# Package 'hts'

July 30, 2024

```
Title Hierarchical and Grouped Time Series
```

Version 6.0.3

**Description** Provides methods for analysing and forecasting hierarchical and grouped time series. The available forecast methods include bottom-up, top-down, optimal combination reconciliation (Hyndman et al. 2011) <doi:10.1016/j.csda.2011.03.006>, and trace minimization reconciliation (Wickramasuriya et al. 2018) <doi:10.1080/01621459.2018.1448825>.

**Depends** R (>= 3.2.0), forecast (>= 8.12)

**Imports** SparseM, Matrix, parallel, utils, methods, graphics, grDevices, stats

Suggests testthat, rmarkdown, covr

**LinkingTo** Rcpp (>= 0.11.0), RcppEigen

LazyLoad yes

LazyData yes

ByteCompile TRUE

ackage	Hierarchical and grouped time series	_

#### **Description**

hts-p

Index

This package presents functions to create, plot and forecast hierarchical and grouped time series. In forecasting hierarchical and grouped time series, the base methods implemented include ETS, ARIMA and the naive (random walk) models. Forecasts for grouped time series are calibrated using bottom-up and optimal combination methods. Forecasts for hierarchical time series are distributed in the hierarchy using bottom-up, top-down, middle-out and optimal combination methods. Three top-down methods are available: the two Gross-Sohl methods and the forecast-proportion approach of Hyndman, Ahmed, and Athanasopoulos (2011).

### Author(s)

accuracy.gts	In-sample or out-of-sample accuracy measures for forecast grouped and hierarchical model

# Description

Returns a range of summary measures of the forecast accuracy. The function measures out-of-sample forecast accuracy based on (holdout data - forecasts) and in-sample accuracy at the bottom level when setting keep.fitted = TRUE in the forecast.gts. All measures are defined and discussed in Hyndman and Koehler (2006).

# Usage

```
## S3 method for class 'gts'
accuracy(object, test, levels, ..., f = NULL)
```

# Arguments

object	An object of class gts, containing the forecasted hierarchical or grouped time series. In-sample accuracy at the bottom level returns when test is missing.
test	An object of class gts, containing the holdout hierarchical time series
levels	Return the specified level(s), when carrying out out-of-sample
	Extra arguments to be ignored
f	Deprecated. Please use object instead.

### **Details**

MASE calculation is scaled using MAE of in-sample naive forecasts for non-seasonal time series, and in-sample seasonal naive forecasts for seasonal time series.

# Value

Matrix giving forecast accuracy measures.

ME	Mean Error
RMSE	Root Mean Square Error
MAE	Mean Absolute Error
MAPE	Mean Absolute Percentage Error
MPE	Mean Percentage Error
MASE	Mean Absolute Scaled Error

4 aggts

# **Examples**

```
data <- window(htseg2, start = 1992, end = 2002)
test <- window(htseg2, start = 2003)
fcasts <- forecast(data, h = 5, method = "bu")
accuracy(fcasts, test)
accuracy(fcasts, test, levels = 1)</pre>
```

aggts

Extract selected time series from a gts object

# **Description**

The time series from selected levels of a hierarchical/grouped time series or a forecasted hierarchical/grouped time series are returned as a multivariate time series.

### Usage

```
aggts(y, levels, forecasts = TRUE)
```

### **Arguments**

y An object of class {gts}.

levels Integer(s) or string(s) giving the specified level(s).

forecasts If y contains forecasts and historical data, then forecasts indicates whether to

return the forecasts or the historical data. Otherwise it is ignored.

6 combinef

combinef	Optimally combine forecasts from a hierarchical or grouped time series
	ries

# **Description**

Using the methods of Hyndman et al. (2016) and Hyndman et al. (2011), this function optimally combines the forecasts at all levels of a hierarchical time series. The forecast.gts calls this function when the comb method is selected.

# Usage

```
combinef(
  fcasts,
  nodes = NULL,
  groups = NULL,
  weights = NULL,
  nonnegative = FALSE,
  algorithms = c("lu", "cg", "chol", "recursive", "slm"),
  keep = c("gts", "all", "bottom"),
  parallel = FALSE,
  num.cores = 2,
  control.nn = list()
)
```

# Arguments

fcasts	Matrix of forecasts for all levels of the hierarchical time series. Each row represents one forecast horizon and each column represents one time series from the hierarchy.
nodes	If the object class is hts, a list contains the number of child nodes referring to hts.
groups	If the object class is gts, a gmatrix is required, which is the same as groups in the function gts.
weights	A numeric vector. The default is NULL which means that ordinary least squares is implemented.
nonnegative	Logical. Should the reconciled forecasts be non-negative?
algorithms	An algorithm to be used for computing reconciled forecasts. See forecast.gts for details.
keep	Return a gts object or the the reconciled forecasts at the bottom level.
parallel	Logical. Import parallel package to allow parallel processing.
num.cores	Numeric. Specify how many cores are going to be used.
control.nn	A list of control parameters to be passed on to the block principal pivoting algorithm. See 'Details'.

combinef 7

#### **Details**

The control.nn argument is a list that can supply any of the following components: ptype Permutation method to be used: "fixed" or "random". Defaults to "fixed". par The number of full exchange rules that may be tried. Defaults to 10. gtol The tolerance of the convergence criteria. Defaults to sqrt(.Machine\$double.eps).

#### Value

Return the (non-negative) reconciled gts object or forecasts at the bottom level.

  algorithms = c("lu", "cg", "chol", "recursive", "slm"),
  covariance = c("shr", "sam"),
  nonnegative = FALSE,
  control.nn = list(),
  keep.fitted = FALSE,
  keep.resid = FALSE,
  positive = FALSE,
  lambda = NULL,
  level,
```

forecast.gts 9

```
FUN = NULL,
xreg = NULL,
newxreg = NULL,
parallel = FALSE,
num.cores = 2,
...
)
```

### **Arguments**

object Hierarchical or grouped time series object of class {gts}

h Forecast horizon

method Method for distributing forecasts within the hierarchy. See details

weights Weights used for "optimal combination" method: weights="ols" uses an un-

weighted combination (as described in Hyndman et al 2011); weights="wls" uses weights based on forecast variances (as described in Hyndman et al 2016); weights="mint" uses a full covariance estimate to determine the weights (as described in Wickramasuriya et al 2019); weights="nseries" uses weights

based on the number of series aggregated at each node.

fmethod Forecasting method to use for each series.

algorithms An algorithm to be used for computing the combination forecasts (when method=="comb").

The combination forecasts are based on an ill-conditioned regression model. "lu" indicates LU decomposition is used; "cg" indicates a conjugate gradient method; "chol" corresponds to a Cholesky decomposition; "recursive" indicates the recursive hierarchical algorithm of Hyndman et al (2016); "slm" uses sparse linear regression. Note that algorithms = "recursive" and algorithms =

"slm" cannot be used if weights="mint".

covariance Type of the covariance matrix to be used with weights="mint": either a shrink-

age estimator ("shr") with shrinkage towards the diagonal; or a sample covari-

ance matrix ("sam").

nonnegative Logical. Should the reconciled forecasts be non-negative?

control . nn A list of control parameters to be passed on to the block principal pivoting algo-

rithm. See 'Details'.

keep.fitted If TRUE, keep fitted values at the bottom level.

keep.resid If TRUE, keep residuals at the bottom level.

positive If TRUE, forecasts are forced to be strictly positive (by setting lambda=0).

lambda Box-Cox transformation parameter.

level Level used for "middle-out" method (only used when method = "mo").

FUN A user-defined function that returns an object which can be passed to the forecast

function. It is applied to all series in order to generate base forecasts. When FUN is not NULL, fmethod, positive and lambda are all ignored. Suitable values for

FUN are thats and stlf for example.

xreg When fmethod = "arima", a vector or matrix of external regressors used for

modelling, which must have the same number of rows as the original univariate

time series

10 forecast.gts

newxreg	When fmethod = "arima", a vector or matrix of external regressors used for forecasting, which must have the same number of rows as the h forecast horizon
parallel	If TRUE, import parallel package to allow parallel processing.
num.cores	If parallel = TRUE, specify how many cores are going to be used.
	Other arguments passed to ets, auto.arima or FUN.

#### **Details**

Base methods implemented include ETS, ARIMA and the naive (random walk) models. Forecasts are distributed in the hierarchy using bottom-up, top-down, middle-out and optimal combination methods.

Three top-down methods are available: the two Gross-Sohl methods and the forecast-proportion approach of Hyndman, Ahmed, and Athanasopoulos (2011). The "middle-out" method "mo" uses bottom-up ("bu") for levels higher than level and top-down forecast proportions ("tdfp") for levels lower than level.

For non-hierarchical grouped data, only bottom-up and combination methods are possible, as any method involving top-down disaggregation requires a hierarchical ordering of groups.

When xreg and newxreg are passed, the same covariates are applied to every series in the hierarchy.

The control. nn argument is a list that can supply any of the following components:

```
ptype Permutation method to be used: "fixed" or "random". Defaults to "fixed".

par The number of full exchange rules that may be tried. Defaults to 10.

gtol The tolerance of the convergence criteria. Defaults to sqrt(.Machine$double.eps).
```

#### Value

A forecasted hierarchical/grouped time series of class gts.

### Note

In-sample fitted values and resiuals are not returned if method = "comb" and nonnegative = TRUE.

#### Author(s)

Earo Wang, Rob J Hyndman and Shanika L Wickramasuriya

get\_groups

Get nodes/groups from an hts/gts object

# Description

Get nodes/groups from an hts/gts object

# Usage

```
get_groups(y)
get_nodes(y)
```

### **Arguments**

У

An hts or gts object series.

12 gts

gts

Create a grouped time series

### **Description**

Method for creating grouped time series.

### Usage

```
gts(y, groups, gnames = rownames(groups), characters)
is.gts(xts)
## S3 method for class 'gts'
print(x, ...)
## S3 method for class 'gts'
summary(object, ...)
```

### **Arguments**

У

A matrix or multivariate time series contains the bottom level series.

groups

Group matrix indicates the group structure, with one column for each series when completely disaggregated, and one row for each grouping of the time series. It allows either a numerical matrix or a matrix consisting of strings that can be used for labelling. If the argument characters is used, then groups will be automatically generated within the function.

gnames

Specify the group names.

characters

A vector of integers, or a list containing vectors of integers, indicating the segments in which bottom level names can be read in order to construct the corresponding grouping matrix and its labels. A list class is used when a grouped time series includes one or more hierarchies. For example, a grouped time series may involve a geographical grouping and a product grouping, with each of them associated with a 2-level hierarchy. In this situation, a bottom level name such as "VICMelbAB" would indicate the state "VIC" (3 characters) followed by the city "Melb" (4 characters), then the product category "A" (1 character) followed by the sub-product category "B" (1 character). In this example, the specification of characters is list(c(3, 4), c(1, 1)), where the first element c(3, 4)corresponds to the geographical hierarchy and the second element corresponds to the product hierarchy. In the special case where there is a non-hierarchical grouped time series, a vector of integers is also possible. For example, a grouped time series may involve state, age and sex grouping variables. In this situation, a bottom level name such as "VIC1F" would indicate the state "VIC", age group "1" and sex "F". Because none of these is hierarchical, we could specify characters = list(3,1, 1), or as a simple numeric vector: characters =

gts 13

c(3, 1, 1). This implies its non-hierarchical structure and its characters segments. Again, all bottom level names must be of the same length. Currently, the use of characters only supports 2-way cross-products for grouping variables. Specifying groups is more general (but more complicated), as any combination of grouping variables can be used.

xts gts object.x gts object.

... Extra arguments passed to print and summary.

object gts object.

#### Value

bts Multivariate time series contains the bottom level series groups Information about the groups of a grouped time series labels Information about the labels that are used for plotting.

#### Author(s)

Earo Wang and Rob J Hyndman

```

14 hts

hts

Create a hierarchical time series

### **Description**

Method for creating hierarchical time series.

# Usage

```
hts(y, nodes, bnames = colnames(y), characters)
is.hts(xts)
## S3 method for class 'hts'
print(x, ...)
## S3 method for class 'hts'
summary(object, ...)
```

# **Arguments**

y A matrix or multivariate time series contain the bottom level series.

nodes A list contains the number of child nodes associated with each level, which

indicates the hierarchical structure. The default is a simple hierarchy with only 2 levels (i.e. total and bottom). If the argument characters is used, nodes will

be automatically generated within the function.

bnames The names of the bottom time series.

characters Integers indicate the segments in which the bottom level names can be read in

order to construct the corresponding node structure and its labels. For instance, suppose one of the bottom series is named "VICMelb" referring to the city of Melbourne within the state of Victoria. Then characters would be specified as c(3, 4) referring to states of 3 characters (e.g., "VIC") and cities of 4 characters (e.g., "Melb") All the bottom names must be of the same length, with number of

characters for each segment the same for all series.

xts hts object. x hts object.

... Extra arguments passed to print and summary.

object hts object.

htseg1 15

### Value

bts	Multivariate time series containing the bottom level series
nodes	Information about the nodes of a hierarchical time series
labels	Information about the labels that are used for plotting.

plot(infantgts)
```

MinT 17

MinT

Trace minimization for hierarchical or grouped time series

# **Description**

Using the method of Wickramasuriya et al. (2019), this function combines the forecasts at all levels of a hierarchical or grouped time series. The forecast.gts calls this function when the MinT method is selected.

# Usage

```
MinT(
   fcasts,
   nodes = NULL,
   groups = NULL,
   residual,
   covariance = c("shr", "sam"),
   nonnegative = FALSE,
   algorithms = c("lu", "cg", "chol"),
   keep = c("gts", "all", "bottom"),
   parallel = FALSE,
   num.cores = 2,
   control.nn = list()
)
```

# **Arguments**

fcasts	Matrix of forecasts for all levels of a hierarchical or grouped time series. Each row represents one forecast horizon and each column represents one time series of aggregated or disaggregated forecasts.
nodes	If the object class is hts, a list contains the number of child nodes referring to hts.
groups	If the object is gts, a gmatrix is required, which is the same as groups in the function gts.
residual	Matrix of insample residuals for all the aggregated and disaggregated time series. The columns must be in the same order as fcasts.
covariance	Type of the covariance matrix to be used. Shrinking towards a diagonal unequal variances ("shr") or sample covariance matrix ("sam").
nonnegative	Logical. Should the reconciled forecasts be non-negative?
algorithms	Algorithm used to compute inverse of the matrices.
keep	Return a gts object or the reconciled forecasts at the bottom level.
parallel	Logical. Import parallel package to allow parallel processing.
num.cores	Numeric. Specify how many cores are going to be used.
control.nn	A list of control parameters to be passed on to the block principal pivoting algorithm. See 'Details'.

18 MinT

#### **Details**

```
The control.nn argument is a list that can supply any of the following components: ptype Permutation method to be used: "fixed" or "random". Defaults to "fixed". par The number of full exchange rules that may be tried. Defaults to 10. gtol The tolerance of the convergence criteria. Defaults to sqrt(.Machine$double.eps).
```

#### Value

Return the reconciled gts object or forecasts at the bottom level.

plot.gts

Plot grouped or hierarchical time series

# Description

Method for plotting grouped or hierarchical time series and their forecasts.

20 plot.gts

### Usage

```
## S3 method for class 'gts'
plot(x, include, levels, labels = TRUE, col = NULL, color_lab = FALSE, ...)
```

# Arguments

X	An object of class gts.
include	Number of values from historical time series to include in the plot of forecasted group/hierarchical time series.
levels	Integer(s) or string(s) giving the specified levels(s) to be plotted
labels	If TRUE, plot the labels next to each series
col	Vector of colours, passed to plot.ts and to lines
color_lab	If TRUE, colour the direct labels to match line colours. If FALSE will be as per par()\$fg.
	Other arguments passing to plot.default

# Author(s)

 ${\it smatrix}$ 

Summing matrix for hierarchical or grouped time series

# **Description**

This function returns the summing matrix for a hierarchical or grouped time series, as defined in Hyndman et al. (2011).

### Usage

```
smatrix(xts)
```

# **Arguments**

xts

Hierarchical or grouped time series of class gts.

#### Value

A numerical matrix.

# Author(s)

Earo Wang

22 window.gts

window.gts

Time window of a gts object

# Description

Extracts a subset of the time series from a grouped time series object.

# Usage

```
## S3 method for class 'gts' window(x, ...)
```

# Arguments

x An object of class gts.

... All other arguments are passed to window.ts.

# Author(s)

Rob J Hyndman

```
window(htseg2, start = 2000, end = 2001)
```
