutive sets of frames belong to different Gaussian distributions. The Probabilistic PCA obtained the best result of all three approaches: 90% precision for 95% recall.

In [17], the authors conducted a survey on sequence classification, in which it is stated that multivariate time series classification has been used for gesture and motion classification. The research by [18] captured motion data using CyberGlove, with 22 sensors in different locations at the glove and 1 angular sensor. The data are split into 3 datasets and used K-folds validation of K = 3. The multi-attribute motion data is reduced to feature vectors with Singular Value Decomposition (SVD) and then classified using Support Vector Machine (SVM). The study results in the accuracy of 96% for dataset 1, and 100% for dataset 2 and 3.

The research by [19] used wearable accelerometers to capture movement data. Several movements such as sitting, sitting down, standing, standing up, and walking, are the subject of classification. The features that are extracted from 4 accelerometers are further pre-processed into an acceleration in x, y, and z-axis for each, resulting in 12 features. The features of the movement data are then selected with Mark Hall's selection algorithm [20] and classified with C4.5 decision tree with AdaBoost ensemble method [21]. The study used 10 iterations of AdaBoost with C4.5 tree confidence factor of 0.25 and with 10-folds cross-validation. The overall performance recognition was 99.4%.

In [22], the authors compared the classification accuracy of several algorithms such as C4.5 decision tree, multilayer perception, Naive Bayes, logistic regression, and k-Nearest Neighbor (kNN). A smartphone with the capability of recording accelerometer and gyroscope data was used as the motion sensor. Waikato Environment for Knowledge Analysis (WEKA) machine learning tool was used to apply the algorithms and compare them. The result of the study shows that kNN algorithm obtained the highest (averaged) accuracy in all motion classification by 84.6%.

The study by [23] used the multi-modal approach, which is using a combination of audio, video, and skeletal joints. The audio segmentation used the Hidden Markov Model (HMM) to determine the "silence" and "event" of motion. The segmentation based on skeletal joints uses the y-coordinate of hand joint location. The first step is to identify the start and end frames of gestures of either left or right hand, and the second step is to identify the same by using both hands. For the RGB and video modalities, SVM is used as the gesture classification. The audio classifier and the SVM classifier is then fused with a fusion algorithm. This study, which used 275 test samples with over 2,000 unlabeled gestures, resulted in an average edit distance of 0.2074.

The study by [24] used a signal captured from movement instead of the joint location. The study used 12 Trigno Wireless electrodes. The signal is divided into several segments, calculates the spectrogram, and then normalized. PCA is then applied to reduce the dimensionality of the data but maintaining important information. The last step is to apply SVM to the data to do the classification. Compared with the Root Mean Square (RMS) method, the method of this study results in higher accuracy of 9.75% and a reduced error rate of 12%.

Lower-limb motion classification was done by using piezoelectret sensors that apply forcemyography (FMG) which reads force distribution generated by muscle contractions [25]. study compared kNN, Linear Discriminant Analysis (LDA), and Artificial Neural Network (ANN) to classify 4 lower-limb motions, namely leg raising, leg dropping, knee extension, and knee flexion. The highest accuracy is obtained by kNN with an accuracy of 92.90%.

The study by [26] goes into more specific, classifying motions into karate stances, movements, and forms. The captured data consists of a 3-axis accelerometer, gyroscope, and magnetometer. The classification is done by averaging the dataset with Dynamic Time Warping (DTW) Barycenter Averaging (DBA) algorithm, which is an averaging method that iteratively refills an initially selected sequence, to minimize its squared distance / DTW [27] to averaged sequences. In this study, a movement template was generated from two different-styled Karate masters and then both are compared. This results in a recognition rate of 94.20%.

In [28], the authors did a study on human motion recognition by using VR. A combination of LDA, Genetic Algorithm (GA), and SVM is proposed to classify human motion. After collecting motion data, LDA is used to extract features, and then GA is used to search for optimal parameters. After optimal parameters are found, SVM is then used for classification. There are 10 motions to be classified and several averaged results are obtained: Precision of 95.65%, Accuracy of 97.05%, Specificity of 92.78%, and Sensitivity (Recall) of 94.01%.

It can be inferred from the related works that there has been various research about human motion recognition and classification for years. SVM seems to be favored among the study of motion classification. When several studies compared algorithms for movement classification, kNN seems to provide the highest accuracy. This paper performs several algorithms that were mentioned in the related works and optimizes its parameters to improve the results.

3. Proposed Method

This study utilizes the features from Oculus Quest VR gear, along with Unreal Engine 4 (UE4), which helps in extracting features of movements. RapidMiner Studio is used to pre-process the data, apply algorithms, and analyze the results.

3.1. Method of extraction

To be able to capture the hand movement, a simple game based on UE4 is developed. When the game starts, the user can press a button on the Oculus Controllers to start capturing movement data. Several movement data that are recorded are basic Wing Chun hand movements such as *Straight Punch*, *Tan Sau*, *Pak Sau*, *Gan Sau*, and *Bong Sau*. The recording starts from the beginning stance to the ending stance of a movement. The same movement is done 10 times within around 40 seconds with around 1 to 2 seconds interval for every time the movement is done.

3.2. Extracted Data

The movement data is generated in the form of CSV files for each movement and each hand, resulting in 10 files. The extracted features are time, **location**, **rotation**, **angular acceleration**, **linear acceleration, angular velocity**, and **linear velocity**. Except for time, all the features are extracted in the form of vectors, and then split into x, y, and z-axis, resulting in a total of 19 features. RapidMiner Studio is used to process the data and give labels to the data. The data is then processed again by mixing all files of each hand and movement into 1 file. The dataset consists of 8,725 rows with a total of 10 labels. For the left hand, the labels are *Punch*, *Tan*, *Pak*, *Gan*, and *Bong*. For the right hand, the labels are *R_Punch*, *R_Tan*, *R_Pak*, *R_Gan*, and *R_Bong*.

3.3. Method of optimizing algorithm

Several algorithms are performed to the dataset using RapidMiner Studio to check for their accuracy. From there, the parameter optimization process is used to make the algorithms perform better. The selected algorithms for comparison are SVM, Decision Tree, and kNN.

Figure 1 shows the flow of the algorithm optimization method. First, an algorithm is applied to the dataset with split validation to check the initial performance. The dataset is first normalized and then split into 80% of the training set and 20% of the testing set by using *Split Data* module. An algorithm is then applied to the dataset, and then measure the performance to obtain accuracy. After performing split validation, the initial results of the algorithms' performances were obtained.

Then, parameter optimization is performed to get the best possible value of the parameters in the algorithm process. The algorithm is applied to the normalized dataset with 10-folds cross-

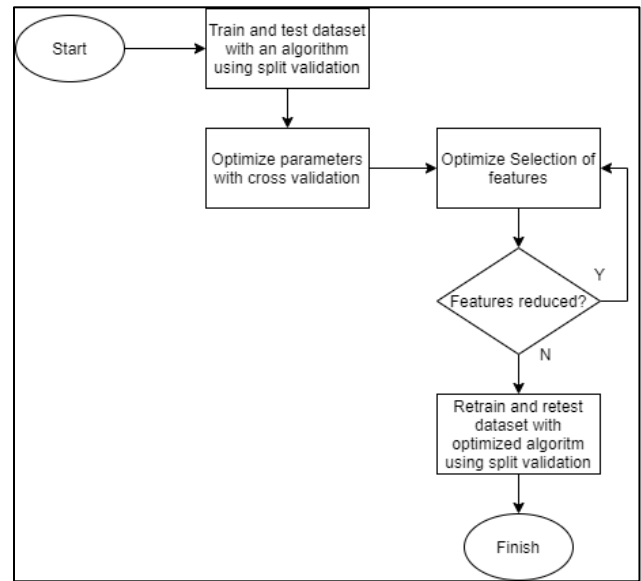
validation, and then put into the *Optimize Paramete*r module. This module executes the cross-validation using all the selected combinations of parameters that are available in the algorithm. This process results in the best accuracy of all selected combinations of parameters.


Figure 1: Flow of algorithm optimization method

After finding the optimized value of parameters, the process of optimizing selection of features is performed to the algorithm. The process is identical to the *Optimize Parameter* module, but this time the algorithm is put into the *Optimize Selection* module. This module executes the cross-validation of the algorithm and weights the features of the dataset that further improve the accuracy. This process can be done until no more features are removed. After this process, a model from the algorithm with optimized parameters and selected features is obtained. This model is then applied to the dataset with split validation process

4. Result and Analysis

The performance indicators were based on the study by [28], in which the 4 most used indicators for action classifications are used: accuracy, precision, recall (sensitivity), and specificity.

4.1. Support Vector Machine

The parameters used to obtain the final result for SVM algorithm are SVM Type: nu-SVC [29] with the nu value of 0.1, in which nu value is an upper bound on the fraction of margin errors and a lower bound on the fraction of support vectors, and kernel type: linear, in which it is suitable when having a lot of features in the dataset [30]. The relevant features obtained from the process of optimize selection are: *time*, *loc_x*, *loc_y*, *loc_z*, *rot_x*, *rot_y*, *rot_z*, *ang_acc_x*, *ang_vel_y*, *lin_vel_x*, and *lin_vel_z*. The result of the optimized SVM model for each movement is shown in Table 1. The movement *R_Tan* and *Gan* obtained the highest result (100%) in all 4 indicators. *R_Gan* and *Tan* reached the highest result (100%) in the recall and specificity. The least accuracy, precision, recall, and specificity are each obtained by *Punch* (99.02%), *Pak* (95.93%), *R_Bong* (95.06%), and *Punch* (99.41%) respectively. The overall accuracy obtained from the optimized SVM model is 98.11%.

Table 1: Result of the optimized SVM model for each movement

SVM	accuracy	precision	recall	specificity
R_Bong	99.42%	98.72%	95.06%	99.49%
R_Gan	99.88%	98.73%	100.00%	100.00%
R_Pak	99.48%	96.82%	97.44%	99.75%
R_Punch	99.71%	99.46%	97.88%	99.74%
R_Tan	100.00%	100.00%	100.00%	100.00%
Pak	99.36%	95.93%	97.63%	99.74%
Bong	99.54%	97.59%	97.59%	99.74%
Gan	100.00%	100.00%	100.00%	100.00%
Tan	99.77%	98.05%	100.00%	100.00%
Punch	99.02%	95.94%	95.45%	99.41%
Average	99.62%	98.12%	98.11%	99.79%

Table 2: Result of the optimized Decision Tree model for each movement

DT	accuracy	precision	recall	specificity
R_Bong	98.59%	92.59%	92.59%	99.22%
R_Gan	99.17%	94.94%	96.15%	99.61%
R_Pak	98.77%	94.70%	91.67%	99.16%
R_Punch	99.47%	98.91%	96.30%	99.54%
R_Tan	100.00%	100.00%	100.00%	100.00%
Pak	98.71%	91.53%	95.86%	99.54%
Bong	99.12%	97.48%	93.37%	99.28%
Gan	99.70%	100.00%	96.64%	99.68%
Tan	99.94%	100.00%	99.50%	99.93%
Punch	98.42%	90.52%	96.46%	99.53%
Average	99.19%	96.07%	95.85%	99.55%

4.2. Decision Tree

The parameters used to obtain the final result for Decision Tree algorithm are Criterion: information gain, Confidence: 0.140, and Minimal Gain: 0.019. Information gain is useful to minimize randomness in the dataset [31]. The relevant features obtained from the process of optimizing selection are *loc_x*, *loc_y*, *lox_z*, *rot_x*, *rot_y*, *rot_z*, *lin_vel_y*, and *lin_vel_z*. The result of the optimized Decision Tree model for each movement is shown in Table 2. The movement *R_Tan* obtained the highest result (100%) in all 4 indicators, with *Gan* and *Tan* obtained the highest

precision as well. The least accuracy, precision, recall, and specificity are each obtained by *Punch* (98.42%), *Punch* (90.52%), *R_Pak* (91.67%), and *R_Pak* (99.16%) respectively. The overall accuracy obtained from the optimized Decision Tree model is 96.06%.

Table 3: Result of the optimized kNN model for each movement

kNN	accuracy	precision	recall	specificity
R_Bong	99.71%	98.16%	98.77%	99.87%
R_Gan	100.00%	100.00%	100.00%	100.00%
R_Pak	100.00%	100.00%	100.00%	100.00%
R_Punch	100.00%	100.00%	100.00%	100.00%

4.3. k-Nearest Neighbor

The parameters used to obtain the result for kNN algorithm are Measure Type: Numerical Measures, Numerical Measure: Manhattan Distance, and k = 5. Manhattan distance is preferable when there is high dimensionality in the dataset [32]. The relevant features obtained from the process of optimizing selection are *time*, *loc_x*, *rot_x*, *rot_y*, *rot_z*, and *ang_vel_x*. The result of the optimized kNN model for each movement is shown in Table 3. All movements except for *R_Bong* and *Bong* obtained the highest result (100%) in all 4 indicators. The least accuracy, precision, recall, and specificity are each obtained by *R_Bong* (99.71%), *R_Bong* (98.16%), *Bong* (98.19%), and *Bong* (99.81%) respectively. The overall accuracy obtained from the optimized kNN model is 99.71%.

4.4. Summary of the result

By using RapidMiner Studio, 10 basic Wing Chun hand movements were classified. The result of the classification by 3 optimized algorithms are shown in Table 1-3. Figure 2 shows the comparison of the averaged results between the optimized SVM, Decision Tree, and kNN algorithms.

The averaged results of the optimized SVM and Decision Tree show that accuracy and specificity have higher results than precision and recall, while in the optimized Decision Tree, the precision and recall results are less than the optimized SVM one. From all 3 algorithms, kNN obtained the highest results in all 4 indicators, reaching more than 99%.
Figure 2: Comparison of average results between the optimized algorithms
Figure 3: Accuracy of all movements from 3 algorithms
Figure 4: Precision of all movements from 3 algorithms

The number of extracted features for optimized SVM, Decision Tree, and kNN are varied. The time feature is not present in the Decision Tree. As for angular acceleration, linear acceleration, angular velocity, and linear velocity, the features present in the 3 algorithms are varied. However, *lin_vel_z* is present in both SVM and Decision Tree. The rotation feature (*rot_x*, *rot_y*, and *rot_z*) are present in all 3 algorithms. Location (*loc_x*, *loc_y*, *loc_z*) are present in SVM and Decision Tree, while only *loc_x* that is present in kNN. This result shows that Wing Chun hand is focused more on positioning than velocity and acceleration. This corresponds according to Master Ip Chun, if the

hand position and movement is not correct, it will not be useful and may be dangerous [33].
Figure 5: Recall of all movements from 3 algorithms
Figure 6: Specificity of all movements from 3 algorithms

From Figure 3-6, kNN has the highest results in all 4 indicators, while Decision Tree has the lowest. While all algorithm's curve has some intersections with each other at some movements, the difference between them is clear enough. It can also be seen that *R_Tan* reached 100% in every indicator and all applied algorithms. For every indicator, the shape of the graphs for kNN is identical, except for *R_Bong* and *Bong*, which are not reaching 100%. This is understandable because even though *Bong Sau* is a basic hand movement, the shape and movement are more complex than other basic movements.
Figure 7: Comparison between the overall accuracy of default and optimized algorithms

The initial accuracy for SVM, Decision Tree, and kNN is 52.57%, 55.14%, and 98.06%, respectively. After the optimization process, the split validation process is done again to obtain the final accuracy. The final accuracy for SVM, Decision Tree, and kNN is 98.11%, 96.06%, and 99.71%, respectively. From the comparison seen in Figure 7, it can be seen that the optimization improves all 3 algorithms, especially SVM and Decision Tree. Both default and optimized results show that kNN obtains the highest accuracy.

To check whether the result shows a statistically significant difference ($p \leq 0.05$ and $p \leq 0.01$), Wilcoxon signed-rank test is performed on all 4 indicators (accuracy, precision, recall, and specificity) of both default and optimized algorithms. The test shows that all 4 indicators in SVM have a statistically significant difference. Both Decision Tree and kNN have a statistically significant difference in all indicators except for precision. Table 4 shows the result of the test.

Wilcoxon signed-rank test is also performed to the comparison of each algorithm in both default and optimized. The result of the comparison of default algorithms shows that SVM and Decision Tree do not have a statistically significant difference. The result of the comparison of the optimized algorithm shows that all the algorithms have a statistically significant difference. Table 5 shows the result of the test.

Table 4: Wilcoxon signed-rank test result of 4 indicators of both default and optimized algorithms

	SVM	DT	kNN
Accuracy	0.005**	0.008**	0.043*
Precision	0.005**	0.093	0.091
Recall	0.008**	0.021*	0.043*
Specificity	0.008**	0.015*	0.028*

Table 5: Wilcoxon signed-rank test result of the comparison of each algorithm in both default and optimized

	SVM-DT	SVM-kNN	DT-kNN
Default	0.721	0.005**	0.008**
Optimized	0.011*	0.012*	0.008**

5. Conclusion

The purpose of this study is to find the best possible method of classifying Wing Chun basic hand movement to create a Wing Chun training simulation system in VR. The results show that movement data features such as location, rotation, and linear velocity are significant enough to classify Wing Chun basic hand movements. Right hand *Tan Sau* has the highest value of all 4 indicators. Meanwhile, based on the result of the optimized kNN algorithm, *Bong Sau* of both hands is the only movement that is not reaching 100% performance, which is understandable because *Bong Sau* is a more complex basic movement. Before the optimization process, only kNN algorithm that has a high-performance result out of 3 algorithms. However, after the optimization of parameters and selection of features, SVM and Decision Tree's performances significantly improved. The

comparison of the results shows that the optimized kNN algorithm obtained the highest results.

6. Discussion

Five basic movements were captured for each left and right, making it 10 movements in total. The process of capturing the movement is done with Oculus Quest VR gear that comes with a pair of handheld Oculus Controller. A simple game is developed with Unreal Engine 4 to capture motion data that consists of several features of movements, such as location, rotation, etc. RapidMiner Studio is used to pre-process the dataset, apply algorithms, and optimize the learning model. This study compares SVM, Decision Tree, and kNN algorithms since 3 of them were commonly used in the earlier study of motion classification and recognition. The performance indicators such as accuracy, precision, recall, and specificity are used to compare the overall results of the 3 algorithms.

In this study, while algorithms like SVM, Decision Tree, and kNN are compared, this study does not include combining algorithms, for example like combining SVM with kNN, etc. RapidMiner Studio has various modules that help in processing data with algorithms. *AdaBoost* module has been applied to the optimized kNN, but the result shows no improvement. The module like *Ensemble Stacking* has yet to be explored further, although attempt to use stacking to stack all 3 algorithms, the result is not as good as the obtained result of each optimized algorithm has been done. Machine learning algorithms such as Deep Learning, Neural Networks, and Spatio-temporal algorithms can also be applied and compared for future studies.

The simple game that is developed to capture the movements also has a limitation in which the user can only stand still. The game can still be developed so that it could improve the motion capture process to include the user able to move around while performing hand movements. While this study shows that the algorithms can accurately classify basic hand movements, there are more basic hand movements that are very similar to each other. These movements can only be distinguished by looking at the area of contact of the hand. This can also be a field of further study for better movement classification. Further classification of sequences could be a field to be explored as well since Wing Chun also has a more complex set of movements that require more than one type of movement.

NO$_X$ and SO$_2$ gas pollution have a direct impact on health problems and environmental damage. Therefore, to map the emission patterns and predict the resulting impacts, complete data and information on emissions of the two pollutants are needed. In Indonesia, data on NO$_X$ and SO$_2$ emissions that are recorded over a long period of time (for example 5 decades) are very difficult to obtain. Meanwhile, REASv3.1 is a global emission inventory that provides complete data on air emissions in Asia during 1950 - 2015. Therefore, this study aimed to analyze NO$_X$ and SO$_2$ emission trends, forecast data for 2016 - 2020, and compare the accuracy of calculations from the method used. The processing of both emission data used two methods, namely trend analysis based on exponential and polynomial approaches, and smoothing methods based on Double Moving Average (DMA) and Double Exponential Smoothing (DES). Furthermore, validation of the accuracy from both methods used the value of Mean Absolute Deviation (MAD), Root Mean Square Error (RMSE), and Mean Absolute Percentage Error (MAPE). The results showed that for the smoothing method, DMA was more accurate than DES. Meanwhile, the indicators are MAD, RMSE, and MAPE values, which are smaller and at a very good category. For forecasting results for 2016 – 2020, it was shown that the total emissions of both NO$_X$ and SO$_2$ showed an increase, but with different gains. Furthermore, the total NO$_X$ emission gain was two times greater than the total of SO$_2$. The road transportation and power plant sectors in NO$_X$ emissions showed an increasing trend, with an emission gain ratio of 3:20. Meanwhile, for SO$_2$, the power plant sector experienced a significant increase, while the industrial sector actually showed a downward trend.

1. Introduction

Air quality is a measure of how much air is free from pollution and not harmful when inhaled by humans [1]. Air is stated to be polluted when it contains substances or energy, and other components that exceeds the quality standard [2]. Meanwhile, the sources of air pollution can come from natural processes or human activities (anthropogenic), and the air that is soiled by pollutants causes its quality to be poor. In fact, air pollution can have a serious impact on environmental damage, human health, and

ecological balance [3]. This can be formed from chemical reactions with other pollutants and physical elements in the atmosphere.

According to The Environmental Protection Agency (EPA), 6 types of air pollutants can cause serious impacts on health and environmental damage, namely CO, NO₂, Pb, PM, O₃, and SO₂ [4]. Therefore, monitoring air pollution is very necessary, because the data obtained can provide a lot of information about air quality in an area and within a certain time. REAS (Regional Emissions inventory in Asia) is an emission inventory owned by the Frontier

Research Center for Global Change (FRCGC), Japan Agency for Marine-Earth Science and Technology (JAMSTEC), which provide data sets and various information about air emissions in the Asian region [5]. Furthermore, the REASv3.1 (latest version) provides complete anthropogenic emission data for the period of 1950 - 2015.

The three anthropogenic emissions that causes respiratory problems, such as airway irritation, bronchitis, asthma, and pneumonia, are NO_X, SO_2, and PM [6–8]. The spread of these emissions is very broad, fast, and has a direct impact on health and the environment [9]. In Indonesia, complete and up to date NO_X and SO_2 emission data is rather difficult to obtain, because many ISPU stations (Air Pollutant Standard Index) that are tasked with monitoring air pollution are not operating properly. Therefore complete data on air emissions in Indonesia are mostly obtained on websites of global emission data providers, even until 2015. This data can be used to analyze air quality trends, and as a basis for forecasting data for 2016 - 2020. Trend analysis is an empirical approach used to determine changes in the values of random variables, whether increasing or decreasing over a period of time in statistical terms. In addition to knowing future air quality conditions, forecasting air emission data is often used to anticipate risks in the event of exposure to poor air quality, as well as to formulate environmental pollution control strategies. [10,11].

Therefore, this research aimed to (1) analyze trends and forecasts of total NO_X and SO_2 emissions in Indonesia from 1950 - 2015, and to compare the methods used to determine the best-performing methods, (2) perform smoothing and forecasting of the dominant sector data from NO_X and SO_2, as well as compare the means used to find out which method has the best performance.

2. Materials and Methods

This study used data from REAS (Regional Emission inventory in Asia) ver.3.1. The data include 10 types of air pollutants (BC, CO, CO_2, NH_3, NO_X, NMNVOC, OC, $PM_{2.5}$, PM_{10}, and SO_2), as well as emission sources, both from the producing sector and the type of fuel used [12]. The data used are 2 types of pollutants (NO_X and SO_2), and the 2 largest emission-producing sectors of each pollutants types.

In this research, air emission data processing used two methods, namely the smoothing method with Double Moving Average (DMA) and Double Exponential Smoothing (DES) for emission data per sector. Furthermore, trend analysis was conducted with the exponential approach and polynomial orders of 2 and 3 for total emissions data. Meanwhile, to determine the accuracy of both methods, the results were validated using the calculation of MAD (Mean Absolute Deviation), RMSE (Root Mean Squared Error), and MAPE (Mean Absolute Percentage Error) [13].

$$MAD = \sum_{t=1}^{n}|y_t - \bar{y}_t|/n \qquad (1)$$

$$RMSE = \sqrt{(\sum_{t=1}^{n}(y_t - \bar{y}_t)^2/n)} \qquad (2)$$

$$MAPE = (\sum_{t=1}^{n}|(y_t - \bar{y}_t)/y_t|/n)x100, \ y_t \neq 0 \qquad (3)$$

where y_t is the real data of each emission
         $\bar{y}_t$ is forecasting data
         n is the amount of data used.

The focus of this study is in Indonesia, and the research methodology can be seen in Figure 1.
Figure 1: Flow diagram of research on forecasting air emission data

To determine the MAPE accuracy criteria, it can be referred to Table 1

Table 1: The accuracy criteria of MAPE [14]

Criteria	The limit of MAPE percentage
Very Good	<10%
Good	10% – 20%
Enough	20% - 50%
Not Accurate	>50%

All data were processed using the Analysis Toolpak, which is a set of "data analysis" tools in the processing group in Microsoft Excel.

The last stage was forecasting data for the next 5 years, starting from 2016 - 2020. For DMA and DES, data forecasting was performed only for the best performance based on the values of MAD, RMSE, and MAPE that met the criteria. For trend analysis, data forecasting was carried out based on the line equation formed from the approach used.

3. Result and Discussion

3.1. Trend analysis of air pollutants (NO_X, and SO_2)

Estimation or forecasting of total emission data from NO_X and SO_2 pollutants in the coming year was carried out using trend analysis with three approaches, namely, exponential, polynomial order 2, and order 3. Furthermore, the selection of this approach was based on the suitability of the graphical patterns formed between real data and the 3 approaches.
Figure 2: Graph of trend analysis for NO_X and SO_2 emissions

Table 2: The validity calculation on the trends analysis results of the NO_X and SO_2 emission

Perform. evaluation	NO_X Emission			SO_2 Emission		
	Exponential	Polynomal		Exponential	Polynomal	
		Orde 2	Orde 3		Orde 2	Orde 3
MAD	99.43	69.37	71.99	158.38	108.78	102.78
RMSE	186.91	107.19	107.03	246.07	143.19	130.65
MAPE	7.74	5.77	6.65	10.23	10.19	10.21
Figure 3: Graph of forecasting data for NO_X and SO_2 emissions in period 1970 - 2020

Table 3: The result of forecasting data for NO_X and SO_2 emissions in the period of 2016 - 2020

Year	Total of NO_X emission (kton/year)	Total of SO_2 Emission (kton/year)	Ratio SO_2/NO_X
	Polynomial orde 2	Polynomial orde 3	
2016	3110.0	2731.5	0.878
2017	3239.3	2792.7	0,862
2018	3371.4	2851.2	0.846
2019	3506.3	2906.8	0.829
2020	3643.9	2959.3	0.812

This study used a lot of data obtained in the period of 1970-2015 or about 45 years. This relatively large data can provide accurate results to minimize errors. Furthermore, this study validated the results using MAD, RMSE, and MAPE to determine the best measurement accuracy of the approach used. Figure 2 showed a graph of trend analysis results on both pollutants, whereas Table 2. showed the performance evaluation results of both graphs

Based on the data validity evaluation, the trend analysis that showed the best performance is the smallest MAD, RMSE, and MAPE values. For NO_X emissions, the use of polynomial order 2 produced a good performance, while for SO_2 emissions, it used a polynomial order 3. Based on the MAPE value, the accuracy of NO_X emission measurements was in the very good category because the value was <10% (5.77%). Meanwhile, for SO_2

emission, it was in a good category because the MAPE value was >10% (10.21%).

For the next stage, the research forecasted data for the next 5 years, between 2016 - 2020, based on graphical equations that have been obtained from trend analysis that showed its best performance. NO_X emission used a polynomial order 2 graph, while SO_2 emission used order 3. The graph equation used for data forecasting was

$$y = 1.404\,x^2 - 4.62x + 200.58 \text{ (NO}_X \text{ emissions)} \tag{4}$$
$$y = -0.032\,x^3 + 3.198\,x^2 - 28.761x + 298.83 \text{ (SO}_2 \text{ emissions) (5)}$$

Forecasting data were obtained by entering $x = 1$ to represent 1970, $x = 2$ for 1971, until $x = 50$ for 2019, and $x = 51$ for 2020 in equations (4), and (5).

Figure 3 showed the results of forecasting NO_X and SO_2 emission data for the period of 1970 – 2020. Figure 3 showed that in Indonesia, there is an upward trend in emissions for both types of pollutants. This is different from what happened in developed countries, where NO_X and SO_2 emissions showed a downward trend, even though there was growth in the economic and industrial sectors [15]. The quantization graph of forecasting emissions of both pollutants in numerical data can be seen in Table 3, which showed the forecasting results of both pollutants for the period of 2016-2020. Meanwhile, SO_2 emission is only 227.8 tons/year. This

means that the NO_X emission gain is more than two times the gain of SO_2. Furthermore, the SO_2 / NO_X ratio has decreased from 0.878 in 2016 to 0.812 in 2020. This showed that the contribution of SO_2 emissions to air pollution in Indonesia is not too significant compared to NO_X

3.2. Smoothing and forecasting data of NO_X and SO_2 emissions

NO_X and SO_2 emission data in this article were collected from 1970 - 2015, and were obtained from REAS version 3.1 [16]. Furthermore, the research smoothed the data for the two dominant sectors in each type of emission. The dominant sectors for NO_X emissions are Road Transportation (Road) and Power Plant (PP), while for SO_2 emissions are Power Plant (PP) and Industry (IND).

Data smoothing is a method used to reduce randomness from time-series data in order to obtain relatively regular data [17,18]. The data smoothing in this research used the Double Moving Average (DMA) and Double Exponential Smoothing (DES) technique. In the DMA technique, 3 variations of the interval were used, namely n = 1, n = 2 and n = 3, while DES used 3 weight variations, namely $\alpha = 0.2$, $\alpha = 0.4$, and $\alpha = 0.5$.

3.2.1. NO_X emissions

Figure 4 showed the results of the smoothing of NO_X emissions data using DMA and DES techniques, for each sector.

Double Moving Average (DMA) Method				Double Exponential Smoothing (DES) Method			
Road Transportation (Road) sector				Road Transportation (Road) sector			
	n=2	n=3	n=4		α=0.2	α=0.4	α=0.5
MAD	17,81	26,11	37,21	MAD	70,64	59,74	58,74
RMSE	36,46	50,98	68,06	RMSE	118,85	102,77	104,58
MAPE	2,72	3,58	4,66	MAPE	14,09	8,26	7,65
Power Plant (PP) sector				Power Plant (PP) sector			
	n=2	n=3	n=4		α=0.2	α=0.4	α=0.5
MAD	19,99	15,10	16,81	MAD	26,47	20,87	22,44
RMSE	34,18	28,41	27,42	RMSE	36,06	34,19	39,97
MAPE	8,38	6,68	6,93	MAPE	14,34	9,39	9,53

Year	Emission (kton/year)
2016	1615.70
2017	1620.06
2018	1624.43
2019	1628.79
2020	1633.16

Year	Emission (kton/year)
2016	737.21
2017	767.21
2018	797.22
2019	827.22
2020	857.23

(a)   (b)
Figure 5: Forecasting data of NO_X emissions (a). by road transportation sector and (b). by power plant sectors

To determine the data smoothing performance, the study validated the results obtained. Table 4 showed the performance validation results based on the MAD, RMSE, and MAPE measurements.

Figure 5 showed forecasting NO_X emission data for the Road and PP sectors in the 2016-2020 period. This data forecasting was based on the best performance obtained, namely at n = 2 (Road) and n = 3 (IND).

Table 4 showed that data smoothing using the DMA was better than the DES methods. This can be seen from the smaller MAD, RMSE, and MAPE values for the DMA than the DES methods. For the road transportation sector, the best performance was in the 2 (n = 2) interval, while for the power plant, it was in the 3 (n = 3) interval. For the MAPE value, NO_X emission measurement in the road transportation sector was 2.72%, while the power plant sector was 6.68%. Therefore, the accuracy was in the very good category because the value was <10%.

Figure 5 showed that the forecasting graph for the transportation sector in 2016-2020 is relatively constant or the changes are not too significant, with a gain of 17.46 kton / year. Meanwhile, the power plant sector showed a significant increase with a gain of 120.02 kton / year

3.2.2. SO₂ emissions

Figure 6 showed the results of smoothing SO_2 emission data using DMA and DES techniques for the power plant (PP) and the industrial sectors (IND). The results of smoothing the data from the two methods were then validated using MAD, RMSE, and MAPE. Subsequently, the results were compared to determine the best performance. Table 5 showed the validation results of both methods used

(a)   (b)

(c)

(d)
Figure 6: Graph of SO₂ emission data smoothing for (a). PP sector using DMA (b). PP sector using DES, (c). IND sector using DMA and (d). IND sector using DES

Table 5: Validation of data smoothing for SO₂ emissions using the DMA and DES methods.

Double Moving Average (DMA) Method				Double Exponential Smoothing (DES) Method			
Power Plant (PP) sector				**Power Plant (PP) sector**			
	n=2	**n=3**	**n=4**		**α=0.2**	**α=0.4**	**α=0.5**
MAD	44,85	49,67	60,42	MAD	98,25	83,24	78,91
RMSE	74,06	90,77	106,36	RMSE	148,86	133,14	131,30
MAPE	8,41	8,89	9,75	MAPE	16,79	13,52	13,56
Industry (IND) sector				**Industry (IND) sector**			
	n=2	**n=3**	**n=4**		**α=0.2**	**α=0.4**	**α=0.5**
MAD	44,06	41,56	36,00	MAD	50,89	54,40	61,13
RMSE	60,01	60,78	53,33	RMSE	79,32	73,14	82,71
MAPE	11,54	11,25	8,45	MAPE	13,54	14,87	16,81

Table 5 showed that the best performing data smoothing for the PP and IND sectors using DMA was at n = 2 and n = 4, while for DES, it lies at weights α=0.4 and α=0.2. When the results are compared, the DMA method was better than DES, because the values of MAD, RMSE, and MAPE were smaller. For MAPE, the measurement of SO₂ emissions in the power plant sector had a value of 8.41%, while the industrial sector was 8.45%. Therefore, the accuracy was in the very good category because the value was <10%.

Forecasting data for SO₂ emissions in the Road and PP sectors in the 2016 - 2020 period can be seen in Figure 7. This forecasting is based on the best performance obtained, namely at n = 2 (PP) and n = 4 (IND). Figure 7 showed that the data forecasting graph

for the power plant sector in 2016-2020 has increased significantly with a gain of 798.5 kton / year, while for the industrial sector showed a decline with a gain of -73.54 kton/year.

In 2015, the installed power capacity for Steam Power Plants (PLTU) was around 53.1% of the total power generation in Indonesia [19]. This showed that the need for coal fuel to supply PLTU needs is very large. Furthermore, the increase in the amount of coal is proportional to the increasing demand for electricity. Therefore, SO₂ gas pollution in the period of 2016 - 2020, appears to have increased significantly. In contrast to the power plant, SO₂ emissions in the industrial sector have decreased, because many industries have implemented the clean production principle by reducing the use of coal as their industrial fuel [20].

Year	Emission (kton/year)
2016	2294.2
2017	2493.8
2018	2693.4
2019	2893.1
2020	3092.7

(a)

Year	Emission (kton/year)
2016	579.91
2017	561.53
2018	543.14
2019	524.76
2020	506.37

(b)
Figure 7: Forecasting data of SO₂ emissions (a). by power plant sector and (b). by industry sector

4. Conclusions

The use of Double Moving Average (DMA) method in smoothing NO_X and SO_2 emission data is better than the Double Exponential Smoothing (DES). This is based on the validation results of both methods, where the MAD, RMSE, and MAPE values for the DMA method are smaller than DES. For NOx and SO_2 emissions, the resulting MAPE value in the DMA method was in the very good category, because the value was <10%. Furthermore, the best variation of the moving average interval for NO_X emissions lies at n = 2 (road transportation sector) and n = 3 (power plant sector), while for SO_2 emissions, it lies at n = 2 (power plant sector) and n = 4 (Industry sector).

The forecasting stage for the period of 2016 - 2020 generally showed that the total emissions of NO_X and SO_2 have increased, with the gains for each emission being 533.9 kton / year and 227.8 kton / year. This means that the total emission gain of NO_X is two times greater than SO_2. Furthermore, in the road transportation sector that produces NO_X emissions, changes are not too big, with an emission gain of 17.46 kton / year. Meanwhile, in the power plant sector, it has a quite significant increase, with an emission gain of 120.02 kton / year. SO_2 emissions showed that there is an increase in emissions of power plant sector with a gain of 798.5 kton / year, while for the industrial sector, there is a decrease with a gain of -73.54 kton / year. In addition, the reduction in SO_2 emissions in the industrial sector showed that there is an industrial policy to reduce the use of coal as its energy source.

	Sizing optimization should be used to design an efficient, sustainable, and feasible hybrid system. In this paper, a hybrid power plant consisting of an off-grid photovoltaic and wind energy system was planned to supply the demand of residential houses in Libya. To minimize installation and operational costs by sizing each part of the hybrid system, the crow search technique was applied. We optimized the number of photovoltaic modules, wind turbine power, and battery capacity and then we compared the performance of the crow algorithm with the particle swarm optimization algorithm for hybrid system design. The results of the crow algorithm suggest better efficiency for sizing lower-cost hybrid power plants consisting of photovoltaic and wind systems.

1. Introduction

Renewable energy systems are basically designed to achieve two objectives: cost-effectiveness and environmental protection. It is possible to achieve these objectives by reducing both dangerous emissions and fuel costs. This type of power system has clear financial benefits [1] other than reducing emissions of carbon dioxide (CO_2), nitrogen oxide (NOx), and sulfur oxide (SOx), which can be detrimental for life on this planet [2]. Whenever these objectives are pursued at the same time, the combined economic emission dispatch (CEED) problem emerges, which can be addressed through traditional mathematical methods like lambda iteration, gradient search, and optimization through modern heuristics [1]. However, in this case, it is not possible to solve the CEED problem because the procedure does not give a single result. Additionally, for achieving two contradictory aims, such as reduction of both pollution and fuel costs, mathematical/gradient information is not required. On the contrary, this optimization problem needs some kind of transactional solution like the Pareto optimal (PO) solution [3], requiring further processing for finding the best optimized and most favorable solution. The literature shows that some multi-objective algorithms help reduce greenhouse gases while decreasing fuel costs at the same time. These algorithms include scatter search [4], the bacterial foraging algorithm [5], particle swarm optimization [6], teaching-learning-based optimization [7], the harmony search algorithm [8], and differential evolution [9].

We have tested different methods to solve the non-convex and non-linear CEED problem.

In this case, the "h" parameter is used to handle dimensional problems that can be solved through the sketched evolutionary algorithm [8]-[10]. We can also solve the CEED problem without using the mentioned parameter by regularizing fuel costs and pollutants. This is possible using evolutionary algorithms (EAs) by solving a single objective function, but such methods have a shortcoming: researchers need to make repeated efforts to find the objective solution.

Results show that hybrid algorithms are useful and efficient in performing parallel processing. For achieving the best solution, a balance is required between exploration and exploitation. While exploration is pivotal for any kind of algorithm, exploitation helps in finding excellent solutions. The present research involves bat [11] and crow [12]algorithms for solving the CEED issue. We have selected a hybrid structure that combines the properties of crow search and bat algorithms and resolves the problems of the mentioned population-based methods. Hybridization was also chosen because it gives more diverse and acceptable solutions.

2. Types of Algorithms

2.1. Particle Swarm Optimization (PSO)

Potential solutions, which are also referred to as "particles," lie within the problem space. Here, "swarms" means the multi-dimensional modeling spaces in which the particles exist, and they

have certain velocities and particular positions. Every particle provides a "candidate solution," moving in the search space before they exceed the computational limitations. During flight, the particles continually adjust their positions, making sure that they gain the best positions while keeping in view neighboring particles and their positions. This means that particles have a tendency of adjusting their velocities and positions depending on their neighbors. Moreover, social, inertial, and cognitive factors keep adjusting the particle velocity until an optimal solution is found [13].

2.2. Crow Search Algorithm (CSA)

It is a common observation that crows are intelligent, which is evident from their brain/body ratios. They have the ability to sense danger, issue warning signs, and recognize faces. The CSA was accordingly developed after observing habits of crows such as living in groups, going together to steal food, snatching food, and remembering their hiding places [14].

Besides other mental capabilities, crows have amazing "awareness probability" (AP). Suppose that, if there are n crows living in a specific space, for the tth iteration, x_i^t shows the location of crow i.

Here, an individual's update mode can be mathematically represented as given below:

$$X_i^{t+1} = \begin{cases} X_i^t + r_1 * fl_i^t * \left(mem_j^t - x_i^t\right), r \geq AP_j^t \\ a \quad random\ position, \quad other \end{cases} \tag{1}$$
Figure 1: An individual crow's movements

3. Hybrid PV/ Wind Power System

3.1. Mathematical Model for PV System

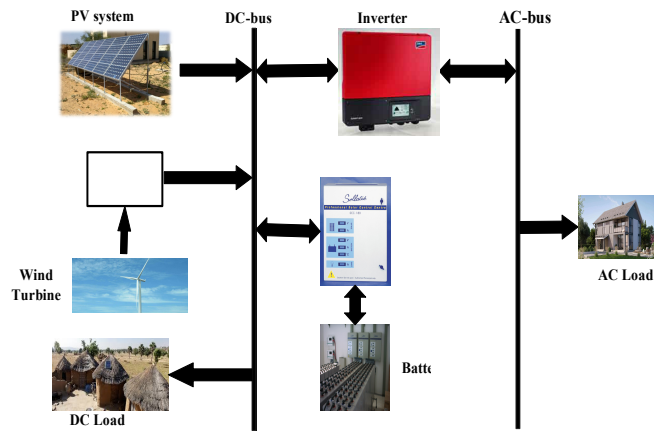
Libya has massive solar power generation potential. For example, in the Libyan city of Ghiryan, there is an average of 7.5 kWh/m² daily solar radiation (Figure 3), and every year, there is complete sunshine for 3700 hours. Photovoltaic (PV) systems are the best systems for use in rural Libya because they provide convenience and economy. Research has shown that solar energy is sufficient to generate 141,000 tWh annually, which is more than the potential of wind (16,000 tWh) and biomass (21,000 tWh) [15], [16].


Figure 2: Hybrid system

Figure 3: Annual average solar radiation in Ghiryan

The mathematic model suggested for the PV system is as follows:

$$P_{PV} = N_{pv} * \left\{P * \frac{G}{G_{ref}}\right\} + \left(1 - m * (tc - tc_{ref})\right) \tag{2}$$

Here, P_{pv} represents the PV arrays' power output under reference conditions, and P represents rated power while N_{pv} is the summation of all PV arrays. G_{ref} is equal to 1000 W/m², where G represents solar radiation (W/m²), and m is equal to -3.7×10^{-3} (1/°C). In the above formula, tc is the PV cell temperature, which has a reference value of 25 °C. We used the following formula to calculate the PV cell temperature [17]:

$$t_c = t_a \left\lfloor \left(\frac{NOCT - 20}{800}\right) \right\rfloor * G \tag{3}$$

In this formula, $NOCT$ represents the nominal operating cell temperature while t_a is ambient temperature.

3.2. Mathematical Model for Wind Turbine

We used the NASA website to obtain 10-year wind data (2005-2015). We found that in the city of Ghiryan, the average wind speed was 6-7.5 m/s. That is sufficient for operating a wind power unit, which should be installed at a height of 50 m. We studied the effects of different seasons on wind speed and found that wind speed is higher from December to May. It remains lower in summer, specifically in July and August. The wind speed in Ghiryan is shown in Figure 4 [18].
Figure 4: Average wind speed in Ghiryan

Climatic variations in Ghiryan include extremely humid and hot summers and mild winters with average wind speeds suitable for power generation. To measure the wind speed, the following formula is used [19]:

$$\frac{V_2}{V_1} = \left(\frac{H_2}{H_1}\right)^a \qquad (4)$$

Here, v_1 is the velocity at the reference height, h_1; v_2 is the velocity at the height of the hub, h_2; and a is the friction coefficient. Certain parameters are specified by a, i.e. terrain roughness, wind speed, temperature, height above ground, time of day, and time of year[20]. Different types of terrain [21]are generally specified in the technical literature; however, the guidelines of the IEC standards [22] suggest a coefficient of friction value of 0.11 for extreme wind conditions and 0.20 for normal wind conditions.

A wind turbine's predicted power output is expressed as follows:

$$
\begin{cases}
0 \\
V^3 \quad \left(\frac{P_{rated}}{V_{rated}^3 - V_{cut-in}^3}\right) - \\
P_{rated}
\end{cases}
$$

$$
P_{rated}\left(\frac{V_{cut-in}^3}{V_{rated}^3 - V_{cut-in}^3}\right)
\left.
\begin{array}{l}
V < V_{cut-in}, V > V_{cut-out} \\
V_{cut-in} \le V \le V_{rated} \\
V_{rated} \le V \le V_{cut-out}
\end{array}
\right\}
\qquad (5)
$$

Here, V is the wind speed of the current time step, the nominal wind speed is V_{rated}, the cut-out wind speed is $V_{cut-out}$, the cut-in wind speed is V_{cut-in}, and the rated power is P_{rated}.

3.3. Mathematical Model for Batteries

Generally, most hybrid systems have lead-acid batteries, and their charging and usage depend on the power generated through the PV system and the wind turbine. Eqs. 6 and 7 show the charge-discharge phenomenon [23].

When the power generated through the wind turbines and PV arrays exceeds the load, it charges the battery bank. The state of charge (SOC) is determined with the following equation [24]:

$$\text{SOC (t)} = \text{SOC}(t-1) - \left(P_{pv}(t) + P_{wt}(t) - P_{dmd}\right) * \eta_{ch} \qquad (6)$$

In this case, $SOC\,(t-1)$ and $SOC(t)$ respectively represent the battery bank charges in the time intervals $t-1$ and t while $Pdmd$ is the load demand. Here, η_{ch} represents the efficiency of the battery bank.

When there is load demand, the battery bank is discharged, which can be mathematically represented with the following equation:

$$\text{SOC (t)} = \text{SOC}(t-1) - \left(P_{pv}(t) + P_{wt}(t) - P_{dmd}\right) * \eta_{disch} \qquad (7)$$

The adjustment of the battery depends on the demand (Eq. 8). In this case, *DOD* represents the discharge depth while *ad* shows the days of autonomy. Here, η_{inv} and η_b respectively represent the inverter and battery efficiencies.

$$C_n = \frac{E_{dmd} * ad}{DOD * \eta_{inv} * \eta_{bat}} \qquad (8)$$

3.4. Electrical Loads

Electrical loads can be classified based on the activity/type of work performed and they depend on the consumer's consumption pattern, including housing, commercial, agricultural, and general loads. For assessing the load of each sector, electric loads should be considered. Generally, the housing sector is internationally considered as the sector consuming the largest quantities of electrical power. Part of its energy transforms into thermal energy when heating/cooling appliances such as air conditioners, water coolers, or refrigerators are used, and some of its energy transforms into optical energy when lighting devices like electric bulbs are turned on. Some energy transforms into dynamic energy when electric motors, mixers, and fans are used [18].

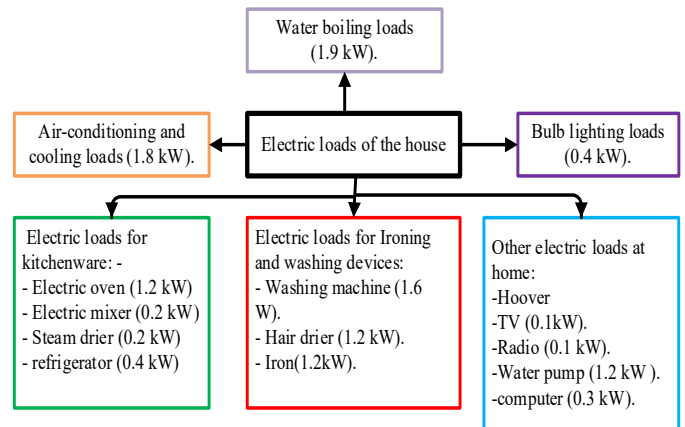
For our experiment, we selected an average power-consuming house. Fig. 5 and Fig. 6 present the appliances and loads.


Figure 5: Load estimation for household electrical equipment
Figure 6: Load profiles for two seasons

4. Optimization Problem

The minimization of the annual expense of the device (ACS) is a major goal of our analysis. The components include costs of upkeep (C_m), resources (C_a), and substitution (C_r) and the mathematical expression of ACS can therefore be given as follows:

$$ACS = C_a + C_m + C_r \qquad (9)$$

$$C_a = CRF * \left(C_{pv_{tot}} + N_{wt_{tot}} + C_{bat_{tot}} \right) \qquad (10)$$

$$C_{pv_{tot}} = N_{pv} * C_{pv} \qquad (11)$$

$$C_{wt_{tot}} = N_{wt} * C_{wt} \qquad (12)$$

$$C_{bat_{tot}} = \left(\frac{n}{LS_{bat}} \right) N_{bat} * C_{bat} \qquad (13)$$

In the terms given, the costs of wind turbines, PV modules, and battery banks are represented by C_{wt}, C_{pv}, and C_{bat}, respectively, and the life span of the renewable energy system is shown by n. The battery life is LS_{bat}, and the capital recovery factor is CRF; CRF can therefore be mathematically expressed as follows [25][26]:

$$CRF = \frac{i(1+i)^n}{(1+i)^n - 1} \qquad (14)$$

5. Optimization of Outcomes

We selected a house located in the mountainous area of Ghiryan. Table 1 shows the investment, technical, and maintenance costs needed to operate the PV panels, wind turbines, and batteries.

Table 1: Design parameter values

	Cost ($)	Parameters	Maintenance costs ($)
Wind turbine	1870.83	500 W	18.70
PV panel	287.82	250 W	2.878
Battery	332.10	600 Ah	31.76

To determine the effectiveness of the crow algorithm for a specific hybrid renewable system size, we applied the optimization techniques both with and without applying the reliability model. We then compared the obtained results with the calculated values, applying PSO to test the performance, robustness, and convergence. The results obtained after applying the crow algorithm and PSO are displayed in Table 2.

Table 2: Crow and PSO algorithm performances

	PSO	Crow
N_{pv}	23	23
N_w	0	0
N_{bat}	12	10
ACS ($)	16534	16065

Obviously, the crow algorithm showed better performance as compared to other optimization methodologies. It can therefore be

deemed superior on the grounds that it reduces computations. According to Table 3, the crow algorithm is again better as compared to PSO. It was found that the power generation cost with a PV array is lower compared to the cost of power generation from the wind. This can be expressed as follows:

$$0 \leq N_{pv} \leq N_{pvmax}$$

$$1 \leq N_{wt} \leq N_{wtmax} \qquad (15)$$

$$0 \leq N_{bat} \leq N_{batmax}$$

Table 3: Crow and PSO algorithm performances based on Eq. (15)

	PSO	Crow
N_w	1	1
N_{pv}	23	23
N_{bat}	11	9
ACS ($)	27943.24	27.260

It is obvious that the crow algorithm helps in reducing the cost. Table 3 shows that the achieved results minimized the annual cost of power generation. In Table 4, wind, PV, and hybrid system reliabilities are presented. It was found that reduced wind availability increases the costs, but it reduces the requirement for batteries. Moreover, the results showed an increase in reliability indices such as energy supplied (ES), reliability of power supply (RSP), and loss of power supply probability.

Table 4: Size, reliability, and cost indices

	PSO			Crow		
%	100	95	90	100	95	90
N_{pv}	23	23	23	23	23	23
N_w	0	0	0	0	0	0
N_{bat}	11	10	10	10	9	9
ACS ($)	16533	15624	14856	16065	15480	14562

6. Conclusion

This paper shows a latest approach pertaining to the sizes of offshore stand-alone wind-powered hybrid PV systems. It was found that the crow algorithm is viable in terms of economic and technical value addition and cost reduction. We found that installation of the suggested system is possible in Ghiryan, a city located in Libya. After collecting the long-term wind speed and solar radiation data, we applied the crow and PSO algorithms. This helped in determining the required numbers of wind turbines, batteries, and PV modules. We then compared the results.

According to the outcomes, the crow algorithm allowed for higher accuracy and simpler calculations in addition to reducing costs. The outcomes indicate that using a reliability model affects the cost, optimum size, and load. We found that if the efficiency of the inverter is increased, it could decrease the cost of the device and boost the reliability of the load supplied. We conclude that the crow algorithm can help avoid local minimums and is a reliable method for optimization.

A B S T R A C T

The purpose of the study was to describe the experiences of teachers in the distance teaching-learning process in early childhood education during the covid-19 pandemic. The methodology used was qualitative descriptive. Interviews were conducted with thirteen teachers from four state educational institutions at the infant level in Lima city through the virtual platform. As a result of the data analysis, five subcategories emerged: Emotions in remote teaching at the beginning of the school year during the pandemic, communication between teachers and families for student learning, management and adaptation of remote teaching-learning, be a teacher of childhood education during the pandemic, and accompaniment in the teaching-learning process. In conclusion, the distance teaching-learning experience of teachers at the beginning of the COVID-19 pandemic is characterized by the presence of certain negative emotions and attitudes towards their educational work; however, self-training on digital and computer resources and empathy with families have improved the generation of learning situations in children.

1. Introduction

The global health situation due to the coronavirus (Covid-19) had social, cultural, economic, and educational effects [1]. Almost 94% of students worldwide, in 190 countries, presented interruption of their academic activities due to policies implemented by governments to mitigate the effects of the pandemic [2] There is a decline in the economy in the countries of Latin America and the Caribbean because of the serious health crisis by the coronavirus [3]. In this context, remote education has been implemented with unprecedented speed, due to the fact that the countries did not have a consolidated national distance education strategy, even less for a scenario in emergency situations [4], [5].

Currently, all teachers at different educational levels are working from home with the resources at their disposal and their conceptions of teaching and learning [6]. The Government of Peru suspended educational activities in public and private entities to reduce the effects of the pandemic. However, since April 6, 2020, the school year began through the implementation of the strategy "I learn at home" to preserve the continuity of educational services

[7]. More than six million users through a thousand radio stations nationwide follow weekly the transmission of this strategy [8].

In this context, Peruvian teachers took on a new challenge, and this implied leaving the classrooms and beginning to teach through virtual environments within the framework of the strategy promoted by the government. However, this teaching modality required the accompaniment of teachers to acquire the necessary digital skills that allow them to handle digital tools for educational purposes. Before the pandemic, the government had not paid due attention, although there were already several published documents on the development and application of these competencies in early childhood education, primary and secondary teachers [9].

During the pandemic, teachers had to learn to use digital resources quickly, to generate learning situations with students and interact with their peers. Currently, teachers can be trained and reinforce their skills through the "Perueduca" digital learning system.

The transition from the face-to-face modality to remote early childhood education is a complex process due to the work carried out with children from three to five years old. The little

development of digital skills of the teachers, the insufficient use of the internet by children through mobile devices or computers, forced parents to accompany their children in the teaching-learning process provided by teachers. The remote teaching and learning process in children requires the participation of four actors: teachers, students, parents and the media such as television [10], and digital devices[11], [12].

Distance education leads teachers to use different teaching strategies and resources to facilitate children's learning [13]. In the case of early childhood education, teachers must capture children's attention and enable the construction of their own learning, which requires the guidance and accompaniment of parents. On the part of teachers, it requires a great commitment to the development of digital skills, the use of resources and materials appropriate to the age and needs of children, because they have less developed levels of physical and verbal skills, and are less capable to work alone [14].

In face-to-face teaching, the same physical space is shared and carried out at the same time; while in remote teaching, the instruction is at a distance [15], and pedagogical activities can be carried out synchronously and asynchronously [16]. Likewise, in face-to-face learning, learning sessions were planned by applying pedagogical processes, while in distance teaching learning experiences were planned. Both must be evaluated in a formative way, so that teachers can observe how the process of acquisition of learning is happening, they need the evidence of the children and based on this evidence, give feedback individually, to obtain information on the development of the competitions.

So far there are no known studies of remote teaching and learning experiences with preschool children, although some research has been found related to the virtual teaching practices of students from a university in the United States [17], and a Spanish public university [18]. Furthermore, digital technologies have the potential both to facilitate communicative and creative tasks and to expand children's repertoires [19].

Therefore, the objective of this work is to describe the experiences of teachers in the remote teaching and learning process at the Early Childhood Education level during the coronavirus pandemic.

2. Methodology

2.1. Design

In this study, the qualitative description was the methodology adopted [20], which allowed to explore in-depth the experiences in the teaching of early childhood teachers in the context of a health emergency. This method was used in order not to stray from the literal description of the experiences reported from the point of view of the participants [21].

This method allows reporting the results based on the subcategories that emerged from the interviews that were interpreted and compared with previous studies.

The results consist of a synthesis based on the subcategories that emerged from the interviews, previously interpreted with the support of the existing literature, and compared with other studies.

2.2. Participants

The study population was made up of 26 early childhood education teachers belonging to the following State Early Childhood Education Centers located in three districts of Lima, Peru: "Francisco Bolognesi" and "José Antonio Encinas" (located in the Santa Anita district), "Los Ángeles de Jesús" (in Rímac district), and "Los Libertadores" (located in Los Olivos district). These teachers have conducted distance classes and have applied the "I learn at home" strategy proposed by the Ministry of Education (MINEDU).

All the participants were recruited when they were undertaking postgraduate studies at a private university in the North of Lima. The sample was selected considering the following process: In the first phase, an invitation was sent by email to 26 teachers, of which 18 voluntarily agreed to participate and signed the informed consent. In the second phase, according to the saturation criteria, there were 13 teachers left, who became the final sample of the study.

The families of the children with whom the teachers work are of low socioeconomic status, most of them work independently and have a complete secondary level.

2.3. Data collection

A semi-structured interview prepared by the researchers was used for data collection. Before its application, it was piloted in 3 teachers who had similar characteristics of the participants in the study, in order to know the relevance of the open questions, as well as to know their experiences regarding the central theme of the study.

After validation of the question guide, the participating teachers provided information on their pedagogical experiences according to the following guiding questions: Tell me, at the beginning of the school year, when the coronavirus pandemic also began, how was your remote teaching-learning experience with the children? What helped you cope with these experiences without being in face-to-face classes? Today, what does it mean to you to be a Remote teacher of Early Childhood Education?

The interviews were recorded and transcribed with the consent of the participating teachers. The interview was conducted in August 2020 through the Zoom® platform, with a duration between 20 and 25 minutes per interview.

2.4. Data analysis

The interviews were analyzed through the thematic analysis method [22]. This method allows us to identify, analyze, organize, and report topics within the data set described in detail. Thematic analysis has various uses, which allows informing experiences, meanings, and the reality of the participants. In the present study, the transcripts, reading, and rereading of the collected information was carried out. Subsequently, the units of meaning that served to summarize and express empirical categories were identified. Finally, results were interpreted, without departing from the literal description of the phenomenon under study [20].

Two aspects related to the validity of the study should be noted. First, to comply with the rigor of the credibility of the data, once the interviews were transcribed they were delivered to the

participants so that they corroborate and accredit the information provided by them. Second, to illustrate the empirical or emerging subcategories, relevant quotes from the interviews were selected. Also, an expert evaluated the information in order to give credibility to the data analysis carried out by the researchers.

3. Results

The expressions of the interviewees made it possible to understand the experiences of the initial level teachers in remote education implemented by the Peruvian state during the period of confinement by COVID-19.

Table 1: Characteristics of the interviewees

Characteristics	n	%
Total	13	100
Age		
< 34	5	38.5
34 a 38	4	30.7
38 a 44	2	15.4
>45	2	15.4
Civil status		
Married	5	38.5
Single	5	38.5
Widow	1	7.6
Divorcee	2	15.4
Employment status		
Appointed	8	61.5
Hired	5	38.5
Academic degree		
Doctorate	1	7.6
Master	8	61.5
Bachelor	4	30.7
Educational institution		
Public	13	100

From the thirteen participating teachers, eight have a master's degree, one of them with a doctoral degree, and four have a bachelor's degree and are currently pursuing a master's degree.

According to the employment status, eight had appointed condition and five hired. The largest proportion of teachers were under 34 years of age as shown in Table 1.

According the interviews carried out with the initial education teachers and the data analysis, five sub-categories finally emerged from the reports as initial education teachers during the health crisis: Emotions in remote teaching at the beginning of the school year during the pandemic, communication between teachers and

families for student learning, management and adaptation of remote teaching-learning, be a teacher of childhood education during the pandemic, and accompaniment in the teaching-learning process (Table 2).

Table 2: Categorization of qualitative information

Study Category	Subcategories
Distance teaching and learning	Emotions in remote teaching at the beginning of the school year.
	Communication between teachers and families for student learning.
	Management and adaptation of remote teaching learning.
	Be an early childhood education teacher during the pandemic.
	Accompaniment in the teaching-learning process.

3.1. Study Category: Distance Teaching and Learning

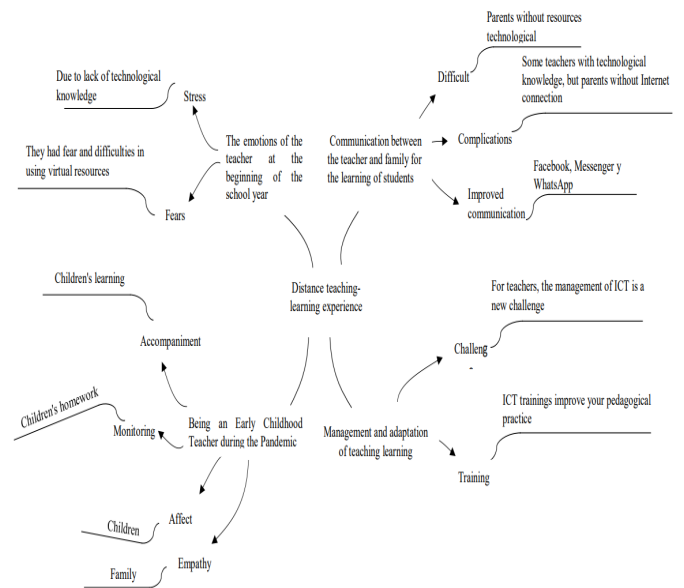
It refers to a modality of distance instruction that is provided to students as a result of the state of health emergency in which didactic activities are carried out both asynchronously and synchronously.


Figure 1: Units of meaning of the participants

In this context, from the descriptive analysis of the qualitative information available in the interviews, subcategories related to the study categories emerged: In the emotions subcategory of the teachers, emotional states such as stress and fear were identified. The subcategory communication between teachers and families for

student learning shows expressions: Difficult, complicated, communication improvement. From the management and adaptation of teaching-learning expressions such as sacrifice, training, challenge, and knowledge were found. The subcategory to be a beginning level teacher during the pandemic shows expressions such as accompaniment, monitoring, emotional support, flexibility, and empathy (Figure 1).

3.2. Emotions in remote teaching at the beginning of the school year during the pandemic

At the beginning of the school year during the pandemic, the emotional situations and negative attitudes of the teachers were linked to the poor use of digital and computer tools, but were subsequently overcome. A part of the teachers have expressed that these tools should be integrated as a complement to face-to-face teaching.

"It was very difficult and stressful at the beginning, as I had little computer knowledge. Thank God, I am already learning and driving better and better. Actually, I thought it was difficult". E7

"At the beginning I saw it somewhat difficult to work remotely with the children, but as the days went by I realized that technology was a valuable resource to learn and teach at the same time". E12

"At the beginning, I presented many fears and difficulties in handling the virtual, but to date I have been teaching and interacting better with my students. (…) I think that this experience with technology should not be put aside when we return to class". E4

3.3. Communication between teachers and families for student learning

The beginning of the school year in the context of the coronavirus pandemic was complicated for teachers because families lacked technological resources (computer and laptop), management of virtual platforms and mobile devices with internet connection. These elements allow for proper storage and communication between students and teachers. Currently, they communicate with families through social networks such as Facebook, Messenger and WhatsApp.

"(...) At the beginning it was difficult, since many of the parents did not have experience with the platforms that MINEDU offers, they did not have computers either, so I had to hold several meetings through social networks such as WhatsApp and Facebook". E9

At the beginning, it was quite complicated and stressful, I had knowledge of ICT (…) but contacting parents was very difficult, since most did not have a computer and a laptop. Now we have organized ourselves better and we communicate by messenger and WhatsApp". E13

3.4. Management and adaptation of remote teaching-learning

The teachers mentioned that the management of any remote teaching resources and their updating contributed to their adaptation; the generation and development of learning situations in their students.

"I knew something about the use of ICT, I think that made it easier for me to adapt to the new way of teaching." E1

"I see that I am having a hard time adjusting to teaching remotely. Two months ago I took training for virtual teaching, which is helping me to give the best of myself to my students". E3

"Little by little I continue to adapt to this new challenge, thanks to the courses promoted by PerúEduca and the tutorials on YouTube." E8

"Little by little I am getting used to the management of these resources, I am seeing that there are many resources that can be used, I still lack quick management of these." E10

3.5. Be an early childhood education teacher during the pandemic

According to the participants, being an early childhood education teacher during the pandemic is associated with the accompaniment, monitoring, and emotional support of students through their families during their learning process.

"Much support, not only in the learning of the children but also in the family in general, I call them, I write them on WhatsApp phrases of encouragement, motivational messages. E1

"(...) Be a companion and dynamic with the children and be in communication with the family to remotely monitor the progress of the children's tasks at home." E4

"Be flexible, and monitor through parents, the tasks that are sent to children by WhatsApp." E11

From the expressions interviewed, the teacher must be empathetic and maintain a good relationship with the students' families, because they act as a link to interact and generate learning situations in the students.

"It is a role of accompaniment, follow-up, and affection, because they need at all times (…) and very empathetic with mothers because they are our allies in their children's learning". E3

"It is having empathy, especially with parents, because most of them work. And very affectionate and charismatic with children so that they can learn and develop their skills ". E13

3.6. Accompaniment in the teaching-learning process

According to the participants, the accompaniment is given through feedback after receiving the evidence from the students. In this process, they have managed to identify the term of feedback and improve their pedagogical practices.

From what was expressed, the teachers interact using social networks, obtaining greater impact for the teaching-learning process, as well as understanding how they should carry out feedback to obtain information about learning.

"[…] I accompany my students on WhatsApp, according to the information provided by the mothers about the difficulties or doubts that their children may have in doing their homework". E 4

"In the past, we had difficulty giving feedback in the classroom, now we do it individually, through social networks to evaluate children". E13

4. Discussion

This study describes the experiences of early childhood education teachers in the remote teaching and learning process

within the framework of the implementation of the strategy "I learn at home" to guarantee the continuity of educational services [7]. From the analysis and synthesis of From the interview data, four subcategories were found, in which emotional experiences, communication, management, adaptability, and the meaning attributed by teachers to their professional work are expressed.

Regarding the experiences and emotional expressions experienced by the teacher as a human being, they are currently more intense [23], due to the new health and social demands in which he had to live and fulfill his role as a professional for new generations.

Emotions, such as moods and feelings, are manifested as responses, signals, or reactions about what is going well for us or what is going wrong, about what we like or dislike[24]. In this sense, the teacher as a human being, manifests these emotions in their inner world, even more so in situations of the pandemic by Covid-19 and being responsible for the training of children who need to continue learning.

The teachers who participated in this study, at the beginning of their work, showed fear and negative attitudes with remote work during the suspension of face-to-face classes due to Covid-19. This result allows us to infer that teaching in times of uncertainty and tension provokes in teachers the presence of certain negative emotions with greater or lesser intensity, amplitude, and continuity in pedagogical practice [25], [26].

On the other hand, despite having had a complicated beginning, the experience of using resources for remote teaching-learning should be integrated into face-to-face classes. From these expressions, it can be interpreted that at first, it was not easy to tune into the remote teaching modality, either due to circumstances generated by themselves and/or beyond their control. There was also a second moment, which could be called empowering resources for remote teaching, which implies not only seeing technology (television, radio, computers, portable and mobile devices) as a mere didactic resource but as a component that influences teaching and learning.

Our results are similar to other studies [27], [28]. Generating good communication channels for educational purposes between teachers and parents favors student learning, especially if they are minors.

In this process of communication and interaction, the teachers must explain the importance of the role of the family in "accompanying children in carrying out tasks and listening to their concerns, preparing spaces and times for tasks" [29], also communicating with the teachers in this distance teaching-learning journey.

The teachers at the beginning of the year had difficulties communicating with the families since most lacked technological resources and had limited use of them. This situation is understandable since the families are of low socioeconomic status and with a secondary education level. Despite this, families with the intention that their children do not miss the school year have continued to study and the teachers have assumed their role as an educational communicator. With the purpose of improving communication, Messenger® and WhatsApp® were used to coordinate the activities organized by the institution, consult or inform the doubts and difficulties of the children in carrying out the tasks at home. From the aforementioned, we can infer for teachers and families that being in a time of pandemic and with certain technological deficiencies may be an opportunity to strengthen communication and interaction through mobile devices that are available for the good of children's development.

Man is a social being because he not only creates and transmits information, but also shares, thanks to this man can adapt to new situations. It is established that human beings are adaptive, that is, with the ability to adapt and create changes in the environment [30]. Along these lines, the participants in the study reported that they have fully adapted to remote teaching-learning, and they also recognize that they are updating and integrating their educational practice for better interaction and student learning. This means that adaptation to a scenario of uncertainty due to the health phenomenon and the rapid transit of the teacher to remote education in unfavorable conditions is not easy and probably never will be, although with affection for knowledge and being updated provides greater possibilities to overcome new situations and support students' learning.

Just as every professional has a role in the execution of their activities, the basic education teacher has the responsibility of fulfilling the three roles established by the Ministry of Education of Peru [31]. These roles are related to identifying the means that the family members should use to access the materials, know the material, and the "I Learn at Home" schedule, and communicate with the family to monitor the progress and difficulties that the students may have. Along these lines, the initial education teacher, in addition to being a monitor and companion, is effective support in the students' learning experience [13]. The findings of the present study agree with the aforementioned, as some characteristics are mentioned such as emotional support, accompaniment, and monitoring.

On the other hand, according to the interviews, it is important to take into account that children need affection, encouragement, and support that gives them security and autonomy in the development of their skills and abilities. These verbal data are similar to those found in [32], given that most of the teachers participating in this study value emotions in the classroom.

Likewise, the teachers consider maintaining an affective connection with the families and students so that mutual understanding is generated, in this way they would improve the learning of the students, because the accompaniment of the parents in their homes is added to this process, generating a shared commitment that would allow obtaining a quality education.

Regarding the teaching-learning resources, the teachers realized that it is possible to use technology at the initial level and it is not necessary to implement a technological classroom, which for the Ministry of Education is difficult due to economic limitations, in this sense considers it optimal to use social networks as resources in the teaching-learning process.

Among the limitations of the present study is the failure to use instruments that allow observing and understanding the teaching action from the platform in real-time. Likewise, not having considered preschoolers as a unit of study, which would have allowed them to know their learning experiences through their

parents. For this reason, it is suggested to carry out research that includes other key actors with ethno-phenomenological approaches to go to the very essence of the phenomenon studied.

5. Conclusions and recommendations

In the remote teaching-learning process, at the beginning of the school year during the COVID-19 pandemic, early childhood education teachers showed certain negative emotions and attitudes due to lack of management of digital and informational resources.

For teachers, it was difficult to generate learning situations in children during the pandemic, since the majority of parents lacked technological resources or how to use them.

The self-training of teachers on digital and computer resources during the pandemic and empathy with families and affection for children have allowed them to fulfill their professional role. Accompaniment through feedback from social networks contributed to strengthening children's learning.

We recommend that the heads of educational institutions strengthen the capacities of their teachers to apply formative assessment throughout the teaching-learning process of students. Provide training to parents to strengthen alliances through collaborative work to generate learning situations in students from home. Coordinate with managers and local authorities to guarantee connectivity in the places where the training action takes place.

Conflict of Interest

The authors declare no conflict of interest.

A R T I C L E I N F O	A B S T R A C T
	The problem of Pulse Width Modulated (PWM) DC-DC converter simulation is faced in this paper. It is shown how the analysis of this kind of circuits, nonlinear and switching for their nature, can be easily and quickly executed by using symbolic analysis techniques. The paper also presents the program SapWinPE, which performs an automatic symbolic analysis of the considered circuit, and its outputs are in MATLAB compatible format. SapWinpPE features make it more attractive than general-purpose software tools for both academy and industry circuit designers. Other characteristics and potentialities, shown through application examples in the paper, can be advantageously exploited by all the circuit designers and CAD professionals, also at the research and educational level in the academic field.

1. Introduction

In all modern electronic circuits it is nearly impossible to find devices that are not supplied by switching-mode power converters. Most of them use Pulse Width Modulated (PWM) DC–DC converters as output voltage regulators, and their behavior affects the operation of the overall systems. In some applications, the reliability of the supplied systems is linked to the proper behavior of PWM DC-DC converters in such a way to lead to fatal consequences in case of poor design. As an example, it is enough to think about artificial heart implants to understand how a proper design of power converters is crucial.

In the realization of any device, the first step is the theoretical design, which consists of a "pencil and paper" circuit creation. To verify the correctness of the obtained circuit, repeated circuit simulations are needed, where the term "circuit simulation" means the analysis of a theoretical circuit with software tools. In the case of DC-DC converters, this is not an easy and fast task to perform because of the interaction of many devices, their interconnection, sizing, and biasing. Moreover, switched current and voltage waveforms result in high values of their derivatives which run the numerical simulators close to their convergence limits. For this reason, the subject of DC-DC converter simulation has interested many researchers in the last thirty years, but a definitive solution has not yet been found. Also, the authors have faced this problem and this paper is an extension of a work originally presented at the

2019 IEEE 5th International Forum on Research and Technology for Society and Industry (RTSI) [1], where a program, named SapWinPE, was presented. SapWinPE is based on the application of symbolic analysis techniques and this constitutes an important novelty because symbolic programs dedicated to PWM DC-DC converters do not exist, at least to the authors' knowledge.

This paper aims to better describe the program in [1] from the theoretical, algorithmic, and applicative points of view, by proposing further examples and comparing the obtained results with those deriving from other programs, like PSPICE based programs, and with experimental results. Finally, a new possible method for simulating switching circuits is proposed together with some results obtained with a new program, still in an embryonic state, implementing this new approach.

The paper is so organized. The implementation methodology and the theoretical basis of SapWinPE are presented in Section 2. Section 3 provides a discussion on the reasons which have led to choose symbolic techniques, a program description is proposed in Section 4. Applicative examples and comparisons with other programs are shown in Section 5. In Section 6 a short description of a further approach to the simulation of switching circuits is presented along with an application examples. Finally, Section 7 contains conclusions and future developments.

2. Theoretical Basis

PWM DC-DC converters are time-variant circuits. This feature is due to the presence in many topologies, such as buck, boost, buck-boost, of a particular cell constituted by a switch and a diode.

---

[*]Maria Cristina Piccirilli , DINFO Via di Santa Marta 3 Firenze - Italy, mariacristina.piccirilli@unifi.it

This switching cell, shown in Figure 1(a), operates as a device alternatively channeling the inductor current through the switch and the diode.

(a)

(b)

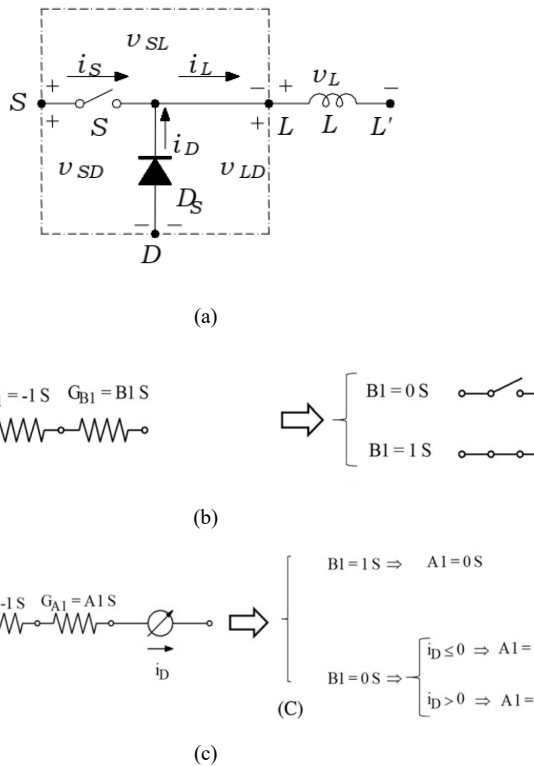
(c)


Figure 1: The switching cell in a PWM DC-DC converter. (a) Switching cell. (b) switch model. (c) diode model.

In other converters, such as Cùk, Flyback, and Forward converters, switch and diode are not connected to the same node, but their combination always acts exactly in the same way. A DC-DC converter circuit switches between two different configurations or among three different configurations, depending on the inductor current value: when it has a nonzero value at the end of the switching period T, the circuit works in Continuous Conduction Mode (CCM); when it assumes a zero value before the end of the switching period T, the circuit works in Discontinuous Conduction Mode (DCM). There is also an intermediate operation mode, called Boundary Conduction Mode (BCM), corresponding to the case of zero inductor current exactly at the end of the switching period T: also in this case, the circuit switches between two different configurations. In any case, moving from a configuration to another one causes a topology change, showing in this way the time-variant nature of the circuit [2].

As well known, the Laplace transform can be classically applied to linear time-invariant circuits. Then, even if converters nonlinearities are neglected, its time-variant nature prevents the application of this method. It is nonetheless true that the circuit remains time-invariant within each assumed configuration, then, the Laplace transform can be applied to every switching state. However, proceeding in this way, the inverse Laplace transform must be applied to each configuration and must be evaluated not only the output of interest in the time-domain but also the inductor current and the capacitor voltage in the time-domain, because their values at the switching instant constitute the initial conditions for

the analysis in the subsequent time interval. In short, this approach is not convenient, not only because the time domain responses require several applications of the inverse Laplace transform, but principally because it is not possible to automatically consider the different operating modes. To circumvent this strong limitation, it is necessary to model the switching cell as a single device whose switching behavior is directly controlled by internal parameters. The switching cell model must have an additional feature: it must be able to take automatically into account the state of the switches via parameter settings. In this way, a circuit depending on the characteristic parameters of the switching cell model can be obtained. Under any switching state, the circuit configuration assumed by the power converter is linear and time-invariant for any switching period, and also in its whole working time: thus the model becomes Laplace transformable. Circuit transfer functions in closed form, dependent on the state of the switches and on the initial conditions of capacitors and inductors at each switching time, can be so obtained. The working conditions determine the parameter values. Proceeding in this way, it is still necessary to apply the inverse Laplace transform in each switching interval for evaluating the time domain responses, but the different operation modes are automatically determined.

The switch model [3] is shown in Figure 1(b). A conductance, equal to -1 S, characterizes one of the two resistors; the parameter B1, a conductance that can take two possible values, 0 S and 1 S, characterizes the other resistor, in series with the former. When B1 is equal to zero, the model represents an open switch, because the equivalent resistance is infinite. When B1 is equal to 1 S, the model represents a closed switch, because the equivalent resistance is zero. In this way, the choice of B1 establishes if the ideal switch is open or closed. A modified switch equivalent circuit simulates the diode. As shown in Figure 1(c), it is derived by connecting the control branch of a current-controlled voltage source in series with the two conductances. In this way the diode operates as a switch controlled by the direction of its own current. Conductance A1 identifies the second resistor and replies the diode state: the diode is OFF when A1 is equal to 0 and this occurs only if B1=1S. If the switch is OFF (that is B1 = 0), the state of the diode depends on its own current i_D: if $i_D<0$, the diode is OFF and A1 returns to zero; if $i_D>0$, the diode is ON and A1=1. This makes the model operate like an ideal lossless diode turning-on when the switch opens and turning-off when its forward current becomes zero.

The switching cell model is obtained joining the switch and the diode models. Hence it is completely represented by the two parameters B1 and A1.

At this point a DC-DC converter equivalent circuit can be built, that allows a time-domain simulation exploiting the Laplace transform. The equivalent circuit is derived by replacing:

- the switching components with the described models;

- inductors and capacitors with their Laplace-domain equivalent circuits, including the sources representing their initial conditions;

- all the other components with their associate Laplace-domain circuits.

A simulation of the Laplace-domain circuit is, then, possible and it produces the desired output and, in addition, the voltages

associated with capacitors and currents associated with inductors and diodes. The corresponding time-domain information are derived by performing the inverse Laplace transform for every switching interval, which is determined by the values of the switch and diode equivalent circuit parameters. The theoretical reasons for this procedure are explained in the following.

Even if a switching converter is a time-varying circuit, the topological configuration it assumes in each switching interval results in a linear, time-invariant circuit and this allows the Laplace transform to be applied for every switching interval. In this way the classical meaning of network function is retained. The so obtained responses also depend on initial conditions (IC): every phase interval starts with given IC and ends restituting new IC to the next interval. These IC are determined by running the inverse Laplace transform of inductor currents and capacitor voltages in every switching time. Also, the inverse Laplace transform of the diode current must be evaluated in every switching time because its sign is used to determine the diode itself state (ON or OFF) .

3. Why to use the Laplace Transform

Time-domain simulations of DC-DC converters are utilized to evaluate current and voltage waveforms and their ripple [4, 5], and also to design the control circuits [6-26]. Many simulation programs miss built-in algorithms able to return as an output the converter steady-state response. Therefore, they are time-consuming because they provide a steady-state response after a transient analysis involving several hundreds of switching periods. Programs providing automated steady-state computation for time-invariant circuits (for example HSPICE or Micro‑Cap 10) are not able to give accurate results for DC-DC converters. The approximations these programs introduce to evaluate current and voltage values during cycle-by-cycle simulations [8] introduce large numerical errors. The switching properties are lost in averaged linear equivalent circuits, which result useful for frequency domain analysis, but not accurate enough for time-domain simulations [10, 11]. There are some attempts to introduce switching effects, as in [12]. Discrete-time domain models are presented in [18, 19], but these models are not suited to simulate power converters with a digital control [15]. Methods for a time-domain large-signal analysis are presented in [25, 26]. However, specific software programs for power converter simulations do not exist. Besides, almost all the available programs are numerical simulators.

The term "numerical" denotes an analysis performed starting from numerical values of the component parameters and providing an output in a purely numerical form. The circuit operation is accurately simulated, but the results only refer to a given set of parameter values. This requires the simulation to be repeated if any single value changes. The numerical simulation is suitable to verify the behavior of a circuit, given a set of parameters, but it does not allow to understand which circuit elements cause the obtained behavior and does not suggest solutions if the desired specifications are not met. A large number of simulations are required for verifying the performance and analyzing parameter variations. In conclusion, numerical simulation is a useful tool supporting the designers in the converter preliminary design, but barely helps in the design optimization.

The design optimization is well accomplished by symbolic simulation [27-30]. The term "symbolic" denotes an analysis that investigates the characteristics of a circuit providing, as an output, the expressions of network functions in closed-form where the parameters are shown with their symbols rather than their numerical values. These symbolic expressions are valid for whatever numerical value. This allows the designer to have an insight of the circuit operation. Symbolic simulation also allows semi-symbolic analysis, when a subset of the elements is replaced with numerical values, so getting useful simplified symbolic expressions. In practice, numerical simulation allows an understating of the circuit operation based on the analysis of the plotted waveforms, while symbolic analysis, which focuses on the expression of circuit functions, is more helpful in the understanding of the circuit behavior. In conclusion, numerical and symbolic simulations are complementary: the first is more suitable to check the operations of already sized circuits, the second is more suitable to understand the unsized circuits behaviors. A very efficient software for power converter design should combine the properties of the two approaches.

Despite its advantages, a symbolic program oriented to the simulation and design of switched circuits is not yet available. This is due to the use of the Laplace transform in almost all symbolic simulators, which, consequently, work on time-invariant circuits. There are some rare examples of Laplace domain modeling, as in [20], where sampling, modulator effects, and delays in the digital control loop are correctly taken into account. Unfortunately, this approach can be easily utilized only for the buck converter [15]. Techniques, based on switch and diode models and employing the Laplace transform, are proposed [31], but they are based on the modified nodal analysis, which is computationally very intensive when the circuit size grows.

On the contrary, with the method proposed in section 2, the Laplace transform is suitably implemented in a computer program through symbolic techniques which do not result in significant computational costs. The next section describes the potentialities and the algorithms of the symbolic program developed by the authors.

4. The Program SapWinPE

The proposed symbolic program, completely coded in C++ language, is called SapWinPE, which stands for SapWin for Power Electronics. SapWin is an integrated program for circuit symbolic analysis and SapWinPE constitutes a module of this package explicitly designed for Power Electronics (PE) [27, 32-35].

SapWinPE main modules are the following:

- a schematic entry where the circuit is designed (here, a graphic list including all the two-terminal or two-port elements is available); when designing the circuit, the user can choose if a component must be considered symbolic or numerical.

- A symbolic analysis package which returns the expression of the selected network function.

- A graphical post-processor that, on a given, user selected set of numerical values for the components, performs the inverse Laplace transform of the network functions and plots the relevant waveforms.

The program is based on a two-graph method [36] which has been improved by the authors for achieving shorter computational times and, therefore, allowing to analyze larger circuit. Models available in literature, such as those presented in [31, 37], cannot be utilized inside the proposed method and, therefore, the model discussed in Section 2 has been developed by the authors.

A SPICE-like netlist can be used for describing the circuit to analyze. When the built-in schematic editor is used, the program automatically translates the scheme into an ASCII netlist in a SPICE compatible format. The schematic editor can also be used to generate circuit schemes, which can be saved and utilized as sub-circuits in large circuit analysis. Also, in subcircuits, the components can be defined as symbolic or not.

The schematic entry saves two files. The first one is a binary file to be used as input for other programs. The second one is an ASCII file including the circuit network functions generated by the Laplace domain analysis. The expressions of the network functions include the circuit components, capacitor and inductor initial conditions, and the parameters describing the state (ON/OFF) of the switches and the diodes. These last parameters are variable because depend on circuit working conditions. Step sources are used to simulate the initial conditions. The actual voltage generator is also a step. This makes the analysis simple and fast, because the network functions are derived simply dividing the outputs by the step Laplace transform. As explained in Section 2, the inductor current and the capacitor voltage are always available, because their time-domain values at the switching instant represent the initial conditions for the analysis in the subsequent time interval.

The simulation results are available both in the Laplace domain and as phasors at a given angular-frequency.

The algorithm for the inversion of the network functions can be found in [37]. Since the diode currents are known, the program automatically recognizes if the DC-DC converter operates in CCM or DCM. The sampling step is automatically adapted to the expected rate of change of the waveforms.

Once the inverse Laplace transform is applied, the program can also plot several diagrams:

- magnitude response;
- loss;
- phase response;
- time delay;
- poles/zeros;
- step response;
- impulse response;
- steady-state response.

The graphic part of the program allows the user to select: the frequency interval, the time interval and the duty cycle. In any diagram an X-Y cursor is available and this helps the numerical values to be read. A built-in function, whose operation is based on the check of the values of all the outputs at the end of each interval, allows the steady-state response to be directly plotted. The program assumes that the circuit operates under steady-state

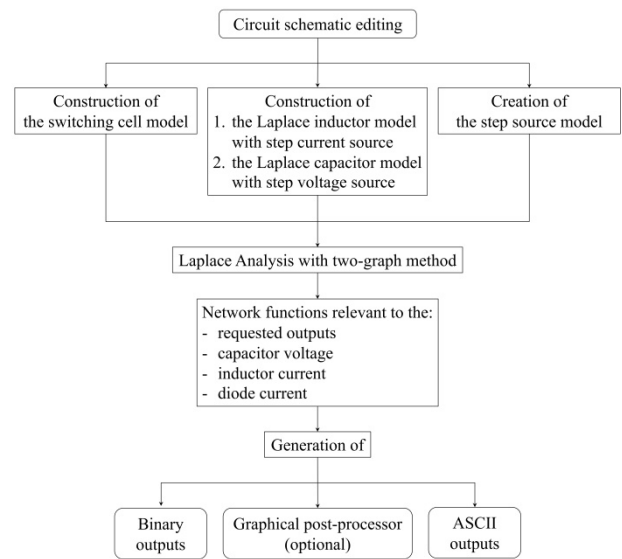
conditions when the difference among the last calculated value of a current or voltage and the value calculated in the previous step is lower than a preselected threshold. This operation is performed in a very short time. The effects of the parasitic components can also be considered e.g., in a pole/zero diagrams [37], plotted for every switching interval.


Figure 2: Block diagram of SapWinPE.

It is important to highlight that the network functions obtained by the program, and therefore by the described method, are not useful for a frequency-domain simulation, because the switch and diode models are not the same used to derive an averaged small-signal equivalent circuit of the switching cell. Note that a frequency domain analysis, resulting in bode plots and poles and zeros diagrams, can be performed by replacing the switching cell with time-invariant equivalent circuits as those presented in [38-45], which are different from those described in Section 2.

To suitably size the component values and evaluate the parasitic element effects during the design phase, it is possible to run a parametric analysis, one of the options of SapWinPE. Since parasitic components highly affect the converter dynamic behavior, multiparametric analysis provided by the program can be advantageously used to design the compensation network and investigate the stability of the converter when operated in closed loop.

The program also allows for multiple outputs, which result useful for a better understanding of the converter behavior. To this aim the knowledge of voltages in specific nodes and currents in different branches is crucial.

The semi-symbolic feature available in SapWinPE allows to better evaluate the effects of certain parameter variations by focusing on a few components, which are assumed as symbolic, while the others are set as numerical.

Note that the models described in Section 2 refer to ideal switches and diodes. By using ideal components, a fast, but inaccurate analysis of the circuit operation is achieved. For a better accuracy, parasitic elements can be externally added by the user. For example, some ringing in the current and voltage waveforms of a real converter are simply reproduced in the simulations by

connecting to the ideal device appropriate parasitic components, affecting the operation of power MOSFETs and ultrafast or Schottky diodes. This allows accurate simulations to be executed by using data from component datasheet, while it is not necessary to know the physical operation of these devices. Of course, the higher is the number of added parasitic elements, the lower will be the processing speed.

Finally, to summarize the program steps, a block diagram of SapWinPE is shown in Figure 2.

5. Applications Examples

Figure 3(a) shows a buck converter including parasitic components as given by the SapWinPE schematic entry. In this section, the results of simulations run by using LTSpice are shown and compared with those achieved by using SapWinPE. In this circuit: R_S is the power MOSFET ON resistance, R_d is the diode ON resistance, R_L is the inductor equivalent series resistance (ESRL), and R_C is the filter capacitor series resistance. An overall inductor equivalent series resistance can be derived as

$$R_{ESR\_L} = \frac{4}{3(D+D_1)}\left(R_L + \frac{DR_S + D_1R_D}{D+D_1}\right) \tag{1}$$

$$D = \frac{t_{MOSFETon}}{T} = t_{MOSFETon} \times f \tag{2}$$

$$D_1 = \frac{t_{DIODEon}}{T} = t_{DIODEon} \times f \tag{3}$$

where $f=1/T$ is the switching frequency. This resistance is series connected with the inductor, includes the parasitic resistances of the switching cell components, as shown in Figure 3(b), and simplifies the circuit analysis when a simulating tool is not available. Since in this paper we are using a power simulation program, the circuit shown in Figure 3(a) allows for a better insight of the circuit operation.
(a)
(b)

Figure 3: Buck converter including parasitic components. (a) Parasitic resistance for each component. (b) Parasitic resistance reduced to a single inductor equivalent series resistance R_ESR_L and to a capacitor parasitic resistance.

In the example, a buck converter designed according to the following specifications has been considered: output power $P_O = 10$ W, input voltage $V_I = 28$ V, load output voltage $V_O = 21$ V, load resistance $R = 3.6$ Ω, switching frequency $f = 40$ kHz. Under these specifications, an inductance $L = 3.3$ µH has been designed, a filter capacitor $C = 470$ µF has been chosen to keep the output voltage ripple below 5%. The converter results to be operated at $D = 0.036$, and the parasitic components, as derived from component data sheets, are $r_S = 3$ mΩ, $r_d = 20$ mΩ, $r_L = 24$ mΩ, and $r_C = 6$ mΩ.

Figures 4(a) and 4(b) show the controlled switch and diode current waveforms as obtained by running simulations with LTSPice and SapWinPE, respectively. The plots show that the results obtained by using SapWinPE are nearly the same as those obtained with LTSpice.

The output voltage plots as derived by using LTSpice and SapWinPE are shown in Figures 5(a) and 5(b), respectively. The transient waveforms are nearly the same, as well as the voltage ripple; the average steady-state output voltage resulting from LTSpice is 20.6 V and that resulting from SapWinPE is 20 V. The transfer functions of the examples shown in this paper have not been included for reasons of brevity. However, it is possible to consult them at the following web address: http://www.cirlab.unifi.it/p122.html .

The small differences in the considered values depend on the different way the components are modeled in the two programs: LTSpice bases its simulations on physical models of the MOSFET and diode, while SapWinPE considers these components as ideal switches and parasitic resistances are added as external components in the simulated circuit.
(a)
(b)

Figure 4: Buck converter current waveforms: power MOSFET current and diode current. (a) Plot resulting from LTSpice. (b) Plot resulting from SapWinPE.

Also, a PWM DC-DC buck-boost converter has been simulated and experimentally tested. The converter component values are as follows: inductance L = 224.62 μH, and its ESR is r_L = 0.023 Ω, the capacitance is C = 662.32 μF, and its ESR is r_C = 0.016 Ω. The power switch is constituted by a SCT3022AL SiC power MOSFET, which results in a breakdown voltage V_{DS} = 650 V and a channel resistance r_S = 22 mΩ. Finally, an FFSP2065B SiC diode has been utilized: it has a reverse voltage V_R = 650 V, a threshold voltage V_F =1.7 V, a continuous rectified forward current I_F = 20 A, and a forward resistance r_D = 33 mΩ. The input voltage is V_I = 17 V, the output voltage is V_O = 25 V, the duty cycle is D = 0.59, and the switching frequency is f = 20 kHz.

(a)

(b)

Figure 5: Output voltage ripple. (a) Plot resulting from LTSpice. (b) Plot resulting from SapWinPE.

Figure 6(a) shows the circuit of the buck-boost converter, as given by the SapWinPE schematic entry, which also includes: the MOSFET output capacitance Cds = 5 pF and inductance Ld = 100 nH, which considers parasitic inductances related to the layout of the experimentally tested circuit, shown in Figure 6(b) [46]. Figures 7(a) and (b) show the diode voltage waveforms resulting from the simulations and the experimental tests, respectively. The experimental waveform is plotted with a 10 μs/div time base and 10 V/div amplitude base.

The plots shown in Figure 7 clearly demonstrate that the simulated results are in good agreement with those experimentally measured. This confirms that SapWinPE results in accurate simulations of power converters, allows each parasitic component of the real circuit to be singularly considered, and, therefore, the user has a very good insight of the studied circuit.

6. New Approach

A new approach to the symbolic analysis of DC-DC converters has been conceived by the authors. The idea is to simulate DC-DC converters through the state variable method, suitable to analyze nonlinear circuits, as converters are. The network functions, determined as in the previous method in the Laplace domain and depending on initial conditions and switch and diode parameters, are relevant to the desired outputs and the converter state variables, that is inductor currents and capacitor voltages. The difference consists in the fact that switches and diodes are represented by parameters depending on analytical expressions reproducing the actual characteristics of these elements. The possibility of easily dealing with nonlinear components is linked with the adopted technique of inverse Laplace transform. It is executed in a discrete way, as the previous method, by using a very small sampling step, carefully chosen on the base of the specific case.

Figure 6: Buck-boost converter. a) Simulated circuit including parasitic components. b) Experimentally tested circuit.

(a)

(b)
Figure 7: Waveforms of the buck-boost diode voltage. (a) Simulated. (b) Measured.

Each sample of the corresponding discretized impulsive response is multiplied by the input value in the sampling instant, so applying a discretized convolution integral for determining, point by point, the time domain response. Also in this case, not only the desired outputs are determined, but also the state variables in the time domain in each sampling step, because their values are necessary for correctly evaluating the desired outputs. The plot of the obtained response is determined by interpolating the output samples.
(a)
(b)

Figure 8. (a) Buck converter circuit simulation (inductor current I_O_L1, capacitor voltage V_O_C1, diode current i_A1, and output voltage V_O) without parameters variation. (b) Buck converter circuit simulation: the duty cycle goes from 0.36 to 0.7 for t=0.25 ms, the resistor R1 goes from 3.6 Ω to 1 Ω for t=0.5 ms.

In this way, it is very easy to treat nonlinear elements, because only their value in the sampling instants is significant.

Whatever input waveform can be used, because it is sampled and held during the sampling step, so resulting in a step function of constant amplitude. The possibility of using any input waveform allows considering harmonics and noise overlapping with the input signal.

The implementation of this approach is still raw. Figure 8 shows the time response of the buck converter of Figure 3, obtained with a sketch of the symbolic program based on this approach.

7. Conclusions

The purpose of this paper is to present a method for applying the Laplace transform to DC-DC converters for simulating this kind of circuits through symbolic techniques.

Time-domain analysis of power converters is performed through the derivation of the circuit network functions. This is achieved by deriving suitable models for both switches and diodes.

The proposed approach is suited to computationally efficient topological methods which allows also large circuits, as, for example, DC-AC inverters and AC-DC rectifiers, to be simulated in short times. A symbolic program, named SapWinPE, implementing the proposed approach is also presented.

This program ensures accurate and fast simulations of switching circuits. It runs in a stand-alone configuration and can provide its outputs also in formats compatible with commercial programs such as MATLAB.

SapWinPE validity is demonstrated by the examples shown in the paper and by its successful application to power converter fault diagnosis and resonant converter design [47-51].

Finally, a new state variable-based analysis technique for symbolic simulation of DC-DC converters is briefly introduced. Even if still in an embryonic state, it is promising. The implementation of a program based on this technique is planned for the near future.

Conflict of Interest

The authors declare no conflict of interest.

This paper presents the generalized integral transform method for solving flexural and elastic stability problems of rectangular thin plates clamped along $y = \pm b/2$ and simply supported along remaining boundaries (x = 0, x = a) (CSCS plate). The considered plate is homogeneous, isotropic and carrying uniformly distributed transversely applied loading causing bending. Also studied, is a plate subject to (i) biaxial (ii) uniaxial uniform compressive load. The method uses the eigenfunctions of vibrating thin beams of equivalent span and support conditions in constructing the basis functions for the plate deflection and the integral kernel function. The transform is applied to the governing domain equation, converting the problem to integral equations for both cases of bending and elastic buckling. The integral equation reduces to algebraic problems for the bending problem, and algebraic eigenvalue problem for the elastic buckling problem. The deflections are obtained as double infinite series with rapidly convergent properties. Bending moments expressions are double series with infinite terms which are rapidly convergent. Maximum deflections and bending moments values occur at the plate centre in agreement with symmetry. The present results gave double series solutions with good convergent properties in closed form for bending problems. The resulting bending solutions were exact. Solving the resulting eigenvalue equation gave closed analytical equation for the buckling loads. Buckling loads are computed for the cases of biaxial and uniaxial uniform compression of square thin plates using one term approximations. The buckling load obtained for one term approximation of the eigenfunction gave results that are 12.23% greater than the exact solution. The use of more terms in the eigenfunction expansion could give more acceptable results for the eigenvalue problem of buckling of CSCS plates.

1. Introduction

Plates can be defined as structural members with inplane dimensions of length and width and transverse dimension of thickness where the least inplane dimension is usually much greater than the thickness. Plate problems are thus three-dimensional (3D) problems of elasticity for dynamic, static or stability cases [1–6]. The behaviour and classification of plates depend on the ratio of the transverse dimension and the smaller inplane dimension of the plate. They can be categorized as thin, moderately thick and thick plates. In thin plate, which is the subject of this study the ratio of the transverse dimension to the least inplane dimension is usually smaller than 1/20.

Under certain simplifying assumptions and hypotheses, the theories of plates have been approximated using two-dimensional (2D) idealizations and classical examples are the thin plate theories [1–6]. Plates are applied extensively in the varied fields of engineering and used in civil, mechanical, aeronautical, naval, spacecraft and structural components. This has resulted in the extensive studies done by many previous scholars on the subject matter [1–10]. Plates are subject to loads that produce dynamic

*Michael Ebie Onyia, Dept of Civil Engineering, University of Nigeria, Nsukka, Enugu State, +2348033821550, michael.onyia@unn.edu.ng

flexural, static flexural, and buckling responses. Plates are categorized by using geometries as rectangular, square, skew, triangular, trapezoidal, sector, circular, elliptical, polygonal, quadrilateral, rhombic; and by their material properties as heterogeneous, homogeneous, anisotropic, orthotropic or isotropic.

This work considers rectangular thin plates made with isotropic, homogeneous, linear elastic materials.

1.1. Theories of plates

Several theories have been derived and developed for plates subjected to flexure and buckling loads [11–17]. Kirchhoff's (classical small deformation thin) plate theory (KPT) used the following assumptions/hypotheses:

(i) Cross-section planes that are orthogonal to the plate's mid-plane prior to loading and bending would continue to be plane and orthogonal to the mid-plane. This is called the normality or orthogonality requirement.

(ii) The thickness remains unchanged during the bending deformation.

The merits of the KPT are:

(i) The equation of equilibrium that governs the problem is a linear equation.

(ii) The governing PDE is expressed in terms of the unknown displacement field in the transverse direction which is found by solving the linear PDE.

(iii) Bending moments and shear force expressions can be found from the transverse displacement using the equations that relate bending moment to transverse deflection, and equations that relate the shear force to transverse deflection.

(iv) The KPT results in parabolic distribution of shear stresses τ_{yz} and τ_{zx} over the thickness, and this agrees with results from structural mechanics.

The demerits include: (i) the limitation of the KPT to small deformations and (ii) the inability of the KPT to cater for transverse shear deformations, thus limiting the scope of application of the KPT to thin plates; for which transverse shear deformations are negligible.

In [11], the author presented the domain PDE for variable thickness thin plate theory. Few problems of plates with variable flexural rigidity have been solved using analytical methods. Large deflection thin plate theory was developed by von-Karman, as a system of equilibrium and compatibility equations.

Reissner derived a stress-based theory for analysing moderately thick plates by the use of Castigliano's theorem resulting in a system of three PDEs. In [3] the author derived a first order shear deformation plate theory (FOSDT). The theory considered transverse shear deformation effects by assuming linear variations across the thickness for the three displacement components. The governing PDE of Mindlin plate theory are a set of three coupled PDEs in terms of three unknown displacements w, θ_x and θ_y where $w(x, y)$ denotes deflection in the transverse coordinate, θ_x and θ_y are the rotations of the plate mid-plane ($z = 0$).

In [18], the authors presented flexural solutions for thin plates subjected to linear variations of transversely applied loading. In [19] the author used the Vlasov variant of Galerkin's methodology to present a bending solution to thin plate resting on one parameter foundations where the plate is submitted to applied loading. In [4] the authors deployed a Vlasov modification of the Galerkin method to the bending problem of rectangular thin plate under uniform distribution of transversely applied loading over the entire plate domain.

In [7], the authors have deployed the Galerkin-Vlasov technique for bending analysis of thin plates with opposite edges fixed and the other edges on simple supports. In [20] the authors have also applied the Galerkin-Vlasov methodology for obtaining solutions to the natural vibration equation of thin plates having simply supported boundaries and obtained the eigenfrequencies and vibration modal shape functions.

Ritz variational methodologies has been deployed for the formulation and solution of classical Kirchhoff plate problems by authors in [21-23].

In [21], the authors deployed Ritz technique for finding solutions to the bending analysis of rectangular Kirchhoff-Love plates subject to transverse hydrostatically varying loading distributions over the plate region. In [22], the author presented systematically the Ritz method for the flexural analysis of simply supported rectangular Kirchhoff plates under distributed transverse loadings. Similarly, in [23], the author used Ritz technique to solve the bending problems of rectangular thin plates resting on one parameter foundations, with the plate subject to uniformly distributed loading over the entire domain.

Shear deformation theories of plates have been formulated by authors in [2], [24] and [25] amongst others to incorporate the transverse shear stresses and strains on their bending, dynamic and stability behaviours.

1.2. Review of solution methods for plate problems

Plate problems of dynamic and static bending and stability have been analysed using numerical and analytical methods by several researchers.

In [1], the author obtained an infinite series solution to the small displacement bending problems of CSCS (or SCSC) rectangular thin plates subject to uniformly distributed loading, by using the superposition principle to the solution for simply supported plates carrying uniform transverse distribution of loading and the solution to the same problem under an applied torque distribution along the clamped edges where the applied torque is of such a magnitude that rotations vanish at the clamped edges.

Integral transform methods were used for determining problems of thin plates under bending deformations by authors in [10] and [26].

In [8], the authors used the finite Fourier sine transformation methodology for flexural analysis of thin plates resting on one parameter foundations. In [26], the author presented the bending solutions of thin plate supported/resting on one-parameter discrete model of Winkler with the aid of finite Fourier sine transformation technique. In [27], the author presented two-dimensional Fourier

cosine series technique to solve bending problems of rectangular thin plates supported by Winkler one-parameter foundations with the plate domain subject to transverse loading.

Kantorovich-Vlasov method was used for the thin plate flexure problems by authors in [9], [28]-[31].

In [9] the authors have studied the use of Kantorovich-Vlasov method for solving bending problems of thin plate with Dirichlet conditions under uniformly distributed transverse loading. In [28], the author presented a mixture of Kantorovich, Euler-Lagrange and Galerkin's techniques and used it for solving bending problems of rectangular thin plates. In [29], the authors used the Kantorovich method to perform natural transverse vibrational analysis of rectangular Kirchhoff plates, thus obtaining the natural frequencies of transverse vibration. In [30], the authors used the Kantorovich-Vlasov methodology for solving the flexural problems of rectangular Kirchhoff plates with opposite sides fixed, and the other two sides simply supported; with the plate subject to distributed uniform loading. In [31], the authors used the Kantorovich method to solve flexural problems of Kirchhoff-Love plates having two sides fixed and the other sides on simple supports.

Thick thick plates modelled using FOSDT and Mindlin plate theories were studied by authors in [5], [12-17].

Elastic stability problems involving rectangular Kirchhoff plates subjected to inplane compressive loads were investigated by authors in [32-36].

In [32], the authors used the two-dimensional finite Fourier sine integral transformation technique for solving the elastic buckling problems of simply supported rectangular thin plates. In [33], the authors used the one-dimensional (single) finite Fourier sine integral transform method for the elastic stability solutions of thin plates simply supported at two opposite sides and fixed along the remaining two sides for uniaxial uniform compression. In [34], the authors used the Galerkin-Kantorovich technique for the elastic buckling analysis of thin rectangular shaped plates with two opposite sides simply supported and the other two sides fixed (SCSC plates). In [35], the authors used the Galerkin-Vlasov variational method for solving the elastic problems of rectangular thin plates with two types of boundary constraints namely: (a) simply supported on two opposite sides, clamped along the third side and free along the fourth side (SSCF plates). (b) simply supported along the four sides (SSSS plates). They obtained for each considered case, closed form solution that satisfies the boundary conditions and domain equation. In [36], the authors performed and obtained stability solutions for rectangular thin SSCF and SSSS plates using the single finite Fourier sine transform method. They obtained for the studied problems, exact solutions that satisfied the deformation and force equations at the restrained boundaries and the governing field equation.

In [37], the authors presented the flexural analysis of annular plates using the indirect Trefftz boundary method. They based their formulation for thin and thick plates on the Kirchhoff classical thin plate theory and the Reissner stress based thick plate theory respectively. They adopted the Trefftz method for their analysis because the Trefftz method uses complete set of solutions satisfying the governing fourth order PDE of the KPT classical thin plate theory and the sixth order PDE of the Reissner plate theory. Another fundamental merit that informed their use of the Trefftz method is that the method avoids singular integrals due to the properties of the solution coordinate functions. They adopted the method because the boundary conditions are automatically considered by the method, rendering the method effective compared with other methods. They solved illustrative problems by the method to demonstrate its effectiveness.

In [38], the authors demonstrated the use of the finite integral transformation technique for solving the flexural problems of clamped orthotropic rectangular shaped thin plates resting on one-parameter elastic foundations. In [39], the authors used the exact wave propagation approach for the natural vibration and stability analysis of thick plates modelled using the third order shear deformation plate theory. In [40], the authors presented the refined plate theory for the natural vibration analysis of nanoplates. In [41], the authors investigated vibrational behaviour of nonlinear rectangular plates modelled using the shear deformation plate theory. In [42], the authors presented a new technique for solving nonlinear vibrational problems of rectangular plates subjected to inplane compressive forces. In [43], the authors used the trigonometric shear deformation plate theory for the flexural analysis of moderately thick plates according to the shear deformation assumptions.

Other contributions to the knowledge of plates are found in such seminal papers as presented by authors in [44-51].

Other contributions to the theory of plates are found in references [52–60].

In [61], the authors used the GITM for obtaining closed-form mathematical expressions for the stability problems of rectangular Kirchhoff plates.

In [62], the authors applied the finite integral transformation method to solve the flexural problems of rectangular Kirchhoff plates made with orthogonally anisotropic materials. They considered plates with two adjacent free boundaries and the other boundaries fixed or on simple suppports (FFCC or FFSS) plates.

In [63], the authors used the two-dimensional finite integral transformaion method to determine the mathematical expressions that solve the flexural problems of Kirchhoff plates that are rectangular in plan shape. They considered and studied such plates that are supported at the corner points.

In [64], the authors used the finte integral transformation method to solve the natural vibration problems for transversely anisotropic thin plates with opposite sides that are prevented from rotational displacement and the other sides free of support.

In [65], the authors used the techniques of finite integral transformation for flexural problems involving plates made of transversely-anisotropic materials where the plates opposite boundaries are fixed while the rest of the edges are free.

In [66], the authors used the two-dimensional finite integral transformation method to determine the mathematical expressions for the flexural problems of rectangular shaped plates with moderate thickness resting on Winkler foundations. They used the Mindlin plate theory to describe the plate and obtained the

solutions to the system of governing equaitons using the two-dimensional finite integral tansformation technique.

2. Theory

2.1. The thin plate flexure problem:

The governing PDE describing flexure for thin plates $a \times b$ which is displayed in Figure 1 is given by the PDE:

$$\nabla^4 w(x, y) - \frac{q}{D}(x, y) = 0 \tag{1}$$

where ∇^4 is the biharmonic operator, $q(x, y)$ represents distribution of applied load intensity, $w(x, y)$ denotes the deflection. D denotes the flexural rigidity of the plate, expressed in terms of the elastic properties and geometrical properties of the plate by Equation (2) as follows:

$$D = \frac{Eh^3}{12(1 - \mu^2)} \tag{2}$$

μ is Poisson's ratio, h is plate thickness. E is Young's modulus of elasticity.

For clamped edges, the restraint equations for displacements are:

$$w(x, y = \pm b/2) = 0 \tag{3}$$

$$\frac{\partial w}{\partial y}\left(x, y = \frac{\pm b}{2}\right) = 0 \tag{4}$$

For $(x = 0, y)$ and $(x = a, y)$ edges, restraint (displacement) and bending moment force equations give:

$$w(x = 0, y) = w(x = a, y) = 0 \tag{5}$$

$$\frac{\partial^2 w}{\partial x^2}(x = 0, y) = \frac{\partial^2 w}{\partial x^2}(x = a, y) = 0 \tag{6}$$

M_{xx} and M_{yy} are:

$$M_{xx} = -D\left(\frac{\partial^2 w}{\partial x^2} + \mu \frac{\partial^2 w}{\partial y^2}\right) \tag{7}$$

$$M_{yy} = -D\left(\frac{\partial^2 w}{\partial y^2} + \mu \frac{\partial^2 w}{\partial x^2}\right) \tag{8}$$
Figure 1: Rectangular thin plate $(a \times b)$ with two opposite clamped boundaries $(y = \pm b/2)$, others on simple supports (SCSC or CSCS plate) subject to uniformly distributed transverse loading

2.2. Field equations for stability of rectangular thin plates subjected to uniaxial and biaxial compressive forces

The governing equation for the problem shown in Figure 2 is for biaxial buckling given by:
Figure 2: Biaxial buckling of rectangular thin (SCSC or CSCS) plates

$$D\nabla^4 w(x, y) + N_x \frac{\partial^2 w(x, y)}{\partial x^2} + N_y \frac{\partial^2 w(x, y)}{\partial y^2} = 0 \tag{9}$$

or, $$\nabla^4 w(x, y) + \frac{N}{D}(\nabla^2 w(x, y)) = 0 \tag{10}$$

when $N_x = N_y = N$

Let $N_y = 0$, then Equation (10) simplifies to become:

$$D\nabla^4 w + N_x \frac{\partial^2 w}{\partial x^2} = 0 \tag{11}$$

The geometric and force equations for the buckling problem are expressed by Equations (3–6).

3. Methodology

In the Generalized Integral Transformation Method (GITM), the basis functions are chosen as the eigenfunctions of a freely vibrating thin beam of equivalent edge support conditions as the plate. The plate is simply supported along the boundaries $x = 0$, and $x = a$. The eigenfunction of a simply supported thin beam of span a at the nth vibration mode is:

$$F_{1n}(x) = \sin\left(\frac{n\pi x}{a}\right) \tag{12}$$

$n = 1, 2, 3, 4, 5, 6, \ldots$

The eigenfuction of a thin beam of span b clamped at $y = \pm b/2$ at the mth vibration mode is given by:

$$F_{2m}(y) = \cos(\beta_m y) - \frac{\cos\left(\frac{\beta_m b}{2}\right)}{\cosh\left(\frac{\beta_m b}{2}\right)} \cosh(\beta_m y) \tag{13}$$

$m = 1, 2, 3, 4, 5, 6, \ldots$

In compact form,

$$F_{2m}(y) = \cos(\beta_m y) - \lambda_m \cosh(\beta_m y) \tag{14}$$

where

$$\lambda_m = \frac{\cos\left(\frac{\beta_m b}{2}\right)}{\cosh\left(\frac{\beta_m b}{2}\right)} \tag{15}$$

where β_m are the roots (eigenvalues) of the eigen equation, which for clamped-clamped thin beams is a transcendental equation.

$$\tan\left(\frac{\beta_m b}{2}\right) + \tanh\left(\frac{\beta_m b}{2}\right) = 0 \qquad (16)$$

The roots (which are infinite in numbers) are obtained for the first five modes of vibration using Mathematica software as follows:

$$\frac{\beta_1 b}{2} = \pm 2.36502037243135\ldots$$

$$\frac{\beta_2 b}{2} = \pm 5.49780391900084\ldots$$

$$\frac{\beta_3 b}{2} = \pm 8.63937982869974\ldots$$

$$\frac{\beta_4 b}{2} = \pm 11.7809724510202\ldots$$

$$\frac{\beta_5 b}{2} = \pm 14.9225651045516\ldots \qquad (17)$$

For large values of $\left(\frac{\beta_m b}{2}\right)$, $\tanh\left(\frac{\beta_m b}{2}\right) = 1$ and

$$\tan\left(\frac{\beta_m b}{2}\right) = -1 = \frac{\sin\left(\frac{\beta_m b}{2}\right)}{\cos\left(\frac{\beta_m b}{2}\right)}$$

Approximate solutions (eigenvalues) of the transcendental equation for $m > 5$ are obtained by solving the equation – Equation (18) using Mathematica and other root-finding software.

$$\left(\frac{\beta_m b}{2}\right) = \tan^{-1}(-1) \qquad (18)$$

The solution to Equation (18) is:

$$\left(\frac{\beta_m b}{2}\right) = \frac{1}{4}(4\pi m - \pi) \qquad (19)$$

$$(m > 5)$$

Then, $w(x, y)$ is constructed from the double infinite series of eigenfunctions in the x and y Cartesian coordinates as the following infinite double series:

$$w(x, y) = \sum_{m=1}^{\infty}\sum_{n=1}^{\infty} C_{mn} F_{1n}(x) F_{2m}(y) \qquad (20)$$

where C_{mn} is an unknown displacement (deflection) parameter sought for $w(x, y)$ to be a solution to the governing equation.

It is easily verified that $F_{1n}(x)$ and $F_{2m}(y)$ both satisfy all the boundary conditions of the thin plate problem for both flexure and elastic buckling.

3.1. The thin plate flexural problem

Applying the GITM to the PDE of the thin plate flexure problem results in the integral equation given as:

$$\int_0^a \int_{-b/2}^{b/2} \left(\nabla^4 \sum_{m=1}^{\infty}\sum_{n=1}^{\infty} C_{mn} F_{1n}(x) F_{2m}(y) - \frac{q_0}{D} \right) F_{1n}(x) F_{2m}(y)\, dxdy = 0$$

$$\ldots(21)$$

where

$$K_{mn}(x, y) = F_{1n}(x) F_{2m}(y) = \sin\left(\frac{n\pi x}{a}\right)(\cos(\beta_m y) - \lambda_m \cosh(\beta_m y)) \quad (22)$$

$K_{nm}(x, y)$ denotes the nucleus (kernel) function.

Hence, simplification of Equation (21) gives:

$$\sum_{m=1}^{\infty}\sum_{n=1}^{\infty} C_{mn} \int_0^a \int_{-b/2}^{b/2} (\nabla^4 F_{1n}(x) F_{2m}(y)) F_{1n}(x) F_{2m}(y)\, dxdy$$

$$= \frac{1}{D}\int_0^a \int_{-b/2}^{b/2} q_0 F_{1n}(x) F_{2m}(y)\, dxdy \qquad (23)$$

Simplifying further, we have:

$$\sum_{m=1}^{\infty}\sum_{n=1}^{\infty} C_{mn} \int_0^a \int_{-b/2}^{b/2} (F_{1n}^{iv}(x) F_{1n}(x) F_{2m}^2(y) +$$

$$2F_{1n}''(x) F_{1n}(x) F_{2m}''(y) F_{2m}(y) + F_{1n}^2(x) F_{2m}^{iv}(y) F_{2m}(y))\, dxdy$$

$$= \frac{q_0}{D}\int_0^a \int_{-b/2}^{b/2} F_{1n}(x) F_{2m}(y)\, dxdy \qquad (24)$$

where the primes represent differentiations with respect to the respective space coordinates.

For any m, n, we have C_{mn} determined by:

$$C_{mn} = \frac{q_0 I_7 I_8}{D(I_1 I_2 + 2I_3 I_4 + I_5 I_6)} = \frac{G_{1mn}}{G_{2mn}} \qquad (25)$$

$$G_{1mn} = q_0 I_7 I_8 \qquad (26)$$

$$G_{2mn} = D(I_1 I_2 + 2I_3 I_4 + I_5 I_6) \qquad (27)$$

where $I_1 = \int_0^a F_{1n}^{iv}(x) F_{1n}(x)\, dx \qquad (28)$

$$I_2 = \int_{-b/2}^{b/2} F_{2m}^2(y)\, dy \qquad (29)$$

$$I_3 = \int_0^a F_{1n}''(x) F_{1n}(x)\, dx \qquad (30)$$

$$I_4 = \int_{-b/2}^{b/2} F_{2m}''(y) F_{2m}(y)\, dy \qquad (31)$$

$$I_5 = \int_0^a F_{1n}^2(x)\, dx \qquad (32)$$

$$I_6 = \int_{-b/2}^{b/2} F_{2m}^{iv}(y) F_{2m}(y)\, dy \qquad (33)$$

$$I_7 = \int_0^a F_{1n}(x)\, dx \qquad (34)$$

$$I_8 = \int_{-b/2}^{b/2} F_{2m}(y)\, dy \qquad (35)$$

Then,

$$w(x, y) = \sum_{m=1}^{\infty}\sum_{n=1}^{\infty} \frac{\dfrac{q_0}{D} I_7 I_8 F_{1n}(x) F_{2m}(y)}{(I_1 I_2 + 2I_3 I_4 + I_5 I_6)} \qquad (36)$$

By differentiation,

$$\frac{\partial^2 w}{\partial x^2} = w_{xx} = \sum_{m=1}^{\infty} \sum_{n=1}^{\infty} \frac{\frac{q_0}{D} I_7 I_8 F_{1n}''(x) F_{2m}(y)}{(I_1 I_2 + 2I_3 I_4 + I_5 I_6)} \quad (37)$$

$$\frac{\partial^2 w}{\partial y^2} = w_{yy} = \sum_{m=1}^{\infty} \sum_{n=1}^{\infty} \frac{\frac{q_0}{D} I_7 I_8 F_{1n}(x) F_{2m}''(y)}{(I_1 I_2 + 2I_3 I_4 + I_5 I_6)} \quad (38)$$

The bending moments are:

$$M_{xx} = -\sum_{m=1}^{\infty} \sum_{n=1}^{\infty} \frac{q_0 I_7 I_8 (F_{1n}''(x) F_{2m}(y) + \mu F_{1n}(x) F_{2m}''(y))}{(I_1 I_2 + 2I_3 I_4 + I_5 I_6)} \quad (39)$$

$$M_{yy} = -\sum_{m=1}^{\infty} \sum_{n=1}^{\infty} \frac{q_0 I_7 I_8 (F_{1n}(x) F_{2m}''(y) + \mu F_{1n}''(x) F_{2m}(y))}{(I_1 I_2 + 2I_3 I_4 + I_5 I_6)} \quad (40)$$

At the plate centre, the bending moment expressions for M_{xx} and M_{yy} found by substitution of the centroidal coordinates are:

$$M_{xx}\left(x = \frac{a}{2}, y = 0\right) = -\sum_{m=1}^{\infty} \sum_{n=1}^{\infty} \frac{q_0 I_7 I_8 (F_{1n}''(a) F_{2m}(0) + \mu F_{1n}(a) F_{2m}''(0))}{(I_1 I_2 + 2I_3 I_4 + I_5 I_6)}$$
$$\dots(41)$$

$$M_{yy}\left(x = \frac{a}{2}, y = 0\right) = -\sum_{m=1}^{\infty} \sum_{n=1}^{\infty} \frac{q_0 I_7 I_8 (F_{1n}(a) F_{2m}''(0) + \mu F_{1n}''(a) F_{2m}(0))}{(I_1 I_2 + 2I_3 I_4 + I_5 I_6)}$$
$$\dots(42)$$

At the middle of the clamped boundaries, the coordinates are:
$$\left(x = \frac{a}{2}, y = \pm\frac{b}{2}\right),$$

The bending moment expressions for the midpoint of the fixed boundaries are found and given by:

$$M_{xx}\left(x = \frac{a}{2}, y = \pm\frac{b}{2}\right)$$
$$= -\sum_{m=1}^{\infty} \sum_{n=1}^{\infty} \frac{q_0 I_7 I_8 \left(F_{1n}''\left(\frac{a}{2}\right) F_{2m}\left(\pm\frac{b}{2}\right) + \mu\left(F_{1n}\left(\frac{a}{2}\right) F_{2m}''\left(\pm\frac{b}{2}\right)\right)\right)}{(I_1 I_2 + 2I_3 I_4 + I_5 I_6)}$$
$$\dots(43)$$

$$M_{yy}\left(x = \frac{a}{2}, y = \pm\frac{b}{2}\right)$$
$$= -\sum_{m=1}^{\infty} \sum_{n=1}^{\infty} \frac{q_0 I_7 I_8 \left(F_{1n}\left(\frac{a}{2}\right) F_{2m}''\left(\pm\frac{b}{2}\right) + \mu F_{1n}''\left(\frac{a}{2}\right) F_{2m}\left(\pm\frac{b}{2}\right)\right)}{(I_1 I_2 + 2I_3 I_4 + I_5 I_6)}$$
$$\dots(44)$$

3.2. Biaxial buckling of SCSC plate

The application of GITM to the elastic buckling equation gives the integral equation:

$$\int_0^a \int_{(-b/2)}^{(b/2)} \left(\nabla^4 \sum_{m=1}^{\infty} \sum_{n=1}^{\infty} C_{mn} F_{1n}(x) F_{2m}(y)\right) +$$
$$\frac{N}{D} \nabla^2 \left(\sum_{m=1}^{\infty} \sum_{n=1}^{\infty} C_{mn} F_{1n}(x) F_{2m}(y)\right) F_{1n}(x) F_{2m}(y) \, dx \, dy = 0 \quad (45)$$

Let $\frac{N}{D} = \alpha^2$ $\quad (46)$

Then,

$$\sum_{m=1}^{\infty} \sum_{n=1}^{\infty} C_{mn} \int_0^a \int_{(-b/2)}^{(b/2)} \left\{ (\nabla^4 F_{1n}(x) F_{2m}(y)) F_{1n}(x) F_{2m}(y) + \right.$$
$$\left. \alpha^2 (\nabla^2 F_{1n}(x) F_{2m}(y)) F_{1n}(x) F_{2m}(y) \right\} dx \, dy = 0 \quad (47)$$

Simplifying Equation (47) gives:

$$\sum_{m=1}^{\infty} \sum_{n=1}^{\infty} C_{mn} \int_0^a \int_{(-b/2)}^{(b/2)} \left\{ (F_{1n}^{iv}(x) F_{1n}(x) F_{2m}^2(y) + \right.$$
$$2 F_{1n}''(x) F_{1n}(x) F_{2m}''(y) F_{2m}(y) + F_{1n}^2(x) F_{2m}^{iv}(y) F_{2m}(y)) +$$
$$\left. \alpha^2 (F_{1n}(x) F_{1n}''(x) F_{2m}^2(y) + F_{1n}^2(x) F_{2m}(y) F_{2m}''(y)) \right\} dx \, dy = 0 \quad (48)$$

Hence,

$$\sum_{m=1}^{\infty} \sum_{n=1}^{\infty} C_{mn} \left\{ (I_1 I_2 + 2I_3 I_4 + I_5 I_6) + \alpha^2 (I_3 I_2 + I_5 I_4) \right\} = 0 \quad (49)$$

For nontrivial solutions, $C_{mn} \neq 0$ and

$$I_1 I_2 + 2I_3 I_4 + I_5 I_6 = -\alpha^2 (I_3 I_2 + I_5 I_4) \quad (50)$$

Solving for α^2,

$$\alpha^2 = \frac{N}{D} = -\left(\frac{I_1 I_2 + 2I_3 I_4 + I_5 I_6}{I_2 I_3 + I_4 I_5}\right) \quad (51)$$

In compact form,

$$\alpha^2 = \frac{-G_{2mn}}{G_{3mn}} \quad (52)$$

where,

$$G_{3mn} = I_2 I_3 + I_4 I_5 \quad (53)$$

Thus, the buckling load is:

$$N = \frac{G_{2mn}}{G_{3mn}} D \quad (54)$$

3.3. Uniaxial buckling of SCSC plate

For uniaxial buckling due to N_x applied alone, $N_y = 0$, and the GITM yields:

$$\alpha^2 = \frac{N}{D} = -\left(\frac{I_1 I_2 + 2I_3 I_4 + I_5 I_6}{I_2 I_3}\right) \quad (55)$$

The buckling load for uniaxial compression in the x direction is:

$$N = \frac{-G_{2mn}}{G_{4mn}} D \quad (56)$$

where, $G_{4mn} = I_2 I_3$ $\quad (57)$

4. Results

By differentiation of the eigenfunctions,

$$F_{1n}''(x) = -\left(\frac{n\pi}{a}\right)^2 \sin\left(\frac{n\pi x}{a}\right) = -\left(\frac{n\pi}{a}\right)^2 F_{1n}(x) \quad (58)$$

$$F_{1n}^{iv}(x) = \left(\frac{n\pi}{a}\right)^4 \sin\left(\frac{n\pi x}{a}\right) = \left(\frac{n\pi}{a}\right)^4 F_{1n}(x) \quad (59)$$

$$F_{2m}''(y) = -\beta_m^2 (\cos(\beta_m y) + \lambda_m \cosh(\beta_m y)) \quad (60)$$

$$F_{2m}^{iv}(y) = \beta_m^4 (\cos(\beta_m y) - \lambda_m \cosh(\beta_m y)) = \beta_m^4 F_{2m}(y) \quad (61)$$

Then,

$$I_1 = \int_0^a F_{1n}^{iv}(x) F_{1n}(x) dx = \left(\frac{n\pi}{a}\right)^4 \int_0^a F_{1n}^2(x) dx \qquad (62)$$

Substitution of the expression for F_{1n} and integration gives:

$$I_1 = \left(\frac{n\pi}{a}\right)^4 \int_0^a \sin^2\left(\frac{n\pi x}{a}\right) dx = \left(\frac{n\pi}{a}\right)^4 \left[\frac{x}{2} - \frac{\sin 2\left(\frac{n\pi x}{a}\right)}{4\left(\frac{n\pi}{a}\right)}\right]_0^a \qquad (63)$$

Substituting the integration limits gives:

$$I_1 = \left(\frac{n\pi}{a}\right)^4 \left(\frac{a}{2}\right) \qquad (64)$$

Similarly, I_2 is evaluated as:

$$I_2 = \int_{(-b/2)}^{(b/2)} F_{2m}^2(y) dy = \int_{(-b/2)}^{(b/2)} \left(\cos(\beta_m y) - \lambda_m \cosh(\beta_m y)\right)^2 dy \qquad (65)$$

Expanding the integrand in Equation (65) gives:

$$I_2 = \int_{(-b/2)}^{(b/2)} \left(\cos^2(\beta_m y) - 2\lambda_m \cosh(\beta_m y)\cos(\beta_m y) + \lambda_m^2 \cosh^2(\beta_m y)\right) dy$$

$$\dots (66)$$

Using the linearity property of integration, Equation (66) simplifies to:

$$I_2 = \int_{(-b/2)}^{(b/2)} \cos^2(\beta_m y) dy - 2\lambda_m \int_{(-b/2)}^{(b/2)} \cosh(\beta_m y)\cos(\beta_m y) dy +$$

$$\lambda_m^2 \int_{(-b/2)}^{(b/2)} \cosh^2(\beta_m y) dy \qquad (67)$$

Each integral in Equation (67) is evaluated.

$$\int_{(-b/2)}^{(b/2)} \cos^2(\beta_m y) dy = \left[\frac{y}{2} + \frac{\sin(2\beta_m y)}{4\beta_m}\right]_{(-b/2)}^{(b/2)} \qquad (68)$$

Substituting the limits, and simplifying, gives:

$$\int_{(-b/2)}^{(b/2)} \cos^2(\beta_m y) dy = \left(\frac{b/2}{2} + \frac{\sin\left(2\beta_m\left(\frac{b}{2}\right)\right)}{4\beta_m}\right) -$$

$$\left(\frac{-b/2}{2} + \frac{\sin\left(2\beta_m\left(\frac{-b}{2}\right)\right)}{4\beta_m}\right) = \frac{b}{2} + \frac{\sin(\beta_m b)}{2\beta_m} \qquad (69)$$

Similarly,

$$\int_{(-b/2)}^{(b/2)} \cosh(\beta_m y)\cos(\beta_m y) dy$$

$$= \left[\frac{\beta_m \sinh(\beta_m y)\cos(\beta_m y) + \beta_m \cosh(\beta_m y)\sin(\beta_m y)}{\beta_m^2 + \beta_m^2}\right] \qquad (70)$$

Also,

$$\int_{(-b/2)}^{(b/2)} \cosh(\beta_m y)\cos(\beta_m y) dy$$

$$= \left(\frac{\sinh\left(\frac{\beta_m b}{2}\right)\cos\left(\frac{\beta_m b}{2}\right) + \cosh\left(\frac{\beta_m b}{2}\right)\sin\left(\frac{\beta_m b}{2}\right)}{2\beta_m}\right) -$$

$$\left(\frac{-\sinh\left(\frac{\beta_m b}{2}\right)\cos\left(\frac{\beta_m b}{2}\right) - \cosh\left(\frac{\beta_m b}{2}\right)\sin\left(\frac{\beta_m b}{2}\right)}{2\beta_m}\right) \qquad (71)$$

Then,

$$\int_{(-b/2)}^{(b/2)} \cosh(\beta_m y)\cos(\beta_m y) dy$$

$$= \frac{\sinh\left(\frac{\beta_m b}{2}\right)\cos\left(\frac{\beta_m b}{2}\right) + \cosh\left(\frac{\beta_m b}{2}\right)\sin\left(\frac{\beta_m b}{2}\right)}{\beta_m} \qquad (72)$$

Also,

$$\int_{(-b/2)}^{(b/2)} \cosh^2(\beta_m y) dy = \left[\frac{y}{2} + \frac{\sinh(\beta_m y)\cosh(\beta_m y)}{2\beta_m}\right]_{(-b/2)}^{(b/2)} \qquad (73)$$

Substituting the limits, gives:

$$\int_{(-b/2)}^{(b/2)} \cosh^2(\beta_m y) dy = \left(\frac{b}{4} + \frac{\sinh\left(\frac{\beta_m b}{2}\right)\cosh\left(\frac{\beta_m b}{2}\right)}{2\beta_m}\right) -$$

$$\left(-\frac{b}{4} - \frac{\sinh\left(\frac{\beta_m b}{2}\right)\cosh\left(\frac{\beta_m b}{2}\right)}{2\beta_m}\right)$$

$$= \frac{b}{2} + \frac{\sinh\left(\frac{\beta_m b}{2}\right)\cosh\left(\frac{\beta_m b}{2}\right)}{\beta_m} \qquad (74)$$

Then, substitution of Equations (69) (72) and (74) into Equation (67) yields:

$$I_2 = \frac{b}{2} + \frac{\sin(\beta_m b)}{2\beta_m} - 2\lambda_m$$

$$\left(\frac{\sinh\left(\frac{\beta_m b}{2}\right)\cos\left(\frac{\beta_m b}{2}\right) + \cosh\left(\frac{\beta_m b}{2}\right)\sin\left(\frac{\beta_m b}{2}\right)}{\beta_m}\right) +$$

$$\lambda_m^2 \left(\frac{b}{2} + \frac{\sinh\left(\frac{\beta_m b}{2}\right)\cosh\left(\frac{\beta_m b}{2}\right)}{\beta_m}\right) \qquad (75)$$

But the eigenvalue equation from which Equation (16) is derived is:

$$\sinh\left(\frac{\beta_m b}{2}\right)\cos\left(\frac{\beta_m b}{2}\right) + \cosh\left(\frac{\beta_m b}{2}\right)\sin\left(\frac{\beta_m b}{2}\right) = 0 \qquad (76)$$

Hence, I_2 expressed by Equation (75) simplifies to:

$$I_2 = \frac{b}{2} + \frac{\sin(\beta_m b)}{2\beta_m} + \lambda_m^2 \left(\frac{b}{2} + \frac{\sinh\left(\frac{\beta_m b}{2}\right)\cosh\left(\frac{\beta_m b}{2}\right)}{\beta_m}\right) \qquad (77)$$

Similarly, I_3 is evaluated as:

$$I_3 = \int_0^a F_{1n}''(x) F_{1n}(x) dx = -\left(\frac{n\pi}{a}\right)^2 \int_0^a F_{1n}^2(x) dx = -\left(\frac{n\pi}{a}\right)^2 \frac{a}{2}$$

$$\dots (78)$$

I_4 is evaluated as:

$$I_4 = \int\limits_{(-b/2)}^{(b/2)} F''_{2m}(y) F_{2m}(y)\, dy = -\beta_m^2 \int\limits_{(-b/2)}^{(b/2)} (\cos(\beta_m y) +$$

$$\lambda_m \cosh(\beta_m y))(\cos(\beta_m y) - \lambda_m \cosh(\beta_m y))\, dy \quad (79)$$

Simplification of Equation (79) gives:

$$I_4 = -\beta_m^2 \int\limits_{(-b/2)}^{(b/2)} \left(\cos^2(\beta_m y) - \lambda_m^2 \cosh^2(\beta_m y) \right) dy \quad (80)$$

Hence,

$$I_4 = -\beta_m^2 \left(\frac{b}{2} + \frac{\sin(\beta_m b)}{2\beta_m} - \lambda_m^2 \left(\frac{b}{2} + \frac{\sinh\left(\frac{\beta_m b}{2}\right)\cosh\left(\frac{\beta_m b}{2}\right)}{\beta_m} \right) \right) \quad \dots(81)$$

Similarly,

$$I_5 = \int\limits_0^a F_{1n}^2(x)\, dx = \int\limits_0^a \sin^2\left(\frac{n\pi x}{a} \right) dx = \frac{a}{2} \quad (82)$$

Also,

$$I_6 = \int\limits_{(-b/2)}^{(b/2)} F_{2m}^{iv}(y) F_{2m}(y)\, dy = \beta_m^4 \int\limits_{(-b/2)}^{(b/2)} F_{2m}^2(y)\, dy \quad (83)$$

$$I_6 = \beta_m^4 I_2 = \beta_m^4 \left(\left(\frac{b}{2} + \frac{\sin(\beta_m b)}{2\beta_m} \right) + \right.$$
$$\left. \lambda_m^2 \left(\frac{b}{2} + \frac{\sinh\left(\frac{\beta_m b}{2}\right)\cosh\left(\frac{\beta_m b}{2}\right)}{\beta_m} \right) \right) \quad (84)$$

Similarly,

$$I_7 = \int\limits_0^a F_{1n}(x)\, dx = \int\limits_0^a \sin\frac{n\pi x}{a}\, dx = \left[-\frac{a}{n\pi} \cos\frac{n\pi x}{a} \right]_0^a \quad (85)$$

Substituting the limits,

$$I_7 = -\frac{a}{n\pi}(\cos(n\pi) - \cos 0) = -\frac{a}{n\pi}(\cos(n\pi) - 1) \quad (86)$$

I_8 is evaluated as:

$$I_8 = \int\limits_{(-b/2)}^{(b/2)} (\cos(\beta_m y) - \lambda_m \cosh(\beta_m y))\, dy$$

$$= \left[\frac{\sin(\beta_m y)}{\beta_m} - \lambda_m \frac{\sinh(\beta_m y)}{\beta_m} \right]_{-b/2}^{b/2} \quad (87)$$

Substituting the limits,

$$I_8 = \frac{2}{\beta_m} \left(\sin\left(\frac{\beta_m b}{2} \right) - \lambda_m \sinh\left(\frac{\beta_m b}{2} \right) \right) \quad (88)$$

4.1. Results for the thin plate flexure problem

Then, substituting the integrals into Equation (25), we have:

$$C_{mn} = \frac{\dfrac{-2aq_0}{n\pi}(\cos(n\pi) - 1)\dfrac{\left(\sin\left(\frac{\beta_m b}{2}\right) - \lambda_m \sinh\left(\frac{\beta_m b}{2}\right) \right)}{\beta_m}}{\left(\dfrac{n\pi}{a}\right)^4 \dfrac{a}{2} \cdot I_2 - 2I_4 \left(\dfrac{n\pi}{a}\right)^2 \dfrac{a}{2} + \dfrac{a}{2} I_6} = \frac{G_{1mn}}{G_{2mn}}$$
$$\dots(89)$$

$$G_{1mn} = \frac{-2aq_0}{n\pi\beta_m}(\cos(n\pi) - 1)\left(\sin\left(\frac{\beta_m b}{2} \right) - \lambda_m \sinh\left(\frac{\beta_m b}{2} \right) \right) \quad (90)$$

$$G_{2mn} = \left(\frac{n\pi}{a}\right)^4 \frac{a}{2}\left[\frac{b}{2} + \frac{\sin(\beta_m b)}{2\beta_m} + \right.$$
$$\lambda_m^2 \left(\frac{b}{2} + \frac{\sinh\left(\frac{\beta_m b}{2}\right)\cosh\left(\frac{\beta_m b}{2}\right)}{\beta_m} \right) \right] -$$
$$2\left(\frac{n\pi}{a}\right)^2 \frac{a}{2}\left[-\beta_m^2 \left\{ \left(\frac{b}{2} + \frac{\sin(\beta_m b)}{2\beta_m} \right) - \right. \right.$$
$$\left. \left. \lambda_m^2 \left(\frac{b}{2} + \frac{\sinh\left(\frac{\beta_m b}{2}\right)\cosh\left(\frac{\beta_m b}{2}\right)}{\beta_m} \right) \right\} \right] + \frac{a}{2}\beta_m^4 \left[\frac{b}{2} + \frac{\sin(\beta_m b)}{2\beta_m} + \right.$$
$$\left. \lambda_m^2 \left(\frac{b}{2} + \frac{\sinh\left(\frac{\beta_m b}{2}\right)\cosh\left(\frac{\beta_m b}{2}\right)}{\beta_m} \right) \right] \quad (91)$$

$$G_{2mn} = \left(\frac{n\pi}{a}\right)^4 \frac{a}{2}\left(\frac{b}{2} + \frac{\sin(\beta_m b)}{2\beta_m} + \lambda_m^2 \left(\frac{b}{2} + \frac{\sinh\left(\frac{\beta_m b}{2}\right)\cosh\left(\frac{\beta_m b}{2}\right)}{\beta_m} \right) \right) +$$
$$2\left(\frac{n\pi}{a}\right)^2 \frac{a}{2}\beta_m^2 \left(\frac{b}{2} + \frac{\sin(\beta_m b)}{2\beta_m} - \lambda_m^2 \left(\frac{b}{2} + \frac{\sinh\left(\frac{\beta_m b}{2}\right)\cosh\left(\frac{\beta_m b}{2}\right)}{\beta_m} \right) \right) +$$
$$\frac{a}{2}\beta_m^4 \left(\frac{b}{2} + \frac{\sin(\beta_m b)}{2\beta_m} + \lambda_m^2 \left(\frac{b}{2} + \frac{\sinh\left(\frac{\beta_m b}{2}\right)\cosh\left(\frac{\beta_m b}{2}\right)}{\beta_m} \right) \right)$$
$$\dots(92)$$

$$G_{2mn} = \left(\left(\frac{n\pi}{a}\right)^4 \frac{a}{2} + \frac{a}{2}\beta_m^4 \right)$$
$$\left(\frac{b}{2} + \frac{\sin(\beta_m b)}{2\beta_m} + \lambda_m^2 \left(\frac{b}{2} + \frac{\sinh\left(\frac{\beta_m b}{2}\right)\cosh\left(\frac{\beta_m b}{2}\right)}{\beta_m} \right) \right) +$$
$$2\left(\frac{n\pi}{a}\right)^2 \frac{a}{2}\beta_m^2 \left(\frac{b}{2} + \frac{\sin(\beta_m b)}{2\beta_m} - \lambda_m^2 \left(\frac{b}{2} + \frac{\sinh\left(\frac{\beta_m b}{2}\right)\cosh\left(\frac{\beta_m b}{2}\right)}{\beta_m} \right) \right)$$
$$\dots(93)$$

$$G_{2mn} = \left(\left(\frac{n\pi}{a}\right)^4 \frac{a}{2} + \frac{a}{2}\beta_m^4 \right) I_2 - 2\left(\frac{n\pi}{a}\right)^2 \frac{a}{2} I_4 \quad (94)$$

Then, $C_{mn} = \dfrac{G_{1mn}}{G_{2mn}}$ is evaluated and $w(x, y)$ is found using Equation (36) as:

$$w(x, y) = \sum_{m=1}^{\infty} \sum_{n=1}^{\infty} \frac{G_{1mn}}{G_{2mn}} F_{1n}(x) F_{2m}(y) \quad (95)$$

where $m = 1, 2, 3, \dots$; $n = 1, 2, 3, \dots$

The bending moments are obtained from substitution of Equation (95) in Equations (7) and (8):

$$F_{2m}(y = 0) = \cos 0 - \lambda_m \cosh 0 = 1 - \lambda_m \quad (96)$$

$$F_{2m}\left(y = \pm\frac{b}{2} \right) = \cos\left(\frac{\beta_m b}{2} \right) - \lambda_m \cosh\left(\frac{\beta_m b}{2} \right) \quad (97)$$

$$F_{2m}''(y=0) = -\beta_m^2(\cos 0 + \lambda_m \cosh 0) = -\beta_m^2(1+\lambda_m) \quad (98)$$

$$F_{2m}''\left(y=\pm\frac{b}{2}\right) = -\beta_m^2\left(\cos\left(\frac{\beta_m b}{2}\right) + \lambda_m \cosh\left(\frac{\beta_m b}{2}\right)\right) \quad (99)$$

$$F_{1n}\left(x=\frac{a}{2}\right) = \sin\left(\frac{(n\pi a/2)}{a}\right) = \sin\left(\frac{n\pi}{2}\right) \quad (100)$$

$$F_{1n}''\left(x=\frac{a}{2}\right) = -\left(\frac{n\pi}{a}\right)^2 \sin\left(\frac{(n\pi a/2)}{a}\right) = -\left(\frac{n\pi}{a}\right)^2 \sin\frac{n\pi}{2} \quad (101)$$

Results for deflections and bending moments evaluated at x = a, y = 0

The deflections and bending moments expressions evaluated at $x = a$, $y = 0$ are found from:

$$w(a,0) = \sum_{m=1}^{\infty}\sum_{n=1}^{\infty} C_{mn} F_{1n}\left(x=\frac{a}{2}\right) F_{2m}(y=0)$$

$$= \sum_{m=1}^{\infty}\sum_{n=1}^{\infty} \frac{G_{1mn}}{G_{2mn}} \sin\frac{n\pi}{2}(1-\lambda_m) \quad (102)$$

$$M_{xx}(a,0) = \sum_{m=1}^{\infty}\sum_{n=1}^{\infty} \frac{G_{1mn}}{G_{2mn}}\left(F_{1n}''\left(\frac{a}{2}\right)F_{2m}(0) + \mu F_{1n}\left(\frac{a}{2}\right)F_{2m}''(0)\right) \quad (103)$$

$$M_{yy}(a,0) = \sum_{m=1}^{\infty}\sum_{n=1}^{\infty} \frac{G_{1mn}}{G_{2mn}}\left(F_{1n}\left(\frac{a}{2}\right)F_{2m}''(0) + \mu F_{1n}''\left(\frac{a}{2}\right)F_{2m}(0)\right) \quad (104)$$

Results for deflection and bending moment expressions evaluated at the midpoint of the fixed edges $\left(x=\dfrac{a}{2}, y=\pm\dfrac{b}{2}\right)$

The deflection and bending moments expressions evaluated at the midpoint of the fixed edges are found and given by:

$$w\left(\frac{a}{2},\pm\frac{b}{2}\right) = \sum_{m=1}^{\infty}\sum_{n=1}^{\infty} \frac{G_{1mn}}{G_{2mn}} F_{1n}\left(x=\frac{a}{2}\right)F_{2m}\left(y=\pm\frac{b}{2}\right) = 0 \quad (105)$$

Since

$$F_{2m}\left(y=\pm\frac{b}{2}\right) = \cos\left(\pm\frac{\beta_m b}{2}\right) - \frac{\cos\left(\frac{\beta_m b}{2}\right)}{\cosh\left(\frac{\beta_m b}{2}\right)}\cosh\left(\pm\frac{\beta_m b}{2}\right)$$

$$= \cos\left(\frac{\beta_m b}{2}\right) - \frac{\cos\left(\frac{\beta_m b}{2}\right)}{\cosh\left(\frac{\beta_m b}{2}\right)}\cosh\left(\frac{\beta_m b}{2}\right) = 0 \quad (106)$$

$$M_{xx}\left(x=\frac{a}{2}, y=\pm\frac{b}{2}\right)$$

$$= \sum_{m=1}^{\infty}\sum_{n=1}^{\infty}\frac{G_{1mn}}{G_{2mn}}\left(F_{1n}''\left(\frac{a}{2}\right)F_{2m}\left(\frac{\pm b}{2}\right) + \mu F_{1n}\left(\frac{a}{2}\right)F_{2m}''\left(\frac{\pm b}{2}\right)\right) \quad (107)$$

$$M_{yy}\left(x=\frac{a}{2}, y=\pm\frac{b}{2}\right)$$

$$= \sum_{m=1}^{\infty}\sum_{n=1}^{\infty}\frac{G_{1mn}}{G_{2mn}}\left(F_{1n}\left(\frac{a}{2}\right)F_{2m}''\left(\frac{\pm b}{2}\right) + \mu F_{1n}''\left(\frac{a}{2}\right)F_{2m}\left(\frac{\pm b}{2}\right)\right) \quad (108)$$

The obtained results are presented in Tables 1, 2, 3, 4, 5, 6, 7, 8 and 9.

Table 1: Maximum deflection coefficients (α_1) of rectangular Kirchhoff CSCS plate having clamped boundaries ($y=-b/2, y=+b/2$) two opposite boundaries ($x=0, x=a$), simply supported and the plates submitted to uniform load of intensity q_0 (case when $b \le a$ or $a \ge b$) for $\mu = 0.30$

4.2. Results for stability problems studied

4.2.1. Biaxial buckling of CSCS plate

G_{2mn} is found from Equation (93)

$$G_{3mn} = -\left(\frac{n\pi}{a}\right)^2 \frac{a}{2}\left(\frac{b}{2} + \frac{\sin(\beta_m b)}{2\beta_m} + \lambda_m^2\left(\frac{b}{2} + \frac{\sinh\left(\frac{\beta_m b}{2}\right)\cosh\left(\frac{\beta_m b}{2}\right)}{\beta_m}\right)\right) -$$

$$\frac{a}{2}\beta_m^2\left(\frac{b}{2} + \frac{\sin(\beta_m b)}{2\beta_m} - \lambda_m^2\left(\frac{b}{2} + \frac{\sinh\left(\frac{\beta_m b}{2}\right)\cosh\left(\frac{\beta_m b}{2}\right)}{\beta_m}\right)\right) \quad (109)$$

$$G_{4mn} = -\left(\frac{n\pi}{a}\right)^2 \frac{a}{2}\left(\frac{b}{2} + \frac{\sin(\beta_m b)}{2\beta_m} + \lambda_m^2\left(\frac{b}{2} + \frac{\sinh\left(\frac{\beta_m b}{2}\right)\cosh\left(\frac{\beta_m b}{2}\right)}{\beta_m}\right)\right)$$
$$\ldots(110)$$

N is calculated from Equation (54).

For $m = 1$, $n = 1$, an approximate value for N for biaxial buckling load as well as the buckling load in uniaxial compression are found as follows:

$$I_1 = \frac{\pi^4}{2a^3} \tag{111}$$

$$I_2 = 0.50883b \tag{112}$$

$$I_6 = \frac{254.702}{b^3} \tag{113}$$

$$I_3 = -\frac{\pi^2}{2a} \tag{114}$$

$$I_5 = \frac{a}{2} \tag{115}$$

$$I_4 = -\frac{6.25988}{b} \tag{116}$$

$$I_3 I_2 = -2.510975 \frac{b}{a} \tag{117}$$

$$I_4 I_5 = -3.12994 \frac{a}{b} \tag{118}$$

$$G_3 = -\left(2.510975 \frac{b}{a} + 3.12994 \frac{a}{b}\right) = -\left(\frac{2.510975}{r} + 3.12994r\right)$$
$$\ldots(119)$$

$$\text{where } r = \frac{a}{b} \tag{120}$$

$$G_2 = \frac{24.7823}{b^2 r^3} + \frac{127.351r}{b^2} + \frac{61.782}{b^2 r} \tag{121}$$

Then,

$$\alpha^2 = \frac{N}{D} = \left(\frac{\dfrac{24.7823}{b^2 r^3} + \dfrac{127.351r}{b^2} + \dfrac{61.782}{b^2 r}}{\dfrac{2.510975}{r} + 3.12994r}\right)$$
$$= \left(\frac{27.7823r^{-2} + 127.351r^2 + 61.782}{2.510975 + 3.12994r^2}\right)\frac{1}{b^2} \tag{122}$$

For $r = 1$,

$$N = 37.9221 \frac{D}{b^2} = 3.8423 \frac{D\pi^2}{b^2} \tag{123}$$

Similarly, a one term solution for the buckling load for uniaxial compression in the x duration is given by:

$$\alpha^2 = \left(\frac{\dfrac{24.7823}{b^2 r^3} + \dfrac{127.351r}{b^2} + \dfrac{61.782}{b^2 r}}{\dfrac{2.510975}{r}}\right) \tag{124}$$

$$N = \left(\frac{9.8696}{r^2} + 50.7177r^2 + 24.6048\right)\frac{D}{b^2} \tag{125}$$

For $r = 1$,

$$N(r = 1, m = n = 1) = 85.1921 \frac{D}{b^2} = 8.63176 \frac{D\pi^2}{b^2} \tag{126}$$

The exact solution for the lowest/critical elastic buckling load in uniaxial compression in the x Cartesian coordinate direction is [1]:

$$N = 7.691 \frac{D\pi^2}{b^2} \tag{127}$$

The obtained GITM solution for the elastic buckling load under uniaxial uniform compression of CSCS plate for a one term approximation is 12.23% greater than the exact solution. It is suggested that more acceptable solutions that do not differ markedly from the exact solution for the elastic stability problems of square CSCS plates under uniaxial compressive loading could be obtained by using more terms in the eigenfunction expansion.

5. Discussion

The Generalized Integral Transform Method (GITM) has been used in this work to solve the bending and buckling problems of rectangular thin plates having two boundaries ($x = 0$, $x = a$) on simple supports and the other two boundaries ($y = \pm b/2$) fixed. In the thin plate bending problem presented, the plate was submitted to a uniform distribution of loading. The PDE for homogeneous, isotropic plates is the inhomogeneous biharmonic equation expressed by Equation (2). The natural and force equations at the supported boundaries are expressed using the Equations (3 – 6). The study thus presented solutions to the domain Equation (2) using the GITM, where the solutions are required to satisfy Equations (3 – 6) along the boundaries.

The elastic buckling problem considered in the study is given for biaxial compressive forces by Equation (9) or Equation (10) when the biaxial compressive forces are equal for both the x and y directions ($N_x = N_y$). The domain PDE for uniaxial buckling in the x direction is given by Equation (11). The boundary conditions for buckling are given by Equations (3 – 6). The two-dimensional GITM which is a generalization of the integral transform methods uses the eigenfunctions of an equivalent vibrating thin beam for the respective Cartesian coordinates as the basis functions in the respective coordinate directions.

Thus the basis functions (eigenfunctions) for the problem considered are chosen as Equations (12) and (13). The unknown displacement $w(x, y)$ is considered to be constructed from the basis functions as the double infinite series given by Equation (20). The unknown deflection $w(x, y)$ is a function of C_{mn}, unknown displacement parameters which are sought such that $w(x, y)$ satisfies the domain equation at all point in the solution space.

The basis functions $F_{1n}(x)$ and $F_{2m}(y)$ each satisfies the geometric and force equation at the supports for both bending and elastic buckling analysis. The GITM transforms the governing PDE for plate bending to the integral equation given by Equation (21) where the kernel function is expressed by Equation (22). The general solution of the integral equation is found for C_{mn} as Equation (25) which is expressible using integrals $I_1, I_2, \ldots, I_8$. Thus $w(x, y)$ is determined as Equation (36). With the aid of bending moments-displacement equations, the bending moments are obtained in general as Equations (39) and (40). The expressions for bending moments evaluated at the plate centre are obtained as Equations (41) and (42). The expressions for M_{xx} and M_{yy} bending moments at the mid-point of the fixed edges are found as Equations (43) and (44).

The generalized integral transformation of the governing equation for elastic buckling (biaxial case) gave the integral

equation – Equation (45). Simplification of the formulation yielded the algebraic eigenvalue problem in Equation (49).

For nontrivial solutions ($C_{mn} \neq 0$) C_{mn} would not vanish and the elastic stability equation was obtained as Equation (50). The solution of the equation gave α^2 from which N could be found as Equation (51). Specializations of the solution for biaxial buckling gave the solution for uniaxial buckling as Equation (55).

The general solutions obtained for both cases of bending and elastic buckling analysis are presented in terms of integrals. The integrals are evaluated in order to determine specific expressions for G_{1mn}, G_{2mn}, G_{3mn}, G_{4mn}, which are determined explicitly as Equations (90), (91), (109) and (110) respectively.

The deflection was thus found explicitly as the double series of infinite terms as Equation (95). The deflection of the plate centre is thus found as Equation (102). The maximum deflection presented in Tables 1 and 2 occurs at the centre and agrees with the symmetrical features of the plate problem. The bending moments M_{xx}, M_{yy} are found at the plate centre and the middle point of the fixed sides and presented in Tables 6, 7, 8 and 9. Tables 3, 4 and 5 which present convergence studies of the double series for maximum deflection at the plate centre confirm the series as rapidly convergent. Satisfactorily accurate results for maximum deflection are found with a small number of terms of the obtained double infinite series for the maximum deflection. The converged results obtained for deflections and bending moments were in excellent agreement with solutions presented using the superposition principle [1].

The eigenvalue problem of buckling yielded the approximate expression for α^2 for $m = 1$, $n = 1$ from which N would be found as Equation (122) for biaxial buckling cases. For square thin plates the biaxial buckling load was found as Equation (123). The approximate expression for α^2 for $m = 1$, $n = 1$ for uniaxial buckling under uniform compression was found as Equation (124). N was obtained as the expression in Equation (125).

6. Conclusion

In conclusion

(i) The GITM assumes the unknown $w(x, y)$ to be a double infinite series constructed as products of the eigenfuncions $F_{1n}(x)$ and $F_{2m}(y)$ of vibrating Euler-Bernoulli beams with equivalent end support conditions respectively in the Cartesian coordinates, and terms C_{mn} sought to be determined.

(ii) In the present problem the GITM assumes $w(x, y)$ as the double infinite series of the product of C_{mn} and $F_{1n}(x)$ and $F_{2m}(y)$. $F_{1n}(x)$ is the eigenfunction of a vibrating Euler-Bernoulli beam with simply supported ends which correspond to the simply supported boundaries of the plate. $F_{2m}(y)$ denotes eigenfunction of a vibrating Euler-Bernoulli beam with clamped ends ($y = \pm b/2$) which corresponds to the clamped boundaries ($y = \pm b/2$) of the thin plate being studied.

(iii) The eigenfunctions $F_{1n}(x)$ and $F_{2m}(y)$ thus satisfy the geometric and force equations of the thin rectangular CSCS plates considered for the two cases of bending

analysis and elastic buckling analysis considered in the study.

(iv) The GITM uses the eigenfunctions $F_{1n}(x)$ and $F_{2m}(y)$ as the integral kernel functions in the formulation of the integral equation from the domain equation for both the bending analysis and the elastic buckling analysis presented.

(v) The application of GITM to the governing domain PDE converts the PDE over the domain to an integral equation in both cases of bending and elastic buckling analysis.

(vi) The integral equations further reduce to algebraic problems for bending analysis leading to the determination of the unknown displacement parameters C_{mn}, and the full determination of the deflection $w(x, y)$.

(vii) The integral equation reduces to an algebraic eigenvalue equation for elastic buckling analysis, leading to the determination of α^2 and thus N for nontrivial solutions.

(viii) The bending moment expressions were found as double series with infinite terms.

(ix) The expressions for the maximum values of the deflection and bending moments are found to be rapidly convergent double series of infinite terms in m, and n.

(x) The maximum values for deflection and bending moments were found to occur at the plate centre, thus agreeing with the symmetrical features of the plate problems considered.

(xi) Convergence studies done and presented in Tables 3, 4 and 5 for the deflection expression computed at the plate centre validate that the deflection expression is rapidly convergent series, and exact solutions are obtained using five terms of the series in x and y directions.

(xii) Satisfactorily accurate results are obtained for the maximum deflection with just a small number of terms of the infinite series expression.

(xiii) For the verification and validation of the plate bending results found using the GITM in this work, the numerical values of the maximum deflections and maximum bending moments obtained were compared with values obtained for the same problem solved using the superposition technique. Good agreement between the present GITM solutions and solutions by superposition presented by authors in [1] was observed.

(xiv) The GITM gave closed form mathematical expression as analytical solutions to the plate bending problem studied.

(xv) The eigenvalue problem of elastic buckling studied for biaxial loading in uniform compression was illustrated using the first terms from the eigenfunction, and the approximate value of the buckling load computed for square CSCS plates.

(xvi) The approximated value of the elastic buckling load was also found for uniaxial uniform compression of square CSCS plate and the obtained result had a relative error of 12.23% compared with the exact solution. This demonstrates, the relative accuracy of the GITT since a 1×1 term approximation gave a relatively small error. The use of more terms would definitely yield better results for the buckling load; however, with huge computational efforts (even with software due to the large demands of computer memory size/space).

Conflict of Interest

The authors hereby affirm and declare that they have no conflict of interest whatsoever in the publication and dissemination of this research work.

Acknowledgment

The authors sincerely and heartily acknowledge the constructive contributions of the reviewers, and the hard work and sincere commitment of the Editor-in-Chief and the Editorial Board members. The authors are grateful for all the efforts leading to the acceptance of the paper for publication in the journal.

A R T I C L E   I N F O

A B S T R A C T

This paper has conducted the study of the impact and effectiveness of Google Classroom in online teaching and learning. Based on the unified theory of acceptance and use of technology (UTAUT2), the first aim was to rank the 8 constructs namely: Performance Expectancy, Effort Expectancy, Social Influence, Facilitating Conditions, Hedonic Motivation, Habit, Behavioral Intention, and the last Use Behavior. Each of the constructs have their respective questions due to the questionnaire formed from the UTAUT2 theory. To evaluate the use of Google Classroom, have been analyzed the feedbacks from every participant based on a 5-likert scale output. Secondly, was completed the rank of the questions based on the most preferred 5-likert scale options. The method proposed for the purposes of this study were fuzzy AHP with triangular fuzzy numbers (TFN) and trapezoidal fuzzy numbers (TpFN). The results suggested that the most preferred construct by fuzzy with TFN numbers was the Behavioral Intention while the least preferred was the Effort Expectancy, whereas for fuzzy TpFN the most preferred construct was the Social Influence and the least preferred was the Effort Expectancy. Based on the questionnaire, the rank resulted to be the same with both methods for the most preferred question and the least important one, that were respectively from Use Behavior construct, and from Performance Expectancy construct, while the ranked questions of other constructs differed slightly with both methods. These results showed that both methods produced the same rank for the 5-likert scale options, where "Agree" option was the more important from the 5-likert scale options and "Strongly disagree" option was less important. From these findings was concluded that these changes in ranking were due to the different defuzzification methods that were used for both types of fuzzy numbers.

1. Introduction

Due to the worldwide situation of the COVID-19 pandemic, in several countries have been applied online teaching methods in schools and universities, including Albania. The most used e-learning platform was Google Classroom which is a free application, mainly used in higher education helping lecturers and students to share files between them referring to [1]. Compared with the traditional teaching style there are advantages and disadvantages in using Google Classroom [2].

In fact the students prefer the engagement in Google Classroom rather than being engaged in a class where the teachers have more active roles [3]. Google Classroom has incorporated some other applications such as Google Docs, Slides, Calendar, Sheets, where users can download them from Play Store or App store [4]. All these applications help the lecturer/tutor and students to have a better communication by attaching assignments or sharing files without the need of face to face learning. The benefit of using Google Classroom is that you can stay organized, save time and paper, interact with other users in a kind of blended learning [5],

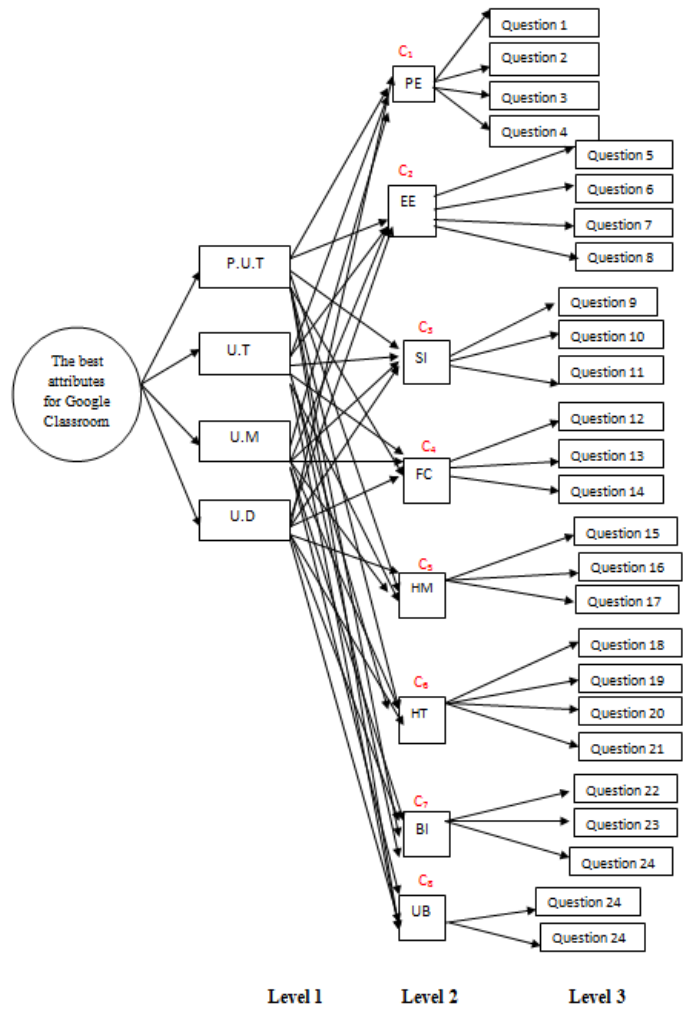
[6]. Classroom use of Google was expected to improve in quality and providing assistance in education [7]. Motivated by these facts the study was focused to find the most important attributes related to Google Classroom, based on the online learning theory of acceptance and use of technology 2 (UTAUT2). This theory is a technology acceptance model formulated by Venkatesh et al [8], and aimed to explain user intentions to use a new technology and subsequent usage behavior. The study questionnaire was based in the questionnaire developed by Jakkaew and Hemrungrote [9] and Jannosy [10]. The survey with 26 questions 5-likert scale have collected data from 528 students that studied mathematical courses in bachelor degree, from four different Universities in Albania. Based on the UTAUT2 theory, the questionnaire has 8 constructs: Performance Expectancy (PE), Effort Expectancy (EE), Social Influence (SI), Facilitating Conditions (FC), Hedonic Motivation (HM), Habit (HT) [11], Behavioral Intention (BI) [12] and Use Behavior (UB) introduced and estimated by Jannosy [10]. For each of the questions, the answers were based on a 5-likert scale where 5 represents "strongly agree", 4 "agree", 3 "neither agree nor disagree", 2 "disagree" and 1 "strongly disagree". PE is determined by how useful Google Classroom is for students and how does it increases the learning productivity [13]. EE determines how easy it is to learn and use Google Classroom [14]. SI determines the degree that an individual will perceive the importance that the closely friends or peers, or people he or she valuate his/her opinion, believe in using Google Classroom [15]. FC describes the perception that the technology will support difficulties while using Google Classroom [8]. HM defines the fun or pleasure in using Google Classroom compared to traditional learning [16]. HT determines the degree of observed automatic behavior to an unconscious stimulus that leads to happy outcome after using Google Classroom [17], [18]. Some studies have found that the more users are in regular contact with each other, the more likely they are to develop a "habit of participation" and act cooperatively with the others [19], [20]. BI is the subjective degree that an individual will use Google Classroom frequently in the future. UB is defined from the subsequent effects of habit and others, but mostly from the effect of behavioral intention [20]. The constructs had their own set of questions, defined by Venkatesh, Jakkaew, Hemrungrote et al. The study referred to each of the construct as an attribute of its level, and each question as an attribute of the question's level, and each alternative response from 5-likert scale, as an attribute of the 5 options. Thomas Saaty [21] introduced analytic hierarchic process (AHP) as a method of measurement with ratio scales to solve real life problems in decision making, but to deal with uncertainty in complex problems and multi criteria decision making (MCDM), AHP is combined with fuzzy logic (Fuzzy AHP) [22]. The fuzzy AHP method converts the Saaty scale of AHP from 1-9, to symmetric triangular fuzzy numbers and symmetric trapezoidal fuzzy numbers. The next step calculates the defuzzification of fuzzy numbers, converting the expected results into crisp numbers and ranking the attributes according to their respective levels [23]. In order to evaluate all the attributes of Google Classroom, has been constructed a hierarchy in levels. The goal was "the best attributes for Google Classroom", level 1 were the four universities of Albania, level 2 included the eight constructs of UTAUT2, level 3 was formed by the questions for each of the constructs, and level 4 included the 5-likert point option for each of the questions. The hierarchy and its levels are as follow in figure 1 and figure 2:


Figure 1: Hierarchy of the questionnaire
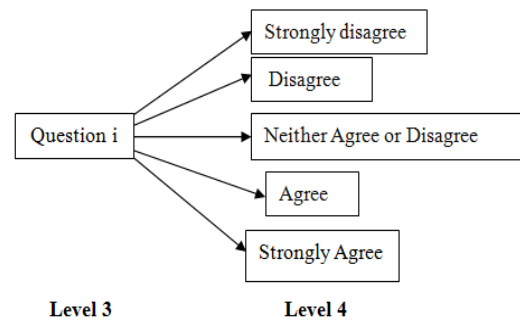

Figure 2: The 5-likert point alternative

The rankings have been evaluated by implementing the method fuzzy AHP with triangular fuzzy numbers and with trapezoidal fuzzy numbers, because it is known that trapezoidal fuzzy numbers are a generalization of triangular fuzzy numbers [24]. Thus have been compared the similar rankings and also the changes in rankings. The results obtained from this study may be very useful for lecturers and students when using Google Classroom. The findings are expected to be used by lecturers in explaining new knowledge, also in their interest to know where students are more focused during the online learning. Multi criteria decision making problems are a group of decision method,

where AHP is one of the most widely used among them. The AHP was first introduced by Saaty [25], [26] which uses the decision matrix and makes the pair-wise comparison evaluations in order to obtain the relative weights for the levels of the hierarchy (criteria and alternatives). This method has disadvantages in its inability to deal with the uncertainty decision making problems [27], [28]. To address this issue, in [29] the author introduced the fuzzy AHP, based on the fuzzy set theory by [30]. The first FAHP was applied with triangular fuzzy numbers and their relative preferences were described with the means of fuzzy numbers [31]. In [31], the author introduced the geometric mean to calculate the fuzzy weights and their combination for finding final weights, in [32], the author introduced a new approach for FAHP based on triangular fuzzy numbers and used the extent analyses to find the vector of weights for each element of the criterion. Most of previous works have used the AHP method and other MCDM methods in Learning Measurement Systems (LMS) while a little attention has been paid to the fuzzy AHP method. In [33], the author evaluated the critical success factors in implementing e-learning system using FAHP with TFN scale. They have treated the success factors from diverse points of view such as system, support from the institution, instructor, and student. In [34], the author has evaluated the LMS systems by using FAHP with TFN and two other methods, fuzzy Topsis and an Integrated Method. In the study has been showed that the content management and development is the most important criteria. In [35], the author applied FAHP in increasing the effectiveness of teaching to massive open online courses (MOOCS) and to determine the most widespread MOOCS. In [36], the author explores in detail the necessary requirements for the successful execution of distance education in industrial engineering using FAHP and SWARA. In [37], the author used the FAHP to weight the e-learning website selection index, for eight C-programming language websites, and concluded that the most important from the quality factor is "functionality", and from e-learning easily specific factors is "easy of learning community". In [38], the author used FAHP to choose the most appropriate system of LMS, and it was Joomla LMS system. In [39], the author applied fuzzy AHP to evaluate significant factors for executing a successful personalized E-Learning system. In [40], the author used FAHP with TFN numbers and other methods to achieve lean attributes for competitive advantages development. In other research papers [41], [42] the authors have evaluated the adoption of a new technology with FAHP method. In [41], the author used FAHP and Structural Equation Modeling (SEM) to predict the adoption of cloud-based technology, and found that the constructs PE, EE, SI of UTAUT2 are the most important factors predicting behavioral intention to adopt cloud-based collaborative learning technology from experts' point of view. In [42], the author applied FAHP with TFN numbers to rank the factors influencing Fin Tech adoption intention, case study China and Korea. They concluded that the price value had the most significant influence on Chinese perceptions while credibility had the most significant effect on korean perceptions. In [43], the author has evaluated the usability of website using combined weighted method: fuzzy AHP and

entropy approach. The entropy approach suggested "Response Time" (RT) as the main contributor while FAHP suggests "Ease of Navigation" (EON) as the main contributor for evaluation of usability of the academic websites. In [44], the author firstly has investigated the effective factors in electronic readiness of governmental and semi-governmental organizations of Tabriz city, and then ranked the effective factors in accepting information technologies and teleworking by fuzzy AHP technique. In general, these papers have mostly applied the FAHP method with TFN numbers. To the best of the knowledge, there is not yet an AHP study or a FAHP study on Google Classroom usage. In this paper have been studied the most important attributes of using Google Classroom for online teaching by the FAHP method with triangular fuzzy numbers and with trapezoidal fuzzy numbers. The study aimed to find the ranked sub-criteria and alternatives according to the hierarchy levels: the ranked constructs based on the students answers for each of the eight of them, the ranked questions from the most to the least important (there are 26 in total) and finally the ranked 5-likert-scale point options.

2. Ranking methods

The FAHP method has been used to find the most important attributes of Google Classroom with symmetric triangular fuzzy numbers and trapezoidal fuzzy numbers. One good reason for the selection of these methods was because the fuzzy numbers describe better the pair-wise comparisons matrices of optimality criteria than simple AHP. If the fuzzy method has been applied, the result score is always 'the-bigger-the-better' [45]. The 26 questions are organized in 8 constructs which are C1 = PE = Performance Expectancy, C2 = EE = Effort Expectancy, C3 = SI = Social Influence, C4 = FC = Facilitating Conditions, C5 = HM = Hedonic Motivation, C6 = HT = Habit, C7 = BI = Behavioral Intention and C8 = UB = Use Behavior, referred in the study as the criteria. The sub-criteria have been represented by the third level of the hierarchy, and the alternatives of the hierarchy have been represented in the fourth level showed also in figure 1.

3. The proposed framework

Both methods have been developed through 7 steps for their application. The first was to construct the hierarchy problem, then have been created the pairwise comparison matrices and checked for consistency for each of them in all levels of the hierarchy. All these steps had the decision matrices with crisp numbers. In step four were converted all crisp numbers of the decision matrices into triangular fuzzy numbers/trapezoidal fuzzy numbers according FAHP-TFN/FAHP-TPFN [46], and then were calculated the fuzzy weights for each method. The deffuzification step was not the same for both methods. This step has converted the fuzzy numbers into crisp numbers, and the greater number (weight) showed the most important attribute among them. The most interested issue was to determine exactly how have changed the ranked results regarding the most important attribute for Google Classroom. In figure 3 and figure 4 have been shown all these steps.

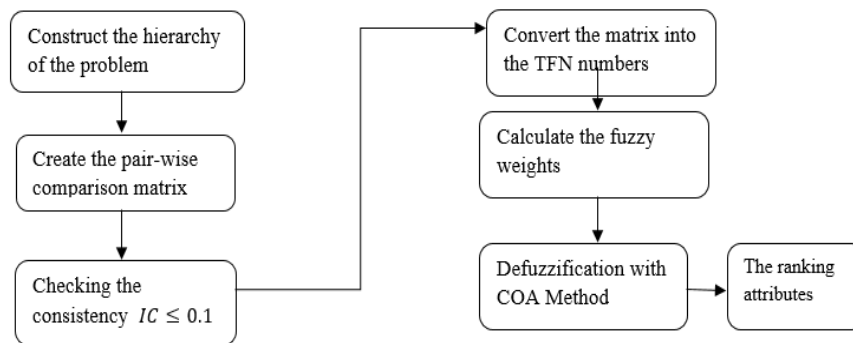
Steps for FAHP-TFN


Figure 3: FAHP with TFN Numbers

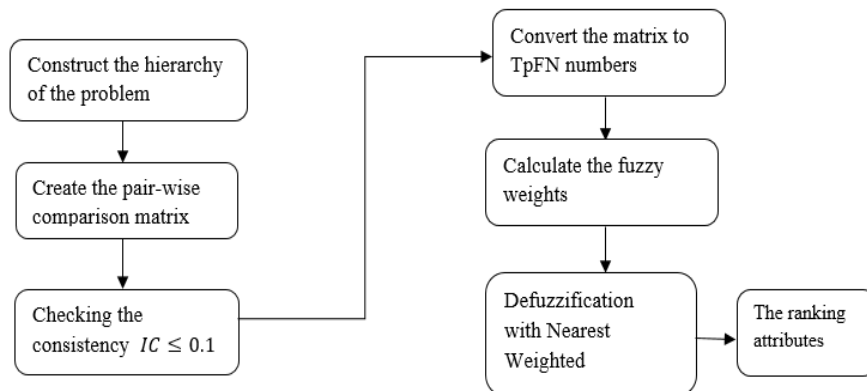
Steps for FAHP-TpFN


Figure 4: FAHP with TpFN Numbers

3.1. Fuzzy AHP with TFN Numbers

Decision-makers often liked to give linguistic variables, rather than giving their judgments in numerical values [47]. A linguistic variable has linguistic terms representing approximate values of a base variable, relevant to a particular application, have been captured by approximate fuzzy numbers [48]. Each linguistic variable consists of the following elements: A name, a base variable, a set of linguistic terms and a semantic rule. To deal with data uncertainty, FAHP is a useful theory in the in the context that crisp numbers are expressed in fuzzy numbers.

Firstly a group of decision makers is formed for evaluating the criteria and attributes as linguistic variables, with the consensus of all its members [49]. The main input for AHP method is the decision matrix formed from the expert's judgment, so there will be a factor of subjectivity in their decisions [50]. The most important thing is that this matrix has to be consistent with index CI less or equal to 0.1 ($CI = \frac{\lambda_{max} - n}{n-1} \leq 0.1$) [51].

Also, it is necessary for the consistence ratio $CR = CI/RI \leq 0.1$, where RI is the random index of the n-order matrix showed in table 1.

The experts have constructed the decision matrices for all levels of the hierarchy, and then converted the numbers into fuzzy symmetric triangular numbers (TFN). The fuzzy numbers were defined from the triangular symmetrical fuzzy membership function.

Table 1: Random Index for matrix of n-order, simple AHP (Saaty 1980)

n	1	2	3	4	5	6	7	8	9	10
RI	0.00	0.00	0.58	0.9	1.12	1.24	1.32	1.41	1.45	1.49

Table 2: Triangular fuzzy numbers and their inverse with Saaty Scale

Relative importance	Importance	TFN	Inverse of TFN
1	Equal	(1,1,1)	(1,1,1)
3	Moderate	(2,3,4)	(1/4,1/3,1/2)
5	Strong	(4,5,6)	(1/6,1/5,1/4)
7	Very strong	(6,7,8)	(1/8,1/7,1/6)
9	Extremely strong	(9,9,9)	(1/9,1/9,1/9)
2	Intermediate values	(1,2,3)	(1/3,1/2,1)
4	Intermediate values	(3,4,5)	(1/5,1/4,1/3)
6	Intermediate values	(5,6,7)	(1/7,1/6,1/5)
8	Intermediate values	(7,8,9)	(1/9,1/8,1/7)

A fuzzy number $\tilde{N}$ is called a triangular fuzzy number (TFN) if its membership function $\mu_{\tilde{N}}(x): R \rightarrow [0,1]$ is as follows:

$$\mu_{\widetilde{N}}(x) = \begin{cases} \frac{x-l}{m-l} & l \leq x \leq m \\ \frac{u-x}{u-m} & m \leq x \leq u \\ 0 & x \neq [l,u] \end{cases} \qquad (1)$$

In figure 5 is shown the triangular membership function.
The fuzzy number $\widetilde{N} = (l, m, u)$ is formed by the lower, medium and upper bounds of the crisp number. Table 2 shows the Saaty scale from 1 to 9 evaluated with symmetric triangular fuzzy numbers, also the inverse of the triangular fuzzy numbers.

In figure 6 are shown the triangular fuzzy numbers with the Saaty relative importance value.
The operational laws with triangular fuzzy numbers are as follow:

a) $\widetilde{N}_1 \oplus \widetilde{N}_2 = (l_1, m_1, u_1) \oplus (l_2, m_2, u_2) =$
$(l_1 + l_2, m_1 + m_2, u_1 + u_2)$

b) $\widetilde{N}_1 \otimes \widetilde{N}_2 = (l_1, m_1, u_1) \otimes (l_2, m_2, u_2) =$
$(l_1 l_2, m_1 m_2, u_1 u_2) \qquad (2)$

c) $\widetilde{N}^{-1} = (l, m, u)^{-1} = (\frac{1}{u}, \frac{1}{m}, \frac{1}{l})$

The decision matrix A was converted into the matrix $\widecheck{A}$ as the fuzzy TFN matrix [52]-[53]:

$$\widecheck{A} = \begin{pmatrix} (1,1,1) & \cdots & (l_{1n}, m_{1n}, u_{1n}) \\ \vdots & \ddots & \vdots \\ (l_{n1}, m_{n1}, u_{n1}) & \cdots & (1,1,1) \end{pmatrix}$$

$$\widecheck{a}_{ij} = (l_{ij}, m_{ij}, u_{ij}),$$

where

$$\widecheck{a}_{ij}^{-1} = (\frac{1}{u_{ij}}, \frac{1}{m_{ij}}, \frac{1}{l_{ij}}) \qquad (3)$$

For each of the criteria have been calculated the fuzzy geometric mean value:

$$\widecheck{r}_i = \left(\prod_{i=1}^{n} \widecheck{a}_{ij}\right)^{1/n} \qquad (4)$$

Next was applied the defuzzification method named Center of Area method (COA) for the fuzzy weights:

$$\widetilde{\omega}_i = \widecheck{r}_i \otimes (\widecheck{r}_1 \oplus \widecheck{r}_2 \oplus \dots \oplus \widecheck{r}_n)^{-1} \qquad (5)$$

According to Voskoglou (2018) the coordinates of the Center of Area for the triangular formed with fuzzy numbers are $G\left(\frac{l+m+n}{3}, \frac{1}{3}\right)$. Point G is the intersection of the medians of the triangle formed by fuzzy numbers [54] (see figure 7).
Figure 7: Center of area for TFN

The last step was to find the average M_i and the normalized weights N_i for all criteria:

$$M_i = \frac{\widetilde{\omega}_1 \oplus \widetilde{\omega}_2 \oplus \dots \oplus \widetilde{\omega}_n}{n} \qquad (6)$$

$$N_i = \frac{M_i}{M_1 \oplus M_2 \oplus \dots \oplus M_n} \qquad (7)$$

These 7 steps must be performed to find the normalized weights for both criteria and their alternatives as they are represented in the hierarchy. According to these results, the alternative with the highest score is suggested to be the best alternative for the decision makers.

Triangular and trapezoidal fuzzy numbers are used very often to deal with the vagueness of the decisions related to alternative choice for each of the criteria [23]. A trapezoidal fuzzy number is denoted as $\widetilde{N} = (l, m, n, u)$ where if $m = n$ it becomes a triangular fuzzy number TFN, so the TFN numbers are a special case of TpFN numbers. In this study all the linguistic variables of the pair-wise comparison matrices have been expressed in trapezoidal fuzzy number. The trapezoidal fuzzy number has the membership function as follows:

Table 3: Trapezoidal fuzzy numbers and inverse of TpFN with Saaty scale.

Relative importance value	Importance	Trapezoidal fuzzy numbers scale	Inverse of trapezoidal fuzzy numbers
1	Equal	(1,1,1,1)	(1,1,1,1)
3	Moderate	(2,5/2,7/2,4)	(0.13,0.2,0.46,0.53)
5	Strong	(4,9/2,11/2,6)	(0.05,0.15,0.25,0.35)
7	Very strong	(6,13/2,15/2,8)	(0.04,0.1,0.18,0.244)
9	Extremely strong	(8,17/2,9,9)	(0.01,0.1,0.12,0.21)
2	Intermediate values	(1,3/2,5/2,3)	(0.2,0.3,0.7,0.8)
4	Intermediate values	(3,7/2,9/2,5)	(0.1,0.15,0.35,0.4)
6	Intermediate values	(5,11/2,13/2,7)	(0.01,0.155,0.175,0.3)
8	Intermediate values	(7,15/2,17/2,9)	(0.05,0.085,0.185,0.2)

$$(x) = \begin{cases} \frac{x-l}{m-l} & l \leq x \leq m \\ 1 & m \leq x \leq n \\ \frac{u-x}{u-m} & m \leq x \leq u \\ 0 & x \neq [l,u] \end{cases} \quad (8)$$

In figure 8 is shown the triangular membership function.
Figure. 8 TpFN membership function

Table 3 has converted the trapezoidal fuzzy numbers and the inverse of them with the Saaty scale.

In figure 9 are shown the trapezoidal fuzzy numbers with Saaty relative scale of importance.
Figure 9: TpFN with relative importance of Saaty scale

The defuzzification was applied with the method of nearest weighted symmetry (NWS) for trapezoidal fuzzy numbers as described in Saneifard [56].

$$a_{ij} = \frac{l+2m+2n+u}{6} \quad (13)$$

The last step included the normalization and the ranking attributes given as:

$$N_i = \frac{a_{ij}}{\sum a_{ij}} \quad (14)$$

3.3. Data collections

In order to analyze the effectiveness and acceptance of Google Classroom, a questionnaire has been prepared based

The operational laws with trapezoidal fuzzy numbers:

a) $\tilde{N}_1 \oplus \tilde{N}_2 = (l_1, m_1, n_1, u_1) \oplus (l_2, m_2, n_2, u_2) = (l_1 + l_2, m_1 + m_2, n_1 + n_2, u_1 + u_2)$

b) $\tilde{N}_1 \otimes \tilde{N}_2 = (l_1, m_1, n_1, u_1) \otimes (l_2, m_2, n_2, u_2) = (l_1 l_2, m_1 m_2, n_1 n_2, u_1 u_2)$ (9)

c) $\tilde{N}^{-1} = (l, m, n, u)^{-1} = (\frac{1}{u}, \frac{1}{n}, \frac{1}{m}, \frac{1}{l})$

The decision matrix A was converted into the matrix $\check{A}$ as the fuzzy TpFN matrix [23]-[55]:

$$\check{A} = \begin{pmatrix} (1,1,1,1) & \cdots & (l_{1n}, m_{1n}, n_{1n}, u_{1n}) \\ \vdots & \ddots & \vdots \\ (l_{n1}, m_{n1}, n_{n1}, u_{n1}) & \cdots & (1,1,1,1) \end{pmatrix}$$

$$\check{a}_{ij} = (l_{ij}, m_{ij} n_{ij}, u_{ij}),$$

$$\check{a}_{ij}^{-1} = (\frac{1}{u_{ij}}, \frac{1}{n_{ij}}, \frac{1}{m_{ij}}, \frac{1}{l_{ij}}) \quad (10)$$

For each of the criteria were calculated the fuzzy geometric mean value:

$$\check{r}_i = \left(\prod_{i=1}^{n} \check{a}_{ij} \right)^{1/n} \quad (11)$$

The fuzzy weights were calculated as follow:

$$\tilde{\omega}_i = \check{r}_i \otimes (\check{r}_1 \oplus \check{r}_2 \oplus \ldots \oplus \check{r}_n)^{-1} \quad (12)$$

firstly from Jakkaew and Hemrungrote. Details of this questionnaire have been given in the Appendix A. The questionnaire has been completed by 528 students from 4 universities in Albania, one month after they started using this platform. In table 4 are described the frequency and percentage for answers of the questionnaire.

4. Results

4.1. Results for Criteria with FAHP –TFN

The hierarchical structure has been constructed based on the questionnaire, combining all the criteria and attributes to find the goal: the most important attributes for Google Classroom. In this study the universities were in the second level, and hence haven't

taken as criteria. The constructs C_1, C_2,…,C_8 have been the criteria, and the questions Q_1, …,Q_{26} have been the sub-criteria Each question has 5 alternatives ,shown in figure 2. The eight criteria have been compared with respect to the goal "the most important attributes for Google Classroom". The decision makers were a group of mathematicians which have evaluated the answers of the questionnaire, and constructed the pair-wise comparison matrix for levels of the hierarchy [22],[57]. The first construction was the pair-wise comparison matrix with triangular fuzzy numbers as follow in table nr 5.

This matrix has the Consistency Index 0.04778 < 0.1, and $CR = CI/RI = 0.034$, so were applied the equations (2)-(7). The results were obtained in table 6.

Based on the results for the most important construct from FAHP-TFN, it was the construct Behavioral Intention, than Social Influence, Hedonic Motivation, Use Behavior, Habit, Performance Expectancy, Facilitating Conditions and the last is Effort Expectancy. So for the students was more important to continue using Google Classroom in the future and to recommend

it for other students. Also the Social Influence have impacted their use of Google Classroom. The last preferred was Effort Expectancy, so they thought was easy to use Google Classroom, to learn to operate with it and the interaction was clear and understandable.

4.2. Results for the FAHP –TpFN Criteria.

After have been found the rank with TFN numbers for the criteria, was converted the decision matrix in table 5 into trapezoidal fuzzy numbers (see table 7).

The crisp numbers less than one were converted into trapezoidal fuzzy numbers with the use of the membership function of the generalized trapezoidal fuzzy number

$(\check{A}) = (a, b, c, d; w), (0 < w \leq 1), \mu_{(\check{A})}(x): R \to [0, w]$, which mapped the set of all fuzzy numbers to a set of real numbers by $R(\check{A}) = \frac{w}{2}((c + d) - (a + b))$ [58], [59]. The study used the trapezoidal fuzzy numbers for $w = 1$. The results that were obtained from equations (9) to (14), are summarized in table 8.

Table 4: Students gender, university and way of access for Google Classroom.

Item	Values	Frequency	Percentage
Gender	Male	192	36.4%
	Female	336	63.6%
University	Polytechnic University of Tirana	151	28.6%
	University of Tirana	130	24.6%
	University of Medicine	53	10.0%
	University of Durres	194	36.7%
Access Google Classroom	Android	192	36.4%
	Smartphone	189	35.8%
	Personal Computer	147	27.8%

Table 9: The ranked criteria with two types of fuzzy numbers.

Method	Rank of the criteria							
FAHP -TFN	C_7	C_3	C_5	C_8	C_6	C_1	C_4	C_2
FAHP-TpFN	C_3	C_5	C_8	C_7	C_6	C_1	C_4	C_2

Table 10: The IC, CR indexes for the matrixes of questions, third level:

	CI	CR
C_1=(Q_1, Q_2, Q_3, Q_4)	0.099	0.1
C_2=(Q_5, Q_6, Q_7, Q_8)	0.03	0.033
C_3=(Q_9, Q_{10}, Q_{11})	0.033	0.056
C_4=(Q_{12}, Q_{13}, Q_{14})	0.0035	0.006

$C_5=(Q_{15}, Q_{16}, Q_{17})$	0.051	0.088
$C_6=(Q_{18}, Q_{19}, Q_{20}, Q_{21})$	0.068	0.075
$C_7=(Q_{22}, Q_{23}, Q_{24})$	0.017	0.03
$C_8=(Q_{25}, Q_{26})$	0	0

Table 11: The ranked results for questions level

TFN	Q_{25}	Q_{12}	Q_9	Q_{15}	Q_5	Q_1	Q_{22}	Q_{18}	Q_{16}	Q_{10}	Q_2	Q_{26}	Q_7
	1	2	3	4	5	6	7	8	9	10	11	12	13
TpFN	Q_{25}	Q_{12}	Q_9	Q_{15}	Q_{22}	Q_1	Q_5	Q_{18}	Q_{16}	Q_{10}	Q_2	Q_{26}	Q_{23}
	1	2	3	4	5	6	7	8	9	10	11	12	13

Q_{14}	Q_{19}	Q_{23}	Q_{24}	Q_{21}	Q_6	Q_3	Q_{13}	Q_{20}	Q_8	Q_{11}	Q_{17}	Q_4
14	15	16	17	18	19	20	21	22	23	24	25	26
Q_{14}	Q_7	Q_{19}	Q_{21}	Q_6	Q_3	Q_{24}	Q_{13}	Q_{20}	Q_{11}	Q_{17}	Q_8	Q_4
14	15	16	17	18	19	20	21	22	23	24	25	26

The FAHP-TpFN method has shown that the most important criteria were C_3 and the last important was C_2. So Social Influence was the most preferred criteria, then Hedonic Motivation, use behavior, Behavioral Intention, Habit, Performance Expectancy, Facilitating Conditions, and the last Effort Expectancy. Social Influence construct has been evaluated as the most preferred criteria that included friends, peers or other people. They had a direct impact for the students in using Google Classroom. The second evaluated was Hedonic Motivation criteria concerning an enjoyable use for Google Classroom. The last was Effort Expectancy criteria, as an easy use of Google Classroom.

4.3. Comparison results for the criteria level

Referred to the results in table 6 and table 8, were summarized the ranking criteria with the triangular and trapezoidal fuzzy numbers in table 9. These results have shown that only criteria C_7 differs in rank between the two methods, all the others have the same rank. This was obtained due to the fact that the method of defuzzification in the two types of fuzzy numbers were not the same according their formulas. The results obtained from them give an important rank for the decision makers to judge the preferences of the Google

Classroom constructs in more detail. In general, the ranked criteria of the most important and the last important one was the same, only the rankings between them differed less.

4.4. Comparison results for questions level

Here have been applied FAHP TFN and FAHP TpFN for the third level of the hierarchy, formed with the 26 questions as alternatives for each of the criteria of the second level. For all of them have been constructed the pair-wise comparisons matrices. The consistency has been less than 0.1, otherwise the decision makers had to reevaluate the comparisons matrix. For the third level, named as the sub-criteria has been constructed the decision matrices. Every matrix of the criteria, has been evaluated for its consistency IC and the consistent ratio CR. If they were consistent

then becomes the application of FAHP. In Table 10 are shown the eight criteria with the sub-criteria, and their consistency value. For all the matrices the coefficients were less or equal to 0.1. So were applied the FAHP-TFN and FAHP-TpFN method. In table 11 are shown only the ranked results. The results after have been applied FAHP – TFN have shown that based on their importance with each other every Q_i had the following rank: Q_{25}, Q_{12}, Q_9, Q_{15}, Q_5, Q_1, Q_{22}, Q_{18}, Q_{16}, Q_{10}, Q_2, Q_{26}, Q_7, Q_{14}, Q_{19}, Q_{23}, Q_{24}, Q_{21}, Q_6, Q_3, Q_{13}, Q_{20}, Q_8, Q_{11}, Q_{17}, Q_4 . So the most important question between them was Q_{25} "I use Google Classroom for writing quizzes and submitting assignments behavior", and the last important was Q_4 "If I use Google Classroom, I will increase my chances of passing the course".

The results that have been applied FAHP – TpFN have shown that every Q_i had the following rank: Q_{25}, Q_{12}, Q_9, Q_{15}, Q_{22}, Q_1, Q_5, Q_{18}, Q_{16}, Q_{10}, Q_2, Q_{26}, Q_{23}, Q_{14}, Q_7, Q_{19}, Q_{21}, Q_6, Q_3, Q_{24}, Q_{13}, Q_{20}, Q_{11}, Q_{17}, Q_8, Q_4. So the most important question between them was Q_{25} and the last important was Q_4. Both methods have ranked the questions and was found that the most important and the last important from them are the same for the decision maker, but the ranking between them differs slightly.

The most important question was Q_{25} in the Use Behavior: "I use Google Classroom for writing quizzes and submitting assignments behavior", and the last important one was Q_4: "If I use Google Classroom, I will increase my chances of passing the course" part of the Performance Expectancy construct. It was known that FAHP with TpFN numbers was the generalization of FAHP with TFN numbers [60], also had a better rank according to the expert opinions. Also, based to the unified index for comparing fuzzy numbers TFN and TpFN [61], [60] was shown that the trapezoidal FAHP method is the most suitable one, as it provides the most accurate results when compared to other methods.

4.5. Comparison results for 5-likert scale level

For the 5-likert scale have been denoted the five points with A_1=Strongly disagree, A_2=Disagree, A_3=Neither agree nor disagree, A_4=Agree, A_5=Strongly agree. Also have been evaluated the fuzzy pair-wise comparison matrices of alternatives according to each of the sub-criteria, and then have been applied FAHP method with both types of fuzzy numbers. Tables 12 and 13 have shown the results of the FAHP method for both cases. According to the theory [23], [31] the total of results preferences was compared for each of them as shown in tables below, and the one that has the highest total was the most important.

Table 12: Results for alternative level with FAHP-TFN

	A_1	A_2	A_3	A_4	A_5
Total	1.0188	1.378	1.867	2.651	1.1027
Rank	5	3	2	1	4

Table 13: Results for alternative level with FAHP-TpFN

	A_1	A_2	A_3	A_4	A_5
Total	0.93937	1.3338	1.875	2.685	1.10274
Rank	5	3	2	1	4

The findings resulted that both methods gave the same ranking (see table 12, 13). It is obvious that the total for each A_i differed slightly with both types of fuzzy numbers. So the alternative that has been the most important and the most selected in the answers was A_4 "Agree", then A_3 "Neither agree nor disagree", then A_2 "Disagree", A_5 "Strongly agree", and lastly A_1 "Strongly disagree".

5. Conclusions

Nowadays due to the situation of COVID-19 pandemic the application of Google Classroom in online teaching played an important role in high education. The evaluations for the usage of Google Classroom have been done by using the questionnaire according to the UTAUT2 model. This study found out the ranked attributes for Google Classroom, from the most to the least preferred. Attributes were three types: criteria, sub-criteria and alternative, based on the hierarchy structure proposed by this paper. In order to make better decisions, have been applied the FAHP method with two types of fuzzy numbers: triangular fuzzy numbers and trapezoidal fuzzy numbers. FAHP could capture the vagueness of the judgments, by making the fuzzy weights more objective to the goal. Based on the results of FAHP-TFN the most preferred criteria or construct was BI (Behavioral Intention), the most preferred question was "I use Google Classroom for writing quizzes and submitting assignments behavior", and the most selected alternative was A_4 "Agree". For the results of FAHP-TpFN the most preferred criteria or construct was SI (Social Influence), the most preferred question was "I use Google Classroom for writing quizzes and submitting assignments behavior", and the most selected alternative was A_4 "Agree". There was a slight difference in the criteria level for the two methods. Trapezoidal fuzzy numbers were the generalization of the triangular fuzzy numbers and have often being used by decision makers for a better selection of the attributes. This study is expected to help the user to evaluate the use of Google Classroom, and also to help policy-makers when deciding to implement e-learning. Especially these study results orient better the direction of institutions of higher learning. For the future

research recommendation, this study will be more complete to consider even the private universities and some other public universities. Maybe this will make differences in the study results. It is thought to include the master degree students, age > 22, and lecturers/tutors to show other results. An important point will be the evaluation of the hierarchy structure of the problem with gaussian fuzzy numbers, in order to eliminate the case of zero weights in order to make an optimal decision.

Appendix

A. Here we present the full questionnaire developed by the authors Venkatesh V. et al (2003), Jakkaew P., Hemrungrote S. (2017) completed by 528 students from 4 universities of Albania.

Questionnaire/Items	Source
Performance Expectancy (PE)	
1. I find Google Classroom useful in this course of math (PE1)	(Jakkaew P, Hemrungrote S)
2. Using Google Classroom enables me to achieve course related tasks more quickly (downloading notes, assignment submission,etc.) (PE2)	(Jakkaew P, Hemrungrote S)
3. Using Google Classroom increases my learning productivity (PE3)	(Jakkaew P, Hemrungrote S)
4. If I use Google Classroom, I will increase my chances of passing the course (PE4)	(Jakkaew P, Hemrungrote S)
Effort Expectancy (EE)	
1. It is easy for me to become skilful at using Google Classroom (EE1)	(Venkatesh et al 2003)
2. I find Google Classroom easy to use (EE2)	(Al-Maroof RAS, Al-Emran M)
3. Learning to operate Google Classroom is easy for me (EE3)	(Venkatesh et al 2003)
4. My interaction with Google Classroom is clear and understandable. (EE4)	(Venkatesh et al 2003)
Social Influence (SI)	
1. My friends who are important to me think that I should participate in Google Classroom (SI1)	(Jakkaew P, Hemrungrote S)
2. My peers who influence my behavior think that I should use Google Classroom(SI2)	(Jakkaew P, Hemrungrote S)
3.Other people whose opinions I value prefer that I use Google Classroom (SI3)	(Jakkaew P, Hemrungrote S)
Facilitating Conditions (FC)	
1.I have the resources necessary to participate in Google Classroom (internet smartphone etc) (FC1)	(Jakkaew P, Hemrungrote S)
2. I have the knowledge necessary to participate in Google Classroom (FC2)	(Jakkaew P, Hemrungrote S)
3. I can get help from others when I have difficulties while using Google Classroom (FC3)	(Jakkaew P, Hemrungrote S)
Hedonic Motivation (HM)	
1.Using Google Classroom is fun, compared to traditional classroom. (HM1)	(Jakkaew P, Hemrungrote S)
2. Using Google Classroom is enjoyable, compared to traditional classroom (HM2)	(Jakkaew P, Hemrungrote S)
3. Using Google Classroom is entertaining, compared to traditional classroom (HM3)	(Jakkaew P, Hemrungrote S)
Habit (HT)	
1. Using Google Classroom has become a habit for me (HT1)	(Jakkaew P, Hemrungrote S)
2. Using Google Classroom has become natural to me (HT2)	(Jakkaew P, Hemrungrote S)
3. Using Google Classroom is addictive (HT3)	(Jakkaew P, Hemrungrote S)
4. I feel that I must use Google Classroom (HT4)	(Jakkaew P, Hemrungrote S)
Behavioral Intention (BI)	
1. I intend to continue using Google Classroom in the future (BI1)	(Jakkaew P, Hemrungrote S)
2. It is worth to recommend the Google Classroom for other students (BI2)	(Al-Maroof RAS, Al-Emran M)
3. I plan to continue to use Google Classroom frequently (BI3)	(Jakkaew P, Hemrungrote S)
Use Behaviour (UB)	
1. I use Google Classroom for writing quizzes and submitting assignments behaviour (UB1)	(Kumar JA, Bervell B)
2. I use Google Classroom to interact with online materials, peers and instructor (UB2)	(Kumar JA,Bervell B)

Optimizing the Wind Farm Layout for Minimizing the Wake Losses

Abdelouahad Bellat*, Khalifa Mansouri, Abdelhadi Raihani, Khalili Tajeddine

SSDIA Laboratory, Hassan II University of Casablanca, ENSET of Mohammedia, 28830, Morocco

A R T I C L E I N F O	A B S T R A C T
	The development of wind farms requires an optimal design of wind turbines layout. The main goal of this optimization is to minimize the wake effect through the optimal placement of the wind turbines. The current study aims to standardize the wake losses among all wind turbines in the wind farm and bringing their losses to a similar level. An objective function was developed for this purpose, and used by the genetic algorithm to maximize the farm energy output and prevent the wake concentration on specific wind turbines. The proposed method has been applied to the Gasiri Wind farm through a simulation approach. The applied optimization process has shown very promising results characterized by a 17% possible energy gain after the adoption of the optimized layout. The study has also shown that the new positions of wind turbines characterized by a high rated power, are more on a forward position following the wind direction compared to the original ones. The study has also shown that there is a significant reduction of mechanical fatigue on the wind turbines blades.

1. Introduction

Increasingly growing efforts have been deployed in recent years to increase the share of clean energy production worldwide. This unprecedented interest in sustainable energy production derives from a serious ambition to prevent environment degradation and provide the much-needed equilibrium with the depletion of traditional energy resources. serious ambition to prevent environmental degradation and provide the necessary balance with the depletion of traditional energy resources. Wind power in particular is today considered one of the green sources in development in the world today. Governments across the globe are according more and more interest to the wind energy, exploiting recent industrial advances. The statistics given by the Wind Power Association clearly show that [1], wind farms represent 63% of European investments in renewable energies in recent years. These investments represent large-scale wind power harnessing farms requiring large sites and hundreds of wind turbines. Therefore, the optimization of wind farms is key component for an efficient exploitation of wind energy.

The objective of the proposed optimization in this paper is the maximization of energy and the reduction of energy losses. In order to achieve this goal, we propose to reduce the wake effects since they significantly contribute to the recorded energy losses [2]. In fact, when crossing the rotors blades of a wind turbine, a certain amount of energy is lost, wind speed decreases behind the turbines, this phenomenon reduces the yields of downstream wind turbines [3]. Indeed, the quality of the energy production produced by the wind farm is generally affected by several factors which contribute to significant energy losses [4]. Efficient wind farms design and development remains the best strategy to minimize these energy losses [5]. The main objective of our work is to establish an algorithm capable of reducing and standardizing the wake effect through all the turbines of the studied wind farm. Numerous articles have addressed this optimization problem using different types of algorithms such as genetic algorithms [6], [7], evolutionary algorithms [8], and the particle swarm optimization algorithm [9].

Generally, the computational domains for modeling wind farms are classified into two main categories, discrete representations using a grid which contains the coordinates and continuous representations with degrees of freedom greater than the discrete representation[10]. The continuous representation is highly beneficial because the wind turbines can be installed freely on the wind farm according to the 2D coordinates [11], [12]. In this case study, the genetic algorithm was chosen because of the binary coding method used.

Many research works have studied the optimized layout of wind farms using genetic algorithms, such as the work carried out in [13], [14]. However, most of these studies use the energy or cost as optimization objective. In some cases, we combine the two optimization criteria cost and energy, other studies developed by the authors in [15] have also made an optimization of the layout taking into account the effects of the consolidation of nearby offshore wind farms, which have been very developed recently. In [16], authors propose an optimization layout aiming to reduce the cost of arranging substations and cables in the offshore wind farm by exploiting an objective function that uses the level production cost. In [17], authors are used a multi-objective optimization of the layout in order to satisfy several design objectives.

The main interest of a wind farm optimization is the maximization of the energy. However, in the case of a small size land, some wind turbines can be significantly affected by the wake effect compared to other wind turbines, resulting in increased turbulence, and consequently fatigue of the wind turbine blades and reduced energy produced by the wind farm[18]. In order to address these problems an objective function has been established, aiming to maximize energy and avoid the influence of wake effect on specific wind turbines.

In this paper, we will start with the modeling of the wind farm and the used wake model, the following parts will present the objective function and the optimization algorithm applied to the Gasiri wind farm, finally a discussion of the results and conclusion are proposed.

2. Wind Farm Modeling

2.1. Wake modeling

The speed of the wind crossing the upstream Wind turbines (WT) is modified by the wake effect phenomenon. The manifestation of growing effects is marked by a reduction in wind speed and a maximization of turbulence in the windiest region. Indeed, the wind turbines placed in the wake zone generate a minimum of energy and more maintenance activities compared to upstream WT. Therefore, wake effect modeling can play à key role in determining the placement of WT. It also should be seriously considered during Wind farm design layout optimization (WFDLO).
Figure 1: Jensen wake model [19]

Indeed, different wake models have been used to show the properties of wind speed losses [20], [21]. There are two main categories: analytical wake models and computer wake models which are at the origin of the resolution of the Navier-Stokes equation and which are more precise compared to other models. They require however more computation and higher cost which makes their use in WFDLO impossible [22]. Alternatively, the analytical wind speed solution is the basis of analytical wake models, they are widely used in optimization methods, often for large WFs with a large number of WTs [23], [24]. The most used wake model is Jensen's with a linear expansion of the wake as an assumption [25]. Figure 1 describes the principle of the model developed by Jensen. The high efficiency of these models results from the power losses reliability and prediction with reasonable accuracy compared to other models as shown in [25]. Therefore, in this study, we adopt the Jensen model to calculate different wind speeds. So, the speed deficit is expressed as follows:

$$V_{df} = V_f \left[\left(1 - \sqrt{1 - C_T}\right) \left(\frac{D}{D_{wake}}\right)^2 \right] \tag{1}$$

where,

D: Rotor Diameter (m)

D_{wake}: Wake diameter (m)

C_T: Trust coefficient

V_f: Free incoming wind speed (m/s)

V_{df}: Wind velocity deficit (m/s)

The Wake diameter varies depending on rotor diameter and wake minimization coefficient, considered as constant throughout the whole study, the calculation of this coefficient is detailed in[26], [27].

2.2. Modeling of Energy Production

The estimation of energy production under the wake effect requires the calculation of the power of each wind turbine. Different expressions are commonly used to estimate the power of WT were carried out in [28]. Thus, the energy production of WT is calculated approximately as follows:

$$P_{WT} = \frac{1}{2} \rho \pi \frac{D^2}{4} C_{EF} (V_f - V_{df})^3 \tag{2}$$

where,

C_{EF} represents the efficiency factor expressed by:

$$C_{EF} = C_p \eta_m \eta_g \tag{3}$$

In this study, the C_{EF} is assumed to be 40%. The total power produced by wind turbines operating under the wake effect is:

$$P_{WF} = \sum_{i=1}^{N_t} P_{WT} \tag{4}$$

The efficiency of the wind farm is expressed by the following equation:

$$\eta_{WF} = \frac{P_{WF}}{(\frac{1}{2}\rho\pi\frac{D^2}{4}C_{EF}V_f{}^3)} \qquad (5)$$

In order to facilitate the optimization of the studied wind farm, the positions of the wind turbines are designated by the Cartesian coordinates (x,y), the distances between the turbines and the calculation of the total wind speed deficit considering the overlapping zones are detailed. In [29][18], the total velocity deficit expression is expressed by:

$$V_{dft} = \sqrt{\sum_{i=1}^{N_{up}}\left(\frac{A_{OV}}{A}\right)(V_{df})^2} \qquad (6)$$

where, A_{OV} is the Overlap area (m^2), A represents the Swept area of wind turbines (m^2) and N_{up} is the number of upstream wind turbines.

3. Methodology

3.1. Objective function

The main objective is to increase the wind farm output in terms of power and to standardize the wake losses for each wind turbine in the wind farm.

Indeed, some turbines of a wind farm are exposed to more wake effects than others, so they tend to have more problems during operation with a reduced lifespan. The objective function proposed below maximizes the energy production of WF and reduces the standard deviation of wake losses to which wind turbines are exposed.

The objective function denoted FOBJ is obtained as follows:

$$FOBJ = \max\left(\frac{P_{WF}}{1-\sqrt{\frac{1}{N_t}\sum_{i=1}^{N_t}(W_a-W_i)^2}}\right) \qquad (7)$$

Where W_a is the Mean wake loss, W_i means the Wake loss of each turbine and N_t is the number of wind turbines on the wind farm.

3.2. Optimization Algorithm

Due to the optimization difficulties, the wind farm design, and the limits of the approach to test errors and deterministic methods, the heuristic methods are chosen, being the most appropriate to solve this type of design problems. Besides, in the presented work we choose to use genetic algorithms to optimize the wind farm.

The choice to use genetic algorithms is due to the fact that these algorithms are considered to be:

- A flexible method to use and configure.
- Efficient in its ability to overcome the difficulty of local optima while exploring the design research space to converge towards the global optimum.

The flowchart of Figure 2 shows the optimization steps adopted to optimize a wind farm. In the MATLAB © software, we

entered the data and models established in the previous part, the optimization process begins to search for an optimal solution. GA research techniques include the following main steps:

- *Step 1*: Random population generation of some turbines while respecting the constraints of the problem treated.

- *Step 2*: Evaluation of objective function WF layouts through the objective function.

- *Step 3*: Contribution to the next generation population by the selection of individuals. The probability of selection in the current generation results in a selection of good individuals. The objective of the crossover operator is to alter two pairs of genes (position) in order to generate another optimization as being a crossover function, the modification of a gene in another position is managed by random activation of the mutation with a determined probability.

- *Step 4*: production of a new location of the wind turbines in the park by the genetic algorithm (GA) which changes the previous population. The above steps are iterated until the maximum number of iterations is reached. The data parameters of our algorithm are shown in Table 1.

Table 1: Defined parameters of genetic algorithm

GA Parameter	Value
Size of initial population	150
Selection pressure	3
Crossover probability	0.25
Mutation Probability	0.75
Iteration number	350

Table 2 contains basic features of the wind turbine (HS50, U50, HJWT77) used in the Gasiri wind farm.

Table 2: Basic information of three types WTs

Wind turbines features	HS50	U50	HJWT77
Rated power (kW)	750	750	1500
Hub height (m)	50	50	70
Rotor diameter (m)	50	50	77
Cut-in wind speed (m/s)	3.5	3	3.5
Rated wind speed (m/s)	12	12.5	13
Cut-out wind speed (m/s)	25	25	25

It is mandatory to initialize the proposed algorithm by information on the characteristics of the wind farm and the model chosen for the present study. Table 3 summarizes the data needed to successfully kickstart the genetic algorithm.

3.1. Case Study: Gasiri Wind Farm

In this part, the study focuses on optimizing the layout of wind turbines in the case of the Gasiri wind farm using the objective function described previously. The results obtained in this study will be compared with other results from the same wind farm [30].

Table 3: Input data for the genetic algorithm

Site characteristics	Matrix of design variables	Models
Wind speed and direction	Configuration	Wake model
Wf size	Limit distance between	Power model
Roughness	WT design variables	WT design variables

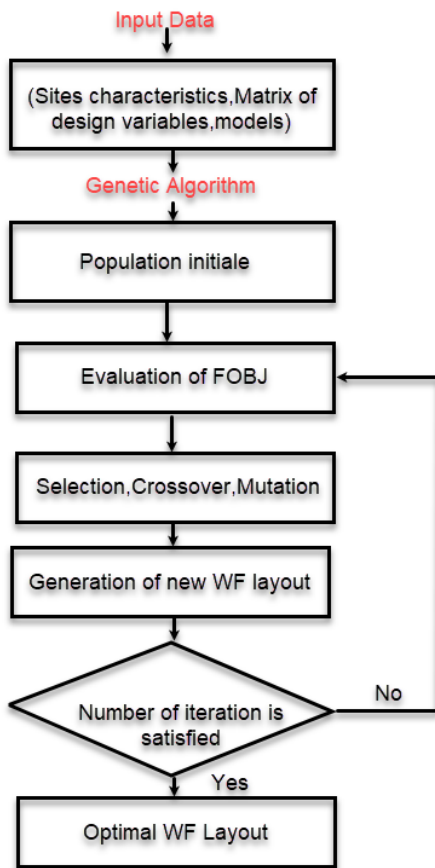
Gasiri wind farm is located in South Korea, precisely on Jeju Island; the distribution of the wind turbines and the wind rose are depicted in Figure 3. The Gasiri wind farm, contains 13 wind turbines of three types (HS50-750 kW, U50-750 kW, HJWT77-1500 kW). In figure 3, the wind turbines are placed in a grid following the NNW direction, this direction is considered to be the dominant direction of the wind on the Gasiri wind farm.


Figure 2: Genetic algorithm for WFDLO

The optimization of the wind farm requires a MATLAB code using the wind data, mentioned in Figure 3, Table 1, Table 2 and Table 3.

The calculation results of the annual AEP energy production are compared with the collected electricity production data in the Gasiri wind farm, as shown in Figure 4, there is a little difference between the real data and the calculated results but significantly more accurate than previous results obtained in the literature [30] using other types of algorithms. The difference is mainly due to the

choice of the used wake model and the actual operation of each wind turbine. Equally large 750 kW wind turbines are not taken into account in the calculation because they have a low recovery rate due to the data collected. Figure 5 summarizes the results collected and calculated.

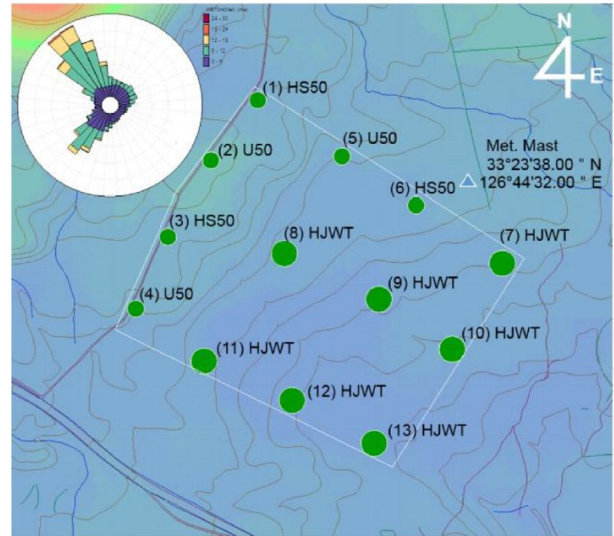
The calculation of the annual production of the wind farm is based on the operating assumption of 365 days per year which is equal to 8760 hours.


Figure 3: Arrangement of wind turbines and wind rose in the Gasiri wind farm [30]

The expression to calculate the annual production is expressed as follows:

$$AEP = 8760 \sum_{i=1}^{N_t} \sum_{j=1}^{N_d} \sum_{k=1}^{N_s} F(U_{ijk}) P(U_{ik}) \quad (8)$$

where $F(U_{ijk})$ is the probability of wind blowing in speed bin k of turbine i at direction sector j, $P(U_{ik})$ is the power of wind turbine i at wind speed bin k, and N_d and N_s represent the division by direction interval of total bearing and the value determined by dividing the range of speed (3-25 m/s) by the range of wind speed respectively.
Figure 4: Comparison of the AEPs collected from Gasiri wind farm with the computed AEPs
Figure 5: Difference in annual energy production between collected and computed energy

4. Results and Discussion

Figure 6 describes the variation of the objective function. We can clearly see that the total performance of the process of our algorithm improves and converges from 350 iterations. The objective function has a high value to be applied, because of the relative size of the value of the objective function which is not related to the accuracy of the optimal layout.

The difference in annual energy production between the collected energy data and the calculated energy is presented in Figure 5, the obtained results shows that the calculation of the sum of the annual production of wind turbines is equal to 23.51. Furthermore, in the case where the collected information on the production is equal to 23.48, this small difference of 0.03 is due to the simplifying assumptions and the uncertainties of the used wake model.
Figure 6: FOBJ evaluation using GA (genetic algorithm)

The calculation domain of our wind farm is delimited as mentioned in Figure 7. The spacing between the wind turbines is set at 230m in order to guarantee the minimum of 3 * D (rotor diameter). Therefore, to improve the free arrangement of wind turbines, the wind turbine location area has been divided into 120 * 110 cells having dimensions of 10m * 10m with respect for prohibited placement zones.

The optimization of the Gasiri wind farm is obtained using the algorithm in figure 8, then is compared by the position of the existing layout. Note that the HJWT77 type wind turbines which

have a high rated power value tend to move forward following the direction of the wind. This can also be explained by the fact that the loss of wakes becomes minimal in the forward positions as shown in Figure 8.
Figure 7: Coordinates of the wind turbines of the Gasiri wind farm
Figure 8: Gasiri wind farm layout optimization results obtained using objective function
Figure 9: Annual energy production for existing layout and optimized layout obtained using objective function

It can be also seen that low-capacity wind turbines tend to move from their positions in the existing configuration and follow the direction of the prevailing wind in accordance with [30] who used the optimization with the simulated annealing algorithm but at levels of annual production the proposed optimization

technique is eventually much more accurate than [30]. The annual energy production of wind turbines 7, 8, 9, 10, 11, 12 and 13, has increased while turbine number 1 has decreased from the current state Figure 9.

This significant increase for the turbines mentioned above is mainly due to the new designated positions following the windiest direction. The net annual energy production is summarized in the Table 4, we can also observe that the difference in the net AEP of the wind farm in the optimized case is 5.68 which is greater than the case of the existing configuration.

However, this annual power increase, in the case of the Gasiri wind farm, shows that the used objective function has achieved the expected goals of minimizing the undesirable effects of wake for all wind turbines which are exposed to these losses and of maximizing the power of the wind farm.
Figure 10: wake losses for the existing layout and the optimized layout

Figure 10, shows a comparison of wake losses between the existing layout and the optimized layout, we can clearly note that there is a significant reduction in wake loss for the optimized layout. This significant improvement justifies the benefice of using the proposed objective function in the genetic algorithm. Such choice leads to finding an optimal arrangement which maximizes the production of energy and standardizes the wake losses for all the wind turbines of the Gasiri wind farm.

Table 4: Comparison of annual energy production among existing layout and optimized layout

Wind Turbine number	Net AEP/Gross AEP	
	Existing layout	Optimized layout
1	1.45/1.52	1.41/1.60
2	1.59/1.69	1.73/1.8
3	1.47/1.56	1.51/1.58
4	1.54/1.58	1.66/1.75
5	1.42/1.55	1.41/1.56
6	1.38/1.54	1.52/1.65
7	3.72/4.15	4.05/4.85
8	3.50/4.06	4.51/5.10

By examining more in details, the results of Figure 11, we can see that the level of wake loss becomes more or less uniform in all the wind turbines, this prevents the difference in energy losses between the different wind turbines of the Gasiri wind farm.
Figure 11: uniformity of wake losses for optimized layout

Moreover, such measures maximize the energy production. Table 5 presents a comparison of the wake losses between the existing layout and the optimized layout. It can be noticed that there is a significant reduction in the level of wake losses which is -18.67 %, this reduction is the result of the new optimized arrangement of the wind turbines which prevents the interference generated between the upstream and downstream turbines. Furthermore, we see a small difference between the wake loss results in the case of an optimized layout which indicates that the wake loss variable follows a uniform law.

Table 5: wake loss percentage values between the existing layout and the optimized layout

Wind turbine number	Wake loss (%)	
	Existing layout	Optimized layout
1	5.16	10.02
2	5.72	8.10
3	6.13	9.02
4	2.32	9.8

12	13.87	10.17
13	14.38	8.06
Total	137.07	118.4
Difference	(-)18.67	

5. Conclusion

In this article, a study of the optimization of a wind farm using a new approach is presented. An objective function was adopted trough the mean of a genetic algorithm in order to optimize the wind turbines layout. This method aims to maximize the energy

production and minimize the wake losses for all wind turbines in the wind farm. The presented method applied to the Gasiri wind farm has shown promising results, it didn't just minimize the wake losses but also uniformizes it among the wind turbines in the farm. The new layout shows that optimized positions of the wind turbines with higher rated power tend to slide forward with the wind direction. Moreover, the analysis of the simulation results in the current study indicates that the adoption of this optimized layout grants a 17% energy gain compared to the existing layout and ensure a considerable reduction in levels of wake losses estimated at -18%.

The layout optimization in this study was primarily based on a cost function targeting the minimization of wake losses. In future studies we aspire to study the correlation between the arrangement of wind turbines using a multi-objective function and the cost related to this optimization.

A B S T R A C T

This research designed an image encryption system that focused on securing teledermatology data in the form of skin disease images. The encryption and decryption process of this system is done on the client side using chaos-based encryption with confusion and diffusion techniques. Arnold's cat map is the chaotic map model used for confusion, while the Henon map is used for diffusion. The initial values of both chaotic maps are obtained from a 30-digit secret key that is generated using Diffie–Hellman key exchange. During Arnold's cat map generation, different p and q values are used for every iteration. On the other side, the precision of the Henon map's x and y values is 10–14. From the tests that have been done, histograms of the encrypted images are relatively flat and distributed through all the gray values. Moreover, the encrypted images have average correlation coefficients of 0.003877 (horizontal), -0.00026 (vertical) and -0.00049 (diagonal) and an average entropy of 7.950304. According to the key sensitivity test, a difference of just one number in the secret key causes big differences, as both results have a similarity index of 0.005337 (0.5%). Meanwhile, in the decryption process, that small key difference cannot be used to restore the encrypted image to its original form and generate another chaotic image with average entropies of 7.964909333 (secret key difference) and 7.994861667 (private key difference).

1. Introduction

Today, most of the information on the Internet is in the form of images, which may contain confidential information, such as patients' medical records. In daily life, clinics or public health centers sometimes find it difficult to determine patients' disease, and they need the help of hospitals or more experienced medical experts for analysis and diagnosis. Therefore, images of patients' medical records must be sent from the clinic/public health center to the destination hospital. The problem is patients' medical records are confidential and contains sensitive data. There are also regulations and legal protection of medical records. For example, Indonesia's medical records regulation can be seen in [1]. So there has to be a way to maintain the security of patients' medical records, which can be done by performing image encryption [2].

Basically, image encryption is a technique that is performed with the aim of protecting the content conveyed therein. This encryption is done by transforming the image into another form so that it does not contain meaningful information and cannot be understood visually or statistically. In general, there are two types of image encryption: traditional encryption and chaos-based encryption. Traditional encryption uses common encryption algorithms, such as the Data Encryption Standard (DES), International Data Encryption Algorithm (IDEA), or Advanced Encryption Standard (AES). Chaos-based encryption uses a sequence of (pseudo-)random numbers called chaotic maps as a key for encrypting images. Of these two types, chaos-based encryption is more suitable for use with images because the image consists of information (i.e., image pixels) with high redundancy and correlation, and the resulting encrypted image will be random and have low correlation between pixels. In contrast, traditionally

encrypted images have more patterns, so they are more vulnerable to attack. In this study, two chaotic map models will be used: Arnold's cat map for confusion or shuffling pixel positions and the Henon map for diffusion or changing gray values [3, 4].

To generate a chaotic map, there are several parameters that can be described as the key to the encryption and decryption process in this system. The generated chaotic map is influenced by these values, so the encryption and decryption process must use exactly the same parameter values. The slightest change to this value will result in a different output matrix, so there must be a mechanism that ensures the encryption and decryption process uses the same parameter values. In [4], author use the shared-key cryptography with Diffie-Hellman method to secure the key exchange process [5].

2. Literature Review

Chaos-based image encryption, commonly known as a chaotic system, is an approach to encrypting an image that involves chaotic maps, which are rows of random numbers generated by a mathematical calculation with certain initial values. This system is widely used in image encryption for several reasons: (1) it sensitive to initial values, (2) the resulting numbers are random, and (3) there are no patterns in the random number sequence, so it is difficult to predict [3, 6].

In general, there are two techniques that can be performed with chaos-based image encryption: confusion and diffusion. [6] Confusion involves shuffling the pixel positions that make up an image, while diffusion involves changing pixels' gray values. In encryption, both techniques should be used; the use of just one can reduce the power of the encryption. In [7], the author used chaotic system, the chaotic map plays a major role in both the confusion and diffusion processes. One of the chaotic map models that can be used for confusion is Arnold's cat map (ACM), and one of the chaotic map models that can be used for diffusion is the Henon map, which is a mathematical model of the discrete-time dynamic system.

2.1. Arnold's Cat Map

ACM is a chaotic map model that is used to randomize the pixel positions in an image. It was first introduced by Vladimir Arnold as a way to shuffle an image of a cat. Mathematically, this concept works by stretching and distorting a square shape and then reassembling it into the same shape [8, 9].

Since it was introduced, ACM has been intended to randomize the pixel position of an image so that it does not look the same, which is a confusion technique. ACM works by scrambling a pixel's position without changing the value of the pixel itself. This can be done using the following formula [8,9]:

$$\begin{bmatrix} x_{n'} \\ y_{n'} \end{bmatrix} = A \begin{bmatrix} x_n \\ y_n \end{bmatrix} mod \ N \tag{1}$$

$$\begin{bmatrix} x_{n'} \\ y_{n'} \end{bmatrix} = \begin{bmatrix} 1 & p \\ q & pq+1 \end{bmatrix} \begin{bmatrix} x_n \\ y_n \end{bmatrix} mod \ N \tag{2}$$

Although ACM is a chaotic map, if iterations are repeated many times, it is possible that the original image will be rearranged because the ACM concept relies on position randomization only. According to researchers, up to 3N iterations may be needed to return to the original image, where N is the dimension of the image [10].

Arnold's cat map is commonly used for image encryption by shuffling the image pixels but actually it can be used to encrypt other form of multimedia data. In [11] and [12], there are good examples of audio encryption using Arnold's cat map for securing voice communication. Arnold's cat map can also be used to watermark an image or video, which is useful for tamper detection. In [13] and [14], there are some good examples of image watermarking, and [15] for video watermarking using Arnold's cat map.

2.2. Henon Map

The Henon map is one of the most commonly studied discrete-time dynamic system models, and it has chaotic properties. It was first introduced as a simplification of the Lorenz model. It is formed by using a point (x_n, y_n) to map the next point using the following equation [16].

$$x_{n+1} = 1 - \alpha \ x_n{}^2 + y_n \tag{3}$$

$$y_{n+1} = \beta \ x_n \tag{4}$$

In equations (3) and (4), x_n and y_n are the current point positions, while x_{n+1} and y_{n+1} are the next point positions. In the initial conditions, the values of x_n and y_n become initial values that will determine the next points. The slightest change in x_n and y_n in the initial conditions can have a big impact on the map that is formed [4, 17, 18].

The classic Henon map uses values of $\alpha = 1.4$ and $\beta = 0.3$, which causes the results to be chaotic. Changes in both values can result in changes in the nature of the resulting map, which may not even be chaotic anymore [17, 18].

In image encryption, the Henon map model is often applied as a key stream generator for diffusion techniques or changing pixel values in images. To create this chaotic map, two initial values are needed, namely, the initial x and y values (x_0 and y_0). These are the key to establishing chaotic maps that will be used in both encryption and decryption processes [4, 17, 18].

Chaotic maps are formed by calculating the Henon map formula with $m \times n \times$ bpc iterations ($m \times n$ represents the dimensions of the image, and bpc represents the number of bits in each pixel. For each iteration, a new x_n and y_n value is obtained and then converted to a bit value (0 or 1) using a threshold value which will later be converted to gray values for each pixel until the chaotic map is sized $m \times n$. In [18] Previous research [19] concluded that the cut-off value should be set at 0.3992 so that the sequence of numbers produced using the Henon map will be balanced. Thus, the decimal value x_n obtained at each iteration will be converted into binary form using a threshold value of 0.3992 based on the following equation:

$$Z_i \begin{cases} 0 \ if \ x_i \leq 0.3992 \\ 1 \ if \ x_i > 0.3992 \end{cases} \tag{5}$$

2.3. Diffie–Hellman Key Exchange

The Diffie–Hellman key exchange (DH) is a method created for safe key exchange through public channels. It addresses the challenges that exist in a symmetrical cryptographic system, which uses only one key for encryption and decryption. Without using this method, key exchanges on symmetric cryptographic systems are performed outside the system, generally conventionally, to avoid key exchanges via public channels such as the Internet. [20]

DH offers the possibility of using both public and private keys for actual key exchange. The two keys are not related to the encryption process that will be carried out, but only serve to produce the actual key. Each client has a private key that only they known. From this private key, a public key can be generated through equation (6) [5, 20]:

$$Public = g^{private} \bmod p \qquad (6)$$

where p is the prime value and g is the value of the agreed-upon generator. The resulting public key can be given to other people because it plays a role in creating a secret key for the two clients. To produce this secret key, the sender must perform a mathematical computation involving their private key and the recipient's public key using equation (7) [5, 20]:

$$Secret = public^{private} \bmod p \qquad (7)$$

Likewise, when the recipient engages in decryption, the recipient must compute their private key and sender's public key to produce a secret key that will be used in the encryption process. [20]

3. Proposed Model

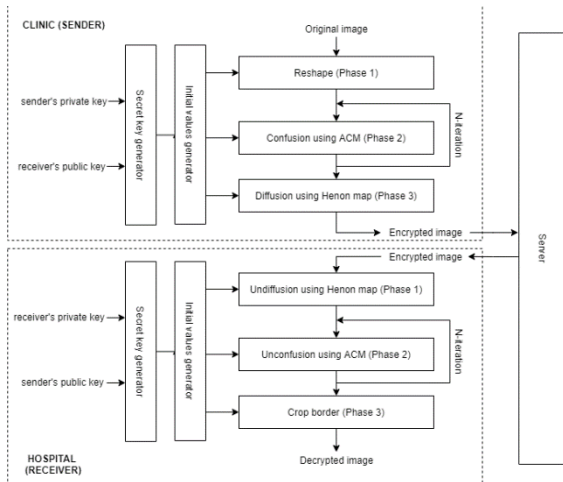
In general, the system involves three parts: sender, receiver, and server. However, the implementation in this research only covers the client side; server settings have not been determined. The sending and receiving client side is where the Chaos-Based Image Encryption Program was run. The clinic/public health center, as the sending client, performs the encryption function, and the hospital, as the receiving client, performs the decryption function. The architecture of the whole system can be seen in Figure 1.


Figure 1: Encryption and decryption architecture

According to this architecture, in order to carry out encryption and decryption, two types of inputs are required: keys and images. Two keys—a private key and a public key—are needed to produce a secret key that will be converted into initial values when making the chaotic map. After the image is encrypted, the image will be saved to the server so that it can be retrieved by the receiver for decryption. There are three stages of encryption: reshaping, confusion, and diffusion. Likewise, there are three stages of decryption: undiffusion, unconfusion, and crop border.

This research uses chaos-based encryption with a combination of confusion and diffusion methods. The choice of chaos-based image encryption is based on the nature of the image, which

contains information (i.e., pixels) that have a high degree of redundancy and correlation with each other. By applying this type of encryption, the resulting image will be random, so it will have low redundancy and correlation between pixels. Another factor that reinforces the choice of chaos-based encryption is the nature of the chaotic maps we used, which are sensitive to changes in initial values or parameters. A slight change in the initial values will result in chaotic maps or rows of random numbers that have significant differences. This phenomenon is commonly referred to as the butterfly effect. Thus, this type of encryption is used to overcome statistical analysis attacks, which is more difficult with chaotic-based encryption results because of the randomness of the pixels making up the encrypted image [3, 21].

The combined use of confusion and diffusion is based on the nature of confusion, which shuffles pixels but does not change their values. This makes the image unrecognizable but still vulnerable to most attacks. Therefore, we used diffusion to change the pixel values of the randomized image. By using a combination of confusion and diffusion, the encryption results become more random and difficult to predict. In this encryption system, different chaotic maps are used for confusion and diffusion; Arnold's cat map is used for confusion, while the Henon map is used for diffusion. This is done to increase resistance to attacks because each method uses a different mathematical model. In addition, we chose them because they have many dimensions and are both two-dimensional chaotic maps [21].

The encryption system designed and developed in this research is based on several previous studies. Eko Hariyanto and Robbi Rahim previously explained the use of Arnold's cat map to encrypt images using the confusion technique in a study entitled "Arnold's Cat Map Algorithm in Digital Image Encryption." In [9], author explained how Henon maps could be used to encrypt images by applying a combination of confusion and diffusion in a study entitled "A Chaotic Confusion-Diffusion Image Encryption Based on Henon Map" [22]. In addition, the author described the use of Arnold's cat map and the Henon map to encrypt images in a study entitled "A Chaotic Cryptosystem for Images Based on Henon and Arnold Cat Map" [4].

In terms of the methods and algorithms used, the encryption method developed in [4] is the closest to the form of encryption developed in this research. The difference is that, in this research, the dimensions of the image are reshaped to form a square at the beginning of the encryption process so that the image can be processed as a whole. In previous studies, there was no such stage, so the input image had to be square or some information would be truncated. In addition, this study used initial values obtained through a set of secret keys produced by calculating the combination of the private and public keys with the DH algorithm. In previous studies, there was no generation of a secret key that was used as the initial values. Further, this study used different *p* and *q* variables in each iteration of Arnold's cat map following a set of numbers taken from the secret key (more details will be discussed in the next section).

3.1. Secret Key and Initial Value Generation

In this Chaos-Based Image Encryption System, several initial value parameters are needed for the encryption and decryption processes during both the confusion and diffusion stages. Therefore, in this design, a random sequence of numbers will be used as the initial value parameter. To decrypt the image perfectly, it is necessary to use the same initial value parameters that are used

during the encryption process, so the keys used for encryption and decryption must be the same. However, the use of the same key in the encryption and decryption process has a weakness: it is possible for the key to be obtained by a third party.

Therefore, to secure the key, this design uses the DH method to produce the key that will be used as the initial values in the encryption and decryption process. In this key exchange mechanism with the DH method, each client has a private key and a public key that are used to generate a secret key. A secret key is needed to perform encryption/decryption, so the secret key generation process must be carried out before running the encryption/decryption process.

After the secret key is obtained, numbers are broken into several parts to be used as initial values in the confusion and diffusion stages. Two initial values are needed for the Henon map: x and y. From this solution, the first 28 key numbers for the Henon map will be broken into 14 digits each. After that, the 14 numbers will be made into decimal fractions $0 < x < 1$. The larger decimal will be used as the value of x, and the smaller one will be used as the value of y. In ACM, three parameters are used, namely, p, q, and the number of iterations. The first half of the secret key is the value of p, and the last half is the value of q. The number of iterations is obtained from the sum of the last 6 digits of the secret key. In this design, the p and q values used in each ACM iteration will be different but still in accordance with the allocated value. For example, in the first iteration, the values 30 and 60 are used, then the second iteration uses the values 04 (or 4) and 03 (or 3), and so on. The illustration of initial value generation can be seen in Figure 2.

Figure 2: Illustration of initial value generation

3.2. Encryption Process

In this design, the image encryption mechanism consists of two main stages, namely, the preparation and manipulation of pixels. In the preparation stage, the image color model is converted to RGBA (red, green, blue, alpha), and the size or dimensions of the image are rectangular. For example, if the original image is 400 × 600, the image will be changed to 600 × 600. The gap between the initial size and the square size (referred to as the border) will be filled with new pixels that have an alpha value of 254, while the original pixel image has an alpha value of 255. Alpha is the channel in the RGBA color model that determines pixel transparency, with a value of 0 indicating transparency and a value of 255 indicating non-transparency. The newly added pixels are given a value of 254 in order to distinguish which pixels are the original pixels in the image and which ones are the border during the decryption process. The newly added pixels have randomly generated values with a range of 0–255. At the pixel manipulation stage, there are two phases: confusion and diffusion. In both

phases, several initial value parameters are used. The values for these parameters are obtained through the secret key, as was explained in the previous section.

3.2.1. Confusion Using Arnold's Cat Map

Confusion is the first pixel manipulation process performed using this image encryption system. Basically, the confusion process involves shuffling or randomizing the position of the pixels comprising the image so that it cannot be recognized anymore. In this design, ACM is used as a chaotic map model to determine the displacement of a pixel.

At the beginning of the formation of ACM, three parameters are needed, namely, p, q, and the number of iterations, which are all positive numbers. The values of the three parameters are obtained from the secret key constituent numbers, as explained in the previous section. The ACM formula is as follows:

$$\begin{bmatrix} x_{n'} \\ y_{n'} \end{bmatrix} = \begin{bmatrix} 1 & p \\ q & pq+1 \end{bmatrix} \begin{bmatrix} x_n \\ y_n \end{bmatrix} mod\ N \qquad (8)$$

where p and q are parameters and N is the size or dimensions of the image. Formula (8) produces a matrix containing $x_{n'}$ and $y_{n'}$, which is the new position. For each time this calculation is performed, the pixels in position (x_n, y_n) will be moved to $(x_{n'}, y_{n'})$. This calculation is carried out continuously until all pixels are shuffled. The displacement of pixel positions in the matrix can be performed more efficiently using the meshgrid, which is one of the functions of Python NumPy. First, the meshgrid will be made for x and y with a size of $N \times N$ to indicate the original position of the pixels in the image. Then, from the two meshgrids, two xmap and ymap matrices will be formed using formula (8), indicating the new pixel position. Thus, the pixel value at its original position (i.e., [x,y]) will be moved to a new position according to (xmap,ymap). This process will continue to be repeated as many times as the iteration parameter has been set. To ensure that the resulting matrix is more random and difficult to predict, in this design, the values of p and q will vary with each iteration by taking two numbers from the overall values of p and q obtained from the secret key.

3.2.2. Diffusion Using the Henon Map

The main concept of this diffusion process is to perform XOR operations on a matrix of image pixels generated by the confusion process with a chaotic map matrix. This system uses the Henon map as the chaotic map model.

At the beginning of the formation of the Henon map, two initial values are needed, namely x_n and y_n. Just like in the confusion stage, the two initial values are obtained from the secret key constituent numbers, as explained in the previous section. In this system, the values of x_n and y_n are between 0 and 1, with a precision level of 10^{-14}. This means that changes in values as small as 10^{-14} can affect the results of the diffusion. In addition to x_n and y_n, there are other parameters, namely, α and β. In this system, the values of $\alpha = 1.4$ and $\beta = 0.3$ are used so that the resulting Henon map is chaotic.

To create a chaotic map, a Henon map formula is calculated with an iteration of m × n × bpc times (m × n represents the dimensions of the image, and bpc is the number of bits in each pixel). For example, if the image to be processed is a 512 × 512 8 bpc image, then the iteration will be performed 512 × 512 × 8, or 262,144, times.

For each iteration, new x_n and y_n values (x_{n+1} and y_{n+1}) are obtained. From these results, the value of x_{n+1} will be converted to a bit value (0 or 1) using a threshold value of 0.3992 according to the results of [19]. In other words, if the value of x_{n+1} is greater than 0.3992, it will produce a value of 1, but if it is smaller or equal to 0.3992, it will produce a value of 0. Then, the bit will be inserted into the bit sequence. The x_{n+1} and y_{n+1} values generated in the current iteration will be x_n and y_n for the next iteration. At each bpc iteration of a certain multiple, the resulting bit sequence will be converted into a decimal form that will represent the gray value of a pixel. For example, in the 8 bpc image, the bit sequence will be changed to a decimal in the 8th, 16th and 24th iterations, and so on. After all the iterations are finished, a chaotic map will be produced with dimensions m × n.

After the chaotic map is formed, bitwise XOR operations will be performed between the image pixels generated by the confusion process with the chaotic map at the bit level. The results of the XOR operation are stored in a new matrix and become the results of the diffusion process. Diffusion is the last process carried out in this series of encryption processes, so the results are the result of this image encryption system.

3.3. Decryption Process

The flow of decryption is the opposite of encryption, which is divided into undiffusion, unconfusion, and crop border phases. The undiffusion and unconfusion processes involve manipulating image pixels that aim to return the encrypted image pixels to their original values and positions. In both phases, several initial value parameters are used. The values for these parameters are obtained through the secret key, as explained in the previous section. To decrypt the image into its original form, the initial value parameters used in the undiffusion and unconfusion processes must be the same as those used in the diffusion and confusion processes during encryption. Differences in values can cause the image to not be decrypted.

After going through the undiffusion and unconfusion phases, there is one more phase that must be completed, namely, the crop border process. In this phase, the original image has been seen, but the dimensions of the image are still not in accordance with the original due to changes in the image dimensions in the encryption process. Therefore, a crop border is performed to remove the pixels added during the encryption process so that the image returns to its original dimensions.

3.3.1. Undiffusion using the Henon Map

The undiffusion process is the opposite of the diffusion process performed at the time of encryption. If diffusion involves changing the value of the pixels that make up the image, the undiffusion process restores encrypted image pixels to their original values. The approach is the same as that carried out during the diffusion process: one makes chaotic maps and then performs a bitwise XOR operation. This can be done with an XOR operation because of its reversible characteristics. The only difference between the diffusion and undiffusion processes is the operand. During the diffusion process, an XOR operation is performed between the confusion matrix and the chaotic map, whereas in the undiffusion process, an XOR operation is performed between the encrypted matrix and the chaotic map. To restore encrypted image pixels to their original values, the chaotic map used in undiffusion must be the same as that used during the diffusion process. Chaotic map

mismatch will cause the pixel values to change from the original values, so the image will not be successfully decrypted.

The unconfusion process is the opposite of the confusion process during encryption. In the confusion process, the original image's pixel positions are randomized, so the pixel positions in the encrypted image are not the same as in the original image. As for the unconfusion process, the pixel positions in the encrypted image, which have been scrambled, will be returned to their original positions. The formula used for unconfusion is as follows:

$$\begin{bmatrix} x_n \\ y_n \end{bmatrix} = \begin{bmatrix} 1 & p \\ q & pq+1 \end{bmatrix} \begin{bmatrix} x_{n'} \\ y_{n'} \end{bmatrix} mod\ N \qquad (9)$$

By using formula (9), the original position of a pixel is obtained (x_n,y_n). Each time this calculation is performed, the value of a pixel at position ($x_{n'}$,$y_{n'}$) will be returned to its original position (x_n,y_n). The calculation is carried out continuously until all the pixels return to their original positions.

The displacement of pixel positions in the matrix can be performed more efficiently by using a meshgrid, as in the confusion process. First, a meshgrid for *x* and *y* of *N* × *N* size will be created to indicate the pixel position in the encrypted image. Then, from the two meshgrids, two xmap and ymap matrices will be created using formula (9), indicating the new pixel position. Thus, the pixel at the position of [xmap, ymap] will be moved to the position of [x, y]. This transfer is the reverse of that performed in the confusion process because the purpose of the unconfusion process is to return the pixels in the encrypted image to their original positions. This process will be repeated as many times as the number of iterations that has been set. The number of iterations carried out in the unconfusion process must correspond to the number of iterations performed during the confusion process. Mismatch in *p*, *q*, or the number of iterations will cause the pixels in the image to not return to their original positions. Just like in the confusion process, the *p* and *q* values in the unconfusion process change with each iteration, but inversely; the *p* and *q* values used in the last iteration in the confusion process will be the *p* and *q* values of the first iteration in unconfusion, and so on.

3.3.2. Unconfusion using Arnold's Cat Map

The unconfusion process is the opposite of the confusion process performed during encryption. In the confusion process, the original image's pixel positions are randomized, so the pixel positions in the encrypted image are not the same as in the original image. As for the unconfusion process, the pixel position in the encrypted image, which have been scrambled, will be returned to their original positions. The formula used in the unconfusion process is as follows:

$$\begin{bmatrix} x_n \\ y_n \end{bmatrix} = \begin{bmatrix} 1 & p \\ q & pq+1 \end{bmatrix} \begin{bmatrix} x_{n'} \\ y_{n'} \end{bmatrix} mod\ N \qquad (10)$$

By using formula (9), the original position of a pixel is obtained (x_n,y_n). Each time this calculation is performed, the value of a pixel at position ($x_{n'}$,$y_{n'}$) will be returned to its original position (x_n,y_n). This calculation is carried out continuously until all the pixels return to their original positions.

The displacement of pixel positions in the matrix can be performed more efficiently by using a meshgrid, as in the confusion process. First, a meshgrid for *x* and *y* of *N* × *N* size will be created to indicate the pixel position in the encrypted image. Then from the two meshgrids, two xmap and ymap matrices will

be created using formula (9), indicating the new pixel position. Thus, the pixel value at the position of [xmap, ymap] will be moved to the position of [x, y]. This transfer is the reverse of that performed in the confusion process because the purpose of the unconfusion process is to return the pixels in the encrypted image to their original positions. This process will be repeated as many times as the number of iterations that has been set. The number of iterations carried out in the unconfusion process must correspond to the number of iterations performed during the confusion process. Mismatch in p, q, or the number of iterations will cause the pixels in the image to not return to their original positions. Just like in the confusion process, the p and q values in the unconfusion process change with each iteration, but inversely; the p and q values used in the last iteration in the confusion process will be the p and q values of the first iteration in unconfusion, and so on.

4. Test and Analysis

4.1. Image Encryption Testing Using Confusion

In this test, encryption was performed on 30 images with only confusion, using ACM as the chaotic map. An example of the encryption result can be seen in Figure 3.

(a)   (b)
Figure 3: (a) Original image and (b) image encrypted using confusion

From the results of this test, we can see that the image does not show the characteristics of the original image because the pixel positions have been shuffled. However, the colors in the encrypted image are the same as the colors in the original image because no pixel values were changed during encryption; new pixels were only added to reshape the image into a square.

In terms of pixel distribution, the histogram generated from 30 encrypted images has the same pixel distribution trend as the original image's histogram. A comparison between the histograms of the original image and the encrypted image can be seen in Figure 4. Although the trends shown by the two images look similar, it should be noted that the number of pixels is different. In the original image, there are several pixels with a value of 0, whereas in encrypted images there are none. This happens because, during the encryption process, new pixels with random values are added to reshape the image into a square. Thus, the number of pixels considered in the histogram increases. Confusion does not change the pixel values at all, so it does not change the distribution of pixel values in the image. Thus, it can be concluded that the confusion method is not safe enough by itself.

Then, analysis of the correlation between pixels is performed by calculating the correlation coefficients between the neighboring pixels horizontally, vertically, and diagonally. Correlation coefficient values range from -1 to 1, where 1 indicates perfect correlation, 0 indicates no correlation at all, and -1 indicates negative correlation. This calculation is performed three times for each channel (red, green, and blue), and then the average value is calculated. A comparison of the average correlation coefficients of the original image and the encrypted image can be seen in Table 1.

(a)   (b)
Figure 4: Histogram of (a) the original image and (b) the image encrypted using confusion

Based on the average correlation coefficient, the neighboring pixels in the original image have a strong linear correlation, with correlation coefficients close to 0. By contrast, in the encrypted image, the correlation coefficients between neighboring pixels are close to 0. This shows that the confusion method successfully weakens the correlation between neighboring pixels in an image.

Table 1: Comparison of average correlation coefficients of the original image and the image encrypted using confusion

Correlation coeff.	Horizontal	Vertical	Diagonal
Original image	0.984251	0.981887	0.974224
Encrypted image	-0.08009	-0.0462	0.084784

After that, entropy analysis is performed to calculate the level of uncertainty of the pixel values in the encrypted image. The ideal entropy of encrypted image is $\log_2(256)$, which equals 8. A comparison of the average entropy of the original and encrypted images can be seen in Table 2.

We can see that images encrypted with confusion have higher entropy than the original image, with an average entropy value above 7. In theory, confusion should not change the entropy value of the image because there is no change in the pixel value. However, in this test, a greater entropy value was obtained because, during the encryption process, new pixels with random values are added to change the shape of the image into a square. The addition of these random pixels makes the entropy value increase from 6.912776 to 7.401581. Even so, the encrypted image with this entropy value is not secure enough and is still predictable. Encrypted images are considered to be safe if they have an entropy value close to 8, which indicates that the pixels in the image are difficult to predict.

Table 2: Comparison of the average entropy of the original image and the image encrypted using confusion

	Entropy
Original image	6.912776
Encrypted image	7.401581

4.2. Image Encryption Testing Using Diffusion

In this test, encryption was performed on 30 images with only diffusion, using the Henon map as the chaotic map. An example of the encryption results can be seen in Figure 5.

We can see that the image does not represent the original color, but instead consists of a variety of random colors. This is a result of changing the image's gray values during encryption. Nevertheless, even though it is very vague, the object or shape depicted in the original image is still visible because no randomization of pixel positions was performed during encryption.

(a)   (b)
Figure 5: (a) Original image and (b) image encrypted using diffusion

In terms of pixel distribution, the histogram of encrypted image is very different from the original image. When viewed as a whole, 30 histograms of encrypted images have the same characteristics; every possible gray value is fairly diffused to all image pixels due to the use of a diffusion method that changes pixel values. An example of a comparison of the original and encrypted images' histograms can be seen in Figure 6. This is because of the nature of the Henon map, which produces a sequence of random numbers that produces very diverse gray values when an XOR operation is performed on the pixels of the original image.

(a)   (b)
Figure 6: Histogram of (a) the original image and (b) the image encrypted using diffusion

Then, the correlation analysis between pixels is performed by calculating the correlation coefficients between the neighboring pixels horizontally, vertically, and diagonally. This calculation is performed 3 times for each channel (red, green, and blue), and then the average value is calculated. A comparison of the average correlation coefficient of the original image and the encrypted image can be seen in Table 3.

From the average correlation coefficient, it can be seen that the neighboring pixels in the image encrypted with diffusion have almost no correlation at all. Indeed, the coefficients are very close to 0, which are even smaller than those for the image encrypted with confusion.

Table 3 Comparison of average correlation coefficient of the original image and the image encrypted using diffusion

Correlation coeff.	Horizontal	Vertical	Diagonal
Original image	0.984251	0.981887	0.974224
Encrypted image	0.000195	-0.00035	-0.00107

After that, entropy analysis is performed to calculate the level of uncertainty of the encrypted image. A comparison of the average entropy of the original and encrypted images can be seen in Table 4. Using the entropy calculation, we can see that encrypted images with diffusion have a much higher entropy than the original image, with an average entropy of 7.950477, which is very close to 8. The entropy value produced in this test is even greater than the entropy value of the image encrypted with confusion in the previous test. This happens because diffusion changes the pixel values, which makes the distribution of pixel values in the image more random. The entropy value of 7.950477

indicates that the pixels in the encrypted image with diffusion are random and difficult to predict.

Table 4 Comparison of the average entropy values of the original image and the image encrypted using diffusion

	Entropy
Original image	6.912776
Encrypted image	7.950477

4.3. Image Encryption Testing Using a Combination of Confusion and Diffusion

In this test, encryption was performed on 30 images with a combination of confusion and diffusion, using ACM and Henon map as the chaotic maps. An example of the encryption results can be seen in Figure 7.

(a)   (b)
Figure 7: (a) Original image and (b) image encrypted using a combination of confusion and diffusion

We can see that image does not represent the original color because the pixel value has been changed at the time of encryption during the diffusion stage. On the other hand, the characteristics of the original image are not visible because the encryption process is done by randomizing the position of the pixel image during the confusion stage.

In terms of pixel distribution, the histogram produced in this test is the same as histogram in test B (diffusion only), although the method used in this test is a combination of confusion and diffusion. An example comparison of the histogram of the original image and the encrypted image can be seen in Figure 7. This can occur because confusion does not change the pixel value, and the value of the pixel changes at only the diffusion stage.

Just like the results of the histogram in test B, all histograms in this test have the same characteristics; every possible gray value is fairly diffused to all pixels in the image due to the use of a diffusion method that changes pixel values. An example comparison of the original and encrypted image histograms can be seen in Figure 8. This is because the Henon map produces a sequence of random numbers, so that very diverse gray values are produced when an XOR operation is performed on the pixels of the original image.

(a)   (b)
Figure 8: Histogram of (a) the original image and (b) the image encrypted using a combination of confusion and diffusion

Then, correlation analysis between pixels is performed by calculating the correlation coefficients between the neighboring

pixels horizontally, vertically, and diagonally. This calculation is performed three times for each channel (red, green, and blue), and then the average value is calculated. A comparison of the average correlation coefficient of the original image and the encrypted image can be seen in Table 5.

Based on the average correlation coefficient, which is very close to 0, the neighboring pixels in the image encrypted with only diffusion have almost no correlation at all.

Table 5: Comparison of the average correlation coefficients of the original image and the image encrypted with a combination of confusion and diffusion

Correlation coeff.	Horizontal	Vertical	Diagonal
Original image	0.984251	0.981887	0.974224
Encrypted image	0.003877	-0.00026	-0.00049

After that, entropy analysis is performed to calculate the level of uncertainty of the encrypted image. A comparison of the average entropy values of the original and encrypted images can be seen in Table 6. Based on the entropy calculation, the images encrypted with diffusion have a much higher entropy value (an average of 7.950304, which is very close to 8) than the original image. The entropy value produced in this test is even greater than the value of the image encrypted with only confusion, and it is more or less the same as the value of the image encrypted with only diffusion. This happens because diffusion changes the pixel values, which makes the distribution of pixel values in the image more random. The entropy of 7.950304 indicates that the pixels in the image encrypted with diffusion are random and difficult to be predicted.

Table 6: Comparison of average entropy of original and encrypted images using confusion and diffusion combined

	Entropy
Original image	6.912776
Encrypted image	7.950304

4.4. Image Encryption Testing Using Modified Secret Keys

In this test, IMG_0130 (a photo taken by the clinic) and ISIC_0024306 (a dataset image) are encrypted using the secret key, **64628632896829413501795 4110561**, producing the image shown in Figure 9. This is the original key that will be used for comparison in a key sensitivity analysis. After that, the encryption test was performed again using the 30 modified secret keys. In this system, the secret key is not actually known by the client because it is the result of DH, but to discover the sensitivity of the key used as the initial values for encryption in this test scenario, an encryption test will be performed using a modified secret key.
Figure 9: Encrypted image: (a) IMG_0130 and (b) ISIC_0024306, which used the original secret key

In each test, the modified secret key is one number different from the original secret key, starting from the largest number (10^{29}) to the smallest (10^0), while the other 29 numbers are the same as the original numbers. Variations of the secret key in this test can be seen in Table 7.

Table 7: Modified secret keys

| Trial no.	Modification precision	Secret key
1	10^{29}	**5**46286328968294135017954110561
2	10^{28}	6**3**6286328968294135017954110561
. .	. .	. .
29	10^1	646286328968294135017954110**5**51
30	10^0	6462863289682941350179541105**6**0

In this test, an analysis is performed by calculating the similarity index (SSIM) to determine the level of similarity between the image encrypted using the original secret key and the one encrypted using the modified secret key. The SSIM index has values ranging from 0 to 1, with 1 meaning that the images are identical or entirely the same. The results of SSIM calculations of the original encryption and encryption with the modified key can be seen in Table 8.

The images encrypted using the original secret key and modified secret key have very significant differences, as indicated by the very small similarity index. In the first 28 trials, which had modification precision of (10^{29}) to (10^2), the similarity index results were only around 0.005, or about 0.5%. In contrast, for the secret key modification of the last two numbers, which had levels of precision of (10^1) and (10^0), the similarity index is around 0.12, or 12%, as the Henon map (diffusion) uses only the first 28 numbers as initial values. Thus, the secret key used to determine the initial values in the encryption process is very sensitive to changes; even the slightest change in the smallest number can generate a completely different image.

Table 8: Similarity index between encrypted image using original secret key and modified secret key

Modification precision	Similarity index (SSIM)		Average
	IMG_0130	ISIC_0024306	
10^{29}	0.00485	0.00556	**0.005205**
.	.	.	.
	.	.	
10^2	0.00497	0.00628	**0.005625**
10^1	0.09249	0.1496	**0.121045**
10^0	0.09231	0.14984	**0.121075**
		Total Average	**0.005337**

4.5. Image Decryption Testing Using Modified Keys

Two kinds of tests are conducted. The first is decryption of the encrypted image in Figure 9b using 30 secret keys, as shown in Table 7. These secret keys are modifications of the actual secret key (**64628632896829413501795 4110561**). The second test is decryption of the encrypted image in Figure 9b using a public key and a private key. This test was conducted 30 times using 30 private keys, as shown in Table 9. These private keys are modifications of the actual private key (**88573348446640252688 8140697877**). The public key used in the tests is always the same (**2037989140015237406 19069244784**).

The first test is carried out to determine the secret key's sensitivity to the resulting encrypted image, while the second test is more like a simulation of image decryption in real circumstances by an attacker (not the actual recipient). This is done because in the image encryption program designed in this research, the user must enter their private key and the sender's public key to be able to decrypt the image. Therefore, the second test in this test scenario is intended to determine the sensitivity of the private key to the encrypted image that is generated.

Table 9: Modified private keys

Trial no.	Modification precision	Private key
1	10^{29}	**7**857334844664025268881 40697877
2	10^{28}	**8**757334844664025268881 40697877
. .	. .	. .
29	10^{1}	8857334844664025268881 406978**6**7
30	10^{0}	8857334844664025268881 406978**6**

From the results of the tests that have been carried out, no image has been successfully decrypted to its original form, but in the last two trials of the decryption test with secret key modifications, the decrypted images represent the colors of the original image, which can be seen in Figure 10.
Figure 10: The last two trials of the decryption test using the modified secret keys
Figure 11: Histograms of the decryption results obtained using modified secret keys (1st, 28th, 29th, and 30th trials)

This section analyzes the decryption results with histogram and entropy analysis. Histograms for the decryption test using modified secret keys can be seen in Figure 11. Overall, the histograms show uniform pixel distribution, except for the 29th and 30th trials. This type of pixel distribution is caused by differences between the initial Henon map values used in the encryption and decryption processes. When the initial values used in the decryption process are not the same as those in the encryption process, an entirely different chaotic map is generated rather than restoring the pixels to their original values. In the 29th and 30th experiments, because the initial values of the Henon map used for decryption were the same as the values used for encryption, the trend of pixel distribution matches the original image, indicating that the encrypted pixel values have returned to their original values. Meanwhile, in the ACM, the initial values

were not the same, so the pixels in the image did not return to their original positions.

Histograms for the decryption test performed using modified private keys can be seen in Figure 12. From these histograms, we can see that all the trials—both those using the Henon map and ACM—failed to decrypt the image to its original form.
Figure 12: Histograms of the decryption results obtained using modified private keys (1st, 28th, 29th, and 30th trials)

Next, entropy analysis was performed to prove that the decryption results are random and difficult to predict. The results of entropy calculations can be seen in Table 10. The failed decryption trial makes the entropy value greater, which means that the image is more random and more difficult to predict. Indeed, the overall entropy is above 7.99, which is very close to 8. However, in the 29th and 30th trials of the secret key modification test, the entropy values of only around 7.54.

Table 10: Entropy of decryption results obtained using modified keys

Trial no.	Image	Entropy	
		Modified secret keys	Modified private keys
1	IMG_0130	7.99484	7.9948
. .	. .	. .	. .
28	ISIC_0024327	7.99468	7.9948
29	ISIC_0024328	7.54545	7.99492
30	ISIC_0024329	7.54545	7.99486

Of the two tests that were carried out, the scenario in the second test, in which the encryption system is designed to use both a public key and a private key as well as a secret key that is a combination of both, is more likely to occur in real life. However, it is also possible for the attacker to use direct brute force on the secret key that is generated. Key space analysis is needed to prove that the keys are secure enough.

Both the secret key and the private key in this design consist of decimal numbers with a length of 30 characters. Thus, there are 10^{30} permutations. Key spaces of this length can overcome brute force attacks.

4.6. Algorithm Complexity Analysis

There are three stages of encryption that are carried out sequentially, namely, reshaping, confusion, and diffusion. During the reshaping phase, the image is converted into a square, adding new pixels to fill in the blanks. Therefore, in this section a random number of $N \times N$ is filled in, where N is the largest dimension of the original image. If calculated using Big-O notation, it is **O(N^2)**. Then, confusion is performed with several operations:

1) Generate a meshgrid of $N \times N$ size, calculated as O(N^2).
2) Loop as many as I iterations, calculated as O(I).
3) Take p and q from the secret key, calculated as O(2×1).
4) Generate an xmap and ymap by calculating the ACM of the values in the meshgrids x and y, calculated as O(2×N^2).

5) Move pixels from position (x, y) to position (xmap, ymap), calculated as $O(N^2)$.

Throughout this calculation, the constant Big-O notation can be removed from the calculation because of its very small effect compared to $O(N^2)$. Therefore, from this confusion stage, we obtain a complexity calculation of $O(N^2) + O(I) \times O(3N^2) = \mathbf{O(N^2) + O(I \times 3N^2)}$.

Diffusion is performed as follows:

1) Loop as many as $N \times N \times 8$ iterations, calculated as $O(8N^2)$.
2) Calculate xN and yN with the Henon map formula, calculated as $O(2\times1)$.
3) xN and yN become x and y values for the next iteration, calculated as$O(2\times1)$.
4) Convert xN to binary bit by using a threshold. In the worst-case scenario, there are four operations that must be performed, so it is calculated as $O(4\times1)$.
5) Insert binary bits into the bit sequence, calculated as $O(1)$.
6) Check whether the current iteration is a multiple of 8, calculated as $O(1)$.
7) If it is a multiple of 8, convert the bit sequence into decimal form, empty the bit sequence, and then insert the decimal value into the chaotic matrix. All of these operations are counted as $O(3\times1)$.
8) After all the iterations are finished, perform an XOR operation between the chaotic matrix and the image matrix for each channel, calculated as $O(3\times8N^2) = O(24N^2)$.

From this confusion phase, we obtain a complexity calculation of $O(8N^2) \times (O(2) + O(2) + O(4) + O(1) + O(1) + O(3)) + O(24N^2) = \mathbf{O(132N^2)}$. When combined, the entire encryption algorithm has a complexity of $O(N^2) + O(N^2) + O(I \times 3N^2) + O(132N^2)$, or $\mathbf{O(3I+134)N^2}$, where I is the number of iterations at the confusion stage and N is the largest dimension of the original image. Based on the complexity notation, the performance and time needed to run the encryption process are influenced by the large number of iterations that must be done at the confusion stage as well as the largest dimension of an image. Of these factors, the largest dimension of the image has the most influence on performance and the time needed to carry out the encryption/decryption process, as indicated by the notation in the form of quadratic time.

The decryption process has more or less the same complexity as the encryption process. The undiffusion and unconfusion stages of decryption perform similar numbers and types of operations to the diffusion and confusion stages of the encryption process, so the complexity calculation is the same. The only difference between decryption and encryption leis in the reshape phase; in the worst-case scenario, the process of returning the image to its original form (crop border) has an operating complexity of $\mathbf{O(2N+3N^2)}$. Thus, the overall complexity of the decryption algorithm is $O(2N+3N^2) + O(N^2) + O(I \times 3N^2) + O(132N^2)$, or $\mathbf{O(2N + 136N^2 + I \times 3N^2)}$.

Overall, there is not much difference between the complexity of encryption and decryption. Similar to the encryption process, the performance and time required to carry out the decryption process are affected by the large number of iterations that need to be performed at the unconfusion stage as well as the length/width of the image to be decrypted. The length/width of the image is the factor with the biggest influence.

5. Conclusions

There are several conclusions that can be made based on the tests conducted in this research:

1. Chaos-based image encryption using only the confusion method is not secure enough, as evidenced by the fact that the pixel distribution trend is similar to the original image and the average entropy value is 7.401581.
2. Chaos-based image encryption using only the diffusion method is secure enough based on the distribution of pixels on the histogram, the average correlation coefficient (which is very close to 0), and the average entropy (7.950477). However, the characteristics of the original image are still vaguely visible.
3. Chaos-based image encryption using a combination of confusion and diffusion methods is the most secure encryption method based on pixel distribution on the histogram, the average correlation coefficient (which is very close to 0), and the average entropy (7.950304). Implementing two methods is more secure because there are two layers of security.
4. Implementation of ACM in the confusion phase with different p and q values in each iteration makes pixel positions more random and difficult to predict.
5. The initial values of the Henon map have a sensitivity level of at least 10^{-14}.
6. A difference of just one number in the secret key during the encryption process results in a significant difference in the encrypted image, as evidenced by the average similarity level of around 0.5%. This indicates that changes in the initial values of the ACM or Henon map can make a big difference in the encryption results.
7. A difference of just one number in the secret key during the decryption process causes the image to not be restored to its original shape and produces a stronger random image with entropy values closer to 8.
8. A 30-character numeric key has a high level of security because there are 10^{30} permutations that might be generated.
9. The largest dimension of an image (length/width) is the factor with the most influence on the performance and time involved in running the encryption/decryption process.

"This paper is an extension of work originally presented in the 4th International Conference on Systems of Collaboration, Big Data, Internet of Things & Security -SysCoBIoTS'19".
The use of complex and dynamic systems modelling to social systems is quite recent and its pertinence in the case of an educational system is continually increasing. For the concrete management of educational systems, a global approach is required. This approach must take into consideration the effects of many parameters that can act and interact together thus making, as a result, the system more or less efficient. Our aim is to develop a model that can capture the dominant dynamics of these systems while being at the same time simple enough to be useful for analyzing, simulating, and quantifying the impact of different parameters on the global performances of educational systems. By viewing education systems as skills production systems and by applying Business Processing modelling methods, a modelling of education systems is proposed in the present work which allows studying the effects of a set of parameters on the behavior of the system and its performance. The focus will be done on the study of the impact of learners' input competence on the performance of a training unit and on the performance of a training program. The obtained simulation results allow us to analyze the evolution of a training program's behavior as well as estimates its performance under the effect of the variation of simulation factors. These results enable to measure the performance variation according to the learners' input competence, their ability to acquire skills, and to the class size. This modelling enables us to test solutions for performance improvement.

1. Introduction

Education is a determining factor for growth and development and education systems and socio-economic development are closely related and interact with each other [1]. Indeed, an education system enables individuals to improve their productivity and increase their employability, and at the community level, it improves the competitiveness and attractiveness of the economy through the availability of skilled human capital. As a result, developing effective education systems whose performance can be quantified and ensured becomes an important issue at many levels for managers and all stakeholders.

But several questions arise: what defines an education system as a high-performing one? How can the performance of an education system be evaluated? What makes an education system efficient? What are the factors that impact its performance? How can we act on these factors to improve this performance?

Answers to these questions are not obvious as far as education systems are complex systems and having tools allowing the objective evaluation of their performance is still a goal to achieve due to the multidimensional and complex nature of these systems.

In [2]-[4], the authors have dealt with the reasons and some consequences of the complex nature of education systems and their nonlinear behavior.

This complexity is related to the existing interconnections between the different levels of educational systems starting from kindergarten to reach high schools and universities. Low performance at one level tends to affect the global performance at subsequent levels. Furthermore, individual's performance in

schools is influenced by several other systems. Education is in fact part of a larger system whose elements, such as economics, culture, society, and politics, interfere with it.

Education systems are also time-dependent and, changes in education often take a long time. Implemented policies may show results many years later, sometimes decades after their implementation. Another issue is that behaviors and actions of one part of the educational system tend to affect other parts of the system. This complexity can lead to unpredictable consequences of implemented actions. Effective management of education systems, therefore, requires a global approach that oversees the effect of all the parameters considered as a whole to ensure an efficient system operation.

Modelling can be one of the useful methods to evaluate performance and to identify the factors or areas of improvement of this performance. Modeling a system consists of designing a representation of this system for analysis and simulation purposes to answer questions. There can be several models for the same system with different levels of precision depending on the phenomena to be studied. Identification of the appropriate model will depend on the questioning under consideration [5].

The use of complex and dynamic systems modelling to social systems is quite recent and its pertinence in the case of an educational system is continually increasing [2]. The main challenge is to develop a model that can capture the dominant dynamics of these systems while being at the same time, simple enough to be useful for analyzing, simulating, and quantifying the impact of different parameters on the global performances of these systems

Several works have focused on the modelling of education systems. They concerned areas such as design, operations, analysis of performance, and management.

In the field of production engineering, studies on education systems modelling have focused on developing an analogy between education systems and systems of production of goods and services. Once this analogy was established, methods and methodologies for production systems modelling were applied to education systems while adapting them to the specificities of the latter. This works has enabled the transfer of business process modelling tools to the field of education and thus provided models for various purposes such as quality assurance, computerization of processes, or the design of new systems.

In this way, in [6], the author used the SADT method (Structured Analysis and Design Technique) for the analysis and the functional decomposition of a school using Le Moigne's systemic approach. Based on CIMOSA (Computer Integrated Manufacturing Open Systems Architecture) and IDEF0 (Integrated Computer-Aided Manufacturing Definition), he proposed modelling of the skills production system and engineering design of this system.

In [7], a model for resource specification for the planning of training activities using UML (Unified Modelling Language) and a model of the business processes of an education system using MECI (Modélisation d'Entreprise pour la Conception Intégrée) are proposed.

In higher education, in [8], the author proposed a model for quality improvement by identifying the skills that graduates must acquire and proposes the activities and means to achieve this objective by using business process modelling BPM.

In relation to the increasing use of digital technologies, the author in [9] proposed a personalized training path per learner according to his/her individual capacity to optimize academic performance using Petri nets.

In [4], the author investigated the application of dynamic systems modelling for educational policy analysis to a better understanding of the dynamics of the current system and the design of evolution scenarios for the future. He applied this approach during a case study during the school year 2007-2008 in the American state of Rhode Island.

Another class concerns the demographic models used for the simulation of educational policies and strategies. This is the case of the EPSSIM code (Education Policy and Strategy Simulation Model) [10] which is a generic model designed by UNESCO. It provides technical and methodological support for the elaboration of educational development plans. It is a demographic model in which schooling objectives are considered as decision variables and expenditures are calculated as a consequence of the achievement of these objectives. It essentially allows the students flow simulation and costs calculations.

These models, which remain partial, can simulate the behavior of the system for a reduced number of basic quantitative parameters and require a high degree of granularity to ensure their operationality and reliability of their results

This paper aims to present an educational system model for studying the impact of various parameters on the behavior of the system and to estimate its performance. The focus will be on the study of the impact of learners' competencies deficit on the performance of a training program.

2. Modelling of an education system

2.1. Modelling a training unit

A previous work [11], allowed us to propose a model of an education system that makes it possible to simulate its behavior to predict its long-term evolution, to evaluate its performance, and to simulate the impact of some factors on the evolution of this performance.

According to previous works which consider that an educational system can be defined as a competence production system [6] and also that any system which includes, even partially, in its missions the increase of learner skills can be considered as a part of an educational system [12], the approach conducted for the modelling of such system consists in proposing a decomposition of this system to introduce the notion of training unit which is the basis of the proposed modelling.

Despite the specificities of each country, educational systems at the global level are fairly homogenous and exhibit a quite similar central core. Therefore, most educational systems around the world have four educational levels: pre-primary, primary, secondary, and tertiary. The present simulation considers also that each training cycle, provided usually in an educational institution,

can be further divided into training programs, with each program composed of a limited number of courses consisting of a defined number of sessions.

Similarly, to the goods or services production systems, educational systems have organizational units, these are the training units. A training unit aims to transform business object inputs (can be physical or informational) into business object outputs within a framework of objectives and constraints fixed by the external conduct rules of the unit. A training unit can correspond to different parts; it can be a whole educational system, a training cycle, a training institution, or even a single classroom session. Thus, the reconstruction of the global system can be done by grouping a range of training units in parallel and/or in series according to well-defined rules.

To model the training unit, we relied on models based on BPM tools and mainly the work related in [13] where the author suggests using a generic processor to characterize the activities of both the physical and decision systems to evaluate its performance. A generic processor is an entity that performs one or more basic transformation activities, and that fits into the structure, thus modifying its behavior and performance. By organizing a set of generic processors in a network, it creates a particular state of the production system which is characterized by a performance level.

Thus, the training unit is an entity of the training system with the objective to transform the inputs competencies' level of the learners into a higher level of output competencies respecting the constraints and objectives of the educational system and thus to contributes to the achievement of the overall objectives of the training system. The reconstruction of the global system will then be reconstructed by grouping together a set of training units, either in parallel or in series according to well-defined rules.

Thus, the objective of a training unit is to increase the level of competencies of learners starting from an input reference competency C_r to a level above an output reference competency C'_r on a fixed time h, by using resources and based on conduct and achievement data as shown in Figure 1.
Figure 1: Model of a training unit

Educational systems present a particularity insofar as learners are co-producers of the service they use. In fact, each student has his own sensitivity to the process of skills acquisition. The objectives to be achieved by a training unit are defined during the design of this training unit. In this way, the reference input competencies needed to correctly follow this training activity, the reference output competencies to be reached, the resources required to carry out the activity, the conduct of data, and the achievement data are defined.

The interest of this modelling lies in the possibility of decomposing or aggregating the education system into networks

of generic processors of different levels and by extension the possibility of evaluating the global or detailed performance of the training system on any level of abstraction.

The educational system is modeled as a series of training units interacting with each other to produce the targeted competencies.
Figure 2: reconstitution of training units into a training program

Figure 2 illustrates an example of aggregating a set of training units by levels to reconstruct a training program. Each level groups together a defined set of training units and each training unit aims to achieve a defined increase in learner's competencies. Resources to be mobilized for a training unit to carry out its activity are defined, as well as related data of realization, data of conduct, and the launcher of the activity of the processor. The rules relating to the access of a learner from one level to the next level are also fixed, thus determining the time evolution of the training program.

This model allows the identification of what the training unit does, its function, as well as the determining factors for its functioning. Subsequently, the current modelling is associated with a simulation model which is built on the educational production function [14] and the learner's theories' results [15] in order to simulate the behavior of the system over time and the effect of some factors on its performance in a quantitative manner.

2.2. Mathematical model a training unit

The training unit is associated with a mathematical model based on the educational production function, that is written in a general form as follows [14]:

$$A = f^*(X1, ..., Xn) \tag{1}$$

where A is some measure of output, expressed as a function of a set of variables X1.....Xn.

In [11], the output A was the increase of competence level of a learner, noted as ΔC_i, while the parameters X_i that will be taken into consideration, at first approximation, are the duration of the training unit, the personal capacity of each learner μ_i, the input competence which represents the characteristics of the learners, the class size and a score for the pedagogical methods which represent some parameters of the resources and the data of conduct. The

other parameters remain constant throughout the simulation and therefore they will not impact the variation of ΔC_i.

Thus, expression (1) may be expressed as follows:

$$\Delta C_i = f(h, \mu_i, k, g) \qquad (2)$$

where ΔC_i is the competence level's increase of the learner i, h the training unit's duration, μ_i the individual capacity of competence acquisition of the learner i, k the coefficient representing the gap between the input competence of learner i and the required input competence of the training unit; g the coefficient taking into account the effect of the class size and the pedagogical methods.

An approach to specifying the function f and the relation linking the parameters h, μ_i, and g to the output ΔC_i to carry simulations is presented in previous work [11].

Expression (2) becomes as follows:

$$\Delta C_i = \frac{(C'_r - C_r)}{2} \cdot \left[1 - \frac{erf\left(\sqrt{\alpha} \cdot \left(-h + \frac{h_r}{2} \right) \right)}{erf\left(\sqrt{\alpha} \cdot \frac{h_r}{2} \right)} \right] \cdot \mu_i \cdot g(n) \cdot k\left(\frac{C_i}{C_r} \right) \quad (3)$$

Where C'_r is the output competence's reference, C_r is the input competence's reference, h the training unit's real duration, h_r the training unit's reference duration, α a parameter characterizing the progressivity of the evolution of the level of competence during the training.

The coefficient μ_i, which is specific to each learner, expresses his ability to achieve the expected competencies with more difficulty ($\mu_i < 1$) or more ease ($\mu_i > 1$) than was projected in the design of training. The reference value for μ_r is 1.

For the coefficient g, we assume, in a first approximation, that a change in excess (resp. in default) of the class size is not beneficial (resp. beneficial) to the learner, so we can use a linear relation to model this coefficient as follows:

$$g(n) = b \ if \ n > n_{max}$$

$$g(n) = b + ((a-b)/2)*n \ if \ n_{min} < n < n_{max} \qquad (4)$$

$$g(n) = a \ if \ n < n_{min}$$

where n is the ratio of the number of students in the group to the number recommended by the pedagogical method, a and b are the maximum and minimum values taken by the function g(n) when the group size is above a value n_{max} or below n_{min}.

Note that for the simulation results that will be presented here, we have used another relation instead of (4), which seems more adapted even if it presents similar characteristics, it is given by:

$$g(n) = b + \frac{(a-b)}{(1+n^4)} \qquad (5)$$

A possible lack of the input competence C_i is taken into consideration through a factor $k(C_i/C_r)$ which reflects the difference between the learner's input competence C_i and the reference input competence C_r required by the training unit.

2.3. Performance of a training unit and a training program

Following [11], performance can be defined as the ratio of the actual result obtained as process output to an expected result under standard conditions to be defined.

The training unit's result is determined as all competence increases accomplished by the students and validated following the outbound validation rules.

The expected standard result can be considered as the sum of the increases in the levels of competencies that are assumed to be validated by the learners when all the parameters of the production function of the training unit defined by relation (3) are taken equal to the reference values of the parameters.

Therefore, the training unit performance can be expressed as follows:

$$P = \frac{\sum_{i=1}^{n}(C'_i - C_i)}{(C'_r - C_r)*n_r} \qquad (6)$$

where P is the performance of the training unit, $(C'_i - C_i)$ the competence level increase of learner i having successfully validated the training unit, n is the number of learners who validate the unit, and $(C'_r - C_r)*n_r$ is the expected increase in the competence level of the class when all parameters are equal to their reference values.

A training program is considered as a network of interconnected training units distributed by the level of training with rules for transition from one level to another. The training units of a training level are connected in parallel and form a block and each training unit performs a defined competence increase activity. Thus, a training program that consists of n blocks, each block consisting of k training units, is schematized by a network of m processors such that m=n*k. The training units are denoted U_{ij} where i (1 ... n) denotes the number of the block to which it belongs and j (1 ... k) its classification within the block.

To define the performance of the training program, the performance of the training blocks making up the training program must first be defined.

We can then define the performance of block i of training units P_i as follows:

$$P_i = \frac{\sum_{j=1}^{k} \sum_{x=1}^{g_{ij}} (C'_{xij} - C_{xij})}{\sum_{j=1}^{k} (C'_{rij} - C_{rij})*g_{rij}} \qquad (7)$$

where $\sum_{j=1}^{k} \sum_{x=1}^{g_{ij}} (C'_{xij} - C_{xij})$ is the sum of all the increases in competencies of the learners who have validated the training units that constitute the training block, $\sum_{j=1}^{k} (C'_{rij} - C_{rij}) * g_{rij}$ is the sum of all the increases in competencies expected by the training units when the other parameters values are those of the reference data.

The performance of the training program can be calculated as the average performance of the training blocks weighted by the respective numbers of learners and can be translated by the following expression:

$$P = \frac{\sum_{i=1}^{n} P_i * g_i}{\sum_{i=1}^{n} g_i} \qquad (8)$$

where, P_i is the performance of training block i, g_i is the overall number of learners in block i, and n the number of blocks in the training program.

Thus, a model based on a mathematical formulation and a numerical simulation is obtained, it allows the calculation of the performance of a training program, based on the performance of the training units constituting this program. The effects on the overall performance of the training program of the variation of different parameters can thus be simulated and quantified.

This model was used in [11] to show the effects of the individual capacity of the learner's competence acquisition, as well as the pedagogical method's sensitivity in association with the group's size on the performance of a training unit.

The objective of this paper is to analyze the effect of the learner input competencies deficit factor on the behavior of a training unit and its performance and also to extend the approach to the case of a training program.

3. Impact of the input competence factor: results and discussion

For the chosen model, the education system is approached as an organized whole for skills production, composed of training units linked in parallel, and series according to rules of arrangement. Each unit has its own training objective, which is to increase specific skills of learners from a given level of competence at the input, assumed to be achieved by all entrants to the unit, to a higher level of competence at the output. The specificity of such a system is that the learners are co-producers of the service they use, which means that their characteristics will influence this increase in competencies. In fact, not all entrants to training have reached the required input level of competence and do not also have the same aptitudes for the acquisition of new skills.

Several studies have shown the important role of the learner in the process of competencies acquisition [16]-[18].

In a study using a multilevel model to identify the most important variables affecting students' performance [16], the authors have found evidence that both the students' and their families' characteristics play a role in the former's performance.

As stated in [19], precedent results and skills already acquired are strongly linked to the ease with which students will develop new skills, and thus have a real effect on their academic performance. In [20] and [21], the authors highlighted the importance of prior knowledge for success in studies.

In previous works [11], the personal characteristics of the learners are incorporated into the model through two factors. The first factor is the "personal capacity for competence acquisition μ_i" factor, which is specific to each learner and for each training unit and which is dedicated to taking into account the specific aptitudes of a learner allowing him to more easily assimilate new content. The impact of this factor on the increase in competencies and on the performance of a training unit was analyzed.

The second factor is the learner's prior knowledge through a "k" factor which quantifies the inadequacy between the student's input competence and the competencies entry level required by the training unit. In what follows, we will focus on the role of the latter, by establishing the effect of the factor k on the development of student's competence, on the training unit's performance, and on the training program's performance.

3.1. Evolution law of the coefficient $k(C_i/C_r)$

The goal sought is to establish an expression of the factor k which includes in the model defined by equation (3) the fact that a learner who would have a lack of competence at the entry of the training unit is less efficient in achieving the expected skills increase during the training. For that, we introduce the following expression:

$$k\left(\frac{C_i}{C_r}\right) = \left(\frac{C_i}{C_r}\right)^2 e^{[1-\left(\frac{C_i}{C_r}\right)^2]} \qquad (9)$$

Equation (9) allows a variation of the coefficient k between the values 0 and 1, with k = 0 when C_i = 0 and k = 1 for C_i = C_r. This reflects the fact that a learner with a zero value of input competence, cannot progress through the training, and a learner who has required competence at the entry should achieve the expected level of competence at the output. While if a learner has achieved a level of competence C_i above the reference input level C_r, the benefit of training is less and allows only a small increase of competence.

The graph below shows the evolution of the factor k as a function of the ratio C_i/C_r.
Figure 3: Evolution of the coefficient k as defined to the expression (9)

The mathematical model of the training unit (3), coupled to (9), is then given by the following expression:

$$\Delta C_i = \frac{(C_r'-C_r)}{2} \cdot \left[1 - \frac{erf\left(\sqrt{\alpha}\cdot\left(-h+\frac{h_r}{2}\right)\right)}{erf\left(\sqrt{\alpha}\cdot\frac{h_r}{2}\right)}\right] \cdot \mu_i \cdot \left(b + \frac{(a-b)}{(1+n^4)}\right) \cdot \left(\frac{C_i}{C_r}\right)^2 e^{\left[1-\left(\frac{C_i}{C_r}\right)^2\right]}$$
$$(10)$$

We will therefore consider three situations for the simulations. The first one shows the effect of the input competence on the competence increase's evolution, the second simulation concerns the effect of this factor on the training unit's performance and the third simulation reveals the effect of this factor associated with other factors on the training program's performance.

3.2. Simulation on the evolution of the increase of competence

The simulations to be carried out aim to determine the effect of the learners' skill level at the beginning of a training course on the progression of skills acquisition during the training process.

To illustrate this impact, we consider three groups of learners, the first group identified by a level of skills C_i below the required reference level C_r, the second having a skills level C_i equal to the required level, and the third having a level above the required level.

For the three groups, we consider all the other parameters of the simulation set to their reference values i.e. the training hours' number performed h is consistent regarding the reference duration of the training unit h_r ($h = h_r$), the students have a competence acquisition capacity $\mu_i = \mu_r$ and the coefficient g(n) is equal to 1.

Expression (10) above then allow simulation of the increase of competence in each of the three cases
Figure 4: Input competence's effect on the competence increase

Figure 4 shows the input competence's effect on competence increase. The learner who starts the training with a deficit of competence's input (curve point), will not reach the expected competence's output. On the opposite, a learner with a competence's input greater than the required level accomplishes an output competence higher than the expected reference competence.

These results are in concordance with the studies [19], [20] and [21] that establish links between preceding results and skills previously acquired by the learners and the ease with which they acquire new skills

3.3. Simulation of the input competence's effect on the performance of a training unit

The goal set here is to simulate the effect of the variation in the input competence factor "k" on a training unit performance. Given the particularity of the educational systems in which every learner is a co-producer of his own competence increase according to his individual capacity of acquiring competencies μ_i, this factor is introduced in the following simulations.

Since the purpose is to focus on the input competence factor's variation, the other parameters are set to their reference values for the training unit, namely (C_r, C'_r, h_r, n_r) as well as the training unit validation's rule that defines the minimum value of ΔC that the learner must reach to validate the training unit.

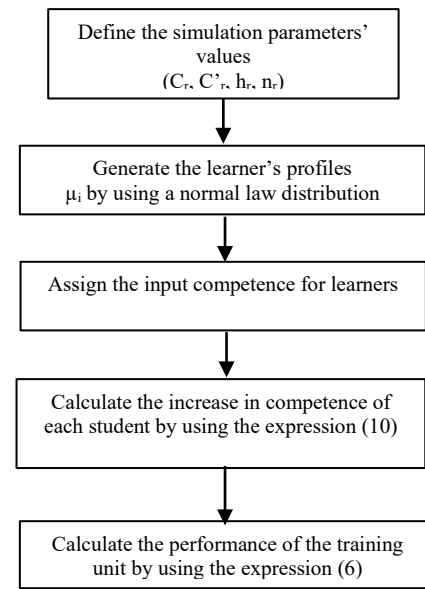
To realize the simulation, we consider, for a training unit, the following parameters reference values. The reference values are C_r=50 for the input competence, C'_r =100 for the output competence, h_r = 50 for the training unit duration, and n_r = 100 for the learner's number. We also consider that learner i validate the training unit if $(C'_i - C_i) \geq (C'_r - C_r)$. The simulation of the effect of the input competence on the training unit performance is executed according to the algorithm illustrated in Figure (5).


Figure 5: The simulation's algorithm

The first step for the simulation is to define the simulation parameter's values, the used values are n_r=100, C_r =50, C'_r =100 and h_r =50, and the training unit validation's rule that determine the minimum value required for ΔC_i that the learner has to reach in order to validate the unit. The second step is the generation of the student's profiles by using a normal law distribution for the parameter μ_i. The third step consists, for every simulation, in assigning the input competence C_i for the students. The fourth step is the calculation by relation (10) of the increase in competence for each learner. In the end, we calculate the performance of the training using relation (6).

Four simulations are carried out by varying the learners' input competence. In the first case, the input competence of learner's C_i is equal to the reference input competence of the training unit C_r, In the second case, the C_i deficit is of -3% compared to C_r, for the third case the C_i deficit is of -5% compared to C_r and the for the last case the C_i deficit of -7% compared to C_r.

The simulations' results are illustrated in the graph below:
Figure 6: Impact of the input competence deficit on the performance of a training unit

These results highlight the effect of the deficit of learners' input competencies on the training unit performance.

We note that when all learners have the required input competence to follow the training unit, i.e. C_i=C_r, the performance of the training unit is around 59%. This percentage is consistent

and is due to the distribution in normal law retained for the personal capacity of competence acquisition μ_i, which is an essential factor of the learner. If these learners have an input competence deficit of -3% compared to the reference input competence, then this performance decreases and becomes of the order of 36%. Therefore, the improvement of a training unit performance, requires to check the input competence of a learner, so that the follow up of the competence acquisition process can be done properly.

3.4. Simulation of the impact of the input competence on the performance of a program training

The purpose is the stimulation of the input competence's impact and other parameters as the individual capacity of competence acquisition μ_i the class size on the performance of a training program and monitor its behavior over time.

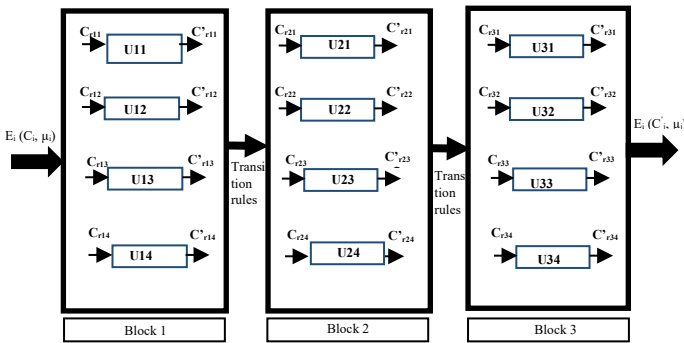
The organization of the training program is illustrated by the following figure:


Figure 7: Organization of a training program

The training program for the simulation consists of three training blocks and each training block consists of four training units. The data of the realization of the training units are given in Table1.

Table 1: Training unit realization data and mobilized resources initialized to reference data

Level of training 1	Reference input competence	Reference output competence	Reference duration	Reference group size	Number of hours realized	Real group size	Number of groups
U 11	50	100	50	25	50	25	2
U 12	50	100	50	25	50	25	2
U 13	50	100	50	25	50	25	2
U 14	50	100	50	25	50	25	2

Level of training 2	Reference input competence	Reference output competence	Reference duration	Reference group size	Number of hours realized	Real group size	Number of groups
U 21	100	150	50	20	50	20	2
U 22	100	150	50	20	50	20	2
U 23	100	150	50	20	50	20	2
U 24	100	150	50	20	50	20	2

Level of training 3	Reference input competence	Reference output competence	Reference duration	Reference group size	Number of hours realized	Real group size	Number of groups
U 31	150	200	50	15	50	15	2
U 32	150	200	50	15	50	15	2
U 33	150	200	50	15	50	15	2
U 34	150	200	50	15	50	15	2

For the simulation, we consider that 100 learners are enrolled per year for level 1, 80 for level 2, and 60 for level 3.

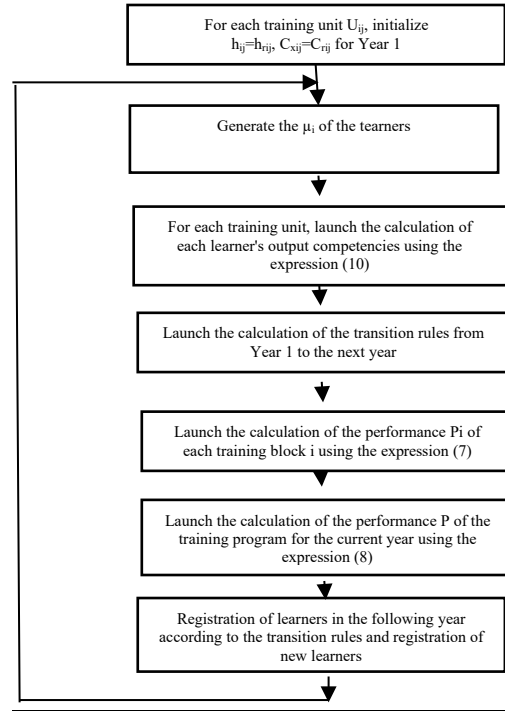
The algorithm in Figure 8 illustrates how the simulation is performed


Figure 8: Algorithm for simulating the performance of a training program

The simulation is performed for seven iterations up to Year 7 of the training program. The objective is to track the behavior of the variation in performance over the seven years of training. The simulation is carried out with a constant number of new learners NI entering Level 1 for each year of study.

Figure 9 below is an illustration of the simulation's result.
Figure 9: Simulation of the performance of a training program with NI constant

Figure 9 illustrates the variation in the performance of the training program on three different curves. The first curve (Curve A with continuous line) represents the impact of the personal capacity of competence acquisition μ_i. In this case, the coefficients of the group size g(n) and the input competencies $k(C_i/C_r)$ are kept equal to 1. The second curve (curve B with dashed line) represents the impact of the personal capacity of competence acquisition μ_i

and the coefficient of the group size g(n). The factor of the input competencies $k(C_i/C_r)$ is kept equal to 1. The third curve (Curve C with dotted line) reflects the impact of the personal capacity of competence acquisition μ_i, the coefficient of group size g(n), and the input skills factor $k(C_i/C_r)$.

For curve (A), in the first year of the training program, the performance of the training program is close to 50%. This is due only to the impact of the learners' μ_i factors, which are distributed according to a normal distribution whose average is 1. Thus, nearly 50% of the learners have a μ_i factor less than 1 and therefore cannot reach the required output competencies. For year 2 this performance increases to nearly 80%. This is explained by the fact that the learners who move up to the higher levels in year 2 satisfy the required input competencies and their μ_i are greater than or equal to 1, which allows them to reach the output competencies. Moreover, for learners at the different levels who fail and repeat some training units, they validate these units since they have re-enrolled with their output competencies from year 1 as input competencies for year 2 that are higher than the required competencies, thus making up for their μ_i deficit. The 20% performance deficit is mainly due to the new learners who enrolled in level 1, 50% of whom have a $\mu_i<1$ factor. Beyond this year, performance stabilizes at just over 80%. Thus, under the conditions of this simulation, i.e., without considering the effects of group size and the deficit in the input competence, the impact of the μ_i factors is offset by the increase in competencies of learners with a $\mu_i<1$ for the second enrolment in the same training unit.

For curve (B), in addition to the impact of μ_i, the impact of the group size is included. By comparing curve (A) and curve (B), the impact of group size is clearly apparent with a decrease in the performance of Year 2 of the training program. In fact, only μ_i has an impact on the performance of year 1. Thus, learners with a $\mu_i<1$ in year 1 are re-enrolled in the same training units in year 2, thus increasing the group size of these training units and consequently this year's performance is impacted by this increase in the number of learners. From year 3 onwards, performance increases and then stabilizes at the end of year 5. This is due, on the one hand, to the increase in the input competencies of learners who repeat a given level, which partially compensates for the impact of μ_i and group size, and, on the other hand, to the stabilized number of learners in the higher levels.

For curve (C), in addition to the impact of μ_i and group size, the impact of learners' input competencies is included. Comparing this curve with the other two curves, we see that the factor of learner input competencies negatively affects the performance of the training program which stabilizes at the end of year 7 at a rate of 40%.

The results of this simulation allow us to compare and visualize the behavior and variation in the performance of a training program under the effect of the different simulation factors. These results also make it possible to quantify this variation in performance. Indeed, by acting on the learners' input competencies through specific training actions for their improvement, the performance of the training program can be improved and go from a rate of 40% to a rate of nearly 80%. If we also act on the size of the group, performance can be further improved. Another performance improvement lever lies in the improvement of the learners' personal capacity to acquire competencies. This simulation is carried out with a constant number of new learners who enroll in the training program each year.

Another simulation is carried out to study the effect of a change in the number of new registrants at the start of the program in year 1. We will consider three situations, the one for which the number of entrants is 100, then the one where this number is increased by 20% then the one where it is decreased by 20%

The results of this simulation are shown in the following graph:
Figure 10: Simulation of the performance of a training program with variable NI

Figure 10 illustrates the variation in the performance of the training program along three different curves. The first curve (curve A with a continuous line) represents the impact of the personal capacity of competence acquisition μ_i and the group size with the new number of learners conforming to the reference number of the block of level 1. The factor of the input competence $k(C_i/C_r)$ is kept equal to 1. This curve corresponds to curve B of the previous simulation. This curve is considered as the reference curve for this simulation. The second curve (curve B with a dashed line) represents the impact of the μ_i and the coefficient of the group size g(n) with a number of new learners at the entrance 20% lower than the reference number. The factor of the input competence $k(C_i/C_r)$ is kept equal to 1 and, the third curve (curve C with dotted line) represents the impact of μ_i, the coefficient of the group size g(n) with a number of new entrants 20% higher than the reference number. The factor of the input competence $k(C_i/C_r)$ is kept equal to 1.

The performance of the training program in the start-up year "Year 1" varies according to the number of learners at the entrance. When the number of new entrants is reduced (curve B), the group size factor g(n) becomes greater than 1, which compensates for the effect of μ_i and therefore the performance of the training program increases, whereas when the number of new entrants is increased (curve C), the group size factor g(n) becomes less than 1, which contributes to the impact of μ_i in reducing the performance of the training program.

Whereas in the second "Year 2", the results are reversed. Indeed, in the case of curve B, given the number of learners who validated in year 1, the group size of the different blocks in year 2 increased and consequently g(n) becomes less than 1 and impacts the increase in learners' competencies and subsequently performance. The performance follows the same behavior until year 5, after which the performance increases, stabilizes, and approaches the performance of curve 1.

As for the behavior of the performance in the case of curve C, it follows the opposite behavior than that of curve B and in the stabilization phase, from year 5 onwards, the performance stabilizes at a rate of 60%, i.e. a decrease of 10% compared to the reference curve A.

These simulations on the performance of a training program illustrate the impact of the factors selected on this performance and make it possible to estimate, in a quantitative manner, the effects of variations in these factors on performance taken separately or in combination. The results of these simulations provide a better understanding of the interaction between the parameters and their impact on performance and can be used to test solutions for performance improvement.

4. Conclusion

By viewing education systems as skills production systems and by applying Business Processing Modelling methods, a modelling of education systems is proposed in the present work. The breakdown of the whole system allows us to introduce the training unit concept and then to organize these units in networks with units connected in series and parallel.

The objective of each training unit is to transform the learners' level of competencies into higher-level output competencies while respecting the objectives and constraints set by the educational system. Each training unit thus contributes to the achievement of the general objectives of the training system. This is achieved by mobilizing resources and according to rules of realization and rules of conduct.

Thus, the model proposed for the training unit has made it possible to determine the key factors influencing its performance. This model was coupled with a simulation model that allows to study the impact of the variation of these factors on the evolution of the system's behavior and performance and to simulate this impact.

The presented results of simulations show the effects of the learners' input competence deficit on the evolution of the process of competence increase and consequently on the performance of the training unit. Thereafter, the impact on the overall performance of a training program of this factor cumulated with those of the factors of the learners' personal capacity to acquire competencies, and the group size is studied.

This modelling allows us to evaluate the performance of the training unit and the training program in a quantitative way and to simulate the behavior of this performance by varying the different factors. This modelling enables us to test solutions for performance improvement.

Let us note that a validation of the model on case studies remains to be carried out and will require in particular the establishment of strategies for identifying the various parameters involved in the laws introduced to characterize the learner's aptitudes.

A R T I C L E I N F O	A B S T R A C T
	Internet Protocol version 6 is being adopted on slow pace and it is taking a long time. This paper intends to discuss the transition process between IPv4 and IPv6 and the major obstacles that prevent deploying IPv6 worldwide. It presents the IPv4 exhaustion reports results and where are the IPv4 address pool. Then it presents the methods that have been used to prolong the life expectancy of IPv4. After that it describes and discusses the mechanisms that have been used to deploy IPv6. Additionally, it describes the recently proposed mechanisms to overcome the problems encountered by the ISPs in migrating to IPv6. Furthermore, it shows the mechanisms that have been proposed to motivate the ISPs to start deploying IPv6 on their access networks. Finally, it presents a comparison between these mechanisms from the authors' point of view.

1. Introduction

'Internet Protocol Version 4" (IPv4) [1] is the current considered primary Internet protocol. It uses a 32-bit address. That provides more than 4 Billion addresses. Due to the frequent use of the internet and the abundance of devices that need an Internet connection, IPv4 was drained. As a temporary solution, many mechanisms have been proposed to prolong the life of IPv4. In the end, there must be a permanent solution. Internet Engineering Task Force (IETF) proposed a solution in which to convert IPv4 to a new protocol which is the "Internet Protocol Version 6" (IPv6) [2].

IPv6 was created by the IETF as a successor protocol to IPv4. It was proposed in 1994 and it became an internet standard on 14 July 2017 [3]. IPv6 uses a 128-bit address which provides approximately 3.4 x 1028. That will fulfill the huge need for IP addresses. The problem is that IPv6 can't be deployed all at once because of the large number of users and devices. Also, the lack of readiness of the infrastructure may delay the process knowing that the users can't be forced to update or change their devices so that they can use IPv6. IPv4 and IPv6 are not compatible and they can't be deployed both at the same time. IETF has proposed many solutions to start deploying IPv6 alongside IPv4. The plan is to start integrating IPv4 with IPv6 until IPv6 is fully deployed.

This Paper is an extension of work originally presented in [4]. In this research paper, we will present the methods that have been used to conserve the public IPv4 addresses. Then we will present some reasons that prevent the IPv6 deployment process. After that, we will present the mechanisms that have been proposed to integrate IPv6 alongside IPv4. Finally, we will compare and discuss these mechanisms from the authors' point of view.

2. IPv4 Exhaustion

The "Internet services providers" ISPs get the IP addresses from the Regional Internet Registry (RIR). There are five RIRs each one is responsible for providing IP addresses in a particular area of the world. which are: "American Registry for Internet Numbers (ARIN), Asia-Pacific Network Information Center (APNIC), Latin America and Caribbean Information Center (LACNIC), Reseaux IP Europeens Network Coordination Center (RIPE NCC), and the African Network Information Center (AFRINIC)". A statement has been made by APNIC that they have been operating under the last/8 framework since April 2011. At that time, they declared that they have 11,028,480 addresses assigned as available and have 15,728,128 unassigned addresses. For more information about the other RIRs reports check [5].

3. Methods to Preserve "Public IPv4 Addresses"

Many mechanisms that have been proposed to prolong the life expectancy of IPv4 the first one is the "Network Address Translation (NAT)" [6]. In short, NAT is a translation mechanism that translates IPv4 public addresses to a group of IPv4 private

addresses. rapid growth of internet users and IP addresses consumption has affected on NAT and it is not useful solution anymore. However, IETF has proposed some mechanisms which are:" Large Scale NAT (NAT444)" [7], and "Address plus Port (A+P)".

3.1. Large Scale NAT (NAT444)

Large Scale NAT or NAT444 is a technology that has been considered by the ISPs to extend the life of IPv4. Using NAT444 ISPs have been able to provide the users with IPv4 during the transition to the IPv6 process. It works by adding a Carrier Grade NAT (CGN) to the ISP's network. It translates one public IPv4 address among various CPEs and the private address in the CPE will again be translated into many private IPv4 addresses to arrive at the end-user with two NATs. NAT444 has many disadvantages, for instance, users may affect each other on bad behaviors because they share one public IPv4 address among a large number of users. Also, losing geolocation information because translation zones will cross traditional geographic boundaries see [8]. VoIP and video applications might be affected by NAT444 with latency, or packet loss, etc. see [9].

3.2. Address Plus Port (A+P)

A+P is a sharing schema that allows multiple users on the same CPE to use the same public IPv4 address. It extends the IPv4 address by using some of the port numbers as additional endpoints identifiers in the TCP/UDP header. Port Range Router (PRR) runs the process of assigning the range of IP addresses among the CPEs. A+P schema can provide 65536 ports for each public IPv4 address and each port can provide an extra 65536 ports. The idea behind A+P is that it divides the public IPv4 address without the need for translating it see [10] for more details.

4. Transition Approaches

Since IPv6 and IPv4 are not corresponding to each other and deploying IPv6 cannot be done all at once, the IETF has proposed techniques and mechanisms in order to achieve a smooth transition to IPv6. The smooth transition can be achieved by deploying IPv6 at the same time as IPv4. To allow communications between IPv4-Only networks and IPv6-Only networks IETF has proposed the transition mechanisms. These mechanisms are Dual-Stack, Tunneling, and Translation Approaches.

4.1. Dual-Stack Approach

The dual-stack approach is providing the user's connectivity for both IPv4 networks and IPv6 networks. A dual-stack device is any device that connects to the internet and configured with multiple IP addresses IPv4 and IPv6 at the same time. The idea behind the dual-stack approach is to configure all devices with both IPv4 and IPv6 addresses so that the devices can communicate over both networks [11]. It uses the perspective protocols (DHCPv4, DHCPv6) [12], [13] to assign addresses to the dual-stack devices. The network administrator is responsible for enabling perspective protocols. See Figure 1 which describes the Dual-Stack approach.

4.2. Tunneling Approach

The tunneling approach is a protocol that allows the movement of data from a network to another through a different type of

network. IPv4/IPv6 Routers and Hosts encapsulate the IPv6 packet in an IPv4 packet and send it through an IPv4 network to another IPv6 network. Tunneling can be used in various ways for instance Router-to-Router, Host-to-Router, Host-to-Host, and Router-to-Host. Because the hosts and routers need to explicitly configure the tunneling endpoints Router-to-Router is probably used. Figure 2 illustrates the Tunneling approach.
Figure 1: Dual-Stack Approach
Figure 2: Tunneling Approach

Tunneling has two types which are: Static Tunneling and Automatic Tunneling.

- Static Tunnels: in static tunneling the address will be configured at the tunnel endpoint and the configuration in this technique is manual. The encapsulating node is the one responsible for storing the tunneling information. It stores the tunnel endpoint address which will be the destination address. in addition, it stores the routing information in order to determine which packet to tunnel. Also, it uses the match technique and the prefix mask to the destination to the packet [14]-[16].

- Automatic Tunnels: in automatic tunneling the IPv6/IPv4 nodes can automatically determine the tunnel endpoint and That can be extracted from the IPv6 address. definitely the IPv6 must be backward compatible with IPv4. Also, the nodes possess the ability to decide which packets are auto tunneled and which are not. The main difference between the dynamic and static tunneling is the automatic determination of the tunnel endpoint.

4.3. Translation Approach

The previous approaches could be useful when communication is needed between two isolated IPv4 networks or two isolated IPv6 networks, while they have no use when an IPv4 only network tries to communicate with an IPv6 only network. The translation approach is a mechanism that allows an IPvX-Only network to communicate directly with an IPvY-only network. It translates the IPvX packet to an IPvY packet to allow communication. Figure 3 describes the translation approach.

The translation mechanism can be classified into two approaches [11]: Host-Based Approach and Network-Based Approach.

- Host-Based Translation

  Host-based translation is needed when there is an incompatibility between the running application type and the current host connectivity. So that, the IPvX will be translated to communicate with the IPvY and vice versa. In host-based translators, the changeover is between the application layer and the IP communication layers. There are three host-based translators was proposed which are: Bump-In-the-Stack (BIS) [17], Bump-In-the-API (BIA) [18], Bump-In-the-Host (BIH) [19]. In the next section we will present the host-based techniques in addition to another technique the author was proposed which is Decupling Application IPv4/IPv6 Operation from the Underlying IPv4/IPv6 Communication (DAC) [20].
Figure 3: Translation Approach

- Network-Base Translation

  In network-based translation, the IP header will be translated to every packet. That to provide the connectivity between IPv4-only networks and IPv6-only networks and vice versa [11]. An example of network-based translators is Stateless IP/ICMP Translation (SIIT) [21], and Stateful Address and Protocol Translation from IPv6 Client to IPv4 Servers (NAT64) [22].

5. IPv6 is Not Fully Deployed Yet

Transition to IPv6 is indeed a big breaking change in the networks. It can't be done all at once for many reasons. This section intends to describe these reasons from the author's point of view.

5.1. End User

End-users are not directly benefiting from the transition process; however, it is considered as an effective part in achieving it. The end-user might pose an obstacle for deploying IPv6. As we discussed earlier the deployment process of IPv6 must be smooth. A smooth transition can be done without affecting the users taking into account the users' application and the host configurations should be upgraded. The end-user can delay the process knowing that not all users have the proper knowledge to update or implement the upgrades.

There are some upgrades that should be implemented on the IP stack, "Transmission Control Protocol (TCP)", and "User Datagram Protocol (UDP)" in addition to the users' old applications [11], [23], [24]. The host configuration process should be automatically performed without the user knowledge because the user can't be expected to be qualified to deal with the manual configurations or any other technical configurations.

Achieving the transition process smoothly could take a while till IPv6 is fully deployed. Within this time there will be IPv6 only

networks and IPv4 only networks that need to be able to communicate with each other. The solution to that problem is the dual connectivity so that dual networks can communicate to both IPv4 and IPv6 networks [25]. The users' applications can be expected to be updated to support dual connectivity if it has good support but there are many applications that are not supported such as home-made applications and out-of-business applications and many other applications that will have the same problem.

There are many mechanisms that have been proposed as a solution to guarantee dual connectivity between incompatible hosts. IETF has proposed mechanisms such as "Bump In The Stack (BIS)" [17], "Bump In the API (BIA)" [18], [26], and "Bump In The Host (BIH)" [19]. Another mechanism that has been proposed by the author of this paper is "Decupling Application IPv4/IPv6 operation from the Underlying IPv4/IPv6 Communication (DAC)" [20], [27], [28].

- Bump in the Stack (BIS)

  Bump-In-the-Stack is a technique that uses the SIIT [29] algorithm to translate the IPv4 packets (i.e. headers) to IPv6 and the IPv6 packets (i.e. headers) to IPv4. In BIS the translation module is inserted between the TCP/IPv4 module and the card driver module. The translation module takes the data that flow between the modules that it is inserted between and translates the packets from IPv4 to IPv6 and vice versa. The DNS server is responsible for assigning the IP addresses. So, the user does not know about the other types of IP addresses that it communicates with. The main idea behind BIS is to provide the communication between IPv4 applications and IPv6 hosts.

- Bump in the API (BIA)

  Is a technique that used to translate the IPv4 socket API functions into IPv6 socket API functions and vice-versa. It detects the IPv4 socket API functions and invokes the equivalent IPv6 socket API functions so that there will be no need for translating the full IP header. BIA expects that TCP/UDP IPv4 and TCP/UDP IPv6 to existing on the local node. Unlike BIS, BIA inserts the API translator between the socket API module and the TCP/IP module in the dual-stack hosts.

- Bump in the Host (BIH)

  BIH technique is a host-based mechanism. It integrates both BIS and BIA techniques together and translates from IPv4 to IPv6. BIH consists of two implementations which are a translator in the API socket which is inserted between the TCP/IP module and socket IP module the other implementation is the translation protocol which inserts it between the network card driver and the TCP/IP module. BIS intends to let the old applications which uses NAT to communicate with the IPv6 only applications.

- Decoupling Application IPv4/IPv6 Operation from the Underlying IPv4/IPv6 Communication (DAC)

  DAC is a technique Allows applications that are compatible with IPv4-only stack and running on hosts with dual stack or with IPv6-only connectivity to communicate with IPv6 hosts. Additionally, it enables applications that are compatible with IPv6-only stack and running on hosts with dual stack and connectivity or with IPv4-only connectivity to communicate with IPv4 hosts. In theory, DAC is a layer that should be inserted between the

application layer and the IP communication stack on top of the API functions and it should perform the same functionalities that the API native functions perform. Translation from IPv4 and IPv6 and vice versa is only done on necessary basis. DAC will be effective between applications with an incompatible type and an incompatible networks connectivity. Furthermore, DAC can be installed at an IPv4 only host, IPv6 only host, and IPv4/IPv6 host.

5.2. Service Provider Network

The Internet Service Providers (ISPs) are the other effective part of the deployment process. as we discussed before the ISPs are cannot provide the users IPv4 addresses anymore and they need to deploy the IPv6 so that they can keep up with the internet users' swift increasing and provide the users with the required IP addresses. The transition process requires an upgrade or change of the infrastructure to one that can withstand the IPv6. That might be very expensive for the ISPs. IETF has proposed a technique that allows the ISPs to start deploying IPv6 over IPv4 networks. This technique is IPv6 Rapid Deployment on IPv4 Infrastructure (6rd) [30], [31].

6rd is an automatic tunneling technique was proposed to support rapidly deployment of IPv6 on existing IPv4 environment. In order to transmit the IPv6 traffic over IPv4 environment, 6rd uses encapsulation technique to transfer IPv6 packets through the IPv4 networks and it uses the ISPs' own IPv6 prefix other than a well-known prefix. Since it uses the network-specific prefix (NSP) each ISP can use its particular prefix that's mean the 6rd operational scope is limited to the ISP's domain. Moreover, the tunnels will be from the ISP's border relay (6rd gateway) to the customer edge (CE). see [30] and [32] for more details.

ISPs have faced determinations that hindered them from starting the deployment process of IPv6 through IPv4 infrastructure. One of these limitations is the need to upgrade or change the 6rd gateways (CE) which will affect them by raising the costs of deploying IPv6. In addition to the time that the process of Configuring the CEs would take after change and upgrade which might stall the process. Also, 6rd protocol upholds only one level of DHCPv4 between the CE and the border router. Never forget to mention the firewalls which might block the tunneled traffic that related to 6rd.

The authors of this research paper have suggested a few techniques that concurs the 6rd obstacles. These techniques are: "Deploying IPv6 Service Across Local IPv4 Access Network (D6across4)" [33], [34], "Configuring hosts to Auto-detect (IPv6, IPv6-in-IPv4, or IPv4) network connectivity (CHANC)" [35], and "Deploying IPv4-only Connectivity across Local IPv6-only Access Networks (D4across6)" [36]. The next section of this research will discuss these techniques and how they have overcome the limitations and obstacles that faced the ISPs before.

- Deploying IPv6 Service Across Local IPv4 Access Network (D6across4)

D6across4 is a mechanism that intends to motivate the ISPs to start the deployment process and start offering IPv6 services to their customers. It is a protocol mechanism to start deploying IPv6 service to host over the existing ISP's IPv4 network. D6across4 assigns an algorithmic mapping between the IPv4 and IPv6 addresses in the ISP network. It automatically resolves the tunnel server (TS) domain name to determine the tunnel endpoints. It

consists of customers' hosts and one or more TSs. Same as in 6to4 it encapsulates the IPv4 packets then forwards them to follow the topology of the IPv4 in the ISP network.

While 6rd and other protocols need upgrade and change the 6rd gateways and the network devices in both ISPs' and end users' sides. D6across4 tries to reduce both cost and time of the deployment process of IPv6 which is one of the problems that faced the ISPs and that prevented them from starting. Even though, in order for D6across4 can encapsulate/de-capsulate traffic IPv6 packets through the local IPv4 networks, it needs to be installed at ISPs' side at the network components, and at the uses side particularly at the applications hosts. See for more details [33].

There are some limitations that could be found in D6across4 that could affect deploying IPv6. These limitations are: if D6across4 has been deployed on a large scall networks it could face some issues regarding the scalability and the performance issues. So, it only could be integrated on a relatively small network. Also, since the D6across4 protocol is a stateful operation, for each packet receival it needs to access the mapping tables that could be exhaustion and consider as an additional load and it would be higher than any other stateless protocol. In addition, using a well-known prefix might shorten IPSs' capability of managing and controlling their traffic. Just like 6rd, D6across4 could be affected by firewalls and its traffic might be blocked.

- Configuring hosts to Auto-detect (IPv6, IPv6-in-IPv4, or IPv4) network connectivity (CHANC)

Same as D6across4 CHANC is a mechanism to encourage the ISPs to start the deploying IPv6 through IPv4 environment. Unlike D6across4 CHANC protocol doesn't need any upgrading or changing in the CEs which represents the extra costs that cause the delay of the deployment process. CHANC protocol gives the ISPs the ability to offer IPv6 to their customers through IPv4 infrastructure with the minimum cost and automatically configure the end-user's host. In fact, CHANC automatically configure the hosts to give them the ability to automatically detect every connectivity with every type that their ISP provide and locating the relay server would also be automatic. Also, CHANC uses the HTTP-in-IPv4 mechanism for transmitting IPv6 traffic through IPv4 environment.

CHANC has many advantages that overcome the other proposed protocols which are:

- The configurations in the end-users' hosts are done automatically which ease the process instead of manual configurations.
- It reduces the costs because there is no need for changing or upgrading the IPv4-only networks on both ISPs' and end-users' sides.

- Because of the IPv4 only access network, the ISPs can immediately begin offering IPv6 without the need support IPv6.
- It prevents the firewalls from blocking the tunneled packets of CHANC. It encapsulates the packets in HTTP protocol which permit the access to the traffic through utmost all firewalls.
- It simplifies administrating IPv6 traffic by allowing every ISP to use the prefix of its own.

Table 1: Comparison between the previously presented techniques and mechanisms

Protocol	Category	Installed At	Functionality	Limitations
BIS	Translation-based	"between the TCP/IP module and the network card driver"	Permit communication between IPv4 only applications on dual stack machines and IPv6 hosts	- Does not work with multicast communication. - invalid for embedded addresses. - It cannot be combined with a secure DNS. - It cannot employ security overhead the network layer.
BIA	Translation-based	"between the socket API module and the TCP/IP module"	Permit communication between IPv4 only applications on dual stack machines and IPv6 hosts	- invalid embedded addresses. - Does not uphold multicast. - Difficulties in translating APIs because of IPv6 API's advance new features.
BIH	Translation-based	"between the TCP/IP module and the network card driver or between socket API module and the TCP/IP module"	Permit communications between IPv4 legacy application and IPv6 only hosts and dual stack host	- invalid for embedded addresses. - Does not uphold multicast. - Does not uphold all types of applications.
DAC	Translation-based	"between the communication stack and the application layer"	Permit communications for both IPv4 and IPv6 applications through IPv4 and IPv6 connections with both IPv4 and IPv6 type capable remote applications.	- invalid for embedded addresses.
6rd	Tunneling-based	between the ISP border relay and the customer edge	Permit IPv6 connectivity through ISPs' IPv4 environment	- Single point of failure. - requires upgrade and change in the CPEs. - Cannot cross firewalls.
D6across4	Tunneling-based	ISP side and end users' host	Permit IPv6 connectivity through ISPs' IPv4 environment	- Single point of failure. - cannot cross firewalls.
CHANC	Tunneling-based	ISP side and end users' host	Permit IPv6 connectivity through ISPs' IPv4 environment	- Single point of failure.

- CHANC is a stateless-based translation mechanism that uphold end to end address translucence while the communication is between IPv4 and IPv6.

The Table below presents a comparison between the techniques and protocols that have been presented in this research.

6. Summary

The internet development has led to exhaustion in the IPv4 addresses and most of the ISPs are running out of IPv4. That makes the deployment of IPv6 has become mandatory. IETF has offered various mechanisms to extend the usage of IPv4. The proposed mechanisms and protocols are considered as a temporary solution. Afterall, the deployment of the IPv6 is unavoidable. ISPs are the major factor that affect the deployment directly. They need to start upgrading and changing the infrastructure to support IPv6. Also, IETF has offered various techniques and protocols to encourage the ISPs to start offering IPv6 alongside with IPv4 or even IPv6 through IPv4 infrastructure. These techniques and protocols can be classified into three classifications: Dual stack, Tunneling, and translation. In addition, various techniques and mechanisms have been offered by the authors of this research and by IETF for instance BIS, BIA, BIH, DAC, 6rd, D6across4, and CHANC. These mechanisms intend to encourage the ISPs and facilitate the deployment process in order for them to start the smooth transition.

Conflict of Interest

Ala Hamarsheh, Yazan Abdalaziz, Shadi Nashwan declare that they have no conflict of interest.

A B S T R A C T

IoT platforms play an important role on modern measurement systems because they allow the ingestion and processing of huge amounts of data (big data). Given the increasing use of these platforms, it is important to characterize their performance and robustness in real application scenarios. The paper analyzes the ThingSpeak platform by measuring the latencies associated to data packets sent to cloud and replied back, and by checking the consistency of the returned data. Several experiments were done considering different ways to access the platform: REST API, MQTT API, and MQTT broker alone. For each experiment, the methodology is explained, results are presented, and conclusions are extracted. The REST and MQTT APIs have similar performances, with roundtrip times between 1 s and 3 s. The MQTT broker alone is more agile, with roundtrip times below 250 ms. In all cases, the up and down links are far from being symmetric, with the uplink delay showing higher variance than the downlink delay. The obtained results can serve as a reference for other IoT platforms and provide guidelines for application development.

1. Introduction

Platforms for IoT (Internet of Things) have become key components in measurement and control systems because they are able to ingest, store and analyze huge quantities of data, on a 24/7 basis, at reasonable prices. They are hosted on the "cloud", which is a fancy name for data centers spread all over the world, equipped with high bandwidth, large storage capacity, and heavy processing power.

The term "cloud" is interesting because IoT platforms have indeed a broader view of the physical processes, as they were somewhere above in the sky. They have a broader view in terms of space because they gather data from different locations, and a broader view in terms of time because they store data persistently. This new level of awareness has flattened the traditional five-level automation pyramid [1] because field devices can now communicate directly with the cloud. Intermediate levels are being bypassed leading to an horizontal structure that is the basis of "smart factory" and "connected manufacturing" [2], two core concepts of "industry 4.0" [3].

Today, the cloud concentrates huge amounts of data making it the ideal place to run large-scale data analytics. Deep leaning, based on artificial neural networks, has benefited a lot from this scenario because it needs lots of data (big data) to perform well. As long as the data are good (big and diverse), deep learning is able to find good computational models for complex processes, even the hardest ones. With a good model in hands, new things can be done (such as preventive maintenance, and just-in-time asset management), and old things can be improved (such as robust control algorithms, and automatic controller tuning). IoT platforms play a key role in this movement because they are the "stage" where things are happening.

IoT platforms began to be used at the top of the automation pyramid because these levels do not need accurate timing. Typical applications include monitoring and supervision [4]-[10], with the

goal of reducing or removing humans in the loop [11]. There are also some applications for closed-loop control [12], [13], but the constrains in terms of low-latency and real-time make harder the penetration of IoT platforms at lower automation levels.

Whether IoT platforms are used for monitoring, supervision, or real-time control, it is important to know how fast and reliable they are. For that purpose, we took a well-known IoT platform – the ThingSpeak platform [14] – and measured the time it takes to upload a data packet and receive a reply. This so-called "roundtrip time" is an indicator of *how fast* the platform is. By checking the resemblance of both packets, outgoing and incoming, we can also have an idea on *how reliable* the platform is. We chose ThingSpeak because it is very easy to use, is open source, is free (with some restrictions), has an active community, and provides a comprehensive set of features, including persistent data storage, data analytics based on MATLAB, easy access through ubiquitous protocols, and security over SSL. For these reasons, the ThingSpeak is one of the makers' favorite platforms [15].

There are similar works trying to characterize experimentally the behavior of cloud servers and IoT platforms. For example, in [16], the author gives a tutorial on network latency measurements using PlanetLab as testbench. He measured the roundtrip times of mobile and non-mobile devices, connected through wireless (WiFi and 3G) and wired (Ethernet) interfaces, while pinging five different AWS servers spread around the world. In [17], the author and his team studied the performance of a cloud database by measuring the time needed to complete a writing on the database and getting back a reaction. They used a Siemens PLC to generate data, the IBM Cloud to store data and fire events, and an industrial computer to catch those events, all connected through a MQTT broker. In [18], the author measured the roundtrip time associated to a MQTT broker when it was accessed from two different continents (Brescia in Europe and São Paulo in South America). In [19], the author evaluated the efficiency and roundtrip time of three protocols commonly used in IoT, namely CoAP (constrained application protocol), WebSockets, and MQTT (message queue telemetry transport). In [20], the author made a quantitative performance analysis of the CoAP and MQTT protocols over various conditions of network capacity, packet loss probability, and link delay. In all these works, a substantial effort was put in characterizing experimentally the behavior of cloud services and the protocols used to access them.

The remaining of this paper is organized as follows: section 2 gives an overview of the ThingSpeak platform; sections 3 and 4 analyze the latencies of the ThingSpeak platform when it is accessed through two different application programming interfaces (API); section 5 focus on the ThingSpeak MQTT broker alone; section 6 discusses the obtained results; and section 7 extracts conclusions.

2. ThingSpeak

The ThingSpeak platform provides resources to store and process data in the cloud. The data are accessed through two well documented APIs: a REST API [21] that communicates over HTTP and follows the request-response model; and a MQTT API [22] that communicates over TCP/IP and follows the publish-subscribe model. Both APIs support authentication through unique read/write keys, but only the REST API supports data encryption

through HTTPS. The REST API works well for one-to-one communications, while the MQTT API is best suited for one-to-many communications. The ThingSpeak MQTT broker only supports QoS = 0 (equivalent to "deliver at most once" or "fire-and-forget").

The ThingSpeak platform organizes information in data channels. Each channel includes eight fields that can hold any data type, plus three fields for location, and one field for status. Each channel is also characterized by a unique ID, a name, and a free description. It is not possible to access the fields individually; all read/write operations are made at the channel level to optimize remote calls. All incoming data receive a sequential ID and a timestamp (with a 1 second resolution). Channels are private by default, but they can also be made public in which case no read key is required. Channels are provided at no charge for non-commercial projects as long as they require no more than 8200 messages/day (~5 messages/minute).

The ThingSpeak provides the following resources to control the dataflow:

- React: Executes an action when stored data meet a certain condition (e.g. when a given field of a given channel crosses a given threshold). The action can be as simple as the execution of a script or the issue of a remote message over HTTP.

- TimeControl: Orders the execution of an action once at a specific time, or periodically on a regular schedule, much like a software timer. The TimeControl supports the same actions as the React.

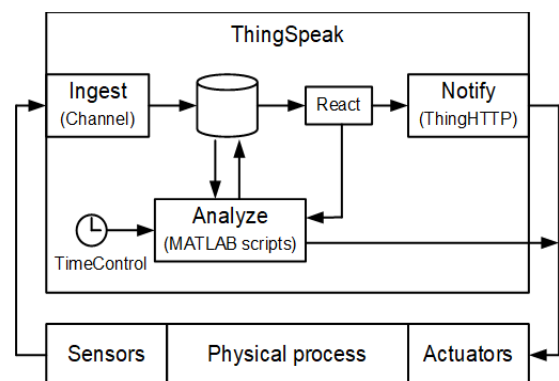
- ThingHTTP: Is a remote call over HTTP, useful to communicate with remote entities such as devices, websites, and web services.


Figure 1: Dataflow inside the ThingSpeak platform

The ThingSpeak platform relies on MATLAB scripts to process stored data. Scripts can be associated to a TimeControl to run one-time or periodically, or to a React to run whenever a given condition is met. Scripts can use the MATLAB toolboxes listed in [23], as long as the user logs into ThingSpeak using its MathWorks account and is licensed to use them. This opens the door to powerful data analytics, supported by robust and well-known software libraries. The results can be visualized on the web, directly from the ThingSpeak site, through ready-to-use charts. The visualization experience can also be enriched with custom widgets and MATLAB plots.

Figure 1 shows the dataflow through the ThingSpeak platform. Data are ingested, stored in a database, and (optionally) analyzed by scripts that run periodically or when a given condition is met. Messages can be sent to third-party applications by a pre-configured ThingHTTP, or by a pre-programmed script using MATLAB functions. The present work focusses on measuring the time it takes to upload data and receive a reply, assuming no processing is made in the interim.

3. ThingSpeak accessed through the REST API

In this section we analyze the performance of the ThingSpeak platform when it is accessed through the REST API. We first explain the methodology used to measure latencies and then we present results.

3.1. Methodology

To measure REST API latencies, we built the closed data path shown in Figure 2, which includes the following stages (the numbers in the list correspond to the numbers in the drawing):

1. LabVIEW application: Is a custom application that runs on our local machine. It makes HTTP calls to the ThingSpeak server, collects the replies, and computes the time elapsed. Each call is a GET request that uploads an order number (n) that is incremented to identify the request. The timestamp of the request (t_{n0}) is registered to serve as reference for the roundtrip time.

2. ThingSpeak channel (name = TestChannel; ID = 515584; access = private): The channel contains a single field (Field1) to store the order number uploaded by the LabVIEW application.

3. React (condition type = numeric; test frequency = on data insertion; condition = TestChannel.Field1 ≥ 0; run = each time the condition is met): A reaction is fired each time a positive order number is received (which is always because n is an unsigned integer). The reaction instructs the MATLAB script to run (see below).

4. MATLAB script: Collects the timestamp at the ThingSpeak server and makes an HTTP call back to the local machine. As shown in Figure 3, the script is programmed to make a POST request to a web service running on the same machine as the LabVIEW application. The request sends back the order number and the timestamp at the ThingSpeak server (τ_n).

5. Router: Accesses from the local machine to an external server are inherently safe and the router forwards them transparently. However, connections in the opposite direction are potentially dangerous and are blocked by default. To overcome this problem, we had to forward port 80 on the local router, so that POST requests coming from the ThingSpeak server reach the LabVIEW web service. In other words, we had to expose the LabVIEW web service to the internet.

6. LabVIEW web service: Is a stateless routine that receives a POST request, extracts the attached order number (n) and timestamp (τ_n), and registers the timestamp of the reply (t_{n1}). The triplet (n, τ_n, t_{n1}) is then sent back to the LabVIEW application by means of a UDP socket. The web service is

hosted by the NI Application Web Server running on port 80 of the local machine.

(n, τ_n, t_{n1}), adds the first timestamp (t_{n0}), and writes the quartet (n, t_{n0}, τ_n, t_{n1}) into the output file for further processing.

```
1   %get source
2   readChannelID=515584;
3   readApiKey='▮▮▮▮▮▮▮▮▮▮▮';
4   n = thingSpeakRead(readChannelID,'ReadKey',readApiKey);
5   %get ThingSpeak's timestamp
6   tau = datetime('now','Format','HH:mm:ss.sss');
7   %call back
8   url='http://95.136.▮▮▮▮:3582/MyWebService/MyCallBack';
9   %method = POST; media type = application/x-www-form-urlencoded
10  webwrite(url,'OrderNumber',n,'Tau',tau);
```

Figure 3: MATLAB script. The reading key of the channel and the IP address of the LabVIEW web service were erased for privacy

The LabVIEW application and the LabVIEW web service run both on our local machine (Intel i7-8550 CPU @ 1.80 GHz, RAM 16 GB, SSD 512 GB, NVIDIA GeForce MX150). The machine connects to an Ethernet port of a general-purpose router (model HS8247W from Huawei), which accesses the internet through a fiber optic link provided by Vodafone Portugal.

The LabVIEW application uploads order umbers (n) at multiples of 20 seconds to respect ThingSpeak free account limitations. On the nth upload, the quartet (n, t_{n0}, τ_n, t_{n1}) is saved on the nth line of the output file. Thus, it is possible to record the timelines shown in Figure 4, where the τ axis represents the timeline of the ThingSpeak server, and the t axis represents the timeline of the local machine. Of course, the two timelines are not

aligned because the clocks of the two systems are not synchronized. Yet, we can extract the following quantities from these timelines:

$$RT_n = t_{n1} - t_{n0} \tag{1}$$

$$d\Delta_n = \Delta_{n+1} - \Delta_n = (\tau_{n+1} - \tau_n) - (t_{(n+1)0} - t_{n0}) \tag{2}$$

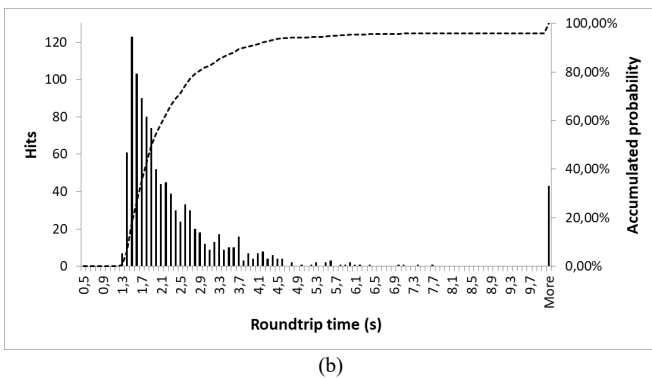
$$d\delta_n = \delta_{n+1} - \delta_n = (t_{(n+1)1} - t_{n1}) - (\tau_{n+1} - \tau_n) \tag{3}$$


Figure 5: Roundtrip times of the REST API: a) plot; b) histogram

3.2. Results

We ran the closed loop illustrated in Figure 2 for 1080 times, from n=0 to n=1079, waiting approximately 20 seconds on each iteration. This number (1080) was a compromise between having statistically relevant results and limiting the test to a reasonable

amount of time (almost six hours). Figure 5a shows the measured roundtrip times, and Figure 5b shows the corresponding histogram. The order number (n) was always replied correctly, which attests the robustness of the ThingSpeak platform.

Figure 5b we see that the roundtrip time has a heavy-tailed distribution, which is characteristic of multipath communication mediums as the Internet. The authors in [24] report similar results and suggest a lognormal distribution for the experimental data. In our case, we got mode = 1,66 s and a roundtrip time that is less than 2.9 s with a probability of 80%.

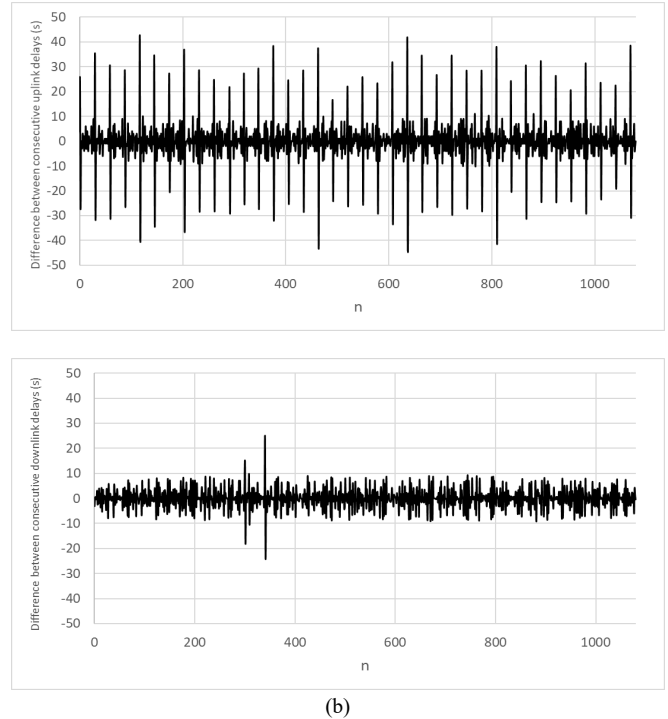
(b)


Figure 6: Difference between consecutive delays: a) uplink; b) downlink

Nevertheless, every 10 min (around 30 points) the roundtrip time increases very sharply up to tens of seconds, suggesting that the ThingSpeak platform stores data in temporary buffers, which, from time to time, are flushed and processed.

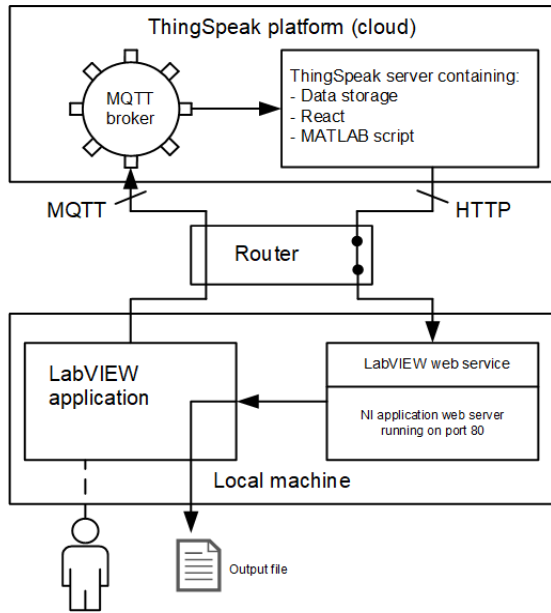
Figure 6 shows the difference between consecutive delays on the uplink and downlink directions. The differences are positive and negative because a higher delay on one iteration discounts on the next iteration. As expected, the uplink delay (Δ) is less stable than the downlink delay (δ) because the upload process is more complex than the reply (in terms of ThingSpeak internals).

If we suppose that consecutive uplink delays are statistically independent, which makes sense because they correspond to different iterations, then the variance of the difference ($d\Delta$ or $d\delta$) will be twice of the variance of the variable itself (Δ or δ). Therefore, if we compute the variances Var($d\Delta$) and Var($d\delta$) from the data of Figure 6, and divide the result by two, we get the variances of the delays: Var(Δ) = 37.52 s^2 and Var(δ) = 7.29 s^2. Applying the squared root, we get the standard deviations: σ_Δ = 6.13 s and σ_δ = 2.70 s.

Finally, it is very difficult to infer about the mean value of the uplink and downlink delays because the clocks of the two systems

are not synchronized and, equally important, the two links are far from being symmetric.

4. ThingSpeak accessed through the MQTT API

built the closed data path shown in Figure 7, which is like that of Figure 2 with the difference that the order numbers are uploaded through the MQTT broker. The LabVIEW application was changed to publish order numbers (n) using a compatible MQTT driver [25]. The quartets (n, t_{n0}, τ_n, t_{n1}) were collected and saved into the output file as before.


(b)

Figure 8: Roundtrip times of the MQTT API: a) plot; b) histogram

We ran the closed loop 1080 times waiting approximately 20 seconds on each iteration. Figure 8a shows the measured roundtrip times, and Figure 8b shows the corresponding histogram. Again, the order number (n) was always replied correctly, with no mismatches or timeouts. From the graphs, we see that the roundtrip time follows a lognormal distribution with mode = 1,13 s and values below 2,8 s with a probability of 80%. We also see outliers coming every 10 min (as we saw in the REST API), suggesting that internal mechanisms of buffering and batch processing also apply to the MQTT API.

The random variables dΔ and dδ were also computed as before. The corresponding variances were extracted and divided by two, leading to Var (Δ) = 51.53 s^2 and Var (δ) = 5.99 s^2. Applying the squared root, we got the standard deviations of the uplink and downlink delays: σ_Δ = 7.18 s and σ_δ = 2.45 s.

5. MQTT broker alone

To analyze the performance of the MQTT broker alone we closed the loop without passing through the ThingSpeak server, as shown in Figure 9. The LabVIEW application was changed to publish order numbers (n) and subscribe the replies using the MQTT driver previously mentioned. In this case, only the triplets (n, t_{n0}, t_{n1}) were collected because the timeline of the ThingSpeak server (τ axis) is not available.

We ran the closed loop 1080 times waiting approximately 20 seconds on each iteration. Figure 10.a shows the measured roundtrip times, and Figure 10.b shows the corresponding histogram. As always, the order number (n) was always replied correctly, with no mismatches or timeouts. From the graphs, we see that the roundtrip time follows a lognormal distribution with mode = 0.189 s, and values below 0,250 s with a probability of 80%. We also see that the outliers observed in the previous tests have almost disappeared. This shows that the MQTT broker is more expeditious than the ThingSpeak server, probably because its buffering and processing needs are much less demanding.

6. Results and Discussions

Table 1 summarizes the latencies measured during all the experiments. From these results we can extract the following conclusions:

- The REST and MQTT APIs have similar performances with a slightly advantage for the MQTT API. In both cases, the roundtrip time was typically between 1 s and 3 s.

- The ThingSpeak server has internal mechanisms of buffering and batch processing that, periodically, introduce extraordinary delays. These mechanisms seem to be absent from the MQTT broker.

- The MQTT broker is very agile in distributing publications, with roundtrip times typically below 250 ms.

- The up and down links are far from being symmetric. The uplink is more complex since it has a higher variance.

- The tests lasted for several hours and were made in different days and in different times of the day, suggesting that the behavior of the ThingSpeak platform is time independent.

A final word about robustness: the order number (n) was never lost or corrupted, proving that the ThingSpeak is reliable, even for free accounts.
Figure 9: Data loop through the MQTT broker only

(a)

(b)
Figure 10: Roundtrip times of the MQTT broker alone (a) plot (b) histogram

Table 1: Experimental characterization of the ThingSpeak platform

		REST API	MQTT API	MQTT broker
Roundtrip time	Min (s)	1.25	0.86	0.158
	Mean (s)	3.28	3.27	0.243
	Mode (s)	1.66	1.13	0.189
	80th percentile (s)	2.90	2.80	0.250
Uplink delay	Std. dev. (s)	6.13	7.18	---
Downlink delay	Std. dev (s)	2.70	2.45	---

7. Conclusions

The paper reported the studies carried on the ThingSpeak platform to evaluate its responsiveness and reliability. We measured the time needed for a data packet to loop back through the platform, and we verified if its content has been corrupted during the trip. Tests were made for all access mediums (REST API, MQTT API and MQTT alone) covering periods of six hours.

We saw that the REST and MQTT APIs have similar performance with typical roundtrip times between 1s and 3s. We observed repetitive outliers that suggest that the ThingSpeak server has periodic mechanisms of buffering and batch processing. The MQTT broker alone did not show such outliers and performed significantly faster. In terms of reliability, no data was lost or corrupted.

We hope that the obtained results can serve as a reference for other IoT platforms and provide guidelines for application development.

Conflict of Interest

The authors declare no conflict of interest.

ARTICLE INFO	ABSTRACT
	Solar energy becomes widely used in the global power grid. Therefore, enhancing the accuracy of solar energy predictions is essential for the efficient planning, managing and operating of power systems. To minimize the negatives impacts of photovoltaics on electricity and energy systems, an approach to highly accurate and advanced forecasting is urgently needed. In this paper, we studied the use of Deep Learning techniques for the solar energy prediction, in particular Recurrent Neural Network (RNN), Long Short-Term Memory (LSTM) and Gated Recurrent Units (GRU). The proposed prediction methods are based on real meteorological data series of Errachidia province, from 2016 to 2018. A set of error metrics were adopted to evaluate the efficiency of these models for real-time photovoltaic forecasting, to achieve more reliable grid management and safe operation, in addition to improve the cost-effectiveness of the photovoltaic system. The results reveal that RNN and LSTM outperform slightly GRU thanks to their capacity to maintain long-term dependencies in time series data.

1 Introduction

Currently, the global trend is to integrate renewable energies to generate electricity and rethink its energy mix. In this regard, the use and expansion of renewable energy have become an important element in maintaining energy security, as well as to establish an ecological and sustainable electrical system [1]. Nevertheless, the energy context is affected by price variations, changes in demand and the volatility of renewable energy production. In order, to confront these main challenges of the energy mix, it is essential to have a good forecasting model for renewable energies, which is particularly useful for optimizing and adapting supply to demand. This must reliably provide advance information on the availability of power, which helps to achieve the grid's stable operation and to allow for optimal unit engagement and economic dispatching [2]. In this work, we concentrate on solar energy forecasting. Photovoltaic (PV) forecasting methods fall into two groups: direct and indirect prediction models. As described in [3, 4], solar radiation at different time scales is predicted with different methods and then converted to power based on the panel characteristics in the case of indirect prediction, while direct predictions are performed directly from the output power of the plant. Besides, Statistical, physical, artificial intelligence (AI) and hybrid approaches were used in pre-

dicting PV solar energy. However, thanks to their great learning and regression capabilities, AI and especially, Deep Learning (DL) techniques [5], have been widely used in this area. They have the capability to extract in-depth features from PV power datasets and get more reliable predictive outputs. Authors in [6] have applied Recurrent Neural Network (RNN) as a good tool for predicting solar irradiation time-series using recorded meteorological data. Besides, Li et al. [7] have proposed an RNN-based forecasting method for short-term PV power prediction. Moreover, another research in [8] has proposed a hybrid deep learning model using Wavelet Packet Decomposition (WPD) and Long Short-Term Memory (LSTM) to forecast PV power for one hour ahead with an interval of five minutes. WPD is applied to split the PV power output time-series and next the LSTM is implemented to forecast high and low-frequency subseries. The results of this study indicate that the WPD-LSTM method outperforms in various seasons and weather conditions than LSTM, Gated Recurrent Units (GRU), RNN, and Multilayer Perceptron (MLP). Authors in [9] have presented a deep LSTM based on historical power data to predict the PV system output power for one hour ahead. The aim in [10] to suggest a hybrid model using LSTM and attention mechanism for short-term PV power forecasting, and employed LSTM to extract features from the historical data and learn in sequence the information on long-term dependence, to

apply the attention mechanism trained at the LSTM to target the extracted relevant features, which has greatly enhanced the original predictive power of LSTM. An LSTM approach for short-term forecasts based on a timescale that includes global horizontal irradiance (GHI) one hour ahead and one day ahead have been applied in [11]. Furthermore, authors in [12] have implemented univariate and multivariate GRU models employing historical solar radiation, external meteorological variables, and cloud cover data to predict solar radiation. In [13], authors have presented multivariate GRU to predict Direct Normal Irradiance (DNI) hourly. And the suggested method is evaluated compared to LSTM using historical irradiance data. In addition, a hybrid deep learning model have introduced in [14] that combines a GRU neural network with an attention mechanism for solar radiation prediction. All these research contributions cited above are valuable. However, they are not able to identify the important parameters that would have an impact on the accuracy of predictions. and make real-time predictions for efficient and optimized management. Given the fluctuating nature of output power generation as a function of meteorological conditions such as the temperature, the wind speed, the cloud cover, the atmospheric aerosol levels and the humidity level, which leads to high uncertainties on the output power of PV [15]. Besides, according to the forecast horizon, PV forecasts range from very short to long term. In general, researchers focus on short-term, hourly and daily forecasts as opposed to long-term. The first are of major significance for the management of PVs and the related security constraints (planning, control of PV storage and the rapprochement of the electricity market, providing the secure operation of generation and distribution services, and reinforcing the security of grid operation), while the long-term forecasts are useful particularly, for maintenance [16]. In this context, we study the efficiency of three DL models. We also focus in this study, on real-time prediction of solar energy in order to help planner, decision-makers, power plant operators and grid operators to making responsive decisions as early as possible, and to manage smart grid PV systems more reliably and efficiently [17]. Moreover, the use of real-time prediction allows to adjust to changes in production and to react to complex events (exceptionally high or low load production or consumption). In addition, it decreases the amount of operating reserves needed by the system, thus reducing system balancing costs [18]. However, the models we have selected give good results and seem to be suitable for long-term forecasting thanks to their power as a deep learning model and their ability to perform complex processing on huge data sets. Moreover, we outline that our work has been experimented with Moroccan's case, particularly in the region of Errachidia. In this perspective, Moroccan decision-makers have launched a global plan to improve the percentage of renewable energy in the energy mix and substantially improve energy efficiency. In view of increasing the percentage of electricity generation capacity from renewable energy sources (42% by 2020 and 52% by 2030) [19]. Therefore, we believe that the case of Morocco remains an interesting case study that could lead to important findings since it is not only a promising future PV energy supplier, but also one of the leading countries in the global energy transition, particularly in Africa. The remainder of this paper is organized into four sections. Section 2 gives an overview of our comparative methodology. Subsequently, section 3 presents the approach applied to elaborate the forecast models. Section 4 presents

and discusses the obtained results. Finally, section 5 summarizes the conclusions and perspectives of this study.

2 Methodology

Solar energy prediction is a key element in enhancing the competitiveness of solar power plants in the energy market, and decreasing reliance on fossil fuels in socio-economic development. Our work aims to accurately predict the solar energy. For this purpose, we explore architectures of the RNN, LSTM and GRU algorithm which is suitable to be used for forecasting such time-series data, and we experiment and evaluate them in Morocco's case, especially Errachidia area. This section presents at first the basis architecture of this recurrent neural network before explaining the important steps that we follow to build our models and perform our comparative study.

2.1 Recurrent Neural Network architecture

Recurrent neural network (RNN) is a category of neural network used in sequential data prediction where the output is dependent on the input [20]. The RNN [21] is capable to capture the dynamic of time-series data by storing information from previous computations in the internal memory. RNN has been applied in a context where past values of the output make a significant contribution to the future. It is mainly used in forecasting applications because of its ability to process sequential data of different length.

The basic principle of RNNs is to consider the input of a hidden neuron which takes input from neurons at the preceding time step [22]. To this purpose, they employ cells represented by gates that influence the output using historical data observations are given to generate the output. RNN is particularly efficient for learning the dynamic temporal behaviors exhibited in time-series data [23]. In RNN, the hidden neuron h_t for a given input sequence x_t, it has information feedback from other neurons in the preceding time step multiplied by a W_{hh} which is the weight of the preceding hidden state h_{t-1} can be calculated sequence by Eq.1. x_t is the input at instant time t, W_{xh} is the weight of the actual input state, tanh is the activation function. The output state y_t is computed according to the Eq.2 where W_{hy} is the weight at the output state.

$$h_t = \tanh(W_{hh}h_{t-1} + W_{xh}x_t) \tag{1}$$

$$y_t = W_{hy}h_t \tag{2}$$

The LSTM is a special kind of RNN, designed to avoid and resolve the vanishing gradient problems that limit the efficiency of simple RNN [8]. LSTM network has memory blocks that are connected through a succession of layers. In the LSTM cells, there are three types of gates: the input gate, the forget gate and the output gate. This makes it possible to achieve good results on a variety of time-series learning tasks, particularly in the nonlinear of a given dataset [24]. Each block of LSTM handles the state of the block and the output, it operates at different time steps and transmits its output to the following block and then the final LSTM block generates the sequential output [9]. Besides, LSTM is a robust algorithm, which

allows the recurrent neural network to efficiently process time-series data. Its key component is memory blocks which have been released to address the vanishing gradient disadvantage by memorizing network parameters for long durations [25].an LSTM block gets an input sequence after that, the activation units are used by each gate to decide whether or not it is activated. This operation enables the change of state and the adding of information passing through the block conditional. In the training phase, the gates have weights that can be learned. In fact, the gates make the LSTM blocks smarter than conventional neurons and allow them to remember current sequences [10]. LSTM is flexible and estimates dependencies of different time scales thanks to its ability to perform long task sequences and to identify long-range features. Basically, LSTM starts with a forget gate layer (f_t) that uses a sigmoid function combined with the preceding hidden layer (h_{t-1}) and the current input (x_t) as described in the following equations:

$$i_t = \sigma(W_i.[h_{t-1}, x_t] + b_i) \tag{3}$$

$$\check{c}_t = \tanh(W_c.[h_{t-1}, x_t] + b_c) \tag{4}$$

$$f_t = \sigma(W_f.[h_{t-1}, x_t] + b_f) \tag{5}$$

$$o_t = \sigma(W_o.[f_{t-1}, x_t] + b_o) \tag{6}$$

$$c_t = f_t.c_{t-1} + i_t.\check{c}_t \tag{7}$$

$$h_t = o_t.\tanh(c_t) \tag{8}$$

where i_t, $\check{c}_t$, f_t, o_t, c_t and h_t represent the input gate, cell input activation, forget gate, output gate, cell state, and the hidden state respectively. W_i, W_c, W_f and W_o represent their weight matrices respectively. b_i, b_c, b_f, and b_o represent the biases. x_t is the input, h_{t-1} is the last hidden state, h_t is the internal state. σ is the sigmoid function.

2.2 Gated Recurrent Units architecture

The GRU [26] is a particular type of recurrent neural network proposed by Cho in 2014 which, is the same as the LSTM) in terms of use to resolve the issue of long-term memory network and back-propagation. The GRU network involves the design of several cells that store important information and forget those that are deemed irrelevant in the future [27]. The feedback loops of the GRU network can be regarded as a time loop, because the output of the cell from the past period is taken as an input in the following cell in addition to the actual input. This key property allows the model to remember the patterns of interest and to predict sequential time-series datasets over time. Unlike the LSTM, the GRU [28] consists of only two gates: update and reset gates. the GRU substitutes the forget gate and the input gate in the LSTM with an update gate that verifies the cell state of the previous state information that will be moved to the current cell, while, the reset gate defines whether new information will be included in the preceding state. For this reason, GRU has proven to be one of the most efficient RNN techniques, because of

its capacity to learn and acquire dependencies over the long term and observations of varying length [29]. This characteristic is particularly useful for time-series data, and it is helpful in reducing the computational complexity [30]. GRU cells are described using the following equations:

$$z_t = \sigma(W_z.[h_{t-1}, x_t]) \tag{9}$$

$$r_t = \sigma(W_r.[h_{t-1}, x_t]) \tag{10}$$

$$\hat{h}_t = \tanh(W.[r_t - h_{t-1}, x_t]) \tag{11}$$

$$h_t = (1 - z_t).h_{t-1} + z_t.\hat{h}_t \tag{12}$$

$$y_t = \sigma(W_0.h_t) \tag{13}$$

where z_t and r_t respectively correspond to the output of the update gate and the reset gate, while W_z, W_r, W, and W_o respectively are the weights of each gate. σ and tanh respectively are the sigmoid and the hyperbolic tangent activation function, and x_t is the network input at time t. ht and h_{t-1} correspond to the hidden layer information of the actual and precedent time, and $\hat{h}_t$ is the candidate state of the input. Initially, the network input x_t at the time of the hidden state h_{t-1} and t at the last state computes the output of the reset gate and the update gate by Eq.9 and 10. Next, after the reset of the reset gate r_t calculates the amount of memory stored, the implicit layer $\hat{h}_t$ is computed by Eq.11, which is the new information at the actual time t. Then, by using Eq.12, the update gate z_z determines the amount of information was removed at the previous time, and how much information is stored in the candidate hidden layer ht at this time. The hidden layer information h_t is subsequently added. Finally, the output of the GRU is switched to the next GRU gated loop unit according to Eq.13: which is a sigmoid function.

3 Our approach for predicting solar energy

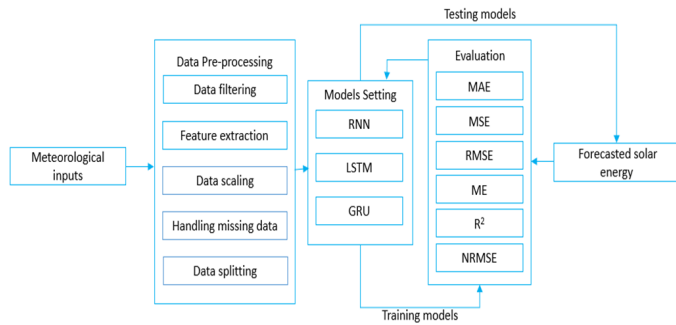
In this study, we apply three different DL models to predict the PV solar energy output, especially RNN, LSTM and GRU for the half-hour ahead. The aim of this study is to compares the relevance of the mentioned models, in order to identify the best algorithm to be used for predicting solar energy. The process of the method employed in this work is illustrated in Figure 1. It is organized into four main stages: data collection, data pre-processing, model training and parameterization, and model testing and validation. This section details how each of these processing/selection steps was performed, as well as key details on the architecture and parameters of the developed models.


Figure 1: Our method for predicting solar energy

3.1 Dataset

The datasets used in this work, they represent meteorological data of Errachidia province, which is situated in the sunny region of Morocco, it benefits from an important solar energy potential during all the year. This data consists of measurements from three years (2016, 2017 and 2018), and they are used to predict the solar energy level based on a set of measurable weather conditions, in purpose of analyzing the performance of the studied models.

3.2 Preprocessing and Feature Selection

Pre-processing and feature selection are fundamental steps in DL approaches for making collected data in an appropriate form. Pre-processing allows numerous tasks and operations to convert the source data in a clean data, in a way that it can be easily integrated into DL models. It impacts the accuracy of the model and its results. Feature selection provides the most appropriate features that properly affect the learning process, and can minimize the number of variables to efficiently enhance the accuracy of the model and avoid costly computations. Therefore, in this work, we proceed with the following steps to prepare and select features from the source data: extraction of target data inputs, selection of relevant features, filling in the null values, normalization of the data, and adjustment of the steps to be taken into account for prediction.

The source data give multiple features but not all of them are important for use in the prediction. In our case, we have selected four important features: solar energy, temperature, humidity and pressure. These features are the most and highly correlated variables to the targeted output (solar energy) according to Pearson correlations [31]. The objective of this step is to help developing most accurate models that learn from the most correlated data in order to give the most accurate forecasts. We note that we have selected the Median in order to fill missing data.

The features of a given dataset are usually presented at different scales. To ensure that all these values are at the same scale and to add uniformity to our dataset, we employ the Min-Max scale that transforms all values between 0 and 1, which removes the noise from our data and simplifying the learning process of our models.

Besides, the meteorological data are time-series with a time step of 30 min, and therefore, the actual data values are needed as inputs for making predictions. Time-series data cannot use future values as input features, whereas the inputs of a time-series model are the values of past features. In this work, we adjust our model

to learn from the past to predict PV solar energy for the next half hour. This choice has been adopted because of the size of the data and to perform real-time predictions for an efficient and optimized management. Finally, based on best practices in the area of data analytics, the dataset is split into 80% and 20% were respectively used to train and test the models developed.

3.3 Training and models parametrization

Each of the models developed must be parameterized during the training phase in order to be able to provide the most accurate forecasts while taking into account the size of the batches. After setting different parameters for our DL models during the training and evaluating the results obtained, the Adam optimizer has proved to be the best optimizer and was then selected as the common parameter for all proposed DL models. ADAM, which is widely used and works better than other stochastic optimizers in empirical results [32], would allow the models to learn quickly. In addition, the tanh activation function has shown a good fitting for all DL models. On the other hand, we notice that our DL models have different architectures and that the number of layers and neurons for example has been fixed after tuning several values and selecting the ones that have given the best precisions. Figure 2 illustrates the neural network architecture, and Table 1 shows details on the architectures and the key parameters of each model suggested for the dataset studied.
Figure 2: ANN architecture for predicting solar energy

Table 1: Architecture and parametrization of the models.

Models	Parameters				
	Layers	*Epocs*	*Activation Function*	*Optimizer*	*Batch size*
RNN	RNN cell Of 100 units	20	Tanh	Adam	12719
LSTM	LSTM cell Of 100 units	20	Tanh	Adam	12719
GRU	GRU cell Of 100 units	20	Tanh	Adam	12719

3.4 Performance metrics

To evaluate the performance of the proposed DL models for PV solar energy prediction. A set of evaluation metrics widely-used are employed to evaluate the results accuracy forecasting. In this step, we have applied the most suitable to the context of DL and regression problems. For this purpose, five performance metrics, whose equations are presented below, have been employed for models testing as well as training: MAE (Mean Absolute Error), MSE (Mean Square Error), RMSE (Root Mean Square Error), Max Error (ME) and R squared (R^2).

$$MAE = \frac{1}{n} \sum_{j=1}^{n} |y_j - \hat{y}_j| \tag{14}$$

$$MAE = \frac{1}{n} \sum_{j=1}^{n} (y_j - \hat{y}_j)^2 \tag{15}$$

$$RMSE = \sqrt{\frac{1}{n} \sum_{j=1}^{n} (y_j - \hat{y}_j)^2} \tag{16}$$

$$ME = \max_{1 \le j \le n} |y_j - \hat{y}_j| \tag{17}$$

$$R^2 = 1 - \frac{SS_{reg}}{SS_{tot}} \tag{18}$$

where y is the actual output, $\hat{y}$ is the predicted output and n is the number of samples. Eq. 14 computes MAE as the average of the absolute errors (absolute values indicating the differences between the actual and the predicted values). Eq. 15 shows the MSE, which is the average squared errors (difference between the real values and what is estimated. Eq. 16 calculates RMSE, which is the square root of the MSE, and is applied in cases with small errors [33], whereas Eq. 17 measures the maximum residual error ME and reveals the worst error between the actual and predicted value. In addition, to calculate the predictive accuracy of proposed models, we also used R-squared, which is a statistical metric in a regression model, to identify the proportion of variance of the dependent variable that can be made explicit by the independent variable. Expressly, Eq. 18 indicates the R-squared measure to which the data correspond in the regression model (the goodness of fit) where SS_{reg} is the sum of the squares due to the regression and SS_{tot} is the total sum of the squares [34]. Eventually, in the different steps outlined in this section, we employed a set of technical tools for the implementation of the studied algorithms based on the Python libraries, including Pandas, NumPy, SciPy and Matplotlib in a Jupiter Notebook, in addition to Scikit-learn (sklearn) and TensorFlow.

4 Results and discussion

In this section, we present and discuss the results of our three studied models tested for PV solar energy forecasting. It should be noted that although R-squared (R^2) is a commonly used metric, it is not regarded as an effective indicator of the models fit with the data [35]. A low or high R^2 value does not always indicate that the model is wrong or that it is automatically right [36]. Due to the controversy

concerning the efficiency of R^2 as an appropriate metric for determining the best regression model [35, 36], we additionally evaluate our results using other statistical metrics that are the most widely used: MAE, MSE, Max Error and RMSE. The RMSE remains the most frequently employed in the regression area [37]. Table 2 show the metrics values corresponding to solar energy prediction in real time of studied models. Considering the parameters presented in Table 2, we can see the results for one-half hour ahead prediction of our experiments for the recurrent neural networks: RNN, LSTM and GRU. In spite of their architectural differences, RNN and LSTM have demonstrated similar performance, showing that the better model is strongly dependent on the task. Thanks to their ability to handle long-term dependencies in sequential information for time-series predicting applications, both RNN and LSTM perform better with very high accuracy as shown by their related R^2 values which are respectively equal to 94.68% and 94.26%. GRU gives slightly less performance than the RNN and LSTM with 90.32 as value. It also causes errors unlike RNN and LSTM. We observe that for GRU, 2.74, 15.53, 3.94, 37.30 are given as MAE, MSE, RMSE and ME values, respectively. Furthermore, these measures are nearly similar for RNN and LSTM with MAE=1.83, MSE=8.53, RMSE=2.92and ME=30.42 for RNN, and MAE=1.90, MSE=9.20, RMSE=3.03 and ME=29.73 for LSTM. Figure 3, Figure 4, Figure 5, Figure 6, Figure 7 and Figure 8 show their training and testing curves. In reality, more accurate prediction results mean less uncertainty and fluctuations in PV solar energy generation. Accuracy is a crucial factor in the efficient planning and use of electrical energy and energy systems with high PV power penetration. In short, as shown in Table 2, the prediction capability of RNN and LSTM seems very reliable compared to GRU under meteorological conditions, and they are better adapted to meet real-time PV solar energy prediction needs with high accuracy. Due to their ability to minimize errors during learning and test processes, they can reduce uncertainties related to the operation and planning of PV energy integrated management systems.

Table 2: Metrics related to PV solar energy dataset.

Models	Data	MAE	MSE	RMSE	ME	ME
RNN	Training	1.73	7.22	2.68	34.06	95.62
	Test	1.83	8.53	2.92	30.42	94.68
LSTM	Training	1.77	7.65	2.76	35.42	95.36
	Test	1.90	9.20	3.03	35.42	94.26
GRU	Training	2.63	13.69	3.70	34.26	91.70
	Test	2.74	15.53	3.94	37.30	90.32
Figure 3: RNN training curves of solar energy
Figure 4: RNN testing curves of solar energy
Figure 5: LSTM training curves of solar energy
Figure 6: LSTM testing curves of solar energy
Figure 7: GRU training curves of solar energy

Besides, while RMSE is regarded in the literature as a good metric for evaluating and comparing regression models, it is still difficult to interpret properly. Therefore, we also normalize the RMSE values to provide a more meaningful representation of our

results, which would allow more efficient conclusions. The normalized RMSE (NRMSE) represents the rate of the RMSE value and the range (the maximum value minus the minimum value) of the actual values. Table 3 shows a results synthesis based on this metric for real-time solar energy prediction. We can observe that RNN and LSTM provide good and similar NRMSE values with 0.055 and 0.058 respectively.
Figure 8: GRU testing curves of solar energy

Table 3: Results synthesis for real time prediction.

Models	Data	NRMSE
RNN	Training	0.055
	Test	0.066
LSTM	Training	0.058
	Test	0.068
GRU	Training	0.077
	Test	0.089

5   Conclusion and Perspectives

With the growing deployment of solar energy into modern grids, PV solar energy prediction has become increasingly important to deal with the volatility and uncertainty associated with solar power in these systems. In the literature, different models have been proposed for the prediction of PVs by using the AI techniques capacity. However, the majority of the research contributions in this area offer different techniques for making separate short-term and long-term forecasts, and do not focus on real-time forecasts. For this reason, we are working to find a model capable of producing continuous real-time forecasts using meteorological data, which is primordial for providing important decision support for power system operators to ensure more efficient management and secure operation of the grid and enhance the cost-effectiveness of the PV system. In this study, we investigated the efficiency of three different DL models: RNN, LSTM and GRU. The models were tested with data from a Moroccan region to make real-time PV forecasts. Further, the analysis of the results was based on six metrics MAE, MSE, RMSE, ME, R^2 and NRMSE to determine both forecast accuracy and margin of error. The results prove the efficiency of RNN and LSTM for real-time PV prediction thanks to their ability to address long-term dependencies in sequential information for time-series regression problems, compared to GRU that gives slightly less performance

than the RNN and LSTM. From these findings, it can be concluded that RNN and LSTM showed very high accuracy and low errors, they are reliable models that can minimize errors in the learning and testing process, in addition to reduce the uncertainties associated with the operation and planning of integrated PV energy management systems. Moreover, they are promising techniques that also appears to be suitable for long-term PV forecasting and should be studied and recommended as a possible unified and standard tool for real-time, short-term and long-term PV prediction. As future work of this study, we plan to enhance these models by employing other approaches, extend them to longer term PV forecasting, as well as to studying other promising deep learning methods in view of providing and deploying a powerful model for PV energy prediction.

Novel Infrastructure Platform for a Flexible and Convertible Manufacturing

Javier Stillig*, Nejila Parspour

University of Stuttgart, Institute of Electrical Energy Conversion, Stuttgart, 70569, Germany

A B S T R A C T

Sales behavior and the technical development of products influence their fabrication. As market influences become increasingly volatile and unpredictable, factories will have to adapt their manufacturing to market trends even more in the future. Adaptation is referred to as convertibility and can be achieved, among other things, by mobile and intercompatible machines. Enabling machines to be mobile, its power supply must be wireless and it should be possible to locate it on the shop floor at any time. With the help of the infrastructure platform Intelligent Floor, machines in future factories can be made more mobile than they are today. In combination with the novel autonomous guided vehicle BoxAGV, the platform offers a cost-efficient and highly flexible solution for in-house transport tasks. The transport of goods can be performed based on lot size one and thereby opens a wide field in logistics automation.
This paper is an extension of work originally presented in MELECON 2020 and describes the concept and the functionality of the open platform that is implemented so far. It shows how to apply the platform to a real industrial manufacturing environment and highlights the resulting manufacturing benefits. Finally, the next development steps on the platform and machine side are presented.

1   Introduction

The rigid linking of specialized individual machines by conveyor belts is the characteristic of today's production lines. Future production lines must consist of mobile, intercompatible machines that can be easily combined to form new production lines. This universality can be achieved with a reduction in functionality of the individual machine and by supplying it wirelessly with energy and data. The compatibility of the individual machines allows a higher-level control system to perform interconnected operation in order to follow in real-time market requirements.

These statements are verified in section 2 by using the automobile production as an example. Adapting today's productions to the new requirements, the Intelligent Floor (IF) poses as a universal platform for the building infrastructure and helps to achieve a flexible and convertible production. The IF is a raised floor that is currently under development. It is designed as a modular floor with individual panel elements that have sensor and actuator functionalities. The V0.5.x prototype can already supply production equipment by wireless power and measures the weight of objects on the floor panel. Furthermore, the IF has an Light Emitting Diodes (LED) display system in each panel included that is built-up with four LED stripes and located in a cross shape on the top of one panel.
Figure 1: Exploded view of the IF and the prototype V0.5.2 test set-up, which has a size of $10\,\text{m} \times 7\,\text{m}$ (L $\times$ W). When the picture was taken, as an example a walking path in the production was reproduced by the IF.

The IF consists of the four main components substructure, control and power unit, module inserts and panel (Figure 1). It receives its sensor and actuator capabilities from the module inserts or individually configurable panels. The IF basic version is already equipped with a detection and display functionality. Due to the modular design as a raised floor, the flexible positioning of machines on the IF is made possible through an omnipresent media supply. The IF can generate advantages for users and operators of production facilities that would not be achievable with conventional solutions. Two prototypes of the IF are currently being tested

in the ARENA 2036[1] using specific use cases of the convertible production.

A first prototype V0.1.1 of the novel Autonomous Guided Vehicle (AGV), hereafter named *BoxAGV* and shown in Figure 2. It is based on a simple frame construction made of aluminum profiles, to which four meccanum wheels are attached. The four drive motors are connected each to an inverter that receive their commands from the controller in real-time. The BoxAGV has installed a camera for identifying the route, which is mounted centrally in the frame. By using the Wireless Power Transfer (WPT) the battery of the vehicle can be charged dynamically. The entire vehicle technique is embedded in a standard box [1] made of polypropylene with the outer dimension $600\,\text{mm} \times 400\,\text{mm} \times 213\,\text{mm}$ (L × W × H). It offers after its integration still 50% of the origin transport volume.
Figure 2: Design of the first BoxAGV prototype V0.1.1, where frame, driving and control components are built-in a standard VDA box.

The combination of IF and BoxAGV meets the requirements of convertible production in terms of logistics flexibility and usability better than the solutions known so far. To verify this hypothesis, a study has been started in the ARENA 2036. Using a $70\,\text{m}^2$ large-scale demonstrator of the IF that interacts with two BoxAGV prototypes, highlights the expected gains for future logistics systems. To initiate a technical discourse, the novel concept is therefore introduced in this paper and evaluated based on a real field application. Additional to the logistic applications, further use cases of the IF are outlined and the importance of WPT for mobile applications is analyzed in more detail.

2 Convertible Production

To understand the purpose of the IF and its benefits for the users, it is essential to get to know more about convertible production. Scientists, in particular the production technology institutes of the University of Stuttgart, have been researching the subject of convertible production since more than 25 years, e.g. [2]–[7]. One of the central findings of their research work, carried out so far, is that in response to the fast changing requirements of the global market, production equipment must be designed to be more modular, mobile and compatible with each other. This is a fundamental of the future factories production concept. To implement this concept is necessary in order to be able of continuing producing economically with a high value-added share. Taking the automotive industry as an example, it will be outlined which factors drive the change in requirements and what kind of solutions can be helpful.

2.1 Driving Factors

The requirement to transform existing production systems to convertible production systems will be illustrated based on two general market developments. These market developments are described using the automotive industry as an example. Based on the research study [8], the number of registered automobile models has increased by 349% between 1990 and 2014 in Germany. In addition, the number of possible equipment options increased with the model variants, so that today almost every new car allows several hundred million of configuration options and is consequently built as a one-off. The second market trend is the shortening of a model's life cycle. While the life cycle of a Volkswagen Golf 1 was nine years in 1983, it has been reduced to just four years in 2012 [9]. These two market movements are critical not only for the automaker, but also for all their suppliers, who must adapt their products and production facilities to market developments.

The driving force behind the increase in the number of variants and the reduction in product lifecycle times is the interaction between the market and suppliers. The customer's desire for choice and product individualization is matched by a large number of competing manufacturers who expect to gain sales advantages by offering variants ever faster. The ongoing connection of people through the Internet means that the market and suppliers are better connected than before. This means that a reduction in the number of variants and an extension of the life cycle time cannot be expected in future. Therefore, it is necessary for product makers to adapt their production concepts to the actual situation and to move to convertible production concepts [10, 11]. Here it is important to couple the product life cycle with the life cycle of the production machine. Thus, the rigid coupling of product and machine is not critical if the period of the product life cycle is equal to or longer than the life cycle of the machine. However, the case in which the life cycle of a product is much shorter than that of a machine is critical for automated manufacturing. This causes production difficulties: Machines can no longer be planned, built and commissioned as quickly as the product life cycle requires. As shown in Figure 3, it is therefore necessary to implement a system that synchronizes both life cycles. This synchronization is the main task of the convertible production, as shown by the example in subsection 2.3.

2.2 Solution

There are many possible solutions for synchronizing product and machine life cycles. Two solutions will be highlighted in this paper: Transparency in the production process and faster product changeovers. Transparency is understood as the knowledge of the current position and status of all objects in the production process. Especially with knowledge of the material positions, the flow of goods can be optimized and non-production-related idle times can

---

[1]ARENA 2036 is a flexible research platform for the mobility and production of the future and is located in Stuttgart.

be reduced or eliminated. By shortening production time, more products can be produced in the same time period. As a result, the proportion of production costs allocated to the product becomes smaller, enabling the product to be produced cheaper. A solution to manage the increase in the speed of product changeovers is the use of modular, manufacturer independent and compatible production equipment. In some cases, solutions for defined manufacturing steps already exist, as it can be shown in the next subsection 2.3.
Figure 3: Product and machine lifecycle coupled by the convertible production.

2.3 Example

The relationship between product and machine life cycle is to be demonstrated using the example of wire harness production. In this case, the product is a wire harness (Figure 4). A wire harness is composed of different wires of various lengths and with a range of wire terminations. The use of wire harnesses is particularly widespread in the automotive industry. For example, an average equipped Volkswagen Golf 7 has a wiring harness with almost 1,000 different wires of a total length around 1.6 km and weighing up to 60 kg [12]. Each individual wire must be prepared individually for installation in the car. Due to the high demand quantities in the automotive industry, this requires a fully automatic machine that cuts wires to length, marks, strips and terminates them with a connector. Figure 5 shows a wire processing machine, type Zeta 640 / 650 that is manufactured by Komax. The machine is able to prepare up to 36 different wires with a cross-section from 0.22 to 6 mm^2 [13].
Figure 4: Wire harnesses are used in various industries, like in the consumer industry for wiring household appliances. One of its main advantages is the significantly reduced assembly time compared to single wire installation. Photo: TES.

Today, wiring harnesses take into account the vehicle equipment features ordered by the customer and they are built-to-order. This is done in order to reduce the overall vehicle weight and thus also

reduce fuel consumption and exhaust emissions. Such a production strategy leads to a large number of theoretical combinations, which [12] puts at 425 billion. Due to the high variance of the wire harness design as a result of changing vehicle equipment options and cyclical model changes, the wire processing machine is modular in itself. For example, there are up to 13 process modules for the model shown, which take over the feeding of different sized ferrules or the wire labeling. This enables the machine operator to react quickly to product changes. With the help of the modular machine design strategy, the fast-moving product cycle is coupled with the long-lasting machine cycle.

Figure 5: Wire processing machine for the fully automatic production of prepared wires for the use in wire harnesses. Photo: Komax.

Figure 6: The photo shows a wire harness production facility where workers assemble prefabricated wires into a wire harness. Photo: OWC.

Looking at the subsequent production process of the wire harness manufacturing, it is obvious that the fully automatic wire preparation is followed by a completely manual production process. As shown in Figure 6, the prepared wires are now assembled by hand on a pin board to form a complete wire harness. So far, it has not

been possible to build a machine for the automatic production of wire harnesses with a development and construction time that is shorter than the product life of a wire harness. Alternatively, it would also be possible to build a modular machine or a combination of individual system modules that are capable of producing complex wire harness layouts automatically. However, this has not yet been achieved either. Thus, product and machine life cycles for wire harness manufacturing in the automotive industry are not synchronized by machines, but manually by workers as shown in Figure 6.

The example of wire harness production can also be applied to other production processes in and outside of the automotive sector. It highlights the demands made on the machine life cycle in terms of flexibility, modularity and degree of automation.

At the same time, fully automatic machines should also be durable and robust investment assets that must guarantee a high output over their life cycle. Therefore, it is necessary to readjust the balance between product and machine life cycle by using new processes and elements from the field of convertible production. The IF described below is a new element from the field of convertible production. It uses an example from intralogistics to show how product and machine life cycles can be synchronized with each other based on machines.

3 Intelligent Floor

The Figure 7 shows a test surface of the IF prototype V0.5.1, which consists of 12 identically constructed panels, their control and power units and its substructure. In addition to the IF basic functionality of visualization and detection, a WPT unit is built into each panel. One panel has a surface area of $1\,\text{m} \times 1\,\text{m}$ and a thickness of $46\,\text{mm}$. The IF is constructed as a modular raised floor, which is adjustable in its height. In this specific case, the IF has a total height of $40\,\text{cm}$. The prototype V0.5.x is designed to carry static loads of min. $1{,}500\,\text{kg/m}^2$. A special feature of the IF is the interconnection of the energy units to form a DC $24\,\text{V}$ grid. This enables higher power to be provided at single points within the grid than could normally be provided by just the power supply unit of each panel. Furthermore, each panel has a control unit for processing its sensors and actuators. The Panel Controller (P-CTRL) is the central element of the control unit and communicates with the higher-level control system, the Section Controller (S-CTRL), over the $100\,\text{Mbps}$ Ethernet network. The S-CTRL itself manages by definition up to 256 panels. It can be implemented as a physically present controller or a cloud-based solution. Neighboring sections can be combined to a cluster, where the Cluster Controller (C-CTRL) is software-based controller. The IF prototype V0.5.x panels are already hot-plug capable and have the following sensor / actuator capabilities:

- The sensor system for object detection, which is based on load cells, is integrated into the substructure of the IF. Each load cell can measure up to 1,000 kg. Since each stand of the floor is equipped with a load cell, a network of weight values is built up over the area, which enables object detection with a positional accuracy of approx. 0.5 m.

- The panel's surface is divided into four quadrants by LED stripes consisting each of up to $144\,\text{LED/m}$. The LEDs are

controlled individually, in groups or all together in color and brightness by the P-CTRL.

- The IF contains up to four module slots, where Figure 7 shows one with a DC $24\,\text{V}$ / $240\,\text{W}$ WPT unit equipped module slot. In the IF prototype V0.5.2, the module slots contain further functionalities. For example, there are installed an e-paper display modul, a radio-based object localisation module and a power socket to provide three-phase current AC $400\,\text{V}$ / $16\,\text{A}$ instead of the WPT unit.

- Depending on the application, it may be useful to combine other functions in addition to the basic functions. This can be done in one panel or over a certain panel area. As the example in Figure 11 shows, the visualization functionality and the WPT unit were used here to charge a BoxAGV.
Figure 7: Prototype V0.5.1 of the IF, which was setup for test purposes in the ARENA 2036. It is assembled from 12 equal panels, each using one module slot for functionality expansion. The module is a 240 W WPT unit. Further, all stands are equipped with load cells, measuring the loads applied to the floor continuously.

3.1 Localization

The object localization in prototypes V0.2 and V0.5 is realized with the help of bending beam load cells, which are mounted under each stand of the substructure. During a measurement process, the weight force acts on the bending beam and generates an elastic deformation. This strain is converted into an electrical signal by the four strain gauges glued to the bending beam. In order to convert the signal into a weight value, the strain gauges are connected in a Wheatstone bridge and are made available to the P-CTRL by a subsequent measuring amplifier with an analog-to-digital converter. The controller forwards the weight values to a database located in the S-CTRL over the Ethernet network at intervals of 1 second. The database is designed as a ring buffer with a storage capacity of 256 panels, equal to one section, and a buffer time of 60 min. This allows the access to a total of 921,600 weight values.

In order to detect static or moving objects on the IF, the weight values of a time point that are above a defined threshold are extracted from the database. Since the position of the load cells is fixed and each weight value can be uniquely assigned to a load cell, it is possible to detect moving objects. The weight value itself can serve as an indicator of which type of object is being detected. For example, a measured value of 50 to 120 kg is an indication of a

human being. Object detection can be further refined by comparing the change in weight of several neighboring panels. If the weight sensors of panel Ⓐ measure the mass m at time t_0 and the weight sensors of panel Ⓑ, which lies next to panel Ⓐ, measure the mass m at time $t_1 > t_0$, it can be assumed that an object with mass m moves in time $t_1 - t_0$. Since the distance s between the panels Ⓐ and Ⓑ is known due to the uniform structure, the velocity v of the object is known as well. This is useful as another indicator of object types. For example, people in production areas typically move at speeds between 0.8 and 1.6 m/s. The object detection gains reliability if weight and velocity values are now combined.

Another possibility of object localization is currently being implemented in a panel of the IF prototype V0.5.2. With the help of a film-based sensor technology that is installed directly under the floor surface, the measuring accuracy and robustness is evaluated. Thus, the substructure of the IF's next prototype will be simplified and made ready for further applications outside industrial use.
Figure 8: The prototype V0.2.1 uses the LED visualization system to show a walkway on the production area and serves as orientation for visitors. In the top left corner of the photo, an area with mobile production equipment can be seen. A red no-entry zone visually warns visitors that they are not allowed to enter this area.

3.2 Visualization

In the prototype V0.2.1, LED stripes with an LED density of 144 LED/m are installed. Thus, a pixel density of 284 px/m² is achieved. In the panels of the prototypes V0.5.x, the pixel density has been reduced to 116 px/m², which is sufficient for information purposes and for steering the BoxAGV. Each LED is from type WS2812B and can be controlled in its color and brightness by the P-CTRL. One LED stripe is embedded in an aluminum profile, on which a translucent cover protects the LEDs. They are wired to a connection box for the data and power supply from the P-CTRL and the DC 5 V source. In version V0.5.x, the panel is connected via cable to the control and power supply. This connection will no longer be necessary in the following prototype generation to ensure a fast and ergonomic change of the panels.

Since the LED visualization system is mounted on the panel in a cross shape, a chessboard-like grid is created on the surface when several panels are installed. Static dot and line patterns, but also dynamic patterns can be displayed in this grid. Thereby the synchronous visualization is performed by the S-CTRL, which updates all P-CTRLs connected to the section at the same time. As shown in Figure 8, the visualization system enables man / machine and inter-machine communication easily. For example, dynamic LED markings can replace static adhesive tape markings for indicating temporary storage locations for materials. As well it can be used as a guidance system for workers to find other persons or specific objects. Instead of separate ANDON displays, production states can be visualized to the worker on the IF. Moreover, it can also be used for zone identification and in combination with a secure object detection, for safeguarding hazardous areas in production environments. This application example is described in more detail in the subsection 3.4.

3.3 Wireless Power Transfer

Convertible production demands high standards for the mobility of production equipment. To ensure mobility, machines must be freely positionable on the shop floor. Today's usual cable- and tube-based media supply of machines is contrary to the mobility requirements of convertible production. Therefore, the use of WPT systems is promising. The WPT primary units shown in Figure 9 transmit up to 240 W unidirectionally to a static, machine-side secondary unit.

The voltage level is DC 24 V on both WPT sides. The efficiency achievable during energy transfer is 91% over an air gap of 5 mm. As the technical data indicate, the WPT system shown is provided for low-power applications. For example, a workshop cart with electrical label printer was equipped with a secondary side, in order to operate the printer on each charging point of the IF. In addition to the low-power system, a mid-power system is available, whose transfer power is 1,000 W with an efficiency of 90% and a transfer distance of up to 10 mm. Also a high-power system is already in the prototype V0.5.2 in operation. It is able to transfer a power of 3 kW at a distance of 15 to 40 mm. Its max. lateral offset of 40 mm from the centers of both coils helps to charge machines easily. The IF panel's design allows to operate up to four WPT units, so that in theory an energy density of max. 12 kW/m² can be achieved.

However, since mobile and thus lightweight production equipment is required for convertible production in particular, the required electrical power is usually rather low. As described in [14], power densities of less than 4 kW/m² are enough for most applications. Fixed and semi-fixed production equipment with a higher power demand, can be supplied using conventional socket units in the raised floor system. One of the most significant challenges of convertible production is the location-independent and dynamically adaptable energy supply of the production equipment. Unfortunately, this challenge can only be solved to a limited extent with the industrial WPT systems on the market today. Therefore, the Institute of Electrical Energy Conversion (IEW) of the University of Stuttgart is researching on the following three fields of WPT:

Dynamic Charging Looking at the operation of industrial WPT systems, it is remarkable that most of them are designed for static coupling of primary (Tx) and secondary (Rx) units – so defined 0D systems. Even small deviations in $x-$ or $y-$direction from the ideal position of the Rx unit in relation to the Tx unit will reduce the transfer power and efficiency. Therefore, only WPT systems capable to couple Rx and Tx units at least along a route (1D systems) are suitable for the use in the convertible production environment. Even more appropriate would be a 1.5 or 2D system. The Table 1 summarizes the coupling of Tx and Rx units in $x-$ or $y-$direction. A

solution further developed by [15] is the introduction of separately switchable Tx modules in a grid-like structure that are able to operate as 1.5D system or better, but without having the disadvantages of today's solutions.
Figure 9: Two low-power Tx units each installed in an IF prototype V0.5.1 panel. The distance between the units is 1 m. Both Tx and Rx units have a uniform size of 100 mm × 100 mm × 47 mm (L × W × H) and can supply on Rx side 10 A at DC 24 V.

Table 1: Five categories of coupling between Tx and Rx coils in x and y planar movements without angular misalignment of the coil planes.

Cat.	Figure	Description
0D		The Tx and Rx are statically coupled, so that the two coils must be exactly aligned with each other.
0.5D		The Tx and Rx are statically coupled, but with a tolerance δ in two dimensions.
1D		The Rx side has one degree of freedom and is static in the second in relationship to the Tx side.
1.5D		The Rx is movable in one dimension and static with a tolerance δ in the second dimension.
2D		The Rx is completely dynamic in both dimensions, so that the Rx can be placed anywhere in relationship to the Tx device.

Bidirectional Power Transfer   Moreover, the industrial WPT systems available on the market are characterized by their unidirectional power transfer. Bidirectional systems are not yet available on the market. However, bidirectional energy transfer would have many

advantages in the environment of convertible production. For example, battery-buffered machines could help to compensate peak loads in production by feeding energy into the IF's DC grid via the bidirectional WPT system. At low-load times, the batteries can be recharged, which results in cost advantages for the operator in terms of a homogenized energy demand of his production [16, 17].

Power Density   A so far unknown key figure is the power density

$$\rho_{\mathrm{p}} = \frac{P_{\mathrm{inst}}}{A}$$, where P_{inst}: installed power [W], A: area [m^2]

needed to operate mobile machines in the environment of convertible production. This figure depends on the machines used and cannot be given as a general rule. However, with the operation of the prototypes V0.2.1 and V0.5.x, first empirical values are emerging which indicate a certain range. Measurements on lightweight mobile assembly and transport machines, showed a power requirement of less than 3.7 kVA per feeding point. For all equipment used in the ARENA 2036 test environment, a power input of 11 kVA was sufficient. In [18], the author calculates that the power requirement of an AGV with 500 kg payload is 347 W during steady driving. According to [14], a continuous power output density of 500 ^{W}/$_{m^2}$ is sufficient to start the supply of mobile production equipment.

3.4   Use Case 'Safety Zone'

Beside the intralogistics use case of the BoxAGV, which is described in more detail in subsection 3.5, another IF application shall be presented briefly. With the help of the safety panels a safety zone can be marked by the LED system and monitored for unauthorized entry of persons or mobile machines. To protect humans from injuries caused by dangerous movements of machines, such movements must be encapsulated according to ISO 13857 or limited in force and torque to non-hazardous values according to ISO/TS 15066. For this reason, protective fences as enclosures, sensors for initiating emergency stops or robots suitable for man-machine operation are used today, among other things. Especially the enclosures are static in their nature and thus in conflict with the goals of the convertible production. The safety zone application described below was implemented on the IF prototype V0.2.1 and shows the potentials as well as the added value for the user and operator of the IF. The application classifies two types of safety zones:

Immobile machinery   The safety zone around a production facility is normally realized with a fence and its access is monitored by safety devices triggering an emergency stop. To enable the access of persons and machines into hazardous areas, these entrances, e.g. doors and rolling gates, are secured with safety locks or safety light curtains. As well as for the safety enclosure of the production equipment and for access supervision in the safety zone, engineering time and capital expenditure must be considered. In the end, the solution remains inflexible with regard to the convertible production, because a relocation of the production facility always means a fully relocation of the safety enclosure. Considering the extensive mechanical and electrical installation of the safety equipment as well as the necessary acceptance test of the safety system, production managers usually decide against relocating machines despite more advantageous production logistics.

Mobile machinery Since the risk analysis of machines must also consider their surrounding space, the common installation of safety zones is much more complex than for stationary machines. This is due to the changing of the surrounding space. Based on the application example of AGVs, one of the central hazards of mobile machines for humans is the risk of becoming crushed [19]. Therefore, minimum safety requirements are placed on an AGV, which demand the presence of a braking system, a speed limiter and a device for object detection. By the interaction of AGV and IF, dynamic safety zones can be generated, which minimize the risk of an accident and at the same time reduce the expensive safety technology on board of the AGV (Figure 10).
Figure 10: AGV and IF interact so that the yellow safety zone moves with the AGV. The IF detects an zone entry and can trigger the AGV to change direction or to stop.

3.5 Use Case 'BoxAGV'

Another application of the IF comes from the field of intralogistics and shows the use of the BoxAGV, which was adapted to the real production scenario described in [20]. The presented example relates to the production of interior parts, like headrests and side bolsters, for various vehicles. It is suitable, because the transition of a Manually Operated Intralogistics (MOL) to the new material supply concept of the In-plant Milkrun System (IMS) is already being discussed there. Furthermore, the paper includes a production layout and data on which the application example of the Novel Box-AGV System (NBS) can be based on. The comparison of the three material supply concepts does not claim to be complete and / or be generally valid. Further, it does not take into account the influencing factors that occur in practice, such as the robustness of the concepts with regard to the failure of critical components, fluctuations in demands or similar. The comparison rather serves as an indication for a possible operational capability of the NBS.

With the beginning of the 1990s, stationary storage capacities were gradually replaced by trucks moving in public roads. Responsible for this is the Just-In-Time (JIT) production concept [21, 22] which is widely used today. This relocation is not only to be criticized from an ecological point of view, but if the development is viewed from a business point of view, the JIT concept is extraordinarily successful: Warehousing and thus its capital tie-up can be significantly reduced. JIT can be scaled and transferred to the logistics of convertible production. This generates the following advantages:

- Liquidation of supermarkets (cf. central warehouse).
- Reduction of material handling (storage and retrieval).
- Minimum quantity of goods in the production process.

- Shorter throughput times and reduced capital tie-up.
Figure 11: The three pictures show a time sequence in which the BoxAGV follows the dynamically controllable blue line to a WPT unit in order to get recharged.
Figure 12: Based on the author's patent [23] an easy to use optical guidance system for mobile robot applications in combination with the IF is proposed. Conventional guiding lines that are painted on the floor, can be replaced by dynamically controllable LED guiding lines.

The IF is suitable in particular for use in internal logistics. Resources (goods, machines and employees) can be organized dynamically with the help of the IF visualization function. This means that it is no longer necessary to depend on rigid production layouts, but can, for example, redefine and reroute goods flows depending on the order situation. If this dynamic route modification is taken as a base for an AGV's track guidance, it is possible to react ad-hoc to unforeseen events in the production. Figure 12 shows that a single LED segment, for example consisting of eight single LEDs, is sufficient to realize track guidance. The segment not only sets the direction of the AGV, but also its speed. With only three colors the speed control can be built up:

- The BoxAGV remains at its current speed, while detecting a green light only.
- While detecting a yellow light, the BoxAGV controller will interpret this as an acceleration command.

- A red light decelerates the BoxAGV from its current speed to zero.

Today's AGVs used in industrial environments are expensive since, as autonomous transport machines, they must have cost-intensive components like battery, on-board computer, localization system and safety devices. As a result, the investment costs for a fully automated logistics are also high. The use of the simply designed BoxAGV, which is centrally navigated and supplied by WPT systems, is a promising approach for the automated logistics of the convertible production. Due to the BoxAGVs slow driving speed of max. 1 $^{km}/_h$ and its max. payload of 50 kg, complexity and costs can be reduced. For example, costs can be saved using simple safety edges instead of laser scanners for mobile safety applications. Additional collision protection measures should also be considered. Here, the IF provides predictive safety through its built-in weight and object detection on the total production area. In order to illustrate the potential savings and technical possibilities of the NBS concept in comparison with the IMS solutions and the MOL, a real production scenario from the operational practice will be examined.

3.5.1 Production Layout

As shown in Figure 13, the predominantly manual production of car interior parts is divided into a logistics and a production sections with a total area of 1,350 m^2. One third of the available area is reserved exclusively for logistics applications and two third is available for production. A closer look at both sections reveal a further subdivision into manufacturing, storage, traffic, administration and infrastructure areas.

The division of areas is partly determined by the building's structure itself (stairwells, escape routes), organizational requirements (offices, social rooms) and the type of manufacturing (workplaces, storage areas, logistics routes). The organizational and production-specific areas can be partially or completely adapted by changes in the production technology. In the following, the areas specified by the construction are considered to be non-adaptable. Table 2 applies the area allocation to the manufacturing plant and determines the area that is required for manually operated production logistics. It is obvious that only one third of the total area can be used for value-added assembly activities, two third of the area is occupied by traffic routes (marked by red lines) and storage areas. Therefore, [20] also highlights that one of the most urgent problems is the lack of space in production. Furthermore, the turnaround time of incoming and/or outgoing materials is criticized too. Materials sometimes lie on the racks for longer than one shift, which means that the logistics process is not optimally synchronized with the production process.

The production logistics process is considered and the three applicable logistics concepts (MOL, IMS and NBS) are compared with each other in terms of their capital and operational expenditure. The comparison is based on the data published in [20] and the available practical and calculated values for the IF and BoxAGV. It serves to identify the market and technology position of the novel logistics concept NBS compared to existing systems, but is not to be understood as an extensive and generally valid research study. This is part of subsequent studies that foresee an implementation of the NBS concept in a real manufacturing environment.

The production is run in two shifts, with one shift lasting eight hours. Of these, 7.5 hours are net working hours. The working and assembly stations are marked as gray areas in Figure 13. The material buffer in the workstations is divided into input (blue) and output (green) materials and has a capacity for two hours of production time. In the current scenario, logistics is provided in each shift by two qualified workers who travel between the supermarket and the workstations with pallet trucks and handcarts. The data basis [20] is accompanied by a component list of a center console as shown in Table 3. It includes the main components only. Small parts such as screws or washers are not listed. The bill of materials also contains information on the packaging unit (PU) of the components and determines their turnaround time based on the target production quantity of 296 pieces per shift.

Table 2: The layout of the manufacturing area is shown in Figure 13, where traffic routes, production and storage areas are the main uses of the total area.

Type of area	Share	
Traffic	463 m^2	34%
Manufacturing	436 m^2	32%
– Area for the workers	*388 m^2*	*28%*
– Workbenches/Machines	*48 m^2*	*4%*
Storage	363 m^2	27%
Administration	74 m^2	6%
Infrastructure	14 m^2	1%
Total	1,350 m^2	100%

Table 3: Bill of materials containing the main components of a center console including the numbers of components per PU, the consumption per shift and the coverage of one PU. The components are provided in a standard VDA box with a capacity of 0.072 m^3, type SLC 8280, 6280 and 6410. `Original data taken from` [20].

Component	Quantity	Consumption	Coverage
① Support arm	192 $^{pcs}/_{PU}$	1.54 $^{PU}/_{shift}$	292 $^{min}/_{PU}$
② Retainer	180 $^{pcs}/_{PU}$	1.64 $^{PU}/_{shift}$	274 $^{min}/_{PU}$
③ Storage	24 $^{pcs}/_{PU}$	12.33 $^{PU}/_{shift}$	36 $^{min}/_{PU}$
④ Handle	1,250 $^{pcs}/_{PU}$	0.24 $^{PU}/_{shift}$	1,900 $^{min}/_{PU}$
⑤ Foam part 1	60 $^{pcs}/_{PU}$	4.93 $^{PU}/_{shift}$	91 $^{min}/_{PU}$
⑥ Foam part 2	16 $^{pcs}/_{PU}$	18.50 $^{PU}/_{shift}$	24 $^{min}/_{PU}$

⑧ Cover lid 2	54 $^{pcs}/_{PU}$	5.48 $^{PU}/_{shift}$	82 $^{min}/_{PU}$
⑨ Cup holder 1	21 $^{pcs}/_{PU}$	14.10 $^{PU}/_{shift}$	32 $^{min}/_{PU}$
⑩ Cup holder 2	432 $^{pcs}/_{PU}$	0.69 $^{PU}/_{shift}$	657 $^{min}/_{PU}$

Since [20] has not synchronized the products assembly location with the layout and the paper does not provide any additional bill of materials, the author has made the following definitions to determine the benchmark figures:

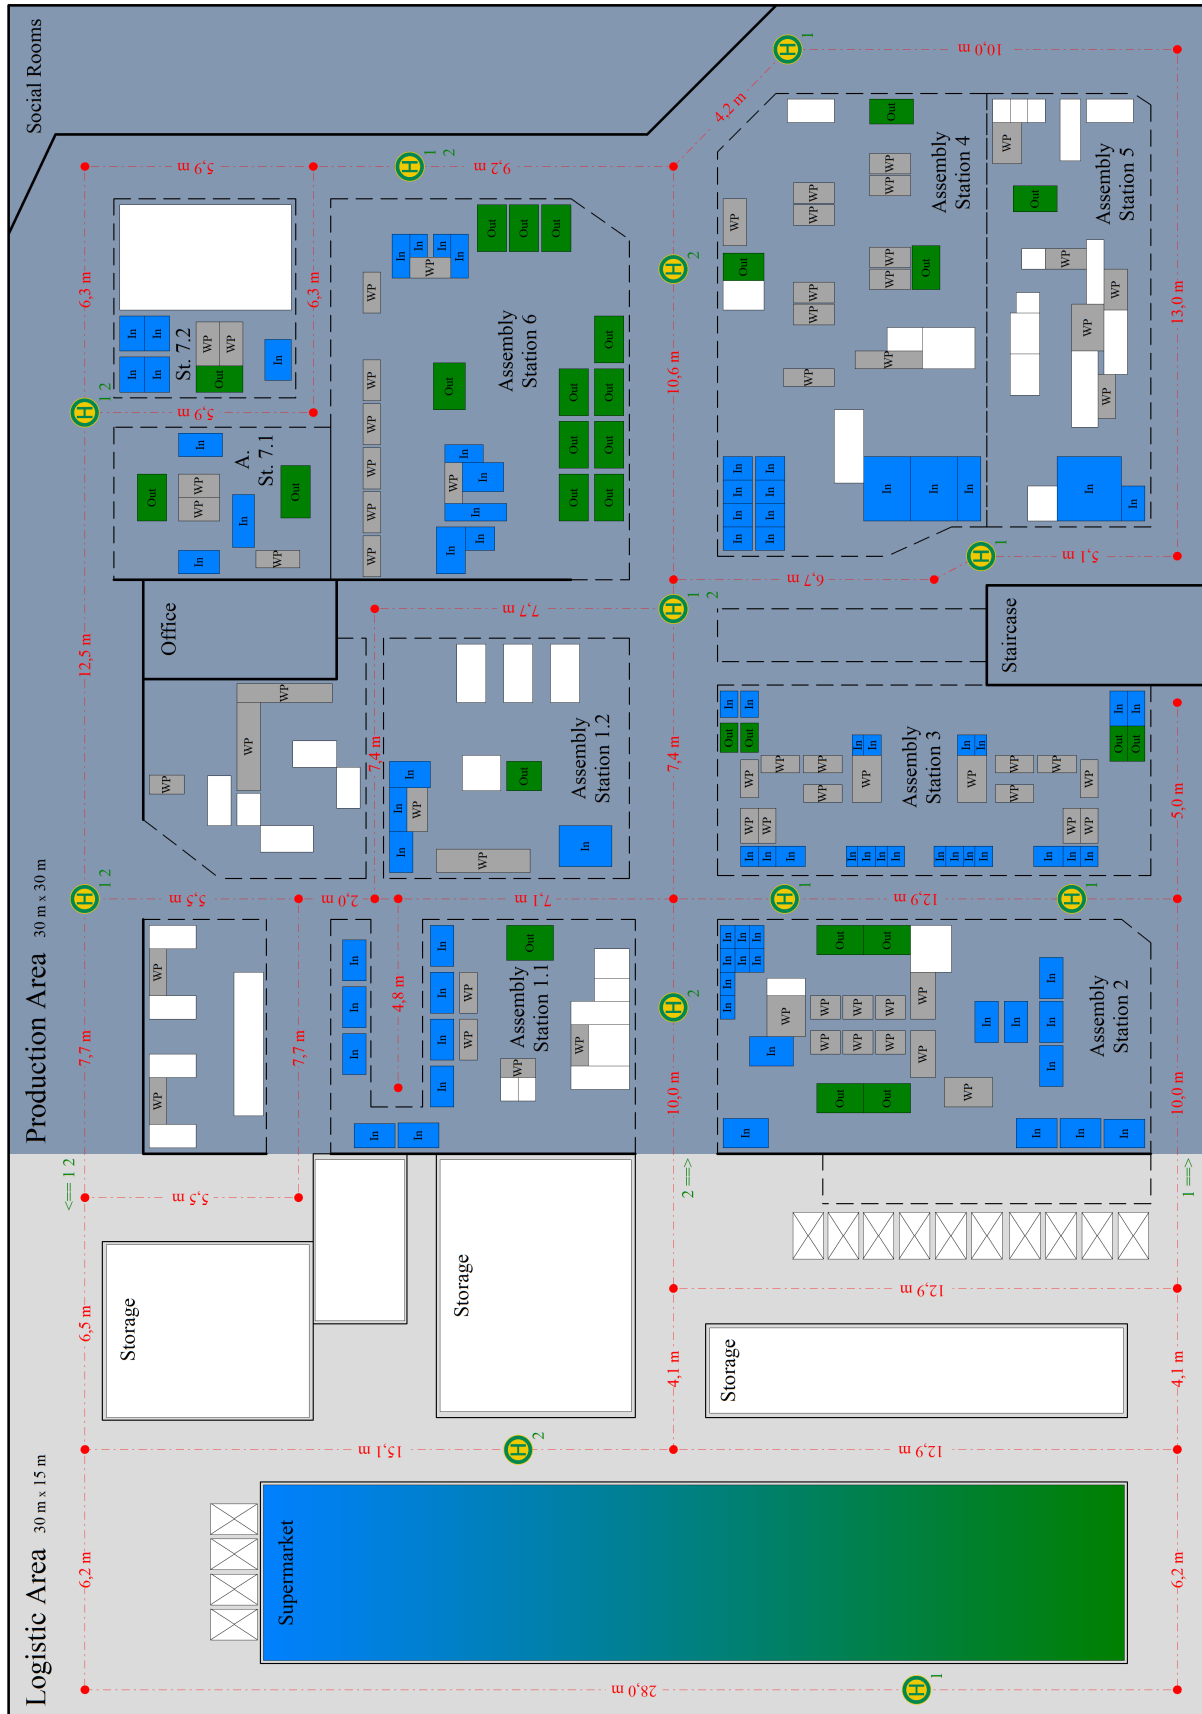
- Similarly, assembly products are produced in the manufacturing, where the center console is taken as example to all assembly stations.


Figure 13: Layout of the logistics and production area for car interior parts, consisting of seven assembly zones, in which the blue rectangles represent goods entry areas, the green ones the goods exit and the grays the workstations. The walking and logistics routes are marked in red and their lengths are listed. The ⓗ–symbols indicate the routes of two milkruns described in [20].

- Ten consoles will be packed into one PU in order to form one outgoing box.
- Milkrun stops are defined according to Figure 13, where the start and end point of a milkrun is located at the supermarket.

With the help of Table's 3 data and the assumptions made, the time-related box throughput in production can now be determined. The Figure 14 shows the time points and quantities of the incoming and outgoing boxes to be handled by the internal logistics over one station and shift. Based on the assumption that similarly complex products are also produced in the other six assembly stations, the handling process can be transferred to them as well. The process does not consider any disturbing effects in the production or logistics chain. It is therefore easy to see that a lack of synchronization between production and logistics, as well as disturbances acting on the logistic chain, can significantly increase the simultaneous material requirements, even though there are buffer at each station.

Furthermore, the number of box storage spaces and the total number of boxes in production can also be calculated from Table 3 and the assumptions made. For this purpose, an assembly station is divided into input, storage and output spaces. In the production start-up configuration, it is planned that all components are available in one box each and that there is also a buffer for each material to bridge a two-hour supply breakdown. The empties storage spaces at the assembly station are dimensioned accordingly. Table 4 shows that the throughput of boxes per shift is 94. This means that in average every five minutes, one box must be fed to or removed from the assembly station. In this case, a usage of the material buffer is not necessary. The buffer capacity is based on the requirement to guarantee a stand-alone manufacturing over two hours.
Figure 14: Throughput of input and output boxes at an assembly station over one shift. The incoming boxes with the ten main components of the center console are marked blue and the outgoing boxes with the finished product are marked green. In total 94 boxes are handled over per shift.

To dimension the storage capacity of an assembly station with components correctly, the autonomous production time of two hours is taken as a basis first. Table 3 shows for each component how much production time can be represented by a full box. This time per box is defined as the coverage. Dividing the buffer time of two hours by the coverage gives the number of boxes required. Since this result is usually not a natural number, the value is rounded up to full boxes. As there should always be a full box of each component at the workplace at the beginning of a shift, the result of the storage space calculation must be reduced by this box. The same number of full boxes in the material buffer must be matched by the number of empty box storage spaces. So, the assembly station has in total 21 storage spaces for empty boxes and 21+10 spaces for full boxes. In order to determine the minimum number of boxes in production, it is assumed that the number of boxes handled per shift as well as in the

storage areas of the assembly stations must be provided. Applying this to the present production, a minimum number of 875 boxes is obtained. The following comparison of the three logistics concepts MOL, IMS and NBS bases on the figures of this subsection.

Table 4: Throughput and number of boxes of one assembly station, considering the start-up phase of production and the buffer for at least two hours continuous production.

Component	Start-up	Buffer for 2 h production		Throughput
	full boxes	full boxes	storage space

3.5.2 Comparison of the Logistics Concepts

Manually Operated Logistics The MOL is characterized by using manual transport equipment and a low degree of digital information and processing systems. MOL is limited in its complexity and can easily be applied to low variant and continuously running productions. Since it is operated manually, high personnel expenditure is necessary to ensure the material supply – corresponding to the variety of parts, their throughput and the logistic routes length.

In-plant Milkrun System The IMS is an extension of MOL. Logistics employees are still in charge of driving tugger trains, loading and unloading boxes and checking the material quantities by visual inspection. In comparison to MOL, the operation of IMS requires more use of digital information and processing systems as well as the extension of organizational processes. For example, a production with IMS requires defined stops in the shop floor and a schedule with accurate arrival times. This requires a good synchronization of production and logistics that can be implemented with an appropriate production automation technology. In return, productivity gains and personnel cost savings are possible.

Novel BoxAGV System The NBS bases on the IF combinated with the BoxAGV. It represents a fully automated logistics concept. Each box can be controlled autonomously, without the investment

cost disadvantage of today's AGV solutions. In contrast to the logistics concepts MOL and IMS, no persons are required to perform the transport task. But the extensive use of networked information and processing systems is necessary or have to be implemented initially. In addition to the automation of the transport task and the associated reduction in personnel costs, the NBS offers a significant saving of space in production by transferring the material storage to the traffic routes. Due to the demand-driven material supply, NBS reduces the risk of production breakdowns and is therefore more robust than MOL and IMS.

Table 5: Investment and operating expenditures of the logistics concepts MOL, IMS and NBS in a quick comparison.

Cost category	MOL	IMS	NAS
Building	44,388 EUR	44,388 EUR	39,604 EUR
– Space costs/month/m² [24]		2.74 EUR	
– Total production area	1.350 m²	1.350 m²	1.205 m² [1]
Logistics equipment	– are not considered –		
Transport equipment	1,270 EUR	2,392 EUR	83,813 EUR
– 4 x Electric pallet truck [25]	10,156 EUR		
– 2 x Platform truck [26]		5,580 EUR	
– 6 x Trailer [27]		3,558 EUR	
– 351 x IF panel acc. Figure 15			280,800 EUR
– 854 x IF cover panel			170,703 EUR
– 438 x BoxAGV [2]			219,000 EUR
Staff costs	159,360 EUR	79,680 EUR	0 EUR
– Workers per shift	2	1	0
Annual expenditures	205,018 EUR	126,460 EUR	123,417 EUR

[1] *Elimination of the supermarket and its traffic area → 145 m².*

[2] *Each BoxAGV can transport up to 2 PU.*

Since the current state of development of NBS and the data basis of the described production do not allow a detailed cost comparison, the Table 5 is intended to provide a rough cost evaluation of the three logistics concepts shown. It shall be proven that NBS is principally interesting from its capital and operational expenditures compared to MOL and IMS. The table bases on a general operating lifetime of the transport equipment of eight years [28]. This period was also applied for the IF, so that the investment sum in the individual logistics concepts is depreciated on a linear method over eight years. Furthermore, the annual income of a logistics employee is set at 33,200 EUR for the comparison, to which an employer's contribution of 20% to social insurances is added to determine the staff costs [29].

The logistics concepts are compared in three cost categories. For the purpose of completeness, immobile logistics equipment, such as racks, signage and similar equipment, is also listed. But this cost category is not used to evaluate the concepts. Typically, transport equipment is included in the investment costs and staff in the operating costs. The cost of the building may fit into one category or the other, depending on whether the company owns the building or not. If the building is rented, the costs of rent, electricity, water and heating should be allocated to the operating costs. When comparing the annual expenditure, it is remarkable that the lower the degree of automation and rationalization in the logistics concept,

the higher the costs. In the MOL concept the personnel costs are dominant and represent the largest part with three quarters of the total costs. The NBS concept is particularly capital-intensive, but it is cheaper over the eight years of operation compared to MOL. NBS and IMS are roughly equal in price. In addition to investment and operating expenditure considerations, the logistics concepts can also be evaluated according to other criteria. For example, the examination of adaptability to changing market and production conditions is an interesting evaluation criterion that should be considered before deciding on a specific logistics concept. Due to the focus of this paper on the NBS introduction, comparing and delimiting studies are described in subsequent papers. Therefore, a preliminary qualitative list of NBS logistic concept advantages is given here:

- The IF can detect obstacles along the traffic routes with its load cells and redirects the flow of materials automatically by changing the displayed route of the BoxAGV.

- Batch tracking can be carried out by using the built-in LED stripes or an e-paper display unit. The visualization makes it easier to find required batches or to implement space-saving chaotic storage on the shop floor.

- Only a limited number of traffic routes in production are suitable for tugger trains. This limits the automation gain of the IMS concept. As shown in the layout Figure 13, tugger trains are used on the main routes, because curves are not large enough or necessary safety distances [30] cannot be guaranteed. Logistics employees are therefore still forced to carry out material transports manually.

- The MOL is basically flexible, but sensitive to disruptions due to the low degree of interconnection between production and logistics. Bottlenecks that arise here, affect the entire manufacturing process. Due to its high degree of interconnection, the NBS is more robust and less error prone.

- Compared to standard AGV solutions, the distances traveled by the BoxAGV are rather short, so that a BoxAGV can generally be built more simply and therefore more economically. Standard AGVs are designed for a daily mileage of 15…20 km [31]. In contrast, the BoxAGV has to run an average travel distance of less than 200 m (warehouse → assembly station → warehouse) in one shift.

4 Conclusion

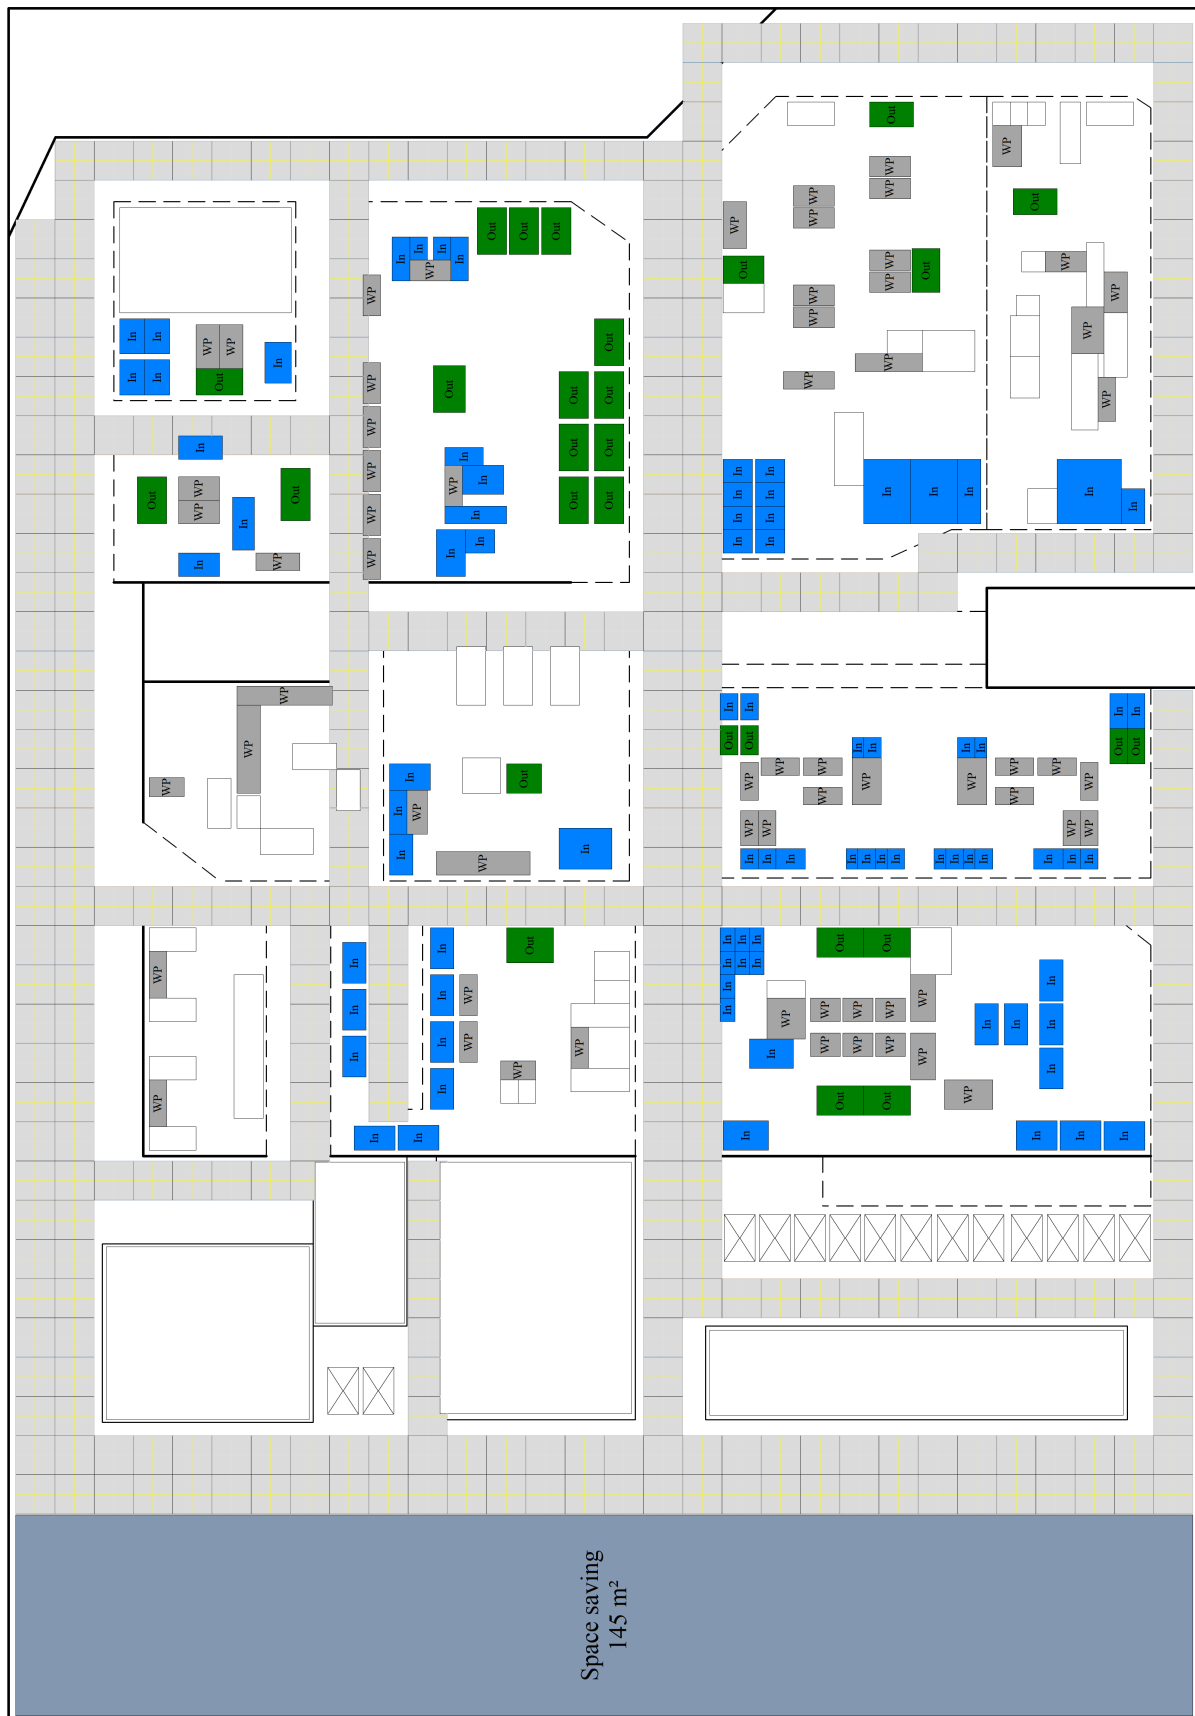
In the factory of the future, the floor, walls and ceiling will be the only elements that are installed fixed. Production equipment is mobile and can be flexibly combined to form new production lines. Particularly the transport of goods is performed automatically and made more flexible in the sense of the convertible production. To ensure the competitiveness and future viability of a production company according to the customer demands, the convertible production is becoming more and more essential. Storage space inside the factory like supermarkets is reduced, since the material is in a continuous flow on the BoxAGV. Communication takes place in real-time and humans are the decision makers, supported by assistance systems that operate on an artificial intelligent core.


Figure 15: Implementation proposal of the IF into the described production, in which the traffic routes are equipped with standard panels. On this area, the basic functionality of the IF *visualization*, *object detection* and *WPT* for BoxAGV charging is provided. The floor in the area of the assembly stations is built up with regular cover panels.

The IF supports convertibility best and is suitable as an universal and open infrastructure platform for the FOF. Using the IF in such an industrial environment, opens a wide range of applications and makes our current manufacturing processes faster, more flexible and more transparent. A contribution to the convertibility is made by the NBS concept, which prospectively offers cost and space advantages over current logistics solutions. It reduces the material stock at the assembly stations by providing a demand-driven supply. Supermarkets can be downsized by chaotic warehousing or eliminated at all by shifting logistics to the traffic routes. This enables rapid changes in company intralogistics and thus a quick response to market-relevant developments. The close integration of production and logistics also makes manufacturing processes faster and more efficient than today. It is not necessary to search for specific batches (boxes) because each BoxAGV can navigate to a defined point on command or the IF can show the user the way to the BoxAGV via its LED system. The BoxAGV can be used to save on personnel costs or to assign logistics staff to higher-value tasks too.

Overall, the combination of IF and BoxAGV seems to be promising for production companies, especially for companies with a high level of manual and multi-variant assembly. For this reason, a further development of the BoxAGV and the IF is planned. It includes the WPT of transportation and production equipment not only at specific spots, but also along a track and in an open area as described in [15].

A B S T R A C T

Data aggregation, gathering and gossiping are all vital communication tasks in wireless sensor networks (WSNs). When all networking devices are always active, scheduling algorithms for these communication tasks have been extensively investigated under both the protocol and physical interference models. However, wireless devices usually switch between the sleep state and the active state for the purpose of energy saving. A networking device with duty-cycled scenarios having sleep/awake cycles may need to transmit the message to all neighbors more than once. Taking the duty-cycled scenarios into consideration, communication scheduling algorithms for these tasks have been extensively investigated under the protocol interference model. As far as we know, scheduling algorithms for these communication tasks have not yet been investigated in WSNs with duty-cycled scenarios under the physical interference model. In this paper, we propose minimum latency scheduling algorithms for these communication tasks in duty-cycled WSNs under the physical interference model. Our innovative scheduling algorithms for both data gathering and gossiping achieve approximation ratios at most a constant time of $|T|$, where $|T|$ is the length of a scheduling period. The approximation ratio of our proposed data aggregation scheduling algorithm is less than or equal to a constant times $|T|$ with bounded maximum degree of the network.

1   Introduction

This paper is an extension of our work originally presented on the 15th IEEE International Conference on Mobile Ad-hoc and Sensor Networks (IEEE MSN 2019) [1].

Wireless sensor networks (WSNs) have been widely employed in automated battlefields, emergency disaster relief, environmental monitoring, real-time pollution monitoring, military surveillance, etc. Most of these WSN applications are time critical. The definitions of data gossiping, data gathering, and data aggregation can be found in [2]. The concepts of a link schedule, data aggregation schedule, data gathering schedule and data gossiping schedule can also be found in [2].

The latency of a data aggregation schedule is the total number of time-slots needed for the sink node to receive the aggregated message from all other networking nodes. Minimum-Latency Aggregation Schedule (**MLAS**) is the research problem for developing a scheduling algorithm for data aggregation in a multi-hop WSNs with the smallest latency. Similarly, the latency of a data gathering

schedule is the total number of time-slots required for the sink node to receive a packet from every other networking node; the latency of a gossiping schedule is the total number of time-slots needed for every device to receive the packets from all other networking devices. Minimum-Latency Gathering Schedule (**MLGS**) is the research problem for developing a scheduling algorithm for data gathering in a multi-hop WSNs with the smallest latency. Minimum-Latency Gossiping Schedule (**MLGoS**) is the research problem for developing a scheduling algorithm for data gossiping in a multi-hop WSNs with the smallest latency. A great number of communication scheduling algorithms have been developed for MLAS, MLGS and MLGoS in multi-hop WSNs under either the physical interference model [2], or the protocol interference model [3]–[13] and the references therein.

However, wireless devices usually switch between the sleep state and the active state for the purpose of energy saving. A networking device with duty-cycled scenarios having sleep/active cycles may need several times to transmit the message to all neighbors. The duty-cycled scenarios is a popular energy-saving method for multi-

hop WSNs. The GreenOrbs projects [14] and the VigilNet projects [15] are two actual applications of duty-cycled WSNs (DC-WSNs). Thus, all the existing approximation solutions for MLAS, MLGS, or MLGoS without duty-cycled scenarios are not working any more on DC-WSNs.

We use the same duty cycle model in this paper as the one we used in our short conference version [1]. The problem MLAS on duty-cycled multi-hop WSNs is represented by **MLAS-DC**. Similarly, MLGS and MLGoS on duty-cycled multi-hop WSNs are represented by **MLGS-DC** and **MLGoS-DC**, respectively. With duty-cycled scenarios, all three problems MLAS-DC, MLGS-DC and MLGoS-DC have been extensively investigated subject to the protocol interference and its simple variations [5], [16]–[24]. To the best of our knowledge, all three duty-cycled scheduling problems have not yet been investigated on duty-cycled multi-hop WSNs subject to the physical interference.

In this paper, we develop short communication schedules for the above three duty-cycled scheduling problems on multi-hop WSNs under the physical interference model which is a realistic model that handles wireless interferences more accurately. Under such a realistic model, a receiver can successfully receive the message if and only if the *Signal-to-Interference-plus-Noise-Ratio* (*SINR*) of the receiver is greater than a threshold value. According to the way the SINR ratio is computed, the SINR value is based on those transmissions are that will be scheduled concurrently in every time slot. Therefore, constructing a conflict graph to model the wireless interference is challenging. Such a nature of the physical interference makes it very hard to analyze the proposed communication scheduling algorithms subject to physical interference. Let $\|uv\|$ represent the Euclidean distance between the two devices u and v. Let σ represent the threshold value for a receiving device can successfully receive the wanted signal subject to physical interference, and ξ power strength of the background noise. Suppose that all the devices use a uniform and fixed power P for transmission. The path loss is represented by a positive reference loss parameter η, and a constant path-loss exponent κ (a value between 2 and 6). Assume that the communication radius of each device is normalized to one. If a device u sends a signal using a transmission power P, the power strength of this signal received by the receiving device v is $\eta P \|uv\|^{-\kappa}$.

By far, [25] is the only work that studied **MLAS-DC** for multi-hop WSNs subject to physical interference. When the SINR ratio of a node u is calculated in EQ(1) of [25], the received power $P_r(u)$ at u is incorrectly calculated in EQ(2) of [25] as it will be greater than the transmission power when the distance $\|uv\| < 1$. When $\|uv\| \geq 1$, the received power $P_r(u)$ is simply set to be the transmission power in [25]. Similarly, the total interference power at u is also incorrectly calculated in EQ(3) of [25]. Therefore, radio signal attenuation is not taken into consideration and the algorithms proposed in [25] for **MLAS-DC** are invalid under the physical interference model. As far as we know, there are no existing algorithms proposed for **MLGS-DC** or **MLGoS-DC** for multi-hop WSNs subject to the physical interference constraint.

Let $|T|$ denote the total number of time-slots in a scheduling period. Below are this paper's main contributions:

1. The approximation ratio of the algorithm we proposed for

MLGS-DC is less than or equal to a constant times $|T|$;

2. The approximation ratio of the algorithm proposed for MLGoS-DC is less than or equal to a constant times $|T|$;

3. The approximation ratio of the algorithm proposed for MLAS-DC is less than or equal to a constant times $|T|$ when the network has bounded maximum degree.

All the notations used in this paper are listed in Table 1 for easy referencing.

The remaining of this paper is organized as follows. The related work for existing approximation scheduling algorithms for data aggregation, gathering and gossiping are given in Section 2. Section 3 gives some basic concepts and preliminary knowledge that are needed for the design of the scheduling algorithms. In Section 4, we create a tree rooted at the sink that will be used for routing. In Section 5, we present an approximation solution to MLAS-DC. In Section 2, we propose an approximation solution to MLGS-DC. An approximation solution to MLGoS-DC is developed in Section 7. Finally in Section 8, a conclusion for this paper and some future research are presented.

2 Related Works

First, let us review the related work for known algorithms that were proposed for MLAS in multi-hop WSNs when all the networking nodes are implicitly assumed to be always active [2]–[4], [7], [9]. If all the networking devices have uniform transmission radii normalized to one on a multi-hop WSN, the network topology forms a UDG (unit-disk graph). For convenience, the number of networking nodes is denoted by n, the radius of the network graph w.r.t. the sink node of data aggregation or gathering is denoted by R. For arbitrary interference radius, any optimal solution to MLAS uses at least R time-slots. So is $\log n$. [3] and [7] proposed two scheduling algorithms for data aggregation with the total latency less than or equal to $(\Delta - 1)R$ and $23R + \Delta - 18$, respectively, where Δ is the maximum degree when the transmission radius is the same as the interference radius. The single-level aggregation was investigated in [4] that developed aggregation scheduling algorithm. When the transmission radius is the same as the interference radius, three approximation algorithms were proposed in [9] with total latency less than or equal to $15R + \Delta - 4$, $2R + \Delta + O(\log R)$ and $\left(1 + O\left(\log R / \sqrt[3]{R}\right)\right)R + \Delta$, respectively. These existing scheduling algorithms for MLAS mentioned above were proposed subject to the protocol interference, and the networking devices are assumed to be always awake.

Subject to the physical interference or the protocol interference, MLGS in multi-hop WSNs has also been extensively investigated when all the networking devices are always awake [2], [10], [11], [13], [26]. Let us review the approximatino solutions developed subject to the protocol interference first. The NP-hardness of MLGS was verified by in [10] that developed a scheduling solution for MLGS that has approximation ratio at most four with the assumption that the communication topology could be reduced to a UDG. In [11], the author proposed a greedy approach for MLGS and proved it to achieve approximation ratio at most 4 in a general setting and achieve approximation ratio at most 3 when

Table 1: All notations used in this paper:

P	the uniform transmission power of every node
η	the parameter of the reference loss
κ	the path-loss exponent
$\|uv\|$	the Euclidean distance of the two nodes u and v
σ	the threshold ratio of the SINR model
ξ	the background noise in the SINR model
T	a scheduling period
$|T|$	the count of the time-slots in a scheduling period T
V	the set of all networking nodes
Δ	the maximum degree of the communication topology of the network
G_r	r-disk graph on V
SPT	a shortest path tree over V
$SPAN$	a spanning tree over V
$\zeta(x)$	the Riemann zeta function
$A(v)$	the active time slot of a node v
s	the sink node of aggregation and gathering
M	the largest latency of the shortest paths from all other nodes to node s in SPT
U_j	the set of the awake nodes in time-slot j
L_i	the subset of the nodes in V from which the latency of the shortest path to node s is i
I_j	the maximum independent set in U_j
I_{ji}	is defined to be $I_j \cap L_i$
$Lat(u, v)$	the Latency of the link (u, v)

the communication topology could be reduced to a UDG. When the transmission radius is the same as the interference radius, a scheduling solution for MLGS was proposed in [26] that has approximation ratio at most $(1 + 1/(k + 1))$ with k being a whole number. In [13], the author developed a scheduling solution for MLGS with the shortest gathering schedule in which several channels were used to speed up communications and make the scheduling solu-tions more efficient. For MLGS, when the interference radii r_i are uniform and no less than the transmission radius, an efficient scheduling solution was proposed in [13] having approximation ratio less than or equal to $2\beta_{r_i}/\lambda$ with λ being the count of the channels that can be used and β_{r_i} the largest number of points in a half-disk of radius $r_i + 1$ with the distance between any two of them is greater than 1.

For MLGoS on multi-hop WSNs, under the UDG model, the authors of [8] designed a gossiping scheme that achieved approximation ratio 27, improved previously known algorithms which have approximation ratio 1000+. In [6], the author considered the problem MLGoS and presented respectively two algorithms with approximation guarantees of 20 and 34, thereby improving the approximation ratio of 27 presented in [8].

When all the devices are always active, [2] developed the shortest communication schedules for MLAS, MLGS and MLGoS subject to the physical interference. [2] developed scheduling algorithms for the four important group communication tasks under the physical interference model. Both the gathering schedule and gossiping schedule developed in [2] achieved constant approximation ratios. For MLGS, [2] proposed an efficient scheduling algorithm with approximation bound less than or equal to $2\beta_\rho$, where ρ and β_ρ are defined in EQ(1) and EQ(3), respectively. For MLGoS, [2] developed a gossiping solution with approximation bound less than

or equal to $5\beta_\rho$. Under mild assumptions, the broadcast schedule and data aggregation schedule developed in [2] could also achieve constant approximation ratios.

However, none of the known research papers described above have considered the situation that some networking devices may be in an inactive state. Taking duty-cycled scenarios into consideration under a graph-based interference model, the problem MLAS-DC has been extensively investigated [5], [17], [20]–[23], [27], [28].

Both [5] and [17] developed short data aggregation schedules for MLAS-DC. Both [20] and [21] studied the MLAS-DC problem in order to minimize the communication delay and maximize sensor nodes' lifetimes, and propsed another distributed algorithm for MLAS-DC. All the above mentioned scheduling algorithms for MLAS-DC were proposed under the simple protocol interference model. A data aggregation scheduling algorithm was developed in [22] for MLAS-DC with minimum latency for the purpose of energy efficiency. [23] studied the MLAS-DC problem with no structures taken into consideration. A distributed aggregation algorithm was proposed for MLAS-DC under the protocol interference model, in which the routing tree used for aggregation and a data aggregation schedule without collision were produced at the same time by the algorithm. In [27], the author investigated the MLAS-DC and developed two distributed aggregation algorithms for MLAS-DC, where the routing tree used for data aggregation and an aggregation schedule were produced at the same time. In [27], the author developed an approximation algorithm for MLAS-DC with better approximation bound. When the networking nodes have changable radii, a aggregation schedule with less number of time slots was developed for MLAS-DC in [28] by constructing a nonlinear mathematical formula.

For MLGS-DC subject to protocol interference, [24] proposed

a data gathering scheduling algorithm that achieves an approximation bound of $10|T|$. For the problem MLGoS-DC, [18] proposed a solution called the UTB algorithm for the all-to-all broadcast in which every message must be sent separately without any combination or aggregation and a more efficient version UTB-P of this algorithm using the Prune method. The approximation bound of these two algorithms for MLGoS-DC are less than or equal to $17|T| + 20$. With the unit-size message model, [24] investigated MLGoS-DC and proposed a scheduling algorithm for gossiping that achieved approximation bound less than or equal to $20|T|$. The paper [19] studied the problem MLGoS-DC in uncoordinated duty-cycled multi-hop wireless networks with unbounded-size messages. The NP-hardness of MLGoS-DC was verfified in [19]. This paper also developed two approximation algorithms for MLGoS-DC with approximation bounds less than or equal to $3\Phi^2(\Delta + 6)|T|$, with $\Phi = \lceil 2(\Psi + 2)/3 \rceil$, and Δ the maximum degree of the network. The value of Ψ is equal to the ratio obtained via dividing the interference radius by the transmission radius of each device.

3   Preliminaries

In this section, we introduce some notations, parameters and concepts that are needed for the design of our scheduling algorithms to be proposed in this paper. Set

$$R = \left(\frac{\eta P}{\sigma \xi}\right)^{1/\kappa}.$$

Given a pair of devices u and v. Clearly, there is a link between u and v in the communication topology when there is no interference from other nodes that are transmitting simultaneously if and only if $\|uv\| \le R$. We call R the *maximum transmission radius*.

Suppose that r is a positive parameter. Denote by R' be the largest edge length of a Euclidean minimum spanning tree over V, the set of all the networking nodes. Clearly, R' equals the minimum value of r satisfying that the r-*disk* graph over V is connected. The relation $R' \le R$ is needed for the network to be connected. An additional assumption we need is that $R' \le (1 - \varepsilon)R$ which holds for certain small positive constant ε.

Denote by Γ the collection of all Euclidean distances of the networking nodes in V less than R, and greater than or equal to R'. That is, we have

$$\Gamma = \{\|uv\| : u, v \in V \text{ and } R' \le \|uv\| < R\}.$$

Through a straightforward calculation, we have $1 \le |\Gamma| \le n(n-1)/2$ with n being the number of nodes.

Under the physical interference model, a collect I of networking nodes is referred to as *r-independent* when the following two conditions hold

(1) if every node in I sends a message at the same time, each such a transmission could be correctly received by every node whose distance from the transmitter is no more than r;

(2) the distance between any two nodes in I is larger than r.

Now we introduce the well-known Riemann zeta function denoted by $\zeta(x)$:

$$\zeta(x) = \sum_{j=1}^{\infty} \frac{1}{j^x}.$$

For each $r \in [R', R)$, define the following parameter ρ that is needed for the design of our scheduling algorithms to be proposed in later sections and its value is clearly explained in [2].

$$\rho = 1 + \left(\frac{\sigma \left(16\zeta(\kappa - 1) + 8\zeta(\kappa) - 6\right)}{1 - (r/R)^\kappa}\right)^{1/\kappa}. \tag{1}$$

Now we introduce the concept of independence for a given collection of links under the physical interference model. A collection C of links is called *independent* subject to the physical interference if the following two conditions hold:

(1) when the senders of all the communication links in C transmit at the same time, the receivers of every communication link in C can correctly receive the message; (2) all the communication links in C are disjoint.

4   Construction of A Routing Tree

A spanning tree $SPAN$ with the root node $s \in V$ is created in this section. This spanning tree will be employed in routing of the group communication tasks studied in this paper. Let $r > 0$. Denote by G_r a connected and undirected r-disk graph over V.

To begin with, a directed graph G'_r is created based on G_r as follows: replaced every edge (u, v) of G_r by two directed links (u, v) and (v, u) on G'_r, and then remove all links leaving s from G'_r. For a vertex $u \in V$, let $A(u) \in T$ be the awake time slot of u. For a link $(u, v) \in E(G'_r)$, it is assumed that u is the sender and v is the receiver. The latency of (u, v) is defined as follows:

$$Lat(u, v) = \begin{cases} A(v) - A(u), & if\ A(u) < A(v); \\ A(v) - A(u) + |T|, & if\ A(u) \ge A(v). \end{cases} \tag{2}$$

We associate each link (u, v) of G'_r with the weight equal to its latency $Lat(u, v)$, then G'_r is a directed weighted graph with all link weights non-negative. Therefore, a shortest path tree SPT of G'_r rooted at s can be computed by applying the Dijkstra's algorithm on G'_r. The tree SPT consists of all the minimum-weight paths from all nodes other than s to s. The largest latency among all the shortest paths in SPT from all other nodes to sink s is represented by M. Clearly, any optimal solution to either MLAS-DC or MLGS-DC is greater than or equal to M.

Let us take the undirected graph G_r with eight nodes in Fig. 1 as an example to explain the constructions of the directed graph G'_r and the shortest path tree SPT rooted at s. In this example, a scheduling period $T = \{0, 1, 2, 3\}$ with $|T| = 4$. Each node is represented by a circle with its active time slot contained inside it.

Based on our discussion above, the directed graph G'_r is constructed below

We compute a shortest path tree SPT of G'_r with the root s via employing the Dijkstra's shortest path algorithm on G'_r. This SPT is shown in Fig. 3.

This tree SPT has three leaf nodes v_3, v_6 and v_7. Let $\langle v_6, v_5, v_2, s \rangle$ denote the path from v_6 to s through v_5 and v_2.
Figure 1: This network has eight vertices. We assume that a scheduling period T has four time slots, that is, $\{0, 1, 2, 3\}$. Each vertex contains a number that is the time-slot at which the vertex is awake.
Figure 2: A directed graph with each link associated with the weight equal to its latency defined in EQ(2).
Figure 3: A shortest path tree T_{SPT} rooted at s of the above directed graph in Fig. 2.

Clearly, $Lat(\langle v_6, v_5, v_2, s \rangle) = 6$. Similarly, $Lat(\langle v_7, v_4, v_1, s \rangle) = 4$ and $Lat(v_3, s) = 3$. Therefore, the maximum latency $M = 6$ in this example.

Due to the likely interference with each other caused by the concurrent transmissions, however, the shortest path tree SPT constructed above cannot directly be used for routing of either data aggregation or data gathering. Therefore, a spanning tree $SPAN$ with root s must be created for the use of routing in data aggregation and gathering operations. Such a spanning tree $SPAN$ is constructed as follows:

The nodes in V are put into distinct layers L_0, L_1, L_2, $\cdots$, L_M according to the latency of the shortest path from each $v \in V$ with $v \neq s$ to s. Let's use the same example above to explain how to divide the nodes of V into different layers and construct the sets U_j with $j = 0, 1, 2, 3$. According to the shortest path tree SPT shown in Fig. 3, we have $L_0 = \{s\}$, $L_1 = \{v_2\}$, $L_2 = \{v_1\}$, $L_3 = \{v_3, v_4, v_5\}$, $L_4 = \{v_7\}$, $L_5 = \emptyset$, and $L_6 = \{v_6\}$. Based on EQ(??), it is easy to see that $U_0 = L_1 \cup L_5 = L_1$; $U_1 = L_0 \cup L_4$; $U_2 = L_3$; and $U_3 = L_2 \cup L_6$.

Note that likely interferences only happen at those active nodes that can receive messages at the time-slot that is under consideration.

For each time slot $0 \leq j \leq |T| - 1$, we construct an MIS $I_j \subset U_j$ layer by layer by following the steps below, based on the disjoint union of the nodes in distinct layers of U_j given in EQ(??):

- Initially, $I_j = \emptyset$.

- Sort all the nodes in the layer $L_{A(s)-j+K_0|T|}$ (with smallest index) in the ascending order of their identifications if $L_{A(s)-j+K_0|T|} \neq \emptyset$, say $L_{A(s)-j+K_0|T|} = \langle v_1, v_2, \cdots, v_z \rangle$ with z being the size of $L_{A(s)-j+K_0|T|}$, and add the first node v_1 to I_j.

- If $I_j \cup \{v_2\}$ is independent in G_r, then $I_j \leftarrow I_j \cup \{v_2\}$. If $I_j \cup \{v_2\}$ is dependent in G_r, then the node v_2 is skipped and then the next node in the list is taken into consideration.

- Do the same thing for v_3 until the last node v_z in $L_{A(s)-j+K_0|T|}$ is either added to I_j or skipped.

- Then do the same thing for all the nodes in $L_{A(s)-j+k|T|}$ with $k = 1 + K_0, \cdots, K_1$ until all the nodes in the last layer $L_{A(s)-j+K_1|T|}$ are processed.

Clearly, the MIS I_j constructed above is an independent subset of U_j. For simplicity, let $I_{ji} = I_j \cap L_i$. For each layer $0 < i \leq M$,

every node $v \in L_i \setminus I_{ji}$ was skipped by the above algorithm for the construction of the MIS I_j. Thus, the union $I_{j1} \cup I_{j2} \cup \cdots \cup I_{ji}$ contains one or more neighbors of $v \in L_i \setminus I_{ji}$.

The algorithm for constructing the spanning tree $SPAN$ over V rooted at s was described in the conference version [1] and omitted here due to space limitation. Let's use the same example above to explain how to construct the MIS $I_j \subset U_j$ for each time slot $0 \le j \le |T| - 1$, and how to construct the tree $SPAN$ rooted at s. For $U_0 = L_1 = \{v_2\}$, $I_0 = \{v_2\}$. For $U_1 = L_0 \cup L_4 = \{s, v_7\}$, $I_1 = \{s, v_7\}$. For $U_2 = L_3 = \{v_3, v_4, v_5\}$, $I_2 = \{v_3, v_4\}$. For $U_3 = L_2 \cup L_6 = \{v_1, v_6\}$, $I_3 = \{v_1, v_6\}$.

Now the tree $SPAN$ with root s for this example is created. For $L_1 = \{v_2\}$, v_2's parent in $SPAN$ is s (the same parent as in SPT) as $v_2 \in I_0 \cap L_1$. For $L_2 = \{v_1\}$, v_1's parent in $SPAN$ is also s as $v_1 \in I_3 \cap L_2$. For $L_3 = \{v_3, v_4, v_5\}$, v_3's parent in $SPAN$ is s as $v_3 \in I_2 \cap L_3$; v_4's parent in $SPAN$ is v_1 as $v_4 \in I_2 \cap L_3$; v_5's parent in $SPAN$ is v_4 (a different parent from SPT) as $v_5 \notin I_2 \cap L_3$. For $L_4 = \{v_7\}$, v_7's parent in $SPAN$ is v_4 as $v_7 \in I_1 \cap L_4$. For $L_6 = \{v_6\}$, v_6's parent in $SPAN$ is v_5 as $v_6 \in I_3 \cap L_6$. The constructed tree $SPAN$ rooted at s is shown in Fig. 4 below:

Finally in this section, the concept of the first-fit distance-d coloring for a subset of V in the lexicographic order is presented and adopted from our prior work [2]. Denote by U a subset of V. We consider the lexicographic order of the nodes in U, then we sort all nodes in U from the left to right, $u_1, u_2, \cdots, u_k$ with $k = |U|$. *The first-fit distance-d coloring of U* in the lexicographic order is described below:

- positive integers $1, 2, 3, \cdots$ represent colors;
- the first node u_1 in the sequence is assigned color 1;
- For $i = 2$ up to k, the node u_i is assigned the smallest possible number that is not utilized by any prior node u_j in the sequence with $j < i$ and $\|u_i u_j\| \le d$.

[2] proved that for a given independent set I of G_r, the first-fit distance-ρr coloring of I with the lexicographic ordering needs at most β_ρ colors. The value of β_ρ is given below (see Corollary 4 of [2]):

$$\beta_\rho = \left\lfloor \frac{\pi\rho^2}{\sqrt{3}} + \left(\frac{\pi}{2} + 1\right)\rho \right\rfloor + 1. \tag{3}$$

5 Aggregation Schedule under the Physical Interference Model Taking Duty Cycles into Consideration

In this section, we consider MLAS-DC subject to the physical interference and develop a short aggregation schedule for this problem. The sink node is represented by s. For a real number r satisfying $R' \le r < R$, we use EQ(1) to calculate ρ. Then follow the steps stated in Section 4, the spanning tree $SPAN$ rooted at s is constructed. The transmission follows a bottom-up approach.

Next we present the first-fit scheduling algorithm for MLAS-DC subject to physical interference. The first layer to transmit is the bottom layer L_M, and then the nodes in layer L_{M-1} transmit. The

scheduling is based on a bottom-up approach. For each layer L_i ($0 < i \le M$), we know that the nodes in L_i are active at time-slot j ($0 \le j \le |T| - 1$). At this layer, the nodes in $L_i \setminus I_j$ will be scheduled to transmit first, followed by the tranmissions of the nodes in $L_i \cap I_j$. Then the nodes in layer L_{M-1} will be scheduled to transmit. For each layer among $L_{M-1}, L_{M-2}, \cdots, L_0$, the nodes in these layers will receive the aggregated data from their children nodes in the decreasing order of the indices of the layers $M - 1, M - 2, \cdots$.

For the details of our first-fit data aggregation scheduling algorithm proposed for the problem MLAS-DC subject to the physical interference, please refer to the conference version [1]. Assume the graph in Figure 1 represents an r-disk graph G_r for some $r \in \Gamma$. We use this example in Figure 1 to illustrate the data aggregation scheduling algorithm we proposed for MLAS-DC.

The tranmission schedules for aggregation outputted by the above algorithm are listed in Table 2. Totally, 6 scheduling periods are required for s to receive eventually the aggregated message in this example.

The algorithm for this example works as follows: At $L_6 = \{v_6\}$, $v_6 \in I_3 \cap L_6$ and its parent in $SPAN$ is v_5 which is active at time-slot 2. Thus, link (v_6, v_5) is scheduled at time-slot 2 of SP 1. We skip $L_5 = \emptyset$. For $L_4 = \{v_7\}$, $v_7 \in I_1 \cap L_4$ and its parent in $SPAN$ is v_4 which is also active at time-slot 2. Thus, link (v_7, v_4) is scheduled at time-slot 2 of SP 2. For $L_3 = \{v_3, v_4, v_5\}$, node $v_5 \in L_3 \setminus I_2$ and its parent in $SPAN$ is v_4 which is active at time-slot 2. Thus, link (v_5, v_4) is scheduled at time-slot 2 of SP 3. The nodes $v_3, v_4 \in I_2 \cap L_3$; v_3's parent in $SPAN$ is s which is active at time-slot 1. Thus, link (v_3, s) is scheduled at time-slot 1 of SP 4. Node v_4's parent in $SPAN$ is v_1 which is active at time-slot 3. Thus, link (v_4, v_1) is scheduled at time-slot 3 of SP 4. For $L_2 = \{v_1\}$, $v_1 \in I_3 \cap L_2$ and its parent in $SPAN$ is s which is active at time-slot 1. Thus, link (v_1, s) is scheduled at time-slot 1 of SP 5. Finally for $L_1 = \{v_2\}$, $v_2 \in I_0 \cap L_1$ and its parent in $SPAN$ is s which is active at time-slot 1. Thus, link (v_2, s) is scheduled at time-slot 1 of SP 6.

We summarize our above discussion in the following theorem. The proof of this theorem can be found in the short conference version [1].

Theorem 1 *The data aggregation scheduling algorithm for MLAS-DC is technically correct and produces a data aggregation schedule without any collision. The latency of the transmission schedule for aggregation outputted via our proposed algorithm is less than or equal to $2\beta_\rho |T| (\Delta - 1)M$. The proposed algorithm for MLAS-DC has approximation ratio upper bounded by $2\beta_\rho |T| (\Delta - 1)$.*

Note that both ρ and β_ρ are constants defined in EQ(1) and EQ(3), respectively. Therefore, the approximation bound for our scheduling algorithm proposed for MLAS-DC is less than or equal to a constant times $|T|$ when the maximum degree Δ is bounded.
Figure 4: The construction of a spanning tree T_{span} rooted at s.

Table 2: The transmission schedule for the aggregation operation outputted by the algorithm proposed for MLAS-DC. In each row, "SP i" means the i-th scheduling period.

6 Gathering Schedule under the Physical Interference Model Taking Duty Cycles into Consideration

In this section, we develop a scheduling algorithm for MLGS-DC subject to physical interference. The sink node is represented by s. For a real number r satisfying $R' \le r < R$ (see Section 3 for the definitions of R' and R), we use EQ(1) to calculate ρ. Then follow the steps stated in Section 4, the spanning tree $SPAN$ rooted at s is constructed.

For any time-slot $0 \le j \le |T| - 1$, each node in U_j is active and ready to receive packets from one of its children nodes in $SPAN$. Let

$$Children(U_j) =$$
$$\{u : u \text{ is a child in } SPAN \text{ of a node in } U_j\},$$

which is the collection of children devices of the devices in U_j. The devices in $Children(U_j)$ will send their packets at time-slot j.

For each $0 \le j \le |T| - 1$, we adopt the data gathering heuristic obtained in our previous work [2] for WSNs with all nodes always active for the time-slot j. Our propsed data gathering scheduling algorithm will have $2n - 3$ rounds in total. For each round k, represent by E_k the collection of tree links of $SPAN$ whose label is k. Suppose that A_k represents the collection of the links in the inward s-arborescence made by the tree edges in E_k. For each round k, a dominator connects no more than one link in A_k (see [2]). For each round k and time-slot j, represent by $A_k^{(j)}$ the sub-collection of links of A_k whose sender belongs to the set $Children(U_j)$.

Next the data gathering scheduling algorithm for MLGS-DC subject to physical interference is presented. In each time slot $0 \le j \le |T| - 1$, the algorithm is divided into $2n - 3$ rounds sequentially, each of which is dedicated to a subset of links in the list:

$$A_{2n-3}^{(j)}, A_{2n-4}^{(j)}, \cdots, A_2^{(j)}, A_1^{(j)},$$

respectively.

For each round k and time-slot j, the links in $A_k^{(j)}$ are scheduled for transmission: Let S denote the set of the dominator ends of the links in $A_k^{(j)}$. A first-fit distance-ρr coloring of the set S is first calculated. At the i-th time-slot of the k-th round, according to this coloring, the link with a dominator end that is assigned the i-th color will send a packet. By Corollary 4 of [2], the maximum number of time-slots each of these rounds uses is β_ρ. The total number of rounds is $2n - 3$. Therefore, for each time slot j, the maximum time-slots used by the solution outputted by our proposed gathering scheduling algorithm is $\beta_\rho(2n - 3)$. Each scheduling period has $|T|$ time-slots in total. Thus, the entire gathering operation uses no more than $\beta_\rho(2n - 3)|T|$ time-slots.

We summarize our above discussion in the following theorem for MLGS-DC under the physical interference model.

Theorem 2 *The gathering scheduling algorithm described above for MLGS-DC can correctly produce a interference-free schedule of data gathering. The latency of the produced data gathering schedule is less than or equal to $\beta_\rho(2n - 3)|T|$.*

Clearly, any optimal solution to the problem MLGS-DC uses at least $n - 1$ time-slots, the approximation bound for the gathering scheduling algorithm presented in this section is less than or equal to $2\beta_\rho|T|$, which is a multiple of $|T|$ as β_ρ is a constant.

At the end, a data gathering schedule is computed by applying the above scheduling algorithm for each $r \in \Gamma$. The one with the smallest latency among all these resulting data gathering schedules will be chosen. Note that the number of element in Γ is a finite and we have its upper bound $|\Gamma| \le n(n - 1)/2$.

7 Gossiping Schedule under the Physical Interference Model Taking Duty Cycles into Consideration

In this section, we develop a scheduling algorithm that produces a short gossiping schedule for MLGoS-DC under the SINR model. Let $r = R'$ (see Section 3 for the definition of R'), we use EQ(1) to calculate ρ. The r-disk graph on V is denoted by G_r. Then we compute the graph center s for the graph G_r.

Our proposed gossiping scheduling algorithm for MLGoS-DC consists of two phases:

Phase 1: s collects all the packets from all other nodes.

Phase 2: s broadcasts all the n packets (including its own) to all other nodes.

For Phase 1, the data gathering scheduling algorithm for MLGS-DC presented in Section 6 will be adopted. After that, the sink node s sends all the n packets to all other $n - 1$ nodes in Phase 2. In this phase, for each time slot $0 \leq j \leq |T| - 1$, we adopt the algorithm that was used in the second phase of the gossiping algorithm from our prior work [2] we developed for MLGoS without duty-cycled scenarios. This algorithm works as follows: To begin with, a spanning tree $SPAN$ over V on the graph G_r is created according to the steps stated in Section 4. The routing used for the broadcast of Phase 2 is the outward spanning s-aborescence oriented from $SPAN$. Then we perform the following three steps:

- For all the dominating nodes, we calculate the first-fit distance-ρr coloring. Assume that this distance-ρr coloring uses Z colors. By Corollary 4 of [2], we have $Z \leq \beta_\rho$.

- For simplicity, suppose that the color 1 is assigned by the graph center s. We divide the time-slots into $2Z$ frames. In each frame of the time-slots, the first Z time-slots make a subframe of dominating nodes and the second Z time-slots make a subframe of connecting nodes. The center s sends one packet in each subframe.

- For each $1 \leq i \leq Z$, the connecting node with the color i receiving a packet in a subframe of dominating nodes sends the received packet in the i-th time-slot.

- For each $1 \leq i \leq Z$, the dominating node with the color i receiving a packet in a subframe of connecting nodes sends the received packet in the i-th time-slot.

According to Theorem 9 of [2] and the discussions thereafter, for each time slot $0 \leq j \leq |T| - 1$, the latency of both phase 1 and phase 2 is at most $\beta_\rho(5n - 5)$. Thus, our proposed gossiping scheduling algorithm generates a solution whose latency is less than or equal to $\beta_\rho(5n - 5)|T|$.

The theorem below summarizes our discussions and analyses in this section

Theorem 3 *The gossiping scheduling algorithm presented in this section works and it generates a gossiping schedule without collision. This gossiping scheduling algorithm produces a solution whose latency is less than or equal to $\beta_\rho(5n - 5)|T|$.*

Clearly, any optimal solution to the problem MLGoS-DC uses at least n time-slots, the approximation ratio of the gossiping scheduling algorithm presented in this section for MLGoS-DC is less than or equal to $5\beta_\rho|T|$, which is a multiple of $|T|$ as β_ρ is a constant.

8 Conclusion

In this paper, approximation algorithms for MLAS-DC, MLGS-DC and MLGoS-DC on duty-cycled multi-hop WSNs under the SINR model were proposed in order to minimized the communication latency. To the best of our knowledge, the paper is the first work that proposed efficient communication scheduling algorithms for these three problems subject to the physical interference. Denote by $|T|$ the count of time-slots contained in a scheduling period. Our proposed approximation algorithms for MLGS-DC has approx. ratios upper bounded by a constant time of $|T|$. So is the proposed approximation algorithms for MLGoS-DC. Our proposed approximation algorithms for MLAS-DC has an approximation bound no more than a constant times $|T|$ when the network maximum degree Δ is bounded. It has been well documented in the literature that analysis for scheduling algorithms developed for MLAS, MLGS and MLGoS under the SINR model is very challenging due to the impossibility of constructing related conflict graphs.

For future work in the design of scheduling algorithms for MLAS-DC, MLGS-DC and MLGoS-DC on duty-cycled multi-hop WSNs under the SINR model, the problems of proposing constant-approximation algorithms are still open, under either the SINR model or the protocol inference model. Any constant-approximation algorithms for MLAS-DC, MLGS-DC and MLGoS-DC will be significant.

The article describes the concept and architecture of a decentralized control system for a solid-state voltage regulator (SSVR). The SSVR is a universal device for controlling the mode and operation parameters of medium voltage electrical networks. SSVR manage the amount of current in line using the vector voltage control method. The SSVR control system consists of two levels: the SSVR semiconductor converter control level (the technological control system), SSVR cluster management level (intelligent control system). The objective of the study is to develop an algorithm for managing the SSVR cluster located in the nodes of the distribution electric network. The Raft consensus algorithm for managing the computing cluster is applied to ensure reliable decentralized network management. The algorithm is iterative. Ethernet and PLC architectures are proposed for constructing a data transmission network between SSVR nodes. A simulation model of the SSVR cluster and its control system is developed to study the operation of the control system (node shutdown, loss of communication). The criteria for the normal operation of the intelligent control system are formulated and an algorithm for its operation in emergency situations is presented. The studies of the SSVR control system confirmed the operability of the developed control system in normal and emergency operation of the cluster on a simulation. The dependence of the control system response time on the number of cluster nodes is investigated. The maximum number of nodes in the SSVR cluster depending on the tasks being solved by the SSVR will be limited by the speed of the control system. If the number of cluster nodes increases, it is necessary to enlarge the minimum time interval between requests for control commands.

1. Introduction

The concept of the Internet of Energy (IoE) is the logical development of smart grid technology [1, 2]. IoE is a new architecture for building a power electricity system with decentralized management. A key role in this system is assigned to intellectualization and economic interaction between all network users (energy transactions).

Distribution networks of the future will have a complex configuration and a large number of types of distributed generation sources. Thus, power flows should be bi-directional unlike traditional networks. To implement this principle, electrical networks of all voltage classes, especially low and medium voltage networks, must become "controlled". From a technical point of view, this is hindered by the lack of Flexible AC Transmission System (FACTS) devices in medium voltage networks.

The design of solid-state voltage regulator (SSVR) is known [3]. The SSVR is a power flow control device built on the basis of two transistor converters (Figure 1). The SSVR control method is based on the voltage vector regulation principle – the SSVR manage the voltage drop vector across network rector L [4], and the converter itself acts as a controlled current source. The SSVR is installed in the nodes of the medium voltage distribution network and allows to control the network operation modes.
Figure 1: SSVR power unit and control system: T1 - shunt transformer; AC/DC - rectifier; C - capacitive storage; DC/AC - inverter; T2-T4 - serial transformers; L - network choke; V – voltmeter; ICS – intelligent control system of a neighbor node with SSVR

It is necessary to install several SSVRs in the distribution network to perform effectively all the specified functions. The required number of devices depends on the network configuration and the tasks being solved.

The SSVR has a two-level control system (Figure 1). The lower level system is a technological control system (TCS) [5]. The upper level control system is an intelligent control system (ICS). The TCS task is to form the required voltage vector and control the power elements of the converter. The ICS task is to manage the SSVR cluster, communication of SSVRs within a cluster and the command generation for the TCS.

The novelty of this work is that the RAFT consensus algorithm is applied in ICS to provide smooth voltage regulation and control of the electrical network with SSVR.

The article presents the results of the development and research of the SSVR decentralized control system of the upper level. The section 2 provides an overview of decentralized control systems used in the electricity industry. The section 3 describes the architecture of the SSVR ICS. The algorithms for the functioning of the ICS (the algorithms for managing a cluster and a network) are given in 4 and 5 sections. The section 6 describes the simulation model of SSVR ICS and the section 7 presents the simulation results of emergency operation modes.

2. Literature Review

Traditional power grid management systems require a central control room. Each control element must communicate with the control center and often not only the main, but also backup communication channels are required. Situations when communication with the control center is impossible may occur during the operation of networks and the need for autonomous operation arises. Decentralized management systems are the solution to this problem.

There are some tools for decentralized control of emergency switching based on reclosers for 6-10 kV distribution networks [6]. Various algorithms [7] of reclosers operation are possible to control emergency modes. The proposed methods of decentralized management are used only for emergency shutdown operations in a medium voltage network. This functionality is not sufficient for smart distribution networks. A smooth voltage regulation is necessary, and switching should be performed in

both emergency and normal modes in order to optimize the power flows in electricity network of up to 20 kV.

The problem of creating a decentralized intelligent management system for networks with distributed generation is most fully considered in [8], where a method of multi-agent service restoration and the digital model of a power system with multi-agent control are proposed. The principles of building a multi-agent system, as well as the stages of its operation are determined.

The most common control system architecture is SCADA (Supervisory Control and Data Acquisition). As shown in [9], to solve similar problems the traditional for SCADA centralized control model requires either improving the existing communication infrastructure to provide higher data transfer rate or storing measured data at a local substation and then organizing data exchange between substations to ensure the operation of complex applications in real time. At the same time, the amount of saved data turns out to be less than the amount of data saved in the SCADA database because each substation is responsible only for its own network section. This allows data to be saved more frequently, such as once per second or millisecond depending on the application. Since most of the data is stored locally, the requirements for communication links between substations and control centers are reduced.

This approach requires the use of decentralized algorithms that can bypass reduced SCADA functionality to provide optimal local control. Local controllers are intelligent enough to coordinate their work and thus provide reliable global control.

Some of these features are found in modern Energy Management Systems (EMS), for example, power flow analysis and generation prediction, that now will have to be used locally. At the same time, the EMS system, together with the Distribution Management System (DMS) and the Outage Management System (OMS), are superstructures of SCADA systems, and do not allow to fully implement the necessary functionality within a distributed control system [10].

In modern smart grid it is necessary to predict possible events (based on monitoring and trend analysis) and take proactive measures based on this data instead of a passive reaction to events in the distribution network. This forecast applies to both generation and consumption. Power flows in such network model will not be strictly deterministic. It is obvious that such a complex unstructured network must have a powerful control system that coordinates the operation of all network components. To do this, all components of the network must "communicate" with each other and with the control center through special communication networks. One of the ways to solve this problem is to use the consensus algorithm [11].

In [12], a distributed control strategy is proposed to share unbalanced currents in three-phase three-wire isolated AC microgrids. The control algorithm is based on an approach where the microgrid is analyzed not as a three-phase system, but as three single-phase subsystems. The consensus algorithm is used in distributed control system [13] to share the imbalance and harmonics between different converters in three-phase four-wire droop-controlled microgrids.

An asynchronous averaging consensus protocol [14] is proposed to estimate the values of inseparable global information. The consensus protocol is then combined with a fully distributed primal dual optimization utilizing an augmented Lagrange function to ensure convergence to a feasible solution with respect to power flow and power mismatch constraints. This algorithm uses only local and neighbourhood communication.

The consensus algorithm can be used to reach an agreement for resources dispatch among multiple controllable components in distribution grids, taking into account the individual voltage support capability of sources [15]. This algorithm reduces the time required to reach a consensus by solving the fastest distributed linear averaging (FDLA) problem.

An algorithm based on the RAFT consensus is used in [16], but in order to ensure the security of the switching infrastructure of the network against a specific type of attack, called a timing attack. In contrast to these studies, the authors use the RAFT consensus algorithm to ensure smooth voltage regulation and control of the electrical network parameters.

3. SSVR Control System

The concept of the IoE implies that the network becomes active and manageable, and the efficiency of management will only increase with an increase in the number of control devices in the network. At each point of the electrical distribution network where the SSVR installation is required, a node consisting of three connected elements is formed:

- solid state voltage regulator (SSVR);

- technological control system (TSC) – realizes the physical execution of SSVR control commands, measurement of the parameters of its functioning and transfer them to the upper level control system;

- intelligent control system (ICS) – provides the functions of SSVR operational control, diagnostics of its state, collecting monitoring data and implementation of algorithms for intelligent control of the SSVR network in order to control effectively power flows, ensure the required power quality and reduce losses during its transmission.

The SSVR control system has a peer-to-peer network structure and the SSVR ICS units are the nodes of this network. The ICS is an industrial computer, geographically located near the SSVR (the maximum distance is determined by the specification of the interface for TCS connecting). Also, the ICS is equipped with an interface for communication with other SSVRs ICS to create a data exchange network on the operating modes of the devices and to implement the algorithms for active-adaptive power transmission network control. At the same time, the results of the work of these algorithms should be propagated to neighboring nodes with minimal delays and with high reliability. This sets high requirements for an information network built in parallel with an electrical one.

The physical implementation of this network is possible using various technologies, including power line communication (PLC) technologies. A scheme of a 6-20 kV distribution network section with transformer substations and jumpers for controlling power flows with SSVR nodes and corresponding TCS and ICS are shown in Figure 2.

(a)

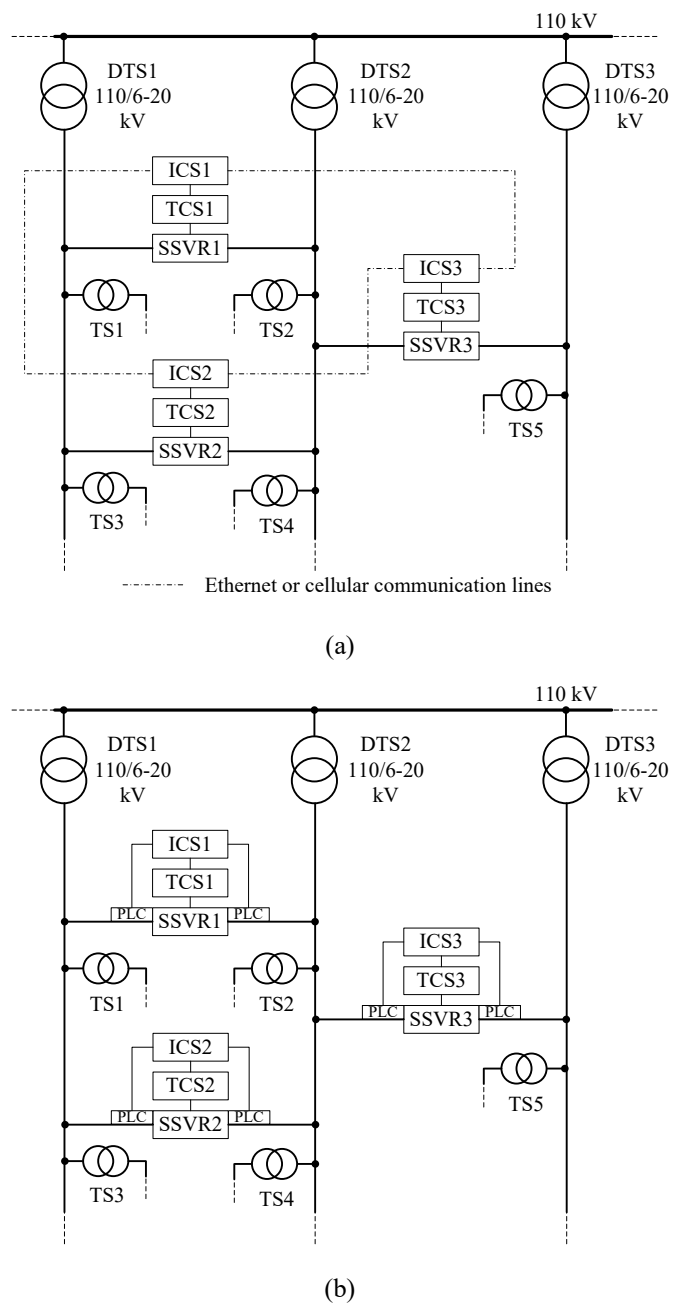
(b)


Figure 2: Structure of SSVR ICS: DTS1-3 – district transformer substations 110/6-20 kV; TS1-5 – transformer substations 6-20/0.4 kV; SSVR1-3 – solid-state voltage regulators; TCS1-3 – technological control system; ICS1-3 – intelligent control system: for Ethernet or cellular communications technology (a); for PLC technology (b)

In Figure 2a the ICS perform the function of routing information flows. The structure of the SSVR ICS for the PLC technology is shown in Figure 2b.

In addition to communication interfaces with TCS and other ICSs connected to SSVR located in the same electrical distribution network, there is an operational control client interface. This interface allows the operator to connect to the operating ICS in order to view the current parameters of its operation and, if necessary, correct the parameters of the operation of control algorithms for a specific SSVR or the SSVR network as a whole.

As indicated above, the automatic control in this system is decentralized and the regulation functions are performed in each SSVR ICS by local software implemented on the basis of the electrical network control algorithm (Figure 3). The developed control algorithm of the ICS is necessary to match the SSVR nodes in the distribution network. The function of distributing information about the state of network nodes is performed by the software for managing a group of industrial computers of the ICS. This group of ICS operates as a single system, called a cluster. The cluster control algorithm is used as the algorithm of this software.
Figure 3: ICS functional diagram

As indicated above, the automatic control in this system is decentralized and the regulation functions are performed in each SSVR ICS by local software implemented on the basis of the electrical network control algorithm (Figure 3). The developed control algorithm of the ICS is necessary to match the SSVR nodes in the distribution network. The function of distributing information about the state of network nodes is performed by the software for managing a group of industrial computers of the ICS. This group of ICS operates as a single system, called a cluster. The cluster control algorithm is used as the algorithm of this software.

4. Network Control Algorithm

4.1. Management Task

Let's imagine a distribution electric network in the form of a graph, at the vertices of which there are transformer substations (TS) with their electricity consumers, and power lines act as arcs, and some neighboring TCs are connected by SSVR (Figure 4).

If the mode parameters in the network node deviate from the permissible (or specified by the operator), the SSVR ICS must send a signal to the TCS about the need for regulation. The effectiveness of the control system commands depends on the quality and completeness of the initial information about the network operation mode. The SSVR is capable of measuring the following parameters [5]:

- the RMS value of phase voltage before and after SSVR installation point;

- the effective value of the phase current in the line with SSVR;

- the phase angle of the line current relative to the voltage.

When information about deviations of the parameters and corresponding node number is obtained, it is possible to make decisions about control actions in order to bring these parameters to the expected values. The SSVR can regulate the amount of

current in the line by controlling the magnitude of the phase voltage and its phase angle.
Figure 4: Graph of distribution electric network: L - power line; TS - transformer substation 6-20/0.4 kV; SSVR - solid state voltage regulator

4.2. Cluster Management Algorithm

To implement the adaptive network control algorithm, a logical computing cluster is formed on top of the electrical distribution network. This cluster formed of industrial computers, each of which controls its own separate SSVR, and is a control network node. It is assumed that all nodes in the cluster can communicate with each other without loss and without delay.

Cluster parameters are controlled by the cluster leader, which task is to control the power flows between the parts of the electrical network by changing the parameters of the cluster nodes. The leader is an arbitrary cluster node, chosen by voting between all cluster nodes, using the Raft consensus algorithm (consensus problem) [17].

The advantages of Raft are reliable leader election and guaranteed delivery of broadcast messages from the leader to the nodes. Despite its relative simplicity, Raft provides a safe and efficient implementation of a state machine on top of a clustered computing system. Raft ensures reliable delivery of signals to all nodes in a given order [18]. This ensures the transition of all state machines through the same sequences of states and each node is guaranteed to come into agreement with the other nodes.

Raft has the following features:

- assumes that there is always only one clearly distinguished leader on the cluster. Only this leader sends new records to other nodes in the cluster. Thus, the rest of the nodes follow the leader and do not interact with each other (except for the voting phase). If an external client connects to the cluster through a regular node, then all his requests are redirected to the leader and only from there come to the nodes.

- involves the decomposition of the cluster management task into several subtasks, the main of which are: leader election (voting) and replication of logs. Each of these tasks allows a more detailed separation. This makes the algorithm easier to understand and reduces the risk of errors in its implementation.

- logs cannot contain gaps. Records are added strictly sequentially. This simplifies the algorithm very much. In addition, the specifics of applied tasks, most often, do not allow correct work with logs containing gaps.

- allows to change easily the configuration of the cluster without interrupting operation: add or remove nodes.

An important circumstance is that Raft numbers strictly all records in the log. The records must go strictly sequentially. These records numbers play an important role in the operation of the algorithm. They determine the degree of relevance of the state of the node. The leader is always the most relevant node. The same numbers are used to number voting sessions. A node can vote only once for each vote request.

4.3. Network Control Algorithm

The network control algorithm is iterative. Each iteration of the algorithm consists of several steps:

- Each node reads its own voltage, phase and current values. Then, the parameter values are analyzed according to the specified criteria. The criteria include the maximum power flow through the node and the ability to share the load with an adjacent part of the network. The criteria are formed separately for each cluster node.

- The desired correction of the parameter values of each node is formed according to the calculation results, and then the desired parameters are transmitted to the cluster leader.

- After receiving the current values from each cluster node, the leader decides to change values on one of the nodes.

- It is assumed that the parameters should be changed iteratively and sequentially, by a small value and only at one node per iteration. The leader selects the node with the maximum required parameter correction among the nodes and sends a request to this node to change the parameter value by a certain step. The size of the step is set by the cluster settings.

- One of the cluster nodes receives a request from the leader to change his operating parameters, makes these changes and sends a message to the leader that the changes were successfully made. This concludes the iteration of the algorithm.

The indication that the node parameter values have been corrected is the change in the iteration number field. If the value of the iteration number is greater than the current number (on the leader's side), then the leader concludes that the node has recalculated the corrections of its parameters and sent updated values. Then the leader collects analysis data from all cluster nodes again. If changes in the correction of parameter values from the nodes are received, then the leader increments its current iteration number and repeats the steps to analyze and change the data.

Thus, at each iteration of the algorithm, small changes are made in the operation of the network at one of its nodes. Due to the fact that changes are made in the operation of only one node, and by a small value, the operation of the algorithm is stable and predictable and does not lead to an imbalance in the network.

Fault tolerance of the algorithm is achieved due to the fact that all network elements are combined into a cluster and each member of cluster is equal. The cluster leader which makes decisions about network management is unknown in advance and is chosen randomly from all the cluster members. That is, each cluster element contains all the necessary logic in order to become a leader, if the other members of the cluster elect it. The leader election procedure is finite and fault-tolerant, and is supported by the proven algorithm in cluster computing – Raft.

If the current cluster leader becomes unavailable due to problems in network connectivity and/or software or hardware failures, the cluster elects a new leader and the algorithm continues to work. If too many members drop out of the cluster due to possible failures, the algorithm determines that it does not have enough quorum to make decisions about network management and stops. In this case, a failure notification is sent to the operator.

The software simulation model of the SSVR ICS has been developed to study the operation of SSVR control algorithms in normal and emergency modes of network operation.

5. SSVR ICS Simulation Model

The simulation model allows to study the operation of the SSVR ICS in isolation without a real connection to the SSVR and without real communication channels. The software simulation model emulates the following objects and parameters:

- SSVR as ModBus slave [19];

- communication channels between SSVR and ICS;

- the topology of a network consisting of a set of SSVR ICS, with a set of communication channels connecting them.

The structural diagram of the simulation model is shown in Figure 5.
Figure 5: The structural diagram of the simulation model

The SSVR emulator has been written in C++ and is a Linux daemon (a background program launched by the operating system). The main task of the SSVR emulator is to respond to the requests of the ICS via the ModBus-over-TCP/IP protocol, just like a real SSVR does. The used implementation of the ModBus protocol defines a set of integer registers. For each of these registers in the SSVR emulator, a range of acceptable values and a period of values change are determined.

During its operation the SSVR emulator determines randomly the value of each register based on its range of changes, and gives it to the ICS in response to its requests. Also, the SSVR emulator changes the value of each register once per period. It is possible to change dynamically the settings for each ModBus register of the SSVR emulator without restarting the emulator itself using the console utility for the dynamic configuration of the emulator.

A configuration file with the network parameters of the available nodes in the topology is created for an instance of the

SSVR ICS software module to organize communication channels with other ICSs in the topology.

The console utility is used to change dynamically the settings for each ModBus register in the SSVR emulator without restarting this emulator, as well as to simulate changes in the network parameters and the occurrence of various emergency situations. So, for example, using this utility, it is possible to simulate the connection of an additional load to the SSVR by changing the values of the voltages and currents on the side after the controller.

6. SSVR ICS Simulation Model

Operating modes (scenarios) of the control network were simulated using the developed simulation model of the ICS SSVR. The cluster nodes were switched off one by one and the operation of the algorithm was monitored along with messages sent to the network operator.

The algorithm of actions of the control system when starting the system and the occurrence of emergency situations is shown in Figure 6.

Voting between the cluster nodes and the leader elections occurs when the ICS is turned on. Normal operation of ICS SSVR is ensured when two groups of conditions are met:

1. the cluster is working correctly;

2. the control algorithm works correctly.

The cluster works correctly when the following conditions are met:

- there is a cluster quorum n_q – the number of nodes in the cluster is sufficient to elect the leader (the minimum required number $n_{q.min} = 3$);

- the chosen leader is functioning normally;

- the set of nodes that have elected a leader is stable.

Algorithm quorum – there is a specified minimum number of controlled nodes which is necessary for the algorithm to work correctly.

Each time an alarm message is received indicating the nature of the problem, the operator must perform the required recovery and restart the system.

The simulation results are presented in Table.

The control system coped with the assigned tasks both in normal and emergency modes of operation. It was found that depending on the number and quantity of disconnected nodes two scenarios are possible:

- in scenarios B1 and C1, the remaining number of nodes was enough to select a leader, the system continued to work and perform the declared functions until the accident was eliminated;

- in scenarios B2, C2, D and E, the election of a new leader is impossible and the cluster stops its work until the accident is eliminated and the operator restarts the control algorithm.
Figure 6: The control system algorithm: the letters A, B, C, D, E indicate the scenarios presented in the Table 1
Figure 7: The dependence of the probability of cluster accessibility on the duration of the time interval between processing requests for a different number of network nodes

7. Determining the Cluster Speed Limit

The iterative control algorithm involves sending requests for data changes to the cluster. Sending commands takes some time, determined by the speed of the industrial computer of the node.

An experimental study on simulation models including 3, 6 and 12 nodes was carried out to determine the minimum cluster response time. Figure 7 shows the dependence of the probability of cluster accessibility on the duration of the time interval between processing requests.

Table 1: Modeling Results of Normal and Emergency Operation of the Control Network

Scenario	Result	Messages to operator
Scenario A. Normal network operation. No accidents.	The network topology does not change. The leader is chosen and does not change. There is a periodic measurement and iterative correction of the parameters of the nodes.	No messages
Scenario B.1. One of the nodes is down. The remaining number of nodes is sufficient for the operation of the cluster or for a quorum for a leader election.	The cluster continues its work according to the algorithm.	Alarm message indicates the ID of the node requiring recovery.
Scenario B.2. One of the nodes is down. One of the nodes is down. The remaining number of nodes is not sufficient for the operation of the cluster or for a quorum for a leader election.	The cluster stops its work.	Alarm message indicates the ID of the node requiring recovery.
Scenario C.1. The leader node is not working. The remaining number of nodes is sufficient for a quorum for voting	Election of a new leader.	Alarm message indicates the ID of the node requiring recovery.
Scenario C.2. The leader node is not working. The remaining number of nodes is not sufficient for a quorum for voting	The cluster stops its work.	Alarm message indicates the ID of the node requiring recovery.
Scenario D. No cluster quorum	The cluster stops its work.	Alarm message indicates the number of nodes.
Scenario E. The failure of one or more nodes led to the division of the network into two areas (partitions)	The cluster stops its work.	Alarm message indicates the ID of the node requiring recovery.

One can conclude that with an increase in the number of nodes in a cluster, the minimum allowable time interval between requests increases. From the given dependencies, it can be seen that the minimum interval between requests is 2.5 seconds for networks with a number of nodes up to 6 and 7 seconds for networks of 12 nodes. Such an interval is acceptable when regulating power flows in the electrical distribution network.

8. Conclusion

Decentralized management system architecture and an adaptive network control algorithm have been developed for solid-state voltage regulators (SSVR) in medium voltage distribution networks.

All SSVRs are combined into a single logical computing cluster using industrial computers, which are controlled by the cluster leader. The Raft consensus algorithm is used to find a leader and manage the entire cluster.

In the course of researching the control system on the simulation model, all cluster nodes were switched off one by one. In all simulated scenarios, the control system acted according to the laid down algorithm and followed the given commands. The research results confirmed the efficiency of the developed algorithm and the stability of its functioning.

Modeling clusters with different numbers of nodes showed that the minimum allowed time between requests for cluster nodes depends on its size. Thus, it is possible to determine the maximum allowable number of nodes in a cluster which will depend on the network topology and the tasks solved by the SSVR. The study of the performance of the algorithm proves the possibility of its application to solve the problem of power flow control in medium voltage distribution networks.

A B S T R A C T

Rescuers escorted search dogs into the disaster area, using their unique sense of smell to find the injured. First, researchers summarize the design requirements in the search process from interviews with rescuers, and construct a conceptual prototype to confirm the interaction mode between the user and the dog. User central design invited people melt into the situation to identify product features. The ideas were selected based on the viability which increases efficiency. The main design proposal includes a strap and a smart collar. Smart sensing (heartbeat, speed, temperature, and GPS) can improve communication and increases the efficiency of rescue. The search area is large in many cases; therefore, we selected the WiFi or Ultra-wideband module as the wireless transmission medium when the rescue team enters this domain. The pre-deploy nodes connect and position with the smart collars. The instructor sends voice commands remotely to prompt the dog to return when the temperature is high. The smart collar design includes an elastic O-ring waterproof shell. Rescuers click the recall button, and the remote device sends a signal of dog returning. This proposed work looks more at user's needs through multi-disciplinary aspects of view, which enhance usability. The case consists of customer interviews, observation, concepts, evaluation (science/ device/ electronic packaging/ and App software); the design process also demonstrated a possible teamwork perspective in the industry. This scenario encourages cross-field extension for design education.

1. Introduction

Rescue dogs are sensitive to hearing and smell [1], and can be used as rubble rescue dogs and mountain rescue dogs after personalized training. This research proposed suitable devices for rescue task. During task, dog will present a stabilize bark to mark the sufferer position and special events [2]. The rescue team fights for gold rescue time to locate suffered people in the mountains or landslides space. Inappropriate equipment reduce efficiency.

The design goal is improving communication efficiency of the training with the help of smart collar through the design process (session 3). The design team collected requirements (session 3.1) through user interviews (session 2.1); after the midterm meeting, we built the prototype (session 4.1, 4.2) to support the interaction between the user and the dog. From the observation of the rescue member's situation, we confirm the rationality of the design (session 4.4, 4.5).

2. Literature survey

2.1. Rescue dog training situation and facilities

Figure 1a shows the rescue dog training cite in central Taiwan, the site is suitable for air scent search of the surrounding or trace the odors. Figure 1b is layout and facilities in Taichung training area. Trainer evaluate dogs and determine working potential to give the dog of their skills to fulfilling its purpose.

The training ground provides olfactory practice and obstacle crossing in a large area, and then enters the building of the injured person through overcome obstacles, such as suspended bridge structure. Simulation provides robustness under various conditions of the dog. Dogs in rocky areas need to be careful not to hurt their paws when moving (Figure 2). The training included the communication skill with the rescue personnel to notify the location of the victim [2]. When the road is in poor condition, the foot is often injured. Dogs often stick out their tongues to strengthen sweat; long-term search can lead to body failure [3]. Passing on the current physical condition allows calling for retreat.

(b)

Figure 1: Rescue dog training in Taiwan: (a) field survey site; (b) Taichung training area.

Figure 2: Training situation and facilities in rocky area.

2.2. Prior art of Strap

There are several ideas of dog lash as follows: Double D-ring rope buckle, LED warning; H-shaped chest for quick-fitting; X-shaped design using breathable fabric, and Y-shaped structure on the front chest. Double leash keep safe of manage reactive dog with a front and back ring. A leash shifts the center of gravity back towards trainer which gives trainer a pivot point [4] without restricting dog's shoulder for freely searching. Dog is dependent on trainer to explore the sights, trainer have to teach "how to follow lead" or teaching commands through strap.

Sokolowski explored 3D hand grip shape for dog walking which captured from civilian's [5] to fulfill product design perspective. Both cognitive and physical abilities help a successful handler design [6]. Figure 3 reveals an ergonomic X-strap dog harness. The traction belt is smooth and evenly bears multi-directional forces. Another design is an enhanced retractable leash [7] which provides multiple handles for controlling the movement. Plastic buckles are utilized with Velcro straps which eliminate the leash pulling forces at the dog's center of mass (middle chest) area.
Figure 3: Ergonomic design X strap for dog, US 29/395,500 [6].

2.3. Scent and airflow

The skin disseminates cells with special odors in the metabolism, which form diffusion due to air convection. When dogs approach, they can feel the odor; after being trained in specific odors, it can increase sensitivity [2]. During the training process, the dog tracked across the sidewalk, turf, and forest path; the notification after sniffing helps people confirm the rescue path.

Researchers [3] developed a two-part dog wearable computer and interface. In the concept design process, the team first interviewed experts to correctly explain the dog's behavior. When the dog finds impure odor sources, timely encouragement by the trainer can improve its ability [8]. The experiment determined the distance and concentration that the dog can recognize, and was surprised to find that the dog can detect the smell at a distance of more than 62 meters.

2.4. IoT device in dog/ human interaction

The elderly-animal friendship bond surveyed elf-perceived criteria by the old people regarding their intimate association with their dogs [9]. A survey of 60 people [10,11] asked people classify the behavior of the nine dogs in the video as "friendly" or "radical." Researchers found that the dog's tail's movement is the main clue to explain the dog's sensation [12,13].
Figure 4: Placement of the major components and main controller [15]

Sensor and actuator help the communication between the blind and the dog; the power spectral density detection method based on breathing sound discovers the physiological state related to different odor detection tasks [14]. Previous study [15] proposed a remote interaction device implemented with Zigbee wireless technology between pet and elderly. The signal provided outdoors activities monitoring and communication, the module placed on

the back of the dog, and issue commands using a voice pager. The control chassis consist of battery, charger circuit and Zigbee circuit (Figure 4). Owner use vibrating actuator to command the dog remotely. Other study developed [16] an algorithm for locating victims in the nearly collapsed building with indoors positioning and extra IR and sound sensors.

2.5. Possibility of WiFi nodes

Many rescue areas do not present a WiFi connection. If WiFi is not available, the trainer depends on the sound to communicate. The mobile station could install, which provides the possibility of access in an emergency. Moreover, Ultra-wideband (UWB) and Long Range (LoRa) were utilized for a high-precision UAV positioning [17] with altitude error reduced to 1.74m. Simultaneous localization could be obtained through WiFi signal strength measurements [18]. Received signal strength data provide a convent way of practical implementation with a set of nodes.

The above technology is accurate, but this study focuses on the interaction between the trainer and the dog. To simplify the complexity, we use the WiFi module for the usability evaluation.

3. Design Method

The successful design of a product takes into account the user response, the alternative designs can amplify designers' understanding of the intended purpose [19]. The user central design reduced error and accelerating the decision-making process [20].

3.1. Design process

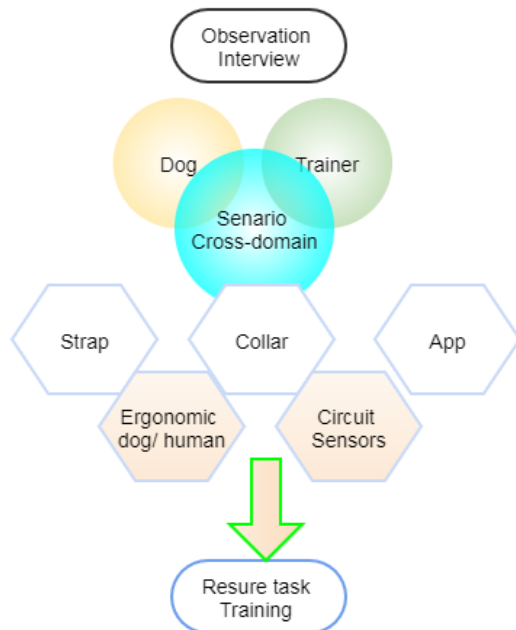
We collected user desire through interviews with rescue team. Organize their feelings into group records and use the data as a source of concept design. A scenario invited people melt into the pre-settled situation and identified needs. The conceptual ideas were evaluated based on the viable characteristics. The design flowchart shows in Figure 5.


Figure 5: The design process and flowchart

Inquiring with professionals from the Taichung rescue team, the researcher also participated volunteer activity to observe the training details. Interview data shows: dog looks down and scans left and right for evidence. When the trainer pulls back, the neck will be red and swollen. An inappropriate chest strap will cause friction and injury to the fur. Don't hinder neck movement; prevent objects from hooking; use breathable materials when hot and humid.

The design begins with the scenario which deduced from insight of the task and following directions were issued;

1) Include small flashlights and emergency relief kits, but do not hinder neck movement.

2) The disaster may face rainy environmental and need waterproof capability.

3) Taiwan is hot and humid, and dogs do not dissipate heat well. Breathable and thin materials is preferred.

4) GPS-path records located the trapped; the App is needed to improve the efficiency of search.

5) Health datas (dog's heartbeat and body condition) are essential for physical condition control.

Figure 6 shows the selected design concepts of a tracking device and straps which reduces the obstacles interference during the mission. The design features overcome the current product are following:

1) Does not hinder the search activities. When the dog looks down, the branches may get caught in the leash or traction loop and be injured.

2) The product frame is breathable, avoiding heat stroke during dog wearing, which satisfied design priority of: comfort, safety and dog's acceptance. The strap disperses pulling forces on the muscles.

3) Dogs and rescuers can support each other through complementarity, but the configuration of equipment cannot interfere with the task.
Figure 6: The idea sketch of design concept

3.2. Multidisciplinary approach

The implementation requires a cross-domain integration by running a multidisciplinary collaborative project. The ability to lead a team through the different work stages of a project is a fundamental contributor to its success [21]. Framework for the conceptual design of unmanned aerial vehicles (UAVs) proposed

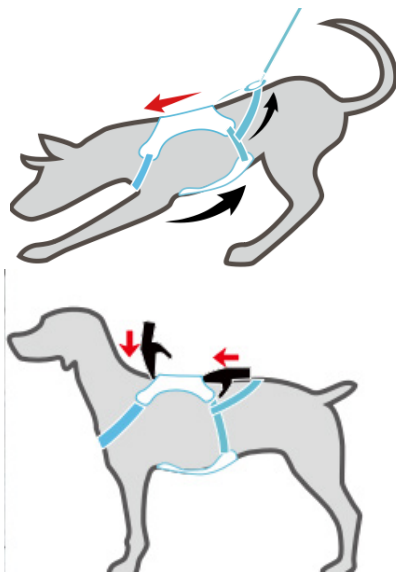
in developing efficient winged design [22] for industrial designer. Teachers used cross-domain design and developed " airflow play with music" to realize the concept of flow guiding.

Comfort rescue dogs' products needs structural mechanics, material applications, and most importantly, software and hardware integration. Cross-domain presentation requires communication and interaction between departments. The conceptual designer proposes idea sketch and functions supported in the context of use, which discussed with the engineer in advance. Finally, it can be realized with appropriate technology. This process includes the assembly of electronic circuit boards, and software and hardware test to present the design concepts. Then through the deduction of the concept the design verified with the cross-domain team.

4. Concept design

4.1. Chest strap

Comfortable shoulder straps need to be worn quickly and fit the body without friction. The chest H-shaped backrest equipped with an adjustable double belt buckle. The Y-shaped structure made of breathable fabrics reduces tensile strength (nylon, plastic and fluorescent reflective tape). The front stainless steel O-ring can release and reduce pressure.

(a)


(b)

Figure 7: (a) the upper chest pad and storage, (b) the force applied to the body during exercise, the lower pad is made of insulating cotton and wear-resistant washed canvas (sandwich mesh).

Figure 7 illustrates the design features of the chest harness: (1) equipped the upper body of the dog with a space for light devices (batteries for smart devices, simple first aid supplies, and communication equipment) for survivor; (2) as shown in the figure 7a, the side rings inserted from both sides and placed on the upper back. During the search, the trainer followed the dog in front, and strap is with tension; the traction point placed in the upper region to avoid neck strain. The illustration (Figure 8) shows that the force is directed to both sides through the outer strap to distribute it. The D-ring connects both sides with the lower abdominal support belt, and control belt of trainer. The force in three directions joined at chest. The overall design of the chest harness shows in the diagram (Figure 9). The abdomen are soft materials to avoid gaps and friction. When the chest harness is properly fitted to the body, the dog will not hook on the protrusions or tree trench when moving.

The flexible adjustment structure avoids gaps. The harness is soft to coordinate with the body shape. The designed strap presents lots of curvature elements. Based on the ergonomic and strap's curvature, the software using for CAD drawing is the Catia version-6.
Figure 8: Combination of straps on chest

Figure 9: The 3D rendering of the chest strap

4.2. Smart Collars

Combined the existing wireless transmission and positioning technology, the communication between the dog and the rescuer is better in a large range search. Traditionally, dog barks to hint trainer, this touching way extended nearby areas. With wireless device, dog barks trigger the signal of the transmission position

data and notify the trainer of the location of the victim (Figure 10a), wireless touching way extended more than 150 m diameter areas. The injury of the dog is a great loss of team, so their physical conditions are monitoring by trainer [23]. The sensor in the collar transmit the physical condition of dog, which allowing the trainer to adjust schedule. This function prevents the dog from being exhaustion.

The search mission is larger in the open field. The indoor Wi-Fi router operating on the 2.4 GHz frequency band has a radio wave of up to 50 m, and it can be greater than 92 m outdoors. Based on IEEE 802.15. 4a standard, above 200 meters electromagnetic wave range can be reach with UWB [24]. User selects suitable module based on desired range. Figure 10b shows the concept of Balloon floating positioning. The UAVs generate a lot of electromagnetic waves and noise, which affect the concentration of dogs. We chose movable balloon set to place the RF module along with the balloon; hovering over the disaster area, it can quickly move to the nearby search areas. The floating balloon will move slightly with the ambient wind but does not affect the position's accuracy much.

(a)

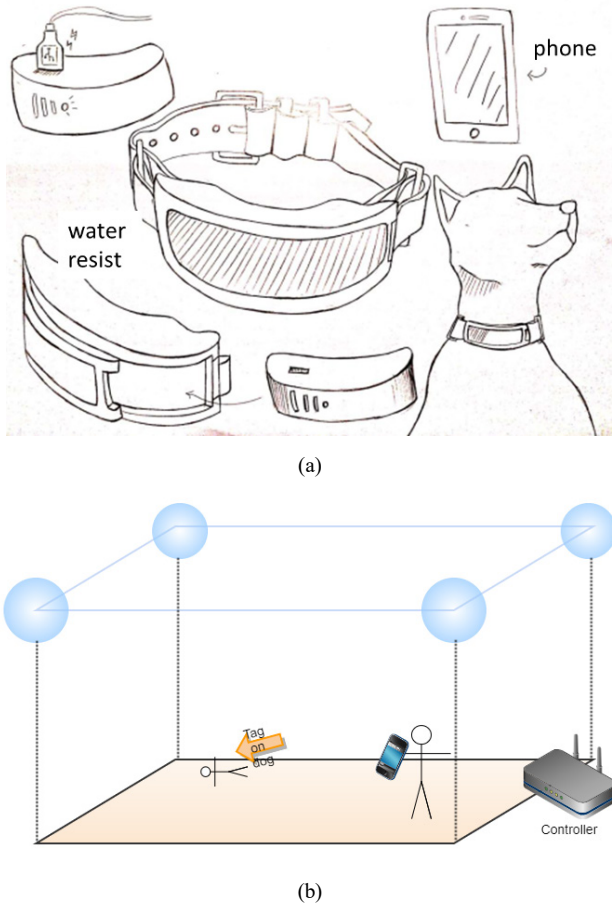
(b)


Figure 10 The proposed design: (a) smart ring module, (b) Balloon floating positioning. The UWB constructed with Semtech SX1276 Dragino LoRa Shield (with Arduino via SPI).

4.3. Implementation

A wireless remote connection collar was realized with Arduino platform, the system included a trainer side App to receive signal and arrange current task. The interaction between the smart collar and the rescuer's mobile phone are using Wifi signal. Since the

Arduino system is an open platform, many Shield modules are available.

Sometimes, the extended search area cannot cover by Bluetooth signal; therefore, we selected the WiFi or Utra-wideband module as the wireless transmission medium. When the rescue team enters this domain, they will deploy nodes which connects with the tag on smart collars. The mobile phones also share connection and able to communicate with other devices.
(a)
(b)

Figure 11: Components used in the circuit: (a) wireless remote connection realized with Arduino Shield (Ameba RTL8195), WiFi antenna, temperature and humidity sensor (DHT22), and sound sensor (NEO-7M-CAPP), (b) 3D printed chassis structure.

The Arduino Shield [25] used include GPS, speakers, Grove main control version. The breadboard wiring implementation shows in Figure 11a. The appearance of the smart collar (3D printed) contains miniaturized circuit board and sensors (Figure 11b); the collar placed on the neck area of the rescue dog with an adjustable belt. During the task, the collar might contact water, to maintain the stability of the circuit, so we installed a rubber O-ring placed in chassis gap for waterproofing of the circuit board.

4.4. Software and Trainer's APP

Heartbeat/ temperature/ and GPS status recorded by Smart collar. The squeak signal is identified with the trainer's App. The user interface can be implemented using Android APK. The dog's track record and the graphical display enhance recognition (Figure 12a). Collected dog's physical condition will display on phone screen so that the trainer can immediately prevent the dog from being exhaustion (Figure 12b).

The major Information are:

- Positioning: The dog's barks activates and informs the trainer which reveal the location of the target (Fig 12b) of the target in the mission.

- Call back: When the body temperature exceeds the set value or the task exceeds the time, the coach issues a warning. Use the withdrawal button to call the module attached to the dog and make a sound (instruction return). The training procedures

are: Call the dog's name enthusiastically and give the command: "Come! Come!" If he walks towards you, praise it. When the dog catches up, give him some snacks and compliments immediately. After several successful exercises, try to say the word alone. The dog understands the sound in previous training when rescuers click the recall button and remotely generate the same sound signal. When the success continues, try the same action with the remote microphone. The proposed device mechanism is vocal sound, the inertia of signal/ action built in early time excites the dog's physiological reasoning.

- Guidance: rescuer asks the survivor person to prompt the dog to get the direction (Figure 13). The recorded path and target's response enabled speed up of target finding.

- Dog's background: The dog's characteristics and the training performance can access by the trainer, through specific description data helps conduct of those tasks with specific dog.

4.5. User survey

Taichung established a search and rescue dog team in 2016, and had passed the Mission Readiness Test international mission rescue certification. Training require a lot of human resources including build society contact to successfully complete search tasks. Among the team, "Tie Xiong" found survivors in the rubble during the Hualien earthquake in 2018. We took the chest strap to the training site and test it by the commander during the exercise. At the verification stage, we made a prototype with soft materials for user test including magnitude of pressure, the shear force on skin, and the loading. The normal stress around chest does decrease due to force distribute on supporting surface. Per Figure

7 and 8, the most considerable stress occurs on the arch ribs due to pull.

The App interface is properly matched with the mobile phone, and the touch interface for quick setting and operation. The timely response is helpful for urgent handling in emergency situations. The current Arduino modules are large in size and easily interfere with the movement of the dog; in the future, this problem can be overcome through the miniaturization of a customized circuit board.

Figure 13: GPS positioning help target located on the trainer mobile App.

5. Conclusions

Based on situational stories and on-site observation data, we have unified the special needs in the rescue situation. The main design proposal includes a strap and a smart collar; the strap that meets the rescue dog's situation. It can be adjusted to suit individual needs. Smart sensing improves task performance; IoT chest strap helps communication and increases the efficiency of search and rescue. The smart collar records the status, and remote voice paging helps to send voice commands. Arduino's rich development modules including GPS and speakers are conducive to the prototype. Researchers found that the dog's wearable sensor improves the dog-human interaction during training.

Many technologies reported; this work looks more at user's needs through multi-disciplinary aspects of view. The conceptual situation requires the realization of the prototype to show the suitability of the concept. From the perspective of design education, we show the main parts through cross-field integration (mechanical/electronic, hardware/software). This proved that designers need to enhance cross-domain sentiment to stand at the high point of design thinking in order to propose appropriate solutions.

A B S T R A C T

There are pressures to adopt sustainable behaviour more so in generating profits and benefiting the society to accelerate green efforts through a green framework. The overarching goal of the paper is premised through various works of literature, building the ecosystem the elements highlighted by most researchers in the field of environmental entrepreneurship. The various models reviewed consists of generic incubators and entrepreneurship, and societal and environmental factors. Environmental entrepreneurship is often used interchangeably with concepts such as green entrepreneurship and ecopreneurship which under-researched globally, with non-existent efforts on the applicability and modelling of key environmental entrepreneurship within a specific context utilising the system dynamics approach. In order to assess the environmental entrepreneurship ecosystem, the authors adopted a system dynamic approach to determine key variables that enable the development of the system. A literature review was conducted, and of the 135 articles reviewed, n=92 peer-reviewed articles met the criteria that the researchers set. Some of the results emanating from a systematic review are environmental policy, green skills, financial and non-financial support, societal and behavioural factors, environmental agility, ethics and governance, and access to markets. The theoretical results are simulated using system dynamics modelling. Due to limited research on the above-mentioned topic, a possible impacting variable (Exogenous variables) was broadened to add value to, and have an impact on, the study. Upon reviewing the above-mentioned models, the framework emerged signalling elements to be simulated in the system dynamics model, which were then theoretically contextualised for the South African context. The theoretical virtual system dynamic model forming part of the framework will be tested and validated in the next study. The applicability of the theoretical ecosystem to South African context as well as future recommendations are provided in the study.

1. Introduction

This paper is an extension of "Green Entrepreneurship Model Utilising the System Dynamics Approach: A Review" presented at the IEEM 2019 Conference in Macau [1]. The conference proceeding argued that Green entrepreneurship as a technology is an area that has not been explored fully, let alone its application the system dynamics spectrum. Furthermore, the paper argued that empirical scholarly research in entrepreneurship within Green

industries is at infancy stages in South Africa, and little research work has been done. In [2], the author conducted a study focusing on green entrepreneurs in the South African context. While [3-5] concentrated on the international markets. However, a complete ecosystem surrounding environmental entrepreneurship, and system dynamics remains a gap under consideration. The existing research is centred around a single factor of green entrepreneurship [1], [3-5], with less focus on finding possible multiple solutions to minimise climatic challenges. In this paper, the focus is on environmental entrepreneurship, particularly with the aim of contributing to social norms and finding innovative

approaches to utilising system dynamics for modelling endogenous and exogenous variables of the system. In the current paper, the focus of environmental entrepreneurship is within the spectrum of key drivers of environmental entrepreneurship, social change and behavioural factors. The latter focus is deliberate in creating access to services for the community through empowerment, development, and awareness, and ultimately laying a theoretical foundation on how environmental entrepreneurship can be utilised. These efforts may accelerate the sustainable development goals as environmental entrepreneurs are always expected by societies to be concerned with the environmental factors [6]. Some of the literature defined environmental entrepreneurship by using phrases such as eco-entrepreneurship, ecopreneurship, and ecological entrepreneurship [7-9].

Green entrepreneurship and ecopreneurship is minimally included in the current paper. This is due to the fact that the authors are advocating for the concept of green entrepreneurship, ecopreneurship and environmental entrepreneurship to be defined and dealt with separately so as to have an impact and foster the implementation thereof. It is notable that the latter terms are somewhat similar. However, there is a slight difference between the concepts, whereby, Green entrepreneurship focuses on exploiting markets for profits and saving the planet by leveraging green thematic areas [5]; ecopreneurship has a distinctive feature of ensuring efficiency and effectiveness [10]; and environmental entrepreneurship has a distinctive feature of social, behavioural norms to develop and create awareness [11, 12]. Environmental entrepreneurship can be defined as the concept of radiating adoption of sustainable behaviour and social entrepreneurship, whilst benefiting the society [11].

The current paper focuses on environmental entrepreneurship by contributing of utilising the system dynamics approach to understand the behaviour of the system and its interaction with sub-systems. A further contribution that the current paper hopes to add is to create a theoretical opportunity of the contribution of environmental entrepreneurship to accelerate the sustainable development goals. The current study illustrates how environmental entrepreneurship contributes to sustainable development, social and behavioural factors affecting environmental entrepreneurship in facilitating access to the service, and fostering environmental entrepreneurship as a form of social change. Social dynamics and sustainable development need to be borne in mind when fully implementing green initiatives to support environmental entrepreneurship. Environmental entrepreneurship, as a complex phenomenon, needs to be viewed from different angles to ensure that solutions are gained from multiple sources at the same time. The underlying goal of the paper is premised through various works such as generic business incubators, environmental factors, and societal norms capitalising on social entrepreneurship to build the ecosystem. From the various models the authors discovered key drivers to environmental entrepreneurship, social and behavioural factors as part of the framework. The theoretical ecosystem consists of key drivers, social and behavioural factors, as well as the theoretical framework contextualised in the South African context. The subsequent sections discuss the research questions methodology, and future recommendations.

2. Research questions

The research questions were identified through the research gaps [13] that were identified while reviewing literature and where possible research contributions can be made setting future research agendas. The research questions are as follows:

What are the theoretical key drivers enabling environmental entrepreneurship as a form of social change?

What are theoretical social and behavioural factors affecting environmental entrepreneurship in facilitating access to the service?

How can theoretical key drivers be applied in formulating a South African context framework?

3. Research Background

3.1. Environmental entrepreneurship for social change

Environmental entrepreneurs need to have an agenda of creating and formulating sustainable and green products and services, and at the same time, meet social, economic and environmental objectives [8], [14-16]. It is essential to focus on social dynamics and sustainable development by fully implementing green initiatives. Goal 5, 'gender equality', of the sustainable development goals can be fulfilled by promoting women in environmental entrepreneurship, and Goal 8, 'inclusive and sustainable economic growth, full and productive employment and decent work for all' [17], can be fulfilled by contributing to a better quality of life and serving as a social change catalyst. Studies have shown that women are more likely to venture into environmental entrepreneurship and are more inclined to uplift communities through social entrepreneurship [11, 18].

Research or publication on environmental entrepreneurship as a contribution to sustainable development goals and its interrelatedness or linkages to the system dynamics in the South African context is minimal. Environmental challenges are due to humans not adopting sustainable efforts [19]. The current authors assert that efforts need to be in the form of environmental psychology to minimise challenges due to human activity. Environmental entrepreneurship focuses heavily on the social sphere, transforming communities and the need to adopt agility for the viability of environmental entrepreneurship. In most instances, environmental entrepreneurship forms the foundation of green entrepreneurship by advocating new or innovative ways to save the planet with green products and services [20].

Worldwide, there is minimal research on women as environmental entrepreneurs. In [21], the author holds a strong view that developing women in green cooperatives, especially in rural areas, may alleviate poverty and promote sustainable rural development. This may ultimately contribute to creating green jobs [22]. There has been some effort in tracking environmental entrepreneurship from the early 1990s [23]. Another social factor that has not received much attention is popularising female entrepreneurs who embark on environmental entrepreneurship. There is lack of research on the female identity in relation to their roles as environmental entrepreneurs, which will need to be taken

into perspective and how they optimise or create a new identity in transitioning into a green economy. In [17], the authors shed some light in proving the motive of women embarking in environmental entrepreneurship is to uplift the society.

The current authors are of the opinion that environmental entrepreneurship can assist in accelerating the sustainable development goals, particularly goal 1: zero poverty, goal 5: gender equality, and goal 8: inclusive and sustainable economic growth, full and productive employment and decent work for all.

3.2. The innovative contribution of environmental entrepreneurship utilising system dynamics modelling

The innovative contribution of environmental entrepreneurship as a social change is in the form of system dynamics modelling. The system dynamics approach models the key drivers and factors affecting environmental entrepreneurship as well as social and behavioural factors that create a new perspective of a theoretical entrepreneurship framework. Environmental entrepreneurship, as a complex phenomenon, needs to be viewed from different angles to ensure that solutions are obtained from multiple sources at the same time. System dynamics is used to conceptualise the causal loop relationships or stocks and flows, with the intention of identifying variables that affect the ecosystem feeding into the whole system [24-26]. "System dynamics is the combination of theory, method and philosophy in analysing the behaviour of the system [26]." Furthermore, system dynamics focuses on a feedback loop and nonlinear relationships [25]. System dynamics is viewed as the process or feedback relationship between different parts to understand complexity and behaviour throughout the lifespan, or the process of the system [27]. The need to utilise the complex system to have holistic thinking serves as a research agenda [28]. Therefore, the authors of the current paper further contribute to the system dynamics approach or modelling by looking at environmental entrepreneurship as a complex factor.

4. Methodology

The research methodology followed was in the form of systematic review. The rationale for using a systematic review as a methodology afforded the authors access to the various methodologies and outcomes within the areas of environmental entrepreneurship and various societal norms. This enabled the researchers to formulate a framework with triangulation of efforts from previous researchers. Furthermore, the rationale for systematic review is to explore the area under investigation, simulate theoretically, the key drivers, social and behavioural support factors in quest to create a future research agenda free of bias. The systematic review as a methodology was beneficial, especially during the COVID-19 pandemic, which has affected the entire world, as interviews or questionnaires would not have succeeded during these challenging times. The use of online data collection still poses challenges due to social inequalities and the majority of people not having access to emails or not being able to afford online video platforms in South Africa. The systematic review focused on peer-reviewed articles utilising search engines such as Google Scholar, Sage (Journal of Entrepreneurship Theory and Practice), the Journal of Cleaner Production, Science Direct and the Journal of Sustainability. Grey resources such as

newspapers media alerts were excluded when conducting a systematic review. A theoretical review was conducted using a literature review of which n=92 sources (peer-reviewed articles) out of 135 articles, met the criteria that the researchers set for the ecosystem. Duplication of results was removed from the 135 articles. The current study is qualitative in nature and thematic content analysis was used to analyse the results. According to [29], the most preferred and effective way to analyse a qualitative study is to use thematic content analysis. Content thematic analysis attempts to summarise comments into meaningful categories [29]. According to [30] content analysis is a general term to analyse text. It is the systematic coding pillar used for exploring a large amount of textual information to determine trends and patterns [30]. Furthermore, content thematic analysis enables the researcher to condense a broad and clear description of a factor. Themes that have emerged from a review of the literature are environmental entrepreneurship (in terms of key drivers and support), and social and behavioural factors regarding environmental entrepreneurship. The search criteria were environmental entrepreneurship, and system dynamic social factors regarding environmental entrepreneurship, with a refined search from 2010-2020. The software, Vensim, was utilised to simulate the virtual abstract system dynamics model. The title, introduction, abstract and findings sections were used to select the relevant articles and discard other articles. The findings are summarised in Table 1.

5. Findings

The identification of environmental key drivers was affected by conducting an entrepreneurship ecosystem. In order for sustainable entrepreneurship to flourish, awareness of environmental challenges and how they currently affect the nation needs to be set as a research agenda. The literature review and themes such as environmental entrepreneurship (in terms of key drivers and support), and social and behavioural factors regarding environmental entrepreneurship, served as a form of reference. The latter enabled the researchers to manipulate the key variables or drivers for environmental entrepreneurship to be popularised. Environmental entrepreneurship needs to be analysed using small and large-scale criteria and weighed up against the weakness and strengths in order for individuals to learn from and serve, as best practices.

The themes and summary of the afore-mentioned findings are explained in the Table 1. The ecosystem of environmental entrepreneurship in this paper comprises of key drivers in a form of financial and non-financial support, social and behavioural factors as depicted in table 1.

The key drivers such as funding, credit, capital financing, investing in environmental entrepreneurship, and crowdfunding, can be classified under green finance mechanisms in support of environmental entrepreneurship with social orientation [9, 29], [30-33], [35, 36], [44, 45]. Funding of enterprises or ventures is always a challenge, more specifically financing environmental entrepreneurship. Green proofing as advocated by [43] gives rise to a consultancy option, which the current authors deduce that the programme can be utilised to facilitate and manage green change dynamics. Some of the pillars supporting environmental entrepreneurship are infrastructure, skills and education, funding,

(environmental entrepreneurship incubators) products, markets affordability and political will [12, 29, 30, 33, 43]. However, the latter financial key drivers cannot operate in isolation and therefore, may need non-financial support in the form of behavioural change. With key drivers illustrated above, the next theme leads us to behavioural and social factors to strengthen the ecosystem of environmental entrepreneurship

Table 1: Ecosystem for environmental entrepreneurship

Key drivers of environmental entrepreneurship	Social and behavioural factors	Authors' contribution to the environmental entrepreneurship (South African context)	Common factors from various models
Strategic support mechanism [29]	Modelling of human behaviour	Ambassadors or society representatives from various cultural groups, tribal kings, ward councillors and volunteers	Strategic alliance
Environmental policy [12, 30]	Societal support, Alertness, motivation, Altruism [32]	Curriculum review and service-learning	Collaboration, wellbeing, alliance and governance
Tax exemptions and tax breaks, financial mechanism, cost effective products and services [31,32]	Crowdfunding, impact of social norms, development agencies [35-38]	Memorandum of understanding, exchange programmes, and international linkages	Financial and Non-financial support
Access to markets, legal support [12; 30,33,34]	Environmental psychology Environmental consciousness, collective Environmental entrepreneurship and green behaviour, Pro environmental behaviour [39-44]	Green change dynamics programme	Green consumer behaviour and adoption of green behaviour

The behavioural and social factors are premised within environmental agility innovation, transformation, motivation, ecopreneurial management, profiling of environmental entrepreneurship, development agencies crowdfunding, environmental policy, legal framework business incubators commitment and green skills to govern the rights of environmental entrepreneurs [28-30], [34-38], [45-54]. More entrepreneurs from small scale enterprises are environmentally conscious [55]. Literature suggests that in order for desired change to take place, social context plays a huge role, drawing from the work of [56, 57]. Society can play a huge role in praising and supporting environmental innovation, whereas entrepreneurs could ensure that they exploit the markets and ensure they offer affordable products and services to the communities at large. The support from government is needed to contribute to the subsidies

and waiving of some costs relating to environmental entrepreneurship, as part of the key drivers [57,58]. Networks, non-governmental stakeholders, financial structural support systems, tax exemptions and tax breaks are some of the key drivers that can support environmental entrepreneurship [29, 59]. The authors are proposing that skills development and human capital need to be the cornerstone of accelerating environmental entrepreneurship through an environmental entrepreneurship talent pipeline. The motives of environmental entrepreneurship have been shown that education is a factor. It has been proved that if individuals have higher levels of education, they tend to embark on environmental entrepreneurship [11].

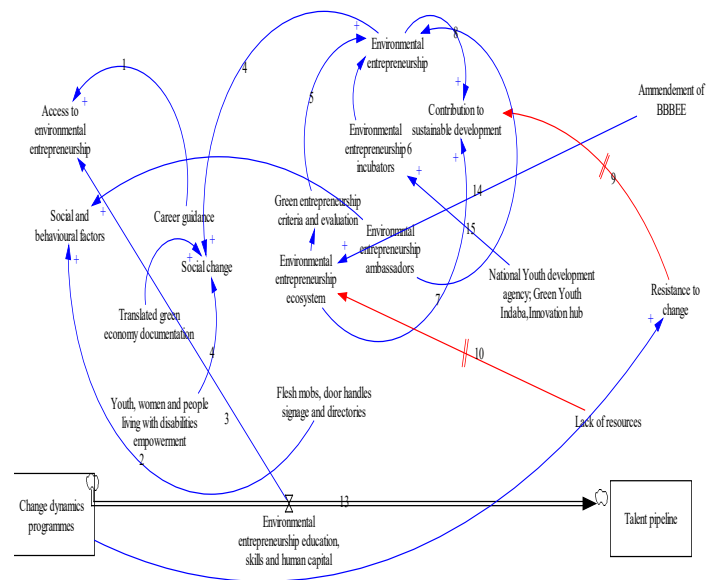
The system dynamics approach is in the form of modelling the key drivers and factors affecting environmental entrepreneurship as explained above, as well as social and behavioural factors creating a new perspective of entrepreneurship. The modelling of the afore-mentioned results can be depicted using the system dynamics model in Figure 1.


Figure 1: Virtual system dynamics model of environmental entrepreneurship

The system dynamics model (Figure 1) illustrates the importance of the interdependency of multiple variables or factors within the environmental entrepreneurship spectrum. The (+) sign represents a positive relationship and the (–) sign represents a negative relationship. Numbers depict each loop, while delays and threats are represented by a red line with two strokes. The system dynamics model consists of stocks and flows. Loop number 1 represents accessibility services that are influenced by career guidance, and the stock is represented by environmental entrepreneurship education, skills and human capital (loops 3 and 13).

Loop 2 represents an order for social and behavioural factors to be understood and incorporated for social change; and societies can be reached through flesh mobs, door handle signage, directories and ambassadors. Empowering youth, women and people living with disabilities about how to enter the environmental markets, contribute to a social change. Social change then may accelerate environmental entrepreneurship. For

environmental entrepreneurship to gain momentum, the criteria and evaluation system needs to be in place (loop 5).

Furthermore, contribution to environmental entrepreneurship can gain momentum because of the ambassadors, environmental entrepreneurship incubators (loop 6) and centres such as the National Youth Development Agency, Green Youth Indaba, Innovation Hub (loop 15) and emerging environmental entrepreneurship non-profit and profit organisations. Additionally, business incubators are influenced by financial and non-financial mechanisms as exogenous variables.

Environmental entrepreneurship serves as catalyst and contribution to sustainable development positively demarcated by loop 8 and loop 7. However, resistance to change and a lack of resources causes delays and threats to the ecosystem represented by loops 9 and 10. At the same time, there are inputs from the environment, which is BBBEE or legislation represented by a loop 14, which contribute positively to the environmental entrepreneurship ecosystem.

Stocks and flows are indicated by number loop 13. Currently, this research proposes two stocks namely change dynamics and talent pipeline, which are influenced and accelerated by environmental entrepreneurship, education and skills. At the same time, environmental change dynamics can be used to minimise resistance to change.

6. Discussions of environmental entrepreneurship key drivers and social factors

6.1. Key drivers of environmental entrepreneurship

Previous research suggests that creating a clientele, market, and support for the business are important pillars for a start-up to flourish [26]. One important factor that will determine the success or failure of a business is customers and customers' attitudes, which is often overlooked. Creation of the market and funding, or any support for green entrepreneurship, appears to be taboo and an unheard-of practice, therefore, it can be deduced that it needs to start with creating awareness, and unpacking human behaviour as an action. The process needs to be simplified for communities to understand the green economy phenomenon and from there, gradually improve to investigating if there is capability to optimise resources and opportunities for business gain and profit generation and saving the planet for future generations.

There is lack of investors which poses challenges and threats to the system. Investors in environmental entrepreneurship, especially in these sectors, are cautious investors, where scepticism and reluctance arise when it comes to investing to environmental entrepreneurship enterprises. In [33], the author serves to close the gap of financing by introducing crowdfunding. Crowdfunding can be explained as the sourcing of funds through other mechanisms within the lenses of cultural and social norms and creating initiatives online to raise funds and finance. The initiatives to enable transition and a green economy are to ensure ambassadors or champions in different sectors are available. These sectors include the private, public, tertiary, and schooling sectors, and are to be included from the planning phase to the implementation phase. However, society at large or communities are bypassed, and this may add to further challenges and delays in

the adoption of new behaviour such as the environmental entrepreneurship. In order to capitalise on collective efficacy in transitioning to a green economy, society, and stakeholders, need to form part of the movement. Collective efficacy can be defined as a group of people coming together to remedy a challenge (as in this instance, the environmental challenges), and have the confidence and capabilities to embark on the movement [41].

The need for curriculum review and inclusion of environmental entrepreneurship in South African basic and higher education needs to be considered to ensure the sustainability of environmental entrepreneurship. In [43], the author echoes the latter idea of curriculum inclusion of environmental entrepreneurship in schools. The green skills documentation and lessons learnt could be drawn from parts of Europe in regulating the economic factor of green skills for the country's economy [59]. The SEED programme is another support mechanism that supports sustainability entrepreneurship [60-62].

6.2. Societal and behavioural factors

There is an action of social responsibilities and environmental policies to be modified concurrently of which the researchers believe that environmental entrepreneurship with the lens of system dynamics could be incorporated onto policies to view the challenge as a system. A study conducted in Bosnia asserts that there is role ambiguity among government stakeholders and educational curricula regarding green entrepreneurship [63]. The latter argument can then be strengthened, and a clear framework provided where relevant stakeholders have stipulated the role and support required to accelerate the agency of adoption of environmental entrepreneurship.

6.3. Threats to the environmental entrepreneurship system

Through the analysis of literature, there have been efforts to investigate green entrepreneurship from international perspectives. Researchers then grouped existing literature to identify barriers to environmental entrepreneurship. Some of the internal barriers were a lack of resources and adequate knowledge, poor implementation of policies and strategies, and attitudes and an organisational culture that discourage environmental management [34]. Furthermore, external barriers that were identified were, difficulty in obtaining certification for environmental practices and systems, economic uncertainty, a lack of legal and institutional frameworks, specialised support and networks among small businesses and the creation of green jobs, and non-compliance with policies. The lens in regard to level of education, support services for incubation, entrepreneurial confidence, business climate, job creation, and clientele may be the solution to the above-mentioned challenges.

6.4. Contextualisation to the South African context

The authors believe that South Africa can implement strong coordination in the form of a memorandum of understanding with the countries that have developed environmental entrepreneurship. This will allow exchange programmes within the SMEs in diverse environmental entrepreneurship, particularly targeting Youth, Black people, women and people living with disabilities.

To broaden this perspective, Broad-based Black Economic Empowerment (BBBEE) needs to also include additional lenses of facilitating environmental entrepreneurship, and points should be allocated in the form of tendering systems in diverse environmental entrepreneurship. To promote gender equality, goal 5 of the sustainable development goals, environmental entrepreneurship can be spearheaded through women empowerment and be integrated into the BBBEE codes to ensure the economic and social standing of women in the South African context. Furthermore, to facilitate the access of services, the scope of career guidance can be expanded to include environmental entrepreneurship as a transformative process. The authors offer recommendations to accelerate access to markets and provide social contexts that are to be embedded in environmental entrepreneurship. In order to further accelerate access to markets, environmental policy needs to specifically stipulate what the rights of environmental entrepreneurs are and how they can access markets [12, 42].

The environmental entrepreneurship pipeline needs to be in place and included in policies, that especially target the youth. The National Youth Development Agency could spearhead funding and include the criteria to promote entrepreneurship in environmentally friendly products, services, consulting or distribution. The National Youth Development Agency could work hand in hand with Green Youth Indaba and an Innovation Hub where several youth programmes are housed, to ensure the sustainability of entrepreneurship in targeting the youth. Environmental change dynamics should be implemented whereby green readiness of change and managing fear of the unknown within Green initiatives could be developed, and awareness and training initiatives with environmental enterprises are instilled into society to contribute to the level of confidence in sustainable energy enterprise sectors. Green skills can be incorporated into the South African Skills Development Act to facilitate an initiative regarding green skills training and development. Change dynamics programmes such as resistance to change and sustainable development goals in a developing country can be introduced. The existing change dynamics programmes can be used as a foundation to design and implement the ecosystem. The South African Skills Development Act could be amended to facilitate the initiative of training and development, and the keeping of training and development records to aid sustainable development goals, and green skills for monitoring of grants and incentives.

7. Future recommendation

Action is needed with regards to social responsibilities. Further action is for environmental policies to incorporate environmental entrepreneurship. The authors further contribute that in order for environmental challenges to be minimised and environmental entrepreneurship to flourish, human behaviour needs to be modelled through environmental Psychology in terms of social psychology, behaviour, motivation, cultural and gender factors, personality traits, and attitudes towards a green economy and environmental entrepreneurship. To further aid environmental entrepreneurship as a social change, the development and focus of research and support needs to be given to women.

8. Conclusions

The current paper explored various works of literature such as key drivers from business incubators, social and behavioural factors, environmental entrepreneurship, and building the theoretical ecosystem of the elements highlighted by most researchers in the field of environmental entrepreneurship. Environmental entrepreneurship, as a complex phenomenon, needs to be viewed from different angles to ensure that solutions are gained from multiple sources at the same time.

The discovery made during the review of literature is that an ecosystem of environmental entrepreneurship can be broadly clustered within key drivers (support and accelerators), and social and behavioural factors that are contextualised in the South African context. The latter broad factors can further be explained through the accessibility of services that are influenced by career guidance, environmental entrepreneurship education skills and human capital. In order for social and behavioural factors to be understood and incorporated for social change, societies can be reached through flesh mobs, door handle signage, directories and ambassadors.

The empowerment of youth, women and people living with disabilities about how to enter the sphere of environmental entrepreneurship needs to be the cornerstone and serve as an accelerator to the system. Therefore, environmental entrepreneurship serves as catalyst and contributes to sustainable development, theoretically. As a way forward, the above hypothesis needs to be tested and validated to build a systems dynamic model taking foundation from the systematic review conducted by the current authors. Furthermore, to try and bridge the gap, more interdisciplinary qualifications need to be encouraged and a call for industrial psychologists to collaborate with experts in the fields of industrial engineering, environmental science and economics, about meeting sustainable development goals, should be undertaken.

Conflict of Interest

The authors declare no conflict of interest

A R T I C L E I N F O	A B S T R A C T
	In the Global sphere, the social, environmental, and economic pillars are the main contributors and accelerators to the sustainable development goals. As a result, the latter creates a platform for interdisciplinary researchers, society and decision-makers to collaborate in formulating ways to minimize factors contributing to environmental concerns. Energy is currently referred to as one of the scarce resources. The scarcity of electricity is mainly experienced in the rural areas of most countries in the world. The mandate of the green economy is to introduce innovative ways to redress the inequalities and lack of access, especially when it comes to Energy. Based on the sector's efforts, questions arise as to what comprises the ecosystem that can be accelerated to enhance entry to the sector. Hence, the researchers focus on Renewable Energy with specific reference to the entrepreneurial motives to meet sustainable goals. The applicable sustainable goals are goal 7 (affordable and clean Energy) and Goal 8 (decent work and economic growth). Furthermore, Energy contributes to modern access and poverty reduction to accelerate the transitioning to a Green economy. The current paper hopes to answer the following questions: Firstly, how Renewable Energy enterprise can contribute to sustainable development goals theoretically. Secondly, how can the theoretical energy enterprise ecosystem be contextualized in the South African context? A theoretical review was conducted through a literature review of which n=47 sources met the criteria that the researchers set for ecosystem variables. The overarching goal of the paper is premised on various works of literature building the ecosystem of the elements highlighted by most researchers in the field of renewable energy enterprises or business ventures. From the various models, the framework emerged singling out the critical success factors of the ecosystem of the Renewable Energy enterprise. The theoretical ecosystem consists of accelerators, social factors, sustainable development goals, as well as selected business models. The latter ecosystem was then contextualized in the South African context for a complete framework. Some of the critical drivers derived from the latter broad ecosystem are: Renewable Energy Feed-in Tarrif (REFIT), Utility Renewable Energy business model, Customer renewable energy business model, Energy Justice (distributive justice), Off-grid (Mini-grid), Saurian Lilting lamp, Renewable powered irrigation system.

1. Introduction

This current paper is emanating from the paper *Green Entrepreneurship Model Utilising the System Dynamics Approach: A Review"* presented at IEEM 2019 Conference in Macau [1]. There are always pressures around social, economic, and political phenomena as part of the triple bottom [2] to meet the green economy expectations and ways were researchers, and society at large can contribute to the process. Figure 1 shows the data world rural electrification rate & Electrification Growth rate.

Figure 1 illustrates the rural electrification and electrification growth rate from the 1990s to 2016. The red line demarcates rural electrification growth rate and the blue line demarcates rural

*Corresponding Author: Dineo Diale, c.diale@ru.ac.za

electrification rate (percentage of rural population). Rural electrification is a process of giving access to the commodity to the population in rural areas [3, 4]. Energy is one of scarce commodity, where millions of people, especially in the rural areas, are not connected to the electricity grid, due to lack of affordability [4].
Figure 1: World Rural Electrification Rate & Electrification Growth Rate [3].

The green economy's mandate is to introduce innovative ways to redress the inequalities and lack of access, especially when it comes to energy [5]. Large numbers of people use fires and fuel lighting for basic energy needs [2], particularly in rural areas. The success factors or contingency plans were then introduced as an alternative mechanism such as renewable energy [2]. The latter serves as an effort to ensure that everyone can be able to light their houses or businesses. In hoping to minimize the challenge of the majority of South Africans without access to electricity, the country has a solar park in the Northern Cape. The solar park is to improve living, promote sustainable tourism. The latter strategy attracts tourists and investors, contributing to the economy of the country [4].

Furthermore, from the efforts on the sector, questions arise as to what would be an ecosystem that can be accelerated to enhance entry to the sector. The current research proposes a focus on specific reference to the entrepreneurial motives in efforts to meet sustainable development goals. Efforts have been made to explore renewable energy enterprises [6, 7] but have not focused on sustainable development goals or social focus within the area. The applicable sustainable development goals identified are Goal 7 (Affordable and Clean Energy) as well as Goal 8 (Decent work and Economic growth) [8] Furthermore, Energy contributes to modern access, and poverty reduction [8-10], to accelerate the transitioning to Green economy. The idea is to focus on one Green economy thematic area, which is Energy, and refining the research to focus only on enterprise within the energy sector.

The paper is premised through various works of literature building the ecosystem, taking into consideration the elements highlighted by most researchers in the field of Renewable Energy enterprises or business ventures. From the various models, the framework emerged singling out the ecosystem of the Renewable Energy enterprise. The theoretical ecosystem consists of accelerators, societal factors, and sustainable development goals as well as selected business models. The latter ecosystem is then contextualized in the South African context for a complete framework. The subsequent section will focus on literature review, research questions, methodology, results and discussions, and future recommendations.

2. Research questions

The research questions were formulated through the research gaps that were identified while reviewing literature and where possible research contributions can be made setting future research agendas. The research questions are as follows:

- How can theoretical Renewable Energy enterprise ecosystem be contextualized in the South African context?
- How can Renewable Energy enterprise contribute to sustainable development theoretically?

3. Research Background

The Literature review discussed in the paper is premised on accelerators and barriers to the Renewable Energy in the formulation of key drivers which can be part of the framework. Furthermore, the theory behind the ideas on how Renewable Energy can be used to contribute to sustainable development goals will be discussed below.

3.1. Accelerators to Renewable Energy

Through the review of literature, support mechanism implemented worldwide are in the form of the non-financial and financial mechanism as well as strategic programmes [9-11]. A generic business framework such as utility renewable energy business and customer renewable energy business model has been developed to facilitate manufacturing to consumption value chain to support Renewable Energy enterprises in the international markets [12-14]. Due to the diffusion of energy supply, support as an investment can accelerate the planning and implementation of the scarce commodity [15].

Other factors such as the biographical determinants such as age, level of education have demonstrated to the adoption of Renewable Energy technology. The generation that tends to adopt to the technology has been proven to be the younger generation than the older generation [16].
Figure 2: Renewable energy non-financial support mechanisms [15].

Figure 2 depicts the non-financial support mechanisms that could accelerate Renewable Energy. Scholars such as [15] have raised that non-financial support needs to be the cornerstone of the planning and implementation of Renewable Energy. The

renewable Energy serves as a "new kid on the block"; therefore, scepticism comes somewhat derails the implementation.

3.2. Access of the commodity by the society through sustainable development goals

In contribution to the access of the commodity by the society, the authors are proposing using sustainable development goals as a framework. Thematic areas of the green economy are inclusive but not limited to Green Energy, sustainable water, waste, agriculture, trade-in low carbon products, cleaner and green technology, green buildings, green chemistry and sustainable transport (mini car/cycles) as well as air quality [17]. Enabling the green economy involves innovation [18] of which needs attention and serves as a research agenda.

There are 17 sustainable development goals namely: *Goal 1 Eradication of poverty; Goal 2 No hunger, Goal 3 Good health, and well-being, Goal 4 Quality education, Goal 5 Gender equality, Goal 6 Clean water and sanitation, Goal 7 Affordable and clean energy, Goal 8 Decent work and economic growth, Goal 9 Industry, innovation and infrastructure, Goal 10 Reduced inequality, Goal 11 Sustainable cities and communities, Goal 12 Responsible consumption and production, Goal 13 Climate Action, Goal 14 Life below Water, Goal 15 Life on land, Goal 16 Peace and Justice and strong institutions, Goal 17 Partnerships to achieve a goal* [19].

Efforts have been made to introduce Energy technologies and policies is to reduce poverty and facilitate Clean Energy [20]. The need to contribute to societal need by reducing the electricity bills for those who cannot afford them, serves as a crucial social context [21], needing collective actions and commitment of relevant stakeholders inclusive of professionals in the field of Industrial Psychology, Industrial engineering, Energy practitioners, community members, governments officials and politicians.

Understanding culture and community needs from a social perspective, spearheaded by social scientists to study the area of Renewable Energy in Sub Saharan Africa [21] is needed, of which the authors believe that this best practice could be implemented in the South African context, to understand and tailor services and products to society leveraging on societal needs. Accelerators and support for Renewable Energy need to be contextualized in Rural, Urban, and semi-rural areas to create the impact and effective implementation. To echo the latter statement, the study conducted in Bangladesh investigated the impact of the implementation of Renewable Energy in rural areas and found that Renewable Energy contributes to social, economic and environmental benefits [22].

The benefits of Renewable Energy can benefit people living in rural areas through better quality of living and health as the majority living in Bangladesh use kerosene, candle and often have to walk a long distance to fetch wood for cooking [22]. Renewable Energy through natural resources such as biogas, solar, wind, hydropower can benefit the society of rural of Bangladesh [22].

3.3. Barriers to Renewable Energy

Some of the challenges identified are wage or salary disparities, skills shortages, shortage of coal, producers, corruption, mismanagement of funds and resources, lack of policy framework, limited absorption of solar manufacturing plants [3]. Developing countries do not have adequate resources, such as technology, lack of institutional support, lack of skills and lack of regulatory policies especially when it comes to Renewable Energy [23, 24] of which the same challenges may be the case in the South African context.

The negative impact of oil prices fluctuation is affecting the economic and political sphere of the continent [25]. According to [26], investors from other continents are reluctant to do business in Africa.

The lack of competencies, failure to create a new value proposition, and competition have been demonstrated to serve as barriers in Renewable Energy ventures [6, 26, 27]. The cornerstone query of creating a market arises, in establishing potential customer clientele, as well as the capacity of understanding the importance of adoption of Renewable Energy and how the technology can be utilised to ensure effectiveness and viability of enterprises [6, 13, 27, 28].

Upon reviewing the literature scholars have demonstrated that the effect of price control, inability to adopt new technologies and lack of market diversification further added to the challenges of full implementation of Renewable Energy technologies [25].

Further barriers, especially in the African context, is the issue of connection to the grid, inability to build relationships with established companies, lack of trade and distribution organisations [23]. In the South African context, it was discovered that barriers in the Energy project are credit risk, market risk, risk of change of legislation as well as technological risks [29].

The lack of the necessary infrastructure and education has been found to be obstacles in quest of the adoption of Renewable Energy as technology [30]. Thus, From the research point of view, lack of research and innovative way incorporated within research methodologies to Renewable Energy as technology serves as a challenge. In [5], the author asserts that the specific research methodologies such as quantitative methodology forms part of the puzzle and may become a solution in implementing the Energy programmes. Further challenges that researchers raise are weak electricity grids, corruption as well as future entrepreneurs in the field of renewable Energy having challenges in handling the complexity of adoption of Renewable Energy as a technology [3, 5, 25, 26].

4. Purpose statement

Upon explaining the research background above, purpose statement is then formulated as follows: Various scientists have conducted empirical studies in an attempt to understand Renewable Energy, sustainable development goals, climate change, Renewable Energy enterprise [31-35] but with less focus on Renewable Energy enterprise in quest of creating a framework nor less focus on mapping the Renewable Energy ecosystem with Sustainable Development goals and societal factors within the South African context theoretically, which the current study fulfils. Studies have been conducted globally and within African context within the Renewable Energy, Renewable Energy enterprise and sustainable development goals [6, 7, 20, 21, 24, 25,

34, 36] with non-existent focus particularly within the South African context in formulation of the ecosystem nor mapping the sustainable development goals utilising the ecosystem.

Table 1: Findings of the ecosystem for environmental entrepreneurship

The theoretical ecosystem of renewable energy enterprise	Contextualisation of theoretical ecosystem Renewable energy enterprise to South African context
Market incentives Demand and supply of renewable energy services	Equity official development assistance.
Infrastructure governance Government subsidies [11, 37]	Empowerment of previously disadvantaged groups, i.e. women, people of colour and disabled people Awareness conferences, symposiums
Best practices/lessons learnt from developing countries.	Human resource development policies and BBBEE
Financial support Venture capital Budget provisions, grants, loans, equity financing [36]	South African Government, subsidies Development Bank of Southern Africa (DBSA), Private energy entities, partners and cooperatives financial support.
Alternative forms of Energy Solar Energy [21] Off-grid (Mini-grid) Saurian Lilting lamp [38;39] Power plants [38] Biomass Renewable powered irrigation system Imported Hydropower generation Rural Energy Enterprise Development (AREED	Mitigation programmes with local municipalities, baseline studies, solar Energy Stakeholder (Green youth Indaba local government, Department of Energy, Department of environmental affairs, an innovation hub

5. Methodology

The research methodology followed was in the form of systematic review. The rationale for using a systematic review as a methodology afforded the authors access to the various methodologies and outcomes within the areas of renewable energy enterprises and sustainable development goals. This enabled the researchers to formulate a framework with triangulation of efforts from previous researchers. Furthermore, the rationale for systematic review is to explore the area under investigation. The systematic review as a methodology was beneficial, especially during the COVID-19 pandemic, which has affected the entire world, as interviews or questionnaires would not have succeeded during these challenging times. The use of online data collection still poses challenges due to social inequalities and the majority of people not having access to emails or not being able to afford online video platforms in South Africa.

A systematic literature review was considered as the Research methodology of the current research paper which focussed on peer-reviewed articles utilising search engines such as Google scholar, Energy policy, Journal of cleaner production, Renewable and Sustainable Energy Reviews, Renewable Energy, Energy, Sustainability and Society. The introduction and findings were used to select the relevant articles for inclusion. A theoretical review was conducted through a literature review of which n=47 sources (peer-reviewed articles) met the criteria that the researchers set for ecosystem or variables sorted from 89 articles. Duplication of results were further removed. The themes were analysed through thematic content analysis, where themes such as key drivers of Renewable Energy enterprise, sustainable development and Renewable Energy enterprise, the applicability of renewable Energy in the South African context as well as access to renewable Energy sorted from 85 peer-reviewed articles are the outcome.

6. Findings

Figure 3 illustrates how the most prominent Sustainable Development Goals can be achieved theoretically using the Renewable Energy Enterprise ecosystem. The subsequent section under discussion will the explain thoroughly the mapping thereof.
Figure 3: Theoretical Mapping of a renewable energy ecosystem and sustainable development goals

7. Discussions

7.1. Discussion of Renewable Energy enterprise Ecosystem within the South African context

Through the review of literature, one of the support mechanisms in the sectors is market incentive [39], which can be described by demand and supply or willingness to support the products or services of Renewable Energy. Alternatives, such as

Solar, off-grid options, especially mini-grids, have been suggested by [40] for rural areas to foster access to Energy.

Majority of business models have not considered the high-level business planning and strategies, before focusing on specifics of business development [41, 42]. The latter notion will equally contribute to entrepreneurship in Renewable Energy in ensuring enough planning, introducing and managing high-level game-changers as well as policies in regard to entrepreneurship in Renewable Energy.

Natural resources such as wind, solar power stations, and water need to be quantified to measure and form part of the baseline in assessing the readiness of the adoption and diffusion of Renewable Energy. Another sustainable sector that has proven to benefit the planning and implementation of Renewable Energy is the agricultural sector, through irrigations system and implementation of Energy park and monitoring [15].

Electrification plans similarly to what Ghana has implemented [23] can benefit South African context. The electrification plan can be possible with baseline studies and projections or estimation where potential areas may be without electricity [23]. Furthermore, some of the initiatives that can be implemented is the Rural Energy Agency similarly to what Tanzania has implemented [23].

Additional support and efforts made in the South African context is the Renewable Energy White paper, long term mitigation programme scenarios, as well as the Renewable Energy Feed-In Tariff (REFIT) as well as Energy policies and Act to support and regulate the Energy technologies [6, 29, 30, 37]. A generic business framework such as utility Renewable Energy business and customer Renewable Energy business model has been developed to facilitate manufacturing to consumption value chain in quest to support Renewable Energy enterprises in the international markets [12, 13].

Infrastructure governance is another support mechanism whereby policies and training can be piloted to the stakeholders. Stakeholders can consist of sustainability specialists, private and public sectors and communities at large. The implementation of a renewable-powered irrigation system [24] can be introduced to minimise challenges of scarcity of resources drawing from [19, 24]. The entrepreneurial confidence in development, consulting and distribution of renewable-powered irrigation system, a budget provision from the government need to support SMEs in the Energy sectors.

The issue of crime and corruption may need to also be factored in budget allocation in the form of investing in security services to safeguard the power stations and Energy technologies.

South Africa is a democratic country where law triumphs all undesirable behaviour and regulate the system. The Energy justice and legal perspective can be implemented when contributing to the sustainable Energy particularly, distributive justice of equal access to resources even to society who cannot afford the services [43].

In [8 10], the author asserts that there should be different tailored types of funding to promote access to Energy in the form of Grants, financing, loans, Equity official development assistance, equity financing and technical assistance in Energy products and services. To translate this mechanism in the South African context, the National Youth development agency, could be a spearhead for funding and include the criteria to promote Energy products, services, consulting or distribution.

The South African national youth development could work hand in hand with Green youth Indaba as well as an Innovation hub where several youth programmes are housed in South Africa, to ensure the sustainability of entrepreneurship in targeting the youth. The authors are proposing the implementation of Green change dynamics as a development programme whereby green readiness of change and managing fear of the unknown within Green initiatives could be introduced to facilitate awareness and training initiatives within Green Energy enterprises, which could be instilled onto the society, to contribute to the level of confidence in Sustainable Energy enterprises sectors.

Clientele and or customers as well as demand and supply serve as the corners and hub of every business incubators. One important factor that will determine the success or failure of a business is customers and customer attitudes, which is often overlooked. However, in the green entrepreneurship field, efforts have been made regarding customer attitude towards green entrepreneurship [44, 45]. Through the analysis of literature, the Utility Renewable Energy business model as well as Customer Renewable Energy business model deemed to be the proposed framework as discovered by scholars in ensuring the monitoring and viability of maintaining clientele with the use of technological assistive programme and stakeholder liaison [9, 12, 13, 46, 47].

Lessons learnt in the form of learning best practices from developed countries, and neighbouring African countries need to be replicated in the South African context, to share the success factors on Energy and advances on technological factors [24]. Furthermore, there should be system management of key holders such as knowledge dissemination through conferences and workshops, the guidance of the search and sponsorship to steer the direction of research and to find how best to formulate policies within the area of Renewable Energy, market niches as well as resource mobilisation such as infrastructure, tax-exempt and micro-financing [48]. The latter mechanisms of financing structures would offer affordable Renewable Energy for a better quality of life to societies at large. In [49], the author asserts that there should be a monitoring tool rating system to ensure that the infrastructure implemented is sustainable. The proposed monitoring tool is sustainable infrastructure rating system [49]. Drawing from this discovery, the authors in the current paper assert the rating system can be used specifically when implementing Energy technologies, services or distribution of renewable Energy tools.

Vat returns, Government subsidies, tax incentives for innovation, price control, demand assurance, venture capital are some of the supporting mechanisms implemented worldwide [9-11] of which we believe that South Africa can also implement these mechanisms. A need for strong coordination and memorandum of understanding with the countries who have

developed these mechanisms is needed, to allow exchange programmes within the SMEs in Energy, particularly targeting Youth, Black people, women as well as people living with disabilities as these group, still fall in the designated, previously disadvantaged backgrounds. To broaden the latter perspective, Broad-Based Black Economic Empowerment (BBBEE) will need to also include additional lenses of facilitating Green entrepreneurship and points to be allocated respectively in the form of tendering systems within the advances of Energy sectors.

A further area of consideration is how can different business models such as Pty Ltd (public companies), private companies, close corporation, partnerships, benefit from Renewable Energy at the same time saving the planet. Furthermore, the authors are of the opinions that once the mapping of success factors of different business models can be understood and investigated, support such as lessons learnt, specific funding and non-financial support can be tailored to different Renewable Energy enterprises.

Globalisation in the current context can be seen as a contributing factor, whereby the country such as South African can benefit from markets internationally. In [38], the author echoes the latter statement in supporting imported goods and services such as imported technology for hydropower generation and Biomass. Scholars have demonstrated that through biomass combustion with coal and setting the technologies to exposed heat generate electricity in an effective way [15]. The latter then has further been tested to have saved enterprises when it comes to cost and effective way to the adoption of Renewable Energy [15].

Although imports may also impact on the level of emissions and the cost of Energy services or products, the import of resources serves as the immediate mechanism as South Africa lack enough resources to engage in Energy thematic area effectively. This may imply that concessions and discounted rate may need to be negotiated between two countries embarking on exports and imports. The researchers are of the opinion that there should be public and private organisations willing to train and invest in imports and exports when it comes to Energy enterprises. The introduction of Public-private partnership (PPP) of policies to accelerate the Energy technologies as well as community members being included from the planning to implementation phase in collaboration with NGOs similarly to Nepal's initiatives [32], is needed and may need to be implemented in the South African context.

Saurian lilting low-cost solar lamps as part of renewable Energy [38] serves as a green entrepreneurship initiative that could be explored in the South African context especially in the rural areas and restoring access of Energy to the society.

Further research conducted in other parts of African countries promulgated by UN is African Rural Energy Enterprise Development (AREED) programme and national strategy for the Development of Renewable Energy [23], which South Africa could benefit from the initiative in accelerating entrepreneurship and collaboration in the sector. The need to contribute to society by reducing the electricity bills for those who cannot afford as a form of contributing to the social context when it comes to Energy [19] serves as a priority. Drawing from this idea, the current researchers are of the opinion that once this idea could flourish,

this may serve as an incentive for the society to support the enterprises in the sector.

7.2. Discussions of Renewable Energy enterprise ecosystem to Sustainable development Goals

In this section, the authors then used the theoretical framework highlighted above through the analysis of literature to map the sustainable development goals to the Renewable Energy ecosystem as depicted in figure 3. A further contribution of the paper is that the authors are arguing that in order to accelerate the sustainable development goals, each thematic area of the green economy needs to be explored and systematically mapped onto the sustainable development goals for an impact. In contribution to the sustainable development goals, the authors are proposing using sustainable development goals as a framework for selecting specific sustainable development goals in mapping the elements of the Renewable Energy enterprise ecosystem.

In order to effect the latter objective the theoretical renewable Energy ecosystem can be used as follows: in order to facilitate the access to the markets, the price of Energy products and services needs to be monitored with set policies and governments subsidies or alternative financial mechanisms upon which the Goal 1 Eradication of poverty, Goal 2 No hunger, Goal 8 Decent work and economic growth, Goal 9 Industry, innovation and infrastructure, Goal 10 Reduced inequality can be accelerated and achieved.

The alternative forms of Energy such as Solar, off the grid, saurian lilting lamp and hydro-powered Energy [21, 30, 38] can further accelerate Goal 7 Affordable and Clean Energy for the better quality of life and livelihoods. Then for further evaluation monitoring and sustainability continuous learning, non-financial support empowering of women and youth, as well as people of colour, can further accelerate Goal 4 Quality education.

8. Future recommendation

The next steps will be to test and validate the proposed key accelerators and ways to minimise the barriers that may affect entry to renewable Energy enterprises. Furthermore, scientific empirical data will be needed to test the theoretical contribution of the mapping of sustainable goal with renewable Energy as Green economy thematic area. Furthermore, research on which type of business survives and gets on the markets quick receiving enough support serves as a future research agenda.

9. Conclusion

The paper explored various works of literature building the ecosystem through the elements highlighted by most researchers in the field of Renewable Energy enterprises or business ventures. Enabling the green economy involves innovation [17], which in the current study, Renewable Energy enterprise ecosystem serves as the innovation the current authors are proposing. The researchers are of the opinion that once this milestone of capacity building in terms of climate change, and the Green economy is fully implemented then this mechanism can be a wheel to Renewable Energy ecosystem in the transition to green economy.

The theoretical ecosystem consists of accelerators, societal factors, sustainable development goals, as well as selected business models. The latter ecosystem was then contextualised in the South African context for a complete framework. Some of the accelerators of Renewable Energy are financial and non-financial support mechanisms, generic business models such as customers and demand and monitoring. In answering how can theoretical Renewable Energy enterprise ecosystem be contextualised in the South African context research question: The applicability in the South African context was discussed highlighting the access to Energy by the society at large through reducing of inequality, entrepreneurship and eradication of poverty in drawing from sustainable development goals. In answering the research question: How can Renewable Energy enterprise contribute to sustainable development goals theoretically: Is through the relevant theoretical contribution of eradication of poverty, decent work for all, access to clean and affordable Energy as well as the quality of education. From the analysis of literature rating system, quantification and measurable goals need to be in place to ensure that the plans for implementation of the Renewable Energy are in place. The researchers are then proposing that entrepreneurial markets to be enabled in this arena, and that is where the motives of entrepreneurship would highly contribute to the sense of social gain and uplift and contributing to sustainable development goals with less attention on profit generation.

The benefits of Renewable Energy, as explained above, can benefit people living in rural area through better quality of living and health. Majority of people living in Bangladesh use kerosene, candle and often have to walk a long distance to fetch wood for cooking, Renewable Energy through natural resources such as biogas, the solar, wind, hydropower can benefit the society of rural of Bangladesh [21]. The latter benefits can also benefit most part of rural areas, and some townships in South Africa as some communities are still using candles, paraffin stove and often have to fetch water and wood to cook.

Conflict of Interest

The authors declare no conflict of interest

Waste To Energy Feedstock Sources for the Production of Biodiesel as Fuel Energy in Diesel Engine - A Review

Maroa Semakula[*], Freddie Inambao

University of KwaZulu-Natal, Mechanical Engineering department, Durban, 4041, South Africa

A R T I C L E I N F O	A B S T R A C T
	In the recent past, there has been a renewed shift into biomass and other recycled waste sources for biodiesel production and utilization. This is a critical area of research and study in which this present work intends to review and identify gaps in literature by shifting the focus of review to non-plant based sources for biodiesel production. Traditional biodiesel feedstock sources have always presented a conflict of food security versus energy. This shift will be identified in literature to see if change to non-plant-based feedstocks sources has increased food security by discouraging the contribution of commercial farming for the production of biodiesel. This work will identify biodiesel families, generations, traditional and non-traditional feedstocks for biodiesel production. It will also discuss the non-edible biodiesel feedstocks sources in relation to waste to energy recovery. The other factor this work will review is to study how the use of non-plant based feedstocks such as municipal solid waste has improved environmental protection by reducing pollution and landfilling. In other words, this work will review the impact of Using waste municipal solid biomass resources such as waste tyres and waste plastics and changing them into energy sources. This review study aims at increasing environmental awareness, sustainability and reporting the progress made in waste to energy policy shift in many countries globally. This review will look at socio-economic opportunities in recycling besides the academic and research impacts of waste to energy policies adopted in many countries. The review will climax with a conclusion and future trends in waste to energy in relation to municipal solid waste resources.

1. Introduction and Historical Background of Biodiesel

The history of biodiesel fuel has its route traced to the discovery of the diesel engine by the German engineer Rudolf Diesel in the 1890s. However, the first use of vegetable oil as a fuel was in the world exposition in Paris in 1900. This was at the request of the French government, which had an interest in development of fuels of local origin for its African colonies for energy and power generation independence. There were a total of 5 engine models displayed and tested during the exposition [1]. After the Second World War, several literatures report the use of vegetable oil in diesel engines and operational difficulties encountered with their application as combustion fuel [2-5].

These reports led to the award of the Belgium patent 422877 in 1937 to Chavanne. However, after the second world war the alternative fuel research took a lull until the energy crisis of the 1970s when [6] came up with work on esters of vegetable oil. Using sunflower oil in a diesel engine, they reported that use of sunflower methyl esters eliminated the problems of viscosity and operational issues. Although fossil-based fuels have been playing a major role in the growth of industries, transportation and agricultural activities, the future of fossil fuel as primary source of energy is not sustainable due to depletion, outstripped demand of fuel energy consumption and use. Fossil based fuel have more qualities that make them appeal to the user readily such as availability, good combustion properties and high heating values [7]. Energy estimates from the international energy agency puts

the estimates of the growth of energy consumption at 53 % by the year 2030 [8, 9].

In the USA the energy information agency (EIA) projects liquid fuel consumption to increase from 86.1 million barrels per day to 110.6 MBD by the year 2035 [10]. The depletion of fossil fuel reserves has occupied world energy forums and decision makers. Therefore, there has been rapid research development in green alternative fuel energy, which is renewable, domestically available, environmentally friendly and feasible technically. Biodiesel therefore has become technically a better choice for researchers as they contain characteristics and identical physical properties to fossil fuel especially diesel fuel. This makes the future of biodiesel more tenable and more promising as sources of alternative fuel energy especially in developing countries. These countries experience a heavy burden on the importation of liquid petroleum fuel for energy, environmental impacts and effects of pollution on the public human health [11]. Table 1 showing a global production of biodiesel in 2015 and the unit cost of production.

Table 1: Worldwide production of biodiesel with cost [12]

Country	Estimated potential (Litres)	Production Cost($/l)
Brazil	2,567,000,000	0.62
Indonesia	7,595,000,000	0.49
Argentina	5,255,000,000	0.62
Malaysia	14,540,000,000	0.53
USA	3,212,000,000	0.85
Netherlands	2,496,000,000	0.75
Germany	2,024,000,000	0.79
Philippines	1,234,000,000	0.53
Belgium	1,213,000,000	0.78
Spain	1,073,000,000	1.71

The importance of modern-day transport systems cannot be gain said, especially the transportation of goods and services and people. The propulsion provided by internal combustion engines with diesel fuel as the primary source of energy, forms the bulk of commercial use and now personal transport, owing to their numerous advantages as compared to other forms or types of propulsion by internal combustion engines. Diesel engines are inherently lean burn engines, and emit relatively low carbon dioxide emissions as compared to petrol propelled internal combustion engines. Other advantages offered by diesel engines include high thermal efficiencies, durability and construction robustness [13]. This makes their continued increase and expansion as more countries move into urbanization, industrialization, and catching up with the highly industrialized

countries. However, there has been a formidable challenge to phase them out, based on environmental and human health issues due to the high levels of NO_X, smoke and PM emissions.

Diesel engines have shown to run stably on most medium blended ratios of waste plastic oil, although they produce more NO_X, UHC and CO emissions. However to stabilize their performance for higher blend ratios, injection timing has been proposed as a method of achieving engine performance stability without upgrading of fuel, engine modification or fuel alteration through addition of additives as observed by [14]. Injection timing was seen to affect performance from WPPO Jatropa blends of 20% tyre oil and 80% Jatropa ester oil resulting into lower fuel consumption, CO, UHC and PM although NO_X emissions increased [15]. Nevertheless In a research study by [16] the authors report increased BTE and NO_X emissions, thus concurring with the findings of Sharma et al. (2015) on emissions of NOx, but decreased results on fuel consumption, CO, and UHC.

The continued increase in stringent emission regulations enacted by global industrial powers, United States of America and the European Union environmental protection agencies including the G-7 and G-20. Have since labelled the diesel engine as primary polluter in the transport sector. Hence the clamour for alternative fuels, which mitigate pollution, are sought in the interest of reducing energy consumption, environmental degradation and air pollution from NO_X gases, which diesel engines emit, thus decelerating atmospheric carbon concentration globally. The road transport sector is an environmental concern, since its rapid expansion is fast eroding all the technological developments and improvements thus so far achieved in the war against pollution from diesel-propelled engines.

Across the globe, significant resources have been mobilized to find alternative sources of energy. Different regions and countries have focused attention at sources of supply and technical processes that give them comparative advantages. In sub-Saharan Africa, renewable energy alternatives for transportation have huge potential sources, one of which is biodiesel derived from municipal solid waste sites, waste tires, waste engine used oil and waste cooking oil. Considerable research has been ongoing in this area but some gaps have not been addressed. There is a clear need to conduct evaluations that enable precise technical classification of the performance and emission of biodiesel derived from the waste sources mentioned above. Figure 1 is showing available general waste data (from municipalities) in South Africa from 1997 to 2011.

This will enable us to filter the data, by comparing it with local South African standards and regulations with global standards and regulations. Through this, challenges can be identified and plans of action mapped out to tackle them. It is necessary to identify and assemble the right set of tools and technique needed to conduct studies on these municipal solid waste feedstock sources in a manner that optimizes them as available resources. The stated goal of this work is to extract, information on solid waste municipal sources for the production

of biodiesel using thermal processes. This information is contained in many published research articles and will be presented here as a review and future development.
Figure 1: Percentage contribution of each waste stream of general solid Analysed from available data 2017 (from municipalities) in South Africa [17]

2. Biodiesel Families and Generations

Traditionally families come in generations defined by the length of time. As such, biofuels have lumped into families or generational categories. Production and use of biofuels has gained significant awareness and attention in academia, industry and government policy makers. Globally 28 countries including developing countries have been prominent in enacting biofuel mandated policies with substantial tax subsidies for biofuels [18]. Biofuels shift targets displacement of 20% of fossil fuels by biodiesel in the coming future [19].

This is driven in part by the potential of biofuels to create a new industry, raise farmer incomes restore degraded lands and promote independence from oil imports hence mitigating climate change [20]. For example, in literature, surveyed India is among the countries that have adopted Jatropa as a second-generation biofuel source of feedstock. However, in literature reviewed, there is no data on, water, pruning, and plant response to fertilizers hence varied planting management practices [21-23].

In biofuels, the main aim has been to identify methods of production by selecting appropriate feedstock, use of efficient conversion technologies and disposal of the product in this case the biofuels. The end product of any process in the world has become critical due to environmental issues and impact products bring, such biofuels production on the immediate environment [24]. One of the leading challenges in the energy sector is the promotion of biofuels compared to fossil fuels through arguments of sustainability i.e. economic environment and social aspects combined [25]. Sustainable development is a common term appearing in the global agenda of development since 1987. It is defined as development tailored to meet the needs of the present generations without compromising on the future generational needs in meeting today's needs [26, 27]. Sustainability requires

that all environmental factors of impact be assessed in each of their phases of the biofuels chain such as (i) Production and collection of feedstock, (ii) Feedstock processing, (iii) Conversion to biofuels, and (iv) Distribution of the end product [28, 29].

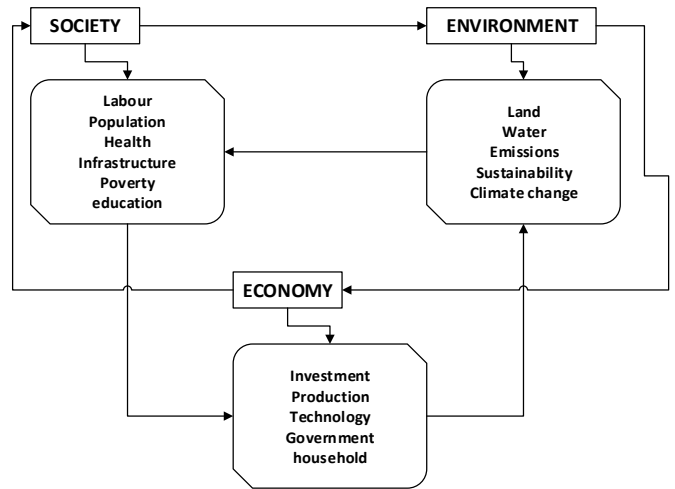
The second point is sustainability, which according to literature surveyed is difficult to conduct and evaluate sustainably. For example due to a great number of competing interests interfacing factors are weighted different by stakeholders hence disagreements and lack of common approach [28, 29]. Measuring sustainability of the biofuels industry is a complex issue especially considering the diverse range of biofuel feedstock, pathways, variation in stakeholder's interests and competing interests. Literature surveyed thus advocates for establishment of other indicators, which will enable assessment of sustainability of bioenergy systems. This should apply to small, large and local infrastructure acceptable to all stakeholder and in diversity [30-32]. Figure 2 showing the interrelated pillars of sustainability between society, the environment and the economy.


Figure 2: Interrelated pillars of sustainability adapted from [25]

2.1. First Generation Biofuels

First generation biofuels are derived from food crop feedstocks usually used as staple food. However, today this generation is vilified as the source of food insecurity and rising inflation in developing countries. Nevertheless, it is important to note even if it is alleged first generation cause increment in food prices and inflation its total influence is minimal [33]. First generation biofuels (otherwise called conventional biofuels) use three different technologies commercially for biodiesel, bioethanol and biogas [34, 35]. These commercial fuels are utilized as solid, gaseous or as liquid fuels. To add value these fuels are upgraded to high-density energy fuels such as charcoal, liquid fuels such as biodiesel, and bioethanol or gaseous fuels such as hydrogen, natural gas or biogas [33]. Table 2 shows the characteristics and demerits of first-generation biofuels.

As a first generation, conventional fuel biodiesel is produced through transesterification of vegetable oil, residual oils and animal fats as alternatives for petroleum diesel with slight engine

modifications. In the processing triglycerides are chemically reacted with alcohol in the presence of a catalyst or enzyme. This process generates biodiesel and glycerol [36, 37]. On the other hand, bioethanol are produced through a Biocatalytic fermentation of sugar or starch as ether (ETBE) which is used as a blend with gasoline. the gaseous category biogas a mixture of methane and carbon dioxide is processed through anaerobic digestion of organic materials [38, 39].

Table 2: Shows characteristics and demerits of first generation biofuels

Characteristic	First generation biofuel	References
Completion with food crops	Made from edible oil and starch feedstock	[40]
Land footprint	Requires arable land	[41]
Conversion to biofuels	Easy conversion	[42]
Water footprint	Potable water is required for cultivation	[43, 44]
Environmentally friendly	Using pesticides and chemical fertilizers	[45]
Commercialization	Commercially produced	[40]
Sustainability	Not sustainable in using natural resources such as water and land	[46-48]
Nutrient requirement	Chemical Fertilizers as main nutrients	[49]
Harvesting	Done by hand or machine	[50]
Regulation	Clear fair regulation	[40, 51]
Financial input	Low capital investment	[40]
Environmental condition	Temperature and humidity must be suitable	[52]

Despite their acceptance first generation, fuels have demerits, which have made their global appeal and wide commercial application difficult. For example, their overdependence on agricultural food crops initiates a heavy social debate on food vs fuel. Hence, their commercialization and adoption threaten food security while inflating food prices in developed countries. In semi-arid areas, production of biofuels would be too costly and limited with determined prices considered as non-competitive to conventional fuels. Figure 3 is showing different biofuel families and their available feedstocks sources.

2.2. Second Generation Biofuels

Second generation biofuels family is also called advanced biofuels. These fuels are also purported to be produced sustainably in a truly carbon neutral environment in terms of CO_2 concentration. The source of feedstocks of these fuels is lignocellulosic biomass, non-food crops, agricultural and forest residues and industrial wastes. The production of second generation is done by utilizing physical, thermochemical and biochemical technologies processing [55, 56]. Using these processes involves use of pre-treatment steps to facilitate the conversion process. Here properties of biomass are technically analysed such as size, moisture and density before treatment and processing is commenced [57].

In physical processing techniques in literature reviewed, the commonly applied techniques are briquetting, pelletizing and fibre extraction. These techniques enhance and convert loose biomass into high density solidified blocks of energy. Pelleting does the same thing pressure does to compact raw fibre particles of biomass into high density. On the other hand in fibre extraction fibre is removed from biomass residues and utilized as sources of energy fuel for heating [55, 58].

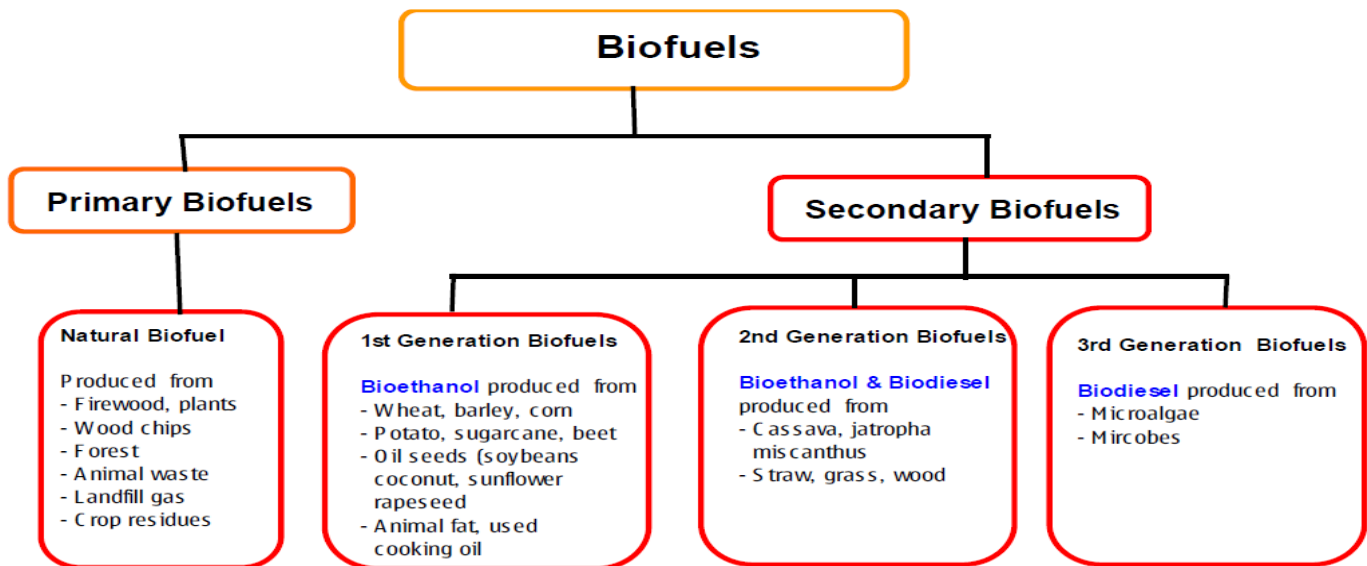
Under thermochemical processes for production of biofuels are found pyrolysis, gasification liquefaction and direct biomass combustion. Thermochemical liquid fuel processing uses thermal decomposition with chemical reformation. This involves heating biomass under the influence of different oxygen concentration leading to conversion of all organic components [39]. Pyrolysis is a slow or fast process depending on the existing operating conditions but in the absence of air [59, 60]. The former favours solid fuel production compared to the latter which is good for liquid fuel production (bio-oils) and gaseous biofuel production [61, 62].


Figure 3. showing different biofuel families and their feedstocks [53, 54]

As a method in second-generation biofuels, gasification coverts biomass into combustible gaseous fuel mixtures also known as syngas. Through partial oxidation of biomass at elevated temperatures of 800 °C to 1400 °C syngas is produced. The medium for gasification can be air oxygen of steam [55, 60]. However gasification is still struggling with challenges of operational and downstream gas utilization problems [63]. The driver of gasification has been the versatility of the gases produced during the process. Reaction of the gasification and the feedstocks of solid carbon structure forms carbon dioxide or hydrocarbons. Nevertheless, as said earlier the gasfying agent has a very critical role in influencing the final product of the process. For example when steam is used as an agent of processing reaction temperatures are lowered to 600°C [39]. Table 3 is showing the principle components of a gasification process.

Table 3: is showing the principle components of a gasification process adapted from [63]

Target compounds	CO, H_2, CH_4, C_2H_x, C_3H_x
'Inert' (non-combustible) compounds	CO_2, H_2O, (N_2)
Trace contaminants	NH_3, HCN, other organic nitrogen compounds
	H_2S, COS, CS_2, other organic sulfur compounds
	HCl, NaCl, and KCl aerosols
Condensable fraction	Benzene, toluene, and xylene (BTX), tar, hetero-organics, (water)
Particles	Ash, mineral matter/salts, char, aerosols

During transformation (conversion) of solid fuel into gaseous components by gasification a number of reactions with intermediate reactions, take place. It is a complex network of reactions; influenced by feedstock sources, and properties, residence time, reactor design temperature gasifying agent and pressure. In this literature review, only a few examples of main reactions are presented in chemical equations 1 to 9. However, the references provided here would be useful to the reader for a detailed study and understanding [39, 64-66]. Table 4 is third generation biofuels characteristics and references.

Chemical reactions with molecular oxygen, which are exothermic in nature (combustion reactions).

$$C + O_2 \leftrightarrows CO_2 \qquad \Delta H = -110.62\text{kJ/mol} \qquad (1)$$

$$2CO + O_2 \leftrightarrows 2CO_2 \quad \Delta H = -283.15 kJ/mol \qquad (2)$$

$$2H + O_2 \leftrightarrows 2H_2O \quad \Delta H = -242.15 kJ/mol \qquad (3)$$
Carbon dioxide and hydrocarbon/CO_2 reaction

Boudouard reaction:

$$C + C O_2 \leftrightarrows 2CO \qquad \Delta H = +172.54 kJ/mol \qquad (4)$$

Hydrocarbon/CO_2 reaction:

$$C_nH_m + nCO_2 \leftrightarrows 2nCO + m/2H_2 \qquad (5)$$
Steam as the reaction agent

$$C + H_2O \leftrightarrows CO + H_2 \quad \Delta H = +131.38\ kJ/mol \quad (6)$$
Hydrocarbon and steam reaction:

$$C_nH_m + nH_2O \leftrightarrows nCO + (\tfrac{m}{2} + n)H_2 \qquad (7)$$
Water gas-shift reaction (homogeneous water-gas shift conversion)

$$CO + H_2 \leftrightarrows CO_2 + H_2 \quad \Delta H = -41.16 kJ/mol \quad (8)$$

Hydrogen reactions in gasification

$$C + 2H_2 \leftrightarrows CH_4 \ \Delta H = -75.00 kJ/mol \qquad (9)$$
2.3. Third Generation Biofuels

The third generation biofuel family comprises of fuels produced from microalgae feedstocks. This generation is currently under research and development as alternative renewable energy sources for biofuel processing and production. This family has been largely been fronted as a solution to overturning the demerits of the first generation and second generation biofuels [55, 68]. Majority of these fuels exist in laboratories under research and development with a few small scale enterprises producing algae oil [69]. The microalgae group of feedstock consists of microalgae, macroalgae (seaweed) cyanobacteria (blue-green algae) [70]. Microalgae consists of 72000 different species and as many as 800000 in fresh water or salty water [69, 71].

Table 4: Shows characteristics and references of third generation biofuels

Generational Characteristics	References
Eliminates food-energy conflict	[40]
Contaminated and Non-arable land used for cultivation	[41]
Easy conversion due to increased hydrolysis and/or fermentation efficiency	[42]
Waste, saline and non-potable water also can be used	
Merits (CO_2 fixation, waste water treatment, reduced cost of fertilizer) demerits (ecological concerns on marine eutrophication)	[43, 44]
Poor biomass production for commercialization	[45]
favorably poor economically	[40]
Large quantities of carbon and nitrogen required. Solar energy is only available at daytime. Nutrients recycling possible	[46-48]
Harvesting of microalgae is expensive, and complicated	[49]
Lack of regulation for marine cultivation	[50]
initial large scale cultivation costs too high	[40, 51]
cultivation in harsh environmental condition such high pH, salinity and light intensities possible	[52, 67]

The rise of algae as an alternative biodiesel feedstock is due to its rapid growth, increased harvest cycle in days compared to months or years. Microalgae need few nutrients for maximum growth and can thrive in severe poor conditions while giving high and increased output per acre ranging from 15 to 300 times more compared to food crops acreage [72, 73]. Algae oil can also be used as feedstock to provide high value products such as ethanol, butanol, biodiesel, jet fuel syngas, and bio-oil chemical feedstocks such as hydrogen and farm fertilizers [53, 70].

Another important factor with algal biofuel is the lack of competition with food crops or feed crops, yet algae is used to

reclaim agricultural wastelands. This seems to obviate and free land use while reducing energy versus food competition. This elevates this family against the first two-biofuel families. However a further research and study aimed at improving algae production methods especially the plant energy content yield and sustainability is required [54]. Table 5 shows different oil contents for a variety of microalgae species.

Table 5: Showing different Oil contents for a variety of microalgae adapted from [41]

Microalga Oil content	Percentage in dry weight (%)
Botryococcus braunii	25–75
Chlorella sp.	28–32
Crypthecodinium cohnii	20
Cylindrotheca sp.	16–37
Dunaliella primolecta	23
Isochrysis sp.	25–33
Monallanthus salina	20
Nannochloris sp.	20–35
Nannochloropsis sp.	31–68
Neochloris oleoabundans	35–54
Nitzschia sp.	45–47
Phaeodactylum tricornutum	20–30
Schizochytrium sp.	50–77
Tetraselmis sueica	15–23

2.4. Fourth Generation Biofuels Sources and Beyond

The birth of fourth generation biofuel has been propagated by the need arising from environmental dilemmas. These dilemmas challenge our human capacity for sustainable solutions to protect nature for our own existence and posterity. For example, the need to protect water sources, agricultural lands for sustainable food production, reduction of GHG, the protection of atmospheric air and weaning overreliance from fossil fuels as the only sources of primary energy supply [74-79]. Table 6 Showing characteristics and references of fourth generation biofuels.

Table 6: Characteristics and references of fourth generation biofuels

Generational Characteristics	References
Eliminates the food-energy conflict	[40]
Contaminated and Non-arable land used for cultivation	[41]
Increased hydrolysis and/or fermentation efficiency	[42]
Waste, saline and non-potable water also can be used	[43, 44]
