Research Report

2020

Table of Contents

Dean's Message	3
Big Data	4
Data Science	8
Data and Software Security	12
Image and Video Processing	14
Big Knowledge, Bioinformatics and Medical Informatics	16
Distributed Systems, Mobile Computing and Networking	18
Cloud and High-Performance Computing	20
Augmented Reality, Virtual Reality Gaming and Graphics	24
Advanced Algorithms	30
Social, Mobile and Education	34

Ying Wu College of Computing (YWCC) was established in 2001, consisting of the computer science and informatics departments, and has grown rapidly to become the second-largest college at New Jersey Institute of Technology. Enrolling more than 3,200 students at all levels and graduating more than 800 computing professionals every year, YWCC is the largest generator of computing tech talent in the greater New York metro area.

The tenure-track faculty and Ph.D. student population of YWCC has also grown significantly. These talented individuals are responsible for the high-quality academic research described in this report. Their research is financially supported by a variety of government agencies and corporate entities, published in top venues, and in some cases patented and commercialized.

Spanning a wide spectrum of topics, from human-computer interaction to cybersecurity to sophisticated data science algorithms, the research conducted by YWCC ranges from deep mathematical theory to practical applications. Committed to sharing beyond publication, much of the software developed in these projects is made available to the general scientific community through open-source repositories.

I invite you to read through the abstracts of the research projects described in this report and encourage you to reach out to the individual researchers for more details, if needed. We welcome new ideas, collaborations and any form of research partnership imaginable.

Sincerely,

A handwritten signature in black ink that reads "C Gotsman".

Craig Gotsman
Distinguished Professor
Dean, Ying Wu College of Computing
New Jersey Institute of Technology

A photograph of a person sitting at a desk in a research or office environment. The person is wearing a grey sweater with red patterns on the sleeves and blue pants. They are sitting on a chair with a patterned seat. In front of them is a desk with several computer monitors. One monitor is displaying a website or application. There is a yellow water bottle on the desk. The background shows a white wall and a desk with more equipment.

Big Data

Faculty at NJIT work on a variety of big data topics including dimension reduction, complex workflows and energy optimization, as well as data mining research with emphasis on keyword search within graphs and trees. The research is a combination of algorithms and techniques to improve performance of large-scale data systems and extract relevant information.

Our researchers have presented their findings at top-tier conferences including VLDB and SIGMOD, and have received various awards including the SIGMOD Test of Time Award in 2015. Researchers have also received best paper awards at conferences for high-performance computing, parallel and distributed computing, multimedia and other relevant themes.

Dimitri Theodoratos
Associate Professor
dimitri.theodoratos@njit.edu

Mining and Summarizing Patterns From Large Trees and Graphs

Extracting frequent patterns hidden in trees and graphs is critical for analyzing data and a first step for downstream data mining. Most pattern-mining algorithms do not scale to big data applications. We have designed algorithms to extract patterns from large trees and graphs, leveraging results using compressed bitmap views.

Searching Structured and Semi-Structured Data With Keyword Queries

Disambiguating a user's intention in posing a keyword query and efficiently retrieving relevant results is an immense challenge for keyword search when using big data. We have devised an approach that exploits a structural summary of the data to extract pattern graphs for keyword queries. This empowers non-expert users to extract information from data sources and databases without mastering a query language and without any knowledge of the organization or structure of data sources.

Research Area: Data mining, pattern extraction

Vincent Oria
Professor
vincent.oria@njit.edu

Dimensionality and Scalability Issues in High-Dimensional Spaces

When researching fundamental operations in areas such as search and retrieval, data mining, machine learning, multimedia, recommendation systems and bioinformatics, the efficiency and effectiveness of implementations depends crucially on the interplay between measures of data similarity and the features by which data objects are represented. When the number of features known as data dimensionality is high, the discriminative ability of similarity measures diminishes to the point where methods that depend on them lose their effectiveness. Our research proposes techniques for local feature selection with application to search and clustering and is currently looking for ways of finding lower dimensions that increase the data discriminability using machine learning techniques.

Multi-Instrument Database of Solar Flares

Solar flares are the most prominent manifestation of the sun's magnetic activity. They emit radiation that could potentially damage power systems, interfere with civilian and military radio frequencies and disrupt spacecraft operations. To improve analysis, in collaboration with the department of physics, we aim to integrate and enrich solar data captured by various solar flare observing instruments around the world.

Research Area: Multimedia databases, spatio-temporal databases, recommender systems

Aritra Dasgupta
Assistant Professor
aritra.dasgupta@njit.edu

Visualization-Driven Transparency in Human-Data Interaction

To communicate actionable insights from data-driven predictive models, we are developing interactive interfaces that can summarize complex information in a transparent and user-interpretable way. We can dynamically update the presented information based on user feedback and preferences. These interfaces integrate the outcome of the predictive models with novel visualization techniques for enabling human judgment and reasoning about data-driven patterns. This ensures we leverage the best of both worlds: computational power for fast extraction of patterns, and perceptual and cognitive human faculties for enabling experts such as domain scientists and social media content moderators to transparently reason about the context, significance and implications of the patterns.

An example of one such interface is MyriadCues with which scientists can distinguish between good and bad simulation models, and incorporate their expert feedback for understanding how model rankings change with respect to different parameters and simulation scenarios. By validating the efficacy of this interface with scientists working at national labs, we demonstrated how visualization can play a critical role in automating the workflow for more trustworthy and effective simulation models.

Research Area: Data visualization, visualization techniques

David Bader
Distinguished Professor
david.bader@njit.edu

Building Faster, Energy-Efficient Analytics Pipelines for Decision-Making

Big data analysis is used for problems related to massive data sets. Today, these data sets are loaded from storage into memory, manipulated and analyzed using high performance computing (HPC) algorithms and then returned in a useful format. This end-to-end workflow provides an excellent platform for forensic analysis, however, there is a critical need for systems that support decision-making with a continuous workflow. HPC systems must focus on ingesting data streams; incorporating new microprocessors and custom data science accelerators that assist with loading and transforming data; and accelerating performance by moving key data science tasks and solutions from software to hardware. These workflows must be energy-efficient and easy to program, while reducing transaction times by orders of magnitude. Analysts and data scientists must be able to ask queries in their subject domain and receive rapid solutions that execute efficiently, rather than requiring sophisticated programming expertise.

Scalable Graph Algorithms

Our research is supported in part by an NVIDIA AI Lab (NVAL) award. NVIDIA makes graphics processing unit (GPU) accelerators such as the DGX Deep Learning server. We contribute to RAPIDS.ai, an open GPU data science framework for accelerating end-to-end data science and analytics pipelines entirely on GPUs. These new analytics pipelines are more energy-efficient and run significantly faster, which is critical for making swift, data-driven decisions.

Scalable Graph Learning Algorithms

This project, with the support of a Facebook Research award for AI system hardware/software design, focuses on developing scalable graph learning algorithms and implementations that open the door for learned graph models on massive graphs. Our lab investigates scalable high performance graph learning systems based on graph convolution network algorithms by improving the workflow on shared memory NUMA machines, balancing computation between threads, optimizing data movement and improving memory locality. We also investigate graph learning algorithm-specific decompositions and new strategies for graph learning that can inherently scale well while maintaining high accuracy.

Data Science Leadership

Bader is the founding director of NJIT's Institute for Data Science, which includes the Center for Big Data, Cybersecurity Research Center and Structural Analysis of Biomedical Ontologies Center (SABOC). He also serves on the leadership team for the Northeast Big Data Innovation Hub supported by the National Science Foundation.

Research Area: Data science, high-performance computing

Chase Wu
Professor
chase.wu@njit.edu

Revolutionizing Processing of Big Data Sets

To reduce processing time of information in complex scientific computing infrastructures, we develop practical computing and networking tool kits to improve efficiency of complex workflows in big data and high-performance environments. Visual inspection can often detect complex models or discover new patterns in big data environments. We develop visualization algorithms for 3-D volume data generated by scientific computations on supercomputers. Visual feedback is critical to the understanding and validation of physics models used for simulations in computational sciences.

Reducing Energy Consumption in Big Data Computation

The transfer of big data across high-performance networks consumes a significant amount of energy. Employing two widely adopted power models — power-down and speed scaling — we have made inroads into green computing in big data environments. Our approach allows network providers to reduce operational costs and reduce carbon dioxide emissions.

Uncovering Low-Level, Hazardous Radiation

Radioactive substances and biological agents present a serious threat to public health and safety, particularly in densely populated areas. We develop reliable tools to detect and contain radioactive materials to protect the populace and reduce the risk of radiological dispersal devices, such as so-called dirty bombs.

Research Area: Big data, green computing and networking, parallel and distributed computing

Data Science

The amazing abundance of data available today has created opportunities for corporations, educators and governments to gain previously unavailable insights through deep analysis of data sets. This knowledge discovery has created real-world, actionable intelligence.

Our faculty work on all aspects of data science including natural language parsing, machine learning and deep learning. These techniques provide tools to address issues ranging from security to fake news detection to health care and genomic data analysis. The work of our researchers has been published in a wide variety of venues including *Nature*, *Science*, *Nature Medicine*, *Cancer Discovery* and *Nature Communications*, as well as top-tier data mining, machine learning, biostatistics and bioinformatics conferences and journals.

Deep Reinforcement Learning Network for Traffic Light Cycle Control

Existing inefficient traffic light cycle control causes numerous problems, such as long delays and waste of energy. We improve efficiency by taking real-time traffic information as input and dynamically adjusting the traffic light duration accordingly. We propose a deep reinforcement learning model to control the traffic light cycle. A convolutional neural network is employed to map states to rewards. The model incorporates multiple optimization elements to improve its performance such as dueling a network, target network, double Q-learning network and prioritized experience replay.

Deep Neural Network Modeling to Predict Vehicle Path Flow

Predicting full spectrum vehicle path flow is challenging because it is determined by spatial and temporal factors, in addition to many random factors such as human behavior and weather. We are developing a spatio-temporal fuzzy neural network to accurately predict vehicle path flow in the near term. The deep neural network is composed of stacked convolutional long short-term memory, fuzzy neural networks, convolutional layers and fully connected layers. Extensive experiments on big data sets are being conducted to evaluate the efficacy and efficiency of the model.

Research Area: Deep Learning, blockchain technologies, IoT

Zhi Wei
Professor
zhi.wei@njit.edu

Advanced Analytics and Learning for Genomics

We are developing statistical modeling and machine learning techniques with applications to biology, medicine and healthcare. We are especially concerned with how model-driven approaches, theories or empirical applications can be used to address challenges arising from exploiting large and complex data. Current research topics of interest include but are not limited to deep learning; probabilistic and statistical models and theories; machine learning; and data mining theories, models and systems. A focus area is analysis of genomic and genetic data with application for cancer and genetic disorders. This includes extensive collaborations with biologists, geneticists and physicians.

KPI-Driven Content Understanding and Generation With Applications to Digital Marketing

In digital marketing it is crucial to distribute valuable, relevant and consistent content to attract and acquire a clearly defined audience. and to optimize various key performance indexes (KPIs) such as conversion rate and click-through rate. This project focuses on developing machine learning techniques for content understanding with application to digital marketing. Understanding content is not interpreting its literal meaning, such as the detection of a dog in an image, but instead refers to elucidating its implication in driving KPIs. This project in collaboration with Adobe will facilitate content personalization using artificial intelligence-driven technologies.

Research Area: Advanced data analytics, data mining, statistical learning

Senjuti Basu Roy
Assistant Professor
senjuti.basuroy@njit.edu

Big Data Analytics Laboratory - Data Science With Humans-in-the-loop

The Big Data Analytics Lab (BDaL) is an interdisciplinary research laboratory that focuses on large-scale data analytics problems rising in different application domains and disciplines. One focus of our lab is to investigate an alternative computational paradigm that involves humans-in-the-loop for large-scale analytics problems. These problems arise at different stages in a traditional data science pipeline, such as data cleaning, query answering, ad-hoc data exploration or predictive modeling, as well as from emerging applications. We study optimization opportunities that arise because of this unique man-machine collaboration and address data management and computational challenges to enable large-scale analytics with humans-in-the-loop. Our focus domains are social networks, health care, climate science, retail and business, and spatial data training.

Research Area: Human-in-the-loop large-scale data analytics, optimization algorithms

Hai Phan
Assistant Professor
hai.phan@njit.edu

Preserving Sensitive Health Care Data

Networks that share electronic health records containing a patient's personal and clinical data promise improved continuity of care and better health outcomes. However, these networks put highly sensitive patient information at risk and expose healthcare providers to legal jeopardy. We created DeepPrivate, a system that uses machine learning techniques to protect personal health information against cyber attacks.

Enable Real-Time Drug Abuse Risk Behavior Detection

Some Twitter users are surprisingly willing to divulge private details of their lives, including their own drug abuse activities. However, such tweets are hidden within hundreds of millions of other posts. We apply machine learning methods to recognize tweets related to drug abuse. Many tweets are geographically tagged and all are temporally labeled. This allows us to recognize hot spots of drug activity and peak days and times to provide nearly real-time information to public health officials for planning tactical and strategic responses.

Ontology-Based Interpretable Deep Learning

Machine learning models are trained with large amounts of data and achieve a certain level of competency in interpreting and classifying new input data. However, even if they work well, it can be difficult to explain why. Lingering doubt persists that in some situations that the classification output of the model might be wrong. In applications such as self-driving cars, this could have spectacularly negative consequences. We tie predictions of the model to a set of keywords taken from a predefined vocabulary of relevant terms. The number of words hard-coded into the model that influence the outcome produced by a machine learning for a new input is reduced, and those words are taken from a limited and relevant ontology. This makes the output of the model easier to interpret as it becomes independent from terms that are irrelevant to the application domain.

Research Area: Social network analysis, machine learning, spatio-temporal data mining

Shaohua (David) Wang
Assistant Professor
shaohua.wang@njit.edu

Mining Concise and Useful Tips for Programming From Heterogeneous Data Sources

A tremendous amount of data containing coding tips or suggestions exists on a wide range of data sources, such as YouTube, Q&A websites, reviews, etc. Mining such tips can help software practitioners, such as developers and students, to learn and use a programming language. We are developing deep learning techniques to accurately classify and extract small, useful and concise coding suggestions from crowdsourcing websites.

Next Generation Question and Answer System for Software Developers

Typically, a software developer's question contains long text, code examples, software semantics and diagrams. This data diversity hinders many state-of-the-art techniques. Systems perform poorly when automatically answering such questions. We are developing AI techniques that analyze developers' questions and documentation using deep learning techniques.

Research Area: Software engineering, artificial intelligence, machine learning

Jason Wang
Professor
jason.t.wang@njit.edu

Mining Big Data Through Deep Learning

We are designing and implementing new deep learning algorithms and architectures for mining big data. We have developed a 3D-atrous convolutional neural network, used it as a deep visual feature extractor and stacked convolutional long short-term memory networks on top of the feature extractor. This allows us to capture not only deep spatial information but also long-term temporal information in the data. In addition, we use stacked de-noising autoencoders to learn latent representations of the data that construct feature vectors suitable for classification. We also develop new recurrent neural networks to mine time-series data for stock market forecasting and space weather prediction. Currently, we are building a deep learning framework with generative adversarial networks. This framework will be used for stochastic video prediction, image synthesis and image-to-image translation. The framework can handle model uncertainty as well as data uncertainty and sparsity. Our deep learning models are suited for big data applications that have few, incomplete, imperfect, missing, noisy or uncertain training data.

Research Area: Data mining, machine learning, deep learning, data science

Data and Software Security

The security research group performs extensive work in homomorphic encryption, supply chain security, blockchain and device/application security. It also makes significant contributions to open-source software.

Kurt Rohloff received the first DARPA Young Faculty Award at NJIT. Initial results of a project in cliptography led to a conference award (top 3 rated) paper at Asiacrypt.

Kurt Rohloff

Associate Professor
kurt.rohloff@njit.edu

Combating Data Leaks: PALISADE

We developed a widely used open-source lattice encryption library and software engineering tools for a new family of encryption technologies. This software library provides encrypted computing capabilities such as homomorphic encryption, allowing organizations to outsource computation to cloud computing environments without risking privacy and leaking sensitive information to potential adversaries.

Improving Usability of Open-Source Software

Funded by the first DARPA Young Faculty Award at NJIT and the IARPA HECTOR project, our MARSHAL and Verona projects focus on making it easier to rapidly optimize open-source software to run on commodity hardware. This research focuses on the deployment of the PALISADE open source lattice encryption library on embedded systems.

Research Area: Encrypted computing, lattice encryption implementation, homomorphic encryption, cryptographic program optimization

Ilulian Neamtii

Professor
ilulian.neamtii@njit.edu

Improving Smartphone Reliability and Security

We have developed a wide range of approaches to improve smartphone reliability and security, including static and dynamic program analyses, record-and-replay systems, runtime systems for moving-target defense, application self-healing and automatic test generators. These approaches were released as open-source code. Users found security and reliability issues in many popular applications such as AirBnB, Facebook, NPR News and Waze.

Protecting Army Networks

As part of the Cybersecurity Collaborative Research Alliance, a joint effort between the U.S. Army Research Laboratory, Applied Communication Services and six universities, our research aims to advance the foundations of cybersecurity in the context of military networks. We are using a two-pronged approach: Theoretical foundations of, and practical approaches for, agile defense of Army devices and networks, as well as measuring and predicting socio-cognitive factors involved in human decision-making during cybersecurity engagements.

Research Area: Programming languages, software engineering and the smartphone side of systems/security

Qiang Tang

Assistant Professor
qiang.tang@njit.edu

Blockchain Technology

Our research focuses on advancing three core layers of blockchain: decentralized applications, blockchain itself (consensus) and supporting cryptographic primitives. We have been pushing asynchronous consensus towards both theoretically and practically optimal performance, and we are also working with JD.com to deploy asynchronous consensus in real-world large systems. Application-wise, we have designed a decentralized cybersecurity management system and showcased possible consumer cost reduction via decentralizing Amazon Mechanical Turk tasks on Ethereum. We also designed new cryptographic tools, such as proof-of-storage-time, to enable clients to verify continuous availability of storage services in cloud and decentralized storage markets.

Cliptography: Cryptography Against Subversion Attacks

Software or hardware implementations, including open-source versions, of cryptographic functions may deviate from formal specifications. We are designing a new generation of cryptographic specifications such that either the subverted implementation can be easily detected via simple blackbox testing, or we can preserve security even when a malicious implementation contains backdoors.

Research Area: Big data analytics, cyber security, parallel and distributed computing

Reza Curtmola

Professor
reza.curtmola@njit.edu

Defending Software Supply Chains Against Hackers

Funded by DARPA and the NSF, we have developed "*in-toto*", an open-source framework that promises to safeguard software for developers and end users. *In-toto* provides organizations with insights into the software development and distribution chain, such as having a provable assurance that proper software development practices were followed. With *in-toto* in place, it will be more difficult for malicious code to be slipped into software products, thus raising the bar significantly for attackers. Through integrations, *in-toto* is currently used by thousands of companies and has improved the security of millions of users.

Research Area: Big data analytics, cyber security, parallel and distributed computing

Image and Video Processing

Our faculty focused on image and video processing continue to advance the science and technology. They work with experts in health care, state and local government, security and the private sector to examine obstacles and to address them by leveraging the latest advancements.

From the diagnosis of pneumonia and brain tumors, to automated systems that can monitor traffic incidents, roadway congestion and public safety risks, the image processing group is making advances with significant work in image forensics and watermarking, pattern and face recognition, medical image analysis, video analytics, deep neural networks and smart transportation systems.

Frank Shih
Professor
frank.y.shih@njit.edu

Deep Learning for Pneumonia Classification and Segmentation on Medical Images

Automatic identification of pneumonia on medical images has attracted intensive study. In this project, we develop a novel joint-task architecture that can learn pneumonia classification and segmentation simultaneously. Two modules, including an image preprocessing module and an attention module, are developed to improve both classification and segmentation accuracies. Experimental results performed on the massive dataset of the Radiology Society of North America have confirmed its superiority over other existing methods.

Deep Morphological Neural Networks and Applications

Given a target image, determining suitable morphological operations and structuring elements is a cumbersome and time-consuming task. In this project, we propose new morphological neural networks, which includes a nonlinear feature extraction layer to learn the structuring element correctly, and an adaptive layer to automatically select appropriate morphological operations. We also use them for their classification applications, including hand-written digits, geometric shapes, traffic signs and brain tumors. Experimental results show higher computational efficiency and higher accuracy when compared with existing convolutional neural network models.

Research Area: Image processing, artificial intelligence, digital watermarking, digital forensics, robot sensing, neural networks

Chenjun Liu
Professor
chengjun.liu@njit.edu

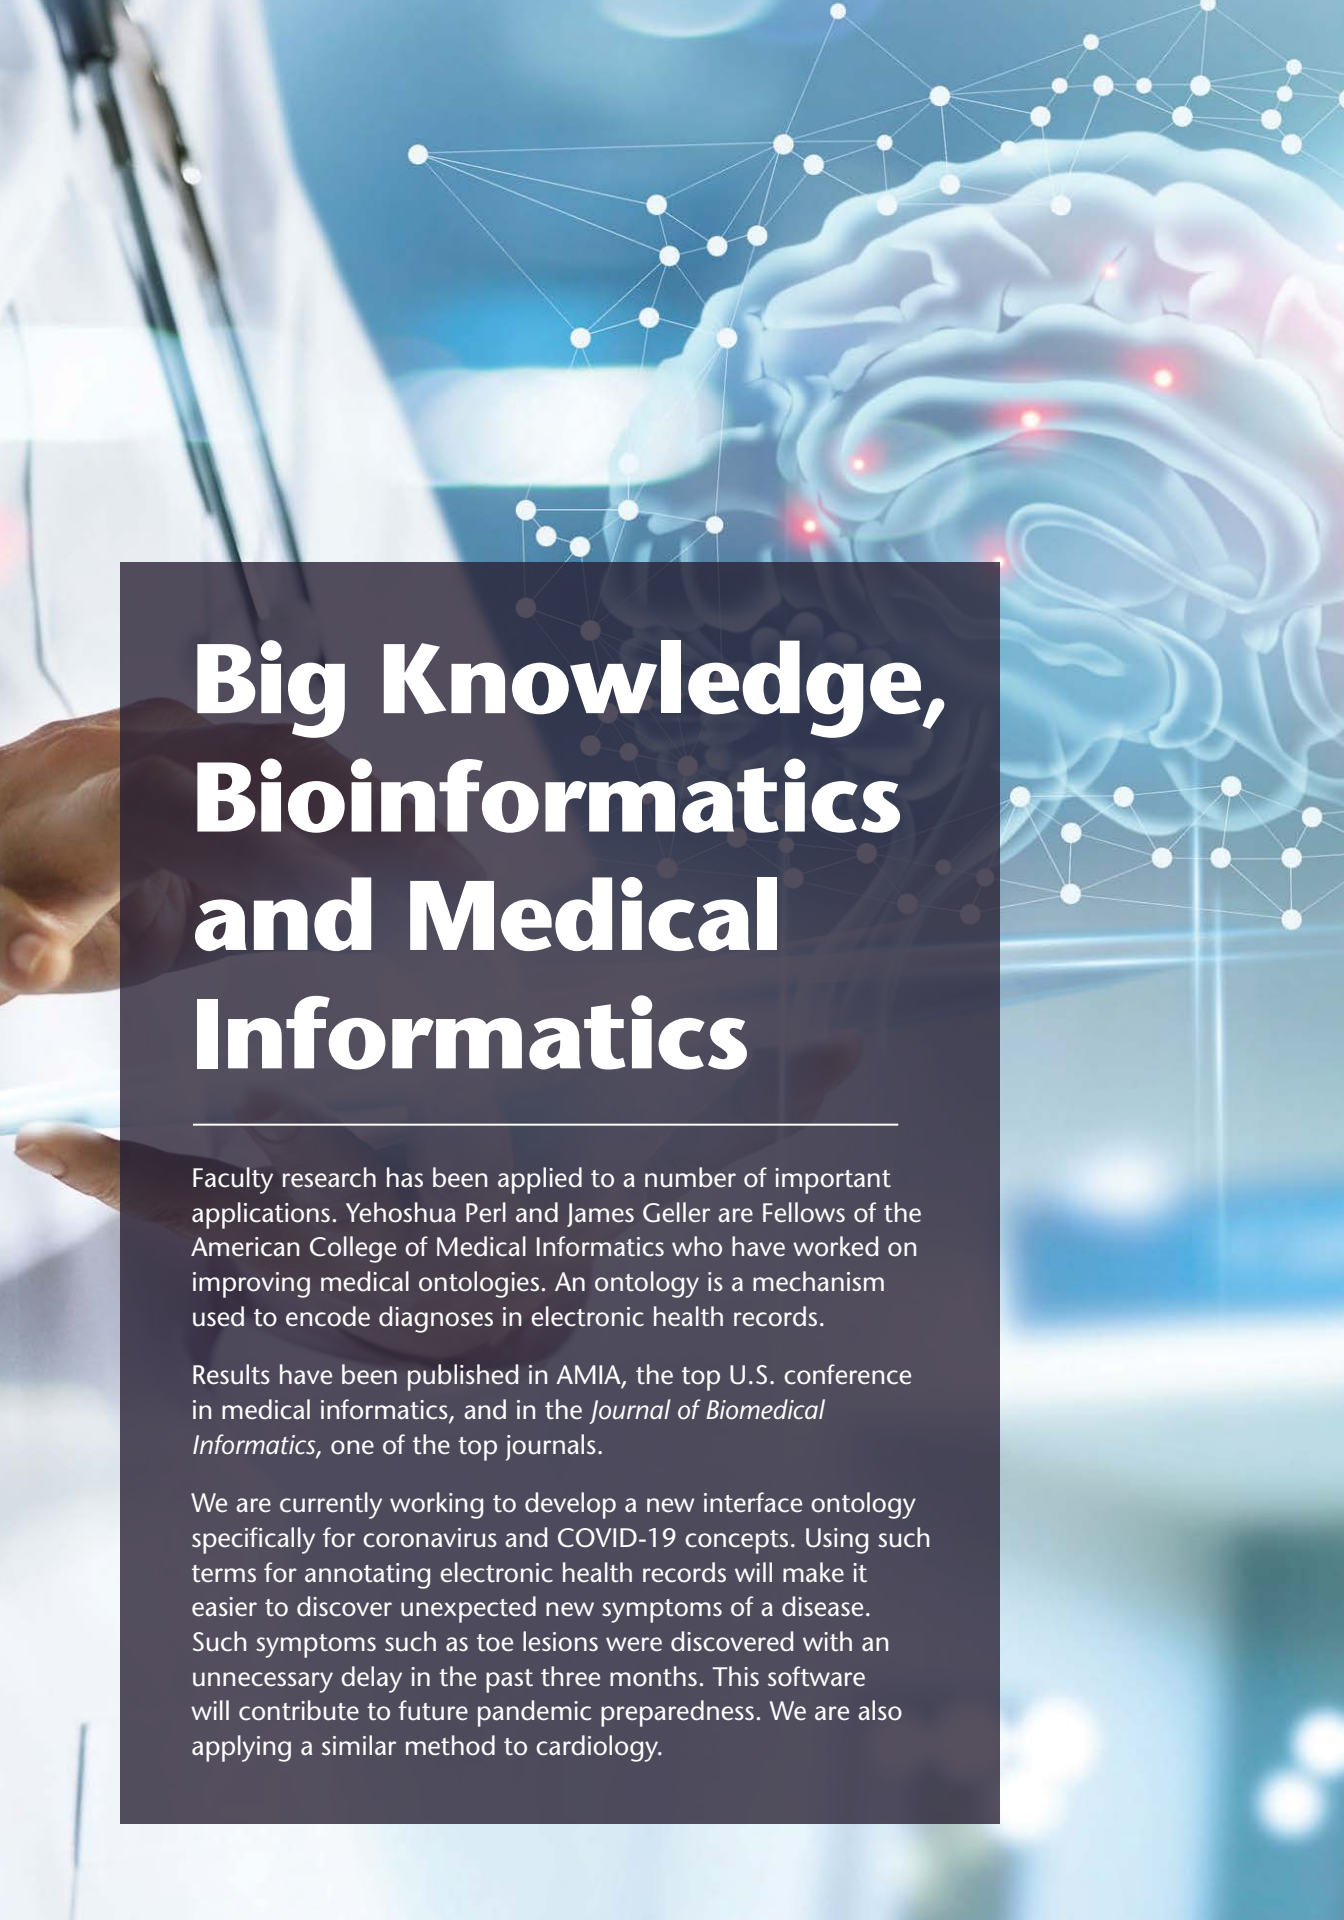

Making Intelligent Transportation Systems Smarter

The New Jersey Department of Transportation designated more than 400 closed-circuit video cameras statewide for incident monitoring, traffic congestion control and public safety operations. Video streams from these cameras feed to a back-end system. There, video analytics software is used to perform target detection and incident monitoring applications. We are actively working on incorporating wireless sensor networks, hierarchical edge-computing and computer vision to mitigate the challenging problems in various illumination and weather conditions in order to achieve fast and automated video-based traffic monitoring.

Video Analytics Pilot Studies and Testing of Technologies

We propose a new modular approach for statistical modeling of traffic incidents and model selection in order to improve state-of-the-art traffic detection and monitoring. We investigated and developed automated video analytics systems to replace human operators for traffic incident detection and to monitor the cameras installed along the major New Jersey highways. We test the proposed technologies and benchmark their performance.

Research Area: Computer vision, pattern and face recognition, video processing

Big Knowledge, Bioinformatics and Medical Informatics

Faculty research has been applied to a number of important applications. Yehoshua Perl and James Geller are Fellows of the American College of Medical Informatics who have worked on improving medical ontologies. An ontology is a mechanism used to encode diagnoses in electronic health records.

Results have been published in AMIA, the top U.S. conference in medical informatics, and in the *Journal of Biomedical Informatics*, one of the top journals.

We are currently working to develop a new interface ontology specifically for coronavirus and COVID-19 concepts. Using such terms for annotating electronic health records will make it easier to discover unexpected new symptoms of a disease. Such symptoms such as toe lesions were discovered with an unnecessary delay in the past three months. This software will contribute to future pandemic preparedness. We are also applying a similar method to cardiology.

James Geller
Professor
james.geller@njit.edu

Yehoshua Perl
Professor
yehoshua.perl@njit.edu

Michael Halper
Professor
michael.halper@njit.edu

Summarizing, Visualizing and Correcting Large Collections of Medical Terms

Biomedical professions have collected large ontologies of medical terms covering diseases, diagnosis, drugs, anatomy, bacteria, genes, chemicals, medical procedures and more. We developed a theoretical framework to create concise summaries of large ontologies and software tools to visualize these summaries. Using this software, medical experts can easily browse large medical ontologies, making it easier to recognize errors in structure and content. Recently, we machine learning methods for updating and curating biomedical ontologies. We are also developing methods to interpret large collections of formal medical knowledge in ontologies, which will aid in the prediction of dangerous drug interactions.

James' Research Area: Medical informatics, semantic web technology, object-oriented database modeling, knowledge representation

Yehoshua's Research Area: Medical informatics, semantic web, ontologies

Michael's Research Area: Controlled terminologies, ontologies, object-oriented databases, conceptual modeling, open data models

Xinyue Ye
Associate Professor
xinyue.ye@njit.edu

Open Knowledge Network for Spatial Decision Support

This project focuses on research critical to the development of open knowledge networks (OKN) through the combination and testing of participatory and automated ontology development processes. Three domain-specific case studies — wild fires, water quality and biodiversity conservation -- will build on participatory geographic information system and ontology development work through engagement of problem-focused stakeholder networks. At the same time, the utility of automated tools for resource discovery, ontology development and social network analysis will be tested in these real-world environments. Through integration and comparison of these techniques, we will deliver insights into efficient and effective methods for OKN development.

Capturing, Managing and Utilizing Geospatial Multimedia Data for Collaborative Field Research

This project focuses on developing spatial social network analytics to integrate multimedia data in space, time and within a network. The software captures and transfers geospatial multimedia data in a variety of different field settings ranging from developed countries with advanced IT infrastructures to countries that still lack reliable access to the internet; manage and explore the collected data; and apply qualitative, quantitative and spatial data analysis with mining algorithms, visual representations and interactions.

Research Area: GIS, urban informatics

Usman Roshan
Associate Professor
usman.w.roshan@njit.edu

Deep Learning for Medical AI Problems

We work on several medical AI problems involving images and DNA. In collaboration with neuroscientists, we are creating new models for tumor identification in brain MRI images and are studying them across different data sources. With vascular surgeons we are proposing novel models for identifying vessel and plaque in vascular ultrasound images from real patients. We are studying simple random networks for the classification of histopathology slide images and find them to be highly accurate there.

Adversarial Robust Machine Learning With 01 Loss:

Machine learning models today are highly accurate but not very robust. They can be fooled to misclassify data with minor perturbations known as adversarial attacks. Adversaries targeting a given convex model are known to affect other convex models. We find this transferability phenomenon to be less effective between 01 loss and convex losses such as hinge and logistic, both of which are approximations to 01 loss and known to be affected by outliers. Consequentially, it is harder to attack 01 loss models with convex substitute model black-box attacks, and when the black-box attacker is 01 loss, the attack is highly ineffective on all models. Based upon these observations, we are researching novel algorithms and design implementations for scalable and faster 01 loss models.

Research Area: Machine learning, medical informatics

Distributed Systems, Mobile Computing and Networking

Our researchers are investigating a wide range of topics related to distributed systems, mobile computing and networking. An area of particular interest and research focus is the development of blockchain systems. Faculty researchers in this area exploring and testing the potential for increasingly secure, independent organizations that help promote an individual user's personal agency in the blockchain space while improving a user's data privacy.

Other areas the group is studying include such diverse issues as how to address the online advertising challenge, balancing revenue objectives, maintaining a high-quality user experience and improving access to available parking in urban environments.

The results of our research are published in premier and competitive venues such as ICDCS, PODC and WWW.

Grace Wang
Professor
guiling.wang@njit.edu

Blockchain and the Sharing Economy

Thanks to the emergence of blockchain technology, we are now moving quickly toward a new world of decentralized and secure organizations. A large number of individuals can coordinate, interact and trade directly, thus governing themselves without the help of centralized platforms. This project studies how people can interact through the blockchain to crowdsource human intelligence securely and efficiently. The design is secure and robust, as it not only eliminates the vulnerable reliance on centralized third-parties, but also mitigates the inherent transparency issues of the blockchain to attain data privacy as well as user anonymity. In addition, the design is efficient, practical and less expensive than existing centralized systems such as Amazon's Mechanical Turk.

A Generic Superlight Client for Permissionless Blockchains

This project conducts a systematic study on the light-client protocol of permissionless blockchains, in the setting where full nodes and light clients are rational. In the game-theoretic model, we design a super-light client protocol to enable a light client to employ some relaying full nodes (two or one) to read the blockchain. The protocol is generic, in that it can be deployed ignoring underlying consensus, and it is also superlight, in that the computational cost of the light client to predicate the existence or nonexistence of a transaction in the blockchain becomes a small constant. Since our protocol resolves a fundamental challenge of broadening the usage of blockchain technology, it captures a wide variety of important use cases such as multi-chain wallets, decentralized application browsers and more.

Research Area: Deep learning, blockchain technologies, IoT

Cristian Borcea
Professor
cristian.m.borcea@njit.edu

Predictive Online Advertisement

Online advertising is a multi-billion dollar industry. We aim to improve online ad efficacy and minimize annoying the users through predictive machine learning algorithms. We propose probabilistic latent class models that predict the viewability, in the technical sense of online advertising, of any given scroll depth for a user-page pair. We also propose deep learning models to predict the viewability of any page depth for any given user dwell time. Currently, we are studying techniques to find a balance between publisher's revenue and user experience in the context of the ad-blocking battles between users and web publishers.

Finding Free Parking in Cities

Finding an available free parking space in a city during peak hours is challenging. We have created a system for assigning free curbside parking spaces to drivers in cities that reduces driving time to the parking spot and walking time from the parking spot to the destination. Currently, we are designing a distributed system for free parking assignment that is scalable and protects the driver's privacy.

Research Area: Mobile computing and sensing, ad hoc and vehicular networks, cloud and distributed systems

Cloud and High- Performance Computing

Researchers are investigating multiple aspects of cloud computing. Reducing latency is one of the key aspects of the research. It includes use of parallelism and algorithms for scheduling.

A key result of this research is enabling applications to fully leverage the computing capability of hardware and devices to achieve optimal data processing speeds. Research results such as APPLES, a solution for reducing spin-lock overhead, attracted interest from companies such as Tencent and Didi.

Jing Li
Assistant Professor
jing.li.2@njit.edu

Scheduling for Interactive Cloud Services

Delivering consistent interactive latencies, such as response delays, is the key performance metric of interactive cloud services that significantly impacts user experience. The need to guarantee low-service latency, while supporting increasing computational demands due to complex functions of the services, requires parallel scheduling infrastructure to effectively harness parallelism in the computation and efficiently utilize system resources. Our research designs, analyzes and implements scheduling strategies that are measurably good and practically efficient to provide various quality-of-service guarantees on cloud service latency.

Parallel Real-Time Systems

Real-time systems need to provide timing guarantees for latency-critical applications in cyber-physical systems that interact with humans or the physical environment. Examples span autonomous vehicles, drones, avionic systems and robotics, to structural health monitoring systems and hybrid simulation systems in earthquake engineering. However, as parallel machines become ubiquitous, we face challenges in designing real-time systems that can fully utilize the efficiencies of parallel computing platforms. We are developing parallel real-time systems by exploiting the untapped efficiencies in the parallel platforms, drastically improving the system performance of a cyber-physical system.

Research Area: Real-time systems, parallel computing, cyber-physical systems, interactive online cloud services architecture

Andrew Sohn
Associate Professor
andrew.sohn@njit.edu

Enabling High-Performance Cloud Computing

The persistent uploading, downloading and processing of images, videos and files to and from the cloud can lead to inefficiency and delayed response times due to irregular computing demands. Our research focuses on live migration of virtual machines, as well as containers that will help alleviate the problem and improve cloud servers such as Amazon's Elastic Compute Cloud and Microsoft Azure. It will also help meet the power and computing requirements of mobile and enterprise cloud applications.

Scalable Parallel Graph Partitioning for Enabling Real-Time Analytics

We are working on high performance computing for large-scale data, in particular large-scale graph partitioning projects called HARP and S-HARP (scalable HARP) designed and implemented with collaborators at the NASA Ames Research Center and the Lawrence Berkeley National Laboratory. Large-scale graph partitioning is critical in real-time social network analytics and is particularly challenging when dealing with dynamic graphs that change over time, as there needs to be balance of partition quality and execution time. We established a framework for partitioning dynamic graphs for NASA applications and continue to improve the technology for real-time social network analytics on a cluster of personal computers.

Research Area: Adaptive computing infrastructure, autonomous migration of Linux virtual machines, maximizing cluster utilization

Multi-Core and Many-Core Algorithm Design, Analysis and Implementation

We study models of computation that abstract and capture parallelism in the presence of multiple memory hierarchies and cores. New approaches are needed to make multi-core architectures accessible to software designers in domains such as machine learning and big data. Abstracting the programming requirements of such architectures in a useful and usable manner is necessary to increase processing speed and improve memory performance.

Parallel Computing Techniques in Sequential Serial Computing

The norm in computing is to port sequential algorithms that work on one processor into multi-core or parallel algorithms intended for multiple cores and processors. Amdahl's Law highlights the limitations of using multiple cores in programs with an inherently sequential component that is not amenable to parallelization. We address this by exploring the utilization of parallel computing techniques to speed up a sequential program by exploiting the multiple memory hierarchies present in contemporary microprocessors, even if its multi-core capabilities are left unexploited.

Research Area: Architecture-independent parallel algorithm design and implementation

Associate Professor
xiaoning.ding@njit.edu

Virtualization of Heterogeneous and Non-Uniform Memory Hierarchies

Accessing data saved in heterogeneous and non-uniform memory hierarchies is an increasingly important factor for application performance. However, cloud-based system software, particularly virtualization software, causes data-intensive applications to suffer a significant performance penalty. We improve memory virtualization technology to build virtual memory hierarchies. Virtual memory hierarchies have similar architectures and features as those of new memory systems. Thus, they can effectively serve as the portal for applications in virtual machines to efficiently access the data in new memory systems.

System Software for Scalable Computation in the Cloud

As computational resources continue to increase, we need ways to scale the performance of these computers by taking advantage of the extra resources. The objective is to guarantee that applications in the cloud can achieve higher performance when presented with more resources.

Research Area: Cloud computing infrastructures, parallel and distributed systems, operating systems, database systems, computer architecture

Augmented Reality, Virtual Reality, Gaming and Graphics

The research being done by faculty in our augmented reality, virtual reality, gaming and graphics groups is as diverse and innovative as one would expect from researchers engaged in these rapidly evolving fields. This group has faculty focused on the relationship between people, human cognition and augmented realities, and developing tools that improve user experience. Our research on the applications of this technology range from access to life-saving health care services, to advances in crowd simulation for urban and space planning, to the use of virtual environments and simulation to improve learning outcomes, and the use of augmented and virtual reality tools to increase efficiencies and support innovation in manufacturing settings.

Design of Virtual Environments and Interfaces to Support Information, Perception and Cognition

Our research examines the design of virtual and augmented reality hardware, software interaction techniques and applications to augment or change user thinking and cognitive performance. This research is done with teams within the distributed Media Interface, and Network Design labs working within the context of medical, scientific and defensive military applications. For example, in an international project collaborating with teams in Spain and Korea, we examine how a brain-computer augmented reality environment can support and trace complex consumer decision-making, political decision-making and psycho-therapeutic applications. Users of the augmented reality environment also wear untethered brain sensors, other psychophysiological sensors and behavioral sensors such as facial emotion-sensing, to detect and measure how features of the virtual environment influence thinking. These neurocognitive indicators are used to adapt the virtual environment to the user in real-time. An example is a virtual character's behavior or the relative amount or complexity of information within medical, decision-making or military applications. Other projects in this research stream involve virtual environments that change the perception of the user's body or how social cognition is affected by immersive, hyper-realistic avatars during negotiation, training and decision-making. The design of virtual environments to augment cognition also applies to interactive scientific visualizations. These augmented reality environments make physical forces or microscopic phenomena experienceable by the senses and allow the user to perceive relations in data. In a recent astrophysics project, we created an augmented reality environment that uses streaming data from head-worn, magnetic sensors to directly see and experience Earth's local magnetic fields.

Research Area: Virtual and augmented reality systems, components for brain-computer interfaces, real-time public opinion measurement

Jacob Chakareski
Associate Professor
jacob.chakareski@njit.edu

Virtual Human Teleportation

Virtual reality and 360-degree video are emerging technologies that can enable virtual human teleportation to any remote corner of the globe. This requires ultra-low latency, gigabit-per-second wireless speeds and data-intensive computing. Our research investigates synergies at the intersection of 6DOF 360-degree video representation methods, edge computing, UAV-IoT, millimeter-wave and free-space optics wireless technologies. It transmits data using much higher electromagnetic wave frequencies to enable the ultra-high data rates and ultra-low latencies required by next generation societal VR applications.

Real-Time Structure-Aware Reinforcement Learning

Reinforcement Learning (RL) provides a natural paradigm for decision-making in diverse emerging applications that operate in unknown environments and with limited data of unknown stochastic characteristics. Paramount to the effective operation of these ultra-low latency applications, such as IoT sensing, autonomous navigation and mobile virtual and augmented reality, is the ability to learn the optimal operation actions online and as quickly as possible. Existing state-of-the-art RL methods either take too long to converge or are too complex to deploy. Our research examines novel structure-aware RL methods that integrate basic system knowledge to compute learning actions updates across multiple states or even the entire state-space of the problem of interest, in parallel. To address the challenge of computational complexity that is introduced, our methods integrate analysis that help effectively trade-off learning acceleration and computing complexity.

Societal Applications

Our research focuses on interdisciplinary synergies to enable next-generation applications. For instance, a National Institutes of Health project at the intersection of networked virtual reality, artificial intelligence and low-vision rehabilitation aims to enable novel, previously inaccessible and unaffordable health care services to be delivered broadly and affordably. Other projects include the integration of virtual reality, real-time reinforcement learning and soft-exoskeletons for future physical therapy and the synergy of UAV-IoT and VR towards next generation forest fire monitoring.

Research Area: Immersive communication, augmented/virtual reality

Tomer Weiss
Associate Professor
tomer.weiss@njit.edu

Computational Design of Virtual and Real Worlds

Virtual worlds are growing in complexity and interactivity and are challenging to construct efficiently and realistically. Interior scenes are an intrinsic part of virtual worlds. They are also needed for non-interactive applications, such as furniture marketing, residential showcasing and other commercial applications. Unfortunately, most of the aesthetic and creative process of designing interiors, real or virtual, is manual. To accelerate this process, we utilize machine learning and computer vision to develop several computational interior design tools. Our research assists users by providing suggestions on which furniture to pick, how well it matches the room's current style and where to place it. Hence, we can facilitate content creation needs for multiple industries and, most importantly, accommodate our common human needs to create our own optimal interior environment.

Simulating the Motion of Multi-Agent Crowds

Crowd simulation is an essential part of multiple domains, from interactive media systems, to pedestrian analysis in evacuation scenarios and urban planning, to autonomous multi-agent path planning and coordination. A crowd is a collection of independent, self-actuated agents, where each agent has individual navigational goals in this shared environment. Agent movement is controlled by a navigation algorithm, which needs to ensure that an agent progresses towards its goal while avoiding collisions. Computing collision-free agent motion is difficult, due to the complexity of such dynamic interactions. Despite more than 30 years in crowd simulation research, simulation methods have subspecialized and are computationally effective for either sparse or dense crowds but not for both. Our work is the first method that allows real-time simulation of both dense and sparse crowds for up to 100,000 agents. This result is made possible by reframing agent motion as a constrained mathematical optimization problem that can be solved effectively on modern GPU computer hardware. Aside from the immediate practical implications for the gaming and visual effects industry, these results inspire future research on large-scale pedestrian dynamics which can affect urban and space planning.

Creating Immersive Classroom Environments

As augmented and virtual reality (AR/VR) technologies become more mainstream, educational technologies will increase use of AR/VR capabilities. Examining AR/VR's impact on STEM education through the fields of learning science and human-computer interaction allow for unique understanding of how these emerging technologies will impact our knowledge-based society. Identifying STEM educational use cases of AR/VR may help scope research efforts and improve technology efficacy. As rich multimedia experiences become everyday facets of student lives, the delivery mechanisms of their educational content need to keep pace and supplement the traditional methods of instruction. Demonstrating that a game-structured virtual learning space can deliver comparable learning outcomes as a traditional, in-person learning environment is a focus of the research, which was proven in recent work involving students taught binary counting in both settings. The learning outcomes from that study were the same, showing that students are capable of learning in a virtual, game-based environment as well as they do in an in-person setting.

Research Area: Interactive computer graphics for training and educational applications

Amy Hoover
Assistant Professor
amy.k.hoover@njit.edu

Human-Computer Collaboration

We explore how humans and computers can work together to solve problems by conceptualizing creativity as a search in a structured space of computational artifacts. Our work has been applied to understanding game design, assessing learning in educational games, creating game content and behavior, and facilitating human creativity.

Research Area: Real-time systems, parallel computing, cyber-physical systems, interactive online cloud services, architecture

Michael Lee
Assistant Professor
michael.j.lee@njit.edu

Advancing STEM Education With Gaming and Virtual Reality

We explore unique approaches to teaching STEM topics in formal and informal learning environments. Our work on Gidget—an online game (helpgidget.org) to teach students introductory programming concepts—is effective in attracting and engaging a broad audience, including women and underrepresented minority groups in computing. Our work with CSpresso uses an interactive VR environment to teach middle school and high school students introductory computer science concepts such as binary counting and sorting algorithms.

Increasing Diversity in STEM Through Mentorship

This project explores how to increase participation and diversity in computing, especially for underserved and underrepresented minorities in STEM. We partner with local nonprofits and schools to provide programming experience to K-12 students, specifically using near-peer mentors to teach and engage middle school and high school students in a programming camp called Newark Kids Code. We also provide an introductory computing course for in-service high school teachers during the summer.

Research Area: Human-computer interaction (HCI), computing education research (CER)

Mixed Reality Simulations to Improve Training

Our research focuses on creating simulations using computer graphics, multimedia and mixed reality to improve training in different domains including health care simulation. We are especially interested in research involving virtual humans and multisensory experiences. We developed a new class of augmented reality patient simulators called physical-virtual patients that allow health care educators to interact with a life-size simulated patient by providing real-time physical tactile cues such as temperature and pulse; auditory cues such as speech and heart sounds; rich dynamic visual cues such as facial expressions indicating pain or emotions; and changes in appearance such as skin color and wounds.

Research Area: Augmented, virtual, and mixed reality, 3D graphics, virtual humans and synthetic reality, modeling simulation and training

Geometric Modeling and Computational Design

The traditional separation of design and manufacturing is currently one of the bottlenecks in the product development process leading to multiple expensive feedback loops. Our research aims at developing computational tools that integrate expert knowledge in 3D geometric modeling, physical simulation and smart algorithms in order to facilitate this process, which will become an important factor for success in increasingly competitive digital markets.

Computational Fabrication

We perform research at the intersection of applied mathematics, computer graphics and computational design. We investigate problems in geometric modeling and geometry processing, shape analysis and synthesis, as well as physical modeling and simulation with the goal of developing novel algorithmic solutions for the rapidly-growing domain of digital fabrication. Our research aims to provide novel solutions for the future design and manufacturing market.

Research Area: Computer graphics, geometric modeling, geometry processing, computational fabrication

Margarita Vinnikov
Assistant Professor
margarita.vinnikov@njit.edu

Immersive Cross-Reality Applications

Our research examines general areas of interactive cross-reality (XR), which encompasses virtual, augmented and mixed reality applications and serious game development. We specialize in eye and body tracking as well as multi-sensory augmentations. Specific topics include the design, development and evaluation of novel XR and cross-model (visual, audio and/or haptic) user experiences through simulations such as walking in European cities and driving in New Jersey and New York. We also build augmented-reality collaborative applications.

Multi-User Gaming and Collaborative Platforms

Virtual collaboration received a lot of attention recently as many people are forced to work away from their usual workspaces due to the COVID-19 pandemic. Providing a realistic environment where people can reliably and efficiently collaborate on tangible objects and models will help many businesses. Primarily, this is relevant to city planners, military and law enforcement, as well as educational settings. We are also interested in a multi-calibration platform between various augmented and mixed reality devices such as mobile phones, HoloLens and Magic Leap.

Visualization of Large Datasets in Virtual and Augmented Reality

Large data sets such as ontology trees or visibility graphs, when loaded into virtual or augmented reality devices, can pose many challenges. For example, continuous loading of data into a mobile device. Similarly, there are no established methods for the most user-friendly way to visualize large data clouds. Hence, we combine various computer science algorithms with user-studies to develop the most efficient ways to visualize large data sets.

Research Area: Immersive and collaborative cross reality, navigation, gaze/body tracking

Advanced Algorithms

There are a wide variety of formal methods and algorithmic research projects at NJIT. The work includes optimization, risk assessment, numerical algorithms and program repair.

Researchers publish in premiere conferences and journals and have received numerous prestigious honors and awards, including best paper prizes at top venues and NSF CAREER grants.

Dynamic Graph Algorithms

Graphs are used extensively to model various kinds of networks, such as transportation or social networks. In most real-life applications these networks change over time so their characteristics are changing as well. The goal of dynamic graph algorithms is to compute these characteristics over time as efficiently as possible. The required output can be recomputed from scratch at each time point, however, in many cases, the slow pace of change relative to the size of the network enables much faster computation. One such characteristic is the maximal independent set (MIS) of the graph, which has extensive connections to many fundamental combinatorial optimization problems, such as maximum matching, minimum vertex cover and graph coloring. We developed several dynamic algorithms for computing MIS including the first sublinear amortized update time algorithm for maintaining an MIS in dynamic graphs.

Location Problems on Euclidean Metrics

Location problems are an important class of combinatorial optimization problems that arise in applications such as choosing facility sites in a supply chain, placing servers in a telecommunication network and clustering data. The underlying distance function in many cases is Euclidean. It is natural to ask whether the Euclidean metrics can be leveraged to obtain more efficient algorithms than the ones known on a general metric space. We considered one such location problem, the classical k-supplier problem, and showed that there exists an algorithm for this problem on Euclidean metrics that beats the lower bound on the time required for any such algorithm on a general metric space.

Associate Professor
ioannis.koutis@njit.edu

Spectral Network Analysis

Networks, also known as graphs, are objects of central interest in data science. A network can be mapped to linear operators whose spectral properties encode valuable connectivity information, enabling the design of novel algorithms for network analysis. These are based on efficient algorithms for fundamental computational problems, such as systems of linear equations and other generalized regression problems. We designed and implemented fast and mathematically robust numerical algorithms in the context of network analysis. We also contributed to spectral graph theory by developing a better understanding of spectral properties of graphs with a prescribed cut structure. These novel methods have potential for applicability. Our research includes concrete applications in data mining and machine learning problems on large graphs.

Exact Algorithms

A multitude of well-studied computational problems are conjectured to require exponential time for their solution. Current research aims to develop a detailed understanding of the computational complexity of these problems beyond the classical NP-completeness theory. The design of faster exact algorithms for such problems and for their parameterized versions is of key importance in the area. In this context, we pioneered the general method of algebraic fingerprints that reduces various combinatorial problems to monomial detection problems that are, in turn, solved via algebraic algorithms. This research led to breakthrough results for classical algorithmic problems, such as the Hamiltonian cycle problem and single exponential time algorithms for problems parameterized by treewidth.

Research Area: Fast Linear system solvers, spectral graph algorithms, machine learning, data mining

Ali Mili
Professor
ali.mili@njit.edu

Science and Engineering in Program Repair

For the past decade, researchers in software engineering have been working on developing automated tools for program repair. In our research, we are interested in evolving theoretical foundations for this discipline and analyzing the impact of these on the state-of-the-art and the state-of-the-practice in program repair.

Redundancy: The Mutants' Elixir of Immortality

Mutants are syntactic variants of a base program used in software testing to assess the quality of test data. Test data is good if, whenever we modify a program, the test data exposes the difference. Sometimes a mutant may be semantically equivalent to a base program despite being syntactically distinct. In this work, we analyze the probability of equivalence between a base program and a mutant, or between two mutants, and we use this probability to analyze the mutation properties of the base program.

James Calvin
Professor
james.m.calvin@njit.edu

Global Optimization

To solve the pervasive optimization problems in engineering, science and commerce, we are developing "global optimization" algorithms where the objective is to solve optimization problems without getting stuck in local minima. This has applications in the design of fuel-efficient aircraft, the error rate of classification algorithms and financial investing.

Research Area: Global optimization, probabilistic analysis of algorithms

Marvin Nakayama
Professor
marvin@njit.edu

Efficient Computational Methods for Risk Assessment

Many disparate fields suffer from uncertainties with detrimental consequences, such as large losses in financial portfolios or failures of critical infrastructure due to natural disasters. Modern society crucially depends on gaining a better understanding of the likelihood and impacts of such calamitous rare events. Our work devises novel approaches for substantially reducing statistical errors in Monte Carlo simulation, a computational technique that can be employed to study risks in decision-making and analytics. One project focuses on designing improved methods for probabilistic safety assessments of nuclear power plants. The work also applies to evaluating the reliability of complex systems such as aircraft navigation computers, package-tracking systems for overnight delivery companies and the dependability of supply chains.

Research Area: Monte Carlo simulation, risk analysis, applied probability, statistics

Algorithm Design to Combat Discriminations in Rideshare Services

Rideshare platforms, such as Uber and Lyft, have gained increasing popularity in recent years. One of the central tasks facing Uber and Lyft is the matching policy pairing drivers and riders. Recently, it has been reported that drivers cancel riders based on their demographic attributes such as gender, race and disability, either intentionally or unintentionally. In our project, we try to leverage the power of algorithm design to curb discriminative cancellations from drivers to riders and improve the social welfare overall. **Research Area:** Artificial intelligence, approximation and randomized algorithm, rideshare and crowdsourcing markets.

Research Area: Artificial intelligence, approximation and randomized algorithm, rideshare and crowdsourcing markets

Social, Mobile and Education

Social media and mobile communications transformed how people interact with one another and how they access information. The social, mobile and education group conducts research that looks at how users engage with these platforms and technologies and examines key issues and opportunities that our increasing reliance and use of these platforms can create. For instance, a grant from the Mozilla Foundation examines how female and LGBTQ live streamers cope with online harassment, while other research focuses on the dissemination of disinformation via social platforms.

Our researchers focused on education are working to improve learning outcomes, automate instructor feedback and examine the effect of mobile technology on student learning and education delivery.

The crisis informatics work was one of three papers that received a Best Paper nomination at this year's ISCRAM conference.

Yvette Wohn
Assistant Professor
donghee.y.wohn@njit.edu

Exploring the Link Between Technology and Well-Being

We are exploring the connection between health and technology usage with an emphasis on the role social media plays in facilitating social support and psychological well-being, such as understanding the impact of mental health disclosures on live streams and how people deal with online harassment. We also look at how enclosed spaces, such as windowless offices, influence well-being and are designing technologies to augment physical spaces.

New Digital Economies

Games, esports and digital patronage systems have novel digital economies with unique digital currency. On the surface, they appear as recreational activities but represent a complex financial ecosystem that could have implications in the future of the digital economy. Our research focused on spending behaviors and exchange patterns of virtual goods in games and other alternative financial platforms and how these activities are tied with creative content generation.

Social Media Content Moderation

Supported by the National Science Foundation, this work focuses on the work of volunteer moderators on various social media platforms and understanding how safe spaces develop online.

Research Area: Content moderation practices, teamwork in esports, social media usage and well-being

Brook Wu
Associate Professor
yi-fang.wu@njit.edu

Early Detection of Fake News on Social Media

A major challenge of effective and early detection of fake news is fully utilizing the limited data observed at the early stage of news propagation. We propose a novel deep neural network to detect fake news early, by combining user- and post-based features into status-sensitive crowd responses. Experimental results show that our proposed model can detect fake news with greater than 90% accuracy within five minutes after it starts to spread and before it is retweeted 50 times. Most importantly, our approach requires only 10% labeled fake news samples to achieve this effectiveness under PU learning settings. We plan to extend this work by incorporating additional social context data extracted from user interactions to further enhance user representations and prediction accuracy.

Automating Feedback for Meaningful Learning

Writing-to-learn is a pedagogical strategy which uses writing to improve students' understanding of course content. However, most existing feedback systems for writing are mainly focused on improving students' writing skills rather than their conceptual development. We developed an automatic approach to generate timely, actionable and individualized feedback to facilitate meaningful learning by comparing knowledge representations extracted from teaching materials and individual students' writing assignments. Our results show that students include more domain concepts and relationships from the course materials in their assignments when using our system. We plan to extend this work to generate feedback for instructors to reinforce the discussion of core concepts in class.

Research Area: Text mining, information extraction, information retrieval

Cody Buntain
Assistant Professor
cody.l.buntain@njit.edu

Detecting Multi-Platform Online Disinformation Campaigns

This project develops multi-platform, multi-modal analytics tools for comparing behaviors of potentially malicious online actors with the goal of detecting inauthentic coordinated action and foreign influence campaigns in online social platforms. Current results suggest such malicious campaigns are consistent with prior work on propaganda but exhibit a distinct signal in how dissimilar the general content they share appears, suggesting an effort to artificially inflate the perceived diversity of their ideas.

Retrieving Critical Information in Social Media Data During Crises

Social media, blogs and other online information sources contain large volumes of data, especially during, and in the aftermath of, crises. This research project is part of an ongoing effort with the Incident Streams track at the National Institute of Standards and Technology and works to develop standardized datasets, tools and machine learning models for classifying social media data by information types and priorities. We use these systems to inform emergency response officers and support their efforts to find and respond to the non-trivial amount of critical information people share on social media during times of crisis.

Research Area: Social media mining, crisis informatics, political engagement, disinformation

Michael Bieber
Professor
michael.p.bieber@njit.edu

Redefining Student Engagement

Participatory learning deepens knowledge through active involvement in the entire lifecycle of assignments, exams and other course activities, including peer grading and self-assessment. We are developing a web application that functions as an educational dashboard, integrating commenting and mentoring capabilities and automatically assigning tasks to students.

Wearable Technology in Classrooms

Classroom dynamics continue to evolve as more students will use their personal wearable technology in ways that are undetectable by instructors and peers, which would create an atmosphere of distrust. We are the first to systematically investigate and determine how best to design learning, teaching and assessment when personal wearable technology is used undetectably in classroom settings.
