- The relations or indexes involved have suddenly grown in size so that they differ significantly from `min_parallel_table_scan_size` or `min_parallel_index_scan_size`.
- Recent changes have been made to `parallel_setup_cost` or `parallel_tuple_cost`.
- Recent changes have been made to `max_parallel_workers` or `max_parallel_workers_per_gather`.

## IO:BufFileRead and IO:BufFileWrite

The `IO:BufFileRead` and `IO:BufFileWrite` events occur when RDS for PostgreSQL creates temporary files. When operations require more memory than the working memory parameters currently define, they write temporary data to persistent storage. This operation is sometimes called "spilling to disk."

### Topics

- [Supported engine versions](#)
- [Context](#)
- [Likely causes of increased waits](#)
- [Actions](#)

## Supported engine versions

This wait event information is supported for all versions of RDS for PostgreSQL.

## Context

`IO:BufFileRead` and `IO:BufFileWrite` relate to the work memory area and maintenance work memory area. For more information about these local memory areas, see [Resource Consumption](#) in the PostgreSQL documentation.

The default value for `work_mem` is 4 MB. If one session performs operations in parallel, each worker handling the parallelism uses 4 MB of memory. For this reason, set `work_mem` carefully. If you increase the value too much, a database running many sessions might consume too much memory. If you set the value too low, RDS for PostgreSQL creates temporary files in local storage. The disk I/O for these temporary files can reduce performance.

If you observe the following sequence of events, your database might be generating temporary files:

1. Sudden and sharp decreases in availability
2. Fast recovery for the free space

You might also see a "chainsaw" pattern. This pattern can indicate that your database is creating small files constantly.

## Likely causes of increased waits

In general, these wait events are caused by operations that consume more memory than the `work_mem` or `maintenance_work_mem` parameters allocate. To compensate, the operations write to temporary files. Common causes for the `IO:BufFileRead` and `IO:BufFileWrite` events include the following:

### Queries that need more memory than exists in the work memory area

Queries with the following characteristics use the work memory area:

- Hash joins
- `ORDER BY` clause
- `GROUP BY` clause
- `DISTINCT`
- Window functions
- `CREATE TABLE AS SELECT`
- Materialized view refresh

## Statements that need more memory than exists in the maintenance work memory area

The following statements use the maintenance work memory area:

- CREATE INDEX
- CLUSTER

## Actions

We recommend different actions depending on the causes of your wait event.

## Topics

- [Identify the problem](#)
- [Examine your join queries](#)
- [Examine your ORDER BY and GROUP BY queries](#)
- [Avoid using the DISTINCT operation](#)
- [Consider using window functions instead of GROUP BY functions](#)
- [Investigate materialized views and CTAS statements](#)
- [Use pg\\_repack when you rebuild indexes](#)
- [Increase maintenance\\_work\\_mem when you cluster tables](#)
- [Tune memory to prevent IO:BufFileRead and IO:BufFileWrite](#)

## Identify the problem

Assume a situation in which Performance Insights isn't turned on and you suspect that IO:BufFileRead and IO:BufFileWrite are occurring more frequently than is normal. To identify the source of the problem, you can set the `log_temp_files` parameter to log all queries that generate more than your specified threshold KB of temporary files. By default, `log_temp_files` is set to `-1`, which turns off this logging feature. If you set this parameter to `0`, RDS for PostgreSQL logs all temporary files. If you set it to `1024`, RDS for PostgreSQL logs all queries that produce temporary files larger than 1 MB. For more information about `log_temp_files`, see [Error Reporting and Logging](#) in the PostgreSQL documentation.

## Examine your join queries

It's likely that your query uses joins. For example, the following query joins four tables.

```
SELECT *
  FROM "order"
 INNER JOIN order_item
  ON (order.id = order_item.order_id)
 INNER JOIN customer
  ON (customer.id = order.customer_id)
 INNER JOIN customer_address
  ON (customer_address.customer_id = customer.id AND
      order.customer_address_id = customer_address.id)
 WHERE customer.id = 1234567890;
```

A possible cause of spikes in temporary file usage is a problem in the query itself. For example, a broken clause might not filter the joins properly. Consider the second inner join in the following example.

```
SELECT *
  FROM "order"
 INNER JOIN order_item
  ON (order.id = order_item.order_id)
 INNER JOIN customer
  ON (customer.id = customer.id)
 INNER JOIN customer_address
  ON (customer_address.customer_id = customer.id AND
      order.customer_address_id = customer_address.id)
 WHERE customer.id = 1234567890;
```

The preceding query mistakenly joins `customer.id` to `customer.id`, generating a Cartesian product between every customer and every order. This type of accidental join generates large temporary files. Depending on the size of the tables, a Cartesian query can even fill up storage. Your application might have Cartesian joins when the following conditions are met:

- You see large, sharp decreases in storage availability, followed by fast recovery.
- No indexes are being created.
- No `CREATE TABLE FROM SELECT` statements are being issued.
- No materialized views are being refreshed.

To see whether the tables are being joined using the proper keys, inspect your query and object-relational mapping directives. Bear in mind that certain queries of your application are not called all the time, and some queries are dynamically generated.

## Examine your ORDER BY and GROUP BY queries

In some cases, an ORDER BY clause can result in excessive temporary files. Consider the following guidelines:

- Only include columns in an ORDER BY clause when they need to be ordered. This guideline is especially important for queries that return thousands of rows and specify many columns in the ORDER BY clause.
- Considering creating indexes to accelerate ORDER BY clauses when they match columns that have the same ascending or descending order. Partial indexes are preferable because they are smaller. Smaller indexes are read and traversed more quickly.
- If you create indexes for columns that can accept null values, consider whether you want the null values stored at the end or at the beginning of the indexes.

If possible, reduce the number of rows that need to be ordered by filtering the result set. If you use WITH clause statements or subqueries, remember that an inner query generates a result set and passes it to the outside query. The more rows that a query can filter out, the less ordering the query needs to do.

- If you don't need to obtain the full result set, use the LIMIT clause. For example, if you only want the top five rows, a query using the LIMIT clause doesn't keep generating results. In this way, the query requires less memory and temporary files.

A query that uses a GROUP BY clause can also require temporary files. GROUP BY queries summarize values by using functions such as the following:

- COUNT
- AVG
- MIN
- MAX
- SUM
- STDDEV

To tune GROUP BY queries, follow the recommendations for ORDER BY queries.

## Avoid using the DISTINCT operation

If possible, avoid using the DISTINCT operation to remove duplicated rows. The more unnecessary and duplicated rows that your query returns, the more expensive the DISTINCT operation becomes. If possible, add filters in the WHERE clause even if you use the same filters for different tables. Filtering the query and joining correctly improves your performance and reduces resource use. It also prevents incorrect reports and results.

If you need to use DISTINCT for multiple rows of a same table, consider creating a composite index. Grouping multiple columns in an index can improve the time to evaluate distinct rows. Also, if you use RDS for PostgreSQL version 10 or higher, you can correlate statistics among multiple columns by using the CREATE STATISTICS command.

## Consider using window functions instead of GROUP BY functions

Using GROUP BY, you change the result set, and then retrieve the aggregated result. Using window functions, you aggregate data without changing the result set. A window function uses the OVER clause to perform calculations across the sets defined by the query, correlating one row with another. You can use all the GROUP BY functions in window functions, but also use functions such as the following:

- RANK
- ARRAY\_AGG
- ROW\_NUMBER
- LAG
- LEAD

To minimize the number of temporary files generated by a window function, remove duplications for the same result set when you need two distinct aggregations. Consider the following query.

```
SELECT sum(salary) OVER (PARTITION BY dept ORDER BY salary DESC) as sum_salary
       , avg(salary) OVER (PARTITION BY dept ORDER BY salary ASC) as avg_salary
FROM empsalary;
```

You can rewrite the query with the WINDOW clause as follows.

```
SELECT sum(salary) OVER w as sum_salary
```

```
    , avg(salary) OVER w as_avg_salary
FROM empsalary
WINDOW w AS (PARTITION BY dept ORDER BY salary DESC);
```

By default, the RDS for PostgreSQL execution planner consolidates similar nodes so that it doesn't duplicate operations. However, by using an explicit declaration for the window block, you can maintain the query more easily. You might also improve performance by preventing duplication.

### Investigate materialized views and CTAS statements

When a materialized view refreshes, it runs a query. This query can contain an operation such as GROUP BY, ORDER BY, or DISTINCT. During a refresh, you might observe large numbers of temporary files and the wait events IO:BufFileWrite and IO:BufFileRead. Similarly, when you create a table based on a SELECT statement, the CREATE TABLE statement runs a query. To reduce the temporary files needed, optimize the query.

### Use pg\_repack when you rebuild indexes

When you create an index, the engine orders the result set. As tables grow in size, and as values in the indexed column become more diverse, the temporary files require more space. In most cases, you can't prevent the creation of temporary files for large tables without modifying the maintenance work memory area. For more information about `maintenance_work_mem`, see <https://www.postgresql.org/docs/current/runtime-config-resource.html> in the PostgreSQL documentation.

A possible workaround when recreating a large index is to use the `pg_repack` extension. For more information, see [Reorganize tables in PostgreSQL databases with minimal locks](#) in the `pg_repack` documentation. For information about setting up the extension in your RDS for PostgreSQL DB instance, see [Reducing bloat in tables and indexes with the pg\\_repack extension](#).

### Increase `maintenance_work_mem` when you cluster tables

The CLUSTER command clusters the table specified by `table_name` based on an existing index specified by `index_name`. RDS for PostgreSQL physically recreates the table to match the order of a given index.

When magnetic storage was prevalent, clustering was common because storage throughput was limited. Now that SSD-based storage is common, clustering is less popular. However, if you cluster tables, you can still increase performance slightly depending on the table size, index, query, and so on.

If you run the `CLUSTER` command and observe the wait events `IO:BufFileWrite` and `IO:BufFileRead`, tune `maintenance_work_mem`. Increase the memory size to a fairly large amount. A high value means that the engine can use more memory for the clustering operation.

### **Tune memory to prevent `IO:BufFileRead` and `IO:BufFileWrite`**

In some situations, you need to tune memory. Your goal is to balance memory across the following areas of consumption using the appropriate parameters, as follows.

- The `work_mem` value
- The memory remaining after discounting the `shared_buffers` value
- The maximum connections opened and in use, which is limited by `max_connections`

For more information about tuning memory, see [Resource Consumption](#) in the PostgreSQL documentation.

### **Increase the size of the work memory area**

In some situations, your only option is to increase the memory used by your session. If your queries are correctly written and are using the correct keys for joins, consider increasing the `work_mem` value.

To find out how many temporary files a query generates, set `log_temp_files` to `0`. If you increase the `work_mem` value to the maximum value identified in the logs, you prevent the query from generating temporary files. However, `work_mem` sets the maximum per plan node for each connection or parallel worker. If the database has 5,000 connections, and if each one uses 256 MiB memory, the engine needs 1.2 TiB of RAM. Thus, your instance might run out of memory.

### **Reserve sufficient memory for the shared buffer pool**

Your database uses memory areas such as the shared buffer pool, not just the work memory area. Consider the requirements of these additional memory areas before you increase `work_mem`.

For example, assume that your RDS for PostgreSQL instance class is `db.r5.2xlarge`. This class has 64 GiB of memory. By default, 25 percent of the memory is reserved for the shared buffer pool. After you subtract the amount allocated to the shared memory area, 16,384 MB remains. Don't allocate the remaining memory exclusively to the work memory area because the operating system and the engine also require memory.

The memory that you can allocate to `work_mem` depends on the instance class. If you use a larger instance class, more memory is available. However, in the preceding example, you can't use more than 16 GiB. Otherwise, your instance becomes unavailable when it runs out of memory. To recover the instance from the unavailable state, the RDS for PostgreSQL automation services automatically restart.

## Manage the number of connections

Suppose that your database instance has 5,000 simultaneous connections. Each connection uses at least 4 MiB of `work_mem`. The high memory consumption of the connections is likely to degrade performance. In response, you have the following options:

- Upgrade to a larger instance class.
- Decrease the number of simultaneous database connections by using a connection proxy or pooler.

For proxies, consider Amazon RDS Proxy, pgBouncer, or a connection pooler based on your application. This solution alleviates the CPU load. It also reduces the risk when all connections require the work memory area. When fewer database connections exist, you can increase the value of `work_mem`. In this way, you reduce the occurrence of the `IO:BufFileRead` and `IO:BufFileWrite` wait events. Also, the queries waiting for the work memory area speed up significantly.

## IO:DataFileRead

The `IO:DataFileRead` event occurs when a connection waits on a backend process to read a required page from storage because the page isn't available in shared memory.

### Topics

- [Supported engine versions](#)
- [Context](#)
- [Likely causes of increased waits](#)
- [Actions](#)

## Supported engine versions

This wait event information is supported for all versions of RDS for PostgreSQL.

## Context

All queries and data manipulation (DML) operations access pages in the buffer pool. Statements that can induce reads include SELECT, UPDATE, and DELETE. For example, an UPDATE can read pages from tables or indexes. If the page being requested or updated isn't in the shared buffer pool, this read can lead to the `IO:DataFileRead` event.

Because the shared buffer pool is finite, it can fill up. In this case, requests for pages that aren't in memory force the database to read blocks from disk. If the `IO:DataFileRead` event occurs frequently, your shared buffer pool might be too small to accommodate your workload. This problem is acute for SELECT queries that read a large number of rows that don't fit in the buffer pool. For more information about the buffer pool, see [Resource Consumption](#) in the PostgreSQL documentation.

## Likely causes of increased waits

Common causes for the `IO:DataFileRead` event include the following:

### Connection spikes

You might find multiple connections generating the same number of `IO:DataFileRead` wait events. In this case, a spike (sudden and large increase) in `IO:DataFileRead` events can occur.

### SELECT and DML statements performing sequential scans

Your application might be performing a new operation. Or an existing operation might change because of a new execution plan. In such cases, look for tables (particularly large tables) that have a greater `seq_scan` value. Find them by querying `pg_stat_user_tables`. To track queries that are generating more read operations, use the extension `pg_stat_statements`.

### CTAS and CREATE INDEX for large data sets

A *CTAS* is a `CREATE TABLE AS SELECT` statement. If you run a CTAS using a large data set as a source, or create an index on a large table, the `IO:DataFileRead` event can occur. When you create an index, the database might need to read the entire object using a sequential scan. A CTAS generates `IO:DataFile` reads when pages aren't in memory.

### Multiple vacuum workers running at the same time

Vacuum workers can be triggered manually or automatically. We recommend adopting an aggressive vacuum strategy. However, when a table has many updated or deleted rows,

the `IO:DataFileRead` waits increase. After space is reclaimed, the vacuum time spent on `IO:DataFileRead` decreases.

## Ingesting large amounts of data

When your application ingests large amounts of data, ANALYZE operations might occur more often. The ANALYZE process can be triggered by an autovacuum launcher or invoked manually.

The ANALYZE operation reads a subset of the table. The number of pages that must be scanned is calculated by multiplying 30 by the `default_statistics_target` value. For more information, see the [PostgreSQL documentation](#). The `default_statistics_target` parameter accepts values between 1 and 10,000, where the default is 100.

## Resource starvation

If instance network bandwidth or CPU are consumed, the `IO:DataFileRead` event might occur more frequently.

## Actions

We recommend different actions depending on the causes of your wait event.

### Topics

- [Check predicate filters for queries that generate waits](#)
- [Minimize the effect of maintenance operations](#)
- [Respond to high numbers of connections](#)

## Check predicate filters for queries that generate waits

Assume that you identify specific queries that are generating `IO:DataFileRead` wait events. You might identify them using the following techniques:

- Performance Insights
- Catalog views such as the one provided by the extension `pg_stat_statements`
- The catalog view `pg_stat_all_tables`, if it periodically shows an increased number of physical reads
- The `pg_statio_all_tables` view, if it shows that `_read` counters are increasing

We recommend that you determine which filters are used in the predicate (WHERE clause) of these queries. Follow these guidelines:

- Run the EXPLAIN command. In the output, identify which types of scans are used. A sequential scan doesn't necessarily indicate a problem. Queries that use sequential scans naturally produce more `IO:DataFileRead` events when compared to queries that use filters.

Find out whether the column listed in the WHERE clause is indexed. If not, consider creating an index for this column. This approach avoids the sequential scans and reduces the `IO:DataFileRead` events. If a query has restrictive filters and still produces sequential scans, evaluate whether the proper indexes are being used.

- Find out whether the query is accessing a very large table. In some cases, partitioning a table can improve performance, allowing the query to only read necessary partitions.
- Examine the cardinality (total number of rows) from your join operations. Note how restrictive the values are that you're passing in the filters for your WHERE clause. If possible, tune your query to reduce the number of rows that are passed in each step of the plan.

### Minimize the effect of maintenance operations

Maintenance operations such as VACUUM and ANALYZE are important. We recommend that you don't turn them off because you find `IO:DataFileRead` wait events related to these maintenance operations. The following approaches can minimize the effect of these operations:

- Run maintenance operations manually during off-peak hours. This technique prevents the database from reaching the threshold for automatic operations.
- For very large tables, consider partitioning the table. This technique reduces the overhead of maintenance operations. The database only accesses the partitions that require maintenance.
- When you ingest large amounts of data, consider disabling the autoanalyze feature.

The autovacuum feature is automatically triggered for a table when the following formula is true.

```
pg_stat_user_tables.n_dead_tup > (pg_class.reltuples x autovacuum_vacuum_scale_factor)
+ autovacuum_vacuum_threshold
```

The view `pg_stat_user_tables` and catalog `pg_class` have multiple rows. One row can correspond to one row in your table. This formula assumes that the `reltuples` are for a specific table. The parameters `autovacuum_vacuum_scale_factor` (0.20 by default) and

`autovacuum_vacuum_threshold` (50 tuples by default) are usually set globally for the whole instance. However, you can set different values for a specific table.

## Topics

- [Find tables consuming space unnecessarily](#)
- [Find indexes consuming space unnecessarily](#)
- [Find tables that are eligible to be autovacuumed](#)

### Find tables consuming space unnecessarily

To find tables consuming space unnecessarily, you can use functions from the PostgreSQL `pgstattuple` extension. This extension (module) is available by default on all RDS for PostgreSQL DB instances and can be instantiated on the instance with the following command.

```
CREATE EXTENSION pgstattuple;
```

For more information about this extension, see [pgstattuple](#) in the PostgreSQL documentation.

You can check for table and index bloat in your application. For more information, see [Diagnosing table and index bloat](#).

### Find indexes consuming space unnecessarily

To find bloated indexes and estimate the amount of space consumed unnecessarily on the tables for which you have read privileges, you can run the following query.

```
-- WARNING: rows with is_na = 't' are known to have bad statistics ("name" type is not
supported).
-- This query is compatible with PostgreSQL 8.2 and later.

SELECT current_database(), nspname AS schemaname, tblname, idxname,
bs*(relpages)::bigint AS real_size,
bs*(relpages-est_pages)::bigint AS extra_size,
100 * (relpages-est_pages)::float / relpages AS extra_ratio,
fillfactor, bs*(relpages-est_pages_ff) AS bloat_size,
100 * (relpages-est_pages_ff)::float / relpages AS bloat_ratio,
is_na
-- , 100-(sub.pst).avg_leaf_density, est_pages, index_tuple_hdr_bm,
-- maxalign, pagehdr, nulldatawidth, nulldatahdrwidth, sub.reltuples, sub.relpages

AND (
  age(relfrozenxid) >= coalesce(cfma.value::float, autovacuum_freeze_max_age::float)
  or
  coalesce(cvbt.value::float, autovacuum_vacuum_threshold::float) +
```

```
        coalesce(cvsf.value::float,autovacuum_vacuum_scale_factor::float) * c.reltuples
    <= n_dead_tup
        -- or 1 = 1
    )
ORDER BY age(relfrozenxid) DESC;
```

## Respond to high numbers of connections

When you monitor Amazon CloudWatch, you might find that the DatabaseConnections metric spikes. This increase indicates an increased number of connections to your database. We recommend the following approach:

- Limit the number of connections that the application can open with each instance. If your application has an embedded connection pool feature, set a reasonable number of connections. Base the number on what the vCPUs in your instance can parallelize effectively.

If your application doesn't use a connection pool feature, considering using Amazon RDS Proxy or an alternative. This approach lets your application open multiple connections with the load balancer. The balancer can then open a restricted number of connections with the database. As fewer connections are running in parallel, your DB instance performs less context switching in the kernel. Queries should progress faster, leading to fewer wait events. For more information, see [Using Amazon RDS Proxy](#).

- Whenever possible, take advantage of read replicas for RDS for PostgreSQL. When your application runs a read-only operation, send these requests to the read replica(s). This technique reduces the I/O pressure on the primary (writer) node.
- Consider scaling up your DB instance. A higher-capacity instance class gives more memory, which gives RDS for PostgreSQL a larger shared buffer pool to hold pages. The larger size also gives the DB instance more vCPUs to handle connections. More vCPUs are particularly helpful when the operations that are generating IO:DataFileRead wait events are writes.

## IO:WALWrite

### Topics

- [Supported engine versions](#)
- [Context](#)
- [Likely causes of increased waits](#)

- [Actions](#)

## Supported engine versions

This wait event information is supported for all versions of RDS for PostgreSQL 10 and higher.

## Context

Activity in the database that's generating write-ahead log data fills up the WAL buffers first and then writes to disk, asynchronously. The wait event `IO:WALWrite` is generated when the SQL session is waiting for the WAL data to complete writing to disk so that it can release the transaction's COMMIT call.

## Likely causes of increased waits

If this wait event occurs often, you should review your workload and the type of updates that your workload performs and their frequency. In particular, look for the following types of activity.

### Heavy DML activity

Changing data in database tables doesn't happen instantaneously. An insert to one table might need to wait for an insert or an update to the same table from another client. The data manipulation language (DML) statements for changing data values (INSERT, UPDATE, DELETE, COMMIT, ROLLBACK TRANSACTION) can result in contention that causes the write-ahead logfile to be waiting for the buffers to be flushed. This situation is captured in the following Amazon RDS Performance Insights metrics that indicate heavy DML activity.

- `tup_inserted`
- `tup_updated`
- `tup_deleted`
- `xact_rollback`
- `xact_commit`

For more information about these metrics, see [Performance Insights counters for Amazon RDS for PostgreSQL](#).

## Frequent checkpoint activity

Frequent checkpoints contribute to larger WAL size. In RDS for PostgreSQL, full page writes are always "on." Full page writes help protect against data loss. However, when checkpointing occurs too frequently, the system can suffer overall performance issues. This is especially true on systems with heavy DML activity. In some cases, you might find error messages in your `postgresql.log` stating that "checkpoints are occurring too frequently."

We recommend that when tuning checkpoints, you carefully balance performance against expected time need to recover in the event of an abnormal shutdown.

## Actions

We recommend the following actions to reduce the numbers of this wait event.

### Topics

- [Reduce the number of commits](#)
- [Monitor your checkpoints](#)
- [Scale up IO](#)
- [Dedicated log volume \(DLV\)](#)

### Reduce the number of commits

To reduce the number of commits, you can combine statements into transaction blocks. Use Amazon RDS Performance Insights to examine the type of queries being run. You can also move large maintenance operations to off-peak hours. For example, create indexes or use `pg_repack` operations during non-production hours.

### Monitor your checkpoints

There are two parameters that you can monitor to see how frequently your RDS for PostgreSQL DB instance is writing to the WAL file for checkpoints.

- `log_checkpoints` – This parameter is set to "on" by default. It causes a message to get sent to the PostgreSQL log for each checkpoint. These log messages include the number of buffers written, the time spent writing them, and the number of WAL files added, removed, or recycled for the given checkpoint.

For more information about this parameter, see [Error Reporting and Logging](#) in the PostgreSQL documentation.

- `checkpoint_warning` – This parameter sets a threshold value (in seconds) for checkpoint frequency above which a warning is generated. By default, this parameter isn't set in RDS for PostgreSQL. You can set the value of this parameter to get a warning when the database changes in your RDS for PostgreSQL DB instance are written at a rate for which the WAL files are not sized to handle. For example, say you set this parameter to 30. If your RDS for PostgreSQL instance needs to write changes more often than every 30 seconds, the warning that "checkpoints are occurring too frequently" is sent to the PostgreSQL log. This can indicate that your `max_wal_size` value should be increased.

For more information, see [Write Ahead Log](#) in the PostgreSQL documentation.

## Scale up IO

This type of input/output (IO) wait event can be remediated by scaling the input/output operations per second (IOPs) to provide faster IO. Scaling IO is preferable to scaling CPU, because scaling CPU can result in even more IO contention because the increased CPU can handle more work and thus make the IO bottleneck even worse. In general, we recommend that you consider tuning your workload before performing scaling operations.

## Dedicated log volume (DLV)

You can use a dedicated log volume (DLV) for a DB instance that uses Provisioned IOPS (PIOPS) storage by using the Amazon RDS console, AWS CLI, or Amazon RDS API. A DLV moves PostgreSQL database transaction logs to a storage volume that's separate from the volume containing the database tables. For more information, see [Dedicated log volume \(DLV\)](#).

## Lock:advisory

The `Lock:advisory` event occurs when a PostgreSQL application uses a lock to coordinate activity across multiple sessions.

### Topics

- [Relevant engine versions](#)
- [Context](#)
- [Causes](#)

- [Actions](#)

## Relevant engine versions

This wait event information is relevant for RDS for PostgreSQL versions 9.6 and higher.

## Context

PostgreSQL advisory locks are application-level, cooperative locks explicitly locked and unlocked by the user's application code. An application can use PostgreSQL advisory locks to coordinate activity across multiple sessions. Unlike regular, object- or row-level locks, the application has full control over the lifetime of the lock. For more information, see [Advisory Locks](#) in the PostgreSQL documentation.

Advisory locks can be released before a transaction ends or be held by a session across transactions. This isn't true for implicit, system-enforced locks, such as an access-exclusive lock on a table acquired by a `CREATE INDEX` statement.

For a description of the functions used to acquire (lock) and release (unlock) advisory locks, see [Advisory Lock Functions](#) in the PostgreSQL documentation.

Advisory locks are implemented on top of the regular PostgreSQL locking system and are visible in the `pg_locks` system view.

## Causes

This lock type is exclusively controlled by an application explicitly using it. Advisory locks that are acquired for each row as part of a query can cause a spike in locks or a long-term buildup.

These effects happen when the query is run in a way that acquires locks on more rows than are returned by the query. The application must eventually release every lock, but if locks are acquired on rows that aren't returned, the application can't find all of the locks.

The following example is from [Advisory Locks](#) in the PostgreSQL documentation.

```
SELECT pg_advisory_lock(id) FROM foo WHERE id > 12345 LIMIT 100;
```

In this example, the `LIMIT` clause can only stop the query's output after the rows have already been internally selected and their ID values locked. This can happen suddenly when a growing

data volume causes the planner to choose a different execution plan that wasn't tested during development. The buildup in this case happens because the application explicitly calls `pg_advisory_unlock` for every ID value that was locked. However, in this case it can't find the set of locks acquired on rows that weren't returned. Because the locks are acquired on the session level, they aren't released automatically at the end of the transaction.

Another possible cause for spikes in blocked lock attempts is unintended conflicts. In these conflicts, unrelated parts of the application share the same lock ID space by mistake.

## Actions

Review application usage of advisory locks and detail where and when in the application flow each type of advisory lock is acquired and released.

Determine whether a session is acquiring too many locks or a long-running session isn't releasing locks early enough, leading to a slow buildup of locks. You can correct a slow buildup of session-level locks by ending the session using `pg_terminate_backend(pid)`.

A client waiting for an advisory lock appears in `pg_stat_activity` with `wait_event_type=Lock` and `wait_event=advisory`. You can obtain specific lock values by querying the `pg_locks` system view for the same `pid`, looking for `locktype=advisory` and `granted=f`.

You can then identify the blocking session by querying `pg_locks` for the same advisory lock having `granted=t`, as shown in the following example.

```
SELECT blocked_locks.pid AS blocked_pid,
       blocking_locks.pid AS blocking_pid,
       blocked_activity.username AS blocked_user,
       blocking_activity.username AS blocking_user,
       now() - blocked_activity.xact_start AS blocked_transaction_duration,
       now() - blocking_activity.xact_start AS blocking_transaction_duration,
       concat(blocked_activity.wait_event_type, ':', blocked_activity.wait_event) AS
blocked_wait_event,
       concat(blocking_activity.wait_event_type, ':', blocking_activity.wait_event) AS
blocking_wait_event,
       blocked_activity.state AS blocked_state,
       blocking_activity.state AS blocking_state,
       blocked_locks.locktype AS blocked_locktype,
       blocking_locks.locktype AS blocking_locktype,
       blocked_activity.query AS blocked_statement,
```

```

        blocking_activity.query AS blocking_statement
FROM pg_catalog.pg_locks blocked_locks
JOIN pg_catalog.pg_stat_activity blocked_activity ON blocked_activity.pid =
blocked_locks.pid
JOIN pg_catalog.pg_locks blocking_locks
    ON blocking_locks.locktype = blocked_locks.locktype
    AND blocking_locks.DATABASE IS NOT DISTINCT FROM blocked_locks.DATABASE
    AND blocking_locks.relation IS NOT DISTINCT FROM blocked_locks.relation
    AND blocking_locks.page IS NOT DISTINCT FROM blocked_locks.page
    AND blocking_locks.tuple IS NOT DISTINCT FROM blocked_locks.tuple
    AND blocking_locks.virtualxid IS NOT DISTINCT FROM blocked_locks.virtualxid
    AND blocking_locks.transactionid IS NOT DISTINCT FROM
blocked_locks.transactionid
    AND blocking_locks.classid IS NOT DISTINCT FROM blocked_locks.classid
    AND blocking_locks.objid IS NOT DISTINCT FROM blocked_locks.objid
    AND blocking_locks.objsubid IS NOT DISTINCT FROM blocked_locks.objsubid
    AND blocking_locks.pid != blocked_locks.pid
JOIN pg_catalog.pg_stat_activity blocking_activity ON blocking_activity.pid =
blocking_locks.pid
WHERE NOT blocked_locks.GRANTED;

```

All of the advisory lock API functions have two sets of arguments, either one bigint argument or two integer arguments:

- For the API functions with one bigint argument, the upper 32 bits are in `pg_locks.classid` and the lower 32 bits are in `pg_locks.objid`.
- For the API functions with two integer arguments, the first argument is `pg_locks.classid` and the second argument is `pg_locks.objid`.

The `pg_locks.objsubid` value indicates which API form was used: 1 means one bigint argument; 2 means two integer arguments.

## Lock:extend

The `Lock:extend` event occurs when a backend process is waiting to lock a relation to extend it while another process has a lock on that relation for the same purpose.

### Topics

- [Supported engine versions](#)
- [Context](#)

- [Likely causes of increased waits](#)
- [Actions](#)

## Supported engine versions

This wait event information is supported for all versions of RDS for PostgreSQL.

## Context

The event `Lock : extend` indicates that a backend process is waiting to extend a relation that another backend process holds a lock on while it's extending that relation. Because only one process at a time can extend a relation, the system generates a `Lock : extend` wait event. `INSERT`, `COPY`, and `UPDATE` operations can generate this event.

## Likely causes of increased waits

When the `Lock : extend` event appears more than normal, possibly indicating a performance problem, typical causes include the following:

### Surge in concurrent inserts or updates to the same table

There might be an increase in the number of concurrent sessions with queries that insert into or update the same table.

### Insufficient network bandwidth

The network bandwidth on the DB instance might be insufficient for the storage communication needs of the current workload. This can contribute to storage latency that causes an increase in `Lock : extend` events.

## Actions

We recommend different actions depending on the causes of your wait event.

## Topics

- [Reduce concurrent inserts and updates to the same relation](#)
- [Increase network bandwidth](#)

## Reduce concurrent inserts and updates to the same relation

First, determine whether there's an increase in `tup_inserted` and `tup_updated` metrics and an accompanying increase in this wait event. If so, check which relations are in high contention for insert and update operations. To determine this, query the `pg_stat_all_tables` view for the values in `n_tup_ins` and `n_tup_upd` fields. For information about the `pg_stat_all_tables` view, see [pg\\_stat\\_all\\_tables](#) in the PostgreSQL documentation.

To get more information about blocking and blocked queries, query `pg_stat_activity` as in the following example:

```
SELECT
    blocked.pid,
    blocked.username,
    blocked.query,
    blocking.pid AS blocking_id,
    blocking.query AS blocking_query,
    blocking.wait_event AS blocking_wait_event,
    blocking.wait_event_type AS blocking_wait_event_type
FROM pg_stat_activity AS blocked
JOIN pg_stat_activity AS blocking ON blocking.pid = ANY(pg_blocking_pids(blocked.pid))
where
blocked.wait_event = 'extend'
and blocked.wait_event_type = 'Lock';
```

pid	username	query	blocking_id	blocking_query	blocking_wait_event	blocking_wait_event_type
7143	myuser	insert into tab1 values (1);	4600	INSERT INTO tab1 (a)	DataFileExtend	IO

After you identify relations that contribute to increase `Lock:extend` events, use the following techniques to reduce the contention:

- Find out whether you can use partitioning to reduce contention for the same table. Separating inserted or updated tuples into different partitions can reduce contention. For information about partitioning, see [Managing PostgreSQL partitions with the pg\\_partman extension](#).

- If the wait event is mainly due to update activity, consider reducing the relation's fillfactor value. This can reduce requests for new blocks during the update. The fillfactor is a storage parameter for a table that determines the maximum amount of space for packing a table page. It's expressed as a percentage of the total space for a page. For more information about the fillfactor parameter, see [CREATE TABLE](#) in the PostgreSQL documentation.

### Important

We highly recommend that you test your system if you change the fillfactor because changing this value can negatively impact performance, depending on your workload.

## Increase network bandwidth

To see whether there's an increase in write latency, check the WriteLatency metric in CloudWatch. If there is, use the WriteThroughput and ReadThroughput Amazon CloudWatch metrics to monitor the storage related traffic on the DB instance. These metrics can help you to determine if network bandwidth is sufficient for the storage activity of your workload.

If your network bandwidth isn't enough, increase it. If your DB instance is reaching the network bandwidth limits, the only way to increase the bandwidth is to increase your DB instance size.

For more information about CloudWatch metrics, see [Amazon CloudWatch instance-level metrics for Amazon RDS](#). For information about network performance for each DB instance class, see [Amazon CloudWatch instance-level metrics for Amazon RDS](#).

## Lock:Relation

The Lock:Relation event occurs when a query is waiting to acquire a lock on a table or view (relation) that's currently locked by another transaction.

### Topics

- [Supported engine versions](#)
- [Context](#)
- [Likely causes of increased waits](#)
- [Actions](#)

## Supported engine versions

This wait event information is supported for all versions of RDS for PostgreSQL.

### Context

Most PostgreSQL commands implicitly use locks to control concurrent access to data in tables. You can also use these locks explicitly in your application code with the `LOCK` command. Many lock modes aren't compatible with each other, and they can block transactions when they're trying to access the same object. When this happens, RDS for PostgreSQL generates a `Lock:Relation` event. Some common examples are the following:

- Exclusive locks such as `ACCESS EXCLUSIVE` can block all concurrent access. Data definition language (DDL) operations such as `DROP TABLE`, `TRUNCATE`, `VACUUM FULL`, and `CLUSTER` acquire `ACCESS EXCLUSIVE` locks implicitly. `ACCESS EXCLUSIVE` is also the default lock mode for `LOCK TABLE` statements that don't specify a mode explicitly.
- Using `CREATE INDEX (without CONCURRENT)` on a table conflicts with data manipulation language (DML) statements `UPDATE`, `DELETE`, and `INSERT`, which acquire `ROW EXCLUSIVE` locks.

For more information about table-level locks and conflicting lock modes, see [Explicit Locking](#) in the PostgreSQL documentation.

Blocking queries and transactions typically unblock in one of the following ways:

- Blocking query – The application can cancel the query or the user can end the process. The engine can also force the query to end because of a session's statement-timeout or a deadlock detection mechanism.
- Blocking transaction – A transaction stops blocking when it runs a `ROLLBACK` or `COMMIT` statement. Rollbacks also happen automatically when sessions are disconnected by a client or by network issues, or are ended. Sessions can be ended when the database engine is shut down, when the system is out of memory, and so forth.

### Likely causes of increased waits

When the `Lock:Relation` event occurs more frequently than normal, it can indicate a performance issue. Typical causes include the following:

## Increased concurrent sessions with conflicting table locks

There might be an increase in the number of concurrent sessions with queries that lock the same table with conflicting locking modes.

### Maintenance operations

Health maintenance operations such as VACUUM and ANALYZE can significantly increase the number of conflicting locks. VACUUM FULL acquires an ACCESS EXCLUSIVE lock, and ANALYZE acquires a SHARE UPDATE EXCLUSIVE lock. Both types of locks can cause a Lock:Relation wait event. Application data maintenance operations such as refreshing a materialized view can also increase blocked queries and transactions.

### Locks on reader instances

There might be a conflict between the relation locks held by the writer and readers. Currently, only ACCESS EXCLUSIVE relation locks are replicated to reader instances. However, the ACCESS EXCLUSIVE relation lock will conflict with any ACCESS SHARE relation locks held by the reader. This can cause an increase in lock relation wait events on the reader.

## Actions

We recommend different actions depending on the causes of your wait event.

### Topics

- [Reduce the impact of blocking SQL statements](#)
- [Minimize the effect of maintenance operations](#)

### Reduce the impact of blocking SQL statements

To reduce the impact of blocking SQL statements, modify your application code where possible. Following are two common techniques for reducing blocks:

- Use the NOWAIT option – Some SQL commands, such as SELECT and LOCK statements, support this option. The NOWAIT directive cancels the lock-requesting query if the lock can't be acquired immediately. This technique can help prevent a blocking session from causing a pile-up of blocked sessions behind it.

For example: Assume that transaction A is waiting on a lock held by transaction B. Now, if B requests a lock on a table that's locked by transaction C, transaction A might be blocked until

transaction C completes. But if transaction B uses a NOWAIT when it requests the lock on C, it can fail fast and ensure that transaction A doesn't have to wait indefinitely.

- Use `SET lock_timeout` – Set a `lock_timeout` value to limit the time a SQL statement waits to acquire a lock on a relation. If the lock isn't acquired within the timeout specified, the transaction requesting the lock is cancelled. Set this value at the session level.

## Minimize the effect of maintenance operations

Maintenance operations such as VACUUM and ANALYZE are important. We recommend that you don't turn them off because you find `Lock:Relation` wait events related to these maintenance operations. The following approaches can minimize the effect of these operations:

- Run maintenance operations manually during off-peak hours.
- To reduce `Lock:Relation` waits caused by autovacuum tasks, perform any needed autovacuum tuning. For information about tuning autovacuum, see [Working with PostgreSQL autovacuum on Amazon RDS](#) in the *Amazon RDS User Guide*.

## Lock:transactionid

The `Lock:transactionid` event occurs when a transaction is waiting for a row-level lock.

### Topics

- [Supported engine versions](#)
- [Context](#)
- [Likely causes of increased waits](#)
- [Actions](#)

## Supported engine versions

This wait event information is supported for all versions of RDS for PostgreSQL.

## Context

The event `Lock:transactionid` occurs when a transaction is trying to acquire a row-level lock that has already been granted to a transaction that is running at the same time. The session that

shows the `Lock:transactionid` wait event is blocked because of this lock. After the blocking transaction ends in either a `COMMIT` or `ROLLBACK` statement, the blocked transaction can proceed.

The multiversion concurrency control semantics of RDS for PostgreSQL guarantee that readers don't block writers and writers don't block readers. For row-level conflicts to occur, blocking and blocked transactions must issue conflicting statements of the following types:

- `UPDATE`
- `SELECT ... FOR UPDATE`
- `SELECT ... FOR KEY SHARE`

The statement `SELECT ... FOR KEY SHARE` is a special case. The database uses the clause `FOR KEY SHARE` to optimize the performance of referential integrity. A row-level lock on a row can block `INSERT`, `UPDATE`, and `DELETE` commands on other tables that reference the row.

## Likely causes of increased waits

When this event appears more than normal, the cause is typically `UPDATE`, `SELECT ... FOR UPDATE`, or `SELECT ... FOR KEY SHARE` statements combined with the following conditions.

### Topics

- [High concurrency](#)
- [Idle in transaction](#)
- [Long-running transactions](#)

### High concurrency

RDS for PostgreSQL can use granular row-level locking semantics. The probability of row-level conflicts increases when the following conditions are met:

- A highly concurrent workload contends for the same rows.
- Concurrency increases.

### Idle in transaction

Sometimes the `pg_stat_activity.state` column shows the value `idle in transaction`. This value appears for sessions that have started a transaction, but haven't yet issued a `COMMIT`

or ROLLBACK. If the `pg_stat_activity.state` value isn't active, the query shown in `pg_stat_activity` is the most recent one to finish running. The blocking session isn't actively processing a query because an open transaction is holding a lock.

If an idle transaction acquired a row-level lock, it might be preventing other sessions from acquiring it. This condition leads to frequent occurrence of the wait event `Lock:transactionid`. To diagnose the issue, examine the output from `pg_stat_activity` and `pg_locks`.

## Long-running transactions

Transactions that run for a long time get locks for a long time. These long-held locks can block other transactions from running.

## Actions

Row-locking is a conflict among UPDATE, SELECT ... FOR UPDATE, or SELECT ... FOR KEY SHARE statements. Before attempting a solution, find out when these statements are running on the same row. Use this information to choose a strategy described in the following sections.

## Topics

- [Respond to high concurrency](#)
- [Respond to idle transactions](#)
- [Respond to long-running transactions](#)

## Respond to high concurrency

If concurrency is the issue, try one of the following techniques:

- Lower the concurrency in the application. For example, decrease the number of active sessions.
- Implement a connection pool. To learn how to pool connections with RDS Proxy, see [Using Amazon RDS Proxy](#).
- Design the application or data model to avoid contending UPDATE and SELECT ... FOR UPDATE statements. You can also decrease the number of foreign keys accessed by SELECT ... FOR KEY SHARE statements.

## Respond to idle transactions

If `pg_stat_activity.state` shows `idle in transaction`, use the following strategies:

- Turn on autocommit wherever possible. This approach prevents transactions from blocking other transactions while waiting for a COMMIT or ROLLBACK.
- Search for code paths that are missing COMMIT, ROLLBACK, or END.
- Make sure that the exception handling logic in your application always has a path to a valid end of transaction.
- Make sure that your application processes query results after ending the transaction with COMMIT or ROLLBACK.

## Respond to long-running transactions

If long-running transactions are causing the frequent occurrence of `Lock:transactionid`, try the following strategies:

- Keep row locks out of long-running transactions.
- Limit the length of queries by implementing autocommit whenever possible.

## Lock:tuple

The `Lock:tuple` event occurs when a backend process is waiting to acquire a lock on a tuple.

### Topics

- [Supported engine versions](#)
- [Context](#)
- [Likely causes of increased waits](#)
- [Actions](#)

## Supported engine versions

This wait event information is supported for all versions of RDS for PostgreSQL.

### Context

The event `Lock:tuple` indicates that a backend is waiting to acquire a lock on a tuple while another backend holds a conflicting lock on the same tuple. The following table illustrates a scenario in which sessions generate the `Lock:tuple` event.

Time	Session 1	Session 2	Session 3
t1	Starts a transaction.		
t2	Updates row 1.		
t3		Updates row 1. The session acquires an exclusive lock on the tuple and then waits for session 1 to release the lock by committing or rolling back.	
t4			Updates row 1. The session waits for session 2 to release the exclusive lock on the tuple.

Or you can simulate this wait event by using the benchmarking tool `pgbench`. Configure a high number of concurrent sessions to update the same row in a table with a custom SQL file.

To learn more about conflicting lock modes, see [Explicit Locking](#) in the PostgreSQL documentation. To learn more about `pgbench`, see [pgbench](#) in the PostgreSQL documentation.

## Likely causes of increased waits

When this event appears more than normal, possibly indicating a performance problem, typical causes include the following:

- A high number of concurrent sessions are trying to acquire a conflicting lock for the same tuple by running `UPDATE` or `DELETE` statements.
- Highly concurrent sessions are running a `SELECT` statement using the `FOR UPDATE` or `FOR NO KEY UPDATE` lock modes.
- Various factors drive application or connection pools to open more sessions to execute the same operations. As new sessions are trying to modify the same rows, DB load can spike, and `Lock:tuple` can appear.

For more information, see [Row-Level Locks](#) in the PostgreSQL documentation.

## Actions

We recommend different actions depending on the causes of your wait event.

### Topics

- [Investigate your application logic](#)
- [Find the blocker session](#)
- [Reduce concurrency when it is high](#)
- [Troubleshoot bottlenecks](#)

### Investigate your application logic

Find out whether a blocker session has been in the `idle in transaction` state for long time. If so, consider ending the blocker session as a short-term solution. You can use the `pg_terminate_backend` function. For more information about this function, see [Server Signaling Functions](#) in the PostgreSQL documentation.

For a long-term solution, do the following:

- Adjust the application logic.
- Use the `idle_in_transaction_session_timeout` parameter. This parameter ends any session with an open transaction that has been idle for longer than the specified amount of time. For more information, see [Client Connection Defaults](#) in the PostgreSQL documentation.
- Use autocommit as much as possible. For more information, see [SET AUTOCOMMIT](#) in the PostgreSQL documentation.

### Find the blocker session

While the `Lock:tuple` wait event is occurring, identify the blocker and blocked session by finding out which locks depend on one another. For more information, see [Lock dependency information](#) in the PostgreSQL wiki.

The following example queries all sessions, filtering on `tuple` and ordering by `wait_time`.

```
SELECT blocked_locks.pid AS blocked_pid,  
       blocking_locks.pid AS blocking_pid,  
       blocked_activity.username AS blocked_user,
```

```

        blocking_activity.username AS blocking_user,
        now() - blocked_activity.xact_start AS blocked_transaction_duration,
        now() - blocking_activity.xact_start AS blocking_transaction_duration,
        concat(blocked_activity.wait_event_type, ':', blocked_activity.wait_event) AS
blocked_wait_event,
        concat(blocking_activity.wait_event_type, ':', blocking_activity.wait_event) AS
blocking_wait_event,
        blocked_activity.state AS blocked_state,
        blocking_activity.state AS blocking_state,
        blocked_locks.locktype AS blocked_locktype,
        blocking_locks.locktype AS blocking_locktype,
        blocked_activity.query AS blocked_statement,
        blocking_activity.query AS blocking_statement
FROM pg_catalog.pg_locks blocked_locks
JOIN pg_catalog.pg_stat_activity blocked_activity ON blocked_activity.pid =
blocked_locks.pid
JOIN pg_catalog.pg_locks blocking_locks
ON blocking_locks.locktype = blocked_locks.locktype
AND blocking_locks.DATABASE IS NOT DISTINCT FROM blocked_locks.DATABASE
AND blocking_locks.relation IS NOT DISTINCT FROM blocked_locks.relation
AND blocking_locks.page IS NOT DISTINCT FROM blocked_locks.page
AND blocking_locks.tuple IS NOT DISTINCT FROM blocked_locks.tuple
AND blocking_locks.virtualxid IS NOT DISTINCT FROM blocked_locks.virtualxid
AND blocking_locks.transactionid IS NOT DISTINCT FROM
blocked_locks.transactionid
AND blocking_locks.classid IS NOT DISTINCT FROM blocked_locks.classid
AND blocking_locks.objid IS NOT DISTINCT FROM blocked_locks.objid
AND blocking_locks.objsubid IS NOT DISTINCT FROM blocked_locks.objsubid
AND blocking_locks.pid != blocked_locks.pid
JOIN pg_catalog.pg_stat_activity blocking_activity ON blocking_activity.pid =
blocking_locks.pid
WHERE NOT blocked_locks.GRANTED;

```

## Reduce concurrency when it is high

The `Lock:tuple` event might occur constantly, especially in a busy workload time. In this situation, consider reducing the high concurrency for very busy rows. Often, just a few rows control a queue or the Boolean logic, which makes these rows very busy.

You can reduce concurrency by using different approaches based in the business requirement, application logic, and workload type. For example, you can do the following:

- Redesign your table and data logic to reduce high concurrency.

- Change the application logic to reduce high concurrency at the row level.
- Leverage and redesign queries with row-level locks.
- Use the NOWAIT clause with retry operations.
- Consider using optimistic and hybrid-locking logic concurrency control.
- Consider changing the database isolation level.

## Troubleshoot bottlenecks

The `Lock:tuple` can occur with bottlenecks such as CPU starvation or maximum usage of Amazon EBS bandwidth. To reduce bottlenecks, consider the following approaches:

- Scale up your instance class type.
- Optimize resource-intensive queries.
- Change the application logic.
- Archive data that is rarely accessed.

## LWLock:BufferMapping (LWLock:buffer\_mapping)

This event occurs when a session is waiting to associate a data block with a buffer in the shared buffer pool.

### Note

This event is named `LWLock:BufferMapping` for RDS for PostgreSQL version 13 and higher versions. For RDS for PostgreSQL version 12 and older versions, this event is named `LWLock:buffer_mapping`.

## Topics

- [Supported engine versions](#)
- [Context](#)
- [Causes](#)
- [Actions](#)

## Supported engine versions

This wait event information is relevant for RDS for PostgreSQL version 9.6 and higher.

### Context

The *shared buffer pool* is a PostgreSQL memory area that holds all pages that are or were being used by processes. When a process needs a page, it reads the page into the shared buffer pool. The `shared_buffers` parameter sets the shared buffer size and reserves a memory area to store the table and index pages. If you change this parameter, make sure to restart the database. .

The `LWLock:buffer_mapping` wait event occurs in the following scenarios:

- A process searches the buffer table for a page and acquires a shared buffer mapping lock.
- A process loads a page into the buffer pool and acquires an exclusive buffer mapping lock.
- A process removes a page from the pool and acquires an exclusive buffer mapping lock.

### Causes

When this event appears more than normal, possibly indicating a performance problem, the database is paging in and out of the shared buffer pool. Typical causes include the following:

- Large queries
- Bloated indexes and tables
- Full table scans
- A shared pool size that is smaller than the working set

### Actions

We recommend different actions depending on the causes of your wait event.

### Topics

- [Monitor buffer-related metrics](#)
- [Assess your indexing strategy](#)
- [Reduce the number of buffers that must be allocated quickly](#)

## Monitor buffer-related metrics

When `LWLock:buffer_mapping` waits spike, investigate the buffer hit ratio. You can use these metrics to get a better understanding of what is happening in the buffer cache. Examine the following metrics:

### `blks_hit`

This Performance Insights counter metric indicates the number of blocks that were retrieved from the shared buffer pool. After the `LWLock:buffer_mapping` wait event appears, you might observe a spike in `blks_hit`.

### `blks_read`

This Performance Insights counter metric indicates the number of blocks that required I/O to be read into the shared buffer pool. You might observe a spike in `blks_read` in the lead-up to the `LWLock:buffer_mapping` wait event.

## Assess your indexing strategy

To confirm that your indexing strategy is not degrading performance, check the following:

### Index bloat

Ensure that index and table bloat aren't leading to unnecessary pages being read into the shared buffer. If your tables contain unused rows, consider archiving the data and removing the rows from the tables. You can then rebuild the indexes for the resized tables.

### Indexes for frequently used queries

To determine whether you have the optimal indexes, monitor DB engine metrics in Performance Insights. The `tup_returned` metric shows the number of rows read. The `tup_fetched` metric shows the number of rows returned to the client. If `tup_returned` is significantly larger than `tup_fetched`, the data might not be properly indexed. Also, your table statistics might not be current.

## Reduce the number of buffers that must be allocated quickly

To reduce the `LWLock:buffer_mapping` wait events, try to reduce the number of buffers that must be allocated quickly. One strategy is to perform smaller batch operations. You might be able to achieve smaller batches by partitioning your tables.

## LWLock:BufferIO (IPC:BufferIO)

The `LWLock:BufferIO` event occurs when RDS for PostgreSQL is waiting for other processes to finish their input/output (I/O) operations when concurrently trying to access a page. Its purpose is for the same page to be read into the shared buffer.

### Topics

- [Relevant engine versions](#)
- [Context](#)
- [Causes](#)
- [Actions](#)

### Relevant engine versions

This wait event information is relevant for all RDS for PostgreSQL versions. For RDS for PostgreSQL 12 and earlier versions this wait event is named as `lwlock:buffer_io` whereas in RDS for PostgreSQL 13 version it is named as `lwlock:bufferio`. From RDS for PostgreSQL 14 version `BufferIO` wait event moved from `LWLock` to `IPC` wait event type (`IPC:BufferIO`).

### Context

Each shared buffer has an I/O lock that is associated with the `LWLock:BufferIO` wait event, each time a block (or a page) has to be retrieved outside the shared buffer pool.

This lock is used to handle multiple sessions that all require access to the same block. This block has to be read from outside the shared buffer pool, defined by the `shared_buffers` parameter.

As soon as the page is read inside the shared buffer pool, the `LWLock:BufferIO` lock is released.

#### Note

The `LWLock:BufferIO` wait event precedes the [IO:DataFileRead](#) wait event. The `IO:DataFileRead` wait event occurs while data is being read from storage.

For more information on lightweight locks, see [Locking Overview](#).

## Causes

Common causes for the `LWLock:BufferIO` event to appear in top waits include the following:

- Multiple backends or connections trying to access the same page that's also pending an I/O operation
- The ratio between the size of the shared buffer pool (defined by the `shared_buffers` parameter) and the number of buffers needed by the current workload
- The size of the shared buffer pool not being well balanced with the number of pages being evicted by other operations
- Large or bloated indexes that require the engine to read more pages than necessary into the shared buffer pool
- Lack of indexes that forces the DB engine to read more pages from the tables than necessary
- Checkpoints occurring too frequently or needing to flush too many modified pages
- Sudden spikes for database connections trying to perform operations on the same page

## Actions

We recommend different actions depending on the causes of your wait event:

- Observe Amazon CloudWatch metrics for correlation between sharp decreases in the `BufferCacheHitRatio` and `LWLock:BufferIO` wait events. This effect can mean that you have a small `shared_buffers` setting. You might need to increase it or scale up your DB instance class. You can split your workload into more reader nodes.
- Tune `max_wal_size` and `checkpoint_timeout` based on your workload peak time if you see `LWLock:BufferIO` coinciding with `BufferCacheHitRatio` metric dips. Then identify which query might be causing it.
- Verify whether you have unused indexes, then remove them.
- Use partitioned tables (which also have partitioned indexes). Doing this helps to keep index reordering low and reduces its impact.
- Avoid indexing columns unnecessarily.
- Prevent sudden database connection spikes by using a connection pool.
- Restrict the maximum number of connections to the database as a best practice.

## LWLock:buffer\_content (BufferContent)

The `LWLock:buffer_content` event occurs when a session is waiting to read or write a data page in memory while another session has that page locked for writing. In RDS for PostgreSQL 13 and higher, this wait event is called `BufferContent`.

### Topics

- [Supported engine versions](#)
- [Context](#)
- [Likely causes of increased waits](#)
- [Actions](#)

### Supported engine versions

This wait event information is supported for all versions of RDS for PostgreSQL.

### Context

To read or manipulate data, PostgreSQL accesses it through shared memory buffers. To read from the buffer, a process gets a lightweight lock (`LWLock`) on the buffer content in shared mode. To write to the buffer, it gets that lock in exclusive mode. Shared locks allow other processes to concurrently acquire shared locks on that content. Exclusive locks prevent other processes from getting any type of lock on it.

The `LWLock:buffer_content` (`BufferContent`) event indicates that multiple processes are attempting to get a lock on contents of a specific buffer.

### Likely causes of increased waits

When the `LWLock:buffer_content` (`BufferContent`) event appears more than normal, possibly indicating a performance problem, typical causes include the following:

#### Increased concurrent updates to the same data

There might be an increase in the number of concurrent sessions with queries that update the same buffer content. This contention can be more pronounced on tables with a lot of indexes.

## Workload data is not in memory

When data that the active workload is processing is not in memory, these wait events can increase. This effect is because processes holding locks can keep them longer while they perform disk I/O operations.

## Excessive use of foreign key constraints

Foreign key constraints can increase the amount of time a process holds onto a buffer content lock. This effect is because read operations require a shared buffer content lock on the referenced key while that key is being updated.

## Actions

We recommend different actions depending on the causes of your wait event. You might identify `LWLock:buffer_content` (`BufferContent`) events by using Amazon RDS Performance Insights or by querying the view `pg_stat_activity`.

## Topics

- [Improve in-memory efficiency](#)
- [Reduce usage of foreign key constraints](#)
- [Remove unused indexes](#)
- [Increase the cache size when using sequences](#)

## Improve in-memory efficiency

To increase the chance that active workload data is in memory, partition tables or scale up your instance class. For information about DB instance classes, see [DB instance classes](#).

## Reduce usage of foreign key constraints

Investigate workloads experiencing high numbers of `LWLock:buffer_content` (`BufferContent`) wait events for usage of foreign key constraints. Remove unnecessary foreign key constraints.

## Remove unused indexes

For workloads experiencing high numbers of `LWLock:buffer_content` (`BufferContent`) wait events, identify unused indexes and remove them.

## Increase the cache size when using sequences

If your tables uses sequences, increase the cache size to remove contention on sequence pages and index pages. Each sequence is a single page in shared memory. The pre-defined cache is per connection. This might not be enough to handle the workload when many concurrent sessions are getting a sequence value.

## LWLock:lock\_manager (LWLock:lockmanager)

This event occurs when the RDS for PostgreSQL engine maintains the shared lock's memory area to allocate, check, and deallocate a lock when a fast path lock isn't possible.

### Topics

- [Supported engine versions](#)
- [Context](#)
- [Likely causes of increased waits](#)
- [Actions](#)

## Supported engine versions

This wait event information is relevant for RDS for PostgreSQL version 9.6 and higher. For RDS for PostgreSQL releases older than version 13, the name of this wait event is `LWLock:lock_manager`. For RDS for PostgreSQL version 13 and higher, the name of this wait event is `LWLock:lockmanager`.

## Context

When you issue a SQL statement, RDS for PostgreSQL records locks to protect the structure, data, and integrity of your database during concurrent operations. The engine can achieve this goal using a fast path lock or a path lock that isn't fast. A path lock that isn't fast is more expensive and creates more overhead than a fast path lock.

## Fast path locking

To reduce the overhead of locks that are taken and released frequently, but that rarely conflict, backend processes can use fast path locking. The database uses this mechanism for locks that meet the following criteria:

- They use the DEFAULT lock method.
- They represent a lock on a database relation rather than a shared relation.
- They are weak locks that are unlikely to conflict.
- The engine can quickly verify that no conflicting locks can possibly exist.

The engine can't use fast path locking when either of the following conditions is true:

- The lock doesn't meet the preceding criteria.
- No more slots are available for the backend process.

To tune your queries for fast-path locking, you can use the following query.

```
SELECT count(*), pid, mode, fastpath
   FROM pg_locks
  WHERE fastpath IS NOT NULL
 GROUP BY 4,3,2
 ORDER BY pid, mode;
count | pid  | mode           | fastpath
-----+-----+-----+-----
  16 | 9185 | AccessShareLock | t
 336 | 9185 | AccessShareLock | f
   1 | 9185 | ExclusiveLock   | t
```

The following query shows only the total across the database.

```
SELECT count(*), mode, fastpath
   FROM pg_locks
  WHERE fastpath IS NOT NULL
 GROUP BY 3,2
 ORDER BY mode,1;
count | mode           | fastpath
-----+-----+-----
  16 | AccessShareLock | t
 337 | AccessShareLock | f
   1 | ExclusiveLock   | t
(3 rows)
```

For more information about fast path locking, see [fast path](#) in the PostgreSQL lock manager README and [pg-locks](#) in the PostgreSQL documentation.

## Example of a scaling problem for the lock manager

In this example, a table named `purchases` stores five years of data, partitioned by day. Each partition has two indexes. The following sequence of events occurs:

1. You query many days worth of data, which requires the database to read many partitions.
2. The database creates a lock entry for each partition. If partition indexes are part of the optimizer access path, the database creates a lock entry for them, too.
3. When the number of requested locks entries for the same backend process is higher than 16, which is the value of `FP_LOCK_SLOTS_PER_BACKEND`, the lock manager uses the non-fast path lock method.

Modern applications might have hundreds of sessions. If concurrent sessions are querying the parent without proper partition pruning, the database might create hundreds or even thousands of non-fast path locks. Typically, when this concurrency is higher than the number of vCPUs, the `LWLock:lock_manager` wait event appears.

### Note

The `LWLock:lock_manager` wait event isn't related to the number of partitions or indexes in a database schema. Instead, it's related to the number of non-fast path locks that the database must control.

## Likely causes of increased waits

When the `LWLock:lock_manager` wait event occurs more than normal, possibly indicating a performance problem, the most likely causes of sudden spikes are as follows:

- Concurrent active sessions are running queries that don't use fast path locks. These sessions also exceed the maximum vCPU.
- A large number of concurrent active sessions are accessing a heavily partitioned table. Each partition has multiple indexes.
- The database is experiencing a connection storm. By default, some applications and connection pool software create more connections when the database is slow. This practice makes the problem worse. Tune your connection pool software so that connection storms don't occur.
- A large number of sessions query a parent table without pruning partitions.

- A data definition language (DDL), data manipulation language (DML), or a maintenance command exclusively locks either a busy relation or tuples that are frequently accessed or modified.

## Actions

If the CPU wait event occurs, it doesn't necessarily indicate a performance problem. Respond to this event only when performance degrades and this wait event is dominating DB load.

## Topics

- [Use partition pruning](#)
- [Remove unnecessary indexes](#)
- [Tune your queries for fast path locking](#)
- [Tune for other wait events](#)
- [Reduce hardware bottlenecks](#)
- [Use a connection pooler](#)
- [Upgrade your RDS for PostgreSQL version](#)

## Use partition pruning

*Partition pruning* is a query optimization strategy for declaratively partitioned tables that excludes unneeded partitions from table scans, thereby improving performance. Partition pruning is turned on by default. If it is turned off, turn it on as follows.

```
SET enable_partition_pruning = on;
```

Queries can take advantage of partition pruning when their *WHERE* clause contains the column used for the partitioning. For more information, see [Partition Pruning](#) in the PostgreSQL documentation.

## Remove unnecessary indexes

Your database might contain unused or rarely used indexes. If so, consider deleting them. Do either of the following:

- Learn how to find unnecessary indexes by reading [Unused Indexes](#) in the PostgreSQL wiki.

- Run PG Collector. This SQL script gathers database information and presents it in a consolidated HTML report. Check the "Unused indexes" section. For more information, see [pg-collector](#) in the AWS Labs GitHub repository.

## Tune your queries for fast path locking

To find out whether your queries use fast path locking, query the `fastpath` column in the `pg_locks` table. If your queries aren't using fast path locking, try to reduce number of relations per query to fewer than 16.

## Tune for other wait events

If `LWLock:lock_manager` is first or second in the list of top waits, check whether the following wait events also appear in the list:

- `Lock:Relation`
- `Lock:transactionid`
- `Lock:tuple`

If the preceding events appear high in the list, consider tuning these wait events first. These events can be a driver for `LWLock:lock_manager`.

## Reduce hardware bottlenecks

You might have a hardware bottleneck, such as CPU starvation or maximum usage of your Amazon EBS bandwidth. In these cases, consider reducing the hardware bottlenecks. Consider the following actions:

- Scale up your instance class.
- Optimize queries that consume large amounts of CPU and memory.
- Change your application logic.
- Archive your data.

For more information about CPU, memory, and EBS network bandwidth, see [Amazon RDS Instance Types](#).

## Use a connection pooler

If your total number of active connections exceeds the maximum vCPU, more OS processes require CPU than your instance type can support. In this case, consider using or tuning a connection pool. For more information about the vCPUs for your instance type, see [Amazon RDS Instance Types](#).

For more information about connection pooling, see the following resources:

- [Using Amazon RDS Proxy](#)
- [pgbouncer](#)
- [Connection Pools and Data Sources](#) in the *PostgreSQL Documentation*

## Upgrade your RDS for PostgreSQL version

If your current version of RDS for PostgreSQL is lower than 12, upgrade to version 12 or higher. PostgreSQL versions 12 and later have an improved partition mechanism. For more information about version 12, see [PostgreSQL 12.0 Release Notes](#). For more information about upgrading RDS for PostgreSQL, see [Upgrading the PostgreSQL DB engine for Amazon RDS](#).

## Timeout:PgSleep

The Timeout:PgSleep event occurs when a server process has called the `pg_sleep` function and is waiting for the sleep timeout to expire.

### Topics

- [Supported engine versions](#)
- [Likely causes of increased waits](#)
- [Actions](#)

## Supported engine versions

This wait event information is supported for all versions of RDS for PostgreSQL.

## Likely causes of increased waits

This wait event occurs when an application, stored function, or user issues a SQL statement that calls one of the following functions:

- `pg_sleep`
- `pg_sleep_for`
- `pg_sleep_until`

The preceding functions delay execution until the specified number of seconds have elapsed. For example, `SELECT pg_sleep(1)` pauses for 1 second. For more information, see [Delaying Execution](#) in the PostgreSQL documentation.

## Actions

Identify the statement that was running the `pg_sleep` function. Determine if the use of the function is appropriate.

## Timeout:VacuumDelay

The `Timeout:VacuumDelay` event indicates that the cost limit for vacuum I/O has been exceeded and that the vacuum process has been put to sleep. Vacuum operations stop for the duration specified in the respective cost delay parameter and then it resumes its work. For the manual vacuum command, the delay is specified in the `vacuum_cost_delay` parameter. For the autovacuum daemon, the delay is specified in the `autovacuum_vacuum_cost_delay` parameter.

## Topics

- [Supported engine versions](#)
- [Context](#)
- [Likely causes of increased waits](#)
- [Actions](#)

## Supported engine versions

This wait event information is supported for all versions of RDS for PostgreSQL.

## Context

PostgreSQL has both an autovacuum daemon and a manual vacuum command. The autovacuum process is "on" by default for RDS for PostgreSQL DB instances. The manual vacuum command is used on an as-needed basis, for example, to purge tables of dead tuples or generate new statistics.

When vacuuming is underway, PostgreSQL uses an internal counter to keep track of estimated costs as the system performs various I/O operations. When the counter reaches the value specified by the cost limit parameter, the process performing the operation sleeps for the brief duration specified in the cost delay parameter. It then resets the counter and continues operations.

The vacuum process has parameters that can be used to regulate resource consumption. The autovacuum and the manual vacuum command have their own parameters for setting the cost limit value. They also have their own parameters to specify a cost delay, an amount of time to put the vacuum to sleep when the limit is reached. In this way, the cost delay parameter works as a throttling mechanism for resource consumption. In the following lists, you can find description of these parameters.

### Parameters that affect throttling of the autovacuum daemon

- [autovacuum\\_vacuum\\_cost\\_limit](#) – Specifies the cost limit value to use in automatic vacuum operations. Increasing the setting for this parameter allows the vacuum process to use more resources and decreases the `Timeout:VacuumDelay` wait event.
- [autovacuum\\_vacuum\\_cost\\_delay](#) – Specifies the cost delay value to use in automatic vacuum operations. The default value is 2 milliseconds. Setting the delay parameter to 0 turns off the throttling mechanism and thus, the `Timeout:VacuumDelay` wait event won't appear.

For more information, see [Automatic Vacuuming](#) in the PostgreSQL documentation.

### Parameters that affect throttling of the manual vacuum process

- `vacuum_cost_limit` – The threshold at which the vacuuming process is put to sleep. By default, the limit is 200. This number represents the accumulated cost estimates for extra I/O needed by various resources. Increasing this value reduces the number of the `Timeout:VacuumDelay` wait event.
- `vacuum_cost_delay` – The amount of time that the vacuum process sleeps when the vacuum cost limit has been reached. The default setting is 0, which means that this feature is off. You can set this to an integer value to specify the number of milliseconds to turn on this feature, but we recommend that you leave it at its default setting.

For more information about the `vacuum_cost_delay` parameter, see [Resource Consumption](#) in the PostgreSQL documentation.

To learn more about how to configure and use the autovacuum with RDS for PostgreSQL, see [Working with the PostgreSQL autovacuum on Amazon RDS for PostgreSQL](#).

## Likely causes of increased waits

The `Timeout:VacuumDelay` is affected by the balance between the cost limit parameter settings (`vacuum_cost_limit`, `autovacuum_vacuum_cost_limit`) and the cost delay parameters (`vacuum_cost_delay`, `autovacuum_vacuum_cost_delay`) that control the vacuum's sleep duration. Raising a cost limit parameter value allows more resources to be used by the vacuum before being put to sleep. That results in fewer `Timeout:VacuumDelay` wait events. Increasing either of the delay parameters causes the `Timeout:VacuumDelay` wait event to occur more frequently and for longer periods of time.

The `autovacuum_max_workers` parameter setting can also increase numbers of the `Timeout:VacuumDelay`. Each additional autovacuum worker process contributes to the internal counter mechanism, and thus the limit can be reached more quickly than with a single autovacuum worker process. As the cost limit is reached more quickly, the cost delay is put to effect more frequently, resulting in more `Timeout:VacuumDelay` wait events. For more information, see [autovacuum\\_max\\_workers](#) in the PostgreSQL documentation.

Large objects, such as 500GB or larger, also raise this wait event because it can take some time for the vacuum to complete processing large objects.

## Actions

If the vacuum operations complete as expected, no remediation is needed. In other words, this wait event doesn't necessarily indicate a problem. It indicates that the vacuum is being put to sleep for the period of time specified in the delay parameter so that resources can be applied to other processes that need to complete.

If you want vacuum operations to complete faster, you can lower the delay parameters. This shortens the time that the vacuum sleeps.

# Tuning RDS for PostgreSQL with Amazon DevOps Guru proactive insights

DevOps Guru proactive insights detects conditions on your RDS for PostgreSQL DB instances that can cause problems, and lets you know about them before they occur. Proactive insights can alert you to a long running idle in transaction connection. For more information about troubleshooting long running idle in transaction connections, see [Database has long running idle in transaction connection](#)

DevOps Guru can do the following:

- Prevent many common database issues by cross-checking your database configuration against common recommended settings.
- Alert you to critical issues in your fleet that, if left unchecked, can lead to larger problems later.
- Alert you to newly discovered problems.

Every proactive insight contains an analysis of the cause of the problem and recommendations for corrective actions.

For more information about Amazon DevOps Guru for Amazon RDS, see [Analyzing performance anomalies with Amazon DevOps Guru for Amazon RDS](#).

## Database has long running idle in transaction connection

A connection to the database has been in the `idle in transaction` state for more than 1800 seconds.

### Topics

- [Supported engine versions](#)
- [Context](#)
- [Likely causes for this issue](#)
- [Actions](#)
- [Relevant metrics](#)

## Supported engine versions

This insight information is supported for all versions of RDS for PostgreSQL.

### Context

A transaction in the `idle in transaction` state can hold locks that block other queries. It can also prevent `VACUUM` (including `autovacuum`) from cleaning up dead rows, leading to index or table bloat or transaction ID wraparound.

### Likely causes for this issue

A transaction initiated in an interactive session with `BEGIN` or `START TRANSACTION` hasn't ended by using a `COMMIT`, `ROLLBACK`, or `END` command. This causes the transaction to move to `idle in transaction` state.

### Actions

You can find idle transactions by querying `pg_stat_activity`.

In your SQL client, run the following query to list all connections in `idle in transaction` state and to order them by duration:

```
SELECT now() - state_change as idle_in_transaction_duration, now() - xact_start as
  xact_duration,*
FROM pg_stat_activity
WHERE state = 'idle in transaction'
AND xact_start is not null
ORDER BY 1 DESC;
```

We recommend different actions depending on the causes of your insight.

### Topics

- [End transaction](#)
- [Terminate the connection](#)
- [Configure the `idle\_in\_transaction\_session\_timeout` parameter](#)
- [Check the `AUTOCOMMIT` status](#)
- [Check the transaction logic in your application code](#)

## End transaction

When you initiate a transaction in an interactive session with `BEGIN` or `START TRANSACTION`, it moves to `idle in transaction` state. It remains in this state until you end the transaction by issuing a `COMMIT`, `ROLLBACK`, `END` command or disconnect the connection completely to roll back the transaction.

## Terminate the connection

Terminate the connection with an idle transaction using the following query:

```
SELECT pg_terminate_backend(pid);
```

`pid` is the process ID of the connection.

## Configure the `idle_in_transaction_session_timeout` parameter

Configure the `idle_in_transaction_session_timeout` parameter in the parameter group. The advantage of configuring this parameter is that it does not require a manual intervention to terminate the long idle in transaction. For more information on this parameter, see [the PostgreSQL documentation](#).

The following message will be reported in the PostgreSQL log file after the connection is terminated, when a transaction is in the `idle_in_transaction` state for longer than the specified time.

```
FATAL: terminating connection due to idle in transaction timeout
```

## Check the `AUTOCOMMIT` status

`AUTOCOMMIT` is turned on by default. But if it is accidentally turned off in the client ensure that you turn it back on.

- In your `psql` client, run the following command:

```
postgres=> \set AUTOCOMMIT on
```

- In `pgadmin`, turn it on by choosing the `AUTOCOMMIT` option from the down arrow.

## Check the transaction logic in your application code

Investigate your application logic for possible problems. Consider the following actions:

- Check if the JDBC auto commit is set true in your application. Also, consider using explicit COMMIT commands in your code.
- Check your error handling logic to see whether it closes a transaction after errors.
- Check whether your application is taking long to process the rows returned by a query while the transaction is open. If so, consider coding the application to close the transaction before processing the rows.
- Check whether a transaction contains many long-running operations. If so, divide a single transaction into multiple transactions.

## Relevant metrics

The following PI metrics are related to this insight:

- `idle_in_transaction_count` - Number of sessions in `idle in transaction` state.
- `idle_in_transaction_max_time` - The duration of the longest running transaction in the `idle in transaction` state.

# Using PostgreSQL extensions with Amazon RDS for PostgreSQL

You can extend the functionality of PostgreSQL by installing a variety of extensions and modules. For example, to work with spatial data you can install and use the PostGIS extension. For more information, see [Managing spatial data with the PostGIS extension](#). As another example, if you want to improve data entry for very large tables, you can consider partitioning your data by using the `pg_partman` extension. To learn more, see [Managing PostgreSQL partitions with the `pg\_partman` extension](#).

## Note

As of RDS for PostgreSQL 14.5, RDS for PostgreSQL supports Trusted Language Extensions for PostgreSQL. This feature is implemented as the extension `pg_tle`, which you can add to your RDS for PostgreSQL DB instance. By using this extension, developers can create their own PostgreSQL extensions in a safe environment that simplifies the setup and configuration requirements. For more information, see [Working with Trusted Language Extensions for PostgreSQL](#).

In some cases, rather than installing an extension, you might add a specific module to the list of `shared_preload_libraries` in your RDS for PostgreSQL DB instance's custom DB parameter group. Typically, the default DB cluster parameter group loads only the `pg_stat_statements`, but several other modules are available to add to the list. For example, you can add scheduling capability by adding the `pg_cron` module, as detailed in [Scheduling maintenance with the PostgreSQL `pg\_cron` extension](#). As another example, you can log query execution plans by loading the `auto_explain` module. To learn more, see [Logging execution plans of queries](#) in the AWS knowledge center.

Depending on your version of RDS for PostgreSQL, installing an extension might require `rds_superuser` permissions, as follows:

- For RDS for PostgreSQL versions 12 and earlier versions, installing extensions requires `rds_superuser` privileges.
- For RDS for PostgreSQL version 13 and higher versions, users (roles) with create permissions on a given database instance can install and use any *trusted extensions*. For a list of trusted extensions, see [PostgreSQL trusted extensions](#).

You can also specify precisely which extensions can be installed on your RDS for PostgreSQL DB instance, by listing them in the `rds.allowed_extensions` parameter. For more information, see [Restricting installation of PostgreSQL extensions](#).

To learn more about the `rds_superuser` role, see [Understanding PostgreSQL roles and permissions](#).

## Topics

- [Using functions from the orafce extension](#)
- [Using Amazon RDS delegated extension support for PostgreSQL](#)
- [Managing PostgreSQL partitions with the pg\\_partman extension](#)
- [Using pgAudit to log database activity](#)
- [Scheduling maintenance with the PostgreSQL pg\\_cron extension](#)
- [Using pglogical to synchronize data across instances](#)
- [Using pgactive to support active-active replication](#)
- [Reducing bloat in tables and indexes with the pg\\_repack extension](#)
- [Upgrading and using the PLV8 extension](#)
- [Using PL/Rust to write PostgreSQL functions in the Rust language](#)
- [Managing spatial data with the PostGIS extension](#)

## Using functions from the orafce extension

The orafce extension provides functions and operators that emulate a subset of functions and packages from an Oracle database. The orafce extension makes it easier for you to port an Oracle application to PostgreSQL. RDS for PostgreSQL versions 9.6.6 and higher support this extension. For more information about orafce, see [orafce](#) on GitHub.

### Note

RDS for PostgreSQL doesn't support the `utl_file` package that is part of the orafce extension. This is because the `utl_file` schema functions provide read and write operations on operating-system text files, which requires superuser access to the underlying host. As a managed service, RDS for PostgreSQL doesn't provide host access.

## To use the orafce extension

1. Connect to the DB instance with the primary user name that you used to create the DB instance.

If you want to turn on orafce for a different database in the same DB instance, use the `/c dbname psql` command. Using this command, you change from the primary database after initiating the connection.

2. Turn on the orafce extension with the `CREATE EXTENSION` statement.

```
CREATE EXTENSION orafce;
```

3. Transfer ownership of the oracle schema to the `rds_superuser` role with the `ALTER SCHEMA` statement.

```
ALTER SCHEMA oracle OWNER TO rds_superuser;
```

If you want to see the list of owners for the oracle schema, use the `\dn psql` command.

## Using Amazon RDS delegated extension support for PostgreSQL

Using Amazon RDS delegated extension support for PostgreSQL, you can delegate the extension management to a user who need not be an `rds_superuser`. With this delegated extension support, a new role called `rds_extension` is created and you must assign this to a user to manage other extensions. This role can create, update, and drop extensions.

You can specify the extensions that can be installed on your RDS DB instance, by listing them in the `rds.allowed_extensions` parameter. For more information, see [Using PostgreSQL extensions with Amazon RDS for PostgreSQL](#).

You can restrict the list of extensions available that can be managed by the user with the `rds_extension` role using `rds.allowed_delegated_extensions` parameter.

The delegated extension support is available in the following versions:

- All higher versions
- 16.4 and higher 16 versions
- 15.8 and higher 15 versions
- 14.13 and higher 14 versions
- 13.16 and higher 13 versions
- 12.20 and higher 12 versions

### Topics

- [Turning on delegate extension support to a user](#)
- [Configuration used in RDS delegated extension support for PostgreSQL](#)
- [Turning off the support for the delegated extension](#)
- [Benefits of using Amazon RDS delegated extension support](#)
- [Limitation of Amazon RDS delegated extension support for PostgreSQL](#)
- [Permissions required for certain extensions](#)
- [Security Considerations](#)
- [Drop extension cascade disabled](#)
- [Example extensions that can be added using delegated extension support](#)

## Turning on delegate extension support to a user

You must perform the following to enable delegate extension support to a user:

1. **Grant `rds_extension` role to a user** – Connect to the database as `rds_superuser` and execute the following command:

```
Postgres => grant rds_extension to user_name;
```

2. **Set the list of extensions available for delegated users to manage** – The `rds.allowed_delegated_extensions` allows you to specify a subset of the available extensions using `rds.allowed_extensions` in the DB cluster parameter. You can perform this at one of the following levels:

- In the cluster or the instance parameter group, through the AWS Management Console or API. For more information, see [Parameter groups for Amazon RDS](#).
- Use the following command at the database level:

```
alter database database_name set rds.allowed_delegated_extensions =  
'extension_name_1,  
   extension_name_2,...extension_name_n';
```

- Use the following command at the user level:

```
alter user user_name set rds.allowed_delegated_extensions = 'extension_name_1,  
   extension_name_2,...extension_name_n';
```

### Note

You need not restart the database after changing the `rds.allowed_delegated_extensions` dynamic parameter.

3. **Allow access to the delegated user to objects created during the extension creation process** – Certain extensions create objects that require additional permissions to be granted before the user with `rds_extension` role can access them. The `rds_superuser` must grant the delegated user access to those objects. One of the options is to use an event trigger to automatically grant permission to the delegated user. For more information, refer to the event trigger example in [Turning off the support for the delegated extension](#).

## Configuration used in RDS delegated extension support for PostgreSQL

Configuration Name	Description	Default Value	Notes	Who can modify or grant permission
<code>rds.allowed_extensions</code>	This parameter limits the extensions a <code>rds_extension_role</code> can manage in a database. It must be a subset of <code>rds.allowed_extensions</code> .	empty string	<ul style="list-style-type: none"> <li>By default, this parameter is empty string, which means that no extensions have been delegated to users with <code>rds_extension</code>.</li> <li>Any supported extension can be added if the user has permission to do so. To do this, set the <code>rds.allowed_extensions</code> parameter to a string of comma-separated extension names. By adding a list of extensions to this parameter, you explicitly identify the extensions that</li> </ul>	<code>rds_superuser</code>

Config tion Name	Description	Default Value	Notes	Who can modify or grant permission
			<p>the user with the <code>rds_extension</code> role can install.</p> <ul style="list-style-type: none"><li>• When set to <code>*</code>, it means that all extensions listed in <code>rds_allowed_extensions</code> are delegated to users with <code>rds_extension</code> role.</li></ul> <p>To learn more about setting up this parameter, see <a href="#">Turning on delegate extension support to a user</a>.</p>	

Config tion Name	Description	Default Value	Notes	Who can modify or grant permission
rds.delegated_extensions	This parameter lets the customer limit the extensions that can be installed in the RDS DB instance. For more information, see <a href="#">Restricting installation of PostgreSQL extensions</a>	"*"	<p>By default, this parameter is set to "*", which means that all extensions supported on RDS for PostgreSQL and Aurora PostgreSQL are allowed to be created by users with necessary privileges.</p> <p>Empty means no extensions can be installed in the RDS DB instance.</p>	administrator

Configuration Name	Description	Default Value	Notes	Who can modify or grant permission
<code>rds-delegated_extension_allow_drop_cascade</code>	This parameter controls the ability for users with <code>rds_extension</code> to drop the extension using a cascade option.	off	<p>By default, <code>rds-delegated_extension_allow_drop_cascade</code> is set to off. This means that users with <code>rds_extension</code> are not allowed to drop an extension using the cascade option.</p> <p>To grant that ability, the <code>rds.delegated_extension_allow_drop_cascade</code> parameter should be set to on.</p>	<code>rds_superuser</code>

## Turning off the support for the delegated extension

### Turning off partially

The delegated users can't create new extensions but can still update existing extensions.

- Reset `rds.allowed_delegated_extensions` to the default value in the DB cluster parameter group.
- Use the following command at the database level:

```
alter database database_name reset rds.allowed_delegated_extensions;
```

- Use the following command at the user level:

```
alter user user_name reset rds.allowed_delegated_extensions;
```

## Turning off fully

Revoking `rds_extension` role from a user will revert the user to standard permissions. The user can no longer create, update, or drop extensions.

```
postgres => revoke rds_extension from user_name;
```

## Example of event trigger

If you want to allow a delegated user with `rds_extension` to use extensions that require setting permissions on their objects created by the extension creation, you can customize the below example of an event trigger and add only the extensions for which you want the delegated users to have access to the full functionality. This event trigger can be created on `template1` (the default template), therefore all database created from `template1` will have that event trigger. When a delegated user installs the extension, this trigger will automatically grant ownership on the objects created by the extension.

```
CREATE OR REPLACE FUNCTION create_ext()  
  
    RETURNS event_trigger AS $$  
  
DECLARE  
  
    schemaname TEXT;  
    databaseowner TEXT;  
  
    r RECORD;  
  
BEGIN  
  
    IF tg_tag = 'CREATE EXTENSION' and current_user != 'rds_superuser' THEN  
        RAISE NOTICE 'SECURITY INVOKER';
```

```

RAISE NOTICE 'user: %', current_user;
FOR r IN SELECT * FROM pg_event_trigger_ddl_commands()
LOOP
    CONTINUE WHEN r.command_tag != 'CREATE EXTENSION' OR r.object_type !=
'extension';

    schemaname = (
        SELECT n.nspname
        FROM pg_catalog.pg_extension AS e
        INNER JOIN pg_catalog.pg_namespace AS n
        ON e.extnamespace = n.oid
        WHERE e.oid = r.objid
    );

    databaseowner = (
        SELECT pg_catalog.pg_get_userbyid(d.datdba)
        FROM pg_catalog.pg_database d
        WHERE d.datname = current_database()
    );

    RAISE NOTICE 'Record for event trigger %, objid: %,tag: %, current_user: %,
schema: %, database_owenr: %', r.object_identity, r.objid, tg_tag, current_user,
schemaname, databaseowner;
    IF r.object_identity = 'address_standardizer_data_us' THEN
        EXECUTE format('GRANT SELECT, UPDATE, INSERT, DELETE ON TABLE %I.us_gaz TO
%i WITH GRANT OPTION;', schemaname, databaseowner);
        EXECUTE format('GRANT SELECT, UPDATE, INSERT, DELETE ON TABLE %I.us_lex TO
%i WITH GRANT OPTION;', schemaname, databaseowner);
        EXECUTE format('GRANT SELECT, UPDATE, INSERT, DELETE ON TABLE %I.us_rules
TO %I WITH GRANT OPTION;', schemaname, databaseowner);
    ELSIF r.object_identity = 'dict_int' THEN
        EXECUTE format('ALTER TEXT SEARCH DICTIONARY %I.intdict OWNER TO %I;',
schemaname, databaseowner);
    ELSIF r.object_identity = 'pg_partman' THEN
        EXECUTE format('GRANT SELECT, UPDATE, INSERT, DELETE ON TABLE
%i.part_config TO %I WITH GRANT OPTION;', schemaname, databaseowner);
        EXECUTE format('GRANT SELECT, UPDATE, INSERT, DELETE ON TABLE
%i.part_config_sub TO %I WITH GRANT OPTION;', schemaname, databaseowner);
        EXECUTE format('GRANT SELECT, UPDATE, INSERT, DELETE ON TABLE
%i.custom_time_partitions TO %I WITH GRANT OPTION;', schemaname, databaseowner);
    ELSIF r.object_identity = 'postgis_topology' THEN
        EXECUTE format('GRANT SELECT, UPDATE, INSERT, DELETE ON ALL TABLES IN

        EXECUTE format('GRANT USAGE ON SCHEMA topology TO %I WITH GRANT OPTION;',
databaseowner);
    END IF;
END LOOP;
END IF;
END;
$$ LANGUAGE plpgsql SECURITY DEFINER;

CREATE EVENT TRIGGER log_create_ext ON ddl_command_end EXECUTE PROCEDURE create_ext();
```

## Benefits of using Amazon RDS delegated extension support

By using Amazon RDS delegated extension support for PostgreSQL, you securely delegate the extension management to users who do not have the `rds_superuser` role. This feature provides the following benefits:

- You can easily delegate extension management to users of your choice.
- This doesn't require `rds_superuser` role.
- Provides ability to support different set of extensions for different databases in the same DB cluster.

## Limitation of Amazon RDS delegated extension support for PostgreSQL

- Objects created during the extension creation process may require additional privileges for the extension to function properly.
- Some extensions can't be managed by the delegated extension user by default, including the following: `log_fdw`, `pg_cron`, `pg_tle`, `pgactive`, `pglogical`, `postgis_raster`, `postgis_tiger_geocoder`, `postgis_topology`.

## Permissions required for certain extensions

In order to create, use, or update the following extensions, the delegated user should have the necessary privileges on the following functions, tables, and schema.

Extensions that need ownership or permissions	Function	Tables	Schema	Text Search Dictionary	Comment
address_standardizer_data	none	us_gaz, us_lex, us_lex, l.us_rules	none	none	none
amcheck	bt_index_check, bt_index_parent_check	none	none	none	none
dict_int	none	none	none	intdict	none
pg_partman	none	custom_time_partitions, part_config, part_config_sub	none	none	none
pg_stat_statements	none	none	none	none	none
PostGIS	st_tileenvelope	spatial_ref_sys	none	none	none
postgis_raster	none	none	none	none	none
postgis_topology	none	topology, layer	topology	none	the delegated user Must be

Extensions that need ownership or permissions	Function	Tables	Schema	Text Search Dictionary	Comment
					the database owner
log_file	create_foreign_table_for_log_file	none	none	none	none
rds_t	role_password_encryption_type	none	none	none	none
postgis_order	none	geocode_settings_default, geocode_settings	tiger	none	none
pg_free	pg_freespace	none	none	none	none
pg_visibility	pg_visibility	none	none	none	none

## Security Considerations

Keep in mind that a user with `rds_extension` role will be able to manage extensions on all databases they have the connect privilege on. If the intention is to have a delegated user manage extension on a single database, a good practice is to revoke all privileges from public on each database, then explicitly grant the connect privilege for that specific database to the delegate user.

There are several extensions that can allow a user to access information from multiple database. Ensure the users you grant `rds_extension` has cross database capabilities before adding these extensions to `rds.allowed_delegated_extensions`. For example, `postgres_fdw` and `dblink` provide functionality to query across databases on the same instance or remote instances. `log_fdw` reads the postgres engine log files, which are for all databases in the instance, potentially containing slow queries or error messages from multiple databases. `pg_cron` enables running scheduled background jobs on the DB instance and can configure jobs to run in a different database.

## Drop extension cascade disabled

The ability to drop the extension with cascade option by a user with the `rds_extension` role is controlled by `rds.delegated_extension_allow_drop_cascade` parameter. By default, `rds-delegated_extension_allow_drop_cascade` is set to `off`. This means that users with the `rds_extension` role are not allowed to drop an extension using the cascade option as shown in the below query.

```
DROP EXTENSION CASCADE;
```

As this will automatically drop objects that depend on the extension, and in turn all objects that depend on those objects. Attempting to use the cascade option will result in an error.

To grant that ability, the `rds.delegated_extension_allow_drop_cascade` parameter should be set to `on`.

Changing the `rds.delegated_extension_allow_drop_cascade` dynamic parameter doesn't require a database restart. You can do this at one of the following levels:

- In the cluster or the instance parameter group, through the AWS Management Console or API.
- Using the following command at the database level:

```
alter database database_name set rds.delegated_extension_allow_drop_cascade = 'on';
```

- Using the following command at the user level:

```
alter role tenant_user set rds.delegated_extension_allow_drop_cascade = 'on';
```

## Example extensions that can be added using delegated extension support

- `rds_tools`

```
extension_test_db=> create extension rds_tools;
CREATE EXTENSION
extension_test_db=> SELECT * from rds_tools.role_password_encryption_type() where
  rolname = 'pg_read_server_files';
ERROR: permission denied for function role_password_encryption_type
```

- `amcheck`

```
extension_test_db=> CREATE TABLE amcheck_test (id int);
CREATE TABLE
extension_test_db=> INSERT INTO amcheck_test VALUES (generate_series(1,100000));
INSERT 0 100000
extension_test_db=> CREATE INDEX amcheck_test_btree_idx ON amcheck_test USING btree
  (id);
CREATE INDEX
extension_test_db=> create extension amcheck;
CREATE EXTENSION
extension_test_db=> SELECT bt_index_check('amcheck_test_btree_idx'::regclass);
ERROR: permission denied for function bt_index_check
extension_test_db=> SELECT bt_index_parent_check('amcheck_test_btree_idx'::regclass);
ERROR: permission denied for function bt_index_parent_check
```

- `pg_freespacemap`

```
extension_test_db=> create extension pg_freespacemap;
CREATE EXTENSION
extension_test_db=> SELECT * FROM pg_freespace('pg_authid');
ERROR: permission denied for function pg_freespace
extension_test_db=> SELECT * FROM pg_freespace('pg_authid',0);
ERROR: permission denied for function pg_freespace
```

- `pg_visibility`

```
extension_test_db=> create extension pg_visibility;
CREATE EXTENSION
extension_test_db=> select * from pg_visibility('pg_database'::regclass);
ERROR: permission denied for function pg_visibility
```

- `postgres_fdw`

```
extension_test_db=> create extension postgres_fdw;  
CREATE EXTENSION  
extension_test_db=> create server myserver foreign data wrapper postgres_fdw options  
  (host 'foo', dbname 'foodb', port '5432');  
ERROR: permission denied for foreign-data wrapper postgres_fdw
```

## Managing PostgreSQL partitions with the `pg_partman` extension

PostgreSQL table partitioning provides a framework for high-performance handling of data input and reporting. Use partitioning for databases that require very fast input of large amounts of data. Partitioning also provides for faster queries of large tables. Partitioning helps maintain data without impacting the database instance because it requires less I/O resources.

By using partitioning, you can split data into custom-sized chunks for processing. For example, you can partition time-series data for ranges such as hourly, daily, weekly, monthly, quarterly, yearly, custom, or any combination of these. For a time-series data example, if you partition the table by hour, each partition contains one hour of data. If you partition the time-series table by day, the partitions holds one day's worth of data, and so on. The partition key controls the size of a partition.

When you use an `INSERT` or `UPDATE` SQL command on a partitioned table, the database engine routes the data to the appropriate partition. PostgreSQL table partitions that store the data are child tables of the main table.

During database query reads, the PostgreSQL optimizer examines the `WHERE` clause of the query and, if possible, directs the database scan to only the relevant partitions.

Starting with version 10, PostgreSQL uses declarative partitioning to implement table partitioning. This is also known as native PostgreSQL partitioning. Before PostgreSQL version 10, you used triggers to implement partitions.

PostgreSQL table partitioning provides the following features:

- Creation of new partitions at any time.
- Variable partition ranges.
- Detachable and reattachable partitions using data definition language (DDL) statements.

For example, detachable partitions are useful for removing historical data from the main partition but keeping historical data for analysis.

- New partitions inherit the parent database table properties, including the following:
  - Indexes
  - Primary keys, which must include the partition key column
  - Foreign keys
  - Check constraints

- References
- Creating indexes for the full table or each specific partition.

You can't alter the schema for an individual partition. However, you can alter the parent table (such as adding a new column), which propagates to partitions.

## Topics

- [Overview of the PostgreSQL `pg\_partman` extension](#)
- [Enabling the `pg\_partman` extension](#)
- [Configuring partitions using the `create\_parent` function](#)
- [Configuring partition maintenance using the `run\_maintenance\_proc` function](#)

## Overview of the PostgreSQL `pg_partman` extension

You can use the PostgreSQL `pg_partman` extension to automate the creation and maintenance of table partitions. For more general information, see [PG Partition Manager](#) in the `pg_partman` documentation.

### Note

The `pg_partman` extension is supported on RDS for PostgreSQL versions 12.5 and higher.

Instead of having to manually create each partition, you configure `pg_partman` with the following settings:

- Table to be partitioned
- Partition type
- Partition key
- Partition granularity
- Partition precreation and management options

After you create a PostgreSQL partitioned table, you register it with `pg_partman` by calling the `create_parent` function. Doing this creates the necessary partitions based on the parameters you pass to the function.

The `pg_partman` extension also provides the `run_maintenance_proc` function, which you can call on a scheduled basis to automatically manage partitions. To ensure that the proper partitions are created as needed, schedule this function to run periodically (such as hourly). You can also ensure that partitions are automatically dropped.

## Enabling the `pg_partman` extension

If you have multiple databases inside the same PostgreSQL DB instance for which you want to manage partitions, enable the `pg_partman` extension separately for each database. To enable the `pg_partman` extension for a specific database, create the partition maintenance schema and then create the `pg_partman` extension as follows.

```
CREATE SCHEMA partman;  
CREATE EXTENSION pg_partman WITH SCHEMA partman;
```

### Note

To create the `pg_partman` extension, make sure that you have `rds_superuser` privileges.

If you receive an error such as the following, grant the `rds_superuser` privileges to the account or use your superuser account.

```
ERROR: permission denied to create extension "pg_partman"  
HINT: Must be superuser to create this extension.
```

To grant `rds_superuser` privileges, connect with your superuser account and run the following command.

```
GRANT rds_superuser TO user-or-role;
```

For the examples that show using the `pg_partman` extension, we use the following sample database table and partition. This database uses a partitioned table based on a timestamp. A schema `data_mart` contains a table named `events` with a column named `created_at`. The following settings are included in the `events` table:

- Primary keys `event_id` and `created_at`, which must have the column used to guide the partition.

- A check constraint `ck_valid_operation` to enforce values for an operation table column.
- Two foreign keys, where one (`fk_orga_membership`) points to the external table `organization` and the other (`fk_parent_event_id`) is a self-referenced foreign key.
- Two indexes, where one (`idx_org_id`) is for the foreign key and the other (`idx_event_type`) is for the event type.

The following DDL statements create these objects, which are automatically included on each partition.

```
CREATE SCHEMA data_mart;
CREATE TABLE data_mart.organization ( org_id BIGSERIAL,
    org_name TEXT,
    CONSTRAINT pk_organization PRIMARY KEY (org_id)
);

CREATE TABLE data_mart.events(
    event_id          BIGSERIAL,
    operation         CHAR(1),
    value            FLOAT(24),
    parent_event_id  BIGINT,
    event_type       VARCHAR(25),
    org_id           BIGSERIAL,
    created_at       timestamp,
    CONSTRAINT pk_data_mart_event PRIMARY KEY (event_id, created_at),
    CONSTRAINT ck_valid_operation CHECK (operation = 'C' OR operation = 'D'),
    CONSTRAINT fk_orga_membership
        FOREIGN KEY(org_id)
        REFERENCES data_mart.organization (org_id),
    CONSTRAINT fk_parent_event_id
        FOREIGN KEY(parent_event_id, created_at)
        REFERENCES data_mart.events (event_id,created_at)
) PARTITION BY RANGE (created_at);

CREATE INDEX idx_org_id      ON data_mart.events(org_id);
CREATE INDEX idx_event_type ON data_mart.events(event_type);
```

## Configuring partitions using the `create_parent` function

After you enable the `pg_partman` extension, use the `create_parent` function to configure partitions inside the partition maintenance schema. The following example uses the `events` table

example created in [Enabling the pg\\_partman extension](#). Call the `create_parent` function as follows.

```
SELECT partman.create_parent( p_parent_table => 'data_mart.events',
  p_control => 'created_at',
  p_type => 'native',
  p_interval=> 'daily',
  p_premake => 30);
```

The parameters are as follows:

- `p_parent_table` – The parent partitioned table. This table must already exist and be fully qualified, including the schema.
- `p_control` – The column on which the partitioning is to be based. The data type must be an integer or time-based.
- `p_type` – The type is either 'native' or 'partman'. You typically use the native type for its performance improvements and flexibility. The partman type relies on inheritance.
- `p_interval` – The time interval or integer range for each partition. Example values include `daily`, `hourly`, and so on.
- `p_premake` – The number of partitions to create in advance to support new inserts.

For a complete description of the `create_parent` function, see [Creation Functions](#) in the `pg_partman` documentation.

## Configuring partition maintenance using the `run_maintenance_proc` function

You can run partition maintenance operations to automatically create new partitions, detach partitions, or remove old partitions. Partition maintenance relies on the `run_maintenance_proc` function of the `pg_partman` extension and the `pg_cron` extension, which initiates an internal scheduler. The `pg_cron` scheduler automatically executes SQL statements, functions, and procedures defined in your databases.

The following example uses the `events` table example created in [Enabling the pg\\_partman extension](#) to set partition maintenance operations to run automatically. As a prerequisite, add `pg_cron` to the `shared_preload_libraries` parameter in the DB instance's parameter group.

```
CREATE EXTENSION pg_cron;
```

```
UPDATE partman.part_config
SET infinite_time_partitions = true,
    retention = '3 months',
    retention_keep_table=true
WHERE parent_table = 'data_mart.events';
SELECT cron.schedule('@hourly', $$CALL partman.run_maintenance_proc()$$);
```

Following, you can find a step-by-step explanation of the preceding example:

1. Modify the parameter group associated with your DB instance and add `pg_cron` to the `shared_preload_libraries` parameter value. This change requires a DB instance restart for it to take effect. For more information, see [Modifying parameters in a DB parameter group in Amazon RDS](#).
2. Run the command `CREATE EXTENSION pg_cron;` using an account that has the `rds_superuser` permissions. Doing this enables the `pg_cron` extension. For more information, see [Scheduling maintenance with the PostgreSQL `pg\_cron` extension](#).
3. Run the command `UPDATE partman.part_config` to adjust the `pg_partman` settings for the `data_mart.events` table.
4. Run the command `SET ...` to configure the `data_mart.events` table, with these clauses:
  - a. `infinite_time_partitions = true`, – Configures the table to be able to automatically create new partitions without any limit.
  - b. `retention = '3 months'`, – Configures the table to have a maximum retention of three months.
  - c. `retention_keep_table=true` – Configures the table so that when the retention period is due, the table isn't deleted automatically. Instead, partitions that are older than the retention period are only detached from the parent table.
5. Run the command `SELECT cron.schedule ...` to make a `pg_cron` function call. This call defines how often the scheduler runs the `pg_partman` maintenance procedure, `partman.run_maintenance_proc`. For this example, the procedure runs every hour.

For a complete description of the `run_maintenance_proc` function, see [Maintenance Functions](#) in the `pg_partman` documentation.

## Using pgAudit to log database activity

Financial institutions, government agencies, and many industries need to keep *audit logs* to meet regulatory requirements. By using the PostgreSQL Audit extension (pgAudit) with your RDS for PostgreSQL DB instance, you can capture the detailed records that are typically needed by auditors or to meet regulatory requirements. For example, you can set up the pgAudit extension to track changes made to specific databases and tables, to record the user who made the change, and many other details.

The pgAudit extension builds on the functionality of the native PostgreSQL logging infrastructure by extending the log messages with more detail. In other words, you use the same approach to view your audit log as you do to view any log messages. For more information about PostgreSQL logging, see [RDS for PostgreSQL database log files](#).

The pgAudit extension redacts sensitive data such as cleartext passwords from the logs. If your RDS for PostgreSQL DB instance is configured to log data manipulation language (DML) statements as detailed in [Turning on query logging for your RDS for PostgreSQL DB instance](#), you can avoid the cleartext password issue by using the PostgreSQL Audit extension.

You can configure auditing on your database instances with a great degree of specificity. You can audit all databases and all users. Or, you can choose to audit only certain databases, users, and other objects. You can also explicitly exclude certain users and databases from being audited. For more information, see [Excluding users or databases from audit logging](#).

Given the amount of detail that can be captured, we recommend that if you do use pgAudit, you monitor your storage consumption.

The pgAudit extension is supported on all available RDS for PostgreSQL versions. For a list of pgAudit versions supported by available RDS for PostgreSQL versions, see [Extension versions for Amazon RDS for PostgreSQL](#) in the *Amazon RDS for PostgreSQL Release Notes*.

### Topics

- [Setting up the pgAudit extension](#)
- [Auditing database objects](#)
- [Excluding users or databases from audit logging](#)
- [Reference for the pgAudit extension](#)

## Setting up the pgAudit extension

To set up the pgAudit extension on your RDS for PostgreSQL DB instance, you first add pgAudit to the shared libraries on the custom DB parameter group for your RDS for PostgreSQL DB instance. For information about creating a custom DB parameter group, see [Parameter groups for Amazon RDS](#). Next, you install the pgAudit extension. Finally, you specify the databases and objects that you want to audit. The procedures in this section show you how. You can use the AWS Management Console or the AWS CLI.

You must have permissions as the `rds_superuser` role to perform all these tasks.

The steps following assume that your RDS for PostgreSQL DB instance is associated with a custom DB parameter group.

### Console

#### To set up the pgAudit extension

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose your RDS for PostgreSQL DB instance.
3. Open the **Configuration** tab for your RDS for PostgreSQL DB instance. Among the Instance details, find the **Parameter group** link.
4. Choose the link to open the custom parameters associated with your RDS for PostgreSQL DB instance.
5. In the **Parameters** search field, type `shared_pre` to find the `shared_preload_libraries` parameter.
6. Choose **Edit parameters** to access the property values.
7. Add `pgaudit` to the list in the **Values** field. Use a comma to separate items in the list of values.

RDS > Parameter groups > docs-lab-rpg-14-custom-db-parameters

## docs-lab-rpg-14-custom-db-parameters

**Parameters**

Q shared\_pre X

<input type="checkbox"/>	Name	Values	Allowed values
<input type="checkbox"/>	shared_preload_libraries	pgaudit,pg_stat_statements	auto_explain, orafce, pgaudit, pglogical, pg_bigm, pg_cron, pg_hint_plan, pg_prewarm, pg_similarity, pg_stat_statements, pg_transport, plprofiler

- Reboot the RDS for PostgreSQL DB instance so that your change to the `shared_preload_libraries` parameter takes effect.
- When the instance is available, verify that pgAudit has been initialized. Use `psql` to connect to the RDS for PostgreSQL DB instance, and then run the following command.

```
SHOW shared_preload_libraries;
shared_preload_libraries
-----
rdsutils,pgaudit
(1 row)
```

- With pgAudit initialized, you can now create the extension. You need to create the extension after initializing the library because the `pgaudit` extension installs event triggers for auditing data definition language (DDL) statements.

```
CREATE EXTENSION pgaudit;
```

- Close the `psql` session.

```
labdb=> \q
```

- Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.

13. Find the `pgaudit.log` parameter in the list and set to the appropriate value for your use case. For example, setting the `pgaudit.log` parameter to `write` as shown in the following image captures inserts, updates, deletes, and some other types changes to the log.

The screenshot shows the Amazon RDS console interface for a custom parameter group named 'docs-lab-rpg-14-custom-db-parameters'. A search bar at the top contains 'pgau'. Below the search bar is a table of parameters. The 'pgaudit.log' parameter is highlighted, with its value set to 'write'. The 'Allowed values' column lists: 'ddl, function, misc, read, role, write, none, all, -ddl, -function, -misc, -read, -role, -write'. The 'Modifiable' column shows 'true'.

<input type="checkbox"/>	Name	Values	Allowed values	Modifiable
<input type="checkbox"/>	pgaudit.log	write	ddl, function, misc, read, role, write, none, all, -ddl, -function, -misc, -read, -role, -write	true

You can also choose one of the following values for the `pgaudit.log` parameter.

- `none` – This is the default. No database changes are logged.
  - `all` – Logs everything (read, write, function, role, ddl, misc).
  - `ddl` – Logs all data definition language (DDL) statements that aren't included in the `ROLE` class.
  - `function` – Logs function calls and D0 blocks.
  - `misc` – Logs miscellaneous commands, such as `DISCARD`, `FETCH`, `CHECKPOINT`, `VACUUM`, and `SET`.
  - `read` – Logs `SELECT` and `COPY` when the source is a relation (such as a table) or a query.
  - `role` – Logs statements related to roles and privileges, such as `GRANT`, `REVOKE`, `CREATE ROLE`, `ALTER ROLE`, and `DROP ROLE`.
  - `write` – Logs `INSERT`, `UPDATE`, `DELETE`, `TRUNCATE`, and `COPY` when the destination is a relation (table).
14. Choose **Save changes**.
15. Open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
16. Choose your RDS for PostgreSQL DB instance from the Databases list.

## AWS CLI

### To setup pgAudit

To setup pgAudit using the AWS CLI, you call the [modify-db-parameter-group](#) operation to modify the audit log parameters in your custom parameter group, as shown in the following procedure.

1. Use the following AWS CLI command to add `pgaudit` to the `shared_preload_libraries` parameter.

```
aws rds modify-db-parameter-group \  
  --db-parameter-group-name custom-param-group-name \  
  --parameters  
  "ParameterName=shared_preload_libraries,ParameterValue=pgaudit,ApplyMethod=pending-  
reboot" \  
  --region aws-region
```

2. Use the following AWS CLI command to reboot the RDS for PostgreSQL DB instance so that the `pgaudit` library is initialized.

```
aws rds reboot-db-instance \  
  --db-instance-identifier your-instance \  
  --region aws-region
```

3. When the instance is available, you can verify that `pgaudit` has been initialized. Use `psql` to connect to the RDS for PostgreSQL DB instance, and then run the following command.

```
SHOW shared_preload_libraries;  
shared_preload_libraries  
-----  
rdsutils,pgaudit  
(1 row)
```

With pgAudit initialized, you can now create the extension.

```
CREATE EXTENSION pgaudit;
```

4. Close the `psql` session so that you can use the AWS CLI.

```
labdb=> \q
```

5. Use the following AWS CLI command to specify the classes of statement that want logged by session audit logging. The example sets the `pgaudit.log` parameter to `write`, which captures inserts, updates, and deletes to the log.

```
aws rds modify-db-parameter-group \  
  --db-parameter-group-name custom-param-group-name \  
  --parameters  
  "ParameterName=pgaudit.log,ParameterValue=write,ApplyMethod=pending-reboot" \  
  --region aws-region
```

You can also choose one of the following values for the `pgaudit.log` parameter.

- `none` – This is the default. No database changes are logged.
- `all` – Logs everything (read, write, function, role, ddl, misc).
- `ddl` – Logs all data definition language (DDL) statements that aren't included in the `ROLE` class.
- `function` – Logs function calls and D0 blocks.
- `misc` – Logs miscellaneous commands, such as `DISCARD`, `FETCH`, `CHECKPOINT`, `VACUUM`, and `SET`.
- `read` – Logs `SELECT` and `COPY` when the source is a relation (such as a table) or a query.
- `role` – Logs statements related to roles and privileges, such as `GRANT`, `REVOKE`, `CREATE ROLE`, `ALTER ROLE`, and `DROP ROLE`.
- `write` – Logs `INSERT`, `UPDATE`, `DELETE`, `TRUNCATE`, and `COPY` when the destination is a relation (table).

Reboot the RDS for PostgreSQL DB instance using the following AWS CLI command.

```
aws rds reboot-db-instance \  
  --db-instance-identifier your-instance \  
  --region aws-region
```

## Auditing database objects

With `pgAudit` set up on your RDS for PostgreSQL DB instance and configured for your requirements, more detailed information is captured in the PostgreSQL log. For example, while the default PostgreSQL logging configuration identifies the date and time that a change was made in

a database table, with the pgAudit extension the log entry can include the schema, user who made the change, and other details depending on how the extension parameters are configured. You can set up auditing to track changes in the following ways.

- For each session, by user. For the session level, you can capture the fully qualified command text.
- For each object, by user and by database.

The object auditing capability is activated when you create the `rds_pgaudit` role on your system and then add this role to the `pgaudit.role` parameter in your custom parameter group. By default, the `pgaudit.role` parameter is unset and the only allowable value is `rds_pgaudit`. The following steps assume that `pgaudit` has been initialized and that you have created the `pgaudit` extension by following the procedure in [Setting up the pgAudit extension](#).

```
2022-10-07 23:36:51 UTC:52.95.4.10(14410):postgres@labdb:[1374]:LOG: statement: SELECT feedback, s.sentiment,s.confidence
FROM support,aws_comprehend.detect_sentiment(feedback, 'en') s
ORDER BY s.confidence DESC;
2022-10-07 23:36:51 UTC:52.95.4.10(14410):postgres@labdb:[1374]:LOG: AUDIT: SESSION,2,1,READ,SELECT,TABLE,public.support,"SELECT
feedback, s.sentiment,s.confidence
FROM support,aws_comprehend.detect_sentiment(feedback, 'en') s
ORDER BY s.confidence DESC;",<none>
2022-10-07 23:36:51 UTC:52.95.4.10(14410):postgres@labdb:[1374]:LOG: QUERY STATISTICS
2022-10-07 23:36:51 UTC:52.95.4.10(14410):postgres@labdb:[1374]:DETAIL: ! system usage stats:
! 0.009494 s user, 0.007442 s system, 0.141985 s elapsed
! [0.022327 s user, 0.007442 s system total]
```

As shown in this example, the "LOG: AUDIT: SESSION" line provides information about the table and its schema, among other details.

## To set up object auditing

1. Use `psql` to connect to the RDS for PostgreSQL DB instance.

```
psql --host=your-instance-name.aws-region.rds.amazonaws.com --port=5432 --
username=postgrespostgres --password --dbname=labdb
```

2. Create a database role named `rds_pgaudit` using the following command.

```
labdb=> CREATE ROLE rds_pgaudit;
CREATE ROLE
labdb=>
```

3. Close the `psql` session.

```
labdb=> \q
```

In the next few steps, use the AWS CLI to modify the audit log parameters in your custom parameter group.

4. Use the following AWS CLI command to set the `pgaudit.role` parameter to `rds_pgaudit`. By default, this parameter is empty, and `rds_pgaudit` is the only allowable value.

```
aws rds modify-db-parameter-group \
  --db-parameter-group-name custom-param-group-name \
  --parameters
  "ParameterName=pgaudit.role,ParameterValue=rds_pgaudit,ApplyMethod=pending-reboot"
  \
  --region aws-region
```

5. Use the following AWS CLI command to reboot the RDS for PostgreSQL DB instance so that your changes to the parameters take effect.

```
aws rds reboot-db-instance \
  --db-instance-identifier your-instance \
  --region aws-region
```

6. Run the following command to confirm that the `pgaudit.role` is set to `rds_pgaudit`.

```
SHOW pgaudit.role;
pgaudit.role
-----
rds_pgaudit
```

To test pgAudit logging, you can run several example commands that you want to audit. For example, you might run the following commands.

```
CREATE TABLE t1 (id int);
GRANT SELECT ON t1 TO rds_pgaudit;
SELECT * FROM t1;
id
----
(0 rows)
```

The database logs should contain an entry similar to the following.

```
...
```

```
2017-06-12 19:09:49 UTC:...:rds_test@postgres:[11701]:LOG: AUDIT:
OBJECT,1,1,READ,SELECT,TABLE,public.t1,select * from t1;
...
```

For information on viewing the logs, see [Monitoring Amazon RDS log files](#).

To learn more about the pgAudit extension, see [pgAudit](#) on GitHub.

## Excluding users or databases from audit logging

As discussed in [RDS for PostgreSQL database log files](#), PostgreSQL logs consume storage space. Using the pgAudit extension adds to the volume of data gathered in your logs to varying degrees, depending on the changes that you track. You might not need to audit every user or database in your RDS for PostgreSQL DB instance.

To minimize impacts to your storage and to avoid needlessly capturing audit records, you can exclude users and databases from being audited. You can also change logging within a given session. The following examples show you how.

### Note

Parameter settings at the session level take precedence over the settings in the custom DB parameter group for the RDS for PostgreSQL DB instance. If you don't want database users to bypass your audit logging configuration settings, be sure to change their permissions.

Suppose that your RDS for PostgreSQL DB instance is configured to audit the same level of activity for all users and databases. You then decide that you don't want to audit the user `myuser`. You can turn off auditing for `myuser` with the following SQL command.

```
ALTER USER myuser SET pgaudit.log TO 'NONE';
```

Then, you can use the following query to check the `user_specific_settings` column for `pgaudit.log` to confirm that the parameter is set to `NONE`.

```
SELECT
    username AS user_name,
    useconfig AS user_specific_settings
FROM
    pg_user
WHERE
```

```
username = 'myuser';
```

You see output such as the following.

```
user_name | user_specific_settings
-----+-----
myuser    | {pgaudit.log=NONE}
(1 row)
```

You can turn off logging for a given user in the midst of their session with the database with the following command.

```
ALTER USER myuser IN DATABASE mydatabase SET pgaudit.log TO 'none';
```

Use the following query to check the settings column for pgaudit.log for a specific user and database combination.

```
SELECT
  username AS "user_name",
  datname AS "database_name",
  pg_catalog.array_to_string(setconfig, E'\n') AS "settings"
FROM
  pg_catalog.pg_db_role_setting s
  LEFT JOIN pg_catalog.pg_database d ON d.oid = setdatabase
  LEFT JOIN pg_catalog.pg_user r ON r.usesysid = setrole
WHERE
  username = 'myuser'
  AND datname = 'mydatabase'
ORDER BY
  1,
  2;
```

You see output similar to the following.

```
user_name | database_name | settings
-----+-----+-----
myuser    | mydatabase    | pgaudit.log=none
(1 row)
```

After turning off auditing for myuser, you decide that you don't want to track changes to mydatabase. You turn off auditing for that specific database by using the following command.

```
ALTER DATABASE mydatabase SET pgaudit.log to 'NONE';
```

Then, use the following query to check the `database_specific_settings` column to confirm that `pgaudit.log` is set to `NONE`.

```
SELECT
a.datname AS database_name,
b.setconfig AS database_specific_settings
FROM
pg_database a
FULL JOIN pg_db_role_setting b ON a.oid = b.setdatabase
WHERE
a.datname = 'mydatabase';
```

You see output such as the following.

```
database_name | database_specific_settings
-----+-----
mydatabase    | {pgaudit.log=NONE}
(1 row)
```

To return settings to the default setting for `myuser`, use the following command:

```
ALTER USER myuser RESET pgaudit.log;
```

To return settings to their default setting for a database, use the following command.

```
ALTER DATABASE mydatabase RESET pgaudit.log;
```

To reset user and database to the default setting, use the following command.

```
ALTER USER myuser IN DATABASE mydatabase RESET pgaudit.log;
```

You can also capture specific events to the log by setting the `pgaudit.log` to one of the other allowed values for the `pgaudit.log` parameter. For more information, see [List of allowable settings for the `pgaudit.log` parameter](#).

```
ALTER USER myuser SET pgaudit.log TO 'read';
ALTER DATABASE mydatabase SET pgaudit.log TO 'function';
```

```
ALTER USER myuser IN DATABASE mydatabase SET pgaudit.log TO 'read,function'
```

## Reference for the pgAudit extension

You can specify the level of detail that you want for your audit log by changing one or more of the parameters listed in this section.

### Controlling pgAudit behavior

You can control the audit logging by changing one or more of the parameters listed in the following table.

Parameter	Description
<code>pgaudit.log</code>	Specifies the statement classes that will be logged by session audit logging. Allowable values include <code>ddl</code> , <code>function</code> , <code>misc</code> , <code>read</code> , <code>role</code> , <code>write</code> , <code>none</code> , <code>all</code> . For more information, see <a href="#">List of allowable settings for the <code>pgaudit.log</code> parameter</a> .
<code>pgaudit.log_catalog</code>	When turned on (set to 1), adds statements to audit trail if all relations in a statement are in <code>pg_catalog</code> .
<code>pgaudit.log_level</code>	Specifies the log level to use for log entries. Allowed values: <code>debug5</code> , <code>debug4</code> , <code>debug3</code> , <code>debug2</code> , <code>debug1</code> , <code>info</code> , <code>notice</code> , <code>warning</code> , <code>log</code>
<code>pgaudit.log_parameter</code>	When turned on (set to 1), parameters passed with the statement are captured in the audit log.
<code>pgaudit.log_relation</code>	When turned on (set to 1), the audit log for the session creates a separate log entry for each relation ( <code>TABLE</code> , <code>VIEW</code> , and so on) referenced in a <code>SELECT</code> or <code>DML</code> statement.
<code>pgaudit.log_statement_once</code>	Specifies whether logging will include the statement text and parameters with the first log entry for a statement/substatement combination or with every entry.
<code>pgaudit.role</code>	Specifies the master role to use for object audit logging. The only allowable entry is <code>rds_pgaudit</code> .

## List of allowable settings for the `pgaudit.log` parameter

Value	Description
<code>none</code>	This is the default. No database changes are logged.
<code>all</code>	Logs everything (read, write, function, role, ddl, misc).
<code>ddl</code>	Logs all data definition language (DDL) statements that aren't included in the <code>ROLE</code> class.
<code>function</code>	Logs function calls and DO blocks.
<code>misc</code>	Logs miscellaneous commands, such as <code>DISCARD</code> , <code>FETCH</code> , <code>CHECKPOINT</code> , <code>VACUUM</code> , and <code>SET</code> .
<code>read</code>	Logs <code>SELECT</code> and <code>COPY</code> when the source is a relation (such as a table) or a query.
<code>role</code>	Logs statements related to roles and privileges, such as <code>GRANT</code> , <code>REVOKE</code> , <code>CREATE ROLE</code> , <code>ALTER ROLE</code> , and <code>DROP ROLE</code> .
<code>write</code>	Logs <code>INSERT</code> , <code>UPDATE</code> , <code>DELETE</code> , <code>TRUNCATE</code> , and <code>COPY</code> when the destination is a relation (table).

To log multiple event types with session auditing, use a comma-separated list. To log all event types, set `pgaudit.log` to `ALL`. Reboot your DB instance to apply the changes.

With object auditing, you can refine audit logging to work with specific relations. For example, you can specify that you want audit logging for `READ` operations on one or more tables.

## Scheduling maintenance with the PostgreSQL `pg_cron` extension

You can use the PostgreSQL `pg_cron` extension to schedule maintenance commands within a PostgreSQL database. For more information about the extension, see [What is `pg\_cron`?](#) in the `pg_cron` documentation.

The `pg_cron` extension is supported on RDS for PostgreSQL engine versions 12.5 and higher.

To learn more about using `pg_cron`, see [Schedule jobs with `pg\_cron` on your RDS for PostgreSQL or your Aurora PostgreSQL-Compatible Edition databases.](#)

### Topics

- [Setting up the `pg\_cron` extension](#)
- [Granting database users permissions to use `pg\_cron`](#)
- [Scheduling `pg\_cron` jobs](#)
- [Reference for the `pg\_cron` extension](#)

### Setting up the `pg_cron` extension

Set up the `pg_cron` extension as follows:

1. Modify the custom parameter group associated with your PostgreSQL DB instance by adding `pg_cron` to the `shared_preload_libraries` parameter value.
  - If your RDS for PostgreSQL DB instance uses the `rds.allowed_extensions` parameter to explicitly list extensions that can be installed, you need to add the `pg_cron` extension to the list. Only certain versions of RDS for PostgreSQL support the `rds.allowed_extensions` parameter. By default, all available extensions are allowed. For more information, see [Restricting installation of PostgreSQL extensions.](#)

Restart the PostgreSQL DB instance to have changes to the parameter group take effect. To learn more about working with parameter groups, see [Modifying parameters in a DB parameter group in Amazon RDS.](#)

2. After the PostgreSQL DB instance has restarted, run the following command using an account that has `rds_superuser` permissions. For example, if you used the default settings when you created your RDS for PostgreSQL DB instance, connect as user `postgres` and create the extension.

```
CREATE EXTENSION pg_cron;
```

The `pg_cron` scheduler is set in the default PostgreSQL database named `postgres`. The `pg_cron` objects are created in this `postgres` database and all scheduling actions run in this database.

3. You can use the default settings, or you can schedule jobs to run in other databases within your PostgreSQL DB instance. To schedule jobs for other databases within your PostgreSQL DB instance, see the example in [Scheduling a cron job for a database other than the default database](#).

## Granting database users permissions to use `pg_cron`

Installing the `pg_cron` extension requires the `rds_superuser` privileges. However, permissions to use the `pg_cron` can be granted (by a member of the `rds_superuser` group/role) to other database users, so that they can schedule their own jobs. We recommend that you grant permissions to the `cron` schema only as needed if it improves operations in your production environment.

To grant a database user permission in the `cron` schema, run the following command:

```
postgres=> GRANT USAGE ON SCHEMA cron TO db-user;
```

This gives *db-user* permission to access the `cron` schema to schedule cron jobs for the objects that they have permissions to access. If the database user doesn't have permissions, the job fails after posting the error message to the `postgresql.log` file, as shown in the following:

```
2020-12-08 16:41:00 UTC::@[30647]:ERROR: permission denied for table table-name
2020-12-08 16:41:00 UTC::@[27071]:LOG: background worker "pg_cron" (PID 30647) exited
with exit code 1
```

In other words, make sure that database users that are granted permissions on the `cron` schema also have permissions on the objects (tables, schemas, and so on) that they plan to schedule.

The details of the cron job and its success or failure are also captured in the `cron.job_run_details` table. For more information, see [Tables for scheduling jobs and capturing status](#).

## Scheduling pg\_cron jobs

The following sections show how you can schedule various management tasks using pg\_cron jobs.

### Note

When you create pg\_cron jobs, check that the `max_worker_processes` setting is larger than the number of `cron.max_running_jobs`. A pg\_cron job fails if it runs out of background worker processes. The default number of pg\_cron jobs is 5. For more information, see [Parameters for managing the pg\\_cron extension](#).

## Topics

- [Vacuuming a table](#)
- [Purging the pg\\_cron history table](#)
- [Logging errors to the postgresql.log file only](#)
- [Scheduling a cron job for a database other than the default database](#)

## Vacuuming a table

Autovacuum handles vacuum maintenance for most cases. However, you might want to schedule a vacuum of a specific table at a time of your choosing.

See also, [Working with the PostgreSQL autovacuum on Amazon RDS for PostgreSQL](#).

Following is an example of using the `cron.schedule` function to set up a job to use VACUUM FREEZE on a specific table every day at 22:00 (GMT).

```
SELECT cron.schedule('manual vacuum', '0 22 * * *', 'VACUUM FREEZE pgbench_accounts');
 schedule
-----
1
(1 row)
```

After the preceding example runs, you can check the history in the `cron.job_run_details` table as follows.

```
postgres=> SELECT * FROM cron.job_run_details;
```

```

jobid | runid | job_pid | database | username | command |
status | return_message | start_time | end_time
-----+-----+-----+-----+-----+-----+-----+-----
+-----+-----+-----+-----+-----+-----+-----+-----
+-----+-----+-----+-----+-----+-----+-----+-----
1 | 1 | 3395 | postgres | adminuser | vacuum freeze pgbench_accounts |
| succeeded | VACUUM | 2020-12-04 21:10:00.050386+00 | 2020-12-04
21:10:00.072028+00
(1 row)

```

Following is a query of the `cron.job_run_details` table to see the failed jobs.

```

postgres=> SELECT * FROM cron.job_run_details WHERE status = 'failed';
jobid | runid | job_pid | database | username | command | status
| return_message | start_time | end_time
-----+-----+-----+-----+-----+-----+-----+-----
+-----+-----+-----+-----+-----+-----+-----+-----
+-----+-----+-----+-----+-----+-----+-----+-----
5 | 4 | 30339 | postgres | adminuser | vacuum freeze pgbench_account | failed
| ERROR: relation "pgbench_account" does not exist | 2020-12-04 21:48:00.015145+00 |
2020-12-04 21:48:00.029567+00
(1 row)

```

For more information, see [Tables for scheduling jobs and capturing status](#).

### Purging the `pg_cron` history table

The `cron.job_run_details` table contains a history of cron jobs that can become very large over time. We recommend that you schedule a job that purges this table. For example, keeping a week's worth of entries might be sufficient for troubleshooting purposes.

The following example uses the [cron.schedule](#) function to schedule a job that runs every day at midnight to purge the `cron.job_run_details` table. The job keeps only the last seven days. Use your `rds_superuser` account to schedule the job such as the following.

```

SELECT cron.schedule('0 0 * * *', $$DELETE
FROM cron.job_run_details
WHERE end_time < now() - interval '7 days'$$);

```

For more information, see [Tables for scheduling jobs and capturing status](#).

## Logging errors to the postgresql.log file only

To prevent writing to the `cron.job_run_details` table, modify the parameter group associated with the PostgreSQL DB instance and set the `cron.log_run` parameter to `off`. The `pg_cron` extension no longer writes to the table and captures errors to the `postgresql.log` file only. For more information, see [Modifying parameters in a DB parameter group in Amazon RDS](#).

Use the following command to check the value of the `cron.log_run` parameter.

```
postgres=> SHOW cron.log_run;
```

For more information, see [Parameters for managing the pg\\_cron extension](#).

## Scheduling a cron job for a database other than the default database

The metadata for `pg_cron` is all held in the PostgreSQL default database named `postgres`. Because background workers are used for running the maintenance cron jobs, you can schedule a job in any of your databases within the PostgreSQL DB instance:

1. In the cron database, schedule the job as you normally do using the [cron.schedule](#).

```
postgres=> SELECT cron.schedule('database1 manual vacuum', '29 03 * * *', 'vacuum
freeze test_table');
```

2. As a user with the `rds_superuser` role, update the database column for the job that you just created so that it runs in another database within your PostgreSQL DB instance.

```
postgres=> UPDATE cron.job SET database = 'database1' WHERE jobid = 106;
```

3. Verify by querying the `cron.job` table.

```
postgres=> SELECT * FROM cron.job;
jobid | schedule      | command                                     | nodename | nodeport |
database | username     | active | jobname
-----+-----+-----+-----+-----+-----+
+-----+-----+-----+-----+-----+-----+
106   | 29 03 * * *  | vacuum freeze test_table                   | localhost | 8192     |
database1 | adminuser   | t      | database1 manual vacuum
   1   | 59 23 * * *  | vacuum freeze pgbench_accounts            | localhost | 8192     |
postgres | adminuser   | t      | manual vacuum
(2 rows)
```

**Note**

In some situations, you might add a cron job that you intend to run on a different database. In such cases, the job might try to run in the default database (postgres) before you update the correct database column. If the user name has permissions, the job successfully runs in the default database.

**Reference for the pg\_cron extension**

You can use the following parameters, functions, and tables with the pg\_cron extension. For more information, see [What is pg\\_cron?](#) in the pg\_cron documentation.

**Topics**

- [Parameters for managing the pg\\_cron extension](#)
- [Function reference: cron.schedule](#)
- [Function reference: cron.unschedule](#)
- [Tables for scheduling jobs and capturing status](#)

**Parameters for managing the pg\_cron extension**

Following is a list of parameters that control the pg\_cron extension behavior.

Parameter	Description
cron.database_name	The database in which pg_cron metadata is kept.
cron.host	The hostname to connect to PostgreSQL. You can't modify this value.
cron.log_run	Log every job that runs in the job_run_details table. Values are on or off. For more information, see <a href="#">Tables for scheduling jobs and capturing status</a> .

Parameter	Description
<code>cron.log_statement</code>	Log all cron statements before running them. Values are on or off.
<code>cron.max_running_jobs</code>	The maximum number of jobs that can run concurrently.
<code>cron.use_background_workers</code>	Use background workers instead of client sessions. You can't modify this value.

Use the following SQL command to display these parameters and their values.

```
postgres=> SELECT name, setting, short_desc FROM pg_settings WHERE name LIKE 'cron.%'  
ORDER BY name;
```

### Function reference: `cron.schedule`

This function schedules a cron job. The job is initially scheduled in the default postgres database. The function returns a `bigint` value representing the job identifier. To schedule jobs to run in other databases within your PostgreSQL DB instance, see the example in [Scheduling a cron job for a database other than the default database](#).

The function has two syntax formats.

### Syntax

```
cron.schedule (job_name,  
              schedule,  
              command  
);  
  
cron.schedule (schedule,  
              command  
);
```

## Parameters

Parameter	Description
job_name	The name of the cron job.
schedule	Text indicating the schedule for the cron job. The format is the standard cron format.
command	Text of the command to run.

## Examples

```
postgres=> SELECT cron.schedule ('test','0 10 * * *', 'VACUUM pgbench_history');
 schedule
-----
          145
(1 row)
```

```
postgres=> SELECT cron.schedule ('0 15 * * *', 'VACUUM pgbench_accounts');
 schedule
-----
          146
(1 row)
```

## Function reference: cron.unschedule

This function deletes a cron job. You can specify either the `job_name` or the `job_id`. A policy makes sure that you are the owner to remove the schedule for the job. The function returns a Boolean indicating success or failure.

The function has the following syntax formats.

### Syntax

```
cron.unschedule (job_id);

cron.unschedule (job_name);
```

## Parameters

Parameter	Description
<code>job_id</code>	A job identifier that was returned from the <code>cron.schedule</code> function when the cron job was scheduled.
<code>job_name</code>	The name of a cron job that was scheduled with the <code>cron.schedule</code> function.

## Examples

```
postgres=> SELECT cron.unschedule(108);
unschedule
-----
t
(1 row)

postgres=> SELECT cron.unschedule('test');
unschedule
-----
t
(1 row)
```

## Tables for scheduling jobs and capturing status

The following tables are used to schedule the cron jobs and record how the jobs completed.

Table	Description
<code>cron.job</code>	Contains the metadata about each scheduled job. Most interactions with this table should be done by using the <code>cron.schedule</code> and <code>cron.unschedule</code> functions.

Table	Description
	<p> <b>Important</b></p> <p>We recommend that you don't give update or insert privileges directly to this table. Doing so would allow the user to update the username column to run as <code>rds-superuser</code> .</p>
cron.job_run_details	<p>Contains historic information about past scheduled jobs that ran. This is useful to investigate the status, return messages, and start and end time from the job that ran.</p> <p> <b>Note</b></p> <p>To prevent this table from growing indefinitely, purge it on a regular basis. For an example, see <a href="#">Purging the pg_cron history table</a>.</p>

## Using `pglogical` to synchronize data across instances

All currently available RDS for PostgreSQL versions support the `pglogical` extension. The `pglogical` extension predates the functionally similar logical replication feature that was introduced by PostgreSQL in version 10. For more information, see [Performing logical replication for Amazon RDS for PostgreSQL](#).

The `pglogical` extension supports logical replication between two or more RDS for PostgreSQL DB instances. It also supports replication between different PostgreSQL versions, and between databases running on RDS for PostgreSQL DB instances and Aurora PostgreSQL DB clusters. The `pglogical` extension uses a publish-subscribe model to replicate changes to tables and other objects, such as sequences, from a publisher to a subscriber. It relies on a replication slot to ensure that changes are synchronized from a publisher node to a subscriber node, defined as follows.

- The *publisher node* is the RDS for PostgreSQL DB instance that's the source of data to be replicated to other nodes. The publisher node defines the tables to be replicated in a publication set.
- The *subscriber node* is the RDS for PostgreSQL DB instance that receives WAL updates from the publisher. The subscriber creates a subscription to connect to the publisher and get the decoded WAL data. When the subscriber creates the subscription, the replication slot is created on the publisher node.

Following, you can find information about setting up the `pglogical` extension.

### Topics

- [Requirements and limitations for the `pglogical` extension](#)
- [Setting up the `pglogical` extension](#)
- [Setting up logical replication for RDS for PostgreSQL DB instance](#)
- [Reestablishing logical replication after a major upgrade](#)
- [Managing logical replication slots for RDS for PostgreSQL](#)
- [Parameter reference for the `pglogical` extension](#)

## Requirements and limitations for the `pglogical` extension

All currently available releases of RDS for PostgreSQL support the `pglogical` extension.

Both the publisher node and the subscriber node must be set up for logical replication.

The tables that you want to replicate from a publisher to a subscriber must have the same names and the same schema. These tables must also contain the same columns, and the columns must use the same data types. Both publisher and subscriber tables must have the same primary keys. We recommend that you use only the PRIMARY KEY as the unique constraint.

The tables on the subscriber node can have more permissive constraints than those on the publisher node for CHECK constraints and NOT NULL constraints.

The `pglogical` extension provides features such as two-way replication that aren't supported by the logical replication feature built into PostgreSQL (version 10 and higher). For more information, see [PostgreSQL bi-directional replication using pglogical](#).

## Setting up the pglogical extension

To set up the `pglogical` extension on your RDS for PostgreSQL DB instance, you add `pglogical` to the shared libraries on the custom DB parameter group for your RDS for PostgreSQL DB instance. You also need to set the value of the `rds.logical_replication` parameter to 1, to turn on logical decoding. Finally, you create the extension in the database. You can use the AWS Management Console or the AWS CLI for these tasks.

You must have permissions as the `rds_superuser` role to perform these tasks.

The steps following assume that your RDS for PostgreSQL DB instance is associated with a custom DB parameter group. For information about creating a custom DB parameter group, see [Parameter groups for Amazon RDS](#).

### Console

#### To set up the pglogical extension

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose your RDS for PostgreSQL DB instance.
3. Open the **Configuration** tab for your RDS for PostgreSQL DB instance. Among the Instance details, find the **Parameter group** link.
4. Choose the link to open the custom parameters associated with your RDS for PostgreSQL DB instance.

- In the **Parameters** search field, type `shared_pre` to find the `shared_preload_libraries` parameter.
- Choose **Edit parameters** to access the property values.
- Add `pglogical` to the list in the **Values** field. Use a comma to separate items in the list of values.

RDS > Parameter groups > docs-lab-rpg-12-parameter-group

## docs-lab-rpg-12-parameter-group

**Parameters**

Q shared\_pre X

<input type="checkbox"/>	Name	Values	Allowed values
<input type="checkbox"/>	shared_preload_libraries	pglogical,pg_stat_statements	auto_explain, orafce, pgaudit, pglogical, pg_bigm, pg_cron, pg_hint_plan, pg_prewarm, pg_similarity, pg_stat_statements, pg_transport, plprofiler

- Find the `rds.logical_replication` parameter and set it to `1`, to turn on logical replication.
- Reboot the RDS for PostgreSQL DB instance so that your changes take effect.
- When the instance is available, you can use `psql` (or `pgAdmin`) to connect to the RDS for PostgreSQL DB instance.

```
psql --host=111122223333.aws-region.rds.amazonaws.com --port=5432 --
username=postgres --password --dbname=labdb
```

- To verify that `pglogical` is initialized, run the following command.

```
SHOW shared_preload_libraries;
shared_preload_libraries
-----
rdsutils,pglogical
(1 row)
```

- Verify the setting that enables logical decoding, as follows.

```
SHOW wal_level;
wal_level
-----
logical
(1 row)
```

13. Create the extension, as follows.

```
CREATE EXTENSION pglogical;
EXTENSION CREATED
```

14. Choose **Save changes**.
15. Open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
16. Choose your RDS for PostgreSQL DB instance from the Databases list to select it, and then choose **Reboot** from the Actions menu.

## AWS CLI

### To setup the pglogical extension

To setup pglogical using the AWS CLI, you call the [modify-db-parameter-group](#) operation to modify certain parameters in your custom parameter group as shown in the following procedure.

1. Use the following AWS CLI command to add pglogical to the shared\_preload\_libraries parameter.

```
aws rds modify-db-parameter-group \
  --db-parameter-group-name custom-param-group-name \
  --parameters
  "ParameterName=shared_preload_libraries,ParameterValue=pglogical,ApplyMethod=pending-
  reboot" \
  --region aws-region
```

2. Use the following AWS CLI command to set rds.logical\_replication to 1 to turn on the logical decoding capability for the RDS for PostgreSQL DB instance.

```
aws rds modify-db-parameter-group \
  --db-parameter-group-name custom-param-group-name \
```

```
--parameters  
"ParameterName=rds.logical_replication,ParameterValue=1,ApplyMethod=pending-  
reboot" \  
--region aws-region
```

3. Use the following AWS CLI command to reboot the RDS for PostgreSQL DB instance so that the pglogical library is initialized.

```
aws rds reboot-db-instance \  
--db-instance-identifier your-instance \  
--region aws-region
```

4. When the instance is available, use `psql` to connect to the RDS for PostgreSQL DB instance.

```
psql --host=111122223333.aws-region.rds.amazonaws.com --port=5432 --  
username=postgres --password --dbname=labdb
```

5. Create the extension, as follows.

```
CREATE EXTENSION pglogical;  
EXTENSION CREATED
```

6. Reboot the RDS for PostgreSQL DB instance using the following AWS CLI command.

```
aws rds reboot-db-instance \  
--db-instance-identifier your-instance \  
--region aws-region
```

## Setting up logical replication for RDS for PostgreSQL DB instance

The following procedure shows you how to start logical replication between two RDS for PostgreSQL DB instances. The steps assume that both the source (publisher) and the target (subscriber) have the `pglogical` extension set up as detailed in [Setting up the pglogical extension](#).

### To create the publisher node and define the tables to replicate

These steps assume that your RDS for PostgreSQL DB instance has a database that has one or more tables that you want to replicate to another node. You need to recreate the table structure from the publisher on the subscriber, so first, get the table structure if necessary. You can do

that by using the `psql` metacommand `\d tablename` and then creating the same table on the subscriber instance. The following procedure creates an example table on the publisher (source) for demonstration purposes.

1. Use `psql` to connect to the instance that has the table you want to use as a source for subscribers.

```
psql --host=source-instance.aws-region.rds.amazonaws.com --port=5432 --  
username=postgres --password --dbname=labdb
```

If you don't have an existing table that you want to replicate, you can create a sample table as follows.

- a. Create an example table using the following SQL statement.

```
CREATE TABLE docs_lab_table (a int PRIMARY KEY);
```

- b. Populate the table with generated data by using the following SQL statement.

```
INSERT INTO docs_lab_table VALUES (generate_series(1,5000));  
INSERT 0 5000
```

- c. Verify that data exists in the table by using the following SQL statement.

```
SELECT count(*) FROM docs_lab_table;
```

2. Identify this RDS for PostgreSQL DB instance as the publisher node, as follows.

```
SELECT pglogical.create_node(  
    node_name := 'docs_lab_provider',  
    dsn := 'host=source-instance.aws-region.rds.amazonaws.com port=5432  
    dbname=labdb');  
create_node  
-----  
    3410995529  
(1 row)
```

3. Add the table that you want to replicate to the default replication set. For more information about replication sets, see [Replication sets](#) in the `pglogical` documentation.

```
SELECT pglogical.replication_set_add_table('default', 'docs_lab_table', 'true',
NULL, NULL);
replication_set_add_table
-----
t
(1 row)
```

The publisher node setup is complete. You can now set up the subscriber node to receive the updates from the publisher.

### To set up the subscriber node and create a subscription to receive updates

These steps assume that the RDS for PostgreSQL DB instance has been set up with the `pglogical` extension. For more information, see [Setting up the pglogical extension](#).

1. Use `psql` to connect to the instance that you want to receive updates from the publisher.

```
psql --host=target-instance.aws-region.rds.amazonaws.com --port=5432 --
username=postgres --password --dbname=labdb
```

2. On the subscriber RDS for PostgreSQL DB instance, create the same table that exists on the publisher. For this example, the table is `docs_lab_table`. You can create the table as follows.

```
CREATE TABLE docs_lab_table (a int PRIMARY KEY);
```

3. Verify that this table is empty.

```
SELECT count(*) FROM docs_lab_table;
count
-----
0
(1 row)
```

4. Identify this RDS for PostgreSQL DB instance as the subscriber node, as follows.

```
SELECT pglogical.create_node(
node_name := 'docs_lab_target',
dsn := 'host=target-instance.aws-region.rds.amazonaws.com port=5432
sslmode=require dbname=labdb user=postgres password=*****');
create_node
```

```

-----
      2182738256
(1 row)

```

## 5. Create the subscription.

```

SELECT pglogical.create_subscription(
  subscription_name := 'docs_lab_subscription',
  provider_dsn := 'host=source-instance.aws-region.rds.amazonaws.com port=5432
sslmode=require dbname=labdb user=postgres password=*****',
  replication_sets := ARRAY['default'],
  synchronize_data := true,
  forward_origins := '{}');
create_subscription
-----
1038357190
(1 row)

```

When you complete this step, the data from the table on the publisher is created in the table on the subscriber. You can verify that this has occurred by using the following SQL query.

```

SELECT count(*) FROM docs_lab_table;
count
-----
   5000
(1 row)

```

From this point forward, changes made to the table on the publisher are replicated to the table on the subscriber.

## Reestablishing logical replication after a major upgrade

Before you can perform a major version upgrade of an RDS for PostgreSQL DB instance that's set up as a publisher node for logical replication, you must drop all replication slots, even those that aren't active. We recommend that you temporarily divert database transactions from the publisher node, drop the replication slots, upgrade the RDS for PostgreSQL DB instance, and then re-establish and restart replication.

The replication slots are hosted on the publisher node only. The RDS for PostgreSQL subscriber node in a logical replication scenario has no slots to drop, but it can't be upgraded to a major

version while it's designated as a subscriber node with a subscription to the publisher. Before upgrading the RDS for PostgreSQL subscriber node, drop the subscription and the node. For more information, see [Managing logical replication slots for RDS for PostgreSQL](#).

## Determining that logical replication has been disrupted

You can determine that the replication process has been disrupted by querying either the publisher node or the subscriber node, as follows.

### To check the publisher node

- Use `psql` to connect to the publisher node, and then query the `pg_replication_slots` function. Note the value in the `active` column. Normally, this will return `t` (true), showing that replication is active. If the query returns `f` (false), it's an indication that replication to the subscriber has stopped.

```
SELECT slot_name,plugin,slot_type,active FROM pg_replication_slots;
          slot_name          |      plugin      | slot_type | active
-----+-----+-----+-----
pgl_labdb_docs_labcb4fa94_docs_lab3de412c | pglogical_output | logical   | f
(1 row)
```

### To check the subscriber node

On the subscriber node, you can check the status of replication in three different ways.

- Look through the PostgreSQL logs on the subscriber node to find failure messages. The log identifies failure with messages that include exit code 1, as shown following.

```
2022-07-06 16:17:03 UTC::@[7361]:LOG: background worker "pglogical apply
16404:2880255011" (PID 14610) exited with exit code 1
2022-07-06 16:19:44 UTC::@[7361]:LOG: background worker "pglogical apply
16404:2880255011" (PID 21783) exited with exit code 1
```

- Query the `pg_replication_origin` function. Connect to the database on the subscriber node using `psql` and query the `pg_replication_origin` function, as follows.

```
SELECT * FROM pg_replication_origin;
 roident | roname
-----+-----
```

```
(0 rows)
```

The empty result set means that replication has been disrupted. Normally, you see output such as the following.

```
roident | roname
-----+-----
      1 | pgl_labdb_docs_labcb4fa94_docs_lab3de412c
(1 row)
```

- Query the `pglogical.show_subscription_status` function as shown in the following example.

```
SELECT subscription_name,status,slot_name FROM pglogical.show_subscription_status();
 subscription_name | status | slot_name
-----+-----+-----
 docs_lab_subscription | down | pgl_labdb_docs_labcb4fa94_docs_lab3de412c
(1 row)
```

This output shows that replication has been disrupted. Its status is down. Normally, the output shows the status as `replicating`.

If your logical replication process has been disrupted, you can re-establish replication by following these steps.

### To reestablish logical replication between publisher and subscriber nodes

To re-establish replication, you first disconnect the subscriber from the publisher node and then re-establish the subscription, as outlined in these steps.

1. Connect to the subscriber node using `psql` as follows.

```
psql --host=222222222222.aws-region.rds.amazonaws.com --port=5432 --
username=postgres --password --dbname=labdb
```

2. Deactivate the subscription by using the `pglogical.alter_subscription_disable` function.

```
SELECT pglogical.alter_subscription_disable('docs_lab_subscription',true);
alter_subscription_disable
```

```
-----
 t
(1 row)
```

3. Get the publisher node's identifier by querying the `pg_replication_origin`, as follows.

```
SELECT * FROM pg_replication_origin;
 roident |          roname
-----+-----
      1 | pgl_labdb_docs_labcb4fa94_docs_lab3de412c
(1 row)
```

4. Use the response from the previous step with the `pg_replication_origin_create` command to assign the identifier that can be used by the subscription when re-established.

```
SELECT pg_replication_origin_create('pgl_labdb_docs_labcb4fa94_docs_lab3de412c');
 pg_replication_origin_create
-----
                               1
(1 row)
```

5. Turn on the subscription by passing its name with a status of `true`, as shown in the following example.

```
SELECT pglogical.alter_subscription_enable('docs_lab_subscription',true);
 alter_subscription_enable
-----
 t
(1 row)
```

Check the status of the node. Its status should be replicating as shown in this example.

```
SELECT subscription_name,status,slot_name
FROM pglogical.show_subscription_status();
 subscription_name | status | slot_name
-----+-----+-----
 docs_lab_subscription | replicating | pgl_labdb_docs_lab98f517b_docs_lab3de412c
(1 row)
```

Check the status of the subscriber's replication slot on the publisher node. The slot's active column should return t (true), indicating that replication has been re-established.

```
SELECT slot_name,plugin,slot_type,active
FROM pg_replication_slots;
      slot_name          |      plugin      | slot_type | active
-----+-----+-----+-----
pgl_labdb_docs_lab98f517b_docs_lab3de412c | pglogical_output | logical  | t
(1 row)
```

## Managing logical replication slots for RDS for PostgreSQL

Before you can perform a major version upgrade on an RDS for PostgreSQL DB instance that's serving as a publisher node in a logical replication scenario, you must drop the replication slots on the instance. The major version upgrade pre-check process notifies you that the upgrade can't proceed until the slots are dropped.

To drop slots from your RDS for PostgreSQL DB instance, first drop the subscription and then drop the slot.

To identify replication slots that were created using the `pglogical` extension, log in to each database and get the name of the nodes. When you query the subscriber node, you get both the publisher and the subscriber nodes in the output, as shown in this example.

```
SELECT * FROM pglogical.node;
node_id | node_name
-----+-----
2182738256 | docs_lab_target
3410995529 | docs_lab_provider
(2 rows)
```

You can get the details about the subscription with the following query.

```
SELECT sub_name,sub_slot_name,sub_target
FROM pglogical.subscription;
sub_name | sub_slot_name          | sub_target
-----+-----+-----
docs_lab_subscription | pgl_labdb_docs_labcb4fa94_docs_lab3de412c | 2182738256
(1 row)
```

You can now drop the subscription, as follows.

```
SELECT pglogical.drop_subscription(subscription_name := 'docs_lab_subscription');
drop_subscription
-----
                1
(1 row)
```

After dropping the subscription, you can delete the node.

```
SELECT pglogical.drop_node(node_name := 'docs-lab-subscriber');
drop_node
-----
t
(1 row)
```

You can verify that the node no longer exists, as follows.

```
SELECT * FROM pglogical.node;
node_id | node_name
-----+-----
(0 rows)
```

## Parameter reference for the pglogical extension

In the table you can find parameters associated with the `pglogical` extension. Parameters such as `pglogical.conflict_log_level` and `pglogical.conflict_resolution` are used to handle update conflicts. Conflicts can emerge when changes are made locally to the same tables that are subscribed to changes from the publisher. Conflicts can also occur during various scenarios, such as two-way replication or when multiple subscribers are replicating from the same publisher. For more information, see [PostgreSQL bi-directional replication using pglogical](#).

Parameter	Description
<code>pglogical.batch_inserts</code>	Batch inserts if possible. Not set by default. Change to '1' to turn on, '0' to turn off.
<code>pglogical.conflict_log_level</code>	Sets the log level to use for logging resolved conflicts. Supported string values are debug5, debug4, debug3, debug2, debug1, info, notice, warning, error, log, fatal, panic.

Parameter	Description
<code>pglogical.conflict_resolution</code>	Sets method to use to resolve conflicts when conflicts are resolvable. Supported string values are <code>error</code> , <code>apply_remote</code> , <code>keep_local</code> , <code>last_update_wins</code> , <code>first_update_wins</code> .
<code>pglogical.extra_connection_options</code>	Connection options to add to all peer node connections.
<code>pglogical.synchronous_commit</code>	pglogical specific synchronous commit value
<code>pglogical.use_spi</code>	Use SPI (server programming interface) instead of low-level API to apply changes. Set to '1' to turn on, '0' to turn off. For more information about SPI, see <a href="#">Server Programming Interface</a> in the PostgreSQL documentation.

## Using `pgactive` to support active-active replication

The `pgactive` extension uses active-active replication to support and coordinate write operations on multiple RDS for PostgreSQL databases. Amazon RDS for PostgreSQL supports the `pgactive` extension on the following versions:

- RDS for PostgreSQL 16.1 and higher 16 versions
- RDS for PostgreSQL 15.4-R2 and higher 15 versions
- RDS for PostgreSQL 14.10 and higher 14 versions
- RDS for PostgreSQL 13.13 and higher 13 versions
- RDS for PostgreSQL 12.17 and higher 12 versions
- RDS for PostgreSQL 11.22

### Note

When there are write operations on more than one database in a replication configuration, conflicts are possible. For more information, see [Handling conflicts in active-active replication](#)

### Topics

- [Initializing the `pgactive` extension capability](#)
- [Setting up active-active replication for RDS for PostgreSQL DB instances](#)
- [Handling conflicts in active-active replication](#)
- [Handling sequences in active-active replication](#)
- [Parameter reference for the `pgactive` extension](#)
- [Measuring replication lag among `pgactive` members](#)
- [Limitations for the `pgactive` extension](#)

## Initializing the `pgactive` extension capability

To initialize the `pgactive` extension capability on your RDS for PostgreSQL DB instance, set the value of the `rds.enable_pgactive` parameter to 1 and then create the extension in the

database. Doing so automatically turns on the parameters `rds.logical_replication` and `track_commit_timestamp` and sets the value of `wal_level` to `logical`.

You must have permissions as the `rds_superuser` role to perform these tasks.

You can use the AWS Management Console or the AWS CLI to create the required RDS for PostgreSQL DB instances. The steps following assume that your RDS for PostgreSQL DB instance is associated with a custom DB parameter group. For information about creating a custom DB parameter group, see [Parameter groups for Amazon RDS](#).

## Console

### To initialize the pgactive extension capability

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose your RDS for PostgreSQL DB instance.
3. Open the **Configuration** tab for your RDS for PostgreSQL DB instance. In the instance details, find the **DB instance parameter group** link.
4. Choose the link to open the custom parameters associated with your RDS for PostgreSQL DB instance.
5. Find the `rds.enable_pgactive` parameter, and set it to 1 to initialize the `pgactive` capability.
6. Choose **Save changes**.
7. In the navigation pane of the Amazon RDS console, choose **Databases**.
8. Select your RDS for PostgreSQL DB instance, and then choose **Reboot** from the **Actions** menu.
9. Confirm the DB instance reboot so that your changes take effect.
10. When the DB instance is available, you can use `psql` or any other PostgreSQL client to connect to the RDS for PostgreSQL DB instance.

The following example assumes that your RDS for PostgreSQL DB instance has a default database named `postgres`.

```
psql --host=mydb.111122223333.aws-region.rds.amazonaws.com --port=5432 --  
username=master_username --password --dbname=postgres
```

11. To verify that `pgactive` is initialized, run the following command.

```
postgres=>SELECT setting ~ 'pgactive'  
FROM pg_catalog.pg_settings  
WHERE name = 'shared_preload_libraries';
```

If `pgactive` is in `shared_preload_libraries`, the preceding command will return the following:

```
?column?  
-----  
t
```

12. Create the extension, as follows.

```
postgres=> CREATE EXTENSION pgactive;
```

## AWS CLI

### To initialize the `pgactive` extension capability

To initialize the `pgactive` using the AWS CLI, call the [modify-db-parameter-group](#) operation to modify certain parameters in your custom parameter group as shown in the following procedure.

1. Use the following AWS CLI command to set `rds.enable_pgactive` to 1 to initialize the `pgactive` capability for the RDS for PostgreSQL DB instance.

```
postgres=>aws rds modify-db-parameter-group \  
  --db-parameter-group-name custom-param-group-name \  
  --parameters  
  "ParameterName=rds.enable_pgactive,ParameterValue=1,ApplyMethod=pending-reboot" \  
  --region aws-region
```

2. Use the following AWS CLI command to reboot the RDS for PostgreSQL DB instance so that the `pgactive` library is initialized.

```
aws rds reboot-db-instance \  
  --db-instance-identifier your-instance \  
  --region aws-region
```

3. When the instance is available, use `psql` to connect to the RDS for PostgreSQL DB instance.

```
psql --host=mydb.111122223333.aws-region.rds.amazonaws.com --port=5432 --  
username=master user --password --dbname=postgres
```

4. Create the extension, as follows.

```
postgres=> CREATE EXTENSION pgactive;
```

## Setting up active-active replication for RDS for PostgreSQL DB instances

The following procedure shows you how to start active-active replication between two RDS for PostgreSQL DB instances running PostgreSQL 15.4 or higher in the same region. To run the multi-region high availability example, you need to deploy Amazon RDS for PostgreSQL instances in two different regions and set up VPC Peering. For more information, see [VPC peering](#).

### Note

Sending traffic between multiple regions may incur additional costs.

These steps assume that the RDS for PostgreSQL DB instance has been setup with the `pgactive` extension. For more information, see [Initializing the pgactive extension capability](#).

### To configure the first RDS for PostgreSQL DB instance with the `pgactive` extension

The following example illustrates how the `pgactive` group is created, along with other steps required to create the `pgactive` extension on the RDS for PostgreSQL DB instance.

1. Use `psql` or another client tool to connect to your first RDS for PostgreSQL DB instance.

```
psql --host=firstinstance.111122223333.aws-region.rds.amazonaws.com --port=5432 --  
username=master username --password --dbname=postgres
```

2. Create a database on the RDS for PostgreSQL instance using the following command:

```
postgres=> CREATE DATABASE app;
```

3. Switch connection to the new database using the following command:

```
\c app
```

4. To check if the `shared_preload_libraries` parameter contains `pgactive`, run the following command:

```
app=>SELECT setting ~ 'pgactive' FROM pg_catalog.pg_settings WHERE name =
'shared_preload_libraries';
```

```
?column?
-----
t
```

5. Create and populate a sample table using the following SQL statements:
  - a. Create an example table using the following SQL statement.

```
app=> CREATE SCHEMA inventory;
CREATE TABLE inventory.products (
id int PRIMARY KEY, product_name text NOT NULL,
created_at timestamptz NOT NULL DEFAULT CURRENT_TIMESTAMP);
```

- b. Populate the table with some sample data by using the following SQL statement.

```
app=> INSERT INTO inventory.products (id, product_name)
VALUES (1, 'soap'), (2, 'shampoo'), (3, 'conditioner');
```

- c. Verify that data exists in the table by using the following SQL statement.

```
app=>SELECT count(*) FROM inventory.products;

count
-----
3
```

6. Create `pgactive` extension on the existing database.

```
app=> CREATE EXTENSION pgactive;
```

7. Create and initialize the `pgactive` group using the following commands:

```
app=> SELECT pgactive.pgactive_create_group(
    node_name := 'node1-app',
    node_dsn := 'dbname=app host=firstinstance.111122223333.aws-
region.rds.amazonaws.com user=master username password=PASSWORD');
```

node1-app is the name that you assign to uniquely identify a node in the pgactive group.

### Note

To perform this step successfully on a DB instance that is publicly accessible, you must turn on the `rds.custom_dns_resolution` parameter by setting it to 1.

8. To check if the DB instance is ready, use the following command:

```
app=> SELECT pgactive.pgactive_wait_for_node_ready();
```

If the command succeeds, you can see the following output:

```
pgactive_wait_for_node_ready
-----
(1 row)
```

## To configure the second RDS for PostgreSQL instance and join it to the pgactive group

The following example illustrates how you can join an RDS for PostgreSQL DB instance to the pgactive group, along with other steps that are required to create the pgactive extension on the DB instance.

These steps assume that another RDS for PostgreSQL DB instances has been set up with the pgactive extension. For more information, see [Initializing the pgactive extension capability](#).

1. Use `psql` to connect to the instance that you want to receive updates from the publisher.

```
psql --host=secondinstance.111122223333.aws-region.rds.amazonaws.com --port=5432 --
username=master username --password --dbname=postgres
```

2. Create a database on the second RDS for PostgreSQL DB instance using the following command:

```
postgres=> CREATE DATABASE app;
```

3. Switch connection to the new database using the following command:

```
\c app
```

4. Create the `pgactive` extension on the existing database.

```
app=> CREATE EXTENSION pgactive;
```

5. Join the RDS for PostgreSQL second DB instance to the `pgactive` group as follows.

```
app=> SELECT pgactive.pgactive_join_group(
node_name := 'node2-app',
node_dsn := 'dbname=app host=secondinstance.111122223333.aws-
region.rds.amazonaws.com user=master username password=PASSWORD',
join_using_dsn := 'dbname=app host=firstinstance.111122223333.aws-
region.rds.amazonaws.com user=postgres password=PASSWORD');
```

`node2-app` is the name that you assign to uniquely identify a node in the `pgactive` group.

6. To check if the DB instance is ready, use the following command:

```
app=> SELECT pgactive.pgactive_wait_for_node_ready();
```

If the command succeeds, you can see the following output:

```
pgactive_wait_for_node_ready
-----
(1 row)
```

If the first RDS for PostgreSQL database is relatively large, you can see `pgactive.pgactive_wait_for_node_ready()` emitting the progress report of the restore operation. The output looks similar to the following:

```
NOTICE: restoring database 'app', 6% of 7483 MB complete
```

```

NOTICE: restoring database 'app', 42% of 7483 MB complete
NOTICE: restoring database 'app', 77% of 7483 MB complete
NOTICE: restoring database 'app', 98% of 7483 MB complete
NOTICE: successfully restored database 'app' from node node1-app in
00:04:12.274956
pgactive_wait_for_node_ready
-----
(1 row)

```

From this point forward, `pgactive` synchronizes the data between the two DB instances.

7. You can use the following command to verify if the database of the second DB instance has the data:

```
app=> SELECT count(*) FROM inventory.products;
```

If the data is successfully synchronized, you'll see the following output:

```

count
-----
3

```

8. Run the following command to insert new values:

```
app=> INSERT INTO inventory.products (id, product_name) VALUES ('lotion');
```

9. Connect to the database of the first DB instance and run the following query:

```
app=> SELECT count(*) FROM inventory.products;
```

If the active-active replication is initialized, the output is similar to the following:

```

count
-----
4

```

## To detach and remove a DB instance from the `pgactive` group

You can detach and remove a DB instance from the `pgactive` group using these steps:

1. You can detach the second DB instance from the first DB instance using the following command:

```
app=> SELECT * FROM pgactive.pgactive_detach_nodes(ARRAY['node2-app']);
```

2. Remove the `pgactive` extension from the second DB instance using the following command:

```
app=> SELECT * FROM pgactive.pgactive_remove();
```

To forcefully remove the extension:

```
app=> SELECT * FROM pgactive.pgactive_remove(true);
```

3. Drop the extension using the following command:

```
app=> DROP EXTENSION pgactive;
```

## Handling conflicts in active-active replication

The `pgactive` extension works per database and not per cluster. Each DB instance that uses `pgactive` is an independent instance and can accept data changes from any source. When a change is sent to a DB instance, PostgreSQL commits it locally and then uses `pgactive` to replicate the change asynchronously to other DB instances. When two PostgreSQL DB instances update the same record at nearly the same time, a conflict can occur.

The `pgactive` extension provides mechanisms for conflict detection and automatic resolution. It tracks the time stamp when the transaction was committed on both the DB instances and automatically applies the change with the latest time stamp. The `pgactive` extension also logs when a conflict occurs in the `pgactive.pgactive_conflict_history` table.

The `pgactive.pgactive_conflict_history` will keep growing. You may want to define a purging policy. This can be done by deleting some records on a regular basis or defining a partitioning scheme for this relation (and later detach, drop, truncate partitions of interest). To implement the purging policy on a regular basis, one option is to use the `pg_cron` extension. See the following information of an example for the `pg_cron` history table, [Scheduling maintenance with the PostgreSQL `pg\_cron` extension](#).

## Handling sequences in active-active replication

An RDS for PostgreSQL DB instance with the `pgactive` extension uses two different sequence mechanisms to generate unique values.

### Global Sequences

To use a global sequence, create a local sequence with the `CREATE SEQUENCE` statement. Use `pgactive.pgactive_snowflake_id_nextval(seqname)` instead of `usingnextval(seqname)` to get the next unique value of the sequence.

The following example creates a global sequence:

```
postgres=> CREATE TABLE gstest (  
    id bigint primary key,  
    parrot text  
);
```

```
postgres=>CREATE SEQUENCE gstest_id_seq OWNED BY gstest.id;
```

```
postgres=> ALTER TABLE gstest \  
    ALTER COLUMN id SET DEFAULT \  
    pgactive.pgactive_snowflake_id_nextval('gstest_id_seq');
```

### Partitioned sequences

In split-step or partitioned sequences, a normal PostgreSQL sequence is used on each node. Each sequence increments by the same amount and starts at different offsets. For example, with step 100, the node 1 generates sequence as 101, 201, 301, and so on and the node 2 generates sequence as 102, 202, 302, and so on. This scheme works well even if the nodes can't communicate for extended periods, but requires that the designer specify a maximum number of nodes when establishing the schema and requires per-node configuration. Mistakes can easily lead to overlapping sequences.

It is relatively simple to configure this approach with `pgactive` by creating the desired sequence on a node as follows:

```
CREATE TABLE some_table (generated_value bigint primary key);
```

```
postgres=> CREATE SEQUENCE some_seq INCREMENT 100 OWNED BY some_table.generated_value;
```

```
postgres=> ALTER TABLE some_table ALTER COLUMN generated_value SET DEFAULT
nextval('some_seq');
```

Then call `setval` on each node to give a different offset starting value as follows.

```
postgres=>
-- On node 1
SELECT setval('some_seq', 1);

-- On node 2
SELECT setval('some_seq', 2);
```

## Parameter reference for the `pgactive` extension

You can use the following query to view all the parameters associated with `pgactive` extension.

```
postgres=> SELECT * FROM pg_settings WHERE name LIKE 'pgactive.%';
```

## Measuring replication lag among `pgactive` members

You can use the following query to view the replication lag among the `pgactive` members. Run this query on every `pgactive` node to get the full picture.

```
postgres=# SELECT *, (last_applied_xact_at - last_applied_xact_committs) AS lag
FROM pgactive.pgactive_node_slots;
-[ RECORD 1 ]-----
+-----
node_name          | node2-app
slot_name          | pgactive_5_7332551165694385385_0_5__
slot_restart_lsn  | 0/1A898A8
slot_confirmed_lsn | 0/1A898E0
walsender_active  | t
walsender_pid     | 69022
sent_lsn          | 0/1A898E0
write_lsn         | 0/1A898E0
flush_lsn        | 0/1A898E0
```

```
replay_lsn          | 0/1A898E0
last_sent_xact_id   | 746
last_sent_xact_committs | 2024-02-06 18:04:22.430376+00
last_sent_xact_at   | 2024-02-06 18:04:22.431359+00
last_applied_xact_id | 746
last_applied_xact_committs | 2024-02-06 18:04:22.430376+00
last_applied_xact_at | 2024-02-06 18:04:52.452465+00
lag                 | 00:00:30.022089
```

## Limitations for the pgactive extension

- All tables require a Primary Key, otherwise Update's and Delete's aren't allowed. The values in the Primary Key column shouldn't be updated.
- Sequences may have gaps and sometimes might not follow an order. Sequences are not replicated. For more information, see [Handling sequences in active-active replication](#).
- DDL and large objects are not replicated.
- Secondary unique indexes can cause data divergence.
- Collation needs to be identical on all node in the group.
- Load balancing across nodes is an anti-pattern.
- Large transactions can cause replication lag.

## Reducing bloat in tables and indexes with the `pg_repack` extension

You can use the `pg_repack` extension to remove bloat from tables and indexes as an alternative to `VACUUM FULL`. This extension is supported on RDS for PostgreSQL versions 9.6.3 and higher. For more information on the `pg_repack` extension and the full table repack, see the [GitHub project documentation](#).

Unlike `VACUUM FULL`, the `pg_repack` extension requires an exclusive lock (`AccessExclusiveLock`) only for a short period of time during the table rebuild operation in the following cases:

- Initial creation of log table – A log table is created to record changes that occur during initial copy of the data, as shown in the following example:

```
postgres=>\dt+ repack.log_*
List of relations
-[ RECORD 1 ]-+-----
Schema      | repack
Name        | log_16490
Type        | table
Owner       | postgres
Persistence | permanent
Access method | heap
Size        | 65 MB
Description |
```

- Final swap-and-drop phase.

For the rest of the rebuild operation, it only needs an `ACCESS SHARE` lock on the original table to copy rows from it to the new table. This helps the `INSERT`, `UPDATE`, and `DELETE` operations to proceed as usual.

### Recommendations

The following recommendations apply when you remove bloat from the tables and indexes using the `pg_repack` extension:

- Perform repack during non-business hours or over a maintenance window to minimize its impact on performance of other database activities.
- Closely monitor blocking sessions during the rebuild activity and ensure that there is no activity on the original table that could potentially block `pg_repack`, specifically during the final swap-

and-drop phase when it needs an exclusive lock on the original table. For more information, see [Identifying what is blocking a query](#).

When you see a blocking session, you can terminate it using the following command after careful consideration. This helps in the continuation of `pg_repack` to finish the rebuild:

```
SELECT pg_terminate_backend(pid);
```

- While applying the accrued changes from the `pg_repack`'s log table on systems with a very high transaction rate, the apply process might not be able to keep up with the rate of changes. In such cases, `pg_repack` would not be able to complete the apply process. For more information, see [Monitoring the new table during the repack](#). If indexes are severely bloated, an alternative solution is to perform an index only repack. This also helps VACUUM's index cleanup cycles to finish faster.

You can skip the index cleanup phase using manual VACUUM from PostgreSQL version 12, and it is skipped automatically during emergency autovacuum from PostgreSQL version 14. This helps VACUUM complete faster without removing the index bloat and is only meant for emergency situations such as preventing wraparound VACUUM. For more information, see [Avoiding bloat in indexes](#) in the Amazon Aurora User Guide.

## Pre-requisites

- The table must have PRIMARY KEY or not-null UNIQUE constraint.
- The extension version must be the same for both the client and the server.
- Ensure that the RDS instance has more FreeStorageSpace than the total size of the table without the bloat. As an example, consider the total size of the table including TOAST and indexes as 2TB, and total bloat in the table as 1TB. The required FreeStorageSpace must be more than value returned by the following calculation:

$$2\text{TB (Table size)} - 1\text{TB (Table bloat)} = 1\text{TB}$$

You can use the following query to check the total size of the table and use `pgstattuple` to derive bloat. For more information, see [Diagnosing table and index bloat](#) in the Amazon Aurora User Guide

```
SELECT pg_size_pretty(pg_total_relation_size('table_name')) AS total_table_size;
```

This space is reclaimed after the completion of the activity.

- Ensure that the RDS instance has enough compute and IO capacity to handle the repack operation. You might consider to scale up the instance class for optimal balance of performance.

## To use the `pg_repack` extension

1. Install the `pg_repack` extension on your RDS for PostgreSQL DB instance by running the following command.

```
CREATE EXTENSION pg_repack;
```

2. Run the following commands to grant write access to temporary log tables created by `pg_repack`.

```
ALTER DEFAULT PRIVILEGES IN SCHEMA repack GRANT INSERT ON TABLES TO PUBLIC;  
ALTER DEFAULT PRIVILEGES IN SCHEMA repack GRANT USAGE, SELECT ON SEQUENCES TO PUBLIC;
```

3. Connect to the database using the `pg_repack` client utility. Use an account that has `rds_superuser` privileges. As an example, assume that `rds_test` role has `rds_superuser` privileges. The following syntax performs `pg_repack` for full tables including all the table indexes in the postgres database.

```
pg_repack -h db-instance-name.111122223333.aws-region.rds.amazonaws.com -U rds_test  
-k postgres
```

### Note

You must connect using the `-k` option. The `-a` option is not supported.

The response from the `pg_repack` client provides information on the tables on the DB instance that are repacked.

```
INFO: repacking table "pgbench_tellers"  
INFO: repacking table "pgbench_accounts"  
INFO: repacking table "pgbench_branches"
```

4. The following syntax repacks a single table `orders` including indexes in postgres database.

```
pg_repack -h db-instance-name.111122223333.aws-region.rds.amazonaws.com -U rds_test
--table orders -k postgres
```

The following syntax repacks only indexes for `orders` table in postgres database.

```
pg_repack -h db-instance-name.111122223333.aws-region.rds.amazonaws.com -U rds_test
--table orders --only-indexes -k postgres
```

## Monitoring the new table during the repack

- The size of the database is increased by the total size of the table minus bloat, until swap-and-drop phase of repack. You can monitor the growth rate of the database size, calculate the speed of the repack, and roughly estimate the time it takes to complete initial data transfer.

As an example, consider the total size of the table as 2TB, the size of the database as 4TB, and total bloat in the table as 1TB. The database total size value returned by the calculation at the end of the repack operation is the following:

$$2\text{TB (Table size)} + 4\text{ TB (Database size)} - 1\text{TB (Table bloat)} = 5\text{TB}$$

You can roughly estimate the speed of the repack operation by sampling the growth rate in bytes between two points in time. If the growth rate is 1GB per minute, it can take 1000 minutes or 16.6 hours approximately to complete the initial table build operation. In addition to the initial table build, `pg_repack` also needs to apply accrued changes. The time it takes depends on the rate of applying ongoing changes plus accrued changes.

### Note

You can use `pgstattuple` extension to calculate the bloat in the table. For more information, see [pgstattuple](#).

- The number of rows in the `pg_repack`'s log table, under the repack schema represents the volume of changes pending to be applied to the new table after the initial load.

You can check the `pg_repack`'s log table in `pg_stat_all_tables` to monitor the changes applied to the new table. `pg_stat_all_tables.n_live_tup` indicates the number of records that are pending to be applied to the new table. For more information, see [pg\\_stat\\_all\\_tables](#).

```
postgres=>SELECT relname,n_live_tup FROM pg_stat_all_tables WHERE schemaname =
'repack' AND relname ILIKE '%log%';
```

```
-[ RECORD 1 ]-----
relname      | log_16490
n_live_tup   | 2000000
```

- You can use the `pg_stat_statements` extension to find out the time taken by each step in the repack operation. This is helpful in preparation for applying the same repack operation in a production environment. You may adjust the `LIMIT` clause for extending the output further.

```
postgres=>SELECT
  SUBSTR(query, 1, 100) query,
  round((round(total_exec_time::numeric, 6) / 1000 / 60),4)
total_exec_time_in_minutes
FROM
  pg_stat_statements
WHERE
  query ILIKE '%repack%'
ORDER BY
  total_exec_time DESC LIMIT 5;
```

```
query |
total_exec_time_in_minutes |
-----+-----
CREATE UNIQUE INDEX index_16493 ON repack.table_16490 USING btree (a) |
6.8627 |
INSERT INTO repack.table_16490 SELECT a FROM ONLY public.t1 |
6.4150 |
SELECT repack.repack_apply($1, $2, $3, $4, $5, $6) |
0.5395 |
SELECT repack.repack_drop($1, $2) |
0.0004 |
SELECT repack.repack_swap($1) |
0.0004 |
(5 rows)
```

Repacking is completely an out-of-place operation so the original table is not impacted and we do not anticipate any unexpected challenges that require recovery of the original table. If repack fails unexpectedly, you must inspect the cause of the error and resolve it.

After the issue is resolved, drop and recreate the `pg_repack` extension in the database where the table exists, and retry the `pg_repack` step. In addition, the availability of compute resources and concurrent accessibility of the table plays a crucial role in the timely completion of the repack operation.

## Upgrading and using the PLV8 extension

PLV8 is a trusted Javascript language extension for PostgreSQL. You can use it for stored procedures, triggers, and other procedural code that's callable from SQL. This language extension is supported by all current releases of PostgreSQL.

If you use [PLV8](#) and upgrade PostgreSQL to a new PLV8 version, you immediately take advantage of the new extension. Take the following steps to synchronize your catalog metadata with the new version of PLV8. These steps are optional, but we highly recommend that you complete them to avoid metadata mismatch warnings.

The upgrade process drops all your existing PLV8 functions. Thus, we recommend that you create a snapshot of your RDS for PostgreSQL DB instance before upgrading. For more information, see [Creating a DB snapshot for a Single-AZ DB instance](#).

### To synchronize your catalog metadata with a new version of PLV8

1. Verify that you need to update. To do this, run the following command while connected to your instance.

```
SELECT * FROM pg_available_extensions WHERE name IN ('plv8','plls','plcoffee');
```

If your results contain values for an installed version that is a lower number than the default version, continue with this procedure to update your extensions. For example, the following result set indicates that you should update.

```

name      | default_version | installed_version |          comment
-----+-----+-----
+-----+-----+-----
plls      | 2.1.0           | 1.5.3             | PL/LiveScript (v8) trusted
procedural language
plcoffee | 2.1.0           | 1.5.3             | PL/CoffeeScript (v8) trusted
procedural language
plv8      | 2.1.0           | 1.5.3             | PL/JavaScript (v8) trusted
procedural language
(3 rows)

```

2. Create a snapshot of your RDS for PostgreSQL DB instance if you haven't done so yet. You can continue with the following steps while the snapshot is being created.

3. Get a count of the number of PLV8 functions in your DB instance so you can validate that they are all in place after the upgrade. For example, the following SQL query returns the number of functions written in plv8, plcoffee, and plls.

```
SELECT proname, nspname, lanname
FROM pg_proc p, pg_language l, pg_namespace n
WHERE p.prolang = l.oid
AND n.oid = p.pronamespace
AND lanname IN ('plv8', 'plcoffee', 'plls');
```

4. Use `pg_dump` to create a schema-only dump file. For example, create a file on your client machine in the `/tmp` directory.

```
./pg_dump -Fc --schema-only -U master postgres >/tmp/test.dmp
```

This example uses the following options:

- `-Fc` – Custom format
- `--schema-only` – Dump only the commands necessary to create schema (functions in this case)
- `-U` – The RDS master user name
- `database` – The database name for our DB instance

For more information on `pg_dump`, see [pg\\_dump](#) in the PostgreSQL documentation.

5. Extract the "CREATE FUNCTION" DDL statement that is present in the dump file. The following example uses the `grep` command to extract the DDL statement that creates the functions and save them to a file. You use this in subsequent steps to recreate the functions.

```
./pg_restore -l /tmp/test.dmp | grep FUNCTION > /tmp/function_list/
```

For more information on `pg_restore`, see [pg\\_restore](#) in the PostgreSQL documentation.

6. Drop the functions and extensions. The following example drops any PLV8 based objects. The cascade option ensures that any dependent are dropped.

```
DROP EXTENSION plv8 CASCADE;
```

If your PostgreSQL instance contains objects based on plcoffee or plls, repeat this step for those extensions.

7. Create the extensions. The following example creates the plv8, plcoffee, and plls extensions.

```
CREATE EXTENSION plv8;
CREATE EXTENSION plcoffee;
CREATE EXTENSION plls;
```

8. Create the functions using the dump file and "driver" file.

The following example recreates the functions that you extracted previously.

```
./pg_restore -U master -d postgres -Fc -L /tmp/function_list /tmp/test.dmp
```

9. Verify that all your functions have been recreated by using the following query.

```
SELECT * FROM pg_available_extensions WHERE name IN ('plv8','plls','plcoffee');
```

The PLV8 version 2 adds the following extra row to your result set:

prname	nspname	laname
plv8_version	pg_catalog	plv8

## Using PL/Rust to write PostgreSQL functions in the Rust language

PL/Rust is a trusted Rust language extension for PostgreSQL. You can use it for stored procedures, functions, and other procedural code that's callable from SQL. The PL/Rust language extension is available in the following versions:

- RDS for PostgreSQL 16.1 and higher 16 versions
- RDS for PostgreSQL 15.2-R2 and higher 15 versions
- RDS for PostgreSQL 14.9 and higher 14 versions
- RDS for PostgreSQL 13.12 and higher 13 versions

For more information, see [PL/Rust](#) on GitHub.

## Topics

- [Setting up PL/Rust](#)
- [Creating functions with PL/Rust](#)
- [Using crates with PL/Rust](#)
- [PL/Rust limitations](#)

## Setting up PL/Rust

To install the `plrust` extension on your DB instance, add `plrust` to the `shared_preload_libraries` parameter in the DB parameter group associated with your DB instance. With the `plrust` extension installed, you can create functions.

To modify the `shared_preload_libraries` parameter, your DB instance must be associated with a custom parameter group. For information about creating a custom DB parameter group, see [Parameter groups for Amazon RDS](#).

You can install the `plrust` extension using the AWS Management Console or the AWS CLI.

The following steps assume that your DB instance is associated with a custom DB parameter group.

### Console

#### Install the `plrust` extension in the `shared_preload_libraries` parameter

Complete the following steps using an account that is a member of the `rds_superuser` group (role).

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Databases**.
3. Choose the name of your DB instance to display its details.
4. Open the **Configuration** tab for your DB instance and find the DB instance parameter group link.
5. Choose the link to open the custom parameters associated with your DB instance.
6. In the **Parameters** search field, type `shared_pre` to find the **`shared_preload_libraries`** parameter.
7. Choose **Edit parameters** to access the property values.

8. Add `plrust` to the list in the **Values** field. Use a comma to separate items in the list of values.
9. Reboot the DB instance so that your change to the `shared_preload_libraries` parameter takes effect. The initial reboot may require additional time to complete.
10. When the instance is available, verify that `plrust` has been initialized. Use `psql` to connect to the DB instance, and then run the following command.

```
SHOW shared_preload_libraries;
```

Your output should look similar to the following:

```
shared_preload_libraries
-----
rdsutils,plrust
(1 row)
```

## AWS CLI

### Install the `plrust` extension in the `shared_preload_libraries` parameter

Complete the following steps using an account that is a member of the `rds_superuser` group (role).

1. Use the [modify-db-parameter-group](#) AWS CLI command to add `plrust` to the `shared_preload_libraries` parameter.

```
aws rds modify-db-parameter-group \  
  --db-parameter-group-name custom-param-group-name \  
  --parameters  
  "ParameterName=shared_preload_libraries,ParameterValue=plrust,ApplyMethod=pending-  
reboot" \  
  --region aws-region
```

2. Use the [reboot-db-instance](#) AWS CLI command to reboot the DB instance and initialize the `plrust` library. The initial reboot may require additional time to complete.

```
aws rds reboot-db-instance \  
  --db-instance-identifier your-instance \  
  --region aws-region
```

3. When the instance is available, you can verify that plrust has been initialized. Use `psql` to connect to the DB instance, and then run the following command.

```
SHOW shared_preload_libraries;
```

Your output should look similar to the following:

```
shared_preload_libraries
-----
rdsutils,plrust
(1 row)
```

## Creating functions with PL/Rust

PL/Rust will compile the function as a dynamic library, load it, and execute it.

The following Rust function filters multiples out of an array.

```
postgres=> CREATE LANGUAGE plrust;
CREATE EXTENSION
```

```
CREATE OR REPLACE FUNCTION filter_multiples(a BIGINT[], multiple BIGINT) RETURNS
BIGINT[]
    IMMUTABLE STRICT
    LANGUAGE PLRUST AS
$$
    Ok(Some(a.into_iter().filter(|x| x.unwrap() % multiple != 0).collect()))
$$;

WITH gen_values AS (
SELECT ARRAY(SELECT * FROM generate_series(1,100)) as arr)
SELECT filter_multiples(arr, 3)
from gen_values;
```

## Using crates with PL/Rust

In RDS for PostgreSQL versions 16.3-R2 and higher, 15.7-R2 and higher 15 versions, 14.12-R2 and higher 14 versions, and 13.15-R2 and higher 13 versions, PL/Rust supports additional crates:

- `url`

- `regex`
- `serde`
- `serde_json`

In RDS for PostgreSQL versions 15.5-R2 and higher, 14.10-R2 and higher 14 versions, and 13.13-R2 and higher 13 versions, PL/Rust supports two additional crates:

- `croaring-rs`
- `num-bigint`

Starting with Amazon RDS for PostgreSQL versions 15.4, 14.9, and 13.12, PL/Rust supports the following crates:

- `aes`
- `ctr`
- `rand`

Only the default features are supported for these crates. New RDS for PostgreSQL versions might contain updated versions of crates, and older versions of crates may no longer be supported.

Follow the best practices for performing a major version upgrade to test whether your PL/Rust functions are compatible with the new major version. For more information, see the blog [Best practices for upgrading Amazon RDS to major and minor versions of PostgreSQL](#) and [Upgrading the PostgreSQL DB engine for Amazon RDS](#) in the Amazon RDS User Guide.

Examples of using dependencies when creating a PL/Rust function are available at [Use dependencies](#).

## PL/Rust limitations

By default, database users can't use PL/Rust. To provide access to PL/Rust, connect as a user with `rds_superuser` privilege, and run the following command:

```
postgres=> GRANT USAGE ON LANGUAGE PLRUST TO user;
```

## Managing spatial data with the PostGIS extension

PostGIS is an extension to PostgreSQL for storing and managing spatial information. To learn more about PostGIS, see [PostGIS.net](https://postgis.net).

Starting with version 10.5, PostgreSQL supports the libprotobuf 1.3.0 library used by PostGIS for working with map box vector tile data.

Setting up the PostGIS extension requires `rds_superuser` privileges. We recommend that you create a user (role) to manage the PostGIS extension and your spatial data. The PostGIS extension and its related components add thousands of functions to PostgreSQL. Consider creating the PostGIS extension in its own schema if that makes sense for your use case. The following example shows how to install the extension in its own database, but this isn't required.

### Topics

- [Step 1: Create a user \(role\) to manage the PostGIS extension](#)
- [Step 2: Load the PostGIS extensions](#)
- [Step 3: Transfer ownership of the extension schemas](#)
- [Step 4: Transfer ownership of the PostGIS tables](#)
- [Step 5: Test the extensions](#)
- [Step 6: Upgrade the PostGIS extension](#)
- [PostGIS extension versions](#)
- [Upgrading PostGIS 2 to PostGIS 3](#)

### Step 1: Create a user (role) to manage the PostGIS extension

First, connect to your RDS for PostgreSQL DB instance as a user that has `rds_superuser` privileges. If you kept the default name when you set up your instance, you connect as `postgres`.

```
psql --host=111122223333.aws-region.rds.amazonaws.com --port=5432 --username=postgres  
--password
```

Create a separate role (user) to administer the PostGIS extension.

```
postgres=> CREATE ROLE gis_admin LOGIN PASSWORD 'change_me';
```

**CREATE ROLE**

Grant this role `rds_superuser` privileges, to allow the role to install the extension.

```
postgres=> GRANT rds_superuser TO gis_admin;  
GRANT
```

Create a database to use for your PostGIS artifacts. This step is optional. Or you can create a schema in your user database for the PostGIS extensions, but this also isn't required.

```
postgres=> CREATE DATABASE lab_gis;  
CREATE DATABASE
```

Give the `gis_admin` all privileges on the `lab_gis` database.

```
postgres=> GRANT ALL PRIVILEGES ON DATABASE lab_gis TO gis_admin;  
GRANT
```

Exit the session and reconnect to your RDS for PostgreSQL DB instance as `gis_admin`.

```
postgres=> psql --host=111122223333.aws-region.rds.amazonaws.com --port=5432 --  
username=gis_admin --password --dbname=lab_gis  
Password for user gis_admin: ...  
lab_gis=>
```

Continue setting up the extension as detailed in the next steps.

## Step 2: Load the PostGIS extensions

The PostGIS extension includes several related extensions that work together to provide geospatial functionality. Depending on your use case, you might not need all the extensions created in this step.

Use `CREATE EXTENSION` statements to load the PostGIS extensions.

```
CREATE EXTENSION postgis;  
CREATE EXTENSION  
CREATE EXTENSION postgis_raster;  
CREATE EXTENSION  
CREATE EXTENSION fuzzystmatch;
```

```
CREATE EXTENSION
CREATE EXTENSION postgis_tiger_geocoder;
CREATE EXTENSION
CREATE EXTENSION postgis_topology;
CREATE EXTENSION
CREATE EXTENSION address_standardizer_data_us;
CREATE EXTENSION
```

You can verify the results by running the SQL query shown in the following example, which lists the extensions and their owners.

```
SELECT n.nspname AS "Name",
       pg_catalog.pg_get_userbyid(n.nspowner) AS "Owner"
FROM pg_catalog.pg_namespace n
WHERE n.nspname !~ '^pg_' AND n.nspname <> 'information_schema'
ORDER BY 1;
```

List of schemas

Name	Owner
public	postgres
tiger	rdsadmin
tiger_data	rdsadmin
topology	rdsadmin

(4 rows)

### Step 3: Transfer ownership of the extension schemas

Use the ALTER SCHEMA statements to transfer ownership of the schemas to the gis\_admin role.

```
ALTER SCHEMA tiger OWNER TO gis_admin;
ALTER SCHEMA
ALTER SCHEMA tiger_data OWNER TO gis_admin;
ALTER SCHEMA
ALTER SCHEMA topology OWNER TO gis_admin;
ALTER SCHEMA
```

You can confirm the ownership change by running the following SQL query. Or you can use the \dn metacommand from the psql command line.

```
SELECT n.nspname AS "Name",
```

```
pg_catalog.pg_get_userbyid(n.nspowner) AS "Owner"
FROM pg_catalog.pg_namespace n
WHERE n.nspname !~ '^pg_' AND n.nspname <> 'information_schema'
ORDER BY 1;
```

```
      List of schemas
  Name      |      Owner
-----+-----
 public     | postgres
 tiger      | gis_admin
 tiger_data | gis_admin
 topology   | gis_admin
(4 rows)
```

## Step 4: Transfer ownership of the PostGIS tables

### Note

Do not change ownership of the PostGIS functions. Proper operation and future upgrades of PostGIS require these functions to retain original ownership. For more information about PostGIS permissions, see [PostgreSQL Security](#).

Use the following function to transfer ownership of the PostGIS tables to the `gis_admin` role. Run the following statement from the `psql` prompt to create the function.

```
CREATE FUNCTION exec(text) returns text language plpgsql volatile AS $$ BEGIN EXECUTE
  $1; RETURN $1; END; $$;
CREATE FUNCTION
```

Next, run the following query to run the `exec` function that in turn runs the statements and alters the permissions.

```
SELECT exec('ALTER TABLE ' || quote_ident(s.nspname) || '.' || quote_ident(s.relname)
|| ' OWNER TO gis_admin;')
FROM (
  SELECT nspname, relname
  FROM pg_class c JOIN pg_namespace n ON (c.relnamespace = n.oid)
  WHERE nspname in ('tiger','topology') AND
  relkind IN ('r','S','v') ORDER BY relkind = 'S')
```

```
s;
```

## Step 5: Test the extensions

To avoid needing to specify the schema name, add the `tiger` schema to your search path using the following command.

```
SET search_path=public,tiger;  
SET
```

Test the `tiger` schema by using the following `SELECT` statement.

```
SELECT address, streetname, streettypeabbrev, zip  
FROM normalize_address('1 Devonshire Place, Boston, MA 02109') AS na;  
address | streetname | streettypeabbrev | zip  
-----+-----+-----+-----  
1 | Devonshire | Pl | 02109  
(1 row)
```

To learn more about this extension, see [Tiger Geocoder](#) in the PostGIS documentation.

Test access to the topology schema by using the following `SELECT` statement. This calls the `createtopology` function to register a new topology object (`my_new_topo`) with the specified spatial reference identifier (26986) and default tolerance (0.5). To learn more, see [CreateTopology](#) in the PostGIS documentation.

```
SELECT topology.createtopology('my_new_topo',26986,0.5);  
createtopology  
-----  
1  
(1 row)
```

## Step 6: Upgrade the PostGIS extension

Each new release of PostgreSQL supports one or more versions of the PostGIS extension compatible with that release. Upgrading the PostgreSQL engine to a new version doesn't automatically upgrade the PostGIS extension. Before upgrading the PostgreSQL engine, you typically upgrade PostGIS to the newest available version for the current PostgreSQL version. For details, see [PostGIS extension versions](#).

After the PostgreSQL engine upgrade, you then upgrade the PostGIS extension again, to the version supported for the newly upgraded PostgreSQL engine version. For more information about upgrading the PostgreSQL engine, see [How to perform a major version upgrade](#).

You can check for available PostGIS extension version updates on your RDS for PostgreSQL DB instance at any time. To do so, run the following command. This function is available with PostGIS 2.5.0 and higher versions.

```
SELECT postGIS_extensions_upgrade();
```

If your application doesn't support the latest PostGIS version, you can install an older version of PostGIS that's available in your major version as follows.

```
CREATE EXTENSION postgis VERSION "2.5.5";
```

If you want to upgrade to a specific PostGIS version from an older version, you can also use the following command.

```
ALTER EXTENSION postgis UPDATE TO "2.5.5";
```

Depending on the version that you're upgrading from, you might need to use this function again. The result of the first run of the function determines if an additional upgrade function is needed. For example, this is the case for upgrading from PostGIS 2 to PostGIS 3. For more information, see [Upgrading PostGIS 2 to PostGIS 3](#).

If you upgraded this extension to prepare for a major version upgrade of the PostgreSQL engine, you can continue with other preliminary tasks. For more information, see [How to perform a major version upgrade](#).

## PostGIS extension versions

We recommend that you install the versions of all extensions such as PostGIS as listed in [Extension versions for Amazon RDS for PostgreSQL](#) in the *Amazon RDS for PostgreSQL Release Notes*. To get a list of versions that are available in your release, use the following command.

```
SELECT * FROM pg_available_extension_versions WHERE name='postgis';
```

You can find version information in the following sections in the *Amazon RDS for PostgreSQL Release Notes*:

- [PostgreSQL version 16 extensions supported on Amazon RDS](#)
- [PostgreSQL version 15 extensions supported on Amazon RDS](#)
- [PostgreSQL version 14 extensions supported on Amazon RDS](#)
- [PostgreSQL version 13 extensions supported on Amazon RDS](#)
- [PostgreSQL version 12 extensions supported on Amazon RDS](#)
- [PostgreSQL version 11 extensions supported on Amazon RDS](#)
- [PostgreSQL version 10 extensions supported on Amazon RDS](#)
- [PostgreSQL version 9.6.x extensions supported on Amazon RDS](#)

## Upgrading PostGIS 2 to PostGIS 3

Starting with version 3.0, the PostGIS raster functionality is now a separate extension, `postgis_raster`. This extension has its own installation and upgrade path. This removes dozens of functions, data types, and other artifacts required for raster image processing from the core `postgis` extension. That means that if your use case doesn't require raster processing, you don't need to install the `postgis_raster` extension.

In the following upgrade example, the first upgrade command extracts raster functionality into the `postgis_raster` extension. A second upgrade command is then required to upgrade `postgis_raster` to the new version.

### To upgrade from PostGIS 2 to PostGIS 3

1. Identify the default version of PostGIS that's available to the PostgreSQL version on your RDS for PostgreSQL DB instance. To do so, run the following query.

```
SELECT * FROM pg_available_extensions
  WHERE default_version > installed_version;
 name   | default_version | installed_version | comment
-----+-----+-----+-----
+-----+-----+-----+-----
 postgis | 3.1.4          | 2.3.7            | PostGIS geometry and geography
 spatial types and functions
(1 row)
```

2. Identify the versions of PostGIS installed in each database on your RDS for PostgreSQL DB instance. In other words, query each user database as follows.

```

SELECT
  e.extname AS "Name",
  e.extversion AS "Version",
  n.nspname AS "Schema",
  c.description AS "Description"
FROM
  pg_catalog.pg_extension e
  LEFT JOIN pg_catalog.pg_namespace n ON n.oid = e.extnamespace
  LEFT JOIN pg_catalog.pg_description c ON c.objoid = e.oid
  AND c.classoid = 'pg_catalog.pg_extension'::pg_catalog.regclass
WHERE
  e.extname LIKE '%postgis%'
ORDER BY
  1;

```

Name	Version	Schema	Description
postgis	2.3.7	public	PostGIS geometry, geography, and raster spatial types and functions

(1 row)

This mismatch between the default version (PostGIS 3.1.4) and the installed version (PostGIS 2.3.7) means that you need to upgrade the PostGIS extension.

```

ALTER EXTENSION postgis UPDATE;
ALTER EXTENSION
WARNING: unpackaging raster
WARNING: PostGIS Raster functionality has been unpackaged

```

3. Run the following query to verify that the raster functionality is now in its own package.

```

SELECT
  probin,
  count(*)
FROM
  pg_proc
WHERE
  probin LIKE '%postgis%'
GROUP BY
  probin;

```

probin	count
--------	-------

```

-----+-----
$libdir/rtpostgis-2.3 | 107
$libdir/postgis-3    | 487
(2 rows)

```

The output shows that there's still a difference between versions. The PostGIS functions are version 3 (postgis-3), while the raster functions (rtpostgis) are version 2 (rtpostgis-2.3). To complete the upgrade, you run the upgrade command again, as follows.

```
postgres=> SELECT postgis_extensions_upgrade();
```

You can safely ignore the warning messages. Run the following query again to verify that the upgrade is complete. The upgrade is complete when PostGIS and all related extensions aren't marked as needing upgrade.

```
SELECT postgis_full_version();
```

4. Use the following query to see the completed upgrade process and the separately packaged extensions, and verify that their versions match.

```

SELECT
  e.extname AS "Name",
  e.extversion AS "Version",
  n.nspname AS "Schema",
  c.description AS "Description"
FROM
  pg_catalog.pg_extension e
  LEFT JOIN pg_catalog.pg_namespace n ON n.oid = e.extnamespace
  LEFT JOIN pg_catalog.pg_description c ON c.objoid = e.oid
      AND c.classoid = 'pg_catalog.pg_extension'::pg_catalog.regclass
WHERE
  e.extname LIKE '%postgis%'
ORDER BY
  1;

```

Name	Version	Schema	Description
postgis	3.1.5	public	PostGIS geometry, geography, and raster spatial types and functions
postgis_raster	3.1.5	public	PostGIS raster types and functions

```

(2 rows)

```

The output shows that the PostGIS 2 extension was upgraded to PostGIS 3, and both `postgis` and the now separate `postgis_raster` extension are version 3.1.5.

After this upgrade completes, if you don't plan to use the raster functionality, you can drop the extension as follows.

```
DROP EXTENSION postgis_raster;
```

# Working with the supported foreign data wrappers for Amazon RDS for PostgreSQL

A foreign data wrapper (FDW) is a specific type of extension that provides access to external data. For example, the `oracle_fdw` extension allows your RDS for PostgreSQL DB cluster to work with Oracle databases. As another example, by using the PostgreSQL native `postgres_fdw` extension you can access data stored in PostgreSQL DB instances external to your RDS for PostgreSQL DB instance.

Following, you can find information about several supported PostgreSQL foreign data wrappers.

## Topics

- [Using the `log\_fdw` extension to access the DB log using SQL](#)
- [Using the `postgres\_fdw` extension to access external data](#)
- [Working with MySQL databases by using the `mysql\_fdw` extension](#)
- [Working with Oracle databases by using the `oracle\_fdw` extension](#)
- [Working with SQL Server databases by using the `tds\_fdw` extension](#)

## Using the `log_fdw` extension to access the DB log using SQL

RDS for PostgreSQL DB instance supports the `log_fdw` extension, which you can use to access your database engine log using a SQL interface. The `log_fdw` extension provides two functions that make it easy to create foreign tables for database logs:

- `list_postgres_log_files` – Lists the files in the database log directory and the file size in bytes.
- `create_foreign_table_for_log_file(table_name text, server_name text, log_file_name text)` – Builds a foreign table for the specified file in the current database.

All functions created by `log_fdw` are owned by `rds_superuser`. Members of the `rds_superuser` role can grant access to these functions to other database users.

By default, the log files are generated by Amazon RDS in `stderr` (standard error) format, as specified in `log_destination` parameter. There are only two options for this parameter, `stderr` and `csvlog` (comma-separated values, CSV). If you add the `csvlog` option to the parameter, Amazon RDS generates both `stderr` and `csvlog` logs. This can affect the storage capacity on

your DB cluster, so you need to be aware of the other parameters that affect log handling. For more information, see [Setting the log destination \(stderr, csvlog\)](#).

One benefit of generating csvlog logs is that the log\_fdw extension lets you build foreign tables with the data neatly split into several columns. To do this, your instance needs to be associated with a custom DB parameter group so that you can change the setting for log\_destination. For more information about how to do so, see [Working with parameters on your RDS for PostgreSQL DB instance](#).

The following example assumes that the log\_destination parameter includes cvslog.

### To use the log\_fdw extension

1. Install the log\_fdw extension.

```
postgres=> CREATE EXTENSION log_fdw;
CREATE EXTENSION
```

2. Create the log server as a foreign data wrapper.

```
postgres=> CREATE SERVER log_server FOREIGN DATA WRAPPER log_fdw;
CREATE SERVER
```

3. Select all from a list of log files.

```
postgres=> SELECT * FROM list_postgres_log_files() ORDER BY 1;
```

A sample response is as follows.

file_name	file_size_bytes
postgresql.log.2023-08-09-22.csv	1111
postgresql.log.2023-08-09-23.csv	1172
postgresql.log.2023-08-10-00.csv	1744
postgresql.log.2023-08-10-01.csv	1102

(4 rows)

4. Create a table with a single 'log\_entry' column for the selected file.

```
postgres=> SELECT create_foreign_table_for_log_file('my_postgres_error_log',
           'log_server', 'postgresql.log.2023-08-09-22.csv');
```

The response provides no detail other than that the table now exists.

```
-----
(1 row)
```

5. Select a sample of the log file. The following code retrieves the log time and error message description.

```
postgres=> SELECT log_time, message FROM my_postgres_error_log ORDER BY 1;
```

A sample response is as follows.

```

          log_time          |          message
-----+-----
Tue Aug 09 15:45:18.172 2023 PDT | ending log output to stderr
Tue Aug 09 15:45:18.175 2023 PDT | database system was interrupted; last known up
at 2023-08-09 22:43:34 UTC
Tue Aug 09 15:45:18.223 2023 PDT | checkpoint record is at 0/90002E0
Tue Aug 09 15:45:18.223 2023 PDT | redo record is at 0/90002A8; shutdown FALSE
Tue Aug 09 15:45:18.223 2023 PDT | next transaction ID: 0/1879; next OID: 24578
Tue Aug 09 15:45:18.223 2023 PDT | next MultiXactId: 1; next MultiXactOffset: 0
Tue Aug 09 15:45:18.223 2023 PDT | oldest unfrozen transaction ID: 1822, in
database 1
(7 rows)
```

## Using the `postgres_fdw` extension to access external data

You can access data in a table on a remote database server with the [postgres\\_fdw](#) extension. If you set up a remote connection from your PostgreSQL DB instance, access is also available to your read replica.

### To use `postgres_fdw` to access a remote database server

1. Install the `postgres_fdw` extension.

```
CREATE EXTENSION postgres_fdw;
```

2. Create a foreign data server using `CREATE SERVER`.

```
CREATE SERVER foreign_server
FOREIGN DATA WRAPPER postgres_fdw
OPTIONS (host 'xxx.xx.xxx.xx', port '5432', dbname 'foreign_db');
```

3. Create a user mapping to identify the role to be used on the remote server.

```
CREATE USER MAPPING FOR local_user
SERVER foreign_server
OPTIONS (user 'foreign_user', password 'password');
```

4. Create a table that maps to the table on the remote server.

```
CREATE FOREIGN TABLE foreign_table (
    id integer NOT NULL,
    data text)
SERVER foreign_server
OPTIONS (schema_name 'some_schema', table_name 'some_table');
```

## Working with MySQL databases by using the `mysql_fdw` extension

To access a MySQL-compatible database from your RDS for PostgreSQL DB instance, you can install and use the `mysql_fdw` extension. This foreign data wrapper lets you work with RDS for MySQL, Aurora MySQL, MariaDB, and other MySQL-compatible databases. The connection from RDS for PostgreSQL DB instance to the MySQL database is encrypted on a best-effort basis, depending on the client and server configurations. However, you can enforce encryption if you like. For more information, see [Using encryption in transit with the extension](#).

The `mysql_fdw` extension is supported on Amazon RDS for PostgreSQL version 14.2, 13.6, and higher releases. It supports selects, inserts, updates, and deletes from an RDS for PostgreSQL DB to tables on a MySQL-compatible database instance.

### Topics

- [Setting up your RDS for PostgreSQL DB to use the `mysql\_fdw` extension](#)
- [Example: Working with an RDS for MySQL database from RDS for PostgreSQL](#)
- [Using encryption in transit with the extension](#)

## Setting up your RDS for PostgreSQL DB to use the `mysql_fdw` extension

Setting up the `mysql_fdw` extension on your RDS for PostgreSQL DB instance involves loading the extension in your DB instance and then creating the connection point to the MySQL DB instance.

For that task, you need to have the following details about the MySQL DB instance:

- Hostname or endpoint. For an RDS for MySQL DB instance, you can find the endpoint by using the Console. Choose the Connectivity & security tab and look in the "Endpoint and port" section.
- Port number. The default port number for MySQL is 3306.
- Name of the database. The DB identifier.

You also need to provide access on the security group or the access control list (ACL) for the MySQL port, 3306. Both the RDS for PostgreSQL DB instance and the RDS for MySQL DB instance need access to port 3306. If access isn't configured correctly, when you try to connect to MySQL-compatible table you see an error message similar to the following:

```
ERROR: failed to connect to MySQL: Can't connect to MySQL server on 'hostname.aws-region.rds.amazonaws.com:3306' (110)
```

In the following procedure, you (as the `rds_superuser` account) create the foreign server. You then grant access to the foreign server to specific users. These users then create their own mappings to the appropriate MySQL user accounts to work with the MySQL DB instance.

### To use `mysql_fdw` to access a MySQL database server

1. Connect to your PostgreSQL DB instance using an account that has the `rds_superuser` role. If you accepted the defaults when you created your RDS for PostgreSQL DB instance, the user name is `postgres`, and you can connect using the `psql` command line tool as follows:

```
psql --host=your-DB-instance.aws-region.rds.amazonaws.com --port=5432 --  
username=postgres --password
```

2. Install the `mysql_fdw` extension as follows:

```
postgres=> CREATE EXTENSION mysql_fdw;  
CREATE EXTENSION
```

After the extension is installed on your RDS for PostgreSQL DB instance, you set up the foreign server that provides the connection to a MySQL database.

## To create the foreign server

Perform these tasks on the RDS for PostgreSQL DB instance. The steps assume that you're connected as a user with `rds_superuser` privileges, such as `postgres`.

1. Create a foreign server in the RDS for PostgreSQL DB instance :

```
postgres=> CREATE SERVER mysql-db FOREIGN DATA WRAPPER mysql_fdw OPTIONS (host 'db-name.111122223333.aws-region.rds.amazonaws.com', port '3306');
CREATE SERVER
```

2. Grant the appropriate users access to the foreign server. These should be non-administrator users, that is, users without the `rds_superuser` role.

```
postgres=> GRANT USAGE ON FOREIGN SERVER mysql-db to user1;
GRANT
```

PostgreSQL users create and manage their own connections to the MySQL database through the foreign server.

## Example: Working with an RDS for MySQL database from RDS for PostgreSQL

Suppose that you have a simple table on an RDS for PostgreSQL DB instance. Your RDS for PostgreSQL users want to query (SELECT), INSERT, UPDATE, and DELETE items on that table. Assume that the `mysql_fdw` extension was created on your RDS for PostgreSQL DB instance, as detailed in the preceding procedure. After you connect to the RDS for PostgreSQL DB instance as a user that has `rds_superuser` privileges, you can proceed with the following steps.

1. On the RDS for PostgreSQL DB instance, create a foreign server:

```
test=> CREATE SERVER mysqlldb FOREIGN DATA WRAPPER mysql_fdw OPTIONS (host 'your-DB.aws-region.rds.amazonaws.com', port '3306');
CREATE SERVER
```

2. Grant usage to a user who doesn't have `rds_superuser` permissions, for example, `user1`:

```
test=> GRANT USAGE ON FOREIGN SERVER mysqlldb TO user1;
```

```
GRANT
```

3. Connect as *user1*, and then create a mapping to the MySQL user:

```
test=> CREATE USER MAPPING FOR user1 SERVER mysqlpdb OPTIONS (username 'myuser',  
password 'mypassword');  
CREATE USER MAPPING
```

4. Create a foreign table linked to the MySQL table:

```
test=> CREATE FOREIGN TABLE mytab (a int, b text) SERVER mysqlpdb OPTIONS (dbname  
'test', table_name '');  
CREATE FOREIGN TABLE
```

5. Run a simple query against the foreign table:

```
test=> SELECT * FROM mytab;  
a | b  
----+-----  
1 | apple  
(1 row)
```

6. You can add, change, and remove data from the MySQL table. For example:

```
test=> INSERT INTO mytab values (2, 'mango');  
INSERT 0 1
```

Run the SELECT query again to see the results:

```
test=> SELECT * FROM mytab ORDER BY 1;  
a | b  
----+-----  
1 | apple  
2 | mango  
(2 rows)
```

## Using encryption in transit with the extension

The connection to MySQL from RDS for PostgreSQL uses encryption in transit (TLS/SSL) by default. However, the connection falls back to non-encrypted when the client and server configuration

differ. You can enforce encryption for all outgoing connections by specifying the `REQUIRE SSL` option on the RDS for MySQL user accounts. This same approach also works for MariaDB and Aurora MySQL user accounts.

For MySQL user accounts configured to `REQUIRE SSL`, the connection attempt fails if a secure connection can't be established.

To enforce encryption for existing MySQL database user accounts, you can use the `ALTER USER` command. The syntax varies, depending on the MySQL version, as shown in the following table. For more information, see [ALTER USER](#) in *MySQL Reference Manual*.

MySQL 5.7, MySQL 8.0	MySQL 5.6
<pre>ALTER USER 'user'@'%' REQUIRE SSL;</pre>	<pre>GRANT USAGE ON *.* to 'user'@'%' REQUIRE SSL;</pre>

For more information about the `mysql_fdw` extension, see the [mysql\\_fdw](#) documentation.

## Working with Oracle databases by using the `oracle_fdw` extension

To access an Oracle database from your RDS for PostgreSQL DB instance you can install and use the `oracle_fdw` extension. This extension is a foreign data wrapper for Oracle databases. To learn more about this extension, see the [oracle\\_fdw](#) documentation.

The `oracle_fdw` extension is supported on RDS for PostgreSQL 12.7, 13.3, and higher versions.

### Topics

- [Turning on the `oracle\_fdw` extension](#)
- [Example: Using a foreign server linked to an Amazon RDS for Oracle database](#)
- [Working with encryption in transit](#)
- [Understanding the `pg\_user\_mappings` view and permissions](#)

## Turning on the `oracle_fdw` extension

To use the `oracle_fdw` extension, perform the following procedure.

## To turn on the `oracle_fdw` extension

- Run the following command using an account that has `rds_superuser` permissions.

```
CREATE EXTENSION oracle_fdw;
```

## Example: Using a foreign server linked to an Amazon RDS for Oracle database

The following example shows the use of a foreign server linked to an Amazon RDS for Oracle database.

### To create a foreign server linked to an RDS for Oracle database

1. Note the following on the RDS for Oracle DB instance:

- Endpoint
- Port
- Database name

2. Create a foreign server.

```
test=> CREATE SERVER oradb FOREIGN DATA WRAPPER oracle_fdw OPTIONS (dbserver
'//endpoint:port/DB_name');
CREATE SERVER
```

3. Grant usage to a user who doesn't have `rds_superuser` privileges, for example `user1`.

```
test=> GRANT USAGE ON FOREIGN SERVER oradb TO user1;
GRANT
```

4. Connect as `user1`, and create a mapping to an Oracle user.

```
test=> CREATE USER MAPPING FOR user1 SERVER oradb OPTIONS (user 'oracleuser',
password 'mypassword');
CREATE USER MAPPING
```

5. Create a foreign table linked to an Oracle table.

```
test=> CREATE FOREIGN TABLE mytab (a int) SERVER oradb OPTIONS (table 'MYTABLE');
CREATE FOREIGN TABLE
```

## 6. Query the foreign table.

```
test=> SELECT * FROM mytab;
a
---
1
(1 row)
```

If the query reports the following error, check your security group and access control list (ACL) to make sure that both instances can communicate.

```
ERROR: connection for foreign table "mytab" cannot be established
DETAIL: ORA-12170: TNS:Connect timeout occurred
```

## Working with encryption in transit

PostgreSQL-to-Oracle encryption in transit is based on a combination of client and server configuration parameters. For an example using Oracle 21c, see [About the Values for Negotiating Encryption and Integrity](#) in the Oracle documentation. The client used for `oracle_fdw` on Amazon RDS is configured with `ACCEPTED`, meaning that the encryption depends on the Oracle database server configuration.

If your database is on RDS for Oracle, see [Oracle native network encryption](#) to configure the encryption.

## Understanding the `pg_user_mappings` view and permissions

The PostgreSQL catalog `pg_user_mapping` stores the mapping from an RDS for PostgreSQL user to the user on a foreign data (remote) server. Access to the catalog is restricted, but you use the `pg_user_mappings` view to see the mappings. In the following, you can find an example that shows how permissions apply with an example Oracle database, but this information applies more generally to any foreign data wrapper.

In the following output, you can find roles and permissions mapped to three different example users. Users `rdssu1` and `rdssu2` are members of the `rds_superuser` role, and `user1` isn't. The example uses the `psql` metacommand `\du` to list existing roles.

```
test=> \du
```

## List of roles

Role name	Member of	Attributes
rdssu1	{rds_superuser}	
rdssu2	{rds_superuser}	
user1		{ }

All users, including users that have `rds_superuser` privileges, are allowed to view their own user mappings (`umoptions`) in the `pg_user_mappings` table. As shown in the following example, when `rdssu1` tries to obtain all user mappings, an error is raised even though `rdssu1` has `rds_superuser` privileges:

```
test=> SELECT * FROM pg_user_mapping;
ERROR: permission denied for table pg_user_mapping
```

Following are some examples.

```
test=> SET SESSION AUTHORIZATION rdssu1;
SET
test=> SELECT * FROM pg_user_mappings;
  umid | srvid | srvname | umuser | username | umoptions
-----+-----+-----+-----+-----+-----
 16414 | 16411 | oradb  | 16412 | user1    |
 16423 | 16411 | oradb  | 16421 | rdssu1   | {user=oracleuser,password=mypwd}
 16424 | 16411 | oradb  | 16422 | rdssu2   |
(3 rows)

test=> SET SESSION AUTHORIZATION rdssu2;
SET
test=> SELECT * FROM pg_user_mappings;
  umid | srvid | srvname | umuser | username | umoptions
-----+-----+-----+-----+-----+-----
 16414 | 16411 | oradb  | 16412 | user1    |
 16423 | 16411 | oradb  | 16421 | rdssu1   |
 16424 | 16411 | oradb  | 16422 | rdssu2   | {user=oracleuser,password=mypwd}
(3 rows)

test=> SET SESSION AUTHORIZATION user1;
```

```
SET
```

```
test=> SELECT * FROM pg_user_mappings;
```

umid	srvid	srvname	umuser	username	umoptions
16414	16411	oradb	16412	user1	{user=oracleuser,password=mypwd}
16423	16411	oradb	16421	rdssu1	
16424	16411	oradb	16422	rdssu2	

(3 rows)

Because of implementation differences between `information_schema._pg_user_mappings` and `pg_catalog.pg_user_mappings`, a manually created `rds_superuser` requires additional permissions to view passwords in `pg_catalog.pg_user_mappings`.

No additional permissions are required for an `rds_superuser` to view passwords in `information_schema._pg_user_mappings`.

Users who don't have the `rds_superuser` role can view passwords in `pg_user_mappings` only under the following conditions:

- The current user is the user being mapped and owns the server or holds the USAGE privilege on it.
- The current user is the server owner and the mapping is for PUBLIC.

## Working with SQL Server databases by using the `tds_fdw` extension

You can use the PostgreSQL `tds_fdw` extension to access databases that support the tabular data stream (TDS) protocol, such as Sybase and Microsoft SQL Server databases. This foreign data wrapper lets you connect from your RDS for PostgreSQL DB instance to databases that use the TDS protocol, including Amazon RDS for Microsoft SQL Server. For more information, see [tds-fdw/tds\\_fdw](#) documentation on GitHub.

The `tds_fdw` extension is supported on Amazon RDS for PostgreSQL version 14.2, 13.6, and higher releases.

## Setting up your Aurora PostgreSQL DB to use the `tds_fdw` extension

In the following procedures, you can find an example of setting up and using the `tds_fdw` with an RDS for PostgreSQL DB instance. Before you can connect to a SQL Server database using `tds_fdw`, you need to get the following details for the instance:

- Hostname or endpoint. For an RDS for SQL Server DB instance, you can find the endpoint by using the Console. Choose the Connectivity & security tab and look in the "Endpoint and port" section.
- Port number. The default port number for Microsoft SQL Server is 1433.
- Name of the database. The DB identifier.

You also need to provide access on the security group or the access control list (ACL) for the SQL Server port, 1433. Both the RDS for PostgreSQL DB instance and the RDS for SQL Server DB instance need access to port 1433. If access isn't configured correctly, when you try to query the Microsoft SQL Server you see the following error message:

```
ERROR: DB-Library error: DB #: 20009, DB Msg: Unable to connect:
Adaptive Server is unavailable or does not exist (mssql2019.aws-
region.rds.amazonaws.com), OS #: 0, OS Msg: Success, Level: 9
```

## To use `tds_fdw` to connect to a SQL Server database

1. Connect to your PostgreSQL DB instance using an account that has the `rds_superuser` role:

```
psql --host=your-DB-instance.aws-region.rds.amazonaws.com --port=5432 --
username=test --password
```

2. Install the `tds_fdw` extension:

```
test=> CREATE EXTENSION tds_fdw;
CREATE EXTENSION
```

After the extension is installed on your RDS for PostgreSQL DB instance, you set up the foreign server.

## To create the foreign server

Perform these tasks on the RDS for PostgreSQL DB instance using an account that has `rds_superuser` privileges.

1. Create a foreign server in the RDS for PostgreSQL DB instance:

```
test=> CREATE SERVER sqlserverdb FOREIGN DATA WRAPPER tds_fdw OPTIONS
  (servername 'mssql2019.aws-region.rds.amazonaws.com', port '1433', database
  'tds_fdw_testing');
CREATE SERVER
```

To access non-ASCII data on the SQLServer side, create a server link with the `character_set` option in the RDS for PostgreSQL DB instance:

```
test=> CREATE SERVER sqlserverdb FOREIGN DATA WRAPPER tds_fdw OPTIONS (servername
  'mssql2019.aws-region.rds.amazonaws.com', port '1433', database 'tds_fdw_testing',
  character_set 'UTF-8');
CREATE SERVER
```

- Grant permissions to a user who doesn't have `rds_superuser` role privileges, for example, `user1`:

```
test=> GRANT USAGE ON FOREIGN SERVER sqlserverdb TO user1;
```

- Connect as `user1` and create a mapping to a SQL Server user:

```
test=> CREATE USER MAPPING FOR user1 SERVER sqlserverdb OPTIONS (username
  'sqlserveruser', password 'password');
CREATE USER MAPPING
```

- Create a foreign table linked to a SQL Server table:

```
test=> CREATE FOREIGN TABLE mytab (a int) SERVER sqlserverdb OPTIONS (table
  'MYTABLE');
CREATE FOREIGN TABLE
```

- Query the foreign table:

```
test=> SELECT * FROM mytab;
 a
 ---
 1
(1 row)
```

## Using encryption in transit for the connection

The connection from RDS for PostgreSQL to SQL Server uses encryption in transit (TLS/SSL) depending on the SQL Server database configuration. If the SQL Server isn't configured for encryption, the RDS for PostgreSQL client making the request to the SQL Server database falls back to unencrypted.

You can enforce encryption for the connection to RDS for SQL Server DB instances by setting the `rds.force_ssl` parameter. To learn how, see [Forcing connections to your DB instance to use SSL](#). For more information about SSL/TLS configuration for RDS for SQL Server, see [Using SSL with a Microsoft SQL Server DB instance](#).

# Working with Trusted Language Extensions for PostgreSQL

Trusted Language Extensions for PostgreSQL is an open source development kit for building PostgreSQL extensions. It allows you to build high performance PostgreSQL extensions and safely run them on your RDS for PostgreSQL DB instance. By using Trusted Language Extensions (TLE) for PostgreSQL, you can create PostgreSQL extensions that follow the documented approach for extending PostgreSQL functionality. For more information, see [Packaging Related Objects into an Extension](#) in the PostgreSQL documentation.

One key benefit of TLE is that you can use it in environments that don't provide access to the file system underlying the PostgreSQL instance. Previously, installing a new extension required access to the file system. TLE removes this constraint. It provides a development environment for creating new extensions for any PostgreSQL database, including those running on your RDS for PostgreSQL DB instances.

TLE is designed to prevent access to unsafe resources for the extensions that you create using TLE. Its runtime environment limits the impact of any extension defect to a single database connection. TLE also gives database administrators fine-grained control over who can install extensions, and it provides a permissions model for running them.

TLE is supported on the following RDS for PostgreSQL versions:

- Version 16.1 and higher 16 versions
- Version 15.2 and higher 15 versions
- Version 14.5 and higher 14 versions
- Version 13.12 and higher 13 versions

The Trusted Language Extensions development environment and runtime are packaged as the `pg_tle` PostgreSQL extension, version 1.0.1. It supports creating extensions in JavaScript, Perl, Tcl, PL/pgSQL, and SQL. You install the `pg_tle` extension in your RDS for PostgreSQL DB instance in the same way that you install other PostgreSQL extensions. After the `pg_tle` is set up, developers can use it to create new PostgreSQL extensions, known as *TLE extensions*.

In the following topics, you can find information about how to set up Trusted Language Extensions and how to get started creating your own TLE extensions.

## Topics

- [Terminology](#)
- [Requirements for using Trusted Language Extensions for PostgreSQL](#)

## Terminology

To help you better understand Trusted Language Extensions, view the following glossary for terms used in this topic.

### Trusted Language Extensions for PostgreSQL

*Trusted Language Extensions for PostgreSQL* is the official name of the open source development kit that's packaged as the `pg_tle` extension. It's available for use on any PostgreSQL system. For more information, see [aws/pg\\_tle](#) on GitHub.

### Trusted Language Extensions

*Trusted Language Extensions* is the short name for Trusted Language Extensions for PostgreSQL. This shortened name and its abbreviation (TLE) are also used in this documentation.

### trusted language

A *trusted language* is a programming or scripting language that has specific security attributes. For example, trusted languages typically restrict access to the file system, and they limit use of specified networking properties. The TLE development kit is designed to support trusted languages. PostgreSQL supports several different languages that are used to create trusted or untrusted extensions. For an example, see [Trusted and Untrusted PL/Perl](#) in the

PostgreSQL documentation. When you create an extension using Trusted Language Extensions, the extension inherently uses trusted language mechanisms.

## TLE extension

A *TLE extension* is a PostgreSQL extension that's been created by using the Trusted Language Extensions (TLE) development kit.

## Requirements for using Trusted Language Extensions for PostgreSQL

The following are requirements for setting up and using the TLE development kit.

- **RDS for PostgreSQL versions** – Trusted Language Extensions is supported on RDS for PostgreSQL versions 13.12 and higher 13 versions, 14.5 and higher 14 versions, and 15.2 and higher versions only.
  - If you need to upgrade your RDS for PostgreSQL instance, see [Upgrading the PostgreSQL DB engine for Amazon RDS](#).
  - If you don't yet have an Amazon RDS DB instance running PostgreSQL, you can create one. For more information, see RDS for PostgreSQL DB instance, see [Creating and connecting to a PostgreSQL DB instance](#).
- **Requires `rds_superuser` privileges** – To set up and configure the `pg_tle` extension, your database user role must have the permissions of the `rds_superuser` role. By default, this role is granted to the `postgres` user that creates the RDS for PostgreSQL DB instance.
- **Requires a custom DB parameter group** – Your RDS for PostgreSQL DB instance must be configured with a custom DB parameter group.
  - If your RDS for PostgreSQL DB instance isn't configured with a custom DB parameter group, you should create one and associate it with your RDS for PostgreSQL DB instance. For a short summary of steps, see [Creating and applying a custom DB parameter group](#).
  - If your RDS for PostgreSQL DB instance is already configured using a custom DB parameter group, you can set up Trusted Language Extensions. For details, see [Setting up Trusted Language Extensions in your RDS for PostgreSQL DB instance](#).

## Creating and applying a custom DB parameter group

Use the following steps to create a custom DB parameter group and configure your RDS for PostgreSQL DB instance to use it.

## Console

### To create a custom DB parameter group and use it with your RDS for PostgreSQL DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. Choose Parameter groups from the Amazon RDS menu.
3. Choose **Create parameter group**.
4. In the **Parameter group details** page, enter the following information.
  - For **Parameter group family**, choose postgres14.
  - For **Type**, choose DB Parameter Group.
  - For **Group name**, give your parameter group a meaningful name in the context of your operations.
  - For **Description**, enter a useful description so that others on your team can easily find it.
5. Choose **Create**. Your custom DB parameter group is created in your AWS Region. You can now modify your RDS for PostgreSQL DB instance to use it by following the next steps.
6. Choose **Databases** from the Amazon RDS menu.
7. Choose the RDS for PostgreSQL DB instance that you want to use with TLE from among those listed, and then choose **Modify**.
8. In the Modify DB instance settings page, find **Database options** in the Additional configuration section and choose your custom DB parameter group from the selector.
9. Choose **Continue** to save the change.
10. Choose **Apply immediately** so that you can continue setting up the RDS for PostgreSQL DB instance to use TLE.

To continue setting up your system for Trusted Language Extensions, see [Setting up Trusted Language Extensions in your RDS for PostgreSQL DB instance](#).

For more information working with DB parameter groups, see [DB parameter groups for Amazon RDS DB instances](#).

## AWS CLI

You can avoid specifying the `--region` argument when you use CLI commands by configuring your AWS CLI with your default AWS Region. For more information, see [Configuration basics](#) in the *AWS Command Line Interface User Guide*.

### To create a custom DB parameter group and use it with your RDS for PostgreSQL DB instance

1. Use the [create-db-parameter-group](#) AWS CLI command to create a custom DB parameter group based on `postgres14` for your AWS Region.

For Linux, macOS, or Unix:

```
aws rds create-db-parameter-group \  
  --region aws-region \  
  --db-parameter-group-name custom-params-for-pg-tle \  
  --db-parameter-group-family postgres14 \  
  --description "My custom DB parameter group for Trusted Language Extensions"
```

For Windows:

```
aws rds create-db-parameter-group ^  
  --region aws-region ^  
  --db-parameter-group-name custom-params-for-pg-tle ^  
  --db-parameter-group-family postgres14 ^  
  --description "My custom DB parameter group for Trusted Language Extensions"
```

Your custom DB parameter group is available in your AWS Region, so you can modify RDS for PostgreSQL DB instance to use it.

2. Use the [modify-db-instance](#) AWS CLI command to apply your custom DB parameter group to your RDS for PostgreSQL DB instance. This command immediately reboots the active instance.

For Linux, macOS, or Unix:

```
aws rds modify-db-instance \  
  --region aws-region \  
  --db-instance-identifier your-instance-name \  
  --db-parameter-group-name custom-params-for-pg-tle \  
  --apply-immediately
```

## For Windows:

```
aws rds modify-db-instance ^
  --region aws-region ^
  --db-instance-identifier your-instance-name ^
  --db-parameter-group-name custom-params-for-pg-tle ^
  --apply-immediately
```

To continue setting up your system for Trusted Language Extensions, see [Setting up Trusted Language Extensions in your RDS for PostgreSQL DB instance](#).

For more information, see [Parameter groups for Amazon RDS](#).

## Setting up Trusted Language Extensions in your RDS for PostgreSQL DB instance

The following steps assume that your RDS for PostgreSQL DB instance is associated with a custom DB parameter group. You can use the AWS Management Console or the AWS CLI for these steps.

When you set up Trusted Language Extensions in your RDS for PostgreSQL DB instance, you install it in a specific database for use by the database users who have permissions on that database.

### Console

#### To set up Trusted Language Extensions

Perform the following steps using an account that's a member of the `rds_superuser` group (role).

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose your RDS for PostgreSQL DB instance.
3. Open the **Configuration** tab for your RDS for PostgreSQL DB instance. Among the Instance details, find the **Parameter group** link.
4. Choose the link to open the custom parameters associated with your RDS for PostgreSQL DB instance.
5. In the **Parameters** search field, type `shared_pre` to find the `shared_preload_libraries` parameter.

6. Choose **Edit parameters** to access the property values.
7. Add `pg_tle` to the list in the **Values** field. Use a comma to separate items in the list of values.

The screenshot shows the 'Parameters' configuration page in the Amazon RDS console. At the top, there are buttons for 'Cancel editing' and 'Preview changes'. Below them is a search bar containing 'shared\_prelo'. A table with columns 'Name', 'Values', and 'Allowed values' is displayed. The row for 'shared\_preload\_libraries' is selected, and its 'Values' field contains 'pg\_tle'. The 'Allowed values' for this parameter are listed as: auto\_explain, orafce, pgaudit, pglogical, pg\_bigm, pg\_cron, pg\_hint\_plan, pg\_prewarm, pg\_similarity, pg\_stat\_statements, pg\_tle, pg\_transport, plprofiler.

8. Reboot the RDS for PostgreSQL DB instance so that your change to the `shared_preload_libraries` parameter takes effect.
9. When the instance is available, verify that `pg_tle` has been initialized. Use `psql` to connect to the RDS for PostgreSQL DB instance, and then run the following command.

```
SHOW shared_preload_libraries;
shared_preload_libraries
-----
rdsutils,pg_tle
(1 row)
```

10. With the `pg_tle` extension initialized, you can now create the extension.

```
CREATE EXTENSION pg_tle;
```

You can verify that the extension is installed by using the following `psql` metacommand.

```
labdb=> \dx
                                List of installed extensions
 Name      | Version | Schema  | Description
-----+-----+-----+-----
 pg_tle    | 1.0.1   | pgtle   | Trusted-Language Extensions for PostgreSQL
 plpgsql   | 1.0     | pg_catalog | PL/pgSQL procedural language
```

- Grant the `pgtle_admin` role to the primary user name that you created for your RDS for PostgreSQL DB instance when you set it up. If you accepted the default, it's `postgres`.

```
labdb=> GRANT pgtle_admin TO postgres;
GRANT ROLE
```

You can verify that the grant has occurred by using the `psql` metacommmand as shown in the following example. Only the `pgtle_admin` and `postgres` roles are shown in the output. For more information, see [Understanding the `rds\_superuser` role](#).

```
labdb=> \du
                                List of roles
  Role name |          Attributes          |      Member of
-----+-----
+-----+-----
pgtle_admin | Cannot login                 | {}
postgres   | Create role, Create DB      +| {rds_superuser,pgtle_admin}
            | Password valid until infinity |...
```

- Close the `psql` session using the `\q` metacommmand.

```
\q
```

To get started creating TLE extensions, see [Example: Creating a trusted language extension using SQL](#).

## AWS CLI

You can avoid specifying the `--region` argument when you use CLI commands by configuring your AWS CLI with your default AWS Region. For more information, see [Configuration basics](#) in the *AWS Command Line Interface User Guide*.

### To set up Trusted Language Extensions

- Use the [modify-db-parameter-group](#) AWS CLI command to add `pg_tle` to the `shared_preload_libraries` parameter.

```
aws rds modify-db-parameter-group \
  --db-parameter-group-name custom-param-group-name \
```

```
--parameters
"ParameterName=shared_preload_libraries,ParameterValue=pg_tle,ApplyMethod=pending-
reboot" \
--region aws-region
```

2. Use the [reboot-db-instance](#) AWS CLI command to reboot the RDS for PostgreSQL DB instance and initialize the `pg_tle` library.

```
aws rds reboot-db-instance \
--db-instance-identifier your-instance \
--region aws-region
```

3. When the instance is available, you can verify that `pg_tle` has been initialized. Use `psql` to connect to the RDS for PostgreSQL DB instance, and then run the following command.

```
SHOW shared_preload_libraries;
shared_preload_libraries
-----
rdsutils,pg_tle
(1 row)
```

With `pg_tle` initialized, you can now create the extension.

```
CREATE EXTENSION pg_tle;
```

4. Grant the `pgtle_admin` role to the primary user name that you created for your RDS for PostgreSQL DB instance when you set it up. If you accepted the default, it's `postgres`.

```
GRANT pgtle_admin TO postgres;
GRANT ROLE
```

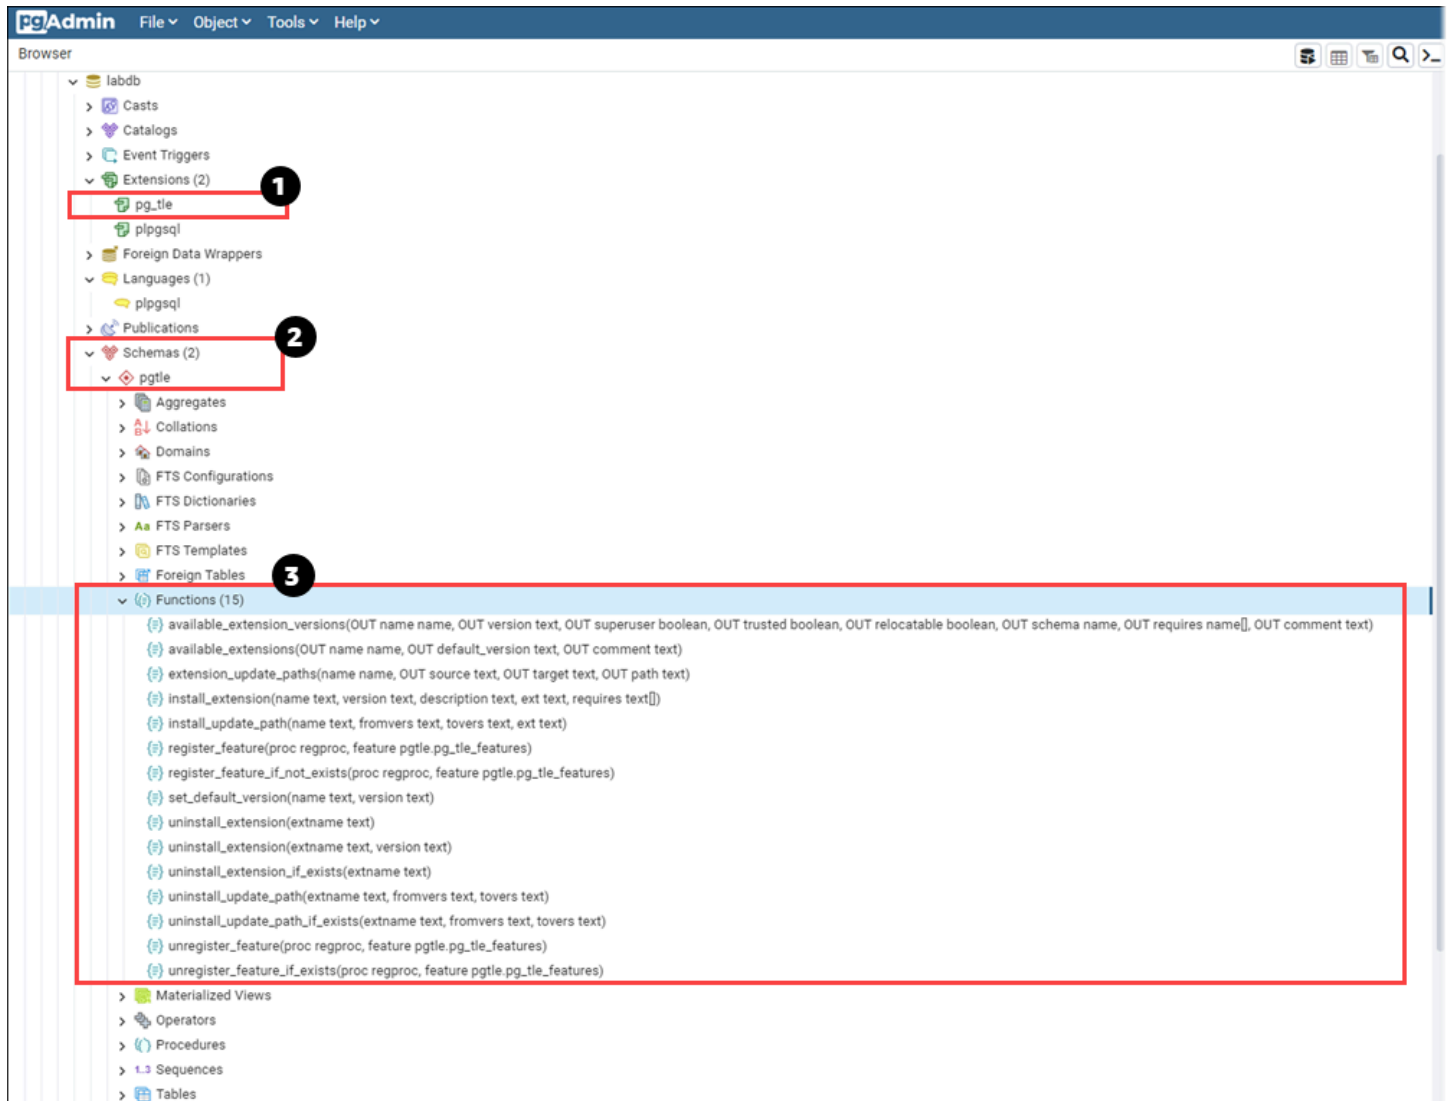

5. Close the `psql` session as follows.

```
labdb=> \q
```

To get started creating TLE extensions, see [Example: Creating a trusted language extension using SQL](#).

# Overview of Trusted Language Extensions for PostgreSQL

Trusted Language Extensions for PostgreSQL is a PostgreSQL extension that you install in your RDS for PostgreSQL DB instance in the same way that you set up other PostgreSQL extensions. In the following image of an example database in the pgAdmin client tool, you can view some of the components that comprise the `pg_tle` extension.

You can see the following details.

1. The Trusted Language Extensions (TLE) for PostgreSQL development kit is packaged as the `pg_tle` extension. As such, `pg_tle` is added to the available extensions for the database in which it's installed.
2. TLE has its own schema, `pgtle`. This schema contains helper functions (3) for installing and managing the extensions that you create.

3. TLE provides over a dozen helper functions for installing, registering, and managing your extensions. To learn more about these functions, see [Function reference for Trusted Language Extensions for PostgreSQL](#).

Other components of the `pg_tle` extension include the following:

- **The `pgtle_admin` role** – The `pgtle_admin` role is created when the `pg_tle` extension is installed. This role is privileged and should be treated as such. We strongly recommend that you follow the principle of *least privilege* when granting the `pgtle_admin` role to database users. In other words, grant the `pgtle_admin` role only to database users that are allowed to create, install, and manage new TLE extensions, such as `postgres`.
- **The `pgtle.feature_info` table** – The `pgtle.feature_info` table is a protected table that contains information about your TLEs, hooks, and the custom stored procedures and functions that they use. If you have `pgtle_admin` privileges, you use the following Trusted Language Extensions functions to add and update that information in the table.
  - [pgtle.register\\_feature](#)
  - [pgtle.register\\_feature\\_if\\_not\\_exists](#)
  - [pgtle.unregister\\_feature](#)
  - [pgtle.unregister\\_feature\\_if\\_exists](#)

## Creating TLE extensions for RDS for PostgreSQL

You can install any extensions that you create with TLE in any RDS for PostgreSQL DB instance that has the `pg_tle` extension installed. The `pg_tle` extension is scoped to the PostgreSQL database in which it's installed. The extensions that you create using TLE are scoped to the same database.

Use the various `pgtle` functions to install the code that makes up your TLE extension. The following Trusted Language Extensions functions all require the `pgtle_admin` role.

- [pgtle.install\\_extension](#)
- [pgtle.install\\_update\\_path](#)
- [pgtle.register\\_feature](#)
- [pgtle.register\\_feature\\_if\\_not\\_exists](#)
- [pgtle.set\\_default\\_version](#)
- [pgtle.uninstall\\_extension\(name\)](#)

- [pgtle.uninstall\\_extension\(name, version\)](#)
- [pgtle.uninstall\\_extension\\_if\\_exists](#)
- [pgtle.uninstall\\_update\\_path](#)
- [pgtle.uninstall\\_update\\_path\\_if\\_exists](#)
- [pgtle.unregister\\_feature](#)
- [pgtle.unregister\\_feature\\_if\\_exists](#)

## Example: Creating a trusted language extension using SQL

The following example shows you how to create a TLE extension named `pg_distance` that contains a few SQL functions for calculating distances using different formulas. In the listing, you can find the function for calculating the Manhattan distance and the function for calculating the Euclidean distance. For more information about the difference between these formulas, see [Taxicab geometry](#) and [Euclidean geometry](#) in Wikipedia.

You can use this example in your own RDS for PostgreSQL DB instance if you have the `pg_tle` extension set up as detailed in [Setting up Trusted Language Extensions in your RDS for PostgreSQL DB instance](#).

### Note

You need to have the privileges of the `pgtle_admin` role to follow this procedure.

## To create the example TLE extension

The following steps use an example database named `labdb`. This database is owned by the `postgres` primary user. The `postgres` role also has the permissions of the `pgtle_admin` role.

1. Use `psql` to connect to RDS for PostgreSQL DB instance.

```
psql --host=db-instance-123456789012.aws-region.rds.amazonaws.com
--port=5432 --username=postgres --password --dbname=labdb
```

2. Create a TLE extension named `pg_distance` by copying the following code and pasting it into your `psql` session console.

```
SELECT pgtle.install_extension
```

```
(
  'pg_distance',
  '0.1',
  'Distance functions for two points',
  $_pg_tle_$
  CREATE FUNCTION dist(x1 float8, y1 float8, x2 float8, y2 float8, norm int)
  RETURNS float8
  AS $$
    SELECT (abs(x2 - x1) ^ norm + abs(y2 - y1) ^ norm) ^ (1::float8 / norm);
  $$ LANGUAGE SQL;

  CREATE FUNCTION manhattan_dist(x1 float8, y1 float8, x2 float8, y2 float8)
  RETURNS float8
  AS $$
    SELECT dist(x1, y1, x2, y2, 1);
  $$ LANGUAGE SQL;

  CREATE FUNCTION euclidean_dist(x1 float8, y1 float8, x2 float8, y2 float8)
  RETURNS float8
  AS $$
    SELECT dist(x1, y1, x2, y2, 2);
  $$ LANGUAGE SQL;
  $_pg_tle_$
);
```

You see the output, such as the following.

```
install_extension
-----
 t
(1 row)
```

The artifacts that make up the `pg_distance` extension are now installed in your database. These artifacts include the control file and the code for the extension, which are items that need to be present so that the extension can be created using the `CREATE EXTENSION` command. In other words, you still need to create the extension to make its functions available to database users.

3. To create the extension, use the `CREATE EXTENSION` command as you do for any other extension. As with other extensions, the database user needs to have the `CREATE` permissions in the database.

```
CREATE EXTENSION pg_distance;
```

4. To test the `pg_distance` TLE extension, you can use it to calculate the [Manhattan distance](#) between four points.

```
labdb=> SELECT manhattan_dist(1, 1, 5, 5);  
8
```

To calculate the [Euclidean distance](#) between the same set of points, you can use the following.

```
labdb=> SELECT euclidean_dist(1, 1, 5, 5);  
5.656854249492381
```

The `pg_distance` extension loads the functions in the database and makes them available to any users with permissions on the database.

## Modifying your TLE extension

To improve query performance for the functions packaged in this TLE extension, add the following two PostgreSQL attributes to their specifications.

- **IMMUTABLE** – The **IMMUTABLE** attribute ensures that the query optimizer can use optimizations to improve query response times. For more information, see [Function Volatility Categories](#) in the PostgreSQL documentation.
- **PARALLEL SAFE** – The **PARALLEL SAFE** attribute is another attribute that allows PostgreSQL to run the function in parallel mode. For more information, see [CREATE FUNCTION](#) in the PostgreSQL documentation.

In the following example, you can see how the `pgtle.install_update_path` function is used to add these attributes to each function to create a version `0.2` of the `pg_distance` TLE extension. For more information about this function, see [pgtle.install\\_update\\_path](#). You need to have the `pgtle_admin` role to perform this task.

### To update an existing TLE extension and specify the default version

1. Connect to RDS for PostgreSQL DB instance using `psql` or another client tool, such as `pgAdmin`.

```
psql --host=db-instance-123456789012.aws-region.rds.amazonaws.com
--port=5432 --username=postgres --password --dbname=labdb
```

2. Modify the existing TLE extension by copying the following code and pasting it into your psql session console.

```
SELECT pgtle.install_update_path
(
  'pg_distance',
  '0.1',
  '0.2',
  $_pg_tle_$
  CREATE OR REPLACE FUNCTION dist(x1 float8, y1 float8, x2 float8, y2 float8,
norm int)
  RETURNS float8
  AS $$
    SELECT (abs(x2 - x1) ^ norm + abs(y2 - y1) ^ norm) ^ (1::float8 / norm);
  $$ LANGUAGE SQL IMMUTABLE PARALLEL SAFE;

  CREATE OR REPLACE FUNCTION manhattan_dist(x1 float8, y1 float8, x2 float8, y2
float8)
  RETURNS float8
  AS $$
    SELECT dist(x1, y1, x2, y2, 1);
  $$ LANGUAGE SQL IMMUTABLE PARALLEL SAFE;

  CREATE OR REPLACE FUNCTION euclidean_dist(x1 float8, y1 float8, x2 float8, y2
float8)
  RETURNS float8
  AS $$
    SELECT dist(x1, y1, x2, y2, 2);
  $$ LANGUAGE SQL IMMUTABLE PARALLEL SAFE;
  $_pg_tle_$
);
```

You see a response similar to the following.

```
install_update_path
-----
t
(1 row)
```

You can make this version of the extension the default version, so that database users don't have to specify a version when they create or update the extension in their database.

3. To specify that the modified version (version 0.2) of your TLE extension is the default version, use the `pgtle.set_default_version` function as shown in the following example.

```
SELECT pgtle.set_default_version('pg_distance', '0.2');
```

For more information about this function, see [pgtle.set\\_default\\_version](#).

4. With the code in place, you can update the installed TLE extension in the usual way, by using `ALTER EXTENSION ... UPDATE` command, as shown here:

```
ALTER EXTENSION pg_distance UPDATE;
```

## Dropping your TLE extensions from a database

You can drop your TLE extensions by using the `DROP EXTENSION` command in the same way that you do for other PostgreSQL extensions. Dropping the extension doesn't remove the installation files that make up the extension, which allows users to re-create the extension. To remove the extension and its installation files, do the following two-step process.

### To drop the TLE extension and remove its installation files

1. Use `psql` or another client tool to connect to the RDS for PostgreSQL DB instance.

```
psql --host=.111122223333.aws-region.rds.amazonaws.com --port=5432 --  
username=postgres --password --dbname=dbname
```

2. Drop the extension as you would any PostgreSQL extension.

```
DROP EXTENSION your-TLE-extension
```

For example, if you create the `pg_distance` extension as detailed in [Example: Creating a trusted language extension using SQL](#), you can drop the extension as follows.

```
DROP EXTENSION pg_distance;
```

You see output confirming that the extension has been dropped, as follows.

```
DROP EXTENSION
```

At this point, the extension is no longer active in the database. However, its installation files and control file are still available in the database, so database users can create the extension again if they like.

- If you want to leave the extension files intact so that database users can create your TLE extension, you can stop here.
  - If you want to remove all files that make up the extension, continue to the next step.
3. To remove all installation files for your extension, use the `pgtle.uninstall_extension` function. This function removes all the code and control files for your extension.

```
SELECT pgtle.uninstall_extension('your-tle-extension-name');
```

For example, to remove all `pg_distance` installation files, use the following command.

```
SELECT pgtle.uninstall_extension('pg_distance');
uninstall_extension
-----
t
(1 row)
```

## Uninstalling Trusted Language Extensions for PostgreSQL

If you no longer want to create your own TLE extensions using TLE, you can drop the `pg_tle` extension and remove all artifacts. This action includes dropping any TLE extensions in the database and dropping the `pgtle` schema.

### To drop the `pg_tle` extension and its schema from a database

1. Use `psql` or another client tool to connect to the RDS for PostgreSQL DB instance.

```
psql --host=.111122223333.aws-region.rds.amazonaws.com --port=5432 --
username=postgres --password --dbname=dbname
```

- Drop the `pg_tle` extension from the database. If the database has your own TLE extensions still running in the database, you need to also drop those extensions. To do so, you can use the `CASCADE` keyword, as shown in the following.

```
DROP EXTENSION pg_tle CASCADE;
```

If the `pg_tle` extension isn't still active in the database, you don't need to use the `CASCADE` keyword.

- Drop the `pgtle` schema. This action removes all the management functions from the database.

```
DROP SCHEMA pgtle CASCADE;
```

The command returns the following when the process completes.

```
DROP SCHEMA
```

The `pg_tle` extension, its schema and functions, and all artifacts are removed. To create new extensions using TLE, go through the setup process again. For more information, see [Setting up Trusted Language Extensions in your RDS for PostgreSQL DB instance](#).

## Using PostgreSQL hooks with your TLE extensions

A *hook* is a callback mechanism available in PostgreSQL that allows developers to call custom functions or other routines during regular database operations. The TLE development kit supports PostgreSQL hooks so that you can integrate custom functions with PostgreSQL behavior at runtime. For example, you can use a hook to associate the authentication process with your own custom code, or to modify the query planning and execution process for your specific needs.

Your TLE extensions can use hooks. If a hook is global in scope, it applies across all databases. Therefore, if your TLE extension uses a global hook, then you need to create your TLE extension in all databases that your users can access.

When you use the `pg_tle` extension to build your own Trusted Language Extensions, you can use the available hooks from a SQL API to build out the functions of your extension. You should register any hooks with `pg_tle`. For some hooks, you might also need to set various configuration parameters. For example, the passcode check hook can be set to `on`, `off`, or `require`. For more

information about specific requirements for available `pg_tle` hooks, see [Hooks reference for Trusted Language Extensions for PostgreSQL](#).

## Example: Creating an extension that uses a PostgreSQL hook

The example discussed in this section uses a PostgreSQL hook to check the password provided during specific SQL operations and prevents database users from setting their passwords to any of those contained in the `password_check.bad_passwords` table. The table contains the top-ten most commonly used, but easily breakable choices for passwords.

To set up this example in your RDS for PostgreSQL DB instance, you must have already installed Trusted Language Extensions. For details, see [Setting up Trusted Language Extensions in your RDS for PostgreSQL DB instance](#).

### To set up the password-check hook example

1. Use `psql` to connect to RDS for PostgreSQL DB instance.

```
psql --host=db-instance-123456789012.aws-region.rds.amazonaws.com
--port=5432 --username=postgres --password --dbname=labdb
```

2. Copy the code from the [Password-check hook code listing](#) and paste it into your database.

```
SELECT pgtle.install_extension (
  'my_password_check_rules',
  '1.0',
  'Do not let users use the 10 most commonly used passwords',
  $_pgtle_$
CREATE SCHEMA password_check;
REVOKE ALL ON SCHEMA password_check FROM PUBLIC;
GRANT USAGE ON SCHEMA password_check TO PUBLIC;

CREATE TABLE password_check.bad_passwords (plaintext) AS
VALUES
  ('123456'),
  ('password'),
  ('12345678'),
  ('qwerty'),
  ('123456789'),
  ('12345'),
  ('1234'),
  ('111111'),
```

```
 ('1234567'),
 ('dragon');
CREATE UNIQUE INDEX ON password_check.bad_passwords (plaintext);

CREATE FUNCTION password_check.passcheck_hook(username text, password text,
password_type pgtle.password_types, valid_until timestampz, valid_null boolean)
RETURNS void AS $$
DECLARE
    invalid bool := false;
BEGIN
    IF password_type = 'PASSWORD_TYPE_MD5' THEN
        SELECT EXISTS(
            SELECT 1
            FROM password_check.bad_passwords bp
            WHERE ('md5' || md5(bp.plaintext || username)) = password
        ) INTO invalid;
        IF invalid THEN
            RAISE EXCEPTION 'Cannot use passwords from the common password
dictionary';
        END IF;
    ELSIF password_type = 'PASSWORD_TYPE_PLAINTEXT' THEN
        SELECT EXISTS(
            SELECT 1
            FROM password_check.bad_passwords bp
            WHERE bp.plaintext = password
        ) INTO invalid;
        IF invalid THEN
            RAISE EXCEPTION 'Cannot use passwords from the common common password
dictionary';
        END IF;
    END IF;
END
$$ LANGUAGE plpgsql SECURITY DEFINER;

GRANT EXECUTE ON FUNCTION password_check.passcheck_hook TO PUBLIC;

SELECT pgtle.register_feature('password_check.passcheck_hook', 'passcheck');
$_pgtle_$
);
```

When the extension has been loaded into your database, you see the output such as the following.

```
install_extension
-----
t
(1 row)
```

3. While still connected to the database, you can now create the extension.

```
CREATE EXTENSION my_password_check_rules;
```

4. You can confirm that the extension has been created in the database by using the following `psql` metacommand.

```
\dx
                                List of installed extensions
      Name                       | Version | Schema |
      Description
-----+-----+-----+
+-----+-----+-----+
my_password_check_rules | 1.0     | public | Prevent use of any of the top-ten
most common bad passwords
pg_tle                    | 1.0.1   | pgtle  | Trusted-Language Extensions for
PostgreSQL
plpgsql                   | 1.0     | pg_catalog | PL/pgSQL procedural language
(3 rows)
```

5. Open another terminal session to work with the AWS CLI. You need to modify your custom DB parameter group to turn on the password-check hook. To do so, use the [modify-db-parameter-group](#) CLI command as shown in the following example.

```
aws rds modify-db-parameter-group \
  --region aws-region \
  --db-parameter-group-name your-custom-parameter-group \
  --parameters
  "ParameterName=pgtle.enable_password_check,ParameterValue=on,ApplyMethod=immediate"
```

When the parameter is successfully turned on, you see the output such as the following.

```
{
  "DBParameterGroupName": "docs-lab-parameters-for-tle"
}
```

It might take a few minutes for the change to the parameter group setting to take effect. This parameter is dynamic, however, so you don't need to restart the RDS for PostgreSQL DB instance for the setting to take effect.

6. Open the `psql` session and query the database to verify that the `password_check` hook has been turned on.

```
labdb=> SHOW pgtle.enable_password_check;
pgtle.enable_password_check
-----
on
(1 row)
```

The password-check hook is now active. You can test it by creating a new role and using one of the bad passwords, as shown in the following example.

```
CREATE ROLE test_role PASSWORD 'password';
ERROR:  Cannot use passwords from the common password dictionary
CONTEXT:  PL/pgSQL function
password_check.passcheck_hook(text,text,pgtle.password_types,timestamp with time
zone,boolean) line 21 at RAISE
SQL statement "SELECT password_check.passcheck_hook(
    $1::pg_catalog.text,
    $2::pg_catalog.text,
    $3::pgtle.password_types,
    $4::pg_catalog.timestampz,
    $5::pg_catalog.bool)"
```

The output has been formatted for readability.

The following example shows that `psql` interactive metacommand `\password` behavior is also affected by the `password_check` hook.

```
postgres=> SET password_encryption TO 'md5';
SET
postgres=> \password
Enter new password for user "postgres":*****
Enter it again:*****
ERROR:  Cannot use passwords from the common password dictionary
```

```
CONTEXT: PL/pgSQL function
password_check.passcheck_hook(text,text,pgtle.password_types,timestamp with time
zone,boolean) line 12 at RAISE
SQL statement "SELECT password_check.passcheck_hook($1::pg_catalog.text,
$2::pg_catalog.text, $3::pgtle.password_types, $4::pg_catalog.timestampz,
$5::pg_catalog.bool)"
```

You can drop this TLE extension and uninstall its source files if you want. For more information, see [Dropping your TLE extensions from a database](#).

### Password-check hook code listing

The example code shown here defines the specification for the `my_password_check_rules` TLE extension. When you copy this code and paste it into your database, the code for the `my_password_check_rules` extension is loaded into the database, and the `password_check` hook is registered for use by the extension.

```
SELECT pgtle.install_extension (
  'my_password_check_rules',
  '1.0',
  'Do not let users use the 10 most commonly used passwords',
  $_pgtle_$
CREATE SCHEMA password_check;
REVOKE ALL ON SCHEMA password_check FROM PUBLIC;
GRANT USAGE ON SCHEMA password_check TO PUBLIC;

CREATE TABLE password_check.bad_passwords (plaintext) AS
VALUES
  ('123456'),
  ('password'),
  ('12345678'),
  ('qwerty'),
  ('123456789'),
  ('12345'),
  ('1234'),
  ('111111'),
  ('1234567'),
  ('dragon');
CREATE UNIQUE INDEX ON password_check.bad_passwords (plaintext);

CREATE FUNCTION password_check.passcheck_hook(username text, password text,
password_type pgtle.password_types, valid_until timestampz, valid_null boolean)
RETURNS void AS $$
```

```
DECLARE
    invalid bool := false;
BEGIN
    IF password_type = 'PASSWORD_TYPE_MD5' THEN
        SELECT EXISTS(
            SELECT 1
            FROM password_check.bad_passwords bp
            WHERE ('md5' || md5(bp.plaintext || username)) = password
        ) INTO invalid;
        IF invalid THEN
            RAISE EXCEPTION 'Cannot use passwords from the common password dictionary';
        END IF;
    ELSIF password_type = 'PASSWORD_TYPE_PLAINTEXT' THEN
        SELECT EXISTS(
            SELECT 1
            FROM password_check.bad_passwords bp
            WHERE bp.plaintext = password
        ) INTO invalid;
        IF invalid THEN
            RAISE EXCEPTION 'Cannot use passwords from the common common password
dictionary';
        END IF;
    END IF;
END
$$ LANGUAGE plpgsql SECURITY DEFINER;

GRANT EXECUTE ON FUNCTION password_check.passcheck_hook TO PUBLIC;

SELECT pgtle.register_feature('password_check.passcheck_hook', 'passcheck');
$_pgtle_$
);
```

## Using Custom Data Types in TLE

PostgreSQL supports commands to register new base types (also known as scalar types) for efficiently handling complex data structures in your database. A base type allows you to customize how the data is stored internally, and how to convert it to and from an external textual representation. These custom data types are helpful when extending PostgreSQL to support functional domains where a built-in type such as number or text can't provide sufficient search semantics.

RDS for PostgreSQL enables you to create custom data types in your trusted language extension and define functions that support SQL and index operations for these new data types. Custom data types are available for the following versions:

- RDS for PostgreSQL 15.4 and higher 15 versions
- RDS for PostgreSQL 14.9 and higher 14 versions
- RDS for PostgreSQL 13.12 and higher 13 versions

For more information, see [Trusted Language Base types](#).

## Function reference for Trusted Language Extensions for PostgreSQL

View the following reference documentation about functions available in Trusted Language Extensions for PostgreSQL. Use these functions to install, register, update, and manage your *TLE extensions*, that is, the PostgreSQL extensions that you develop using the Trusted Language Extensions development kit.

### Topics

- [pgtle.available\\_extensions](#)
- [pgtle.available\\_extension\\_versions](#)
- [pgtle.extension\\_update\\_paths](#)
- [pgtle.install\\_extension](#)
- [pgtle.install\\_update\\_path](#)

- [pgtle.unregister\\_feature\\_if\\_exists](#)

## pgtle.available\_extensions

The `pgtle.available_extensions` function is a set-returning function. It returns all available TLE extensions in the database. Each returned row contains information about a single TLE extension.

### Function prototype

```
pgtle.available_extensions()
```

### Role

None.

### Arguments

None.

### Output

- `name` – The name of the TLE extension.
- `default_version` – The version of the TLE extension to use when `CREATE EXTENSION` is called without a version specified.
- `description` – A more detailed description about the TLE extension.

### Usage example

```
SELECT * FROM pgtle.available_extensions();
```

## pgtle.available\_extension\_versions

The `available_extension_versions` function is a set-returning function. It returns a list of all available TLE extensions and their versions. Each row contains information about a specific version of the given TLE extension, including whether it requires a specific role.

### Function prototype

```
pgtle.available_extension_versions()
```

## Role

None.

## Arguments

None.

## Output

- `name` – The name of the TLE extension.
- `version` – The version of the TLE extension.
- `superuser` – This value is always `false` for your TLE extensions. The permissions needed to create the TLE extension or update it are the same as for creating other objects in the given database.
- `trusted` – This value is always `false` for a TLE extension.
- `relocatable` – This value is always `false` for a TLE extension.
- `schema` – Specifies the name of the schema in which the TLE extension is installed.
- `requires` – An array containing the names of other extensions needed by this TLE extension.
- `description` – A detailed description of the TLE extension.

For more information about output values, see [Packaging Related Objects into an Extension > Extension Files](#) in the PostgreSQL documentation.

## Usage example

```
SELECT * FROM pgtle.available_extension_versions();
```

## `pgtle.extension_update_paths`

The `extension_update_paths` function is a set-returning function. It returns a list of all the possible update paths for a TLE extension. Each row includes the available upgrades or downgrades for that TLE extension.

## Function prototype

```
pgtle.extension_update_paths(name)
```

## Role

None.

## Arguments

`name` – The name of the TLE extension from which to get upgrade paths.

## Output

- `source` – The source version for an update.
- `target` – The target version for an update.
- `path` – The upgrade path used to update a TLE extension from source version to target version, for example, `0.1--0.2`.

## Usage example

```
SELECT * FROM pgtle.extension_update_paths('your-TLE');
```

## `pgtle.install_extension`

The `install_extension` function lets you install the artifacts that make up your TLE extension in the database, after which it can be created using the `CREATE EXTENSION` command.

## Function prototype

```
pgtle.install_extension(name text, version text, description text, ext text, requires text[] DEFAULT NULL::text[])
```

## Role

None.

## Arguments

- `name` – The name of the TLE extension. This value is used when calling `CREATE EXTENSION`.
- `version` – The version of the TLE extension.
- `description` – A detailed description about the TLE extension. This description is displayed in the comment field in `pgtle.available_extensions()`.
- `ext` – The contents of the TLE extension. This value contains objects such as functions.

- **requires** – An optional parameter that specifies dependencies for this TLE extension. The `pg_tle` extension is automatically added as a dependency.

Many of these arguments are the same as those that are included in an extension control file for installing a PostgreSQL extension on the file system of a PostgreSQL instance. For more information, see the [Extension Files](#) in [Packaging Related Objects into an Extension](#) in the PostgreSQL documentation.

## Output

This function returns OK on success and NULL on error.

- OK – The TLE extension has been successfully installed in the database.
- NULL – The TLE extension hasn't been successfully installed in the database.

## Usage example

```
SELECT pgtle.install_extension(  
  'pg_tle_test',  
  '0.1',  
  'My first pg_tle extension',  
  $_pgtle_$  
  CREATE FUNCTION my_test()  
  RETURNS INT  
  AS $$  
    SELECT 42;  
  $$ LANGUAGE SQL IMMUTABLE;  
  $_pgtle_$  
);
```

## `pgtle.install_update_path`

The `install_update_path` function provides an update path between two different versions of a TLE extension. This function allows users of your TLE extension to update its version by using the `ALTER EXTENSION ... UPDATE` syntax.

## Function prototype

```
pgtle.install_update_path(name text, fromvers text, tovers text, ext text)
```

## Role

pgtle\_admin

## Arguments

- `name` – The name of the TLE extension. This value is used when calling `CREATE EXTENSION`.
- `fromvers` – The source version of the TLE extension for the upgrade.
- `tovers` – The destination version of the TLE extension for the upgrade.
- `ext` – The contents of the update. This value contains objects such as functions.

## Output

None.

## Usage example

```
SELECT pgtle.install_update_path('pg_tle_test', '0.1', '0.2',
    $_pgtle_$
    CREATE OR REPLACE FUNCTION my_test()
    RETURNS INT
    AS $$
        SELECT 21;
    $$ LANGUAGE SQL IMMUTABLE;
    $_pgtle_$
);
```

## pgtle.register\_feature

The `register_feature` function adds the specified internal PostgreSQL feature to the `pgtle.feature_info` table. PostgreSQL hooks are an example of an internal PostgreSQL feature. The Trusted Language Extensions development kit supports the use of PostgreSQL hooks. Currently, this function supports the following feature.

- `passcheck` – Registers the password-check hook with your procedure or function that customizes PostgreSQL's password-check behavior.

## Function prototype

```
pgtle.register_feature(proc regproc, feature pg_tle_feature)
```

### Role

pgtle\_admin

### Arguments

- `proc` – The name of a stored procedure or function to use for the feature.
- `feature` – The name of the `pg_tle` feature (such as `passcheck`) to register with the function.

### Output

None.

### Usage example

```
SELECT pgtle.register_feature('pw_hook', 'passcheck');
```

## pgtle.register\_feature\_if\_not\_exists

The `pgtle.register_feature_if_not_exists` function adds the specified PostgreSQL feature to the `pgtle.feature_info` table and identifies the TLE extension or other procedure or function that uses the feature. For more information about hooks and Trusted Language Extensions, see [Using PostgreSQL hooks with your TLE extensions](#).

### Function prototype

```
pgtle.register_feature_if_not_exists(proc regproc, feature pg_tle_feature)
```

### Role

pgtle\_admin

### Arguments

- `proc` – The name of a stored procedure or function that contains the logic (code) to use as a feature for your TLE extension. For example, the `pw_hook` code.

- **feature** – The name of the PostgreSQL feature to register for the TLE function. Currently, the only available feature is the passcheck hook. For more information, see [Password-check hook \(passcheck\)](#).

## Output

Returns `true` after registering the feature for the specified extension. Returns `false` if the feature is already registered.

## Usage example

```
SELECT pgtle.register_feature_if_not_exists('pw_hook', 'passcheck');
```

## pgtle.set\_default\_version

The `set_default_version` function lets you specify a `default_version` for your TLE extension. You can use this function to define an upgrade path and designate the version as the default for your TLE extension. When database users specify your TLE extension in the `CREATE EXTENSION` and `ALTER EXTENSION . . . UPDATE` commands, that version of your TLE extension is created in the database for that user.

This function returns `true` on success. If the TLE extension specified in the `name` argument doesn't exist, the function returns an error. Similarly, if the `version` of the TLE extension doesn't exist, it returns an error.

## Function prototype

```
pgtle.set_default_version(name text, version text)
```

## Role

`pgtle_admin`

## Arguments

- **name** – The name of the TLE extension. This value is used when calling `CREATE EXTENSION`.
- **version** – The version of the TLE extension to set the default.

## Output

- `true` – When setting default version succeeds, the function returns `true`.
- `ERROR` – Returns an error message if a TLE extension with the specified name or version doesn't exist.

## Usage example

```
SELECT * FROM pgtle.set_default_version('my-extension', '1.1');
```

## `pgtle.uninstall_extension(name)`

The `uninstall_extension` function removes all versions of a TLE extension from a database. This function prevents future calls of `CREATE EXTENSION` from installing the TLE extension. If the TLE extension doesn't exist in the database, an error is raised.

The `uninstall_extension` function won't drop a TLE extension that's currently active in the database. To remove a TLE extension that's currently active, you need to explicitly call `DROP EXTENSION` to remove it.

## Function prototype

```
pgtle.uninstall_extension(extname text)
```

## Role

`pgtle_admin`

## Arguments

- `extname` – The name of the TLE extension to uninstall. This name is the same as the one used with `CREATE EXTENSION` to load the TLE extension for use in a given database.

## Output

None.

## Usage example

```
SELECT * FROM pgtle.uninstall_extension('pg_tle_test');
```

## **pgtle.uninstall\_extension(name, version)**

The `uninstall_extension(name, version)` function removes the specified version of the TLE extension from the database. This function prevents `CREATE EXTENSION` and `ALTER EXTENSION` from installing or updating a TLE extension to the specified version. This function also removes all update paths for the specified version of the TLE extension. This function won't uninstall the TLE extension if it's currently active in the database. You must explicitly call `DROP EXTENSION` to remove the TLE extension. To uninstall all versions of a TLE extension, see [pgtle.uninstall\\_extension\(name\)](#).

### **Function prototype**

```
pgtle.uninstall_extension(extname text, version text)
```

### **Role**

`pgtle_admin`

### **Arguments**

- `extname` – The name of the TLE extension. This value is used when calling `CREATE EXTENSION`.
- `version` – The version of the TLE extension to uninstall from the database.

### **Output**

None.

### **Usage example**

```
SELECT * FROM pgtle.uninstall_extension('pg_tle_test', '0.2');
```

## **pgtle.uninstall\_extension\_if\_exists**

The `uninstall_extension_if_exists` function removes all versions of a TLE extension from a given database. If the TLE extension doesn't exist, the function returns silently (no error message is raised). If the specified extension is currently active within a database, this function doesn't drop it. You must explicitly call `DROP EXTENSION` to remove the TLE extension before using this function to uninstall its artifacts.

## Function prototype

```
pgtle.uninstall_extension_if_exists(extname text)
```

### Role

pgtle\_admin

### Arguments

- `extname` – The name of the TLE extension. This value is used when calling `CREATE EXTENSION`.

### Output

The `uninstall_extension_if_exists` function returns `true` after uninstalling the specified extension. If the specified extension doesn't exist, the function returns `false`.

- `true` – Returns `true` after uninstalling the TLE extension.
- `false` – Returns `false` when the TLE extension doesn't exist in the database.

### Usage example

```
SELECT * FROM pgtle.uninstall_extension_if_exists('pg_tle_test');
```

## pgtle.uninstall\_update\_path

The `uninstall_update_path` function removes the specific update path from a TLE extension. This prevents `ALTER EXTENSION ... UPDATE TO` from using this as an update path.

If the TLE extension is currently being used by one of the versions on this update path, it remains in the database.

If the update path specified doesn't exist, this function raises an error.

### Function prototype

```
pgtle.uninstall_update_path(extname text, fromvers text, tovers text)
```

### Role

pgtle\_admin

## Arguments

- `extname` – The name of the TLE extension. This value is used when calling `CREATE EXTENSION`.
- `fromvers` – The source version of the TLE extension used on the update path.
- `tovers` – The destination version of the TLE extension used on the update path.

## Output

None.

## Usage example

```
SELECT * FROM pgtle.uninstall_update_path('pg_tle_test', '0.1', '0.2');
```

## `pgtle.uninstall_update_path_if_exists`

The `uninstall_update_path_if_exists` function is similar to `uninstall_update_path` in that it removes the specified update path from a TLE extension. However, if the update path doesn't exist, this function doesn't raise an error message. Instead, the function returns `false`.

## Function prototype

```
pgtle.uninstall_update_path_if_exists(extname text, fromvers text, tovers text)
```

## Role

`pgtle_admin`

## Arguments

- `extname` – The name of the TLE extension. This value is used when calling `CREATE EXTENSION`.
- `fromvers` – The source version of the TLE extension used on the update path.
- `tovers` – The destination version of the TLE extension used on the update path.

## Output

- `true` – The function has successfully updated the path for the TLE extension.
- `false` – The function wasn't able to update the path for the TLE extension.

## Usage example

```
SELECT * FROM pgtle.uninstall_update_path_if_exists('pg_tle_test', '0.1', '0.2');
```

## pgtle.unregister\_feature

The `unregister_feature` function provides a way to remove functions that were registered to use `pg_tle` features, such as hooks. For information about registering a feature, see [pgtle.register\\_feature](#).

## Function prototype

```
pgtle.unregister_feature(proc regproc, feature pg_tle_features)
```

## Role

`pgtle_admin`

## Arguments

- `proc` – The name of a stored function to register with a `pg_tle` feature.
- `feature` – The name of the `pg_tle` feature to register with the function. For example, `passcheck` is a feature that can be registered for use by the trusted language extensions that you develop. For more information, see [Password-check hook \(passcheck\)](#).

## Output

None.

## Usage example

```
SELECT * FROM pgtle.unregister_feature('pw_hook', 'passcheck');
```

## pgtle.unregister\_feature\_if\_exists

The `unregister_feature` function provides a way to remove functions that were registered to use `pg_tle` features, such as hooks. For more information, see [Using PostgreSQL hooks with your TLE extensions](#). Returns `true` after successfully unregistering the feature. Returns `false` if the feature wasn't registered.

For information about registering `pg_tle` features for your TLE extensions, see [pgtle.register\\_feature](#).

## Function prototype

```
pgtle.unregister_feature_if_exists('proc regproc', 'feature pg_tle_features')
```

## Role

`pgtle_admin`

## Arguments

- `proc` – The name of the stored function that was registered to include a `pg_tle` feature.
- `feature` – The name of the `pg_tle` feature that was registered with the trusted language extension.

## Output

Returns `true` or `false`, as follows.

- `true` – The function has successfully unregistered the feature from extension.
- `false` – The function wasn't able to unregister the feature from the TLE extension.

## Usage example

```
SELECT * FROM pgtle.unregister_feature_if_exists('pw_hook', 'passcheck');
```

## Hooks reference for Trusted Language Extensions for PostgreSQL

Trusted Language Extensions for PostgreSQL supports PostgreSQL hooks. A *hook* is an internal callback mechanism available to developers for extending PostgreSQL's core functionality. By using hooks, developers can implement their own functions or procedures for use during various database operations, thereby modifying PostgreSQL's behavior in some way. For example, you can use a `passcheck` hook to customize how PostgreSQL handles the passwords supplied when creating or changing passwords for users (roles).

View the following documentation to learn about the `passcheck` hook available for your TLE extensions.

## Password-check hook (passcheck)

The `passcheck` hook is used to customize PostgreSQL behavior during the password-checking process for the following SQL commands and `psql` metacommand.

- `CREATE ROLE username . . . PASSWORD` – For more information, see [CREATE ROLE](#) in the PostgreSQL documentation.
- `ALTER ROLE username . . . PASSWORD` – For more information, see [ALTER ROLE](#) in the PostgreSQL documentation.
- `\password username` – This interactive `psql` metacommand securely changes the password for the specified user by hashing the password before transparently using the `ALTER ROLE . . . PASSWORD` syntax. The metacommand is a secure wrapper for the `ALTER ROLE . . . PASSWORD` command, thus the hook applies to the behavior of the `psql` metacommand.

For an example, see [Password-check hook code listing](#).

### Contents

- [Function prototype](#)
- [Arguments](#)
- [Configuration](#)
- [Usage notes](#)

### Function prototype

```
passcheck_hook(username text, password text, password_type pgtle.password_types,  
valid_until timestamptz, valid_null boolean)
```

### Arguments

A `passcheck` hook function takes the following arguments.

- `username` – The name (as text) of the role (`username`) that's setting a password.
- `password` – The plaintext or hashed password. The password entered should match the type specified in `password_type`.
- `password_type` – Specify the `pgtle.password_type` format of the password. This format can be one of the following options.

- `PASSWORD_TYPE_PLAINTEXT` – A plaintext password.
- `PASSWORD_TYPE_MD5` – A password that's been hashed using MD5 (message digest 5) algorithm.
- `PASSWORD_TYPE_SCRAM_SHA_256` – A password that's been hashed using SCRAM-SHA-256 algorithm.
- `valid_until` – Specify the time when the password becomes invalid. This argument is optional. If you use this argument, specify the time as a `timestampz` value.
- `valid_null` – If this Boolean is set to `true`, the `valid_until` option is set to `NULL`.

## Configuration

The function `pgtle.enable_password_check` controls whether the passcheck hook is active. The passcheck hook has three possible settings.

- `off` – Turns off the passcheck password-check hook. This is the default value.
- `on` – Turns on the passcode password-check hook so that passwords are checked against the table.
- `require` – Requires a password check hook to be defined.

## Usage notes

To turn the passcheck hook on or off, you need to modify the custom DB parameter group for your RDS for PostgreSQL DB instance.

For Linux, macOS, or Unix:

```
aws rds modify-db-parameter-group \  
  --region aws-region \  
  --db-parameter-group-name your-custom-parameter-group \  
  --parameters  
  "ParameterName=pgtle.enable_password_check,ParameterValue=on,ApplyMethod=immediate"
```

For Windows:

```
aws rds modify-db-parameter-group ^  
  --region aws-region ^  
  --db-parameter-group-name your-custom-parameter-group ^
```

**--parameters**

```
"ParameterName=pgtle.enable_password_check,ParameterValue=on,ApplyMethod=immediate"
```

# Code examples for Amazon RDS using AWS SDKs

The following code examples show how to use Amazon RDS with an AWS software development kit (SDK).

*Basics* are code examples that show you how to perform the essential operations within a service.

*Actions* are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios.

*Scenarios* are code examples that show you how to accomplish specific tasks by calling multiple functions within a service or combined with other AWS services.

For a complete list of AWS SDK developer guides and code examples, see [Using this service with an AWS SDK](#). This topic also includes information about getting started and details about previous SDK versions.

## Get started

### Hello Amazon RDS

The following code examples show how to get started using Amazon RDS.

.NET

#### AWS SDK for .NET

##### Note

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](#).

```
using System;
using System.Threading.Tasks;
using Amazon.RDS;
using Amazon.RDS.Model;

namespace RDSActions;

public static class HelloRds
```

```
{
    static async Task Main(string[] args)
    {
        var rdsClient = new AmazonRDSClient();

        Console.WriteLine($"Hello Amazon RDS! Following are some of your DB
instances:");
        Console.WriteLine();

        // You can use await and any of the async methods to get a response.
        // Let's get the first twenty DB instances.
        var response = await rdsClient.DescribeDBInstancesAsync(
            new DescribeDBInstancesRequest()
            {
                MaxRecords = 20 // Must be between 20 and 100.
            });

        foreach (var instance in response.DBInstances)
        {
            Console.WriteLine($"\\tDB name: {instance.DBName}");
            Console.WriteLine($"\\tArn: {instance.DBInstanceArn}");
            Console.WriteLine($"\\tIdentifier: {instance.DBInstanceIdentifier}");
            Console.WriteLine();
        }
    }
}
```

- For API details, see [DescribeDBInstances](#) in *AWS SDK for .NET API Reference*.

## C++

### SDK for C++

#### Note

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](#).

Code for the CMakeLists.txt CMake file.

```
# Set the minimum required version of CMake for this project.
cmake_minimum_required(VERSION 3.13)

# Set the AWS service components used by this project.
set(SERVICE_COMPONENTS rds)

# Set this project's name.
project("hello_rds")

# Set the C++ standard to use to build this target.
# At least C++ 11 is required for the AWS SDK for C++.
set(CMAKE_CXX_STANDARD 11)

# Use the MSVC variable to determine if this is a Windows build.
set(WINDOWS_BUILD ${MSVC})

if (WINDOWS_BUILD) # Set the location where CMake can find the installed
  libraries for the AWS SDK.
  string(REPLACE ";" "/aws-cpp-sdk-all;" SYSTEM_MODULE_PATH
    "${CMAKE_SYSTEM_PREFIX_PATH}/aws-cpp-sdk-all")
  list(APPEND CMAKE_PREFIX_PATH ${SYSTEM_MODULE_PATH})
endif ()

# Find the AWS SDK for C++ package.
find_package(AWSSDK REQUIRED COMPONENTS ${SERVICE_COMPONENTS})

if (WINDOWS_BUILD AND AWSSDK_INSTALL_AS_SHARED_LIBS)
  # Copy relevant AWS SDK for C++ libraries into the current binary directory
  for running and debugging.

  # set(BIN_SUB_DIR "/Debug") # If you are building from the command line, you
  may need to uncomment this
  # and set the proper subdirectory to the
  executables' location.

  AWSSDK_CPY_DYN_LIBS(SERVICE_COMPONENTS ""
    ${CMAKE_CURRENT_BINARY_DIR}${BIN_SUB_DIR})
endif ()

add_executable(${PROJECT_NAME}
  hello_rds.cpp)

target_link_libraries(${PROJECT_NAME}
```

```
#{AWSSDK_LINK_LIBRARIES})
```

### Code for the hello\_rds.cpp source file.

```
#include <aws/core/Aws.h>
#include <aws/rds/RDSClient.h>
#include <aws/rds/model/DescribeDBInstancesRequest.h>
#include <iostream>

/*
 * A "Hello Rds" starter application which initializes an Amazon Relational
 * Database Service (Amazon RDS) client and
 * describes the Amazon RDS instances.
 *
 * main function
 *
 * Usage: 'hello_rds'
 *
 */

int main(int argc, char **argv) {
    Aws::SDKOptions options;
    // Optionally change the log level for debugging.
    // options.loggingOptions.logLevel = Utils::Logging::LogLevel::Debug;
    Aws::InitAPI(options); // Should only be called once.
    int result = 0;
    {
        Aws::Client::ClientConfiguration clientConfig;
        // Optional: Set to the AWS Region (overrides config file).
        // clientConfig.region = "us-east-1";

        Aws::RDS::RDSClient rdsClient(clientConfig);
        Aws::String marker;
        std::vector<Aws::String> instanceDBIDs;

        do {
            Aws::RDS::Model::DescribeDBInstancesRequest request;

            if (!marker.empty()) {
                request.SetMarker(marker);
            }
        }
```

```
Aws::RDS::Model::DescribeDBInstancesOutcome outcome =
    rdsClient.DescribeDBInstances(request);

if (outcome.IsSuccess()) {
    for (auto &instance: outcome.GetResult().GetDBInstances()) {
        instanceDBIDs.push_back(instance.GetDBInstanceIdentifier());
    }
    marker = outcome.GetResult().GetMarker();
} else {
    result = 1;
    std::cerr << "Error with RDS::DescribeDBInstances. "
        << outcome.GetError().GetMessage()
        << std::endl;

    break;
}
} while (!marker.empty());

std::cout << instanceDBIDs.size() << " RDS instances found." <<
std::endl;
for (auto &instanceDBID: instanceDBIDs) {
    std::cout << " Instance: " << instanceDBID << std::endl;
}
}

Aws::ShutdownAPI(options); // Should only be called once.
return result;
}
```

Go

## SDK for Go V2

### Note

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](#).

```
package main

import (
    "context"
    "fmt"

    "github.com/aws/aws-sdk-go-v2/aws"
    "github.com/aws/aws-sdk-go-v2/config"
    "github.com/aws/aws-sdk-go-v2/service/rds"
)

// main uses the AWS SDK for Go V2 to create an Amazon Relational Database
// Service (Amazon RDS)
// client and list up to 20 DB instances in your account.
// This example uses the default settings specified in your shared credentials
// and config files.
func main() {
    sdkConfig, err := config.LoadDefaultConfig(context.TODO())
    if err != nil {
        fmt.Println("Couldn't load default configuration. Have you set up your AWS
account?")
        fmt.Println(err)
        return
    }
    rdsClient := rds.NewFromConfig(sdkConfig)
    const maxInstances = 20
    fmt.Printf("Let's list up to %v DB instances.\n", maxInstances)
    output, err := rdsClient.DescribeDBInstances(context.TODO(),
        &rds.DescribeDBInstancesInput{MaxRecords: aws.Int32(maxInstances)})
    if err != nil {
        fmt.Printf("Couldn't list DB instances: %v\n", err)
        return
    }
    if len(output.DBInstances) == 0 {
        fmt.Println("No DB instances found.")
    } else {
        for _, instance := range output.DBInstances {
            fmt.Printf("DB instance %v has database %v.\n",
                *instance.DBInstanceIdentifier,
                *instance.DBName)
        }
    }
}
```

- For API details, see [DescribeDBInstances](#) in *AWS SDK for Go API Reference*.

## Java

### SDK for Java 2.x

#### Note

For a complete list of AWS SDK developer guides and code examples, see [Using this service with an AWS SDK](#). This topic also includes information about getting started and details about previous SDK versions.

## Learn the basics of Amazon RDS with an AWS SDK

The following code examples show how to:

- Create a custom DB parameter group and set parameter values.
- Create a DB instance that's configured to use the parameter group. The DB instance also contains a database.

- Take a snapshot of the instance.
- Delete the instance and parameter group.

## .NET

### AWS SDK for .NET

#### Note

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](#).

Run an interactive scenario at a command prompt.

```
/// <summary>
/// Scenario for RDS DB instance example.
/// </summary>
public class RDSInstanceScenario
{
    /*
    Before running this .NET code example, set up your development environment,
    including your credentials.

    This .NET example performs the following tasks:
    1. Returns a list of the available DB engine families using the
    DescribeDBEngineVersionsAsync method.
    2. Selects an engine family and creates a custom DB parameter group using
    the CreateDBParameterGroupAsync method.
    3. Gets the parameter groups using the DescribeDBParameterGroupsAsync
    method.
    4. Gets parameters in the group using the DescribeDBParameters method.
    5. Parses and displays parameters in the group.
    6. Modifies both the auto_increment_offset and auto_increment_increment
    parameters
    using the ModifyDBParameterGroupAsync method.
    7. Gets and displays the updated parameters using the DescribeDBParameters
    method with a source of "user".
    8. Gets a list of allowed engine versions using the
    DescribeDBEngineVersionsAsync method.
```

9. Displays and selects from a list of micro instance classes available for the selected engine and version.
  10. Creates an RDS DB instance that contains a MySQL database and uses the parameter group using the `CreateDBInstanceAsync` method.
  11. Waits for DB instance to be ready using the `DescribeDBInstancesAsync` method.
  12. Prints out the connection endpoint string for the new DB instance.
  13. Creates a snapshot of the DB instance using the `CreateDBSnapshotAsync` method.
  14. Waits for DB snapshot to be ready using the `DescribeDBSnapshots` method.
  15. Deletes the DB instance using the `DeleteDBInstanceAsync` method.
  16. Waits for DB instance to be deleted using the `DescribeDbInstances` method.
  17. Deletes the parameter group using the `DeleteDBParameterGroupAsync`.

Go

## SDK for Go V2

### Note

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](#).

Run an interactive scenario at a command prompt.

```
// GetStartedInstances is an interactive example that shows you how to use the
// AWS SDK for Go
// with Amazon Relation Database Service (Amazon RDS) to do the following:
//
// 1. Create a custom DB parameter group and set parameter values.
// 2. Create a DB instance that is configured to use the parameter group. The DB
// instance
// also contains a database.
```

```
// 3. Take a snapshot of the DB instance.
// 4. Delete the DB instance and parameter group.
type GetStartedInstances struct {
    sdkConfig  aws.Config
    instances  actions.DbInstances
    questioner demotools.IQuestioner
    helper     IScenarioHelper
    isTestRun  bool
}

// NewGetStartedInstances constructs a GetStartedInstances instance from a
// configuration.
// It uses the specified config to get an Amazon RDS
// client and create wrappers for the actions used in the scenario.

/**
 * Before running this Java (v2) code example, set up your development
 * environment, including your credentials.
 *
 * For more information, see the following documentation topic:
 *
 * https://docs.aws.amazon.com/sdk-for-java/latest/developer-guide/get-started.html
 *
 * This example requires an AWS Secrets Manager secret that contains the
 * database credentials. If you do not create a
 * secret, this example will not work. For details, see:
 *
 * https://docs.aws.amazon.com/secretsmanager/latest/userguide/integrating\_how-services-use-secrets\_RS.html
 *
 * This Java example performs these tasks:
 *
 * 1. Returns a list of the available DB engines.
 * 2. Selects an engine family and create a custom DB parameter group.
 * 3. Gets the parameter groups.
 * 4. Gets parameters in the group.
```

```

* 5. Modifies the auto_increment_offset parameter.
* 6. Gets and displays the updated parameters.
* 7. Gets a list of allowed engine versions.
* 8. Gets a list of micro instance classes available for the selected engine.
* 9. Creates an RDS database instance that contains a MySQL database and uses
* the parameter group.
* 10. Waits for the DB instance to be ready and prints out the connection
* endpoint value.
* 11. Creates a snapshot of the DB instance.
* 12. Waits for an RDS DB snapshot to be ready.
* 13. Deletes the RDS DB instance.
* 14. Deletes the parameter group.

## Kotlin

### SDK for Kotlin

#### Note

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](#).

```
/**
```

```
Before running this code example, set up your development environment, including your credentials.
```

```
For more information, see the following documentation topic:
```

<https://docs.aws.amazon.com/sdk-for-kotlin/latest/developer-guide/setup.html>

This example requires an AWS Secrets Manager secret that contains the database credentials. If you do not create a secret, this example will not work. For more details, see:

[https://docs.aws.amazon.com/secretsmanager/latest/userguide/integrating\\_how-services-use-secrets\\_RS.html](https://docs.aws.amazon.com/secretsmanager/latest/userguide/integrating_how-services-use-secrets_RS.html)

This example performs the following tasks:

1. Returns a list of the available DB engines by invoking the DescribeDbEngineVersions method.
2. Selects an engine family and create a custom DB parameter group by invoking the createDBParameterGroup method.
3. Gets the parameter groups by invoking the DescribeDbParameterGroups method.
4. Gets parameters in the group by invoking the DescribeDbParameters method.
5. Modifies both the auto\_increment\_offset and auto\_increment\_increment parameters by invoking the modifyDbParameterGroup method.
6. Gets and displays the updated parameters.
7. Gets a list of allowed engine versions by invoking the describeDbEngineVersions method.
8. Gets a list of micro instance classes available for the selected engine.
9. Creates an Amazon Relational Database Service (Amazon RDS) database instance that contains a MySQL database and uses the parameter group.
10. Waits for DB instance to be ready and prints out the connection endpoint value.
11. Creates a snapshot of the DB instance.
12. Waits for the DB snapshot to be ready.
13. Deletes the DB instance.
14. Deletes the parameter group.

## Actions for Amazon RDS using AWS SDKs

The following code examples demonstrate how to perform individual Amazon RDS actions with AWS SDKs. Each example includes a link to GitHub, where you can find instructions for setting up and running the code.

These excerpts call the Amazon RDS API and are code excerpts from larger programs that must be run in context. You can see actions in context in [Scenarios for Amazon RDS using AWS SDKs](#).

The following examples include only the most commonly used actions. For a complete list, see the [Amazon Relational Database Service API Reference](#).

### Examples

- [Use CreateDBInstance with an AWS SDK or CLI](#)
- [Use CreateDBParameterGroup with an AWS SDK or CLI](#)
- [Use CreateDBSnapshot with an AWS SDK or CLI](#)
- [Use DeleteDBInstance with an AWS SDK or CLI](#)
- [Use DeleteDBParameterGroup with an AWS SDK or CLI](#)
- [Use DescribeAccountAttributes with an AWS SDK or CLI](#)
- [Use DescribeDBEngineVersions with an AWS SDK or CLI](#)
- [Use DescribeDBInstances with an AWS SDK or CLI](#)
- [Use DescribeDBParameterGroups with an AWS SDK or CLI](#)
- [Use DescribeDBParameters with an AWS SDK or CLI](#)
- [Use DescribeDBSnapshots with an AWS SDK or CLI](#)
- [Use DescribeOrderableDBInstanceOptions with an AWS SDK or CLI](#)
- [Use GenerateRDSEAuthToken with an AWS SDK or CLI](#)
- [Use ModifyDBInstance with an AWS SDK or CLI](#)
- [Use ModifyDBParameterGroup with an AWS SDK or CLI](#)
- [Use RebootDBInstance with an AWS SDK or CLI](#)

## Use CreateDBInstance with an AWS SDK or CLI

The following code examples show how to use CreateDBInstance.

Action examples are code excerpts from larger programs and must be run in context. You can see this action in context in the following code example:

## CLI

### AWS CLI

#### To create a DB instance

The following `create-db-instance` example uses the required options to launch a new DB instance.

```
aws rds create-db-instance \  
  --db-instance-identifier test-mysql-instance \  
  --db-instance-class db.t3.micro \  
  --engine mysql \  
  --master-username admin \  
  --master-user-password secret99 \  
  --allocated-storage 20
```

**Output:**

```
{
  "DBInstance": {
    "DBInstanceIdentifier": "test-mysql-instance",
    "DBInstanceClass": "db.t3.micro",
    "Engine": "mysql",

## CLI

### AWS CLI

#### To create a DB parameter group

The following create-db-parameter-group example creates a DB parameter group.

```
aws rds create-db-parameter-group \
  --db-parameter-group-name mydbparametergroup \
  --db-parameter-group-family MySQL5.6 \
  --description "My new parameter group"
```

Output:

```
{
  "DBParameterGroup": {
    "DBParameterGroupName": "mydbparametergroup",
    "DBParameterGroupFamily": "mysql5.6",
    "Description": "My new parameter group",
    "DBParameterGroupArn": "arn:aws:rds:us-
east-1:123456789012:pg:mydbparametergroup"
  }
}
```

```
}
```

For more information, see [Creating a DB Parameter Group](#) in the *Amazon RDS User Guide*.

- For API details, see [CreateDBParameterGroup](#) in *AWS CLI Command Reference*.

## CLI

### AWS CLI

#### To delete a DB instance

The following `delete-db-instance` example deletes the specified DB instance after creating a final DB snapshot named `test-instance-final-snap`.

```
aws rds delete-db-instance \
  --db-instance-identifier test-instance \
  --final-db-snapshot-identifier test-instance-final-snap
```

Output:

```
{
  "DBInstance": {
    "DBInstanceIdentifier": "test-instance",
    "DBInstanceStatus": "deleting",
    ...some output truncated...
  }
}
```

- For API details, see [DeleteDBInstance](#) in *AWS CLI Command Reference*.

## Use DescribeAccountAttributes with an AWS SDK or CLI

The following code examples show how to use DescribeAccountAttributes.

### CLI

#### AWS CLI

##### To describe account attributes

The following describe-account-attributes example retrieves the attributes for the current AWS account.

```
aws rds describe-account-attributes
```

Output:

```
{
  "AccountQuotas": [
    {
      "Max": 40,
```

```
    "Used": 4,
    "AccountQuotaName": "DBInstances"
  },
  {
    "Max": 40,
    "Used": 0,
    "AccountQuotaName": "ReservedDBInstances"
  },
  {
    "Max": 100000,
    "Used": 40,
    "AccountQuotaName": "AllocatedStorage"
  },
  {
    "Max": 25,
    "Used": 0,
    "AccountQuotaName": "DBSecurityGroups"
  },
  {
    "Max": 20,
    "Used": 0,
    "AccountQuotaName": "AuthorizationsPerDBSecurityGroup"
  },
  {
    "Max": 50,
    "Used": 1,
    "AccountQuotaName": "DBParameterGroups"
  },
  {
    "Max": 100,
    "Used": 3,
    "AccountQuotaName": "ManualSnapshots"
  },
  {
    "Max": 20,
    "Used": 0,
    "AccountQuotaName": "EventSubscriptions"
  },
  {
    "Max": 50,
    "Used": 1,
    "AccountQuotaName": "DBSubnetGroups"
  },
  {
```

```

        "Max": 20,
        "Used": 1,
        "AccountQuotaName": "OptionGroups"
    },
    {
        "Max": 20,
        "Used": 6,
        "AccountQuotaName": "SubnetsPerDBSubnetGroup"
    },
    {
        "Max": 5,
        "Used": 0,
        "AccountQuotaName": "ReadReplicasPerMaster"
    },
    {
        "Max": 40,
        "Used": 1,
        "AccountQuotaName": "DBClusters"
    },
    {
        "Max": 50,
        "Used": 0,
        "AccountQuotaName": "DBClusterParameterGroups"
    },

## CLI

### AWS CLI

#### To describe the DB engine versions for the MySQL DB engine

The following describe-db-engine-versions example displays details about each of the DB engine versions for the specified DB engine.

```
aws rds describe-db-engine-versions \
```

```
--engine mysql
```

### Output:

```
{
  "DBEngineVersions": [
    {
      "Engine": "mysql",
      "EngineVersion": "5.5.46",
      "DBParameterGroupFamily": "mysql5.5",
      "DBEngineDescription": "MySQL Community Edition",
      "DBEngineVersionDescription": "MySQL 5.5.46",
      "ValidUpgradeTarget": [
        {
          "Engine": "mysql",
          "EngineVersion": "5.5.53",
          "Description": "MySQL 5.5.53",
          "AutoUpgrade": false,
          "IsMajorVersionUpgrade": false
        },
        {
          "Engine": "mysql",
          "EngineVersion": "5.5.54",
          "Description": "MySQL 5.5.54",
          "AutoUpgrade": false,
          "IsMajorVersionUpgrade": false
        },
        {
          "Engine": "mysql",
          "EngineVersion": "5.5.57",
          "Description": "MySQL 5.5.57",
          "AutoUpgrade": false,
          "IsMajorVersionUpgrade": false
        },
        ...some output truncated...
      ]
    }
  ]
}
```

        "DbiResourceId": "db-AKIAIOSFODNN7EXAMPLE"
    }
]
}

```

For more information, see [Creating a DB Snapshot](#) in the *Amazon RDS User Guide*.

### Example 2: To find the number of manual snapshots taken

The following `describe-db-snapshots` example uses the `length` operator in the `--query` option to return the number of manual snapshots that have been taken in a particular AWS Region.

```

aws rds describe-db-snapshots \
  --snapshot-type manual \
  --query "length(*[].[DBSnapshots:SnapshotType])" \
  --region eu-central-1

```

Output:

```
35
```

For more information, see [Creating a DB Snapshot](#) in the *Amazon RDS User Guide*.

- For API details, see [DescribeDBSnapshots](#) in *AWS CLI Command Reference*.

## Use GenerateRDSToken with an AWS SDK or CLI

The following code example shows how to use GenerateRDSToken.

Java

### SDK for Java 2.x

#### Note

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](#).

Use the [RdsUtilities](#) class to generate an authentication token.

```
public class GenerateRDSToken {
    public static void main(String[] args) {
        final String usage = ""

            Usage:
                <dbInstanceIdentifier> <masterUsername>

            Where:
                dbInstanceIdentifier - The database instance identifier.\s
                masterUsername - The master user name.\s
            """;
```

```
    if (args.length != 2) {
        System.out.println(usage);
        System.exit(1);
    }

    String dbInstanceIdentifier = args[0];
    String masterUsername = args[1];
    Region region = Region.US_WEST_2;
    RdsClient rdsClient = RdsClient.builder()
        .region(region)
        .build();

    String token = getAuthToken(rdsClient, dbInstanceIdentifier,
masterUsername);
    System.out.println("The token response is " + token);
}

public static String getAuthToken(RdsClient rdsClient, String
dbInstanceIdentifier, String masterUsername) {

    RdsUtilities utilities = rdsClient.utilities();
    try {
        GenerateAuthenticationTokenRequest tokenRequest =
GenerateAuthenticationTokenRequest.builder()
            .credentialsProvider(ProfileCredentialsProvider.create())
            .username(masterUsername)
            .port(3306)
            .hostname(dbInstanceIdentifier)
            .build();

        return utilities.generateAuthenticationToken(tokenRequest);

    } catch (RdsException e) {
        System.out.println(e.getLocalizedMessage());
        System.exit(1);
    }
    return "";
}
}
```

- For API details, see [GenerateRDSAuthToken](#) in *AWS SDK for Java 2.x API Reference*.

For a complete list of AWS SDK developer guides and code examples, see [Using this service with an AWS SDK](#). This topic also includes information about getting started and details about previous SDK versions.

## Use ModifyDBInstance with an AWS SDK or CLI

The following code examples show how to use ModifyDBInstance.

CLI

### AWS CLI

#### Example 1: To modify a DB instance

The following `modify-db-instance` example associates an option group and a parameter group with a compatible Microsoft SQL Server DB instance. The `--apply-immediately` parameter causes the option and parameter groups to be associated immediately, instead of waiting until the next maintenance window.

```
aws rds modify-db-instance \  
  --db-instance-identifier database-2 \  
  --option-group-name test-se-2017 \  
  --db-parameter-group-name test-sqlserver-se-2017 \  
  --apply-immediately
```

Output:

```
{  
  "DBInstance": {  
    "DBInstanceIdentifier": "database-2",  
    "DBInstanceClass": "db.r4.large",  
    "Engine": "sqlserver-se",  
    "DBInstanceStatus": "available",  
  
    ...output omitted...  
  
    "DBParameterGroups": [  
      {  
        "DBParameterGroupName": "test-sqlserver-se-2017",  
        "ParameterApplyStatus": "applying"  
      }  
    ]  
  }  
}
```

```

    ],
    "AvailabilityZone": "us-west-2d",

    ...output omitted...

    "MultiAZ": true,
    "EngineVersion": "14.00.3281.6.v1",
    "AutoMinorVersionUpgrade": false,
    "ReadReplicaDBInstanceIdentifiers": [],
    "LicenseModel": "license-included",
    "OptionGroupMemberships": [
      {
        "OptionGroupName": "test-se-2017",
        "Status": "pending-apply"
      }
    ],
    "CharacterSetName": "SQL_Latin1_General_CP1_CI_AS",
    "SecondaryAvailabilityZone": "us-west-2c",
    "PubliclyAccessible": true,
    "StorageType": "gp2",

    ...output omitted...

    "DeletionProtection": false,
    "AssociatedRoles": [],
    "MaxAllocatedStorage": 1000
  }
}

```

For more information, see [Modifying an Amazon RDS DB Instance](#) in the *Amazon RDS User Guide*.

### Example 2: To associate VPC security group with a DB instance

The following `modify-db-instance` example associates a specific VPC security group and removes DB security groups from a DB instance:

```

aws rds modify-db-instance \
  --db-instance-identifier dbName \
  --vpc-security-group-ids sg-ID

```

Output:

```
{
  "DBInstance": {
    "DBInstanceIdentifier": "dbName",
    "DBInstanceClass": "db.t3.micro",
    "Engine": "mysql",
    "DBInstanceStatus": "available",
    "MasterUsername": "admin",
    "Endpoint": {
      "Address": "dbName.abcdefghijkl.us-west-2.rds.amazonaws.com",
      "Port": 3306,
      "HostedZoneId": "ABCDEFGHIJK1234"
    },
    "AllocatedStorage": 20,
    "InstanceCreateTime": "2024-02-15T00:37:58.793000+00:00",
    "PreferredBackupWindow": "11:57-12:27",
    "BackupRetentionPeriod": 7,
    "DBSecurityGroups": [],
    "VpcSecurityGroups": [
      {
        "VpcSecurityGroupId": "sg-ID",
        "Status": "active"
      }
    ],
    ... output omitted ...
    "MultiAZ": false,
    "EngineVersion": "8.0.35",
    "AutoMinorVersionUpgrade": true,
    "ReadReplicaDBInstanceIdentifiers": [],
    "LicenseModel": "general-public-license",

    ... output omitted ...
  }
}
```

For more information, see [Controlling access with security groups](#) in the *Amazon RDS User Guide*.

- For API details, see [ModifyDBInstance](#) in *AWS CLI Command Reference*.

```
Aws::Client::ClientConfiguration clientConfig;
// Optional: Set to the AWS Region (overrides config file).
// clientConfig.region = "us-east-1";

Aws::RDS::RDSClient client(clientConfig);

Aws::RDS::Model::ModifyDBParameterGroupRequest request;
request.SetDBParameterGroupName(PARAMETER_GROUP_NAME);
request.SetParameters(updateParameters);

Aws::RDS::Model::ModifyDBParameterGroupOutcome outcome =
    client.ModifyDBParameterGroup(request);

if (outcome.IsSuccess()) {
    std::cout << "The DB parameter group was successfully modified."
              << std::endl;
}
else {
    std::cerr << "Error with RDS::ModifyDBParameterGroup. "
              << outcome.GetError().GetMessage()
              << std::endl;
}
```

- For API details, see [ModifyDBParameterGroup](#) in *AWS SDK for C++ API Reference*.

## CLI

## AWS CLI

**To modify a DB parameter group**

The following `modify-db-parameter-group` example changes the value of the `clr` enabled parameter in a DB parameter group. The `--apply-immediately` parameter causes the DB parameter group to be modified immediately, instead of waiting until the next maintenance window.

```
aws rds modify-db-parameter-group \  
  --db-parameter-group-name test-sqlserver-se-2017 \  
  --parameters "ParameterName='clr  
enabled',ParameterValue=1,ApplyMethod=immediate"
```

Output:

```
{  
  "DBParameterGroupName": "test-sqlserver-se-2017"  
}
```

For more information, see [Modifying Parameters in a DB Parameter Group](#) in the *Amazon RDS User Guide*.

- For API details, see [ModifyDBParameterGroup](#) in *AWS CLI Command Reference*.

## Scenarios for Amazon RDS using AWS SDKs

The following code examples show you how to implement common scenarios in Amazon RDS with AWS SDKs. These scenarios show you how to accomplish specific tasks by calling multiple functions

within Amazon RDS or combined with other AWS services. Each scenario includes a link to the complete source code, where you can find instructions on how to set up and run the code.

Scenarios target an intermediate level of experience to help you understand service actions in context.

## Examples

- [Create an Aurora Serverless work item tracker](#)

## Create an Aurora Serverless work item tracker

The following code examples show how to create a web application that tracks work items in an Amazon Aurora Serverless database and uses Amazon Simple Email Service (Amazon SES) to send reports.

.NET

### AWS SDK for .NET

Shows how to use the AWS SDK for .NET to create a web application that tracks work items in an Amazon Aurora database and emails reports by using Amazon Simple Email Service (Amazon SES). This example uses a front end built with React.js to interact with a RESTful .NET backend.

- Integrate a React web application with AWS services.
- List, add, update, and delete items in an Aurora table.
- Send an email report of filtered work items using Amazon SES.
- Deploy and manage example resources with the included AWS CloudFormation script.

For complete source code and instructions on how to set up and run, see the full example on [GitHub](#).

### Services used in this example

- Aurora
- Amazon RDS
- Amazon RDS Data Service
- Amazon SES

## C++

### SDK for C++

Shows how to create a web application that tracks and reports on work items stored in an Amazon Aurora Serverless database.

For complete source code and instructions on how to set up a C++ REST API that queries Amazon Aurora Serverless data and for use by a React application, see the full example on [GitHub](#).

#### Services used in this example

- Aurora
- Amazon RDS
- Amazon RDS Data Service
- Amazon SES

## Java

### SDK for Java 2.x

Shows how to create a web application that tracks and reports on work items stored in an Amazon RDS database.

For complete source code and instructions on how to set up a Spring REST API that queries Amazon Aurora Serverless data and for use by a React application, see the full example on [GitHub](#).

For complete source code and instructions on how to set up and run an example that uses the JDBC API, see the full example on [GitHub](#).

#### Services used in this example

- Aurora
- Amazon RDS
- Amazon RDS Data Service
- Amazon SES

## JavaScript

### SDK for JavaScript (v3)

Shows how to use the AWS SDK for JavaScript (v3) to create a web application that tracks work items in an Amazon Aurora database and emails reports by using Amazon Simple Email Service (Amazon SES). This example uses a front end built with React.js to interact with an Express Node.js backend.

- Integrate a React.js web application with AWS services.
- List, add, and update items in an Aurora table.
- Send an email report of filtered work items by using Amazon SES.
- Deploy and manage example resources with the included AWS CloudFormation script.

For complete source code and instructions on how to set up and run, see the full example on [GitHub](#).

#### Services used in this example

- Aurora
- Amazon RDS
- Amazon RDS Data Service
- Amazon SES

## Kotlin

### SDK for Kotlin

Shows how to create a web application that tracks and reports on work items stored in an Amazon RDS database.

For complete source code and instructions on how to set up a Spring REST API that queries Amazon Aurora Serverless data and for use by a React application, see the full example on [GitHub](#).

#### Services used in this example

- Aurora
- Amazon RDS
- Amazon RDS Data Service

- Amazon SES

## PHP

### SDK for PHP

Shows how to use the AWS SDK for PHP to create a web application that tracks work items in an Amazon RDS database and emails reports by using Amazon Simple Email Service (Amazon SES). This example uses a front end built with React.js to interact with a RESTful PHP backend.

- Integrate a React.js web application with AWS services.
- List, add, update, and delete items in an Amazon RDS table.
- Send an email report of filtered work items using Amazon SES.
- Deploy and manage example resources with the included AWS CloudFormation script.

For complete source code and instructions on how to set up and run, see the full example on [GitHub](#).

### Services used in this example

- Aurora
- Amazon RDS
- Amazon RDS Data Service
- Amazon SES

## Python

### SDK for Python (Boto3)

Shows how to use the AWS SDK for Python (Boto3) to create a REST service that tracks work items in an Amazon Aurora Serverless database and emails reports by using Amazon Simple Email Service (Amazon SES). This example uses the Flask web framework to handle HTTP routing and integrates with a React webpage to present a fully functional web application.

- Build a Flask REST service that integrates with AWS services.
- Read, write, and update work items that are stored in an Aurora Serverless database.
- Create an AWS Secrets Manager secret that contains database credentials and use it to authenticate calls to the database.

- Use Amazon SES to send email reports of work items.

For complete source code and instructions on how to set up and run, see the full example on [GitHub](#).

### Services used in this example

- Aurora
- Amazon RDS
- Amazon RDS Data Service
- Amazon SES

For a complete list of AWS SDK developer guides and code examples, see [Using this service with an AWS SDK](#). This topic also includes information about getting started and details about previous SDK versions.

## Serverless examples for Amazon RDS using AWS SDKs

The following code examples show how to use Amazon RDS with AWS SDKs.

### Examples

- [Connecting to an Amazon RDS database in a Lambda function](#)

## Connecting to an Amazon RDS database in a Lambda function

The following code examples show how to implement a Lambda function that connects to an RDS database. The function makes a simple database request and returns the result.

Go

### SDK for Go V2

  // Define connection configuration
  let connectionConfig = {
    host: process.env.ProxyHostName,
    user: process.env.DBUserName,
    password: token,
    database: process.env.DBName,
    ssl: 'Amazon RDS'
  }
  // Create the connection to the DB
  const conn = await mysql.createConnection(connectionConfig);
  // Obtain the result of the query
  const [res,] = await conn.execute('select ?+? as sum', [3, 2]);
  return res;
}

export const handler = async (event) => {
  // Execute database flow
  const result = await dbOps();
  // Return result
  return {
    statusCode: 200,
    body: JSON.stringify("The selected sum is: " + result[0].sum)
  }
};
```

## Connecting to an Amazon RDS database in a Lambda function using TypeScript.

```
import { Signer } from "@aws-sdk/rds-signer";
import mysql from 'mysql2/promise';

// RDS settings
// Using '!' (non-null assertion operator) to tell the TypeScript compiler that
// the DB settings are not null or undefined,
const proxy_host_name = process.env.PROXY_HOST_NAME!
const port = parseInt(process.env.PORT!)
const db_name = process.env.DB_NAME!
const db_user_name = process.env.DB_USER_NAME!
const aws_region = process.env.AWS_REGION!

async function createAuthToken(): Promise<string> {

    // Create RDS Signer object
    const signer = new Signer({
        hostname: proxy_host_name,
        port: port,
        region: aws_region,
        username: db_user_name
    });

    // Request authorization token from RDS, specifying the username
    const token = await signer.getAuthToken();
    return token;
}

async function dbOps(): Promise<mysql.QueryResult | undefined> {
    try {
        // Obtain auth token
        const token = await createAuthToken();
        const conn = await mysql.createConnection({
            host: proxy_host_name,
            user: db_user_name,
            password: token,
            database: db_name,
            ssl: 'Amazon RDS' // Ensure you have the CA bundle for SSL connection
        });
        const [rows, fields] = await conn.execute('SELECT ? + ? AS sum', [3, 2]);
        console.log('result:', rows);
    }
}
```

```
        return rows;
    }
    catch (err) {
        console.log(err);
    }
}

export const lambdaHandler = async (event: any): Promise<{ statusCode: number;
body: string }> => {
    // Execute database flow
    const result = await dbOps();

    // Return error is result is undefined
    if (result == undefined)
        return {
            statusCode: 500,
            body: JSON.stringify(`Error with connection to DB host`)
        }

    // Return result
    return {
        statusCode: 200,
        body: JSON.stringify(`The selected sum is: ${result[0].sum}`)
    };
};
```

    })))
}
```

For a complete list of AWS SDK developer guides and code examples, see [Using this service with an AWS SDK](#). This topic also includes information about getting started and details about previous SDK versions.

# Security in Amazon RDS

Cloud security at AWS is the highest priority. As an AWS customer, you benefit from a data center and network architecture that are built to meet the requirements of the most security-sensitive organizations.

Security is a shared responsibility between AWS and you. The [shared responsibility model](#) describes this as security *of* the cloud and security *in* the cloud:

- **Security of the cloud** – AWS is responsible for protecting the infrastructure that runs AWS services in the AWS Cloud. AWS also provides you with services that you can use securely. Third-party auditors regularly test and verify the effectiveness of our security as part of the [AWS compliance programs](#). To learn about the compliance programs that apply to Amazon RDS, see [AWS services in scope by compliance program](#).
- **Security in the cloud** – Your responsibility is determined by the AWS service that you use. You are also responsible for other factors including the sensitivity of your data, your organization's requirements, and applicable laws and regulations.

This documentation helps you understand how to apply the shared responsibility model when using Amazon RDS. The following topics show you how to configure Amazon RDS to meet your security and compliance objectives. You also learn how to use other AWS services that help you monitor and secure your Amazon RDS resources.

You can manage access to your Amazon RDS resources and your databases on a DB instance. The method you use to manage access depends on what type of task the user needs to perform with Amazon RDS:

- Run your DB instance in a virtual private cloud (VPC) based on the Amazon VPC service for the greatest possible network access control. For more information about creating a DB instance in a VPC, see [Amazon VPC and Amazon RDS](#).
- Use AWS Identity and Access Management (IAM) policies to assign permissions that determine who is allowed to manage Amazon RDS resources. For example, you can use IAM to determine who is allowed to create, describe, modify, and delete DB instances, tag resources, or modify security groups.

- Use security groups to control what IP addresses or Amazon EC2 instances can connect to your databases on a DB instance. When you first create a DB instance, its firewall prevents any database access except through rules specified by an associated security group.
- Use Secure Socket Layer (SSL) or Transport Layer Security (TLS) connections with DB instances running the Db2, MySQL, MariaDB, PostgreSQL, Oracle, or Microsoft SQL Server database engines. For more information on using SSL/TLS with a DB instance, see [Using SSL/TLS to encrypt a connection to a DB instance or cluster](#).
- Use Amazon RDS encryption to secure your DB instances and snapshots at rest. Amazon RDS encryption uses the industry standard AES-256 encryption algorithm to encrypt your data on the server that hosts your DB instance. For more information, see [Encrypting Amazon RDS resources](#).
- Use network encryption and transparent data encryption with Oracle DB instances; for more information, see [Oracle native network encryption](#) and [Oracle Transparent Data Encryption](#)
- Use the security features of your DB engine to control who can log in to the databases on a DB instance. These features work just as if the database was on your local network.

**Note**

You have to configure security only for your use cases. You don't have to configure security access for processes that Amazon RDS manages. These include creating backups, replicating data between a primary DB instance and a read replica, and other processes.

For more information on managing access to Amazon RDS resources and your databases on a DB instance, see the following topics.

**Topics**

## Database authentication with Amazon RDS

Amazon RDS supports several ways to authenticate database users.

Password, Kerberos, and IAM database authentication use different methods of authenticating to the database. Therefore, a specific user can log in to a database using only one authentication method.

For PostgreSQL, use only one of the following role settings for a user of a specific database:

- To use IAM database authentication, assign the `rds_iam` role to the user.
- To use Kerberos authentication, assign the `rds_ad` role to the user.
- To use password authentication, don't assign either the `rds_iam` or `rds_ad` roles to the user.

Don't assign both the `rds_iam` and `rds_ad` roles to a user of a PostgreSQL database either directly or indirectly by nested grant access. If the `rds_iam` role is added to the master user, IAM authentication takes precedence over password authentication so the master user has to log in as an IAM user.

### Important

We strongly recommend that you do not use the master user directly in your applications. Instead, adhere to the best practice of using a database user created with the minimal privileges required for your application.

## Topics

- [Password authentication](#)

- [IAM database authentication](#)
- [Kerberos authentication](#)

## Password authentication

With *password authentication*, your database performs all administration of user accounts. You create users with SQL statements such as `CREATE USER`, with the appropriate clause required by the DB engine for specifying passwords. For example, in MySQL the statement is `CREATE USER name IDENTIFIED BY password`, while in PostgreSQL, the statement is `CREATE USER name WITH PASSWORD password`.

With password authentication, your database controls and authenticates user accounts. If a DB engine has strong password management features, they can enhance security. Database authentication might be easier to administer using password authentication when you have small user communities. Because clear text passwords are generated in this case, integrating with AWS Secrets Manager can enhance security.

For information about using Secrets Manager with Amazon RDS, see [Creating a basic secret](#) and [Rotating secrets for supported Amazon RDS databases](#) in the *AWS Secrets Manager User Guide*. For information about programmatically retrieving your secrets in your custom applications, see [Retrieving the secret value](#) in the *AWS Secrets Manager User Guide*.

## IAM database authentication

You can authenticate to your DB instance using AWS Identity and Access Management (IAM) database authentication. With this authentication method, you don't need to use a password when you connect to a DB instance. Instead, you use an authentication token.

For more information about IAM database authentication, including information about availability for specific DB engines, see [IAM database authentication for MariaDB, MySQL, and PostgreSQL](#).

## Kerberos authentication

Amazon RDS supports external authentication of database users using Kerberos and Microsoft Active Directory. Kerberos is a network authentication protocol that uses tickets and symmetric-key cryptography to eliminate the need to transmit passwords over the network. Kerberos has been built into Active Directory and is designed to authenticate users to network resources, such as databases.

Amazon RDS support for Kerberos and Active Directory provides the benefits of single sign-on and centralized authentication of database users. You can keep your user credentials in Active Directory. Active Directory provides a centralized place for storing and managing credentials for multiple DB instances.

You can make it possible for your database users to authenticate against DB instances in two ways. They can use credentials stored either in AWS Directory Service for Microsoft Active Directory or in your on-premises Active Directory.

RDS for PostgreSQL and RDS for MySQL don't support selective authentication type in forest trust, only forest wide authentication.

Microsoft SQL Server and PostgreSQL DB instances support one- and two-way forest trust relationships. Oracle DB instances support one- and two-way external and forest trust relationships. For more information, see [When to create a trust relationship](#) in the *AWS Directory Service Administration Guide*.

For information about Kerberos authentication with a specific DB engine, see the following:

- [Working with AWS Managed Active Directory with RDS for SQL Server](#)
- [Using Kerberos authentication for MySQL](#)
- [Configuring Kerberos authentication for Amazon RDS for Oracle](#)
- [Using Kerberos authentication with Amazon RDS for PostgreSQL](#)
- [Using Kerberos authentication for Amazon RDS for Db2.](#)

 **Note**

Currently, Kerberos authentication isn't supported for MariaDB DB instances.

# Password management with Amazon RDS and AWS Secrets Manager

Amazon RDS integrates with Secrets Manager to manage master user passwords for your DB instances and Multi-AZ DB clusters.

## Topics

- [Limitations for Secrets Manager integration with Amazon RDS](#)
- [Overview of managing master user passwords with AWS Secrets Manager](#)
- [Benefits of managing master user passwords with Secrets Manager](#)
- [Permissions required for Secrets Manager integration](#)
- [Enforcing RDS management of the master user password in AWS Secrets Manager](#)
- [Managing the master user password for a DB instance with Secrets Manager](#)
- [Managing the master user password for a Multi-AZ DB cluster with Secrets Manager](#)
- [Rotating the master user password secret for a DB instance](#)
- [Rotating the master user password secret for a Multi-AZ DB cluster](#)
- [Viewing the details about a secret for a DB instance](#)
- [Viewing the details about a secret for a Multi-AZ DB cluster](#)
- [Region and version availability](#)

## Limitations for Secrets Manager integration with Amazon RDS

Managing master user passwords with Secrets Manager isn't supported for the following features:

- Creating a read replica when the source DB or DB cluster manages credentials with Secrets Manager. This applies to all DB engines except RDS for SQL Server.
- Amazon RDS Blue/Green Deployments
- Amazon RDS Custom
- Oracle Data Guard switchover
- RDS for Oracle with CDB

## Overview of managing master user passwords with AWS Secrets Manager

With AWS Secrets Manager, you can replace hard-coded credentials in your code, including database passwords, with an API call to Secrets Manager to retrieve the secret programmatically. For more information about Secrets Manager, see the [AWS Secrets Manager User Guide](#).

When you store database secrets in Secrets Manager, your AWS account incurs charges. For information about pricing, see [AWS Secrets Manager Pricing](#).

You can specify that RDS manages the master user password in Secrets Manager for an Amazon RDS DB instance or Multi-AZ DB cluster when you perform one of the following operations:

- Create the DB instance
- Create the Multi-AZ DB cluster
- Modify the DB instance
- Modify the Multi-AZ DB cluster
- Restore the DB instance from Amazon S3

When you specify that RDS manages the master user password in Secrets Manager, RDS generates the password and stores it in Secrets Manager. You can interact directly with the secret to retrieve the credentials for the master user. You can also specify a customer managed key to encrypt the secret, or use the KMS key that is provided by Secrets Manager.

RDS manages the settings for the secret and rotates the secret every seven days by default. You can modify some of the settings, such as the rotation schedule. If you delete a DB instance that manages a secret in Secrets Manager, the secret and its associated metadata are also deleted.

To connect to a DB instance or Multi-AZ DB cluster with the credentials in a secret, you can retrieve the secret from Secrets Manager. For more information, see [Retrieve secrets from AWS Secrets Manager](#) and [Connect to a SQL database with credentials in an AWS Secrets Manager secret](#) in the *AWS Secrets Manager User Guide*.

## Benefits of managing master user passwords with Secrets Manager

Managing RDS master user passwords with Secrets Manager provides the following benefits:

- RDS automatically generates database credentials.

- RDS automatically stores and manages database credentials in AWS Secrets Manager.
- RDS rotates database credentials regularly, without requiring application changes.
- Secrets Manager secures database credentials from human access and plain text view.
- Secrets Manager allows retrieval of database credentials in secrets for database connections.
- Secrets Manager allows fine-grained control of access to database credentials in secrets using IAM.
- You can optionally separate database encryption from credentials encryption with different KMS keys.
- You can eliminate manual management and rotation of database credentials.
- You can monitor database credentials easily with AWS CloudTrail and Amazon CloudWatch.

For more information about the benefits of Secrets Manager, see the [AWS Secrets Manager User Guide](#).

## Permissions required for Secrets Manager integration

Users must have the required permissions to perform operations related to Secrets Manager integration. You can create IAM policies that grant permissions to perform specific API operations on the specified resources they need. You can then attach those policies to the IAM permission sets or roles that require those permissions. For more information, see [Identity and access management for Amazon RDS](#).

For create, modify, or restore operations, the user who specifies that Amazon RDS manages the master user password in Secrets Manager must have permissions to perform the following operations:

- `kms:DescribeKey`
- `secretsmanager:CreateSecret`
- `secretsmanager:TagResource`

For create, modify, or restore operations, the user who specifies the customer managed key to encrypt the secret in Secrets Manager must have permissions to perform the following operations:

- `kms:Decrypt`
- `kms:GenerateDataKey`

- `kms:CreateGrant`

For modify operations, the user who rotates the master user password in Secrets Manager must have permissions to perform the following operation:

- `secretsmanager:RotateSecret`

## Enforcing RDS management of the master user password in AWS Secrets Manager

You can use IAM condition keys to enforce RDS management of the master user password in AWS Secrets Manager. The following policy doesn't allow users to create or restore DB instances or DB clusters unless the master user password is managed by RDS in Secrets Manager.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Deny",
      "Action": ["rds:CreateDBInstance", "rds:CreateDBCluster",
        "rds:RestoreDBInstanceFromS3", "rds:RestoreDBClusterFromS3"],
      "Resource": "*",
      "Condition": {
        "Bool": {
          "rds:ManageMasterUserPassword": false
        }
      }
    }
  ]
}
```

### Note

This policy enforces password management in AWS Secrets Manager at creation. However, you can still disable Secrets Manager integration and manually set a master password by modifying the instance.

To prevent this, include `rds:ModifyDBInstance`, `rds:ModifyDBCluster` in the action block of the policy. Be aware, this prevents the user from applying any further modifications to existing instances that don't have Secrets Manager integration enabled.

For more information about using condition keys in IAM policies, see [Policy condition keys for Amazon RDS](#) and [Example policies: Using condition keys](#).

## Managing the master user password for a DB instance with Secrets Manager

You can configure RDS management of the master user password in Secrets Manager when you perform the following actions:

- [Creating an Amazon RDS DB instance](#)
- [Modifying an Amazon RDS DB instance](#)
- [Restoring a backup into a MySQL DB instance](#)

You can use the RDS console, the AWS CLI, or the RDS API to perform these actions.

### Console

Follow the instructions for creating or modifying a DB instance with the RDS console:

- [Creating a DB instance](#)
- [Modifying an Amazon RDS DB instance](#)
- [Importing data from Amazon S3 to a new MySQL DB instance](#)

When you use the RDS console to perform one of these operations, you can specify that the master user password is managed by RDS in Secrets Manager. To do so when you are creating or restoring a DB instance, select **Manage master credentials in AWS Secrets Manager** in **Credential settings**. When you are modifying a DB instance, select **Manage master credentials in AWS Secrets Manager** in **Settings**.

The following image is an example of the **Manage master credentials in AWS Secrets Manager** setting when you are creating or restoring a DB instance.

▼ **Credentials Settings**

**Master username** [Info](#)  
Type a login ID for the master user of your DB instance.

1 to 16 alphanumeric characters. First character must be a letter.

**Manage master credentials in AWS Secrets Manager**  
Manage master user credentials in Secrets Manager. RDS can generate a password for you and manage it throughout its lifecycle.

**Auto generate a password**  
Amazon RDS can generate a password for you, or you can specify your own password.

**Master password** [Info](#)

Constraints: At least 8 printable ASCII characters. Can't contain any of the following: / (slash), '(single quote), "(double quote) and @ (at sign).

**Confirm master password** [Info](#)

When you select this option, RDS generates the master user password and manages it throughout its lifecycle in Secrets Manager.

▼ **Credentials Settings**

**Master username** [Info](#)  
Type a login ID for the master user of your DB instance.

1 to 16 alphanumeric characters. First character must be a letter.

**Manage master credentials in AWS Secrets Manager**  
Manage master user credentials in Secrets Manager. RDS can generate a password for you and manage it throughout its lifecycle.

**Select the encryption key** [Info](#)  
You can encrypt using the KMS key that Secrets Manager creates or a customer managed KMS key that you create.

aws/secretsmanager (default) ▼

[Add new key](#) 

You can choose to encrypt the secret with a KMS key that Secrets Manager provides or with a customer managed key that you create. After RDS is managing the database credentials for a DB instance, you can't change the KMS key that is used to encrypt the secret.

You can choose other settings to meet your requirements. For more information about the available settings when you are creating a DB instance, see [Settings for DB instances](#). For more information about the available settings when you are modifying a DB instance, see [Settings for DB instances](#).

## AWS CLI

To manage the master user password with RDS in Secrets Manager, specify the `--manage-master-user-password` option in one of the following AWS CLI commands:

- [create-db-instance](#)
- [modify-db-instance](#)
- [restore-db-instance-from-s3](#)

When you specify the `--manage-master-user-password` option in these commands, RDS generates the master user password and manages it throughout its lifecycle in Secrets Manager.

To encrypt the secret, you can specify a customer managed key or use the default KMS key that is provided by Secrets Manager. Use the `--master-user-secret-kms-key-id` option to specify a customer managed key. The AWS KMS key identifier is the key ARN, key ID, alias ARN, or alias name for the KMS key. To use a KMS key in a different AWS account, specify the key ARN or alias ARN. After RDS is managing the database credentials for a DB instance, you can't change the KMS key that is used to encrypt the secret.

You can choose other settings to meet your requirements. For more information about the available settings when you are creating a DB instance, see [Settings for DB instances](#). For more information about the available settings when you are modifying a DB instance, see [Settings for DB instances](#).

This example creates a DB instance and specifies that RDS manages the master user password in Secrets Manager. The secret is encrypted using the KMS key that is provided by Secrets Manager.

## Example

For Linux, macOS, or Unix:

```
aws rds create-db-instance \  
  --db-instance-identifier mydbinstance \  
  --engine mysql \  
  --engine-version 8.0.30 \  
  --db-instance-class db.r5b.large \  
  --allocated-storage 200 \  
  --manage-master-user-password
```

For Windows:

```
aws rds create-db-instance ^  
  --db-instance-identifier mydbinstance ^  
  --engine mysql ^  
  --engine-version 8.0.30 ^  
  --db-instance-class db.r5b.large ^  
  --allocated-storage 200 ^  
  --manage-master-user-password
```

## RDS API

To specify that RDS manages the master user password in Secrets Manager, set the `ManageMasterUserPassword` parameter to `true` in one of the following RDS API operations:

- [CreateDBInstance](#)
- [ModifyDBInstance](#)
- [RestoreDBInstanceFromS3](#)

When you set the `ManageMasterUserPassword` parameter to `true` in one of these operations, RDS generates the master user password and manages it throughout its lifecycle in Secrets Manager.

To encrypt the secret, you can specify a customer managed key or use the default KMS key that is provided by Secrets Manager. Use the `MasterUserSecretKmsKeyId` parameter to specify a customer managed key. The AWS KMS key identifier is the key ARN, key ID, alias ARN, or alias name for the KMS key. To use a KMS key in a different AWS account, specify the key ARN or alias ARN. After RDS is managing the database credentials for a DB instance, you can't change the KMS key that is used to encrypt the secret.

## Managing the master user password for a Multi-AZ DB cluster with Secrets Manager

You can configure RDS management of the master user password in Secrets Manager when you perform the following actions:

- [Creating a Multi-AZ DB cluster](#)
- [Modifying a Multi-AZ DB cluster](#)

You can use the RDS console, the AWS CLI, or the RDS API to perform these actions.

### Console

Follow the instructions for creating or modifying a Multi-AZ DB cluster with the RDS console:

- [Creating a DB cluster](#)
- [Modifying a Multi-AZ DB cluster](#)

When you use the RDS console to perform one of these operations, you can specify that the master user password is managed by RDS in Secrets Manager. To do so when you are creating a DB cluster, select **Manage master credentials in AWS Secrets Manager** in **Credential settings**. When you are modifying a DB cluster, select **Manage master credentials in AWS Secrets Manager** in **Settings**.

The following image is an example of the **Manage master credentials in AWS Secrets Manager** setting when you are creating a DB cluster.

▼ **Credentials Settings**

**Master username** [Info](#)  
Type a login ID for the master user of your DB cluster.

1 to 16 alphanumeric characters. First character must be a letter.

**Manage master credentials in AWS Secrets Manager**  
Manage master user credentials in Secrets Manager. RDS can generate a password for you and manage it throughout its lifecycle.

**Auto generate a password**  
Amazon RDS can generate a password for you, or you can specify your own password.

**Master password** [Info](#)

Constraints: At least 8 printable ASCII characters. Can't contain any of the following: / (slash), '(single quote), "(double quote) and @ (at sign).

**Confirm master password** [Info](#)

When you select this option, RDS generates the master user password and manages it throughout its lifecycle in Secrets Manager.

▼ **Credentials Settings**

**Master username** [Info](#)  
Type a login ID for the master user of your DB cluster.

1 to 16 alphanumeric characters. First character must be a letter.

**Manage master credentials in AWS Secrets Manager**  
Manage master user credentials in Secrets Manager. RDS can generate a password for you and manage it throughout its lifecycle.

**Select the encryption key** [Info](#)  
You can encrypt using the KMS key that Secrets Manager creates or a customer managed KMS key that you create.

aws/secretsmanager (default) ▼

[Add new key](#) [↗](#)

You can choose to encrypt the secret with a KMS key that Secrets Manager provides or with a customer managed key that you create. After RDS is managing the database credentials for a DB cluster, you can't change the KMS key that is used to encrypt the secret.

You can choose other settings to meet your requirements.

For more information about the available settings when you are creating a Multi-AZ DB cluster, see [Settings for creating Multi-AZ DB clusters](#). For more information about the available settings when you are modifying a Multi-AZ DB cluster, see [Settings for modifying Multi-AZ DB clusters](#).

## AWS CLI

To specify that RDS manages the master user password in Secrets Manager, specify the `--manage-master-user-password` option in one of the following commands:

- [create-db-cluster](#)
- [modify-db-cluster](#)

When you specify the `--manage-master-user-password` option in these commands, RDS generates the master user password and manages it throughout its lifecycle in Secrets Manager.

To encrypt the secret, you can specify a customer managed key or use the default KMS key that is provided by Secrets Manager. Use the `--master-user-secret-kms-key-id` option to specify a customer managed key. The AWS KMS key identifier is the key ARN, key ID, alias ARN, or alias name for the KMS key. To use a KMS key in a different AWS account, specify the key ARN or alias ARN. After RDS is managing the database credentials for a DB cluster, you can't change the KMS key that is used to encrypt the secret.

You can choose other settings to meet your requirements.

For more information about the available settings when you are creating a Multi-AZ DB cluster, see [Settings for creating Multi-AZ DB clusters](#). For more information about the available settings when you are modifying a Multi-AZ DB cluster, see [Settings for modifying Multi-AZ DB clusters](#).

This example creates a Multi-AZ DB cluster and specifies that RDS manages the password in Secrets Manager. The secret is encrypted using the KMS key that is provided by Secrets Manager.

## Example

For Linux, macOS, or Unix:

```
aws rds create-db-cluster \  
  --db-cluster-identifier mysql-multi-az-db-cluster \  
  --engine mysql \  
  --engine-version 8.0.28 \  
  --backup-retention-period 1 \  
  --allocated-storage 4000 \  
  --storage-type io1 \  
  --iops 10000 \  
  --db-cluster-instance-class db.r6gd.xlarge \  
  --manage-master-user-password
```

### For Windows:

```
aws rds create-db-cluster ^  
  --db-cluster-identifier mysql-multi-az-db-cluster ^  
  --engine mysql ^  
  --engine-version 8.0.28 ^  
  --backup-retention-period 1 ^  
  --allocated-storage 4000 ^  
  --storage-type io1 ^  
  --iops 10000 ^  
  --db-cluster-instance-class db.r6gd.xlarge ^  
  --manage-master-user-password
```

## RDS API

To specify that RDS manages the master user password in Secrets Manager, set the `ManageMasterUserPassword` parameter to `true` in one of the following operations:

- [CreateDBCluster](#)
- [ModifyDBCluster](#)

When you set the `ManageMasterUserPassword` parameter to `true` in one of these operations, RDS generates the master user password and manages it throughout its lifecycle in Secrets Manager.

To encrypt the secret, you can specify a customer managed key or use the default KMS key that is provided by Secrets Manager. Use the `MasterUserSecretKmsKeyId` parameter to specify a customer managed key. The AWS KMS key identifier is the key ARN, key ID, alias ARN, or alias name for the KMS key. To use a KMS key in a different AWS account, specify the key ARN or alias ARN.

After RDS is managing the database credentials for a DB cluster, you can't change the KMS key that is used to encrypt the secret.

## Rotating the master user password secret for a DB instance

When RDS rotates a master user password secret, Secrets Manager generates a new secret version for the existing secret. The new version of the secret contains the new master user password. Amazon RDS changes the master user password for the DB instance to match the password for the new secret version.

You can rotate a secret immediately instead of waiting for a scheduled rotation. To rotate a master user password secret in Secrets Manager, modify the DB instance. For information about modifying a DB instance, see [Modifying an Amazon RDS DB instance](#).

You can rotate a master user password secret immediately with the RDS console, the AWS CLI, or the RDS API. The new password is always 28 characters long and contains at least one upper and lowercase character, one number, and one punctuation.

### Console

To rotate a master user password secret using the RDS console, modify the DB instance and select **Rotate secret immediately** in **Settings**.

### Settings

**DB engine version**  
Version number of the database engine to be used for this database

8.0.30 ▼

**DB instance identifier** [Info](#)  
Type a name for your DB instance. The name must be unique across all DB instances owned by your AWS account in the current AWS Region.

database-1

The DB instance identifier is case-insensitive, but is stored as all lowercase (as in "mydbinstance"). Constraints: 1 to 60 alphanumeric characters or hyphens. First character must be a letter. Can't contain two consecutive hyphens. Can't end with a hyphen.

**Manage master credentials in AWS Secrets Manager**  
Manage master user credentials in Secrets Manager. RDS can generate a password for you and manage it throughout its lifecycle.

**Rotate secret immediately**  
When you rotate a secret, you update the credentials in both the secret and the database.

Follow the instructions for modifying a DB instance with the RDS console in [Modifying an Amazon RDS DB instance](#). You must choose **Apply immediately** on the confirmation page.

## AWS CLI

To rotate a master user password secret using the AWS CLI, use the [modify-db-instance](#) command and specify the `--rotate-master-user-password` option. You must specify the `--apply-immediately` option when you rotate the master password.

This example rotates a master user password secret.

## Example

For Linux, macOS, or Unix:

```
aws rds modify-db-instance \  
  --db-instance-identifier mydbinstance \  
  --rotate-master-user-password \  
  --apply-immediately
```

For Windows:

```
aws rds modify-db-instance ^  
  --db-instance-identifier mydbinstance ^  
  --rotate-master-user-password ^  
  --apply-immediately
```

## RDS API

You can rotate a master user password secret using the [ModifyDBInstance](#) operation and setting the `RotateMasterUserPassword` parameter to `true`. You must set the `ApplyImmediately` parameter to `true` when you rotate the master password.

## Rotating the master user password secret for a Multi-AZ DB cluster

When RDS rotates a master user password secret, Secrets Manager generates a new secret version for the existing secret. The new version of the secret contains the new master user password. Amazon RDS changes the master user password for the Multi-AZ DB cluster to match the password for the new secret version.

You can rotate a secret immediately instead of waiting for a scheduled rotation. To rotate a master user password secret in Secrets Manager, modify the Multi-AZ DB cluster. For information about modifying a Multi-AZ DB cluster, see [Modifying a Multi-AZ DB cluster](#).

You can rotate a master user password secret immediately with the RDS console, the AWS CLI, or the RDS API. The new password is always 28 characters long and contains at least one upper and lowercase character, one number, and one punctuation.

## Console

To rotate a master user password secret using the RDS console, modify the Multi-AZ DB cluster and select **Rotate secret immediately** in **Settings**.

**Settings**

Engine Version [Info](#)

MySQL 8.0.30 ▼

To see more versions, modify the capacity types. [Info](#)

DB cluster identifier [Info](#)

Enter a name for your DB cluster. The name must be unique across all DB clusters owned by your AWS account in the current AWS Region.

database-2

The DB cluster identifier is case-insensitive, but is stored as all lowercase (as in "mydbcluster"). Constraints: 1 to 60 alphanumeric characters or hyphens. First character must be a letter. Can't contain two consecutive hyphens. Can't end with a hyphen.

DB cluster identifier

The identifier for the DB cluster.

database-2

**Manage master credentials in AWS Secrets Manager**  
Manage master user credentials in Secrets Manager. RDS can generate a password for you and manage it throughout its lifecycle.

**Rotate secret immediately**  
When you rotate a secret, you update the credentials in both the secret and the database.

Follow the instructions for modifying a Multi-AZ DB cluster with the RDS console in [Modifying a Multi-AZ DB cluster](#). You must choose **Apply immediately** on the confirmation page.

## AWS CLI

To rotate a master user password secret using the AWS CLI, use the [modify-db-cluster](#) command and specify the `--rotate-master-user-password` option. You must specify the `--apply-immediately` option when you rotate the master password.

This example rotates a master user password secret.

### Example

For Linux, macOS, or Unix:

```
aws rds modify-db-cluster \  
  --db-cluster-identifier mydbcluster \  
  --rotate-master-user-password \  
  --apply-immediately
```

For Windows:

```
aws rds modify-db-cluster ^  
  --db-cluster-identifier mydbcluster ^  
  --rotate-master-user-password ^  
  --apply-immediately
```

## RDS API

You can rotate a master user password secret using the [ModifyDBCluster](#) operation and setting the `RotateMasterUserPassword` parameter to `true`. You must set the `ApplyImmediately` parameter to `true` when you rotate the master password.

## Viewing the details about a secret for a DB instance

You can retrieve your secrets using the console (<https://console.aws.amazon.com/secretsmanager/>) or the AWS CLI ([get-secret-value](#) Secrets Manager command).

You can find the Amazon Resource Name (ARN) of a secret managed by RDS in Secrets Manager with the RDS console, the AWS CLI, or the RDS API.

## Console

### To view the details about a secret managed by RDS in Secrets Manager

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Databases**.
3. Choose the name of the DB instance to show its details.
4. Choose the **Configuration** tab.

In **Master Credentials ARN**, you can view the secret ARN.

The screenshot displays the AWS Management Console interface for an Amazon RDS instance. The top navigation bar includes tabs for Connectivity & security, Monitoring, Logs & events, Configuration (selected), Maintenance & backups, and Troubleshooting. The main content area is titled 'Instance' and is divided into three columns: Configuration, Instance class, and Storage.

**Configuration Column:**

- DB instance ID: database-1
- Engine version: 8.0.30
- DB name: -
- License model: General Public License
- Option groups: default:mysql-8-0 ✔ In sync
- Amazon Resource Name (ARN): arn:aws:rds:ap-south-1: [redacted]:db:database-1
- Resource ID: db-[redacted]
- Created time: December 20, 2022, 09:10 (UTC-08:00)
- Parameter group: default.mysql8.0 ✔ In sync
- Deletion protection: Enabled

**Instance class Column:**

- Instance class: db.m6g.large
- vCPU: 2
- RAM: 8 GB
- Availability:
  - Master username: admin
  - IAM DB authentication: Not enabled
  - Multi-AZ: No
  - Secondary Zone: -

**Storage Column:**

- Encryption: Enabled
- AWS KMS key: aws/rds [↗](#)
- Storage type: Provisioned
- Storage: 400 GiB
- Provisioned: 3000 IOPS
- Storage throughput: -
- Storage auto: Enabled
- Maximum storage: 1000 GiB

**Master Credentials ARN (highlighted in red box):**

arn:aws:secretsmanager:ap-south-1:[redacted]:secret:rds!db-71d9c43d-4022-44a6-bc18-a67bb156d5a8-RzRqmA [Manage in Secrets Manager](#) [↗](#)

You can follow the **Manage in Secrets Manager** link to view and manage the secret in the Secrets Manager console.

## AWS CLI

You can use the [describe-db-instances](#) RDS CLI command to find the following information about a secret managed by RDS in Secrets Manager:

- `SecretArn` – The ARN of the secret
- `SecretStatus` – The status of the secret

The possible status values include the following:

- `creating` – The secret is being created.
- `active` – The secret is available for normal use and rotation.
- `rotating` – The secret is being rotated.
- `impaired` – The secret can be used to access database credentials, but it can't be rotated. A secret might have this status if, for example, permissions are changed so that RDS can no longer access the secret or the KMS key for the secret.

When a secret has this status, you can correct the condition that caused the status. If you correct the condition that caused status, the status remains `impaired` until the next rotation. Alternatively, you can modify the DB instance to turn off automatic management of database credentials, and then modify the DB instance again to turn on automatic management of database credentials. To modify the DB instance, use the `--manage-master-user-password` option in the [modify-db-instance](#) command.

- `KmsKeyId` – The ARN of the KMS key that is used to encrypt the secret

Specify the `--db-instance-identifier` option to show output for a specific DB instance. This example shows the output for a secret that is used by a DB instance.

## Example

```
aws rds describe-db-instances --db-instance-identifier mydbinstance
```

Following is sample output for a secret:

```
"MasterUserSecret": {
    "SecretArn": "arn:aws:secretsmanager:eu-west-1:123456789012:secret:rds!
db-033d7456-2c96-450d-9d48-f5de3025e51c-xmJRDx",
    "SecretStatus": "active",
    "KmsKeyId": "arn:aws:kms:eu-
west-1:123456789012:key/0987dcba-09fe-87dc-65ba-ab0987654321"
}
```

When you have the secret ARN, you can view details about the secret using the [get-secret-value](#) Secrets Manager CLI command.

This example shows the details for the secret in the previous sample output.

## Example

For Linux, macOS, or Unix:

```
aws secretsmanager get-secret-value \  
  --secret-id 'arn:aws:secretsmanager:eu-west-1:123456789012:secret:rds!  
db-033d7456-2c96-450d-9d48-f5de3025e51c-xmJRDx'
```

For Windows:

```
aws secretsmanager get-secret-value ^  
  --secret-id 'arn:aws:secretsmanager:eu-west-1:123456789012:secret:rds!  
db-033d7456-2c96-450d-9d48-f5de3025e51c-xmJRDx'
```

## RDS API

You can view the ARN, status, and KMS key for a secret managed by RDS in Secrets Manager by using the [DescribeDBInstances](#) operation and setting the `DBInstanceIdentifier` parameter to a DB instance identifier. Details about the secret are included in the output.

When you have the secret ARN, you can view details about the secret using the [GetSecretValue](#) Secrets Manager operation.

## Viewing the details about a secret for a Multi-AZ DB cluster

You can retrieve your secrets using the console (<https://console.aws.amazon.com/secretsmanager/>) or the AWS CLI ([get-secret-value](#) Secrets Manager command).

You can find the Amazon Resource Name (ARN) of a secret managed by RDS in Secrets Manager with the RDS console, the AWS CLI, or the RDS API.

### Console

#### To view the details about a secret managed by RDS in Secrets Manager

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.

2. In the navigation pane, choose **Databases**.
3. Choose the name of the Multi-AZ DB cluster to show its details.
4. Choose the **Configuration** tab.

In **Master Credentials ARN**, you can view the secret ARN.

The screenshot displays the AWS Management Console interface for a Multi-AZ DB cluster. The 'Configuration' tab is selected, showing various settings for the cluster. The 'Master Credentials ARN' is highlighted in a red box, indicating the secret ARN used for the cluster's master instance.

Configuration	Instance class	Storage
DB cluster ID database-2	Instance class db.m5d.large	Encrypti Enabled
DB cluster role Multi-AZ DB cluster	vCPU 2	AWS KM <a href="#">aws/rds</a>
Engine version 8.0.30	RAM 8 GB	Storage Provision
Amazon Resource Name (ARN) arn:aws:rds:ap-south-1: [redacted]:cluster:database-2	Instance Store <a href="#">Info</a> 75 GB	Storage 400 GiB
Resource ID cluster-[redacted]	Availability	Provision 3000 IO
Created time December 20, 2022, 09:08 (UTC-08:00)	Master username admin	Storage -
Parameter group default.mysql8.0	IAM DB authentication Not enabled	Storage Disabled
Deletion protection Enabled	Multi-AZ 3 Zones	
	Master Credentials ARN <a href="#">arn:aws:secretsmanager:ap-south-1:[redacted]:secret:rds!cluster-701e5459-f820-4a7f-abae-5427f13037af-f8c17f</a> <a href="#">Manage in Secrets Manager</a>	

You can follow the **Manage in Secrets Manager** link to view and manage the secret in the Secrets Manager console.

## AWS CLI

You can use the RDS AWS CLI [describe-db-clusters](#) command to find the following information about a secret managed by RDS in Secrets Manager:

- `SecretArn` – The ARN of the secret
- `SecretStatus` – The status of the secret

The possible status values include the following:

- `creating` – The secret is being created.
- `active` – The secret is available for normal use and rotation.
- `rotating` – The secret is being rotated.
- `impaired` – The secret can be used to access database credentials, but it can't be rotated. A secret might have this status if, for example, permissions are changed so that RDS can no longer access the secret or the KMS key for the secret.

When a secret has this status, you can correct the condition that caused the status. If you correct the condition that caused status, the status remains `impaired` until the next rotation. Alternatively, you can modify the DB cluster to turn off automatic management of database credentials, and then modify the DB cluster again to turn on automatic management of database credentials. To modify the DB cluster, use the `--manage-master-user-password` option in the [modify-db-cluster](#) command.

- `KmsKeyId` – The ARN of the KMS key that is used to encrypt the secret

Specify the `--db-cluster-identifier` option to show output for a specific DB cluster. This example shows the output for a secret that is used by a DB cluster.

## Example

```
aws rds describe-db-clusters --db-cluster-identifier mydbcluster
```

The following sample shows the output for a secret:

```
"MasterUserSecret": {
    "SecretArn": "arn:aws:secretsmanager:eu-west-1:123456789012:secret:rds!
cluster-033d7456-2c96-450d-9d48-f5de3025e51c-xmJRDx",
    "SecretStatus": "active",
    "KmsKeyId": "arn:aws:kms:eu-
west-1:123456789012:key/0987dcba-09fe-87dc-65ba-ab0987654321"
}
```

When you have the secret ARN, you can view details about the secret using the [get-secret-value](#) Secrets Manager CLI command.

This example shows the details for the secret in the previous sample output.

### Example

For Linux, macOS, or Unix:

```
aws secretsmanager get-secret-value \
  --secret-id 'arn:aws:secretsmanager:eu-west-1:123456789012:secret:rds!
cluster-033d7456-2c96-450d-9d48-f5de3025e51c-xmJRDx'
```

For Windows:

```
aws secretsmanager get-secret-value ^
  --secret-id 'arn:aws:secretsmanager:eu-west-1:123456789012:secret:rds!
cluster-033d7456-2c96-450d-9d48-f5de3025e51c-xmJRDx'
```

### RDS API

You can view the ARN, status, and KMS key for a secret managed by RDS in Secrets Manager using the [DescribeDBClusters](#) RDS operation and setting the `DBClusterIdentifier` parameter to a DB cluster identifier. Details about the secret are included in the output.

When you have the secret ARN, you can view details about the secret using the [GetSecretValue](#) Secrets Manager operation.

## Region and version availability

Feature availability and support varies across specific versions of each database engine and across AWS Regions. For more information about version and Region availability with Secrets Manager

integration with Amazon RDS, see [Supported Regions and DB engines for the Secrets Manager integration with Amazon RDS](#).

## Data protection in Amazon RDS

The AWS [shared responsibility model](#) applies to data protection in Amazon Relational Database Service. As described in this model, AWS is responsible for protecting the global infrastructure that runs all of the AWS Cloud. You are responsible for maintaining control over your content that is hosted on this infrastructure. You are also responsible for the security configuration and management tasks for the AWS services that you use. For more information about data privacy, see the [Data Privacy FAQ](#). For information about data protection in Europe, see the [AWS Shared Responsibility Model and GDPR](#) blog post on the *AWS Security Blog*.

For data protection purposes, we recommend that you protect AWS account credentials and set up individual users with AWS IAM Identity Center or AWS Identity and Access Management (IAM). That way, each user is given only the permissions necessary to fulfill their job duties. We also recommend that you secure your data in the following ways:

- Use multi-factor authentication (MFA) with each account.
- Use SSL/TLS to communicate with AWS resources. We require TLS 1.2 and recommend TLS 1.3.
- Set up API and user activity logging with AWS CloudTrail.
- Use AWS encryption solutions, along with all default security controls within AWS services.
- Use advanced managed security services such as Amazon Macie, which assists in discovering and securing sensitive data that is stored in Amazon S3.
- If you require FIPS 140-3 validated cryptographic modules when accessing AWS through a command line interface or an API, use a FIPS endpoint. For more information about the available FIPS endpoints, see [Federal Information Processing Standard \(FIPS\) 140-3](#).

We strongly recommend that you never put confidential or sensitive information, such as your customers' email addresses, into tags or free-form text fields such as a **Name** field. This includes when you work with Amazon RDS or other AWS services using the console, API, AWS CLI, or AWS SDKs. Any data that you enter into tags or free-form text fields used for names may be used for billing or diagnostic logs. If you provide a URL to an external server, we strongly recommend that you do not include credentials information in the URL to validate your request to that server.

## Encrypting Amazon RDS resources

Amazon RDS can encrypt your Amazon RDS DB instances. Data that is encrypted at rest includes the underlying storage for DB instances, its automated backups, read replicas, and snapshots.

Amazon RDS encrypted DB instances use the industry standard AES-256 encryption algorithm to encrypt your data on the server that hosts your Amazon RDS DB instances. After your data is encrypted, Amazon RDS handles authentication of access and decryption of your data transparently with a minimal impact on performance. You don't need to modify your database client applications to use encryption.

### Note

For encrypted and unencrypted DB instances, data that is in transit between the source and the read replicas is encrypted, even when replicating across AWS Regions.

### Topics

## Overview of encrypting Amazon RDS resources

Amazon RDS encrypted DB instances provide an additional layer of data protection by securing your data from unauthorized access to the underlying storage. You can use Amazon RDS encryption to increase data protection of your applications deployed in the cloud, and to fulfill compliance requirements for encryption at rest.

For an Amazon RDS encrypted DB instance, all logs, backups, and snapshots are encrypted. Amazon RDS uses an AWS Key Management Service key to encrypt these resources. For more information about KMS keys, see [AWS KMS keys](#) in the *AWS Key Management Service Developer Guide* and [AWS KMS key management](#). If you copy an encrypted snapshot, you can use a different KMS key to encrypt the target snapshot than the one that was used to encrypt the source snapshot.

A read replica of an Amazon RDS encrypted instance must be encrypted using the same KMS key as the primary DB instance when both are in the same AWS Region. If the primary DB instance and read replica are in different AWS Regions, you encrypt the read replica using the KMS key for that AWS Region.

You can use an AWS managed key, or you can create customer managed keys. To manage the customer managed keys used for encrypting and decrypting your Amazon RDS resources, you use the [AWS Key Management Service \(AWS KMS\)](#). AWS KMS combines secure, highly available hardware and software to provide a key management system scaled for the cloud. Using AWS KMS, you can create customer managed keys and define the policies that control how these customer managed keys can be used. AWS KMS supports CloudTrail, so you can audit KMS key usage to verify that customer managed keys are being used appropriately. You can use your customer managed keys with Amazon Aurora and supported AWS services such as Amazon S3, Amazon EBS, and Amazon Redshift. For a list of services that are integrated with AWS KMS, see [AWS Service Integration](#).

Amazon RDS also supports encrypting an Oracle or SQL Server DB instance with Transparent Data Encryption (TDE). TDE can be used with RDS encryption at rest, although using TDE and RDS encryption at rest simultaneously might slightly affect the performance of your database. You

must manage different keys for each encryption method. For more information on TDE, see [Oracle Transparent Data Encryption](#) or [Support for Transparent Data Encryption in SQL Server](#).

## Encrypting a DB instance

To encrypt a new DB instance, choose **Enable encryption** on the Amazon RDS console. For information on creating a DB instance, see [Creating an Amazon RDS DB instance](#).

If you use the [create-db-instance](#) AWS CLI command to create an encrypted DB instance, set the `--storage-encrypted` parameter. If you use the [CreateDBInstance](#) API operation, set the `StorageEncrypted` parameter to true.

When you create an encrypted DB instance, you can choose a customer managed key or the AWS managed key for Amazon RDS to encrypt your DB instance. If you don't specify the key identifier for a customer managed key, Amazon RDS uses the AWS managed key for your new DB instance. Amazon RDS creates an AWS managed key for Amazon RDS for your AWS account. Your AWS account has a different AWS managed key for Amazon RDS for each AWS Region.

For more information about KMS keys, see [AWS KMS keys](#) in the *AWS Key Management Service Developer Guide*.

Once you have created an encrypted DB instance, you can't change the KMS key used by that DB instance. Therefore, be sure to determine your KMS key requirements before you create your encrypted DB instance.

If you use the AWS CLI `create-db-instance` command to create an encrypted DB instance with a customer managed key, set the `--kms-key-id` parameter to any key identifier for the KMS key. If you use the Amazon RDS API `CreateDBInstance` operation, set the `KmsKeyId` parameter to any key identifier for the KMS key. To use a customer managed key in a different AWS account, specify the key ARN or alias ARN.

### Important

Amazon RDS can lose access to the KMS key for a DB instance when you disable the KMS key. In these cases, the encrypted DB instance shortly goes into `inaccessible-encryption-credentials-recoverable` state. The DB instance remains in this state for seven days, during which the instance is stopped. API calls made to the DB instance during this time might not succeed. To recover the DB instance, enable the KMS key and restart this DB instance. Enable the KMS key from the AWS Management Console. Restart

the DB instance using the AWS CLI command [start-db-instance](#) or AWS Management Console.

If the DB instance isn't recovered within seven days, it goes into the terminal `inaccessible-encryption-credentials` state. In this state, the DB instance is not usable anymore and you can only restore the DB instance from a backup. We strongly recommend that you always turn on backups for encrypted DB instances to guard against the loss of encrypted data in your databases.

During the creation of a DB instance, Amazon RDS checks if the calling principal has access to the KMS key and generates a grant from the KMS key that it uses for the entire lifetime of the DB instance. Revoking the calling principal's access to the KMS key does not affect a running database. When using KMS keys in cross-account scenarios, such as copying a snapshot to another account, the KMS key needs to be shared with the other account. If you create a DB instance from the snapshot without specifying a different KMS key, the new instance uses the KMS key from the source account. Revoking access to the key after you create the DB instance does not affect the instance. However, disabling the key impacts all DB instances encrypted with that key. To prevent this, specify a different key during the snapshot copy operation.

## Determining whether encryption is turned on for a DB instance

You can use the AWS Management Console, AWS CLI, or RDS API to determine whether encryption at rest is turned on for a DB instance.

### Console

#### To determine whether encryption at rest is turned on for a DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Databases**.
3. Choose the name of the DB instance that you want to check to view its details.
4. Choose the **Configuration** tab, and check the **Encryption** value under **Storage**.

It shows either **Enabled** or **Not enabled**.

RDS > Databases > postgres-database-1

## postgres-database-1 Modify Actions ▾

### Summary

DB identifier postgres-database-1	CPU 4.92%	Status Available	Class db.t3.small
Role Primary	Current activity 0.00 sessions	Engine PostgreSQL	Region & AZ us-east-1f

Connectivity & security | Monitoring | Logs & events | **Configuration** | Maintenance & backups | Tags

### Instance

Configuration DB instance ID postgres-database-1	Instance class Instance class db.t3.small	<b>Storage</b> Encryption Enabled	Performance Insights Performance Insights enabled Yes
--	---	---	---

## AWS CLI

To determine whether encryption at rest is turned on for a DB instance by using the AWS CLI, call the [describe-db-instances](#) command with the following option:

- `--db-instance-identifier` – The name of the DB instance.

The following example uses a query to return either TRUE or FALSE regarding encryption at rest for the mydb DB instance.

## Example

```
aws rds describe-db-instances --db-instance-identifier mydb --query "*[].[StorageEncrypted:StorageEncrypted]" --output text
```

## RDS API

To determine whether encryption at rest is turned on for a DB instance by using the Amazon RDS API, call the [DescribeDBInstances](#) operation with the following parameter:

- `DBInstanceIdentifier` – The name of the DB instance.

## Availability of Amazon RDS encryption

Amazon RDS encryption is currently available for all database engines and storage types, except for SQL Server Express Edition.

Amazon RDS encryption is available for most DB instance classes. The following table lists DB instance classes that *don't support* Amazon RDS encryption:

Instance type	Instance class
General purpose (M1)	db.m1.small
	db.m1.medium
	db.m1.large
	db.m1.xlarge
Memory optimized (M2)	db.m2.xlarge
	db.m2.2xlarge
	db.m2.4xlarge
Burstable (T2)	db.t2.micro

## Encryption in transit

AWS provides secure and private connectivity between DB instances of all types. In addition, some instance types use the offload capabilities of the underlying Nitro System hardware to automatically encrypt in-transit traffic between instances. This encryption uses Authenticated Encryption with Associated Data (AEAD) algorithms, with 256-bit encryption. There is no impact on network performance. To support this additional in-transit traffic encryption between instances, the following requirements must be met:

- The instances use the following instance types:
  - **General purpose:** M6i, M6id, M6in, M6idn, M7g
  - **Memory optimized:** R6i, R6id, R6in, R6idn, R7g, X2idn, X2iedn, X2iezn
- The instances are in the same AWS Region.

- The instances are in the same VPC or peered VPCs, and the traffic does not pass through a virtual network device or service, such as a load balancer or a transit gateway.

For more information about the underlying EC2 instances and the associated encryption, see [Encryption in transit](#) in the Amazon EC2 User Guide.

## Limitations of Amazon RDS encrypted DB instances

The following limitations exist for Amazon RDS encrypted DB instances:

- You can only encrypt an Amazon RDS DB instance when you create it, not after the DB instance is created.

However, because you can encrypt a copy of an unencrypted snapshot, you can effectively add encryption to an unencrypted DB instance. That is, you can create a snapshot of your DB instance, and then create an encrypted copy of that snapshot. You can then restore a DB instance from the encrypted snapshot, and thus you have an encrypted copy of your original DB instance. For more information, see [Copying a DB snapshot](#).

- You can't turn off encryption on an encrypted DB instance.
- You can't create an encrypted snapshot of an unencrypted DB instance.
- A snapshot of an encrypted DB instance must be encrypted using the same KMS key as the DB instance.
- You can't have an encrypted read replica of an unencrypted DB instance or an unencrypted read replica of an encrypted DB instance.
- Encrypted read replicas must be encrypted with the same KMS key as the source DB instance when both are in the same AWS Region.
- You can't restore an unencrypted backup or snapshot to an encrypted DB instance.
- To copy an encrypted snapshot from one AWS Region to another, you must specify the KMS key in the destination AWS Region. This is because KMS keys are specific to the AWS Region that they are created in.

The source snapshot remains encrypted throughout the copy process. Amazon RDS uses envelope encryption to protect data during the copy process. For more information about envelope encryption, see [Envelope encryption](#) in the *AWS Key Management Service Developer Guide*.

- You can't unencrypt an encrypted DB instance. However, you can export data from an encrypted DB instance and import the data into an unencrypted DB instance.

## AWS KMS key management

Amazon RDS automatically integrates with [AWS Key Management Service \(AWS KMS\)](#) for key management. Amazon RDS uses envelope encryption. For more information about envelope encryption, see [Envelope encryption](#) in the *AWS Key Management Service Developer Guide*.

You can use two types of AWS KMS keys to encrypt your DB instances.

- If you want full control over a KMS key, you must create a *customer managed key*. For more information about customer managed keys, see [Customer managed keys](#) in the *AWS Key Management Service Developer Guide*.

You can't share a snapshot that has been encrypted using the AWS managed key of the AWS account that shared the snapshot.

- *AWS managed keys* are KMS keys in your account that are created, managed, and used on your behalf by an AWS service that is integrated with AWS KMS. By default, the RDS AWS managed key (`aws/rds`) is used for encryption. You can't manage, rotate, or delete the RDS AWS managed key. For more information about AWS managed keys, see [AWS managed keys](#) in the *AWS Key Management Service Developer Guide*.

To manage KMS keys used for Amazon RDS encrypted DB instances, use the [AWS Key Management Service \(AWS KMS\)](#) in the [AWS KMS console](#), the AWS CLI, or the AWS KMS API. To view audit logs of every action taken with an AWS managed or customer managed key, use [AWS CloudTrail](#). For more information about key rotation, see [Rotating AWS KMS keys](#).

### Authorizing use of a customer managed key

When RDS uses a customer managed key in cryptographic operations, it acts on behalf of the user who is creating or changing the RDS resource.

To create an RDS resource using a customer managed key, a user must have permissions to call the following operations on the customer managed key:

- `kms:CreateGrant`
- `kms:DescribeKey`

You can specify these required permissions in a key policy, or in an IAM policy if the key policy allows it.

**Tip**

To follow the principle of least privilege, do not allow full access to `kms:CreateGrant`. Instead, use the [kms:ViaService condition key](#) to allow the user to create grants on the KMS key only when the grant is created on the user's behalf by an AWS service.

You can make the IAM policy stricter in various ways. For example, if you want to allow the customer managed key to be used only for requests that originate in RDS, use the [kms:ViaService condition key](#) with the `rds.<region>.amazonaws.com` value. Also, you can use the keys or values in the [Amazon RDS encryption context](#) as a condition for using the customer managed key for encryption.

For more information, see [Allowing users in other accounts to use a KMS key](#) in the *AWS Key Management Service Developer Guide* and [Key policies in AWS KMS](#).

### Amazon RDS encryption context

When RDS uses your KMS key, or when Amazon EBS uses the KMS key on behalf of RDS, the service specifies an [encryption context](#). The encryption context is [additional authenticated data](#) (AAD) that AWS KMS uses to ensure data integrity. When an encryption context is specified for an encryption operation, the service must specify the same encryption context for the decryption operation. Otherwise, decryption fails. The encryption context is also written to your [AWS CloudTrail](#) logs to help you understand why a given KMS key was used. Your CloudTrail logs might contain many entries describing the use of a KMS key, but the encryption context in each log entry can help you determine the reason for that particular use.

At minimum, Amazon RDS always uses the DB instance ID for the encryption context, as in the following JSON-formatted example:

```
{ "aws:rds:db-id": "db-CQYSMDPBRZ7BPMH7Y3RTDG5QY" }
```

This encryption context can help you identify the DB instance for which your KMS key was used.

When your KMS key is used for a specific DB instance and a specific Amazon EBS volume, both the DB instance ID and the Amazon EBS volume ID are used for the encryption context, as in the following JSON-formatted example:

```
{
  "aws:rds:db-id": "db-BRG7VYS3SVIFQW7234EJQ0M5RQ",
  "aws:ebs:id": "vol-ad8c6542"
}
```

## Using SSL/TLS to encrypt a connection to a DB instance or cluster

You can use Secure Socket Layer (SSL) or Transport Layer Security (TLS) from your application to encrypt a connection to a database running Db2, MariaDB, Microsoft SQL Server, MySQL, Oracle, or PostgreSQL.

SSL/TLS connections provide a layer of security by encrypting data that moves between your client and DB instance or cluster. Optionally, your SSL/TLS connection can perform server identity verification by validating the server certificate installed on your database. To require server identity verification, follow this general process:

1. Choose the **certificate authority (CA)** that signs the **DB server certificate**, for your database. For more information about certificate authorities, see [Certificate authorities](#).
2. Download a certificate bundle to use when you are connecting to the database. To download a certificate bundle, see [Certificate bundles by AWS Region](#).

### Note

All certificates are only available for download using SSL/TLS connections.

3. Connect to the database using your DB engine's process for implementing SSL/TLS connections. Each DB engine has its own process for implementing SSL/TLS. To learn how to implement SSL/TLS for your database, follow the link that corresponds to your DB engine:
  - [Using SSL/TLS with an Amazon RDS for Db2 DB instance](#)
  - [Using SSL/TLS with a MariaDB DB instance](#)
  - [Using SSL with a Microsoft SQL Server DB instance](#)
  - [Using SSL/TLS with a MySQL DB instance](#)
  - [Using SSL with an RDS for Oracle DB instance](#)
  - [Using SSL with a PostgreSQL DB instance](#)

## Certificate authorities

The **certificate authority (CA)** is the certificate that identifies the root CA at the top of the certificate chain. The CA signs the **DB server certificate**, which is installed on each DB instance. The DB server certificate identifies the DB instance as a trusted server.

Amazon RDS provides the following CAs to sign the DB server certificate for a database.

Certificate authority (CA)	Description	Common name (CN)
rds-ca-2019	Uses a certificate authority with RSA 2048 private key algorithm and SHA256 signing algorithm. This CA expires in 2024 and doesn't support automatic server certificate rotation. If you are using this CA and want to keep the same standard, we recommend that you switch to the rds-ca-rsa2048-g1 CA.	Amazon RDS <i>region-id</i> <i>entifier</i> CA 2019

Certificate authority (CA)	Description	Common name (CN)
rds-ca-rsa2048-g1	<p>Uses a certificate authority with RSA 2048 private key algorithm and SHA256 signing algorithm in most AWS Regions.</p> <p>In the AWS GovCloud (US) Regions, this CA uses a certificate authority with RSA 2048 private key algorithm and SHA384 signing algorithm.</p> <p>This CA remains valid for longer than the rds-ca-2019 CA. This CA supports automatic server certificate rotation.</p>	Amazon RDS <i>region-id</i> <i>entifier</i> RSA2048 G1
rds-ca-rsa4096-g1	Uses a certificate authority with RSA 4096 private key algorithm and SHA384 signing algorithm. This CA supports automatic server certificate rotation.	Amazon RDS <i>region-id</i> <i>entifier</i> RSA4096 G1
rds-ca-ecc384-g1	Uses a certificate authority with ECC 384 private key algorithm and SHA384 signing algorithm. This CA supports automatic server certificate rotation.	Amazon RDS <i>region-id</i> <i>entifier</i> ECC384 G1

 **Note**

If you are using the AWS CLI, you can see the validities of the certificate authorities listed above by using [describe-certificates](#).

These CA certificates are included in the regional and global certificate bundle. When you use the rds-ca-rsa2048-g1, rds-ca-rsa4096-g1, or rds-ca-ecc384-g1 CA with a database, RDS manages the DB server certificate on the database. RDS rotates the DB server certificate automatically before it expires.

## Setting the CA for your database

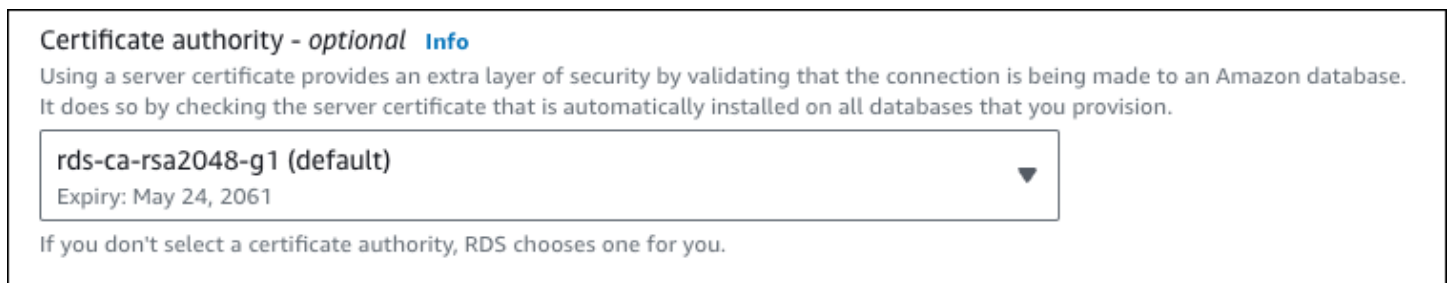

You can set the CA for a database when you perform the following tasks:

- Create a DB instance or Multi-AZ DB cluster – You can set the CA when you create a DB instance or cluster. For instructions, see [the section called “Creating a DB instance”](#) or [the section called “Creating a Multi-AZ DB cluster”](#).
- Modify a DB instance or Multi-AZ DB cluster – You can set the CA for a DB instance or cluster by modifying it. For instructions, see [the section called “Modifying a DB instance”](#) or [the section called “Modifying a Multi-AZ DB cluster”](#).

### Note

The default CA is set to rds-ca-rsa2048-g1. You can override the default CA for your AWS account by using the [modify-certificates](#) command.

The available CAs depend on the DB engine and DB engine version. When you use the AWS Management Console, you can choose the CA using the **Certificate authority** setting, as shown in the following image.

The console only shows the CAs that are available for the DB engine and DB engine version. If you're using the AWS CLI, you can set the CA for a DB instance using the [create-db-instance](#) or [modify-db-instance](#) command. You can set the CA for a Multi-AZ DB cluster using the [create-db-cluster](#) or [modify-db-cluster](#) command.

If you're using the AWS CLI, you can see the available CAs for your account by using the [describe-certificates](#) command. This command also shows the expiration date for each CA in ValidTill in the output. You can find the CAs that are available for a specific DB engine and DB engine version using the [describe-db-engine-versions](#) command.

The following example shows the CAs available for the default RDS for PostgreSQL DB engine version.

```
aws rds describe-db-engine-versions --default-only --engine postgres
```

Your output is similar to the following. The available CAs are listed in `SupportedCACertificateIdentifiers`. The output also shows whether the DB engine version supports rotating the certificate without restart in `SupportsCertificateRotationWithoutRestart`.

```
{
  "DBEngineVersions": [
    {
      "Engine": "postgres",
      "MajorEngineVersion": "13",
      "EngineVersion": "13.4",
      "DBParameterGroupFamily": "postgres13",
      "DBEngineDescription": "PostgreSQL",
      "DBEngineVersionDescription": "PostgreSQL 13.4-R1",
      "ValidUpgradeTarget": [],
      "SupportsLogExportsToCloudwatchLogs": false,
      "SupportsReadReplica": true,
      "SupportedFeatureNames": [
        "Lambda"
      ],
      "Status": "available",
      "SupportsParallelQuery": false,
      "SupportsGlobalDatabases": false,
      "SupportsBabelfish": false,
      "SupportsCertificateRotationWithoutRestart": true,
      "SupportedCACertificateIdentifiers": [
        "rds-ca-2019",
        "rds-ca-rsa2048-g1",
        "rds-ca-ecc384-g1",
        "rds-ca-rsa4096-g1"
      ]
    }
  ]
}
```

## DB server certificate validities

The validity of DB server certificate depends on the DB engine and DB engine version. If the DB engine version supports rotating the certificate without restart, the validity of the DB server certificate is 1 year. Otherwise the validity is 3 years.

For more information about DB server certificate rotation, see [Automatic server certificate rotation](#).

## Viewing the CA for your DB instance

You can view the details about the CA for a database by viewing the **Connectivity & security** tab in the console, as in the following image.

The screenshot shows the AWS Management Console interface for a database instance. The 'Connectivity & security' tab is selected and highlighted with a red box. The console displays three main sections: Endpoint & port, Networking, and Security. The 'Certificate authority' section is highlighted with a red box and contains the following information:

Section	Value
Endpoint & port	Endpoint: mysql-8-0-23-1.rds.amazonaws.com.eu-west-1.amazonaws.com Port: 3306
Networking	Availability Zone: eu-west-1c VPC: vpc-0946fa4490fbdfd65 Subnet group: default-vpc-0946fa4490fbdfd65 Subnets: subnet-0cd82b36ede3b3b8e, subnet-00c5326717b78fe7e, subnet-0bda8129ae376fe70
Security	VPC security groups: default (sg-062c8f43392f87f49) <span>Active</span> Publicly accessible: No
Certificate authority	rds-ca-2019 Certificate authority date: August 22, 2024, 19:08 (UTC+02:00) DB instance certificate expiration date: August 22, 2024, 19:08 (UTC+02:00)

If you're using the AWS CLI, you can view the details about the CA for a DB instance by using the [describe-db-instances](#) command. You can view the details about the CA for a Multi-AZ DB cluster by using the [describe-db-clusters](#) command.

## Download certificate bundles for Amazon RDS

When you connect to your database with SSL or TLS, the database instance requires a trust certificate from Amazon RDS. Select the appropriate link in the following table to download the bundle that corresponds with the AWS Region where you host your database.

### Certificate bundles by AWS Region

The certificate bundles for all AWS Regions and GovCloud (US) Regions contain the following certificates:

- `rds-ca-2019` intermediate and root certificates.
- `rds-ca-rsa2048-g1`, `rds-ca-rsa4096-g1`, and `rds-ca-ecc384-g1` root CA certificates. Your application trust store only needs to register the root CA certificate.

**Note**

Amazon RDS Proxy uses certificates from the AWS Certificate Manager (ACM). If you're using RDS Proxy, you don't need to download Amazon RDS certificates or update applications that use RDS Proxy connections. For more information, see [Using TLS/SSL with RDS Proxy](#).

To download a certificate bundle for an AWS Region, select the link for the AWS Region that hosts your database in the following table.

AWS Region	Certificate bundle (PEM)	Certificate bundle (PKCS7)
Any commercial AWS Region	<a href="#">global-bundle.pem</a>	<a href="#">global-bundle.p7b</a>
US East (N. Virginia)	<a href="#">us-east-1-bundle.pem</a>	<a href="#">us-east-1-bundle.p7b</a>
US East (Ohio)	<a href="#">us-east-2-bundle.pem</a>	<a href="#">us-east-2-bundle.p7b</a>
US West (N. California)	<a href="#">us-west-1-bundle.pem</a>	<a href="#">us-west-1-bundle.p7b</a>
US West (Oregon)	<a href="#">us-west-2-bundle.pem</a>	<a href="#">us-west-2-bundle.p7b</a>
Africa (Cape Town)	<a href="#">af-south-1-bundle.pem</a>	<a href="#">af-south-1-bundle.p7b</a>
Asia Pacific (Hong Kong)	<a href="#">ap-east-1-bundle.pem</a>	<a href="#">ap-east-1-bundle.p7b</a>
Asia Pacific (Hyderabad)	<a href="#">ap-south-2-bundle.pem</a>	<a href="#">ap-south-2-bundle.p7b</a>
Asia Pacific (Jakarta)	<a href="#">ap-southeast-3-bundle.pem</a>	<a href="#">ap-southeast-3-bundle.p7b</a>
Asia Pacific (Malaysia)	<a href="#">ap-southeast-5-bundle.pem</a>	<a href="#">ap-southeast-5-bundle.p7b</a>
Asia Pacific (Melbourne)	<a href="#">ap-southeast-4-bundle.pem</a>	<a href="#">ap-southeast-4-bundle.p7b</a>

## Viewing the contents of your CA certificate

To check the contents of your CA certificate bundle, use the following command:

```
keytool -printcert -v -file global-bundle.pem
```

## Rotating your SSL/TLS certificate

Amazon RDS Certificate Authority certificates `rds-ca-2019` are set to expire in August, 2024. If you use or plan to use Secure Sockets Layer (SSL) or Transport Layer Security (TLS) with certificate verification to connect to your RDS DB instances or Multi-AZ DB clusters, consider using one of the new CA certificates `rds-ca-rsa2048-g1`, `rds-ca-rsa4096-g1` or `rds-ca-ecc384-g1`. If you currently do not use SSL/TLS with certificate verification, you might still have an expired CA certificate and must update them to a new CA certificate if you plan to use SSL/TLS with certificate verification to connect to your RDS databases.

Amazon RDS provides new CA certificates as an AWS security best practice. For information about the new certificates and the supported AWS Regions, see [Using SSL/TLS to encrypt a connection to a DB instance or cluster](#).

To update the CA certificate for your database, use the following methods:

- [Updating your CA certificate by modifying your DB instance or cluster](#)
- [Updating your CA certificate by applying maintenance](#)

Before you update your DB instances or Multi-AZ DB clusters to use the new CA certificate, make sure that you update your clients or applications connecting to your RDS databases.

## Considerations for rotating certificates

Consider the following situations before rotating your certificate:

- Amazon RDS Proxy uses certificates from the AWS Certificate Manager (ACM). If you're using RDS Proxy, when you rotate your SSL/TLS certificate, you don't need to update applications that use RDS Proxy connections. For more information, see [Using TLS/SSL with RDS Proxy](#).
- If you're using a Go version 1.15 application with a DB instance or Multi-AZ DB cluster that was created or updated to the `rds-ca-2019` certificate prior to July 28, 2020, you must update the certificate again. Update the certificate to `rds-ca-rsa2048-g1`, `rds-ca-rsa4096-g1`, or `rds-ca-ecc384-g1` depending on your engine.

Use the `modify-db-instance` command for a DB instance, or the `modify-db-cluster` command for a Multi-AZ DB cluster, using the new CA certificate identifier. You can find the CAs that are available for a specific DB engine and DB engine version using the `describe-db-engine-versions` command.

If you created your database or updated its certificate after July 28, 2020, no action is required. For more information, see [Go GitHub issue #39568](#).

## Updating your CA certificate by modifying your DB instance or cluster

The following example updates your CA certificate from `rds-ca-2019` to `rds-ca-rsa2048-g1`. You can choose a different certificate. For more information, see [Certificate authorities](#).

Update your application trust store to reduce any down time associated with updating your CA certificate. For more information about restarts associated with CA certificate rotation, see [Automatic server certificate rotation](#).

### To update your CA certificate by modifying your DB instance or cluster

1. Download the new SSL/TLS certificate as described in [Using SSL/TLS to encrypt a connection to a DB instance or cluster](#).
2. Update your applications to use the new SSL/TLS certificate.

The methods for updating applications for new SSL/TLS certificates depend on your specific applications. Work with your application developers to update the SSL/TLS certificates for your applications.

For information about checking for SSL/TLS connections and updating applications for each DB engine, see the following topics:

- [Updating applications to connect to MariaDB instances using new SSL/TLS certificates](#)
- [Updating applications to connect to Microsoft SQL Server DB instances using new SSL/TLS certificates](#)
- [Updating applications to connect to MySQL DB instances using new SSL/TLS certificates](#)
- [Updating applications to connect to Oracle DB instances using new SSL/TLS certificates](#)
- [Updating applications to connect to PostgreSQL DB instances using new SSL/TLS certificates](#)

For a sample script that updates a trust store for a Linux operating system, see [Sample script for importing certificates into your trust store](#).

 **Note**

The certificate bundle contains certificates for both the old and new CA, so you can upgrade your application safely and maintain connectivity during the transition period. If you are using the AWS Database Migration Service to migrate a database to a DB instance or cluster, we recommend using the certificate bundle to ensure connectivity during the migration.

3. Modify the DB instance or Multi-AZ DB cluster to change the CA from **rds-ca-2019** to **rds-ca-rsa2048-g1**. To check if your database requires a restart to update the CA certificates, use the [describe-db-engine-versions](#) command and check the `SupportsCertificateRotationWithoutRestart` flag.

 **Important**

If you are experiencing connectivity issues after certificate expiry, use the `apply immediately` option by specifying **Apply immediately** in the console or by specifying the `--apply-immediately` option using the AWS CLI. By default, this operation is scheduled to run during your next maintenance window.

To set an override for your instance CA that's different from the default RDS CA, use the [modify-certificates](#) CLI command.

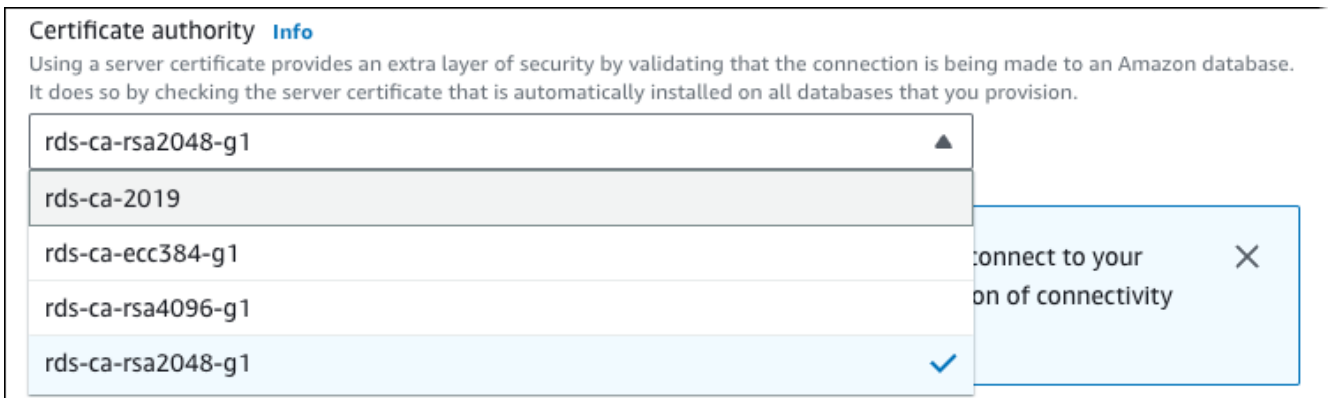

You can use the AWS Management Console or the AWS CLI to change the CA certificate from **rds-ca-2019** to **rds-ca-rsa2048-g1** for a DB instance or Multi-AZ DB cluster.

## Console

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Databases**, and then choose the DB instance or Multi-AZ DB cluster that you want to modify.
3. Choose **Modify**.

4. In the **Connectivity** section, choose **rds-ca-rsa2048-g1**.

5. Choose **Continue** and check the summary of modifications.
6. To apply the changes immediately, choose **Apply immediately**.
7. On the confirmation page, review your changes. If they are correct, choose **Modify DB Instance** or **Modify cluster** to save your changes.

**⚠ Important**

When you schedule this operation, make sure that you have updated your client-side trust store beforehand.

Or choose **Back** to edit your changes or **Cancel** to cancel your changes.

## AWS CLI

To use the AWS CLI to change the CA from **rds-ca-2019** to **rds-ca-rsa2048-g1** for a DB instance or Multi-AZ DB cluster, call the [modify-db-instance](#) or [modify-db-cluster](#) command. Specify the DB instance or cluster identifier and the `--ca-certificate-identifier` option.

Use the `--apply-immediately` parameter to apply the update immediately. By default, this operation is scheduled to run during your next maintenance window.

**⚠ Important**

When you schedule this operation, make sure that you have updated your client-side trust store beforehand.

## Example

### DB instance

The following example modifies `mydbinstance` by setting the CA certificate to `rds-ca-rsa2048-g1`.

For Linux, macOS, or Unix:

```
aws rds modify-db-instance \  
  --db-instance-identifier mydbinstance \  
  --ca-certificate-identifier rds-ca-rsa2048-g1
```

For Windows:

```
aws rds modify-db-instance ^
```

```
--db-instance-identifier mydbinstance ^  
--ca-certificate-identifier rds-ca-rsa2048-g1
```

**Note**

If your instance requires reboot, you can use the [modify-db-instance](#) CLI command and specify the `--no-certificate-rotation-restart` option.

**Example****Multi-AZ DB cluster**

The following example modifies `mydbcluster` by setting the CA certificate to `rds-ca-rsa2048-g1`.

For Linux, macOS, or Unix:

```
aws rds modify-db-cluster \  
  --db-cluster-identifier mydbcluster \  
  --ca-certificate-identifier rds-ca-rsa2048-g1
```

For Windows:

```
aws rds modify-db-cluster ^  
  --db-cluster-identifier mydbcluster ^  
  --ca-certificate-identifier rds-ca-rsa2048-g1
```

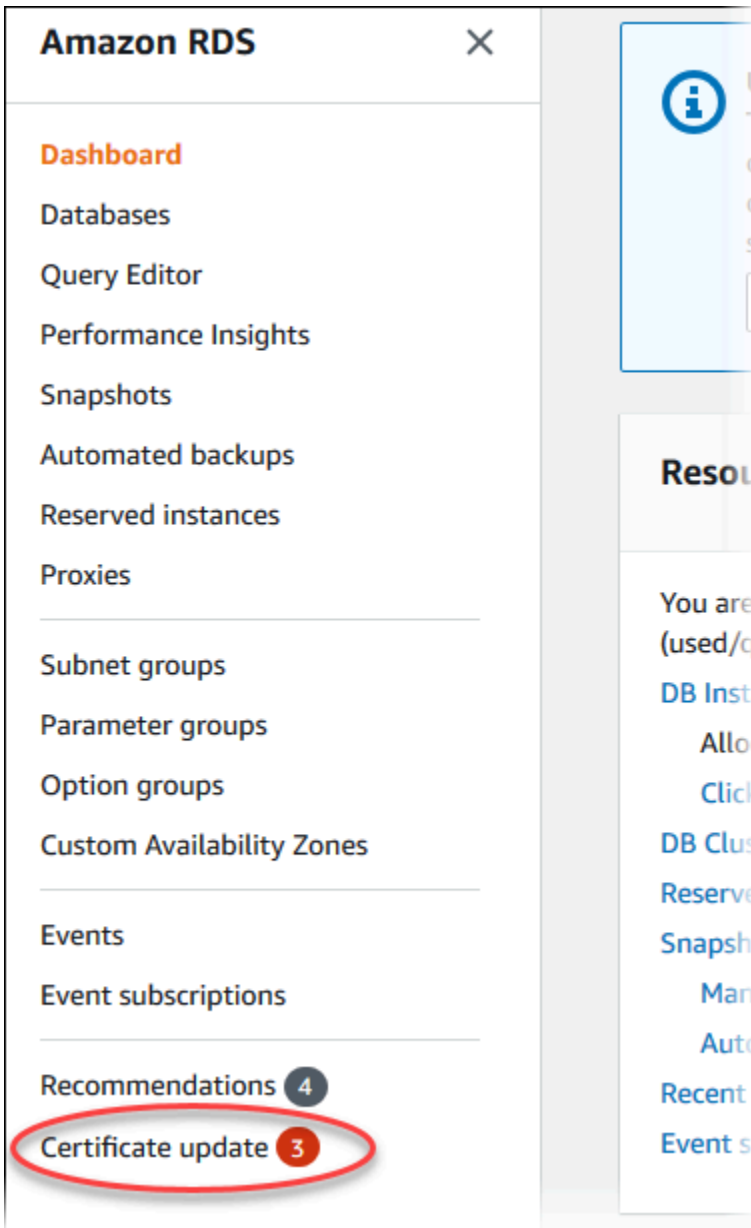

**Updating your CA certificate by applying maintenance**

Perform the following steps to update your CA certificate by applying maintenance.

Console

**To update your CA certificate by applying maintenance**

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Certificate update**.

The **Databases requiring certificate update** page appears.

RDS > Certificate update

**Databases requiring certificate update (2)** Refresh Export list Schedule Apply now

Rotate your CA Certificates before expiry date or risk losing SSL/TLS connectivity to your existing DB instances.

Filter by Databases < 1 > Settings

DB identifier ▲	Status ▼	Certificate authority ▼	CA expiration date ▼	Role ▼	Restart Required ▼	Scheduled Changes ▼	Mainten
<a href="#">database-1</a>	Available	rds-ca-2019	June 30, 2024, 10:26 (UTC-07:00)	Instance	No	No	March 05
<a href="#">database-2</a>	Available	rds-ca-2019	June 30, 2024, 10:26 (UTC-07:00)	Multi-AZ DB cluster	No	No	March 07

**Note**

This page only shows the DB instances and clusters for the current AWS Region. If you have databases in more than one AWS Region, check this page in each AWS Region to see all DB instances with old SSL/TLS certificates.

3. Choose the DB instance or Multi-AZ DB cluster that you want to update.

You can schedule the certificate rotation for your next maintenance window by choosing **Schedule**. Apply the rotation immediately by choosing **Apply now**.

**Important**

If you experience connectivity issues after certificate expiry, use the **Apply now** option.

4. a. If you choose **Schedule**, you are prompted to confirm the CA certificate rotation. This prompt also states the scheduled window for your update.

## Schedule updating your certificates ✕

**Select Certificate Authority (CA)**

Using a server certificate provides an extra layer of security by validating that the connection is being made to an Amazon database. It does so by checking the server certificate that is automatically installed on all databases that you provision.

rds-ca-rsa2048-g1  
Expiry: May 24, 2061

 **RDS Certificate Authority**  
For more information about the certificate, see [RDS Certificate Authority](#).  
Certificate update **does not require restarting your database.**

Click **Schedule** to update your certificate during the next scheduled maintenance window at September 11, 2023 02:17 - 02:47 UTC-7

Cancel Schedule

- b. If you choose **Apply now**, you are prompted to confirm the CA certificate rotation.

### Confirm updating your certificates now ✕

**Select Certificate Authority (CA)**  
Using a server certificate provides an extra layer of security by validating that the connection is being made to an Amazon database. It does so by checking the server certificate that is automatically installed on all databases that you provision.

rds-ca-rsa2048-g1 ▼  
Expiry: May 24, 2061

 **RDS Certificate Authority**  
For more information about the certificate, see [RDS Certificate Authority](#) .

Certificate update **does not require restarting your database.**

Click **Confirm** to apply certificate immediately.

Cancel **Confirm**

 **Important**

Before scheduling the CA certificate rotation on your database, update any client applications that use SSL/TLS and the server certificate to connect. These updates are specific to your DB engine. After you have updated these client applications, you can confirm the CA certificate rotation.

To continue, choose the check box, and then choose **Confirm**.

- Repeat steps 3 and 4 for each DB instance and cluster that you want to update.

## Automatic server certificate rotation

If your root CA supports automatic server certificate rotation, RDS automatically handles the rotation of the DB server certificate. RDS uses the same root CA for this automatic rotation, so you don't need to download a new CA bundle. See [Certificate authorities](#).

The rotation and validity of your DB server certificate depend on your DB engine:

- If your DB engine supports rotation without restart, RDS automatically rotates the DB server certificate without requiring any action from you. RDS attempts to rotate your DB server certificate in your preferred maintenance window at the DB server certificate half life. The new DB server certificate is valid for 12 months.
- If your DB engine doesn't support rotation without restart, RDS notifies you about a maintenance event at least 6 months before the DB server certificate expires. The new DB server certificate is valid for 36 months.

Use the [describe-db-engine-versions](#) command and inspect the `SupportsCertificateRotationWithoutRestart` flag to identify whether the DB engine version supports rotating the certificate without restart. For more information, see [Setting the CA for your database](#).

## Sample script for importing certificates into your trust store

The following are sample shell scripts that import the certificate bundle into a trust store.

Each sample shell script uses `keytool`, which is part of the Java Development Kit (JDK). For information about installing the JDK, see [JDK Installation Guide](#).

### Linux

The following is a sample shell script that imports the certificate bundle into a trust store on a Linux operating system.

```
mydir=tmp/certs
if [ ! -e "${mydir}" ]
then
mkdir -p "${mydir}"
fi
```

```

truststore=${mydir}/rds-truststore.jks
storepassword=changeit

curl -sS "https://truststore.pki.rds.amazonaws.com/global/global-bundle.pem" >
  ${mydir}/global-bundle.pem
awk 'split_after == 1 {n++;split_after=0} /-----END CERTIFICATE-----/
  {split_after=1}{print > "rds-ca-" n+1 ".pem"}' < ${mydir}/global-bundle.pem

for CERT in rds-ca-*; do
  alias=$(openssl x509 -noout -text -in $CERT | perl -ne 'next unless /Subject:;/
  s/.*(CN=|CN = )//; print')
  echo "Importing $alias"
  keytool -import -file ${CERT} -alias "${alias}" -storepass ${storepassword} -
  keystore ${truststore} -noprompt
  rm $CERT
done

rm ${mydir}/global-bundle.pem

echo "Trust store content is: "

keytool -list -v -keystore "$truststore" -storepass ${storepassword} | grep Alias |
  cut -d " " -f3- | while read alias
do
  expiry=`keytool -list -v -keystore "$truststore" -storepass ${storepassword} -
  alias "${alias}" | grep Valid | perl -ne 'if(/until: (.*?)\n/) { print "$1\n"; }`
  echo " Certificate ${alias} expires in '$expiry'"
done

```

## macOS

The following is a sample shell script that imports the certificate bundle into a trust store on macOS.

```

mydir=tmp/certs
if [ ! -e "${mydir}" ]
then
mkdir -p "${mydir}"
fi

truststore=${mydir}/rds-truststore.jks

```

```
storepassword=changeit

curl -sS "https://truststore.pki.rds.amazonaws.com/global/global-bundle.pem" >
  ${mydir}/global-bundle.pem
split -p "-----BEGIN CERTIFICATE-----" ${mydir}/global-bundle.pem rds-ca-

for CERT in rds-ca-*; do
  alias=$(openssl x509 -noout -text -in $CERT | perl -ne 'next unless /Subject:/;
  s/.*(CN=|CN = )//; print')
  echo "Importing $alias"
  keytool -import -file ${CERT} -alias "${alias}" -storepass ${storepassword} -
  keystore ${truststore} -noprompt
  rm $CERT
done

rm ${mydir}/global-bundle.pem

echo "Trust store content is: "

keytool -list -v -keystore "$truststore" -storepass ${storepassword} | grep Alias |
  cut -d " " -f3- | while read alias
do
  expiry=`keytool -list -v -keystore "$truststore" -storepass ${storepassword} -
  alias "${alias}" | grep Valid | perl -ne 'if(/until: (.*?)\n/) { print "$1\n"; }`
  echo " Certificate ${alias} expires in '$expiry'"
done
```

## Internetwork traffic privacy

Connections are protected both between Amazon RDS and on-premises applications and between Amazon RDS and other AWS resources within the same AWS Region.

### Traffic between service and on-premises clients and applications

You have two connectivity options between your private network and AWS:

- An AWS Site-to-Site VPN connection. For more information, see [What is AWS Site-to-Site VPN?](#)
- An AWS Direct Connect connection. For more information, see [What is AWS Direct Connect?](#)

You get access to Amazon RDS through the network by using AWS-published API operations. Clients must support the following:

- Transport Layer Security (TLS). We require TLS 1.2 and recommend TLS 1.3.
- Cipher suites with perfect forward secrecy (PFS) such as DHE (Ephemeral Diffie-Hellman) or ECDHE (Elliptic Curve Ephemeral Diffie-Hellman). Most modern systems such as Java 7 and later support these modes.

Additionally, requests must be signed by using an access key ID and a secret access key that is associated with an IAM principal. Or you can use the [AWS Security Token Service](#) (AWS STS) to generate temporary security credentials to sign requests.

# Identity and access management for Amazon RDS

AWS Identity and Access Management (IAM) is an AWS service that helps an administrator securely control access to AWS resources. IAM administrators control who can be *authenticated* (signed in) and *authorized* (have permissions) to use Amazon RDS resources. IAM is an AWS service that you can use with no additional charge.

## Topics

- [Audience](#)
- [Authenticating with identities](#)
- [Managing access using policies](#)
- [How Amazon RDS works with IAM](#)
- [Identity-based policy examples for Amazon RDS](#)
- [AWS managed policies for Amazon RDS](#)
- [Amazon RDS updates to AWS managed policies](#)
- [Preventing cross-service confused deputy problems](#)
- [IAM database authentication for MariaDB, MySQL, and PostgreSQL](#)
- [Troubleshooting Amazon RDS identity and access](#)

## Audience

How you use AWS Identity and Access Management (IAM) differs, depending on the work you do in Amazon RDS.

**Service user** – If you use the Amazon RDS service to do your job, then your administrator provides you with the credentials and permissions that you need. As you use more Amazon RDS features to do your work, you might need additional permissions. Understanding how access is managed can help you request the right permissions from your administrator. If you cannot access a feature in Amazon RDS, see [Troubleshooting Amazon RDS identity and access](#).

**Service administrator** – If you're in charge of Amazon RDS resources at your company, you probably have full access to Amazon RDS. It's your job to determine which Amazon RDS features and resources your employees should access. You must then submit requests to your administrator to change the permissions of your service users. Review the information on this page to understand

the basic concepts of IAM. To learn more about how your company can use IAM with Amazon RDS, see [How Amazon RDS works with IAM](#).

**Administrator** – If you're an administrator, you might want to learn details about how you can write policies to manage access to Amazon RDS. To view example Amazon RDS identity-based policies that you can use in IAM, see [Identity-based policy examples for Amazon RDS](#).

## Authenticating with identities

Authentication is how you sign in to AWS using your identity credentials. You must be *authenticated* (signed in to AWS) as the AWS account root user, as an IAM user, or by assuming an IAM role.

You can sign in to AWS as a federated identity by using credentials provided through an identity source. AWS IAM Identity Center (IAM Identity Center) users, your company's single sign-on authentication, and your Google or Facebook credentials are examples of federated identities. When you sign in as a federated identity, your administrator previously set up identity federation using IAM roles. When you access AWS by using federation, you are indirectly assuming a role.

Depending on the type of user you are, you can sign in to the AWS Management Console or the AWS access portal. For more information about signing in to AWS, see [How to sign in to your AWS account](#) in the *AWS Sign-In User Guide*.

If you access AWS programmatically, AWS provides a software development kit (SDK) and a command line interface (CLI) to cryptographically sign your requests by using your credentials. If you don't use AWS tools, you must sign requests yourself. For more information about using the recommended method to sign requests yourself, see [Signing AWS API requests](#) in the *IAM User Guide*.

Regardless of the authentication method that you use, you might be required to provide additional security information. For example, AWS recommends that you use multi-factor authentication (MFA) to increase the security of your account. To learn more, see [Multi-factor authentication](#) in the *AWS IAM Identity Center User Guide* and [Using multi-factor authentication \(MFA\) in AWS](#) in the *IAM User Guide*.

## AWS account root user

When you create an AWS account, you begin with one sign-in identity that has complete access to all AWS services and resources in the account. This identity is called the AWS account *root user* and is accessed by signing in with the email address and password that you used to create the account.

We strongly recommend that you don't use the root user for your everyday tasks. Safeguard your root user credentials and use them to perform the tasks that only the root user can perform. For the complete list of tasks that require you to sign in as the root user, see [Tasks that require root user credentials](#) in the *IAM User Guide*.

## Federated identity

As a best practice, require human users, including users that require administrator access, to use federation with an identity provider to access AWS services by using temporary credentials.

A *federated identity* is a user from your enterprise user directory, a web identity provider, the AWS Directory Service, the Identity Center directory, or any user that accesses AWS services by using credentials provided through an identity source. When federated identities access AWS accounts, they assume roles, and the roles provide temporary credentials.

For centralized access management, we recommend that you use AWS IAM Identity Center. You can create users and groups in IAM Identity Center, or you can connect and synchronize to a set of users and groups in your own identity source for use across all your AWS accounts and applications. For information about IAM Identity Center, see [What is IAM Identity Center?](#) in the *AWS IAM Identity Center User Guide*.

## IAM users and groups

An [IAM user](#) is an identity within your AWS account that has specific permissions for a single person or application. Where possible, we recommend relying on temporary credentials instead of creating IAM users who have long-term credentials such as passwords and access keys. However, if you have specific use cases that require long-term credentials with IAM users, we recommend that you rotate access keys. For more information, see [Rotate access keys regularly for use cases that require long-term credentials](#) in the *IAM User Guide*.

An [IAM group](#) is an identity that specifies a collection of IAM users. You can't sign in as a group. You can use groups to specify permissions for multiple users at a time. Groups make permissions easier to manage for large sets of users. For example, you could have a group named *IAMAdmins* and give that group permissions to administer IAM resources.

Users are different from roles. A user is uniquely associated with one person or application, but a role is intended to be assumable by anyone who needs it. Users have permanent long-term credentials, but roles provide temporary credentials. To learn more, see [When to create an IAM user \(instead of a role\)](#) in the *IAM User Guide*.

You can authenticate to your DB instance using IAM database authentication.

IAM database authentication works with the following DB engines:

- RDS for MariaDB
- RDS for MySQL
- RDS for PostgreSQL

For more information about authenticating to your DB instance using IAM, see [IAM database authentication for MariaDB, MySQL, and PostgreSQL](#).

## IAM roles

An [IAM role](#) is an identity within your AWS account that has specific permissions. It is similar to a user, but is not associated with a specific person. You can temporarily assume an IAM role in the AWS Management Console by [switching roles](#). You can assume a role by calling an AWS CLI or AWS API operation or by using a custom URL. For more information about methods for using roles, see [Using IAM roles](#) in the *IAM User Guide*.

IAM roles with temporary credentials are useful in the following situations:

- **Temporary user permissions** – A user can assume an IAM role to temporarily take on different permissions for a specific task.
- **Federated user access** – To assign permissions to a federated identity, you create a role and define permissions for the role. When a federated identity authenticates, the identity is associated with the role and is granted the permissions that are defined by the role. For information about roles for federation, see [Creating a role for a third-party Identity Provider](#) in the *IAM User Guide*. If you use IAM Identity Center, you configure a permission set. To control what your identities can access after they authenticate, IAM Identity Center correlates the permission set to a role in IAM. For information about permission sets, see [Permission sets](#) in the *AWS IAM Identity Center User Guide*.
- **Cross-account access** – You can use an IAM role to allow someone (a trusted principal) in a different account to access resources in your account. Roles are the primary way to grant cross-account access. However, with some AWS services, you can attach a policy directly to a resource (instead of using a role as a proxy). To learn the difference between roles and resource-based policies for cross-account access, see [How IAM roles differ from resource-based policies](#) in the *IAM User Guide*.

- **Cross-service access** – Some AWS services use features in other AWS services. For example, when you make a call in a service, it's common for that service to run applications in Amazon EC2 or store objects in Amazon S3. A service might do this using the calling principal's permissions, using a service role, or using a service-linked role.
- **Forward access sessions** – When you use an IAM user or role to perform actions in AWS, you are considered a principal. When you use some services, you might perform an action that then initiates another action in a different service. FAS uses the permissions of the principal calling an AWS service, combined with the requesting AWS service to make requests to downstream services. FAS requests are only made when a service receives a request that requires interactions with other AWS services or resources to complete. In this case, you must have permissions to perform both actions. For policy details when making FAS requests, see [Forward access sessions](#).
- **Service role** – A service role is an [IAM role](#) that a service assumes to perform actions on your behalf. An IAM administrator can create, modify, and delete a service role from within IAM. For more information, see [Creating a role to delegate permissions to an AWS service](#) in the *IAM User Guide*.
- **Service-linked role** – A service-linked role is a type of service role that is linked to an AWS service. The service can assume the role to perform an action on your behalf. Service-linked roles appear in your AWS account and are owned by the service. An IAM administrator can view, but not edit the permissions for service-linked roles.
- **Applications running on Amazon EC2** – You can use an IAM role to manage temporary credentials for applications that are running on an EC2 instance and making AWS CLI or AWS API requests. This is preferable to storing access keys within the EC2 instance. To assign an AWS role to an EC2 instance and make it available to all of its applications, you create an instance profile that is attached to the instance. An instance profile contains the role and enables programs that are running on the EC2 instance to get temporary credentials. For more information, see [Using an IAM role to grant permissions to applications running on Amazon EC2 instances](#) in the *IAM User Guide*.

To learn whether to use IAM roles, see [When to create an IAM role \(instead of a user\)](#) in the *IAM User Guide*.

## Managing access using policies

You control access in AWS by creating policies and attaching them to IAM identities or AWS resources. A policy is an object in AWS that, when associated with an identity or resource, defines

their permissions. AWS evaluates these policies when an entity (root user, user, or IAM role) makes a request. Permissions in the policies determine whether the request is allowed or denied. Most policies are stored in AWS as JSON documents. For more information about the structure and contents of JSON policy documents, see [Overview of JSON policies](#) in the *IAM User Guide*.

An administrator can use policies to specify who has access to AWS resources, and what actions they can perform on those resources. Every IAM entity (permission set or role) starts with no permissions. In other words, by default, users can do nothing, not even change their own password. To give a user permission to do something, an administrator must attach a permissions policy to a user. Or the administrator can add the user to a group that has the intended permissions. When an administrator gives permissions to a group, all users in that group are granted those permissions.

IAM policies define permissions for an action regardless of the method that you use to perform the operation. For example, suppose that you have a policy that allows the `iam:GetRole` action. A user with that policy can get role information from the AWS Management Console, the AWS CLI, or the AWS API.

## Identity-based policies

Identity-based policies are JSON permissions policy documents that you can attach to an identity, such as a permission set or role. These policies control what actions that identity can perform, on which resources, and under what conditions. To learn how to create an identity-based policy, see [Creating IAM policies](#) in the *IAM User Guide*.

Identity-based policies can be further categorized as *inline policies* or *managed policies*. Inline policies are embedded directly into a single permission set or role. Managed policies are standalone policies that you can attach to multiple permission sets and roles in your AWS account. Managed policies include AWS managed policies and customer managed policies. To learn how to choose between a managed policy or an inline policy, see [Choosing between managed policies and inline policies](#) in the *IAM User Guide*.

For information about AWS managed policies that are specific to Amazon RDS, see [AWS managed policies for Amazon RDS](#).

## Other policy types

AWS supports additional, less-common policy types. These policy types can set the maximum permissions granted to you by the more common policy types.

- **Permissions boundaries** – A permissions boundary is an advanced feature in which you set the maximum permissions that an identity-based policy can grant to an IAM entity (permission set or role). You can set a permissions boundary for an entity. The resulting permissions are the intersection of entity's identity-based policies and its permissions boundaries. Resource-based policies that specify the permission set or role in the `Principal` field are not limited by the permissions boundary. An explicit deny in any of these policies overrides the allow. For more information about permissions boundaries, see [Permissions boundaries for IAM entities](#) in the *IAM User Guide*.
- **Service control policies (SCPs)** – SCPs are JSON policies that specify the maximum permissions for an organization or organizational unit (OU) in AWS Organizations. AWS Organizations is a service for grouping and centrally managing multiple AWS accounts that your business owns. If you enable all features in an organization, then you can apply service control policies (SCPs) to any or all of your accounts. The SCP limits permissions for entities in member accounts, including each AWS account root user. For more information about Organizations and SCPs, see [How SCPs work](#) in the *AWS Organizations User Guide*.
- **Session policies** – Session policies are advanced policies that you pass as a parameter when you programmatically create a temporary session for a role or federated user. The resulting session's permissions are the intersection of the permission sets or role's identity-based policies and the session policies. Permissions can also come from a resource-based policy. An explicit deny in any of these policies overrides the allow. For more information, see [Session policies](#) in the *IAM User Guide*.

## Multiple policy types

When multiple types of policies apply to a request, the resulting permissions are more complicated to understand. To learn how AWS determines whether to allow a request when multiple policy types are involved, see [Policy evaluation logic](#) in the *IAM User Guide*.

## How Amazon RDS works with IAM

Before you use IAM to manage access to Amazon RDS, you should understand what IAM features are available to use with Amazon RDS.

The following table lists IAM features you can use with Amazon RDS:

IAM feature	Amazon RDS support
<a href="#">Identity-based policies</a>	Yes
<a href="#">Resource-based policies</a>	No
<a href="#">Policy actions</a>	Yes
<a href="#">Policy resources</a>	Yes
<a href="#">Policy condition keys (service-specific)</a>	Yes
<a href="#">ACLs</a>	No
<a href="#">Attribute-based access control (ABAC) (tags in policies)</a>	Yes
<a href="#">Temporary credentials</a>	Yes
<a href="#">Forward access sessions</a>	Yes
<a href="#">Service roles</a>	Yes
<a href="#">Service-linked roles</a>	Yes

To get a high-level view of how Amazon RDS and other AWS services work with IAM, see [AWS services that work with IAM](#) in the *IAM User Guide*.

## Topics

- [Resource-based policies within Amazon RDS](#)
- [Policy actions for Amazon RDS](#)
- [Policy resources for Amazon RDS](#)
- [Policy condition keys for Amazon RDS](#)
- [Access control lists \(ACLs\) in Amazon RDS](#)
- [Attribute-based access control \(ABAC\) in policies with Amazon RDS tags](#)
- [Using temporary credentials with Amazon RDS](#)

- [Forward access sessions for Amazon RDS](#)
- [Service roles for Amazon RDS](#)
- [Service-linked roles for Amazon RDS](#)

## Amazon RDS identity-based policies

**Supports identity-based policies:** Yes.

Identity-based policies are JSON permissions policy documents that you can attach to an identity, such as an IAM user, group of users, or role. These policies control what actions users and roles can perform, on which resources, and under what conditions. To learn how to create an identity-based policy, see [Creating IAM policies](#) in the *IAM User Guide*.

With IAM identity-based policies, you can specify allowed or denied actions and resources as well as the conditions under which actions are allowed or denied. You can't specify the principal in an identity-based policy because it applies to the user or role to which it is attached. To learn about all of the elements that you can use in a JSON policy, see [IAM JSON policy elements reference](#) in the *IAM User Guide*.

### Identity-based policy examples for Amazon RDS

To view examples of Amazon RDS identity-based policies, see [Identity-based policy examples for Amazon RDS](#).

## Resource-based policies within Amazon RDS

**Supports resource-based policies:** No.

Resource-based policies are JSON policy documents that you attach to a resource. Examples of resource-based policies are *IAM role trust policies* and *Amazon S3 bucket policies*. In services that support resource-based policies, service administrators can use them to control access to a specific resource. For the resource where the policy is attached, the policy defines what actions a specified principal can perform on that resource and under what conditions. You must [specify a principal](#) in a resource-based policy. Principals can include accounts, users, roles, federated users, or AWS services.

To enable cross-account access, you can specify an entire account or IAM entities in another account as the principal in a resource-based policy. Adding a cross-account principal to a resource-

based policy is only half of establishing the trust relationship. When the principal and the resource are in different AWS accounts, an IAM administrator in the trusted account must also grant the principal entity (user or role) permission to access the resource. They grant permission by attaching an identity-based policy to the entity. However, if a resource-based policy grants access to a principal in the same account, no additional identity-based policy is required. For more information, see [Cross account resource access in IAM](#) in the *IAM User Guide*.

## Policy actions for Amazon RDS

**Supports policy actions:** Yes.

Administrators can use AWS JSON policies to specify who has access to what. That is, which **principal** can perform **actions** on what **resources**, and under what **conditions**.

The **Action** element of a JSON policy describes the actions that you can use to allow or deny access in a policy. Policy actions usually have the same name as the associated AWS API operation. There are some exceptions, such as *permission-only actions* that don't have a matching API operation. There are also some operations that require multiple actions in a policy. These additional actions are called *dependent actions*.

Include actions in a policy to grant permissions to perform the associated operation.

Policy actions in Amazon RDS use the following prefix before the action: `rds:`. For example, to grant someone permission to describe DB instances with the Amazon RDS `DescribeDBInstances` API operation, you include the `rds:DescribeDBInstances` action in their policy. Policy statements must include either an **Action** or **NotAction** element. Amazon RDS defines its own set of actions that describe tasks that you can perform with this service.

To specify multiple actions in a single statement, separate them with commas as follows.

```
"Action": [  
    "rds:action1",  
    "rds:action2"
```

You can specify multiple actions using wildcards (\*). For example, to specify all actions that begin with the word `Describe`, include the following action.

```
"Action": "rds:Describe*"
```

To see a list of Amazon RDS actions, see [Actions Defined by Amazon RDS](#) in the *Service Authorization Reference*.

## Policy resources for Amazon RDS

**Supports policy resources:** Yes.

Administrators can use AWS JSON policies to specify who has access to what. That is, which **principal** can perform **actions** on what **resources**, and under what **conditions**.

The Resource JSON policy element specifies the object or objects to which the action applies. Statements must include either a Resource or a NotResource element. As a best practice, specify a resource using its [Amazon Resource Name \(ARN\)](#). You can do this for actions that support a specific resource type, known as *resource-level permissions*.

For actions that don't support resource-level permissions, such as listing operations, use a wildcard (\*) to indicate that the statement applies to all resources.

```
"Resource": "*" 
```

The DB instance resource has the following Amazon Resource Name (ARN).

```
arn:${Partition}:rds:${Region}:${Account}:{ResourceType}/${Resource}
```

For more information about the format of ARNs, see [Amazon Resource Names \(ARNs\) and AWS service namespaces](#).

For example, to specify the dbtest DB instance in your statement, use the following ARN.

```
"Resource": "arn:aws:rds:us-west-2:123456789012:db:dbtest" 
```

To specify all DB instances that belong to a specific account, use the wildcard (\*).

```
"Resource": "arn:aws:rds:us-east-1:123456789012:db:*" 
```

Some RDS API operations, such as those for creating resources, can't be performed on a specific resource. In those cases, use the wildcard (\*).

```
"Resource": "*"
```

Many Amazon RDS API operations involve multiple resources. For example, `CreateDBInstance` creates a DB instance. You can specify that an user must use a specific security group and parameter group when creating a DB instance. To specify multiple resources in a single statement, separate the ARNs with commas.

```
"Resource": [  
    "resource1",  
    "resource2"
```

To see a list of Amazon RDS resource types and their ARNs, see [Resources Defined by Amazon RDS](#) in the *Service Authorization Reference*. To learn with which actions you can specify the ARN of each resource, see [Actions Defined by Amazon RDS](#).

## Policy condition keys for Amazon RDS

**Supports service-specific policy condition keys:** Yes.

Administrators can use AWS JSON policies to specify who has access to what. That is, which **principal** can perform **actions** on what **resources**, and under what **conditions**.

The `Condition` element (or *Condition block*) lets you specify conditions in which a statement is in effect. The `Condition` element is optional. You can create conditional expressions that use [condition operators](#), such as equals or less than, to match the condition in the policy with values in the request.

If you specify multiple `Condition` elements in a statement, or multiple keys in a single `Condition` element, AWS evaluates them using a logical AND operation. If you specify multiple values for a single condition key, AWS evaluates the condition using a logical OR operation. All of the conditions must be met before the statement's permissions are granted.

You can also use placeholder variables when you specify conditions. For example, you can grant an IAM user permission to access a resource only if it is tagged with their IAM user name. For more information, see [IAM policy elements: variables and tags](#) in the *IAM User Guide*.

AWS supports global condition keys and service-specific condition keys. To see all AWS global condition keys, see [AWS global condition context keys](#) in the *IAM User Guide*.

Amazon RDS defines its own set of condition keys and also supports using some global condition keys. To see all AWS global condition keys, see [AWS global condition context keys](#) in the *IAM User Guide*.

All RDS API operations support the `aws:RequestedRegion` condition key.

To see a list of Amazon RDS condition keys, see [Condition Keys for Amazon RDS](#) in the *Service Authorization Reference*. To learn with which actions and resources you can use a condition key, see [Actions Defined by Amazon RDS](#).

## Access control lists (ACLs) in Amazon RDS

**Supports access control lists (ACLs):** No

Access control lists (ACLs) control which principals (account members, users, or roles) have permissions to access a resource. ACLs are similar to resource-based policies, although they do not use the JSON policy document format.

## Attribute-based access control (ABAC) in policies with Amazon RDS tags

**Supports attribute-based access control (ABAC) tags in policies:** Yes

Attribute-based access control (ABAC) is an authorization strategy that defines permissions based on attributes. In AWS, these attributes are called *tags*. You can attach tags to IAM entities (users or roles) and to many AWS resources. Tagging entities and resources is the first step of ABAC. Then you design ABAC policies to allow operations when the principal's tag matches the tag on the resource that they are trying to access.

ABAC is helpful in environments that are growing rapidly and helps with situations where policy management becomes cumbersome.

To control access based on tags, you provide tag information in the [condition element](#) of a policy using the `aws:ResourceTag/key-name`, `aws:RequestTag/key-name`, or `aws:TagKeys` condition keys.

If a service supports all three condition keys for every resource type, then the value is **Yes** for the service. If a service supports all three condition keys for only some resource types, then the value is **Partial**.

For more information about ABAC, see [What is ABAC?](#) in the *IAM User Guide*. To view a tutorial with steps for setting up ABAC, see [Use attribute-based access control \(ABAC\)](#) in the *IAM User Guide*.

For more information about tagging Amazon RDS resources, see [Specifying conditions: Using custom tags](#). To view an example identity-based policy for limiting access to a resource based on the tags on that resource, see [Grant permission for actions on a resource with a specific tag with two different values](#).

## Using temporary credentials with Amazon RDS

**Supports temporary credentials:** Yes.

Some AWS services don't work when you sign in using temporary credentials. For additional information, including which AWS services work with temporary credentials, see [AWS services that work with IAM](#) in the *IAM User Guide*.

You are using temporary credentials if you sign in to the AWS Management Console using any method except a user name and password. For example, when you access AWS using your company's single sign-on (SSO) link, that process automatically creates temporary credentials. You also automatically create temporary credentials when you sign in to the console as a user and then switch roles. For more information about switching roles, see [Switching to a role \(console\)](#) in the *IAM User Guide*.

You can manually create temporary credentials using the AWS CLI or AWS API. You can then use those temporary credentials to access AWS. AWS recommends that you dynamically generate temporary credentials instead of using long-term access keys. For more information, see [Temporary security credentials in IAM](#).

## Forward access sessions for Amazon RDS

**Supports forward access sessions:** Yes.

When you use an IAM user or role to perform actions in AWS, you are considered a principal. When you use some services, you might perform an action that then initiates another action in a different service. FAS uses the permissions of the principal calling an AWS service, combined with the requesting AWS service to make requests to downstream services. FAS requests are only made when a service receives a request that requires interactions with other AWS services or resources to complete. In this case, you must have permissions to perform both actions. For policy details when making FAS requests, see [Forward access sessions](#).

## Service roles for Amazon RDS

**Supports service roles:** Yes.

A service role is an [IAM role](#) that a service assumes to perform actions on your behalf. An IAM administrator can create, modify, and delete a service role from within IAM. For more information, see [Creating a role to delegate permissions to an AWS service](#) in the *IAM User Guide*.

### **Warning**

Changing the permissions for a service role might break Amazon RDS functionality. Edit service roles only when Amazon RDS provides guidance to do so.

## Service-linked roles for Amazon RDS

**Supports service-linked roles:** Yes.

A service-linked role is a type of service role that is linked to an AWS service. The service can assume the role to perform an action on your behalf. Service-linked roles appear in your AWS account and are owned by the service. An IAM administrator can view, but not edit the permissions for service-linked roles.

For details about using Amazon RDS service-linked roles, see [Using service-linked roles for Amazon RDS](#).

## Identity-based policy examples for Amazon RDS

By default, permission sets and roles don't have permission to create or modify Amazon RDS resources. They also can't perform tasks using the AWS Management Console, AWS CLI, or AWS API. An administrator must create IAM policies that grant permission sets and roles permission to perform specific API operations on the specified resources they need. The administrator must then attach those policies to the permission sets or roles that require those permissions.

To learn how to create an IAM identity-based policy using these example JSON policy documents, see [Creating policies on the JSON tab](#) in the *IAM User Guide*.

### Topics

- [Policy best practices](#)
- [Using the Amazon RDS console](#)
- [Permissions required to use the console](#)
- [Allow users to view their own permissions](#)

- [Permission policies to create, modify and, delete resources in Amazon RDS](#)
- [Example policies: Using condition keys](#)
- [Specifying conditions: Using custom tags](#)

## Policy best practices

Identity-based policies determine whether someone can create, access, or delete Amazon RDS resources in your account. These actions can incur costs for your AWS account. When you create or edit identity-based policies, follow these guidelines and recommendations:

- **Get started with AWS managed policies and move toward least-privilege permissions** – To get started granting permissions to your users and workloads, use the *AWS managed policies* that grant permissions for many common use cases. They are available in your AWS account. We recommend that you reduce permissions further by defining AWS customer managed policies that are specific to your use cases. For more information, see [AWS managed policies](#) or [AWS managed policies for job functions](#) in the *IAM User Guide*.
- **Apply least-privilege permissions** – When you set permissions with IAM policies, grant only the permissions required to perform a task. You do this by defining the actions that can be taken on specific resources under specific conditions, also known as *least-privilege permissions*. For more information about using IAM to apply permissions, see [Policies and permissions in IAM](#) in the *IAM User Guide*.
- **Use conditions in IAM policies to further restrict access** – You can add a condition to your policies to limit access to actions and resources. For example, you can write a policy condition to specify that all requests must be sent using SSL. You can also use conditions to grant access to service actions if they are used through a specific AWS service, such as AWS CloudFormation. For more information, see [IAM JSON policy elements: Condition](#) in the *IAM User Guide*.
- **Use IAM Access Analyzer to validate your IAM policies to ensure secure and functional permissions** – IAM Access Analyzer validates new and existing policies so that the policies adhere to the IAM policy language (JSON) and IAM best practices. IAM Access Analyzer provides more than 100 policy checks and actionable recommendations to help you author secure and functional policies. For more information, see [IAM Access Analyzer policy validation](#) in the *IAM User Guide*.
- **Require multi-factor authentication (MFA)** – If you have a scenario that requires IAM users or a root user in your AWS account, turn on MFA for additional security. To require MFA when API operations are called, add MFA conditions to your policies. For more information, see [Configuring MFA-protected API access](#) in the *IAM User Guide*.

For more information about best practices in IAM, see [Security best practices in IAM](#) in the *IAM User Guide*.

## Using the Amazon RDS console

To access the Amazon RDS console, you must have a minimum set of permissions. These permissions must allow you to list and view details about the Amazon RDS resources in your AWS account. If you create an identity-based policy that is more restrictive than the minimum required permissions, the console won't function as intended for entities (users or roles) with that policy.

You don't need to allow minimum console permissions for users that are making calls only to the AWS CLI or the AWS API. Instead, allow access to only the actions that match the API operation that you're trying to perform.

To ensure that those entities can still use the Amazon RDS console, also attach the following AWS managed policy to the entities.

```
AmazonRDSReadOnlyAccess
```

For more information, see [Adding permissions to a user](#) in the *IAM User Guide*.

## Permissions required to use the console

For a user to work with the console, that user must have a minimum set of permissions. These permissions allow the user to describe the Amazon RDS resources for their AWS account and to provide other related information, including Amazon EC2 security and network information.

If you create an IAM policy that is more restrictive than the minimum required permissions, the console doesn't function as intended for users with that IAM policy. To ensure that those users can still use the console, also attach the AmazonRDSReadOnlyAccess managed policy to the user, as described in [Managing access using policies](#).

You don't need to allow minimum console permissions for users that are making calls only to the AWS CLI or the Amazon RDS API.

The following policy grants full access to all Amazon RDS resources for the root AWS account:

```
AmazonRDSFullAccess
```

## Allow users to view their own permissions

This example shows how you might create a policy that allows IAM users to view the inline and managed policies that are attached to their user identity. This policy includes permissions to complete this action on the console or programmatically using the AWS CLI or AWS API.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "ViewOwnUserInfo",
      "Effect": "Allow",
      "Action": [
        "iam:GetUserPolicy",
        "iam:ListGroupsForUser",
        "iam:ListAttachedUserPolicies",
        "iam:ListUserPolicies",
        "iam:GetUser"
      ],
      "Resource": ["arn:aws:iam::*:user/${aws:username}"]
    },
    {
      "Sid": "NavigateInConsole",
      "Effect": "Allow",
      "Action": [
        "iam:GetGroupPolicy",
        "iam:GetPolicyVersion",
        "iam:GetPolicy",
        "iam:ListAttachedGroupPolicies",
        "iam:ListGroupPolicies",
        "iam:ListPolicyVersions",
        "iam:ListPolicies",
        "iam:ListUsers"
      ],
      "Resource": "*"
    }
  ]
}
```

## Permission policies to create, modify and, delete resources in Amazon RDS

The following sections present examples of permission policies that grant and restrict access to resources:

## Allow a user to create DB instances in an AWS account

The following is an example policy that allows the account with the ID 123456789012 to create DB instances for your AWS account. The policy requires that the name of the new DB instance begin with `test`. The new DB instance must also use the MySQL database engine and the `db.t2.micro` DB instance class. In addition, the new DB instance must use an option group and a DB parameter group that starts with `default`, and it must use the `default` subnet group.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "AllowCreateDBInstanceOnly",
      "Effect": "Allow",
      "Action": [
        "rds:CreateDBInstance"
      ],
      "Resource": [
        "arn:aws:rds*:123456789012:db:test*",
        "arn:aws:rds*:123456789012:og:default*",
        "arn:aws:rds*:123456789012:pg:default*",
        "arn:aws:rds*:123456789012:subgrp:default"
      ],
      "Condition": {
        "StringEquals": {
          "rds:DatabaseEngine": "mysql",
          "rds:DatabaseClass": "db.t2.micro"
        }
      }
    }
  ]
}
```

The policy includes a single statement that specifies the following permissions for the user:

- The policy allows the account to create a DB instance using the [CreateDBInstance](#) API operation (this also applies to the [create-db-instance](#) AWS CLI command and the AWS Management Console).
- The `Resource` element specifies that the user can perform actions on or with resources. You specify resources using an Amazon Resources Name (ARN). This ARN includes the name of the service that the resource belongs to (`rds`), the AWS Region (`*` indicates any region in this

example), the AWS account number (123456789012 is the account number in this example), and the type of resource. For more information about creating ARNs, see [Amazon Resource Names \(ARNs\) in Amazon RDS](#).

The Resource element in the example specifies the following policy constraints on resources for the user:

- The DB instance identifier for the new DB instance must begin with `test` (for example, `testCustomerData1`, `test-region2-data`).
- The option group for the new DB instance must begin with `default`.
- The DB parameter group for the new DB instance must begin with `default`.
- The subnet group for the new DB instance must be the `default` subnet group.
- The Condition element specifies that the DB engine must be MySQL and the DB instance class must be `db.t2.micro`. The Condition element specifies the conditions when a policy should take effect. You can add additional permissions or restrictions by using the Condition element. For more information about specifying conditions, see [Policy condition keys for Amazon RDS](#). This example specifies the `rds:DatabaseEngine` and `rds:DatabaseClass` conditions. For information about the valid condition values for `rds:DatabaseEngine`, see the list under the Engine parameter in [CreateDBInstance](#). For information about the valid condition values for `rds:DatabaseClass`, see [Supported DB engines for DB instance classes](#).

The policy doesn't specify the Principal element because in an identity-based policy you don't specify the principal who gets the permission. When you attach policy to a user, the user is the implicit principal. When you attach a permission policy to an IAM role, the principal identified in the role's trust policy gets the permissions.

To see a list of Amazon RDS actions, see [Actions Defined by Amazon RDS](#) in the *Service Authorization Reference*.

### Allow a user to perform any describe action on any RDS resource

The following permissions policy grants permissions to a user to run all of the actions that begin with `Describe`. These actions show information about an RDS resource, such as a DB instance. The wildcard character (\*) in the Resource element indicates that the actions are allowed for all Amazon RDS resources owned by the account.

```
{
  "Version": "2012-10-17",
```

```

"Statement": [
  {
    "Sid": "AllowRDSDescribe",
    "Effect": "Allow",
    "Action": "rds:Describe*",
    "Resource": "*"
  }
]
}

```

## Allow a user to create a DB instance that uses the specified DB parameter group and subnet group

The following permissions policy grants permissions to allow a user to only create a DB instance that must use the mydbpg DB parameter group and the mydbsubnetgroup DB subnet group.

```

{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "VisualEditor0",
      "Effect": "Allow",
      "Action": "rds:CreateDBInstance",
      "Resource": [
        "arn:aws:rds:*:*:pg:mydbpg",
        "arn:aws:rds:*:*:subgrp:mydbsubnetgroup"
      ]
    }
  ]
}

```

## Grant permission for actions on a resource with a specific tag with two different values

You can use conditions in your identity-based policy to control access to Amazon RDS resources based on tags. The following policy allows permission to perform the CreateDBSnapshot API operation on DB instances with either the stage tag set to development or test.

```

{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "AllowAnySnapshotName",

```

```

    "Effect": "Allow",
    "Action": [
        "rds:CreateDBSnapshot"
    ],
    "Resource": "arn:aws:rds:*:123456789012:snapshot:*"
},
{
    "Sid": "AllowDevTestToCreateSnapshot",
    "Effect": "Allow",
    "Action": [
        "rds:CreateDBSnapshot"
    ],
    "Resource": "arn:aws:rds:*:123456789012:db:*",
    "Condition": {
        "StringEquals": {
            "rds:db-tag/stage": [
                "development",
                "test"
            ]
        }
    }
}
]
}

```

The following policy allows permission to perform the `ModifyDBInstance` API operation on DB instances with either the stage tag set to development or test.

```

{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "AllowChangingParameterOptionSecurityGroups",
            "Effect": "Allow",
            "Action": [
                "rds:ModifyDBInstance"
            ],
            "Resource": [
                "arn:aws:rds:*:123456789012:pg:*",
                "arn:aws:rds:*:123456789012:secgrp:*",
                "arn:aws:rds:*:123456789012:og:*"
            ]
        }
    ],
}

```

```
{
  "Sid": "AllowDevTestToModifyInstance",
  "Effect": "Allow",
  "Action": [
    "rds:ModifyDBInstance"
  ],
  "Resource": "arn:aws:rds:*:123456789012:db:*",
  "Condition": {
    "StringEquals": {
      "rds:db-tag/stage": [
        "development",
        "test"
      ]
    }
  }
}
```

## Prevent a user from deleting a DB instance

The following permissions policy grants permissions to prevent a user from deleting a specific DB instance. For example, you might want to deny the ability to delete your production DB instances to any user that is not an administrator.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "DenyDelete1",
      "Effect": "Deny",
      "Action": "rds:DeleteDBInstance",
      "Resource": "arn:aws:rds:us-west-2:123456789012:db:my-mysql-instance"
    }
  ]
}
```

## Deny all access to a resource

You can explicitly deny access to a resource. Deny policies take precedence over allow policies. The following policy explicitly denies a user the ability to manage a resource:

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Deny",
      "Action": "rds:*",
      "Resource": "arn:aws:rds:us-east-1:123456789012:db:mydb"
    }
  ]
}
```

## Example policies: Using condition keys

Following are examples of how you can use condition keys in Amazon RDS IAM permissions policies.

### Example 1: Grant permission to create a DB instance that uses a specific DB engine and isn't MultiAZ

The following policy uses an RDS condition key and allows a user to create only DB instances that use the MySQL database engine and don't use MultiAZ. The Condition element indicates the requirement that the database engine is MySQL.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "AllowMySQLCreate",
      "Effect": "Allow",
      "Action": "rds:CreateDBInstance",
      "Resource": "*",
      "Condition": {
        "StringEquals": {
          "rds:DatabaseEngine": "mysql"
        },
        "Bool": {
          "rds:MultiAz": false
        }
      }
    }
  ]
}
```

## Example 2: Explicitly deny permission to create DB instances for certain DB instance classes and create DB instances that use Provisioned IOPS

The following policy explicitly denies permission to create DB instances that use the DB instance classes `r3.8xlarge` and `m4.10xlarge`, which are the largest and most expensive DB instance classes. This policy also prevents users from creating DB instances that use Provisioned IOPS, which incurs an additional cost.

Explicitly denying permission supersedes any other permissions granted. This ensures that identities do not accidentally get permission that you never want to grant.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "DenyLargeCreate",
      "Effect": "Deny",
      "Action": "rds:CreateDBInstance",
      "Resource": "*",
      "Condition": {
        "StringEquals": {
          "rds:DatabaseClass": [
            "db.r3.8xlarge",
            "db.m4.10xlarge"
          ]
        }
      }
    },
    {
      "Sid": "DenyPIOPSCreate",
      "Effect": "Deny",
      "Action": "rds:CreateDBInstance",
      "Resource": "*",
      "Condition": {
        "NumericNotEquals": {
          "rds:Piops": "0"
        }
      }
    }
  ]
}
```

### Example 3: Limit the set of tag keys and values that can be used to tag a resource

The following policy uses an RDS condition key and allows the addition of a tag with the key `stage` to be added to a resource with the values `test`, `qa`, and `production`.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "rds:AddTagsToResource",
        "rds:RemoveTagsFromResource"
      ],
      "Resource": "*",
      "Condition": {
        "streq": {
          "rds:req-tag/stage": [
            "test",
            "qa",
            "production"
          ]
        }
      }
    }
  ]
}
```

### Specifying conditions: Using custom tags

Amazon RDS supports specifying conditions in an IAM policy using custom tags.

For example, suppose that you add a tag named `environment` to your DB instances with values such as `beta`, `staging`, `production`, and so on. If you do, you can create a policy that restricts certain users to DB instances based on the `environment` tag value.

#### Note

Custom tag identifiers are case-sensitive.

The following table lists the RDS tag identifiers that you can use in a `Condition` element.

RDS tag identifier	Applies to
db-tag	DB instances, including read replicas
snapshot-tag	DB snapshots
ri-tag	Reserved DB instances
og-tag	DB option groups
pg-tag	DB parameter groups
subgrp-tag	DB subnet groups
es-tag	Event subscriptions
cluster-tag	DB clusters
cluster-pg-tag	DB cluster parameter groups
cluster-snapshot-tag	DB cluster snapshots

The syntax for a custom tag condition is as follows:

```
"Condition":{"StringEquals":{"rds:rds-tag-identifier/tag-name":["value"]}} }
```

For example, the following Condition element applies to DB instances with a tag named environment and a tag value of production.

```
"Condition":{"StringEquals":{"rds:db-tag/environment":["production"]}} }
```

For information about creating tags, see [Tagging Amazon RDS resources](#).

### Important

If you manage access to your RDS resources using tagging, we recommend that you secure access to the tags for your RDS resources. You can manage access to tags by creating policies for the AddTagsToResource and RemoveTagsFromResource actions.

For example, the following policy denies users the ability to add or remove tags for all resources. You can then create policies to allow specific users to add or remove tags.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "DenyTagUpdates",
      "Effect": "Deny",
      "Action": [
        "rds:AddTagsToResource",
        "rds:RemoveTagsFromResource"
      ],
      "Resource": "*"
    }
  ]
}
```

To see a list of Amazon RDS actions, see [Actions Defined by Amazon RDS](#) in the *Service Authorization Reference*.

### Example policies: Using custom tags

Following are examples of how you can use custom tags in Amazon RDS IAM permissions policies. For more information about adding tags to an Amazon RDS resource, see [Amazon Resource Names \(ARNs\) in Amazon RDS](#).

#### Note

All examples use the us-west-2 region and contain fictitious account IDs.

### Example 1: Grant permission for actions on a resource with a specific tag with two different values

The following policy allows permission to perform the `CreateDBSnapshot` API operation on DB instances with either the `stage` tag set to `development` or `test`.

```
{
```

```

"Version":"2012-10-17",
"Statement":[
  {
    "Sid":"AllowAnySnapshotName",
    "Effect":"Allow",
    "Action":[
      "rds:CreateDBSnapshot"
    ],
    "Resource":"arn:aws:rds:*:123456789012:snapshot:*"
  },
  {
    "Sid":"AllowDevTestToCreateSnapshot",
    "Effect":"Allow",
    "Action":[
      "rds:CreateDBSnapshot"
    ],
    "Resource":"arn:aws:rds:*:123456789012:db:*",
    "Condition":{"
      "StringEquals":{"
        "rds:db-tag/stage":[
          "development",
          "test"
        ]
      }
    }
  }
]
}

```

The following policy allows permission to perform the `ModifyDBInstance` API operation on DB instances with either the stage tag set to development or test.

```

{
  "Version":"2012-10-17",
  "Statement":[
    {
      "Sid":"AllowChangingParameterOptionSecurityGroups",
      "Effect":"Allow",
      "Action":[
        "rds:ModifyDBInstance"
      ],
      "Resource":["
        "arn:aws:rds:*:123456789012:pg:*",

```

```

        "arn:aws:rds*:123456789012:secgrp:*",
        "arn:aws:rds*:123456789012:og:*"
    ]
},
{
    "Sid": "AllowDevTestToModifyInstance",
    "Effect": "Allow",
    "Action": [
        "rds:ModifyDBInstance"
    ],
    "Resource": "arn:aws:rds*:123456789012:db:*",
    "Condition": {
        "StringEquals": {
            "rds:db-tag/stage": [
                "development",
                "test"
            ]
        }
    }
}
]
}

```

## Example 2: Explicitly deny permission to create a DB instance that uses specified DB parameter groups

The following policy explicitly denies permission to create a DB instance that uses DB parameter groups with specific tag values. You might apply this policy if you require that a specific customer-created DB parameter group always be used when creating DB instances. Policies that use Deny are most often used to restrict access that was granted by a broader policy.

Explicitly denying permission supersedes any other permissions granted. This ensures that identities do not accidentally get permission that you never want to grant.

```

{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "DenyProductionCreate",
            "Effect": "Deny",
            "Action": "rds:CreateDBInstance",

```

```

    "Resource": "arn:aws:rds:*:123456789012:pg:*",
    "Condition": {
      "StringEquals": {
        "rds:pg-tag/usage": "prod"
      }
    }
  ]
}

```

### Example 3: Grant permission for actions on a DB instance with an instance name that is prefixed with a user name

The following policy allows permission to call any API (except to `AddTagsToResource` or `RemoveTagsFromResource`) on a DB instance that has a DB instance name that is prefixed with the user's name and that has a tag called `stage` equal to `devo` or that has no tag called `stage`.

The `Resource` line in the policy identifies a resource by its Amazon Resource Name (ARN). For more information about using ARNs with Amazon RDS resources, see [Amazon Resource Names \(ARNs\) in Amazon RDS](#).

```

{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "AllowFullDevAccessNoTags",
      "Effect": "Allow",
      "NotAction": [
        "rds:AddTagsToResource",
        "rds:RemoveTagsFromResource"
      ],
      "Resource": "arn:aws:rds:*:123456789012:db:${aws:username}*",
      "Condition": {
        "StringEqualsIfExists": {
          "rds:db-tag/stage": "devo"
        }
      }
    }
  ]
}

```

## AWS managed policies for Amazon RDS

To add permissions to permission sets and roles, it's easier to use AWS managed policies than to write policies yourself. It takes time and expertise to [create IAM customer managed policies](#) that provide your team with only the permissions they need. To get started quickly, you can use our AWS managed policies. These policies cover common use cases and are available in your AWS account. For more information about AWS managed policies, see [AWS managed policies](#) in the *IAM User Guide*.

AWS services maintain and update AWS managed policies. You can't change the permissions in AWS managed policies. Services occasionally add additional permissions to an AWS managed policy to support new features. This type of update affects all identities (permission sets and roles) where the policy is attached. Services are most likely to update an AWS managed policy when a new feature is launched or when new operations become available. Services don't remove permissions from an AWS managed policy, so policy updates don't break your existing permissions.

Additionally, AWS supports managed policies for job functions that span multiple services. For example, the `ReadOnlyAccess` AWS managed policy provides read-only access to all AWS services and resources. When a service launches a new feature, AWS adds read-only permissions for new operations and resources. For a list and descriptions of job function policies, see [AWS managed policies for job functions](#) in the *IAM User Guide*.

### Topics

- [AWS managed policy: AmazonRDSBetaServiceRolePolicy](#)

## **AWS managed policy: AmazonRDSReadOnlyAccess**

This policy allows read-only access to Amazon RDS through the AWS Management Console.

### **Permissions details**

This policy includes the following permissions:

- `rds` – Allows principals to describe Amazon RDS resources and list the tags for Amazon RDS resources.
- `cloudwatch` – Allows principals to get Amazon CloudWatch metric statistics.
- `ec2` – Allows principals to describe Availability Zones and networking resources.
- `logs` – Allows principals to describe CloudWatch Logs log streams of log groups, and get CloudWatch Logs log events.
- `devops-guru` – Allows principals to describe resources that have Amazon DevOps Guru coverage, which is specified either by CloudFormation stack names or resource tags.

For more information about this policy, including the JSON policy document, see [AmazonRDSReadOnlyAccess](#) in the *AWS Managed Policy Reference Guide*.

## **AWS managed policy: AmazonRDSFullAccess**

This policy provides full access to Amazon RDS through the AWS Management Console.

### **Permissions details**

This policy includes the following permissions:

- `rds` – Allows principals full access to Amazon RDS.
- `application-autoscaling` – Allows principals describe and manage Application Auto Scaling scaling targets and policies.
- `cloudwatch` – Allows principals get CloudWatch metric statics and manage CloudWatch alarms.
- `ec2` – Allows principals to describe Availability Zones and networking resources.
- `logs` – Allows principals to describe CloudWatch Logs log streams of log groups, and get CloudWatch Logs log events.

- `outposts` – Allows principals to get AWS Outposts instance types.
- `pi` – Allows principals to get Performance Insights metrics.
- `sns` – Allows principals to Amazon Simple Notification Service (Amazon SNS) subscriptions and topics, and to publish Amazon SNS messages.
- `devops-guru` – Allows principals to describe resources that have Amazon DevOps Guru coverage, which is specified either by CloudFormation stack names or resource tags.

For more information about this policy, including the JSON policy document, see [AmazonRDSFullAccess](#) in the *AWS Managed Policy Reference Guide*.

### **AWS managed policy: AmazonRDSDataFullAccess**

This policy allows full access to use the Data API and the query editor on Aurora Serverless clusters in a specific AWS account. This policy allows the AWS account to get the value of a secret from AWS Secrets Manager.

You can attach the `AmazonRDSDataFullAccess` policy to your IAM identities.

#### **Permissions details**

This policy includes the following permissions:

- `dbqms` – Allows principals to access, create, delete, describe, and update queries. The Database Query Metadata Service (dbqms) is an internal-only service. It provides your recent and saved queries for the query editor on the AWS Management Console for multiple AWS services, including Amazon RDS.
- `rds-data` – Allows principals to run SQL statements on Aurora Serverless databases.
- `secretsmanager` – Allows principals to get the value of a secret from AWS Secrets Manager.

For more information about this policy, including the JSON policy document, see [AmazonRDSDataFullAccess](#) in the *AWS Managed Policy Reference Guide*.

### **AWS managed policy: AmazonRDSEnhancedMonitoringRole**

This policy provides access to Amazon CloudWatch Logs for Amazon RDS Enhanced Monitoring.

#### **Permissions details**

This policy includes the following permissions:

- `logs` – Allows principals to create CloudWatch Logs log groups and retention policies, and to create and describe CloudWatch Logs log streams of log groups. It also allows principals to put and get CloudWatch Logs log events.

For more information about this policy, including the JSON policy document, see [AmazonRDSEnhancedMonitoringRole](#) in the *AWS Managed Policy Reference Guide*.

### **AWS managed policy: AmazonRDSPerformanceInsightsReadOnly**

This policy provides read-only access to Amazon RDS Performance Insights for Amazon RDS DB instances and Amazon Aurora DB clusters.

This policy now includes `Sid` (statement ID) as an identifier for the policy statement.

#### **Permissions details**

This policy includes the following permissions:

- `rds` – Allows principals to describe Amazon RDS DB instances and Amazon Aurora DB clusters.
- `pi` – Allows principals make calls to the Amazon RDS Performance Insights API and access Performance Insights metrics.

For more information about this policy, including the JSON policy document, see [AmazonRDSPerformanceInsightsReadOnly](#) in the *AWS Managed Policy Reference Guide*.

### **AWS managed policy: AmazonRDSPerformanceInsightsFullAccess**

This policy provides full access to Amazon RDS Performance Insights for Amazon RDS DB instances and Amazon Aurora DB clusters.

This policy now includes `Sid` (statement ID) as an identifier for the policy statement.

#### **Permissions details**

This policy includes the following permissions:

- `rds` – Allows principals to describe Amazon RDS DB instances and Amazon Aurora DB clusters.

- `pi` – Allows principals make calls to the Amazon RDS Performance Insights API, and create, view, and delete performance analysis reports.
- `cloudwatch` – Allows principals to list all the Amazon CloudWatch metrics, and get metric data and statistics.

For more information about this policy, including the JSON policy document, see [AmazonRDSPerformanceInsightsFullAccess](#) in the *AWS Managed Policy Reference Guide*.

## **AWS managed policy: AmazonRDSDirectoryServiceAccess**

This policy allows Amazon RDS to make calls to the AWS Directory Service.

### **Permissions details**

This policy includes the following permission:

- `ds` – Allows principals to describe AWS Directory Service directories and control authorization to AWS Directory Service directories.

For more information about this policy, including the JSON policy document, see [AmazonRDSDirectoryServiceAccess](#) in the *AWS Managed Policy Reference Guide*.

## **AWS managed policy: AmazonRDSServiceRolePolicy**

You can't attach the `AmazonRDSServiceRolePolicy` policy to your IAM entities. This policy is attached to a service-linked role that allows Amazon RDS to perform actions on your behalf. For more information, see [Service-linked role permissions for Amazon RDS](#).

## **AWS managed policy: AmazonRDSCustomServiceRolePolicy**

You can't attach the `AmazonRDSCustomServiceRolePolicy` policy to your IAM entities. This policy is attached to a service-linked role that allows Amazon RDS to call AWS services on behalf of your RDS DB resources.

This policy includes the following permissions:

- `ec2` - Allows RDS Custom to perform backup operations on the DB instance that provides point-in-time restore capabilities.

- `secretsmanager` - Allows RDS Custom to manage DB instance specific secrets created by RDS Custom.
- `cloudwatch` - Allows RDS Custom to upload DB instance metrics and logs to CloudWatch through CloudWatch agent.
- `events`, `sqs` - Allows RDS Custom to send and receive status information about the DB instance.

For more information about this policy, including the JSON policy document, see [AmazonRDSCustomServiceRolePolicy](#) in the *AWS Managed Policy Reference Guide*.

## **AWS managed policy: AmazonRDSCustomInstanceProfileRolePolicy**

You shouldn't attach `AmazonRDSCustomInstanceProfileRolePolicy` to your IAM entities. It should only be attached to an instance profile role that is used to grant permissions to your Amazon RDS Custom DB instance to perform various automation actions and database management tasks. Pass the instance profile as `custom-iam-instance-profile` parameter during the RDS Custom instance creation and RDS Custom associates this instance profile to your DB instance.

### **Permissions details**

This policy includes the following permissions:

- `ssm`, `ssmmessages`, `ec2messages` - Allows RDS Custom to communicate, execute automation and maintain agents on the DB instance through Systems Manager.
- `ec2`, `s3` - Allows RDS Custom to perform backup operations on the DB instance that provides point-in-time restore capabilities.
- `secretsmanager` - Allows RDS Custom to manage DB instance specific secrets created by RDS Custom.
- `cloudwatch`, `logs` - Allows RDS Custom to upload DB instance metrics and logs to CloudWatch through CloudWatch agent.
- `events`, `sqs` - Allows RDS Custom to send and receive status information about the DB instance.
- `kms` - Allows RDS Custom to use an instance-specific KMS key to perform encryption of secrets and S3 objects that RDS Custom manages.

For more information about this policy, including the JSON policy document, see [AmazonRDSCustomInstanceProfileRolePolicy](#) in the *AWS Managed Policy Reference Guide*.

## AWS managed policy: AmazonRDSPreviewServiceRolePolicy

You shouldn't attach `AmazonRDSPreviewServiceRolePolicy` to your IAM entities. This policy is attached to a service-linked role that allows Amazon RDS to call AWS services on behalf of your RDS DB resources. For more information, see [Service-linked role for Amazon RDS Preview](#).

### Permissions details

This policy includes the following permissions:

- `ec2` - Allows principals to describe Availability Zones and networking resources.
- `secretsmanager` - Allows principals to get the value of a secret from AWS Secrets Manager.
- `cloudwatch, logs` - Allows Amazon RDS to upload DB instance metrics and logs to CloudWatch through CloudWatch agent.

For more information about this policy, including the JSON policy document, see [AmazonRDSDataFullAccess](#) in the *AWS Managed Policy Reference Guide*.

## AWS managed policy: AmazonRDSBetaServiceRolePolicy

You shouldn't attach `AmazonRDSBetaServiceRolePolicy` to your IAM entities. This policy is attached to a service-linked role that allows Amazon RDS to call AWS services on behalf of your RDS DB resources. For more information, see [Service-linked role permissions for Amazon RDS Beta](#).

### Permissions details

This policy includes the following permissions:

- `ec2` - Allows Amazon RDS to perform backup operations on the DB instance that provides point-in-time restore capabilities.
- `secretsmanager` - Allows Amazon RDS to manage DB instance specific secrets created by Amazon RDS.
- `cloudwatch, logs` - Allows Amazon RDS to upload DB instance metrics and logs to CloudWatch through CloudWatch agent.

For more information about this policy, including the JSON policy document, see [AmazonRDSBetaServiceRolePolicy](#) in the *AWS Managed Policy Reference Guide*.

## Amazon RDS updates to AWS managed policies

View details about updates to AWS managed policies for Amazon RDS since this service began tracking these changes. For automatic alerts about changes to this page, subscribe to the RSS feed on the Amazon RDS [Document history](#) page.

Change	Description	Date
<a href="#">AWS managed policy: AmazonRDSPreviewServiceRolePolicy</a> – Update to existing policy	Amazon RDS removed <code>sns:Publish</code> permission from the AmazonRDSPreviewServiceRolePolicy of the AWSServiceRoleForRDSPreview service-linked role. For more information, see <a href="#">AWS managed policy: AmazonRDSPreviewServiceRolePolicy</a> .	August 7, 2024
<a href="#">AWS managed policy: AmazonRDSBetaServiceRolePolicy</a> – Update to existing policy	Amazon RDS removed <code>sns:Publish</code> permission from the AmazonRDSBetaServiceRolePolicy of the AWSServiceRoleForRDSBeta service-linked role. For more information, see <a href="#">AWS managed policy: AmazonRDSBetaServiceRolePolicy</a> .	August 7, 2024
<a href="#">Service-linked role permissions for Amazon RDS Custom</a> – Update to existing policy	Amazon RDS added new permissions to the AmazonRDSCustomServiceRolePolicy of the AWSServiceRoleForRDSCustom service-linked role. The permissions allow	July 18, 2024

Change	Description	Date
	<p>RDS Custom to communicate with Amazon RDS services in another AWS Region and copy EC2 images. For more information, see <a href="#">Service-linked role permissions for Amazon RDS Custom</a>.</p>

## Preventing cross-service confused deputy problems

The *confused deputy problem* is a security issue where an entity that doesn't have permission to perform an action can coerce a more-privileged entity to perform the action. In AWS, cross-service impersonation can result in the confused deputy problem.

Cross-service impersonation can occur when one service (the *calling service*) calls another service (the *called service*). The calling service can be manipulated to use its permissions to act on another customer's resources in a way that it shouldn't have permission to access. To prevent this, AWS provides tools that can help you protect your data for all services with service principals that have been given access to resources in your account. For more information, see [The confused deputy problem](#) in the *IAM User Guide*.

To limit the permissions that Amazon RDS gives another service for a specific resource, we recommend using the [aws:SourceArn](#) and [aws:SourceAccount](#) global condition context keys in resource policies.

In some cases, the `aws:SourceArn` value doesn't contain the account ID, for example when you use the Amazon Resource Name (ARN) for an Amazon S3 bucket. In these cases, make sure to use both global condition context keys to limit permissions. In some cases, you use both global condition context keys and the `aws:SourceArn` value contains the account ID. In these cases, make sure that the `aws:SourceAccount` value and the account in the `aws:SourceArn` use the same account ID when they're used in the same policy statement. If you want only one resource to be associated with the cross-service access, use `aws:SourceArn`. If you want to allow any resource in the specified AWS account to be associated with the cross-service use, use `aws:SourceAccount`.

Make sure that the value of `aws:SourceArn` is an ARN for an Amazon RDS resource type. For more information, see [Amazon Resource Names \(ARNs\) in Amazon RDS](#).

The most effective way to protect against the confused deputy problem is to use the `aws:SourceArn` global condition context key with the full ARN of the resource. In some cases, you might not know the full ARN of the resource or you might be specifying multiple resources. In these cases, use the `aws:SourceArn` global context condition key with wildcards (\*) for the unknown portions of the ARN. An example is `arn:aws:rds:*:123456789012:*`.

The following example shows how you can use the `aws:SourceArn` and `aws:SourceAccount` global condition context keys in Amazon RDS to prevent the confused deputy problem.

```
{
  "Version": "2012-10-17",
  "Statement": {
    "Sid": "ConfusedDeputyPreventionExamplePolicy",
    "Effect": "Allow",
    "Principal": {
      "Service": "rds.amazonaws.com"
    },
    "Action": "sts:AssumeRole",
    "Condition": {
      "ArnLike": {
        "aws:SourceArn": "arn:aws:rds:us-east-1:123456789012:db:mydbinstance"
      },
      "StringEquals": {
        "aws:SourceAccount": "123456789012"
      }
    }
  }
}
```

For more examples of policies that use the `aws:SourceArn` and `aws:SourceAccount` global condition context keys, see the following sections:

- [Granting permissions to publish notifications to an Amazon SNS topic](#)

- [Setting up access to an Amazon S3 bucket \(PostgreSQL import\)](#)
- [Setting up access to an Amazon S3 bucket \(PostgreSQL export\)](#)

## IAM database authentication for MariaDB, MySQL, and PostgreSQL

You can authenticate to your DB instance using AWS Identity and Access Management (IAM) database authentication. IAM database authentication works with MariaDB, MySQL, and PostgreSQL. With this authentication method, you don't need to use a password when you connect to a DB instance. Instead, you use an authentication token.

An *authentication token* is a unique string of characters that Amazon RDS generates on request. Authentication tokens are generated using AWS Signature Version 4. Each token has a lifetime of 15 minutes. You don't need to store user credentials in the database, because authentication is managed externally using IAM. You can also still use standard database authentication. The token is only used for authentication and doesn't affect the session after it is established.

IAM database authentication provides the following benefits:

- Network traffic to and from the database is encrypted using Secure Socket Layer (SSL) or Transport Layer Security (TLS). For more information about using SSL/TLS with Amazon RDS, see [Using SSL/TLS to encrypt a connection to a DB instance or cluster](#).
- You can use IAM to centrally manage access to your database resources, instead of managing access individually on each DB instance.
- For applications running on Amazon EC2, you can use profile credentials specific to your EC2 instance to access your database instead of a password, for greater security.

In general, consider using IAM database authentication when your applications create fewer than 200 connections per second, and you don't want to manage usernames and passwords directly in your application code.

The Amazon Web Services (AWS) JDBC Driver supports IAM database authentication. For more information, see [AWS IAM Authentication Plugin](#) in the [Amazon Web Services \(AWS\) JDBC Driver GitHub repository](#).

The Amazon Web Services (AWS) Python Driver supports IAM database authentication. For more information, see [AWS IAM Authentication Plugin](#) in the [Amazon Web Services \(AWS\) Python Driver GitHub repository](#).

### Topics

- [Region and version availability](#)
- [CLI and SDK support](#)

- [Limitations for IAM database authentication](#)
- [Recommendations for IAM database authentication](#)
- [Unsupported AWS global condition context keys](#)
- [Enabling and disabling IAM database authentication](#)
- [Creating and using an IAM policy for IAM database access](#)
- [Creating a database account using IAM authentication](#)
- [Connecting to your DB instance using IAM authentication](#)

## Region and version availability

Feature availability and support varies across specific versions of each database engine, and across AWS Regions. For more information on version and Region availability with Amazon RDS and IAM database authentication, see [Supported Regions and DB engines for IAM database authentication in Amazon RDS](#).

## CLI and SDK support

IAM database authentication is available for the [AWS CLI](#) and for the following language-specific AWS SDKs:

- [AWS SDK for .NET](#)
- [AWS SDK for C++](#)
- [AWS SDK for Go](#)
- [AWS SDK for Java](#)
- [AWS SDK for JavaScript](#)
- [AWS SDK for PHP](#)
- [AWS SDK for Python \(Boto3\)](#)
- [AWS SDK for Ruby](#)

## Limitations for IAM database authentication

When using IAM database authentication, the following limitations apply:

- IAM database authentication throttles connections in the following scenarios:

- You exceed 20 connections per second using authentication tokens each signed by a different IAM identity.
- You exceed 200 connections per second using different authentication tokens.

Connections that use the same authentication token are not throttled. We recommend that you reuse authentication tokens when possible.

- Currently, IAM database authentication doesn't support all global condition context keys.

For more information about global condition context keys, see [AWS global condition context keys](#) in the *IAM User Guide*.

- For PostgreSQL, if the IAM role (`rds_iam`) is added to a user (including the RDS master user), IAM authentication takes precedence over password authentication, so the user must log in as an IAM user.
- For PostgreSQL, Amazon RDS does not support enabling both IAM and Kerberos authentication methods at the same time.
- For PostgreSQL, you cannot use IAM authentication to establish a replication connection.
- You cannot use a custom Route 53 DNS record instead of the DB instance endpoint to generate the authentication token.
- CloudWatch and CloudTrail don't log IAM authentication. These services do not track `generate-db-auth-token` API calls that authorize the IAM role to enable database connection.

## Recommendations for IAM database authentication

We recommend the following when using IAM database authentication:

- Use IAM database authentication when your application requires fewer than 200 new IAM database authentication connections per second.

The database engines that work with Amazon RDS don't impose any limits on authentication attempts per second. However, when you use IAM database authentication, your application must generate an authentication token. Your application then uses that token to connect to the DB instance. If you exceed the limit of maximum new connections per second, then the extra overhead of IAM database authentication can cause connection throttling.

Consider using connection pooling in your applications to mitigate constant connection creation. This can reduce the overhead from IAM DB authentication and allow your applications to reuse

existing connections. Alternatively, consider using RDS Proxy for these use cases. RDS Proxy has additional costs. See [RDS Proxy pricing](#).

- The size of an IAM database authentication token depends on many things including the number of IAM tags, IAM service policies, ARN lengths, as well as other IAM and database properties. The minimum size of this token is generally about 1 KB but can be larger. Since this token is used as the password in the connection string to the database using IAM authentication, you should ensure that your database driver (e.g., ODBC) and/or any tools do not limit or otherwise truncate this token due to its size. A truncated token will cause the authentication validation done by the database and IAM to fail.
- If you are using temporary credentials when creating an IAM database authentication token, the temporary credentials must still be valid when using the IAM database authentication token to make a connection request.

## Unsupported AWS global condition context keys

IAM database authentication does not support the following subset of AWS global condition context keys.

- `aws:Referer`
- `aws:SourceIp`
- `aws:SourceVpc`
- `aws:SourceVpce`
- `aws:UserAgent`
- `aws:VpcSourceIp`

For more information, see [AWS global condition context keys](#) in the *IAM User Guide*.

## Enabling and disabling IAM database authentication

By default, IAM database authentication is disabled on DB instances. You can enable or disable IAM database authentication using the AWS Management Console, AWS CLI, or the API.

You can enable IAM database authentication when you perform one of the following actions:

- To create a new DB instance with IAM database authentication enabled, see [Creating an Amazon RDS DB instance](#).

- To modify a DB instance to enable IAM database authentication, see [Modifying an Amazon RDS DB instance](#).
- To restore a DB instance from a snapshot with IAM database authentication enabled, see [Restoring to a DB instance](#).
- To restore a DB instance to a point in time with IAM database authentication enabled, see [Restoring a DB instance to a specified time](#).

IAM authentication for PostgreSQL DB instances requires that the SSL value be 1. You can't enable IAM authentication for a PostgreSQL DB instance if the SSL value is 0. You can't change the SSL value to 0 if IAM authentication is enabled for a PostgreSQL DB instance.

## Console

Each creation or modification workflow has a **Database authentication** section, where you can enable or disable IAM database authentication. In that section, choose **Password and IAM database authentication** to enable IAM database authentication.

### To enable or disable IAM database authentication for an existing DB instance

1. Open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Databases**.
3. Choose the DB instance that you want to modify.

#### Note

Make sure that the DB instance is compatible with IAM authentication. Check the compatibility requirements in [Region and version availability](#).

4. Choose **Modify**.
5. In the **Database authentication** section, choose **Password and IAM database authentication** to enable IAM database authentication. Choose **Password authentication** or **Password and Kerberos authentication** to disable IAM authentication.
6. Choose **Continue**.
7. To apply the changes immediately, choose **Immediately** in the **Scheduling of modifications** section.
8. Choose **Modify DB instance**.

## AWS CLI

To create a new DB instance with IAM authentication by using the AWS CLI, use the [create-db-instance](#) command. Specify the `--enable-iam-database-authentication` option, as shown in the following example.

```
aws rds create-db-instance \  
  --db-instance-identifier mydbinstance \  
  --db-instance-class db.m3.medium \  
  --engine MySQL \  
  --allocated-storage 20 \  
  --master-username masterawsuser \  
  --manage-master-user-password \  
  --enable-iam-database-authentication
```

To update an existing DB instance to have or not have IAM authentication, use the AWS CLI command [modify-db-instance](#). Specify either the `--enable-iam-database-authentication` or `--no-enable-iam-database-authentication` option, as appropriate.

### Note

Make sure that the DB instance is compatible with IAM authentication. Check the compatibility requirements in [Region and version availability](#).

By default, Amazon RDS performs the modification during the next maintenance window. If you want to override this and enable IAM DB authentication as soon as possible, use the `--apply-immediately` parameter.

The following example shows how to immediately enable IAM authentication for an existing DB instance.

```
aws rds modify-db-instance \  
  --db-instance-identifier mydbinstance \  
  --apply-immediately \  
  --enable-iam-database-authentication
```

If you are restoring a DB instance, use one of the following AWS CLI commands:

- [restore-db-instance-to-point-in-time](#)

- [restore-db-instance-from-db-snapshot](#)

The IAM database authentication setting defaults to that of the source snapshot. To change this setting, set the `--enable-iam-database-authentication` or `--no-enable-iam-database-authentication` option, as appropriate.

## RDS API

To create a new DB instance with IAM authentication by using the API, use the API operation [CreateDBInstance](#). Set the `EnableIAMDatabaseAuthentication` parameter to `true`.

To update an existing DB instance to have IAM authentication, use the API operation [ModifyDBInstance](#). Set the `EnableIAMDatabaseAuthentication` parameter to `true` to enable IAM authentication, or `false` to disable it.

### Note

Make sure that the DB instance is compatible with IAM authentication. Check the compatibility requirements in [Region and version availability](#).

If you are restoring a DB instance, use one of the following API operations:

- [RestoreDBInstanceFromDBSnapshot](#)
- [RestoreDBInstanceToPointInTime](#)

The IAM database authentication setting defaults to that of the source snapshot. To change this setting, set the `EnableIAMDatabaseAuthentication` parameter to `true` to enable IAM authentication, or `false` to disable it.

## Creating and using an IAM policy for IAM database access

To allow a user or role to connect to your DB instance, you must create an IAM policy. After that, you attach the policy to a permissions set or role.

### Note

To learn more about IAM policies, see [Identity and access management for Amazon RDS](#).

The following example policy allows a user to connect to a DB instance using IAM database authentication.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "rds-db:connect"
      ],
      "Resource": [
        "arn:aws:rds-db:us-east-2:1234567890:dbuser:db-ABCDEFGHIJKL01234/db_user"
      ]
    }
  ]
}
```

### Important

A user with administrator permissions can access DB instances without explicit permissions in an IAM policy. If you want to restrict administrator access to DB instances, you can create an IAM role with the appropriate, lesser privileged permissions and assign it to the administrator.

### Note

Don't confuse the `rds-db:` prefix with other RDS API operation prefixes that begin with `rds:`. You use the `rds-db:` prefix and the `rds-db:connect` action only for IAM database authentication. They aren't valid in any other context.

The example policy includes a single statement with the following elements:

- **Effect** – Specify `Allow` to grant access to the DB instance. If you don't explicitly allow access, then access is denied by default.
- **Action** – Specify `rds-db:connect` to allow connections to the DB instance.

- **Resource** – Specify an Amazon Resource Name (ARN) that describes one database account in one DB instance. The ARN format is as follows.

```
arn:aws:rds-db:region:account-id:dbuser:DbiResourceId/db-user-name
```

In this format, replace the following:

- *region* is the AWS Region for the DB instance. In the example policy, the AWS Region is us-east-2.
- *account-id* is the AWS account number for the DB instance. In the example policy, the account number is 1234567890. The user must be in the same account as the account for the DB instance.

To perform cross-account access, create an IAM role with the policy shown above in the account for the DB instance and allow your other account to assume the role.

- *DbiResourceId* is the identifier for the DB instance. This identifier is unique to an AWS Region and never changes. In the example policy, the identifier is db-ABCDEFGHIJKL01234.

To find a DB instance resource ID in the AWS Management Console for Amazon RDS, choose the DB instance to see its details. Then choose the **Configuration** tab. The **Resource ID** is shown in the **Configuration** section.

Alternatively, you can use the AWS CLI command to list the identifiers and resource IDs for all of your DB instance in the current AWS Region, as shown following.

```
aws rds describe-db-instances --query "DBInstances[*].  
[DBInstanceIdentifier,DbiResourceId]"
```

If you are using Amazon Aurora, specify a `DbClusterResourceId` instead of a `DbiResourceId`. For more information, see [Creating and using an IAM policy for IAM database access](#) in the *Amazon Aurora User Guide*.

**Note**

If you are connecting to a database through RDS Proxy, specify the proxy resource ID, such as `prx-ABCDEFGHijkl01234`. For information about using IAM database authentication with RDS Proxy, see [Connecting to a proxy using IAM authentication](#).

- `db-user-name` is the name of the database account to associate with IAM authentication. In the example policy, the database account is `db_user`.

You can construct other ARNs to support various access patterns. The following policy allows access to two different database accounts in a DB instance.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "rds-db:connect"
      ],
      "Resource": [
        "arn:aws:rds-db:us-east-2:123456789012:dbuser:db-ABCDEFGHijkl01234/
jane_doe",
        "arn:aws:rds-db:us-east-2:123456789012:dbuser:db-ABCDEFGHijkl01234/
mary_roe"
      ]
    }
  ]
}
```

The following policy uses the "\*" character to match all DB instances and database accounts for a particular AWS account and AWS Region.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
```

```
        "Effect": "Allow",
        "Action": [
            "rds-db:connect"
        ],
        "Resource": [
            "arn:aws:rds-db:us-east-2:1234567890:dbuser:*/*"
        ]
    }
]
```

The following policy matches all of the DB instances for a particular AWS account and AWS Region. However, the policy only grants access to DB instances that have a `jane_doe` database account.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "rds-db:connect"
      ],
      "Resource": [
        "arn:aws:rds-db:us-east-2:123456789012:dbuser:*/jane_doe"
      ]
    }
  ]
}
```

The user or role has access to only those databases that the database user does. For example, suppose that your DB instance has a database named `dev`, and another database named `test`. If the database user `jane_doe` has access only to `dev`, any users or roles that access that DB instance with the `jane_doe` user also have access only to `dev`. This access restriction is also true for other database objects, such as tables, views, and so on.

An administrator must create IAM policies that grant entities permission to perform specific API operations on the specified resources they need. The administrator must then attach those policies to the permission sets or roles that require those permissions. For examples of policies, see [Identity-based policy examples for Amazon RDS](#).

## Attaching an IAM policy to a permission set or role

After you create an IAM policy to allow database authentication, you need to attach the policy to a permission set or role. For a tutorial on this topic, see [Create and attach your first customer managed policy](#) in the *IAM User Guide*.

As you work through the tutorial, you can use one of the policy examples shown in this section as a starting point and tailor it to your needs. At the end of the tutorial, you have a permission set with an attached policy that can make use of the `rds-db:connect` action.

### Note

You can map multiple permission sets or roles to the same database user account. For example, suppose that your IAM policy specified the following resource ARN.

```
arn:aws:rds-db:us-east-2:123456789012:dbuser:db-12ABC34DEFG5HIJ6KLMNOP78QR/
jane_doe
```

If you attach the policy to *Jane*, *Bob*, and *Diego*, then each of those users can connect to the specified DB instance using the `jane_doe` database account.

## Creating a database account using IAM authentication

With IAM database authentication, you don't need to assign database passwords to the user accounts you create. If you remove a user that is mapped to a database account, you should also remove the database account with the `DROP USER` statement.

### Note

The user name used for IAM authentication must match the case of the user name in the database.

## Topics

- [Using IAM authentication with MariaDB and MySQL](#)

- [Using IAM authentication with PostgreSQL](#)

## Using IAM authentication with MariaDB and MySQL

With MariaDB and MySQL, authentication is handled by `AWSAuthenticationPlugin`—an AWS-provided plugin that works seamlessly with IAM to authenticate your users. Connect to the DB instance as the master user or a different user who can create users and grant privileges. After connecting, issue the `CREATE USER` statement, as shown in the following example.

```
CREATE USER 'jane_doe' IDENTIFIED WITH AWSAuthenticationPlugin AS 'RDS';
```

The `IDENTIFIED WITH` clause allows MariaDB and MySQL to use the `AWSAuthenticationPlugin` to authenticate the database account (`jane_doe`). The `AS 'RDS'` clause refers to the authentication method. Make sure the specified database user name is the same as a resource in the IAM policy for IAM database access. For more information, see [Creating and using an IAM policy for IAM database access](#).

### Note

If you see the following message, it means that the AWS-provided plugin is not available for the current DB instance.

```
ERROR 1524 (HY000): Plugin 'AWSAuthenticationPlugin' is not loaded
```

To troubleshoot this error, verify that you are using a supported configuration and that you have enabled IAM database authentication on your DB instance. For more information, see [Region and version availability](#) and [Enabling and disabling IAM database authentication](#).

After you create an account using `AWSAuthenticationPlugin`, you manage it in the same way as other database accounts. For example, you can modify account privileges with `GRANT` and `REVOKE` statements, or modify various account attributes with the `ALTER USER` statement.

Database network traffic is encrypted using SSL/TLS when using IAM. To allow SSL connections, modify the user account with the following command.

```
ALTER USER 'jane_doe'@'%' REQUIRE SSL;
```

## Using IAM authentication with PostgreSQL

To use IAM authentication with PostgreSQL, connect to the DB instance as the master user or a different user who can create users and grant privileges. After connecting, create database users and then grant them the `rds_iam` role as shown in the following example.

```
CREATE USER db_userx;  
GRANT rds_iam TO db_userx;
```

Make sure the specified database user name is the same as a resource in the IAM policy for IAM database access. For more information, see [Creating and using an IAM policy for IAM database access](#). You must grant the `rds_iam` role to use IAM authentication. You can use nested memberships or indirect grants of the role as well.

## Connecting to your DB instance using IAM authentication

With IAM database authentication, you use an authentication token when you connect to your DB instance. An *authentication token* is a string of characters that you use instead of a password. After you generate an authentication token, it's valid for 15 minutes before it expires. If you try to connect using an expired token, the connection request is denied.

Every authentication token must be accompanied by a valid signature, using AWS signature version 4. (For more information, see [Signature Version 4 signing process](#) in the *AWS General Reference*.) The AWS CLI and an AWS SDK, such as the AWS SDK for Java or AWS SDK for Python (Boto3), can automatically sign each token you create.

You can use an authentication token when you connect to Amazon RDS from another AWS service, such as AWS Lambda. By using a token, you can avoid placing a password in your code. Alternatively, you can use an AWS SDK to programmatically create and programmatically sign an authentication token.

After you have a signed IAM authentication token, you can connect to an Amazon RDS DB instance. Following, you can find out how to do this using either a command line tool or an AWS SDK, such as the AWS SDK for Java or AWS SDK for Python (Boto3).

For more information, see the following blog posts:

- [Use IAM authentication to connect with SQL Workbench/J to Aurora MySQL or Amazon RDS for MySQL](#)

- [Using IAM authentication to connect with pgAdmin Amazon Aurora PostgreSQL or Amazon RDS for PostgreSQL](#)

## Prerequisites

The following are prerequisites for connecting to your DB instance using IAM authentication:

- [Enabling and disabling IAM database authentication](#)
- [Creating and using an IAM policy for IAM database access](#)
- [Creating a database account using IAM authentication](#)

## Topics

- [Connecting to your DB instance using IAM authentication with the AWS drivers](#)

- [Connecting to your DB instance using IAM authentication and the AWS SDK for Java](#)
- [Connecting to your DB instance using IAM authentication and the AWS SDK for Python \(Boto3\)](#)

## Connecting to your DB instance using IAM authentication with the AWS drivers

The AWS suite of drivers has been designed to provide support for faster switchover and failover times, and authentication with AWS Secrets Manager, AWS Identity and Access Management (IAM), and Federated Identity. The AWS drivers rely on monitoring DB instance status and being aware of the instance topology to determine the new writer. This approach reduces switchover and failover times to single-digit seconds, compared to tens of seconds for open-source drivers.

For more information on the AWS drivers, see the corresponding language driver for your [RDS for MariaDB](#), [RDS for MySQL](#), or [RDS for PostgreSQL](#) DB instance.

**Note**

The only features supported for RDS for MariaDB are authentication with AWS Secrets Manager, AWS Identity and Access Management (IAM), and Federated Identity.

## Connecting to your DB instance using IAM authentication from the command line: AWS CLI and mysql client

You can connect from the command line to an Amazon RDS DB instance with the AWS CLI and `mysql` command line tool as described following.

### Prerequisites

The following are prerequisites for connecting to your DB instance using IAM authentication:

- [Enabling and disabling IAM database authentication](#)
- [Creating and using an IAM policy for IAM database access](#)
- [Creating a database account using IAM authentication](#)

**Note**

For information about connecting to your database using SQL Workbench/J with IAM authentication, see the blog post [Use IAM authentication to connect with SQL Workbench/J to Aurora MySQL or Amazon RDS for MySQL](#).

### Topics

- [Generating an IAM authentication token](#)
- [Connecting to a DB instance](#)

### Generating an IAM authentication token

The following example shows how to get a signed authentication token using the AWS CLI.

```
aws rds generate-db-auth-token \  
  --hostname rdsmysql.123456789012.us-west-2.rds.amazonaws.com \  
  --
```

```
--port 3306 \  
--region us-west-2 \  
--username jane_doe
```

In the example, the parameters are as follows:

- `--hostname` – The host name of the DB instance that you want to access
- `--port` – The port number used for connecting to your DB instance
- `--region` – The AWS Region where the DB instance is running
- `--username` – The database account that you want to access

The first several characters of the token look like the following.

```
rdsmysql.123456789012.us-west-2.rds.amazonaws.com:3306/?  
Action=connect&DBUser=jane_doe&X-Amz-Algorithm=AWS4-HMAC-SHA256&X-Amz-Expires=900...
```

#### Note

You cannot use a custom Route 53 DNS record instead of the DB instance endpoint to generate the authentication token.

## Connecting to a DB instance

The general format for connecting is shown following.

```
mysql --host=hostName --port=portNumber --ssl-ca=full_path_to_ssl_certificate --enable-  
cleartext-plugin --user=userName --password=authToken
```

The parameters are as follows:

- `--host` – The host name of the DB instance that you want to access
- `--port` – The port number used for connecting to your DB instance
- `--ssl-ca` – The full path to the SSL certificate file that contains the public key

For more information about SSL/TLS support for MariaDB, see [Using SSL/TLS with a MariaDB DB instance](#).

For more information about SSL/TLS support for MySQL, see [Using SSL/TLS with a MySQL DB instance](#).

To download an SSL certificate, see [Using SSL/TLS to encrypt a connection to a DB instance or cluster](#).

- `--enable-cleartext-plugin` – A value that specifies that `AWSAuthenticationPlugin` must be used for this connection

If you are using a MariaDB client, the `--enable-cleartext-plugin` option isn't required.

- `--user` – The database account that you want to access
- `--password` – A signed IAM authentication token

The authentication token consists of several hundred characters. It can be unwieldy on the command line. One way to work around this is to save the token to an environment variable, and then use that variable when you connect. The following example shows one way to perform this workaround. In the example, `/sample_dir/` is the full path to the SSL certificate file that contains the public key.

```
RDSHOST="mysqldb.123456789012.us-east-1.rds.amazonaws.com"
TOKEN="$(aws rds generate-db-auth-token --hostname $RDSHOST --port 3306 --region us-west-2 --username jane_doe )"

mysql --host=$RDSHOST --port=3306 --ssl-ca=/sample_dir/global-bundle.pem --enable-cleartext-plugin --user=jane_doe --password=$TOKEN
```

When you connect using `AWSAuthenticationPlugin`, the connection is secured using SSL. To verify this, type the following at the `mysql>` command prompt.

```
show status like 'Ssl%';
```

The following lines in the output show more details.

```
+-----+-----+
| Variable_name | Value
```

```
+-----+-----+
| ...      | ...
| Ssl_cipher | AES256-SHA
|
|
|
| ...      | ...
| Ssl_version | TLSv1.1
|
|
| ...      | ...
+-----+-----+
```

If you want to connect to a DB instance through a proxy, see [Connecting to a proxy using IAM authentication](#).

## Connecting to your DB instance using IAM authentication from the command line: AWS CLI and psql client

You can connect from the command line to an Amazon RDS for PostgreSQL DB instance with the AWS CLI and psql command line tool as described following.

### Prerequisites

The following are prerequisites for connecting to your DB instance using IAM authentication:

- [Enabling and disabling IAM database authentication](#)
- [Creating and using an IAM policy for IAM database access](#)
- [Creating a database account using IAM authentication](#)

#### Note

For information about connecting to your database using pgAdmin with IAM authentication, see the blog post [Using IAM authentication to connect with pgAdmin Amazon Aurora PostgreSQL or Amazon RDS for PostgreSQL](#).

### Topics

- [Generating an IAM authentication token](#)
- [Connecting to an Amazon RDS PostgreSQL instance](#)

## Generating an IAM authentication token

The authentication token consists of several hundred characters so it can be unwieldy on the command line. One way to work around this is to save the token to an environment variable, and then use that variable when you connect. The following example shows how to use the AWS CLI to get a signed authentication token using the `generate-db-auth-token` command, and store it in a `PGPASSWORD` environment variable.

```
export RDSHOST="rdspostgres.123456789012.us-west-2.rds.amazonaws.com"
export PGPASSWORD="$(aws rds generate-db-auth-token --hostname $RDSHOST --port 5432 --
region us-west-2 --username jane_doe )"
```

In the example, the parameters to the `generate-db-auth-token` command are as follows:

- `--hostname` – The host name of the DB instance that you want to access
- `--port` – The port number used for connecting to your DB instance
- `--region` – The AWS Region where the DB instance is running
- `--username` – The database account that you want to access

The first several characters of the generated token look like the following.

```
rdspostgres.123456789012.us-west-2.rds.amazonaws.com:5432/?
Action=connect&DBUser=jane_doe&X-Amz-Algorithm=AWS4-HMAC-SHA256&X-Amz-Expires=900...
```

### Note

You cannot use a custom Route 53 DNS record instead of the DB instance endpoint to generate the authentication token.

## Connecting to an Amazon RDS PostgreSQL instance

The general format for using `psql` to connect is shown following.

```
psql "host=hostName port=portNumber sslmode=verify-full
sslrootcert=full_path_to_ssl_certificate dbname=DBName user=userName
password=authToken"
```

The parameters are as follows:

- `host` – The host name of the DB instance that you want to access
- `port` – The port number used for connecting to your DB instance
- `sslmode` – The SSL mode to use

When you use `sslmode=verify-full`, the SSL connection verifies the DB instance endpoint against the endpoint in the SSL certificate.

- `sslrootcert` – The full path to the SSL certificate file that contains the public key

For more information, see [Using SSL with a PostgreSQL DB instance](#).

To download an SSL certificate, see [Using SSL/TLS to encrypt a connection to a DB instance or cluster](#).

- `dbname` – The database that you want to access
- `user` – The database account that you want to access
- `password` – A signed IAM authentication token

 **Note**

You cannot use a custom Route 53 DNS record instead of the DB instance endpoint to generate the authentication token.

The following example shows using `psql` to connect. In the example, `psql` uses the environment variable `RDSHOST` for the host and the environment variable `PGPASSWORD` for the generated token. Also, `/sample_dir/` is the full path to the SSL certificate file that contains the public key.

```
export RDSHOST="rdspostgres.123456789012.us-west-2.rds.amazonaws.com"
export PGPASSWORD="$(aws rds generate-db-auth-token --hostname $RDSHOST --port 5432 --
region us-west-2 --username jane_doe )"

psql "host=$RDSHOST port=5432 sslmode=verify-full sslrootcert=/sample_dir/global-
bundle.pem dbname=DBName user=jane_doe password=$PGPASSWORD"
```

If you want to connect to a DB instance through a proxy, see [Connecting to a proxy using IAM authentication](#).

## Connecting to your DB instance using IAM authentication and the AWS SDK for .NET

You can connect to an RDS for MariaDB, MySQL, or PostgreSQL DB instance with the AWS SDK for .NET as described following.

### Prerequisites

The following are prerequisites for connecting to your DB instance using IAM authentication:

- [Enabling and disabling IAM database authentication](#)
- [Creating and using an IAM policy for IAM database access](#)
- [Creating a database account using IAM authentication](#)

### Examples

The following code examples show how to generate an authentication token, and then use it to connect to a DB instance.

To run this code example, you need the [AWS SDK for .NET](#), found on the AWS site. The `AWSSDK.CORE` and the `AWSSDK.RDS` packages are required. To connect to a DB instance, use the .NET database connector for the DB engine, such as `MySqlConnection` for MariaDB or MySQL, or `Npgsql` for PostgreSQL.

This code connects to a MariaDB or MySQL DB instance. Modify the values of the following variables as needed:

- `server` – The endpoint of the DB instance that you want to access
- `user` – The database account that you want to access
- `database` – The database that you want to access
- `port` – The port number used for connecting to your DB instance
- `SslMode` – The SSL mode to use

When you use `SslMode=Required`, the SSL connection verifies the DB instance endpoint against the endpoint in the SSL certificate.

- `SslCa` – The full path to the SSL certificate for Amazon RDS

To download a certificate, see [Using SSL/TLS to encrypt a connection to a DB instance or cluster](#).

**Note**

You cannot use a custom Route 53 DNS record instead of the DB instance endpoint to generate the authentication token.

```
using System;
using System.Data;
using MySql.Data;
using MySql.Data.MySqlClient;
using Amazon;

namespace ubuntu
{
    class Program
    {
        static void Main(string[] args)
        {
            var pwd =
Amazon.RDS.Util.RDSAuthTokenGenerator.GenerateAuthToken(RegionEndpoint.USEast1,
"mysqldb.123456789012.us-east-1.rds.amazonaws.com", 3306, "jane_doe");
            // for debug only Console.WriteLine("{0}\n", pwd); //this verifies the token is
generated

            MySqlConnection conn = new MySqlConnection($"server=mysqldb.123456789012.us-
east-1.rds.amazonaws.com;user=jane_doe;database=mydB;port=3306;password={pwd};SslMode=Required;
            conn.Open();

            // Define a query
            MySqlCommand sampleCommand = new MySqlCommand("SHOW DATABASES;", conn);

            // Execute a query
            MySqlDataReader mysqlDataRdr = sampleCommand.ExecuteReader();

            // Read all rows and output the first column in each row
            while (mysqlDataRdr.Read())
                Console.WriteLine(mysqlDataRdr[0]);

            mysqlDataRdr.Close();
            // Close connection
            conn.Close();
        }
    }
}
```

```
}  
}
```

This code connects to a PostgreSQL DB instance.

Modify the values of the following variables as needed:

- `Server` – The endpoint of the DB instance that you want to access
- `User ID` – The database account that you want to access
- `Database` – The database that you want to access
- `Port` – The port number used for connecting to your DB instance
- `SSL Mode` – The SSL mode to use

When you use `SSL Mode=Required`, the SSL connection verifies the DB instance endpoint against the endpoint in the SSL certificate.

- `Root Certificate` – The full path to the SSL certificate for Amazon RDS

To download a certificate, see [Using SSL/TLS to encrypt a connection to a DB instance or cluster](#).

### Note

You cannot use a custom Route 53 DNS record instead of the DB instance endpoint to generate the authentication token.

```
using System;  
using Npgsql;  
using Amazon.RDS.Util;  
  
namespace ConsoleApp1  
{  
    class Program  
    {  
        static void Main(string[] args)  
        {  
            var pwd =  
                RDSAuthTokenGenerator.GenerateAuthToken("postgresmydb.123456789012.us-  
east-1.rds.amazonaws.com", 5432, "jane_doe");  
            // for debug only Console.WriteLine("{0}\n", pwd); //this verifies the token is generated
```

```
        NpgsqlConnection conn = new
NpgsqlConnection($"Server=postgresmydb.123456789012.us-east-1.rds.amazonaws.com;User
Id=jane_doe;Password={pwd};Database=mydb;SSL Mode=Require;Root
Certificate=full_path_to_ssl_certificate");
        conn.Open();

        // Define a query
        NpgsqlCommand cmd = new NpgsqlCommand("select count(*) FROM
pg_user", conn);

        // Execute a query
        NpgsqlDataReader dr = cmd.ExecuteReader();

        // Read all rows and output the first column in each row
        while (dr.Read())
            Console.WriteLine("{0}\n", dr[0]);

        // Close connection
        conn.Close();
    }
}
```

If you want to connect to a DB instance through a proxy, see [Connecting to a proxy using IAM authentication](#).

## Connecting to your DB instance using IAM authentication and the AWS SDK for Go

You can connect to an RDS for MariaDB, MySQL, or PostgreSQL DB instance with the AWS SDK for Go as described following.

### Prerequisites

The following are prerequisites for connecting to your DB instance using IAM authentication:

- [Enabling and disabling IAM database authentication](#)
- [Creating and using an IAM policy for IAM database access](#)
- [Creating a database account using IAM authentication](#)

### Examples

To run these code examples, you need the [AWS SDK for Go](#), found on the AWS site.

Modify the values of the following variables as needed:

- `dbName` – The database that you want to access
- `dbUser` – The database account that you want to access
- `dbHost` – The endpoint of the DB instance that you want to access

**Note**

You cannot use a custom Route 53 DNS record instead of the DB instance endpoint to generate the authentication token.

- `dbPort` – The port number used for connecting to your DB instance
- `region` – The AWS Region where the DB instance is running

In addition, make sure the imported libraries in the sample code exist on your system.

**Important**

The examples in this section use the following code to provide credentials that access a database from a local environment:

```
creds := credentials.NewEnvCredentials()
```

If you are accessing a database from an AWS service, such as Amazon EC2 or Amazon ECS, you can replace the code with the following code:

```
sess := session.Must(session.NewSession())
```

```
creds := sess.Config.Credentials
```

If you make this change, make sure you add the following import:

```
"github.com/aws/aws-sdk-go/aws/session"
```

## Topics

- [Connecting using IAM authentication and the AWS SDK for Go V2](#)
- [Connecting using IAM authentication and the AWS SDK for Go V1.](#)

## Connecting using IAM authentication and the AWS SDK for Go V2

You can connect to a DB instance using IAM authentication and the AWS SDK for Go V2.

The following code examples show how to generate an authentication token, and then use it to connect to a DB instance.

This code connects to a MariaDB or MySQL DB instance.

```
package main

import (
    "context"
    "database/sql"
    "fmt"

    "github.com/aws/aws-sdk-go-v2/config"
    "github.com/aws/aws-sdk-go-v2/feature/rds/auth"
    _ "github.com/go-sql-driver/mysql"
)

func main() {

    var dbName string = "DatabaseName"
    var dbUser string = "DatabaseUser"
    var dbHost string = "mysqldb.123456789012.us-east-1.rds.amazonaws.com"
    var dbPort int = 3306
    var dbEndpoint string = fmt.Sprintf("%s:%d", dbHost, dbPort)
    var region string = "us-east-1"

    cfg, err := config.LoadDefaultConfig(context.TODO())
    if err != nil {
        panic("configuration error: " + err.Error())
    }

    authenticationToken, err := auth.BuildAuthToken(
        context.TODO(), dbEndpoint, region, dbUser, cfg.Credentials)
    if err != nil {
        panic("failed to create authentication token: " + err.Error())
    }

    dsn := fmt.Sprintf("%s:%s@tcp(%s)/%s?tls=true&allowCleartextPasswords=true",
        dbUser, authenticationToken, dbEndpoint, dbName,
    )
}
```

```
db, err := sql.Open("mysql", dsn)
if err != nil {
    panic(err)
}

err = db.Ping()
if err != nil {
    panic(err)
}
}
```

This code connects to a PostgreSQL DB instance.

```
package main

import (
    "context"
    "database/sql"
    "fmt"

    "github.com/aws/aws-sdk-go-v2/config"
    "github.com/aws/aws-sdk-go-v2/feature/rds/auth"
    _ "github.com/lib/pq"
)

func main() {

    var dbName string = "DatabaseName"
    var dbUser string = "DatabaseUser"
    var dbHost string = "postgresmydb.123456789012.us-east-1.rds.amazonaws.com"
    var dbPort int = 5432
    var dbEndpoint string = fmt.Sprintf("%s:%d", dbHost, dbPort)
    var region string = "us-east-1"

    cfg, err := config.LoadDefaultConfig(context.TODO())
    if err != nil {
        panic("configuration error: " + err.Error())
    }

    authenticationToken, err := auth.BuildAuthToken(
        context.TODO(), dbEndpoint, region, dbUser, cfg.Credentials)
    if err != nil {
```

```
    panic("failed to create authentication token: " + err.Error())
}

dsn := fmt.Sprintf("host=%s port=%d user=%s password=%s dbname=%s",
    dbHost, dbPort, dbUser, authenticationToken, dbName,
)

db, err := sql.Open("postgres", dsn)
if err != nil {
    panic(err)
}

err = db.Ping()
if err != nil {
    panic(err)
}
}
```

If you want to connect to a DB instance through a proxy, see [Connecting to a proxy using IAM authentication](#).

### Connecting using IAM authentication and the AWS SDK for Go V1.

You can connect to a DB instance using IAM authentication and the AWS SDK for Go V1

The following code examples show how to generate an authentication token, and then use it to connect to a DB instance.

This code connects to a MariaDB or MySQL DB instance.

```
package main

import (
    "database/sql"
    "fmt"
    "log"

    "github.com/aws/aws-sdk-go/aws/credentials"
    "github.com/aws/aws-sdk-go/service/rds/rdsutils"
    _ "github.com/go-sql-driver/mysql"
)

func main() {
```

```
dbName := "app"
dbUser := "jane_doe"
dbHost := "mysqldb.123456789012.us-east-1.rds.amazonaws.com"
dbPort := 3306
dbEndpoint := fmt.Sprintf("%s:%d", dbHost, dbPort)
region := "us-east-1"

creds := credentials.NewEnvCredentials()
authToken, err := rdsutils.BuildAuthToken(dbEndpoint, region, dbUser, creds)
if err != nil {
    panic(err)
}

dsn := fmt.Sprintf("%s:%s@tcp(%s)/%s?tls=true&allowCleartextPasswords=true",
    dbUser, authToken, dbEndpoint, dbName,
)

db, err := sql.Open("mysql", dsn)
if err != nil {
    panic(err)
}

err = db.Ping()
if err != nil {
    panic(err)
}
}
```

This code connects to a PostgreSQL DB instance.

```
package main

import (
    "database/sql"
    "fmt"

    "github.com/aws/aws-sdk-go/aws/credentials"
    "github.com/aws/aws-sdk-go/service/rds/rdsutils"
    _ "github.com/lib/pq"
)

func main() {
    dbName := "app"
```

```
dbUser := "jane_doe"
dbHost := "postgresmydb.123456789012.us-east-1.rds.amazonaws.com"
dbPort := 5432
dbEndpoint := fmt.Sprintf("%s:%d", dbHost, dbPort)
region := "us-east-1"

creds := credentials.NewEnvCredentials()
authToken, err := rdsutils.BuildAuthToken(dbEndpoint, region, dbUser, creds)
if err != nil {
    panic(err)
}

dsn := fmt.Sprintf("host=%s port=%d user=%s password=%s dbname=%s",
    dbHost, dbPort, dbUser, authToken, dbName,
)

db, err := sql.Open("postgres", dsn)
if err != nil {
    panic(err)
}

err = db.Ping()
if err != nil {
    panic(err)
}
}
```

If you want to connect to a DB instance through a proxy, see [Connecting to a proxy using IAM authentication](#).

## Connecting to your DB instance using IAM authentication and the AWS SDK for Java

You can connect to an RDS for MariaDB, MySQL, or PostgreSQL DB instance with the AWS SDK for Java as described following.

### Prerequisites

The following are prerequisites for connecting to your DB instance using IAM authentication:

- [Enabling and disabling IAM database authentication](#)
- [Creating and using an IAM policy for IAM database access](#)
- [Creating a database account using IAM authentication](#)

- [Set up the AWS SDK for Java](#)

For examples on how to use the SDK for Java 2.x, see [Amazon RDS examples using SDK for Java 2.x](#).

## Topics

- [Generating an IAM authentication token](#)
- [Manually constructing an IAM authentication token](#)
- [Connecting to a DB instance](#)

## Generating an IAM authentication token

If you are writing programs using the AWS SDK for Java, you can get a signed authentication token using the `RdsIamAuthTokenGenerator` class. Using this class requires that you provide AWS credentials. To do this, you create an instance of the `DefaultAWSCredentialsProviderChain` class. `DefaultAWSCredentialsProviderChain` uses the first AWS access key and secret key that it finds in the [default credential provider chain](#). For more information about AWS access keys, see [Managing access keys for users](#).

### Note

You cannot use a custom Route 53 DNS record instead of the DB instance endpoint to generate the authentication token.

After you create an instance of `RdsIamAuthTokenGenerator`, you can call the `getAuthToken` method to obtain a signed token. Provide the AWS Region, host name, port number, and user name. The following code example illustrates how to do this.

```
package com.amazonaws.codesamples;

import com.amazonaws.auth.DefaultAWSCredentialsProviderChain;
import com.amazonaws.services.rds.auth.GetIamAuthTokenRequest;
import com.amazonaws.services.rds.auth.RdsIamAuthTokenGenerator;

public class GenerateRDSAuthToken {

    public static void main(String[] args) {
```

```
String region = "us-west-2";
String hostname = "rdsmysql.123456789012.us-west-2.rds.amazonaws.com";
String port = "3306";
String username = "jane_doe";

System.out.println(generateAuthToken(region, hostname, port, username));
}

static String generateAuthToken(String region, String hostName, String port, String
username) {

    RdsIamAuthTokenGenerator generator = RdsIamAuthTokenGenerator.builder()
        .credentials(new DefaultAWSCredentialsProviderChain())
        .region(region)
        .build();

    String authToken = generator.getAuthToken(
        GetIamAuthTokenRequest.builder()
            .hostname(hostName)
            .port(Integer.parseInt(port))
            .userName(username)
            .build());

    return authToken;
}
}
```

## Manually constructing an IAM authentication token

In Java, the easiest way to generate an authentication token is to use `RdsIamAuthTokenGenerator`. This class creates an authentication token for you, and then signs it using AWS signature version 4. For more information, see [Signature version 4 signing process](#) in the *AWS General Reference*.

However, you can also construct and sign an authentication token manually, as shown in the following code example.

```
package com.amazonaws.codesamples;

import com.amazonaws.SdkClientException;
import com.amazonaws.auth.DefaultAWSCredentialsProviderChain;
```

```
import com.amazonaws.auth.SigningAlgorithm;
import com.amazonaws.util.BinaryUtils;
import org.apache.commons.lang3.StringUtils;

import javax.crypto.Mac;
import javax.crypto.spec.SecretKeySpec;
import java.nio.charset.Charset;
import java.security.MessageDigest;
import java.text.SimpleDateFormat;
import java.util.Date;
import java.util.SortedMap;
import java.util.TreeMap;

import static com.amazonaws.auth.internal.SignerConstants.AWS4_TERMINATOR;
import static com.amazonaws.util.StringUtils.UTF8;

public class CreateRDSAuthTokenManually {
    public static String httpMethod = "GET";
    public static String action = "connect";
    public static String canonicalURIPParameter = "/";
    public static SortedMap<String, String> canonicalQueryParameters = new TreeMap();
    public static String payload = StringUtils.EMPTY;
    public static String signedHeader = "host";
    public static String algorithm = "AWS4-HMAC-SHA256";
    public static String serviceName = "rds-db";
    public static String requestWithoutSignature;

    public static void main(String[] args) throws Exception {

        String region = "us-west-2";
        String instanceName = "rdsmysql.123456789012.us-west-2.rds.amazonaws.com";
        String port = "3306";
        String username = "jane_doe";

        Date now = new Date();
        String date = new SimpleDateFormat("yyyyMMdd").format(now);
        String dateTimeStamp = new

    }
}
```

```
    }  
  }  
}
```

## Connecting to a DB instance

The following code example shows how to generate an authentication token, and then use it to connect to an instance running MariaDB or MySQL.

To run this code example, you need the [AWS SDK for Java](#), found on the AWS site. In addition, you need the following:

- MySQL Connector/J. This code example was tested with `mysql-connector-java-5.1.33-bin.jar`.
- An intermediate certificate for Amazon RDS that is specific to an AWS Region. (For more information, see [Using SSL/TLS to encrypt a connection to a DB instance or cluster](#).) At runtime, the class loader looks for the certificate in the same directory as this Java code example, so that the class loader can find it.
- Modify the values of the following variables as needed:
  - `RDS_INSTANCE_HOSTNAME` – The host name of the DB instance that you want to access.
  - `RDS_INSTANCE_PORT` – The port number used for connecting to your PostgreSQL DB instance.
  - `REGION_NAME` – The AWS Region where the DB instance is running.
  - `DB_USER` – The database account that you want to access.
  - `SSL_CERTIFICATE` – An SSL certificate for Amazon RDS that is specific to an AWS Region.

To download a certificate for your AWS Region, see [Using SSL/TLS to encrypt a connection to a DB instance or cluster](#). Place the SSL certificate in the same directory as this Java program file, so that the class loader can find the certificate at runtime.

This code example obtains AWS credentials from the [default credential provider chain](#).

### Note

Specify a password for `DEFAULT_KEY_STORE_PASSWORD` other than the prompt shown here as a security best practice.

```

If you want to connect to a DB instance through a proxy, see [Connecting to a proxy using IAM authentication](#).

## Connecting to your DB instance using IAM authentication and the AWS SDK for Python (Boto3)

You can connect to an RDS for MariaDB, MySQL, or PostgreSQL DB instance with the AWS SDK for Python (Boto3) as described following.

### Prerequisites

The following are prerequisites for connecting to your DB instance using IAM authentication:

- [Enabling and disabling IAM database authentication](#)
- [Creating and using an IAM policy for IAM database access](#)
- [Creating a database account using IAM authentication](#)

In addition, make sure the imported libraries in the sample code exist on your system.

### Examples

The code examples use profiles for shared credentials. For information about the specifying credentials, see [Credentials](#) in the AWS SDK for Python (Boto3) documentation.

The following code examples show how to generate an authentication token, and then use it to connect to a DB instance.

To run this code example, you need the [AWS SDK for Python \(Boto3\)](#), found on the AWS site.

Modify the values of the following variables as needed:

- ENDPOINT – The endpoint of the DB instance that you want to access
- PORT – The port number used for connecting to your DB instance
- USER – The database account that you want to access
- REGION – The AWS Region where the DB instance is running
- DBNAME – The database that you want to access
- SSLCERTIFICATE – The full path to the SSL certificate for Amazon RDS

For `ssl_ca`, specify an SSL certificate. To download an SSL certificate, see [Using SSL/TLS to encrypt a connection to a DB instance or cluster](#).

**Note**

You cannot use a custom Route 53 DNS record instead of the DB instance endpoint to generate the authentication token.

This code connects to a MariaDB or MySQL DB instance.

Before running this code, install the PyMySQL driver by following the instructions in the [Python Package Index](#).

```
import pymysql
import sys
import boto3
import os

ENDPOINT="mysql.db.123456789012.us-east-1.rds.amazonaws.com"
PORT="3306"
USER="jane_doe"
REGION="us-east-1"
DBNAME="mydb"
os.environ['LIBMYSQL_ENABLE_CLEARTEXT_PLUGIN'] = '1'

#gets the credentials from .aws/credentials
session = boto3.Session(profile_name='default')
client = session.client('rds')
```

```
token = client.generate_db_auth_token(DBHostname=ENDPOINT, Port=PORT, DBUsername=USER,
    Region=REGION)

try:
    conn = pymysql.connect(host=ENDPOINT, user=USER, passwd=token, port=PORT,
        database=DBNAME, ssl_ca='SSLCERTIFICATE')
    cur = conn.cursor()
    cur.execute("""SELECT now()""")
    query_results = cur.fetchall()
    print(query_results)
except Exception as e:
    print("Database connection failed due to {}".format(e))
```

This code connects to a PostgreSQL DB instance.

Before running this code, install `psycopg2` by following the instructions in [Psycopg documentation](#).

```
import psycopg2
import sys
import boto3
import os

ENDPOINT="postgresmydb.123456789012.us-east-1.rds.amazonaws.com"
PORT="5432"
USER="jane_doe"
REGION="us-east-1"
DBNAME="mydb"

#gets the credentials from .aws/credentials
session = boto3.Session(profile_name='RDSCreds')
client = session.client('rds')

token = client.generate_db_auth_token(DBHostname=ENDPOINT, Port=PORT, DBUsername=USER,
    Region=REGION)

try:
    conn = psycopg2.connect(host=ENDPOINT, port=PORT, database=DBNAME, user=USER,
        password=token, sslrootcert="SSLCERTIFICATE")
    cur = conn.cursor()
    cur.execute("""SELECT now()""")
```

```
query_results = cur.fetchall()
print(query_results)
except Exception as e:
    print("Database connection failed due to {}".format(e))
```

If you want to connect to a DB instance through a proxy, see [Connecting to a proxy using IAM authentication](#).

## Troubleshooting Amazon RDS identity and access

Use the following information to help you diagnose and fix common issues that you might encounter when working with Amazon RDS and IAM.

### Topics

- [I'm not authorized to perform an action in Amazon RDS](#)
- [I'm not authorized to perform iam:PassRole](#)
- [I want to allow people outside of my AWS account to access my Amazon RDS resources](#)

### I'm not authorized to perform an action in Amazon RDS

If the AWS Management Console tells you that you're not authorized to perform an action, then you must contact your administrator for assistance. Your administrator is the person that provided you with your sign-in credentials.

The following example error occurs when the `mateojackson` user tries to use the console to view details about a `widget` but does not have `rds:GetWidget` permissions.

```
User: arn:aws:iam::123456789012:user/mateojackson is not authorized to perform:
rds:GetWidget on resource: my-example-widget
```

In this case, Mateo asks his administrator to update his policies to allow him to access the `my-example-widget` resource using the `rds:GetWidget` action.

### I'm not authorized to perform iam:PassRole

If you receive an error that you're not authorized to perform the `iam:PassRole` action, then you must contact your administrator for assistance. Your administrator is the person that provided you

with your sign-in credentials. Ask that person to update your policies to allow you to pass a role to Amazon RDS.

Some AWS services allow you to pass an existing role to that service, instead of creating a new service role or service-linked role. To do this, you must have permissions to pass the role to the service.

The following example error occurs when a user named `marymajor` tries to use the console to perform an action in Amazon RDS. However, the action requires the service to have permissions granted by a service role. Mary does not have permissions to pass the role to the service.

```
User: arn:aws:iam::123456789012:user/marymajor is not authorized to perform:
iam:PassRole
```

In this case, Mary asks her administrator to update her policies to allow her to perform the `iam:PassRole` action.

## I want to allow people outside of my AWS account to access my Amazon RDS resources

You can create a role that users in other accounts or people outside of your organization can use to access your resources. You can specify who is trusted to assume the role. For services that support resource-based policies or access control lists (ACLs), you can use those policies to grant people access to your resources.

To learn more, consult the following:

- To learn whether Amazon RDS supports these features, see [How Amazon RDS works with IAM](#).
- To learn how to provide access to your resources across AWS accounts that you own, see [Providing access to an IAM user in another AWS account that you own](#) in the *IAM User Guide*.
- To learn how to provide access to your resources to third-party AWS accounts, see [Providing access to AWS accounts owned by third parties](#) in the *IAM User Guide*.
- To learn how to provide access through identity federation, see [Providing access to externally authenticated users \(identity federation\)](#) in the *IAM User Guide*.
- To learn the difference between using roles and resource-based policies for cross-account access, see [How IAM roles differ from resource-based policies](#) in the *IAM User Guide*.

# Logging and monitoring in Amazon RDS

Monitoring is an important part of maintaining the reliability, availability, and performance of Amazon RDS and your AWS solutions. You should collect monitoring data from all of the parts of your AWS solution so that you can more easily debug a multi-point failure if one occurs. AWS provides several tools for monitoring your Amazon RDS resources and responding to potential incidents:

## Amazon CloudWatch Alarms

Using Amazon CloudWatch alarms, you watch a single metric over a time period that you specify. If the metric exceeds a given threshold, a notification is sent to an Amazon SNS topic or AWS Auto Scaling policy. CloudWatch alarms do not invoke actions because they are in a particular state. Rather the state must have changed and been maintained for a specified number of periods.

## AWS CloudTrail Logs

CloudTrail provides a record of actions taken by a user, role, or an AWS service in Amazon RDS. CloudTrail captures all API calls for Amazon RDS as events, including calls from the console and from code calls to Amazon RDS API operations. Using the information collected by CloudTrail, you can determine the request that was made to Amazon RDS, the IP address from which the request was made, who made the request, when it was made, and additional details. For more information, see [Monitoring Amazon RDS API calls in AWS CloudTrail](#).

## Enhanced Monitoring

Amazon RDS provides metrics in real time for the operating system (OS) that your DB instance runs on. You can view the metrics for your DB instance using the console, or consume the Enhanced Monitoring JSON output from Amazon CloudWatch Logs in a monitoring system of your choice. For more information, see [Monitoring OS metrics with Enhanced Monitoring](#).

## Amazon RDS Performance Insights

Performance Insights expands on existing Amazon RDS monitoring features to illustrate your database's performance and help you analyze any issues that affect it. With the Performance Insights dashboard, you can visualize the database load and filter the load by waits, SQL statements, hosts, or users. For more information, see [Monitoring DB load with Performance Insights on Amazon RDS](#).

## Database Logs

You can view, download, and watch database logs using the AWS Management Console, AWS CLI, or RDS API. For more information, see [Monitoring Amazon RDS log files](#).

## Amazon RDS Recommendations

Amazon RDS provides automated recommendations for database resources. These recommendations provide best practice guidance by analyzing DB instance configuration, usage, and performance data. For more information, see [Recommendations from Amazon RDS](#).

## Amazon RDS Event Notification

Amazon RDS uses the Amazon Simple Notification Service (Amazon SNS) to provide notification when an Amazon RDS event occurs. These notifications can be in any notification form supported by Amazon SNS for an AWS Region, such as an email, a text message, or a call to an HTTP endpoint. For more information, see [Working with Amazon RDS event notification](#).

## AWS Trusted Advisor

Trusted Advisor draws upon best practices learned from serving hundreds of thousands of AWS customers. Trusted Advisor inspects your AWS environment and then makes recommendations when opportunities exist to save money, improve system availability and performance, or help close security gaps. All AWS customers have access to five Trusted Advisor checks. Customers with a Business or Enterprise support plan can view all Trusted Advisor checks.

Trusted Advisor has the following Amazon RDS-related checks:

- Amazon RDS Idle DB Instances
- Amazon RDS Security Group Access Risk
- Amazon RDS Backups
- Amazon RDS Multi-AZ

For more information on these checks, see [Trusted Advisor best practices \(checks\)](#).

For more information about monitoring Amazon RDS, see [Monitoring metrics in an Amazon RDS instance](#).

# Compliance validation for Amazon RDS

Third-party auditors assess the security and compliance of Amazon RDS as part of multiple AWS compliance programs. These include SOC, PCI, FedRAMP, HIPAA, and others.

For a list of AWS services in scope of specific compliance programs, see [AWS services in scope by compliance program](#). For general information, see [AWS compliance programs](#).

You can download third-party audit reports using AWS Artifact. For more information, see [Downloading reports in AWS Artifact](#).

Your compliance responsibility when using Amazon RDS is determined by the sensitivity of your data, your organization's compliance objectives, and applicable laws and regulations. AWS provides the following resources to help with compliance:

- [Security and compliance quick start guides](#) – These deployment guides discuss architectural considerations and provide steps for deploying security- and compliance-focused baseline environments on AWS.
- [Architecting for HIPAA Security and Compliance on Amazon Web Services](#) – This whitepaper describes how companies can use AWS to create HIPAA-compliant applications.
- [AWS compliance resources](#) – This collection of workbooks and guides that might apply to your industry and location.
- [AWS Config](#) – This AWS service assesses how well your resource configurations comply with internal practices, industry guidelines, and regulations.
- [AWS Security Hub](#) – This AWS service provides a comprehensive view of your security state within AWS. Security Hub uses security controls to evaluate your AWS resources and to check your compliance against security industry standards and best practices. For a list of supported services and controls, see [Security Hub controls reference](#).

## Resilience in Amazon RDS

The AWS global infrastructure is built around AWS Regions and Availability Zones. AWS Regions provide multiple physically separated and isolated Availability Zones, which are connected with low-latency, high-throughput, and highly redundant networking. With Availability Zones, you can design and operate applications and databases that automatically fail over between Availability Zones without interruption. Availability Zones are more highly available, fault tolerant, and scalable than traditional single or multiple data center infrastructures.

For more information about AWS Regions and Availability Zones, see [AWS global infrastructure](#).

In addition to the AWS global infrastructure, Amazon RDS offers features to help support your data resiliency and backup needs.

### Backup and restore

Amazon RDS creates and saves automated backups of your DB instance. Amazon RDS creates a storage volume snapshot of your DB instance, backing up the entire DB instance and not just individual databases.

Amazon RDS creates automated backups of your DB instance during the backup window of your DB instance. Amazon RDS saves the automated backups of your DB instance according to the backup retention period that you specify. If necessary, you can recover your database to any point in time during the backup retention period. You can also back up your DB instance manually, by manually creating a DB snapshot.

You can create a DB instance by restoring from this DB snapshot as a disaster recovery solution if the source DB instance fails.

For more information, see [Backing up, restoring, and exporting data](#).

### Replication

Amazon RDS uses the MariaDB, MySQL, Oracle, and PostgreSQL DB engines' built-in replication functionality to create a special type of DB instance called a read replica from a source DB instance. Updates made to the source DB instance are asynchronously copied to the read replica. You can reduce the load on your source DB instance by routing read queries from your applications to the read replica. Using read replicas, you can elastically scale out beyond the capacity constraints of a single DB instance for read-heavy database workloads. You can promote a read replica to a

standalone instance as a disaster recovery solution if the source DB instance fails. For some DB engines, Amazon RDS also supports other replication options.

For more information, see [Working with DB instance read replicas](#).

## Failover

Amazon RDS provides high availability and failover support for DB instances using Multi-AZ deployments. Amazon RDS uses several different technologies to provide failover support. Multi-AZ deployments for Oracle, PostgreSQL, MySQL, and MariaDB DB instances use Amazon's failover technology. SQL Server DB instances use SQL Server Database Mirroring (DBM).

For more information, see [Configuring and managing a Multi-AZ deployment](#).

## Infrastructure security in Amazon RDS

As a managed service, Amazon Relational Database Service is protected by AWS global network security. For information about AWS security services and how AWS protects infrastructure, see [AWS Cloud Security](#). To design your AWS environment using the best practices for infrastructure security, see [Infrastructure Protection](#) in *Security Pillar AWS Well-Architected Framework*.

You use AWS published API calls to access Amazon RDS through the network. Clients must support the following:

- Transport Layer Security (TLS). We require TLS 1.2 and recommend TLS 1.3.
- Cipher suites with perfect forward secrecy (PFS) such as DHE (Ephemeral Diffie-Hellman) or ECDHE (Elliptic Curve Ephemeral Diffie-Hellman). Most modern systems such as Java 7 and later support these modes.

Additionally, requests must be signed by using an access key ID and a secret access key that is associated with an IAM principal. Or you can use the [AWS Security Token Service](#) (AWS STS) to generate temporary security credentials to sign requests.

In addition, Amazon RDS offers features to help support infrastructure security.

### Security groups

Security groups control the access that traffic has in and out of a DB instance. By default, network access is turned off to a DB instance. You can specify rules in a security group that allow access from an IP address range, port, or security group. After ingress rules are configured, the same rules apply to all DB instances that are associated with that security group.

For more information, see [Controlling access with security groups](#).

### Public accessibility

When you launch a DB instance inside a virtual private cloud (VPC) based on the Amazon VPC service, you can turn on or off public accessibility for that DB instance. To designate whether the DB instance that you create has a DNS name that resolves to a public IP address, you use the *Public accessibility* parameter. By using this parameter, you can designate whether there is public access to the DB instance. You can modify a DB instance to turn on or off public accessibility by modifying the *Public accessibility* parameter.

For more information, see [Hiding a DB instance in a VPC from the internet](#).

 **Note**

If your DB instance is in a VPC but isn't publicly accessible, you can also use an AWS Site-to-Site VPN connection or an AWS Direct Connect connection to access it from a private network. For more information, see [Internet traffic privacy](#).

# Amazon RDS API and interface VPC endpoints (AWS PrivateLink)

You can establish a private connection between your VPC and Amazon RDS API endpoints by creating an *interface VPC endpoint*. Interface endpoints are powered by [AWS PrivateLink](#).

AWS PrivateLink enables you to privately access Amazon RDS API operations without an internet gateway, NAT device, VPN connection, or AWS Direct Connect connection. DB instances in your VPC don't need public IP addresses to communicate with Amazon RDS API endpoints to launch, modify, or terminate DB instances. Your DB instances also don't need public IP addresses to use any of the available RDS API operations. Traffic between your VPC and Amazon RDS doesn't leave the Amazon network.

Each interface endpoint is represented by one or more elastic network interfaces in your subnets. For more information on elastic network interfaces, see [Elastic network interfaces](#) in the *Amazon EC2 User Guide*.

For more information about VPC endpoints, see [Interface VPC endpoints \(AWS PrivateLink\)](#) in the *Amazon VPC User Guide*. For more information about RDS API operations, see [Amazon RDS API Reference](#).

You don't need an interface VPC endpoint to connect to a DB instance. For more information, see [Scenarios for accessing a DB instance in a VPC](#).

## Considerations for VPC endpoints

Before you set up an interface VPC endpoint for Amazon RDS API endpoints, ensure that you review [Interface endpoint properties and limitations](#) in the *Amazon VPC User Guide*.

All RDS API operations relevant to managing Amazon RDS resources are available from your VPC using AWS PrivateLink.

VPC endpoint policies are supported for RDS API endpoints. By default, full access to RDS API operations is allowed through the endpoint. For more information, see [Controlling access to services with VPC endpoints](#) in the *Amazon VPC User Guide*.

## Availability

Amazon RDS API currently supports VPC endpoints in the following AWS Regions:

- US East (Ohio)
- US East (N. Virginia)
- US West (N. California)
- US West (Oregon)
- Africa (Cape Town)
- Asia Pacific (Hong Kong)
- Asia Pacific (Mumbai)
- Asia Pacific (Osaka)
- Asia Pacific (Seoul)
- Asia Pacific (Singapore)
- Asia Pacific (Sydney)
- Asia Pacific (Tokyo)
- Canada (Central)
- Canada West (Calgary)
- China (Beijing)
- China (Ningxia)
- Europe (Frankfurt)
- Europe (Zurich)
- Europe (Ireland)
- Europe (London)
- Europe (Paris)
- Europe (Stockholm)
- Europe (Milan)
- Israel (Tel Aviv)
- Middle East (Bahrain)
- South America (São Paulo)
- AWS GovCloud (US-East)
- AWS GovCloud (US-West)

## Creating an interface VPC endpoint for Amazon RDS API

You can create a VPC endpoint for the Amazon RDS API using either the Amazon VPC console or the AWS Command Line Interface (AWS CLI). For more information, see [Creating an interface endpoint](#) in the *Amazon VPC User Guide*.

Create a VPC endpoint for Amazon RDS API using the service name `com.amazonaws.region.rds`.

Excluding AWS Regions in China, if you enable private DNS for the endpoint, you can make API requests to Amazon RDS with the VPC endpoint using its default DNS name for the AWS Region, for example `rds.us-east-1.amazonaws.com`. For the China (Beijing) and China (Ningxia) AWS Regions, you can make API requests with the VPC endpoint using `rds-api.cn-north-1.amazonaws.com.cn` and `rds-api.cn-northwest-1.amazonaws.com.cn`, respectively.

For more information, see [Accessing a service through an interface endpoint](#) in the *Amazon VPC User Guide*.

## Creating a VPC endpoint policy for Amazon RDS API

You can attach an endpoint policy to your VPC endpoint that controls access to Amazon RDS API. The policy specifies the following information:

- The principal that can perform actions.
- The actions that can be performed.
- The resources on which actions can be performed.

For more information, see [Controlling access to services with VPC endpoints](#) in the *Amazon VPC User Guide*.

### Example: VPC endpoint policy for Amazon RDS API actions

The following is an example of an endpoint policy for Amazon RDS API. When attached to an endpoint, this policy grants access to the listed Amazon RDS API actions for all principals on all resources.

```
{
  "Statement": [
    {
```

```
    "Principal": "*",
    "Effect": "Allow",
    "Action": [
        "rds:CreateDBInstance",
        "rds:ModifyDBInstance",
        "rds:CreateDBSnapshot"
    ],
    "Resource": "*"
  }
]
```

### Example: VPC endpoint policy that denies all access from a specified AWS account

The following VPC endpoint policy denies AWS account 123456789012 all access to resources using the endpoint. The policy allows all actions from other accounts.

```
{
  "Statement": [
    {
      "Action": "*",
      "Effect": "Allow",
      "Resource": "*",
      "Principal": "*"
    },
    {
      "Action": "*",
      "Effect": "Deny",
      "Resource": "*",
      "Principal": { "AWS": [ "123456789012" ] }
    }
  ]
}
```

## Security best practices for Amazon RDS

Use AWS Identity and Access Management (IAM) accounts to control access to Amazon RDS API operations, especially operations that create, modify, or delete Amazon RDS resources. Such resources include DB instances, security groups, and parameter groups. Also use IAM to control actions that perform common administrative actions such as backing up and restoring DB instances.

- Create an individual user for each person who manages Amazon RDS resources, including yourself. Don't use AWS root credentials to manage Amazon RDS resources.
- Grant each user the minimum set of permissions required to perform his or her duties.
- Use IAM groups to effectively manage permissions for multiple users.
- Rotate your IAM credentials regularly.
- Configure AWS Secrets Manager to automatically rotate the secrets for Amazon RDS. For more information, see [Rotating your AWS Secrets Manager secrets](#) in the *AWS Secrets Manager User Guide*. You can also retrieve the credential from AWS Secrets Manager programmatically. For more information, see [Retrieving the secret value](#) in the *AWS Secrets Manager User Guide*.

For more information about Amazon RDS security, see [Security in Amazon RDS](#). For more information about IAM, see [AWS Identity and Access Management](#). For information on IAM best practices, see [IAM best practices](#).

AWS Security Hub uses security controls to evaluate resource configurations and security standards to help you comply with various compliance frameworks. For more information about using Security Hub to evaluate RDS resources, see [Amazon Relational Database Service controls](#) in the AWS Security Hub User Guide.

You can monitor your usage of RDS as it relates to security best practices by using Security Hub. For more information, see [What is AWS Security Hub?](#)

Use the AWS Management Console, the AWS CLI, or the RDS API to change the password for your master user. If you use another tool, such as a SQL client, to change the master user password, it might result in privileges being revoked for the user unintentionally.

## Controlling access with security groups

VPC security groups control the access that traffic has in and out of a DB instance. By default, network access is turned off for a DB instance. You can specify rules in a security group that allow access from an IP address range, port, or security group. After ingress rules are configured, the same rules apply to all DB instances that are associated with that security group. You can specify up to 20 rules in a security group.

### Overview of VPC security groups

Each VPC security group rule makes it possible for a specific source to access a DB instance in a VPC that is associated with that VPC security group. The source can be a range of addresses (for

example, 203.0.113.0/24), or another VPC security group. By specifying a VPC security group as the source, you allow incoming traffic from all instances (typically application servers) that use the source VPC security group. VPC security groups can have rules that govern both inbound and outbound traffic. However, the outbound traffic rules typically don't apply to DB instances. Outbound traffic rules apply only if the DB instance acts as a client. For example, outbound traffic rules apply to an Oracle DB instance with outbound database links. You must use the [Amazon EC2 API](#) or the **Security Group** option on the VPC console to create VPC security groups.

When you create rules for your VPC security group that allow access to the instances in your VPC, you must specify a port for each range of addresses that the rule allows access for. For example, if you want to turn on Secure Shell (SSH) access for instances in the VPC, create a rule allowing access to TCP port 22 for the specified range of addresses.

You can configure multiple VPC security groups that allow access to different ports for different instances in your VPC. For example, you can create a VPC security group that allows access to TCP port 80 for web servers in your VPC. You can then create another VPC security group that allows access to TCP port 3306 for RDS for MySQL DB instances in your VPC.

For more information on VPC security groups, see [Security groups](#) in the *Amazon Virtual Private Cloud User Guide*.

#### Note

If your DB instance is in a VPC but isn't publicly accessible, you can also use an AWS Site-to-Site VPN connection or an AWS Direct Connect connection to access it from a private network. For more information, see [Internet traffic privacy](#).

## Security group scenario

A common use of a DB instance in a VPC is to share data with an application server running in an Amazon EC2 instance in the same VPC, which is accessed by a client application outside the VPC. For this scenario, you use the RDS and VPC pages on the AWS Management Console or the RDS and EC2 API operations to create the necessary instances and security groups:

1. Create a VPC security group (for example, sg-0123ec2example) and define inbound rules that use the IP addresses of the client application as the source. This security group allows your client application to connect to EC2 instances in a VPC that uses this security group.

2. Create an EC2 instance for the application and add the EC2 instance to the VPC security group (sg-0123ec2example) that you created in the previous step.
3. Create a second VPC security group (for example, sg-6789rdsexample) and create a new rule by specifying the VPC security group that you created in step 1 (sg-0123ec2example) as the source.
4. Create a new DB instance and add the DB instance to the VPC security group (sg-6789rdsexample) that you created in the previous step. When you create the DB instance, use the same port number as the one specified for the VPC security group (sg-6789rdsexample) rule that you created in step 3.

The following diagram shows this scenario.

For detailed instructions about configuring a VPC for this scenario, see [Tutorial: Create a VPC for use with a DB instance \(IPv4 only\)](#). For more information about using a VPC, see [Amazon VPC and Amazon RDS](#).

## Creating a VPC security group

You can create a VPC security group for a DB instance by using the VPC console. For information about creating a security group, see [Provide access to your DB instance in your VPC by creating a security group](#) and [Security groups](#) in the *Amazon Virtual Private Cloud User Guide*.

## Associating a security group with a DB instance

You can associate a security group with a DB instance by using **Modify** on the RDS console, the `ModifyDBInstance` Amazon RDS API, or the `modify-db-instance` AWS CLI command.

The following CLI example associates a specific VPC security group and removes DB security groups from the DB instance

```
aws rds modify-db-instance --db-instance-identifier dbName --vpc-security-group-ids sg-ID
```

For information about modifying a DB instance, see [Modifying an Amazon RDS DB instance](#). For security group considerations when you restore a DB instance from a DB snapshot, see [Security group considerations](#).

### Note

The RDS console displays different security group rule names for your database if the Port value is configured to a non-default value.

For RDS for Oracle DB instances, additional security groups can be associated by populating the security group options setting for the Oracle Enterprise Manager Database Express (OEM), Oracle Management Agent for Enterprise Manager Cloud Control (OEM Agent) and the Oracle Secure Sockets Layer options. In this case, both security groups associated with the DB instance and options settings apply to the DB instance. For more information about these option groups, see [Oracle Enterprise Manager](#), [Oracle Management Agent for Enterprise Manager Cloud Control](#), and [Oracle Secure Sockets Layer](#).

## Master user account privileges

When you create a new DB instance, the default master user that you use gets certain privileges for that DB instance. You can't change the master user name after the DB instance is created.

### Important

We strongly recommend that you do not use the master user directly in your applications. Instead, adhere to the best practice of using a database user created with the minimal privileges required for your application.

### Note

If you accidentally delete the permissions for the master user, you can restore them by modifying the DB instance and setting a new master user password. For more information about modifying a DB instance, see [Modifying an Amazon RDS DB instance](#).

The following table shows the privileges and database roles the master user gets for each of the database engines.

Database engine	System privilege	Database role
RDS for Db2	The master user is assigned to the masterdba group and assigned the master_user_role .  SYSMON, DBADM with DATAACCESS AND ACCESSCTRL , BINDADD, CONNECT, CREATETAB , CREATE_SECURE_OBJECT , EXPLAIN, IMPLICIT_SCHEMA , LOAD, SQLADM, WLMADM	DBA, DBA_RESTRICTED , DEVELOPER , ROLE_NULL ID_PACKAGES , ROLE_PROCEDURES , ROLE_TABLESPACES  For more information, see <a href="#">Amazon RDS for Db2 default roles</a> .
RDS for MariaDB	SELECT, INSERT, UPDATE, DELETE, CREATE, DROP, RELOAD, PROCESS, REFERENCES , INDEX, ALTER, SHOW DATABASES , CREATE TEMPORARY	—

Database engine	System privilege	Database role
	TABLES , LOCK TABLES, EXECUTE, REPLICATION CLIENT , CREATE VIEW, SHOW VIEW, CREATE ROUTINE, ALTER ROUTINE, CREATE USER, EVENT, TRIGGER, REPLICATION SLAVE	
RDS for MySQL 8.0.36 and higher	SELECT, INSERT, UPDATE, DELETE, CREATE, DROP, RELOAD, PROCESS, REFERENCES , INDEX, ALTER, SHOW DATABASES , CREATE TEMPORARY TABLES, LOCK TABLES, EXECUTE, REPLICATION SLAVE, REPLICATION CLIENT , CREATE VIEW, SHOW VIEW, CREATE ROUTINE, ALTER ROUTINE, CREATE USER, EVENT, TRIGGER, CREATE ROLE, DROP ROLE, APPLICATION_PASSWORD_ADMIN , ROLE_ADMIN , SET_USER_ID , XA_RECOVER_ADMIN	rds_superuser_role  For more information about rds_superuser_role , see <a href="#">Role-based privilege model</a> .
RDS for MySQL versions lower than 8.0.36	SELECT, INSERT, UPDATE, DELETE, CREATE, DROP, RELOAD, PROCESS, REFERENCES , INDEX, ALTER, SHOW DATABASES , CREATE TEMPORARY TABLES , LOCK TABLES, EXECUTE, REPLICATION CLIENT , CREATE VIEW, SHOW VIEW, CREATE ROUTINE, ALTER ROUTINE, CREATE USER, EVENT, TRIGGER, REPLICATION SLAVE	—

Database engine	System privilege	Database role
RDS for PostgreSQL	CREATE ROLE, CREATE DB, PASSWORD VALID UNTIL INFINITY, CREATE EXTENSION , ALTER EXTENSION , DROP EXTENSION , CREATE TABLESPACE , ALTER <OBJECT> OWNER, CHECKPOINT , PG_CANCEL_BACKEND( ) , PG_TERMINATE_BACKEND( ) , SELECT PG_STAT_REPLICATION , EXECUTE PG_STAT_STATEMENTS_RESET( ) , OWN POSTGRES_FDW_HANDLER( ) , OWN POSTGRES_FDW_VALIDATOR( ) , OWN POSTGRES_FDW , EXECUTE PG_BUFFERCACHE_PAGES( ) , SELECT PG_BUFFERCACHE	RDS_SUPERUSER  For more information about RDS_SUPERUSER, see <a href="#">Understanding PostgreSQL roles and permissions</a> .
RDS for Oracle	ADMINISTER DATABASE TRIGGER , ALTER DATABASE LINK, ALTER PUBLIC DATABASE LINK, AUDIT SYSTEM, CHANGE NOTIFICATION , DROP ANY DIRECTORY , EXEMPT ACCESS POLICY, EXEMPT IDENTITY POLICY, EXEMPT REDACTION POLICY, FLASHBACK ANY TABLE, GRANT ANY OBJECT PRIVILEGE , RESTRICTED SESSION , SELECT ANY TABLE, UNLIMITED TABLESPACE	DBA  <div data-bbox="1068 961 1507 1759" style="border: 1px solid #add8e6; border-radius: 10px; padding: 10px;"> <p><b>Note</b></p> <p>The DBA role is exempt from the following privileges:</p> <ul style="list-style-type: none"> <li>ALTER DATABASE,</li> <li>ALTER SYSTEM,</li> <li>CREATE ANY DIRECTORY ,</li> <li>CREATE EXTERNAL JOB,</li> <li>CREATE PLUGGABLE DATABASE,</li> <li>GRANT ANY PRIVILEGE ,</li> <li>GRANT ANY ROLE,</li> <li>READ ANY FILE GROUP</li> </ul> </div>

Database engine	System privilege	Database role
Amazon RDS for Microsoft SQL Server	ADMINISTER BULK OPERATIONS , ALTER ANY CONNECTION , ALTER ANY CREDENTIAL , ALTER ANY EVENT SESSION, ALTER ANY LINKED SERVER, ALTER ANY LOGIN, ALTER ANY SERVER AUDIT, ALTER ANY SERVER ROLE, ALTER SERVER STATE, ALTER TRACE, CONNECT SQL, CREATE ANY DATABASE, VIEW ANY DATABASE, VIEW ANY DEFINITION , VIEW SERVER STATE, ALTER ON ROLE SQLAgentOperatorRole	DB_OWNER (database-level role), PROCESSADMIN (server-level role), SETUPADMIN (server-level role), SQLAgentUserRole (database-level role)

## Using service-linked roles for Amazon RDS

Amazon RDS uses AWS Identity and Access Management (IAM) [service-linked roles](#). A service-linked role is a unique type of IAM role that is linked directly to Amazon RDS. Service-linked roles are predefined by Amazon RDS and include all the permissions that the service requires to call other AWS services on your behalf.

A service-linked role makes using Amazon RDS easier because you don't have to manually add the necessary permissions. Amazon RDS defines the permissions of its service-linked roles, and unless defined otherwise, only Amazon RDS can assume its roles. The defined permissions include the trust policy and the permissions policy, and that permissions policy cannot be attached to any other IAM entity.

You can delete the roles only after first deleting their related resources. This protects your Amazon RDS resources because you can't inadvertently remove permission to access the resources.

For information about other services that support service-linked roles, see [AWS services that work with IAM](#) and look for the services that have **Yes** in the **Service-Linked Role** column. Choose a **Yes** with a link to view the service-linked role documentation for that service.

### Service-linked role permissions for Amazon RDS

Amazon RDS uses the service-linked role named `AWSServiceRoleForRDS` to allow Amazon RDS to call AWS services on behalf of your DB instances.

The `AWSServiceRoleForRDS` service-linked role trusts the following services to assume the role:

- `rds.amazonaws.com`

This service-linked role has a permissions policy attached to it called `AmazonRDSServiceRolePolicy` that grants it permissions to operate in your account.

For more information about this policy, including the JSON policy document, see [AmazonRDSServiceRolePolicy](#) in the *AWS Managed Policy Reference Guide*.

#### Note

You must configure permissions to allow an IAM entity (such as a user, group, or role) to create, edit, or delete a service-linked role. If you encounter the following error message:

**Unable to create the resource. Verify that you have permission to create service linked role. Otherwise wait and try again later.**

Make sure you have the following permissions enabled:

```
{
  "Action": "iam:CreateServiceLinkedRole",
  "Effect": "Allow",
  "Resource": "arn:aws:iam::*:role/aws-service-role/rds.amazonaws.com/
AWSServiceRoleForRDS",
  "Condition": {
    "StringLike": {
      "iam:AWSServiceName": "rds.amazonaws.com"
    }
  }
}
```

For more information, see [Service-linked role permissions](#) in the *IAM User Guide*.

## Creating a service-linked role for Amazon RDS

You don't need to manually create a service-linked role. When you create a DB instance, Amazon RDS creates the service-linked role for you.

### Important

If you were using the Amazon RDS service before December 1, 2017, when it began supporting service-linked roles, then Amazon RDS created the `AWSServiceRoleForRDS` role in your account. To learn more, see [A new role appeared in my AWS account](#).

If you delete this service-linked role, and then need to create it again, you can use the same process to recreate the role in your account. When you create a DB instance, Amazon RDS creates the service-linked role for you again.

## Editing a service-linked role for Amazon RDS

Amazon RDS does not allow you to edit the `AWSServiceRoleForRDS` service-linked role. After you create a service-linked role, you cannot change the name of the role because various entities

might reference the role. However, you can edit the description of the role using IAM. For more information, see [Editing a service-linked role](#) in the *IAM User Guide*.

## Deleting a service-linked role for Amazon RDS

If you no longer need to use a feature or service that requires a service-linked role, we recommend that you delete that role. That way you don't have an unused entity that is not actively monitored or maintained. However, you must delete all of your DB instances before you can delete the service-linked role.

### Cleaning up a service-linked role

Before you can use IAM to delete a service-linked role, you must first confirm that the role has no active sessions and remove any resources used by the role.

#### To check whether the service-linked role has an active session in the IAM console

1. Sign in to the AWS Management Console and open the IAM console at <https://console.aws.amazon.com/iam/>.
2. In the navigation pane of the IAM console, choose **Roles**. Then choose the name (not the check box) of the `AWSServiceRoleForRDS` role.
3. On the **Summary** page for the chosen role, choose the **Access Advisor** tab.
4. On the **Access Advisor** tab, review recent activity for the service-linked role.

#### Note

If you are unsure whether Amazon RDS is using the `AWSServiceRoleForRDS` role, you can try to delete the role. If the service is using the role, then the deletion fails and you can view the AWS Regions where the role is being used. If the role is being used, then you must wait for the session to end before you can delete the role. You cannot revoke the session for a service-linked role.

If you want to remove the `AWSServiceRoleForRDS` role, you must first delete *all* of your DB instances .

### Deleting all of your instances

Use one of these procedures to delete each of your instances.

## To delete an instance (console)

1. Open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Databases**.
3. Choose the instance that you want to delete.
4. For **Actions**, choose **Delete**.
5. If you are prompted for **Create final Snapshot?**, choose **Yes** or **No**.
6. If you chose **Yes** in the previous step, for **Final snapshot name** enter the name of your final snapshot.
7. Choose **Delete**.

## To delete an instance (CLI)

See [delete-db-instance](#) in the *AWS CLI Command Reference*.

## To delete an instance (API)

See [DeleteDBInstance](#) in the *Amazon RDS API Reference*.

You can use the IAM console, the IAM CLI, or the IAM API to delete the `AWSServiceRoleForRDS` service-linked role. For more information, see [Deleting a service-linked role](#) in the *IAM User Guide*.

## Service-linked role permissions for Amazon RDS Custom

Amazon RDS Custom uses the service-linked role named `AWSServiceRoleForRDSCustom` to allow RDS Custom to call AWS services on behalf of your RDS DB resources.

The `AWSServiceRoleForRDSCustom` service-linked role trusts the following services to assume the role:

- `custom.rds.amazonaws.com`

This service-linked role has a permissions policy attached to it called `AmazonRDSCustomServiceRolePolicy` that grants it permissions to operate in your account.

Creating, editing, or deleting the service-linked role for RDS Custom works the same as for Amazon RDS. For more information, see [AWS managed policy: AmazonRDSCustomServiceRolePolicy](#).

**Note**

You must configure permissions to allow an IAM entity (such as a user, group, or role) to create, edit, or delete a service-linked role. If you encounter the following error message: **Unable to create the resource. Verify that you have permission to create service linked role. Otherwise wait and try again later.**

Make sure you have the following permissions enabled:

```
{
  "Action": "iam:CreateServiceLinkedRole",
  "Effect": "Allow",
  "Resource": "arn:aws:iam::*:role/aws-service-role/custom.rds.amazonaws.com/
AmazonRDSCustomServiceRolePolicy",
  "Condition": {
    "StringLike": {
      "iam:AWSServiceName": "custom.rds.amazonaws.com"
    }
  }
}
```

For more information, see [Service-linked role permissions](#) in the *IAM User Guide*.

## Service-linked role permissions for Amazon RDS Beta

Amazon RDS uses the service-linked role named `AWSServiceRoleForRDSBeta` to allow Amazon RDS to call AWS services on behalf of your RDS DB resources.

The `AWSServiceRoleForRDSBeta` service-linked role trusts the following services to assume the role:

- `rds.amazonaws.com`

This service-linked role has a permissions policy attached to it called `AmazonRDSBetaServiceRolePolicy` that grants it permissions to operate in your account. For more information, see [AWS managed policy: AmazonRDSBetaServiceRolePolicy](#).

**Note**

You must configure permissions to allow an IAM entity (such as a user, group, or role) to create, edit, or delete a service-linked role. If you encounter the following error message: **Unable to create the resource. Verify that you have permission to create service linked role. Otherwise wait and try again later.**

Make sure you have the following permissions enabled:

```
{
  "Action": "iam:CreateServiceLinkedRole",
  "Effect": "Allow",
  "Resource": "arn:aws:iam::*:role/aws-service-role/custom.rds.amazonaws.com/AmazonRDSBetaServiceRolePolicy",
  "Condition": {
    "StringLike": {
      "iam:AWSServiceName": "custom.rds.amazonaws.com"
    }
  }
}
```

For more information, see [Service-linked role permissions](#) in the *IAM User Guide*.

## Service-linked role for Amazon RDS Preview

Amazon RDS uses the service-linked role named `AWSServiceRoleForRDSPreview` to allow Amazon RDS to call AWS services on behalf of your RDS DB resources.

The `AWSServiceRoleForRDSPreview` service-linked role trusts the following services to assume the role:

- `rds.amazonaws.com`

This service-linked role has a permissions policy attached to it called `AmazonRDSPreviewServiceRolePolicy` that grants it permissions to operate in your account. For more information, see [AWS managed policy: AmazonRDSPreviewServiceRolePolicy](#).

**Note**

You must configure permissions to allow an IAM entity (such as a user, group, or role) to create, edit, or delete a service-linked role. If you encounter the following error message: **Unable to create the resource. Verify that you have permission to create service linked role. Otherwise wait and try again later.**

Make sure you have the following permissions enabled:

```
{
  "Action": "iam:CreateServiceLinkedRole",
  "Effect": "Allow",
  "Resource": "arn:aws:iam::*:role/aws-service-role/custom.rds.amazonaws.com/
AmazonRDSPreviewServiceRolePolicy",
  "Condition": {
    "StringLike": {
      "iam:AWSServiceName": "custom.rds.amazonaws.com"
    }
  }
}
```

For more information, see [Service-linked role permissions](#) in the *IAM User Guide*.

# Amazon VPC and Amazon RDS

Amazon Virtual Private Cloud (Amazon VPC) makes it possible for you to launch AWS resources, such as Amazon RDS DB instances, into a virtual private cloud (VPC).

When you use a VPC, you have control over your virtual networking environment. You can choose your own IP address range, create subnets, and configure routing and access control lists. There is no additional cost to run your DB instance in a VPC.

Accounts have a default VPC. All new DB instances are created in the default VPC unless you specify otherwise.

Following, you can find a discussion about VPC functionality relevant to Amazon RDS DB instances. For more information about Amazon VPC, see [Amazon VPC Getting Started Guide](#) and [Amazon VPC User Guide](#).

## Working with a DB instance in a VPC

Your DB instance is in a virtual private cloud (VPC). A VPC is a virtual network that is logically isolated from other virtual networks in the AWS Cloud. Amazon VPC makes it possible for you to launch AWS resources, such as an Amazon RDS DB instance or Amazon EC2 instance, into a VPC. The VPC can either be a default VPC that comes with your account or one that you create. All VPCs are associated with your AWS account.

Your default VPC has three subnets that you can use to isolate resources inside the VPC. The default VPC also has an internet gateway that can be used to provide access to resources inside the VPC from outside the VPC.

For a list of scenarios involving Amazon RDS DB instances in a VPC and outside of a VPC, see [Scenarios for accessing a DB instance in a VPC](#).

- [Hiding a DB instance in a VPC from the internet](#)
- [Creating a DB instance in a VPC](#)

In the following tutorials, you can learn to create a VPC that you can use for a common Amazon RDS scenario:

- [Tutorial: Create a VPC for use with a DB instance \(IPv4 only\)](#)
- [Tutorial: Create a VPC for use with a DB instance \(dual-stack mode\)](#)

## Working with a DB instance in a VPC

Here are some tips on working with a DB instance in a VPC:

- Your VPC must have at least two subnets. These subnets must be in two different Availability Zones in the AWS Region where you want to deploy your DB instance. A *subnet* is a segment of a VPC's IP address range that you can specify and that you can use to group DB instances based on your security and operational needs.

For Multi-AZ deployments, defining a subnet for two or more Availability Zones in an AWS Region allows Amazon RDS to create a new standby in another Availability Zone as needed. Make sure to do this even for Single-AZ deployments, just in case you want to convert them to Multi-AZ deployments at some point.

### Note

The DB subnet group for a Local Zone can have only one subnet.

- If you want your DB instance in the VPC to be publicly accessible, make sure to turn on the VPC attributes *DNS hostnames* and *DNS resolution*.
- Your VPC must have a DB subnet group that you create. You create a DB subnet group by specifying the subnets you created. Amazon RDS chooses a subnet and an IP address within that

subnet group to associate with your DB instance. The DB instance uses the Availability Zone that contains the subnet.

- Your VPC must have a VPC security group that allows access to the DB instance.

For more information, see [Scenarios for accessing a DB instance in a VPC](#).

- The CIDR blocks in each of your subnets must be large enough to accommodate spare IP addresses for Amazon RDS to use during maintenance activities, including failover and compute scaling. For example, a range such as 10.0.0.0/24 and 10.0.1.0/24 is typically large enough.
- A VPC can have an *instance tenancy* attribute of either *default* or *dedicated*. All default VPCs have the instance tenancy attribute set to default, and a default VPC can support any DB instance class.

If you choose to have your DB instance in a dedicated VPC where the instance tenancy attribute is set to dedicated, the DB instance class of your DB instance must be one of the approved Amazon EC2 dedicated instance types. For example, the r5.large EC2 dedicated instance corresponds to the db.r5.large DB instance class. For information about instance tenancy in a VPC, see [Dedicated instances](#) in the *Amazon Elastic Compute Cloud User Guide*.

For more information about the instance types that can be in a dedicated instance, see [Amazon EC2 dedicated instances](#) on the EC2 pricing page.

**Note**

When you set the instance tenancy attribute to dedicated for a DB instance, it doesn't guarantee that the DB instance will run on a dedicated host.

- When an option group is assigned to a DB instance, it's associated with the DB instance's VPC. This linkage means that you can't use the option group assigned to a DB instance if you attempt to restore the DB instance into a different VPC.
- If you restore a DB instance into a different VPC, make sure to either assign the default option group to the DB instance, assign an option group that is linked to that VPC, or create a new option group and assign it to the DB instance. With persistent or permanent options, such as Oracle TDE, you must create a new option group that includes the persistent or permanent option when restoring a DB instance into a different VPC.

## Working with DB subnet groups

*Subnets* are segments of a VPC's IP address range that you designate to group your resources based on security and operational needs. A *DB subnet group* is a collection of subnets (typically private) that you create in a VPC and that you then designate for your DB instances. By using a DB subnet group, you can specify a particular VPC when creating DB instances using the AWS CLI or RDS API. If you use the console, you can choose the VPC and subnet groups you want to use.

Each DB subnet group should have subnets in at least two Availability Zones in a given AWS Region. When creating a DB instance in a VPC, you choose a DB subnet group for it. From the DB subnet group, Amazon RDS chooses a subnet and an IP address within that subnet to associate with the DB instance. The DB uses the Availability Zone that contains the subnet.

If the primary DB instance of a Multi-AZ deployment fails, Amazon RDS can promote the corresponding standby and later create a new standby using an IP address of the subnet in one of the other Availability Zones.

The subnets in a DB subnet group are either public or private. The subnets are public or private, depending on the configuration that you set for their network access control lists (network ACLs) and routing tables. For a DB instance to be publicly accessible, all of the subnets in its DB subnet group must be public. If a subnet that's associated with a publicly accessible DB instance changes from public to private, it can affect DB instance availability.

To create a DB subnet group that supports dual-stack mode, make sure that each subnet that you add to the DB subnet group has an Internet Protocol version 6 (IPv6) CIDR block associated with it. For more information, see [Amazon RDS IP addressing](#) and [Migrating to IPv6](#) in the *Amazon VPC User Guide*.

### Note

The DB subnet group for a Local Zone can have only one subnet.

When Amazon RDS creates a DB instance in a VPC, it assigns a network interface to your DB instance by using an IP address from your DB subnet group. However, we strongly recommend that you use the Domain Name System (DNS) name to connect to your DB instance. We recommend this because the underlying IP address changes during failover.

**Note**

For each DB instance that you run in a VPC, make sure to reserve at least one address in each subnet in the DB subnet group for use by Amazon RDS for recovery actions.

## Shared subnets

You can create a DB instance in a shared VPC.

Some considerations to keep in mind while using shared VPCs:

- You can move a DB instance from a shared VPC subnet to a non-shared VPC subnet and vice-versa.
- Participants in a shared VPC must create a security group in the VPC to allow them to create a DB instance.
- Owners and participants in a shared VPC can access the database by using SQL queries. However, only the creator of a resource can make any API calls on the resource.

## Amazon RDS IP addressing

IP addresses enable resources in your VPC to communicate with each other, and with resources over the internet. Amazon RDS supports both IPv4 and IPv6 addressing protocols. By default, Amazon RDS and Amazon VPC use the IPv4 addressing protocol. You can't turn off this behavior. When you create a VPC, make sure to specify an IPv4 CIDR block (a range of private IPv4 addresses). You can optionally assign an IPv6 CIDR block to your VPC and subnets, and assign IPv6 addresses from that block to DB instances in your subnet.

Support for the IPv6 protocol expands the number of supported IP addresses. By using the IPv6 protocol, you ensure that you have sufficient available addresses for the future growth of the internet. New and existing RDS resources can use IPv4 and IPv6 addresses within your VPC. Configuring, securing, and translating network traffic between the two protocols used in different parts of an application can cause operational overhead. You can standardize on the IPv6 protocol for Amazon RDS resources to simplify your network configuration.

### Topics

- [IPv4 addresses](#)

- [IPv6 addresses](#)
- [Dual-stack mode](#)

## IPv4 addresses

When you create a VPC, you must specify a range of IPv4 addresses for the VPC in the form of a CIDR block, such as `10.0.0.0/16`. A *DB subnet group* defines the range of IP addresses in this CIDR block that a DB instance can use. These IP addresses can be private or public.

A private IPv4 address is an IP address that's not reachable over the internet. You can use private IPv4 addresses for communication between your DB instance and other resources, such as Amazon EC2 instances, in the same VPC. Each DB instance has a private IP address for communication in the VPC.

A public IP address is an IPv4 address that's reachable from the internet. You can use public addresses for communication between your DB instance and resources on the internet, such as a SQL client. You control whether your DB instance receives a public IP address.

For a tutorial that shows you how to create a VPC with only private IPv4 addresses that you can use for a common Amazon RDS scenario, see [Tutorial: Create a VPC for use with a DB instance \(IPv4 only\)](#).

## IPv6 addresses

You can optionally associate an IPv6 CIDR block with your VPC and subnets, and assign IPv6 addresses from that block to the resources in your VPC. Each IPv6 address is globally unique.

The IPv6 CIDR block for your VPC is automatically assigned from Amazon's pool of IPv6 addresses. You can't choose the range yourself.

When connecting to an IPv6 address, make sure that the following conditions are met:

- The client is configured so that client to database traffic over IPv6 is allowed.
- RDS security groups used by the DB instance are configured correctly so that client to database traffic over IPv6 is allowed.
- The client operating system stack allows traffic on the IPv6 address, and operating system drivers and libraries are configured to choose the correct default DB instance endpoint (either IPv4 or IPv6).

For more information about IPv6, see [IP Addressing](#) in the *Amazon VPC User Guide*.

## Dual-stack mode

When a DB instance can communicate over both the IPv4 and IPv6 addressing protocols, it's running in dual-stack mode. So, resources can communicate with the DB instance over IPv4, IPv6, or both. RDS disables Internet Gateway access for IPv6 endpoints of private dual-stack mode DB instances. RDS does this to ensure that your IPv6 endpoints are private and can only be accessed from within your VPC.

### Topics

- [Dual-stack mode and DB subnet groups](#)
- [Working with dual-stack mode DB instances](#)
- [Modifying IPv4-only DB instances to use dual-stack mode](#)
- [Region and version availability](#)
- [Limitations for dual-stack network DB instances](#)

For a tutorial that shows you how to create a VPC with both IPv4 and IPv6 addresses that you can use for a common Amazon RDS scenario, see [Tutorial: Create a VPC for use with a DB instance \(dual-stack mode\)](#).

### Dual-stack mode and DB subnet groups

To use dual-stack mode, make sure that each subnet in the DB subnet group that you associate with the DB instance has an IPv6 CIDR block associated with it. You can create a new DB subnet group or modify an existing DB subnet group to meet this requirement. After a DB instance is in dual-stack mode, clients can connect to it normally. Make sure that client security firewalls and RDS DB instance security groups are accurately configured to allow traffic over IPv6. To connect, clients use the DB instance's endpoint. Client applications can specify which protocol is preferred when connecting to a database. In dual-stack mode, the DB instance detects the client's preferred network protocol, either IPv4 or IPv6, and uses that protocol for the connection.

If a DB subnet group stops supporting dual-stack mode because of subnet deletion or CIDR disassociation, there's a risk of an incompatible network state for DB instances that are associated with the DB subnet group. Also, you can't use the DB subnet group when you create a new dual-stack mode DB instance.

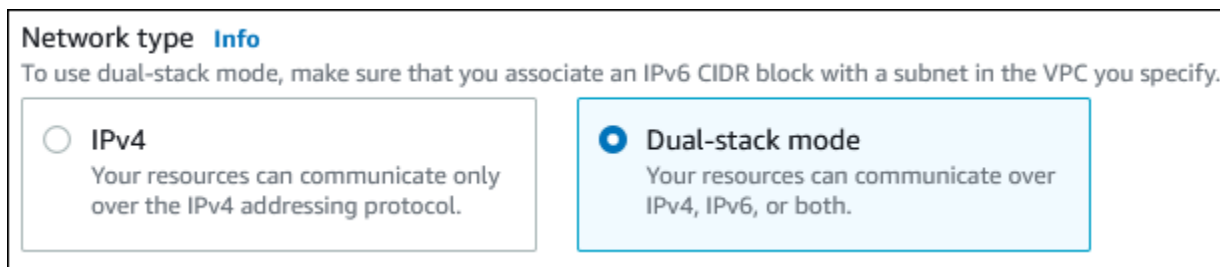

To determine whether a DB subnet group supports dual-stack mode by using the AWS Management Console, view the **Network type** on the details page of the DB subnet group. To determine whether a DB subnet group supports dual-stack mode by using the AWS CLI, run the [describe-db-subnet-groups](#) command and view `SupportedNetworkTypes` in the output.

Read replicas are treated as independent DB instances and can have a network type that's different from the primary DB instance. If you change the network type of a read replica's primary DB instance, the read replica isn't affected. When you are restoring a DB instance, you can restore it to any network type that's supported.

## Working with dual-stack mode DB instances

When you create or modify a DB instance, you can specify dual-stack mode to allow your resources to communicate with your DB instance over IPv4, IPv6, or both.

When you use the AWS Management Console to create or modify a DB instance, you can specify dual-stack mode in the **Network type** section. The following image shows the **Network type** section in the console.

The screenshot shows the 'Network type' section in the AWS Management Console. It includes an 'Info' icon and a note: 'To use dual-stack mode, make sure that you associate an IPv6 CIDR block with a subnet in the VPC you specify.' There are two radio button options: 'IPv4' (unselected) with the description 'Your resources can communicate only over the IPv4 addressing protocol.' and 'Dual-stack mode' (selected) with the description 'Your resources can communicate over IPv4, IPv6, or both.'

When you use the AWS CLI to create or modify a DB instance, set the `--network-type` option to `DUAL` to use dual-stack mode. When you use the RDS API to create or modify a DB instance, set the `NetworkType` parameter to `DUAL` to use dual-stack mode. When you are modifying the network type of a DB instance, downtime is possible. If dual-stack mode isn't supported by the specified DB engine version or DB subnet group, the `NetworkTypeNotSupported` error is returned.

For more information about creating a DB instance, see [Creating an Amazon RDS DB instance](#). For more information about modifying a DB instance, see [Modifying an Amazon RDS DB instance](#).

To determine whether a DB instance is in dual-stack mode by using the console, view the **Network type** on the **Connectivity & security** tab for the DB instance.

## Modifying IPv4-only DB instances to use dual-stack mode

You can modify an IPv4-only DB instance to use dual-stack mode. To do so, change the network type of the DB instance. The modification might result in downtime.

It is recommended that you change the network type of your Amazon RDS DB instances during a maintenance window. Currently, setting the network type of new instances to dual-stack mode isn't supported. You can set network type manually by using the `modify-db-instance` command.

Before modifying a DB instance to use dual-stack mode, make sure that its DB subnet group supports dual-stack mode. If the DB subnet group associated with the DB instance doesn't support dual-stack mode, specify a different DB subnet group that supports it when you modify the DB instance. Modifying the DB subnet group of a DB instance can cause downtime.

If you modify the DB subnet group of a DB instance before you change the DB instance to use dual-stack mode, make sure that the DB subnet group is valid for the DB instance before and after the change.

For RDS for PostgreSQL, RDS for MySQL, RDS for Oracle, and RDS for MariaDB Single-AZ instances, we recommend that you run the [modify-db-instance](#) command with only the `--network-type` parameter set to DUAL to change the network to dual-stack mode. Adding other parameters along with the `--network-type` parameter in the same API call could result in downtime. To modify multiple parameters, ensure that the network type modification is successfully completed before sending another `modify-db-instance` request with other parameters.

Network type modifications for RDS for PostgreSQL, RDS for MySQL, RDS for Oracle, and RDS for MariaDB Multi-AZ DB instances cause a brief downtime and trigger a failover if you only use the `--network-type` parameter or if you combine parameters in a `modify-db-instance` command.

Network type modifications on RDS for SQL Server Single-AZ or Multi-AZ DB instances cause downtime if you only use the `--network-type` parameter or if you combine parameters in a `modify-db-instance` command. Network type modifications cause failover in an SQL Server Multi-AZ instance.

If you can't connect to the DB instance after the change, make sure that the client and database security firewalls and route tables are accurately configured to allow traffic to the database on the selected network (either IPv4 or IPv6). You might also need to modify operating system parameter, libraries, or drivers to connect using an IPv6 address.

When you modify a DB instance to use dual-stack mode, there can't be a pending change from a Single-AZ deployment to a Multi-AZ deployment, or from a Multi-AZ deployment to a Single-AZ deployment.

## To modify an IPv4-only DB instance to use dual-stack mode

1. Modify a DB subnet group to support dual-stack mode, or create a DB subnet group that supports dual-stack mode:

- a. Associate an IPv6 CIDR block with your VPC.

For instructions, see [Add an IPv6 CIDR block to your VPC](#) in the *Amazon VPC User Guide*.

- b. Attach the IPv6 CIDR block to all of the subnets in your the DB subnet group.

For instructions, see [Add an IPv6 CIDR block to your subnet](#) in the *Amazon VPC User Guide*.

- c. Confirm that the DB subnet group supports dual-stack mode.

If you are using the AWS Management Console, select the DB subnet group, and make sure that the **Supported network types** value is **Dual, IPv4**.

If you are using the AWS CLI, run the [describe-db-subnet-groups](#) command, and make sure that the `SupportedNetworkType` value for the DB instance is `Dual, IPv4`.

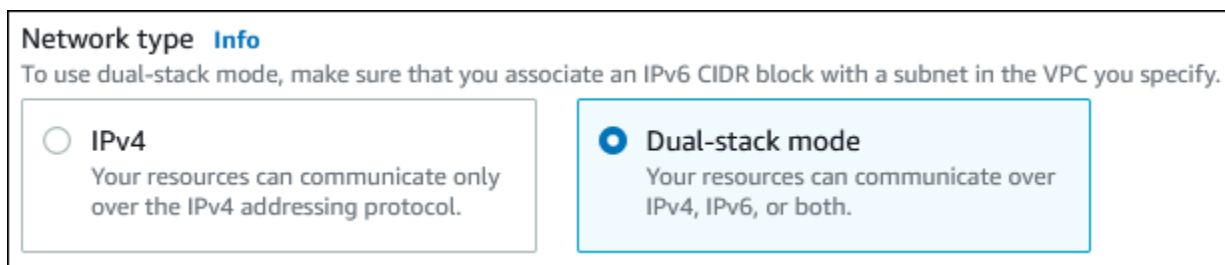

2. Modify the security group associated with the DB instance to allow IPv6 connections to the database, or create a new security group that allows IPv6 connections.

For instructions, see [Security group rules](#) in the *Amazon VPC User Guide*.

3. Modify the DB instance to support dual-stack mode. To do so, set the **Network type** to **Dual-stack mode**.

If you are using the console, make sure that the following settings are correct:

- **Network type – Dual-stack mode**

The screenshot shows a configuration panel for 'Network type' with an 'Info' icon. Below the title is a note: 'To use dual-stack mode, make sure that you associate an IPv6 CIDR block with a subnet in the VPC you specify.' There are two radio button options: 'IPv4' (unselected) and 'Dual-stack mode' (selected). The 'Dual-stack mode' option is highlighted with a light blue border. Below each option is a brief description of its capabilities.

Network type	Description
<input type="radio"/> IPv4	Your resources can communicate only over the IPv4 addressing protocol.
<input checked="" type="radio"/> Dual-stack mode	Your resources can communicate over IPv4, IPv6, or both.

- **DB subnet group** – The DB subnet group that you configured in a previous step
- **Security group** – The security that you configured in a previous step

If you are using the AWS CLI, make sure that the following settings are correct:

- `--network-type` – `dual`
- `--db-subnet-group-name` – The DB subnet group that you configured in a previous step
- `--vpc-security-group-ids` – The VPC security group that you configured in a previous step

For example:

```
aws rds modify-db-instance --db-instance-identifier my-instance --network-type "DUAL"
```

#### 4. Confirm that the DB instance supports dual-stack mode.

If you are using the console, choose the **Connectivity & security** tab for the DB instance. On that tab, make sure that the **Network type** value is **Dual-stack mode**.

If you are using the AWS CLI, run the [describe-db-instances](#) command, and make sure that the `NetworkType` value for the DB instance is `dual`.

Run the `dig` command on the DB instance endpoint to identify the IPv6 address associated with it.

```
dig db-instance-endpoint AAAA
```

Use the DB instance endpoint, not the IPv6 address, to connect to the DB instance.

## Region and version availability

Feature availability and support varies across specific versions of each database engine, and across AWS Regions. For more information on version and Region availability with dual-stack mode, see [Supported Regions and DB engines for dual-stack mode in Amazon RDS](#).

## Limitations for dual-stack network DB instances

The following limitations apply to dual-stack network DB instances:

- DB instances can't use the IPv6 protocol exclusively. They can use IPv4 exclusively, or they can use the IPv4 and IPv6 protocol (dual-stack mode).
- Amazon RDS doesn't support native IPv6 subnets.
- DB instances that use dual-stack mode must be private. They can't be publicly accessible.
- Dual-stack mode doesn't support the db.m3 and db.r3 DB instance classes.
- For RDS for SQL Server, dual-stack mode DB instances that use Always On AGs availability group listener endpoints only present IPv4 addresses.
- You can't use RDS Proxy with dual-stack mode DB instances.
- You can't use dual-stack mode with RDS on AWS Outposts DB instances.
- You can't use dual-stack mode with DB instances in a Local Zone.

## Hiding a DB instance in a VPC from the internet

One common Amazon RDS scenario is to have a VPC in which you have an EC2 instance with a public-facing web application and a DB instance with a database that isn't publicly accessible. For example, you can create a VPC that has a public subnet and a private subnet. Amazon EC2 instances that function as web servers can be deployed in the public subnet. The DB instances are deployed in the private subnet. In such a deployment, only the web servers have access to the DB instances. For an illustration of this scenario, see [A DB instance in a VPC accessed by an EC2 instance in the same VPC](#).

When you launch a DB instance inside a VPC, the DB instance has a private IP address for traffic inside the VPC. This private IP address isn't publicly accessible. You can use the **Public access** option to designate whether the DB instance also has a public IP address in addition to the private IP address. If the DB instance is designated as publicly accessible, its DNS endpoint resolves to the private IP address from within the VPC. It resolves to the public IP address from outside of the VPC. Access to the DB instance is ultimately controlled by the security group it uses. That public access is not permitted if the security group assigned to the DB instance doesn't include inbound rules that permit it. In addition, for a DB instance to be publicly accessible, the subnets in its DB subnet group must have an internet gateway. For more information, see [Can't connect to Amazon RDS DB instance](#)

You can modify a DB instance to turn on or off public accessibility by modifying the **Public access** option. The following illustration shows the **Public access** option in the **Additional connectivity configuration** section. To set the option, open the **Additional connectivity configuration** section in the **Connectivity** section.

## Connectivity G

**Virtual private cloud (VPC) [Info](#)**  
VPC that defines the virtual networking environment for this DB instance.

Default VPC (vpc-2aed394c) ▼

Only VPCs with a corresponding DB subnet group are listed.

**i** After a database is created, you can't change its VPC.

**Subnet group [Info](#)**  
DB subnet group that defines which subnets and IP ranges the DB cluster can use in the VPC you selected.

## Creating a DB instance in a VPC

The following procedures help you create a DB instance in a VPC. To use the default VPC, you can begin with step 2, and use the VPC and DB subnet group have already been created for you. If you want to create an additional VPC, you can create a new VPC.

### Note

If you want your DB instance in the VPC to be publicly accessible, you must update the DNS information for the VPC by enabling the VPC attributes *DNS hostnames* and *DNS resolution*. For information about updating the DNS information for a VPC instance, see [Updating DNS support for your VPC](#).

Follow these steps to create a DB instance in a VPC:

- [Step 1: Create a VPC](#)
- [Step 2: Create a DB subnet group](#)
- [Step 3: Create a VPC security group](#)
- [Step 4: Create a DB instance in the VPC](#)

### Step 1: Create a VPC

Create a VPC with subnets in at least two Availability Zones. You use these subnets when you create a DB subnet group. If you have a default VPC, a subnet is automatically created for you in each Availability Zone in the AWS Region.

For more information, see [Create a VPC with private and public subnets](#), or see [Create a VPC](#) in the *Amazon VPC User Guide*.

### Step 2: Create a DB subnet group

A DB subnet group is a collection of subnets (typically private) that you create for a VPC and that you then designate for your DB instances. A DB subnet group allows you to specify a particular VPC when you create DB instances using the AWS CLI or RDS API. If you use the console, you can just choose the VPC and subnets you want to use. Each DB subnet group must have at least one subnet in at least two Availability Zones in the AWS Region. As a best practice, each DB subnet group should have at least one subnet for every Availability Zone in the AWS Region.

For Multi-AZ deployments, defining a subnet for all Availability Zones in an AWS Region enables Amazon RDS to create a new standby replica in another Availability Zone if necessary. You can follow this best practice even for Single-AZ deployments, because you might convert them to Multi-AZ deployments in the future.

For a DB instance to be publicly accessible, the subnets in the DB subnet group must have an internet gateway. For more information about internet gateways for subnets, see [Connect to the internet using an internet gateway](#) in the *Amazon VPC User Guide*.

 **Note**

The DB subnet group for a Local Zone can have only one subnet.

When you create a DB instance in a VPC, you can choose a DB subnet group. Amazon RDS chooses a subnet and an IP address within that subnet to associate with your DB instance. If no DB subnet groups exist, Amazon RDS creates a default subnet group when you create a DB instance. Amazon RDS creates and associates an Elastic Network Interface to your DB instance with that IP address. The DB instance uses the Availability Zone that contains the subnet.

For Multi-AZ deployments, defining a subnet for two or more Availability Zones in an AWS Region allows Amazon RDS to create a new standby in another Availability Zone should the need arise. You need to do this even for Single-AZ deployments, just in case you want to convert them to Multi-AZ deployments at some point.

In this step, you create a DB subnet group and add the subnets that you created for your VPC.

### To create a DB subnet group

1. Open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Subnet groups**.
3. Choose **Create DB Subnet Group**.
4. For **Name**, type the name of your DB subnet group.
5. For **Description**, type a description for your DB subnet group.
6. For **VPC**, choose the default VPC or the VPC that you created.
7. In the **Add subnets** section, choose the Availability Zones that include the subnets from **Availability Zones**, and then choose the subnets from **Subnets**.

# Create DB Subnet Group

To create a new subnet group, give it a name and a description, and choose an existing VPC. You will then be able to add subnets related to that VPC.

## Subnet group details

### Name

You won't be able to modify the name after your subnet group has been created.

mydbsubnetgroup

Must contain from 1 to 255 characters. Alphanumeric characters, spaces, hyphens, underscores, and periods are allowed.

### Description

My DB Subnet Group

### VPC

Choose a VPC identifier that corresponds to the subnets you want to use for your DB subnet group. You won't be able to choose a different VPC identifier after your subnet group has been created.

tutorial-vpc (vpc-068fe388385afc014)

## Add subnets

### Availability Zones

Choose the Availability Zones that include the subnets you want to add.

Choose an availability zone

us-east-1a X

us-east-1c X

### Subnets

Choose the subnets that you want to add. The list includes the subnets in the selected Availability Zones.

Select subnets

subnet-079bd4b8953aee1dd (10.0.0.0/24) X

subnet-057e85b72c46fdd9a (10.0.1.0/24) X

### Subnets selected (2)

Availability zone	Subnet ID	CIDR block
us-east-1a	subnet-079bd4b8953aee1dd	10.0.0.0/24
us-east-1c	subnet-057e85b72c46fdd9a	10.0.1.0/24

Cancel

Create

**Note**

If you have enabled a Local Zone, you can choose an Availability Zone group on the **Create DB subnet group** page. In this case, choose the **Availability Zone group**, **Availability Zones**, and **Subnets**.

**8. Choose Create.**

Your new DB subnet group appears in the DB subnet groups list on the RDS console. You can choose the DB subnet group to see details, including all of the subnets associated with the group, in the details pane at the bottom of the window.

**Step 3: Create a VPC security group**

Before you create your DB instance, you can create a VPC security group to associate with your DB instance. If you don't create a VPC security group, you can use the default security group when you create a DB instance. For instructions on how to create a security group for your DB instance, see [Create a VPC security group for a private DB instance](#), or see [Control traffic to resources using security groups](#) in the *Amazon VPC User Guide*.

**Step 4: Create a DB instance in the VPC**

In this step, you create a DB instance and use the VPC name, the DB subnet group, and the VPC security group you created in the previous steps.

**Note**

If you want your DB instance in the VPC to be publicly accessible, you must enable the VPC attributes *DNS hostnames* and *DNS resolution*. For more information, see [DNS attributes for your VPC](#) in the *Amazon VPC User Guide*.

For details on how to create a DB instance, see [Creating an Amazon RDS DB instance](#).

When prompted in the **Connectivity** section, enter the VPC name, the DB subnet group, and the VPC security group.

## Updating the VPC for a DB instance

You can use the AWS Management Console to move your DB instance to a different VPC.

For information about modifying a DB instance, see [Modifying an Amazon RDS DB instance](#). In the **Connectivity** section of the modify page, shown following, enter the new DB subnet group for **DB subnet group**. The new subnet group must be a subnet group in a new VPC.

**Connectivity**

Subnet group

default-vpc-665e7a1f ▼

Security group

List of DB security groups to associate with this DB instance.

You can't change the VPC for a DB instance if the following conditions apply:

- The DB instance is in multiple Availability Zones. You can convert the DB instance to a single Availability Zone, move it to a new VPC, and then convert it back to a Multi-AZ DB instance. For more information, see [Configuring and managing a Multi-AZ deployment](#).
- The DB instance has one or more read replicas. You can remove the read replicas, move the DB instance to a new VPC, and then add the read replicas again. For more information, see [Working with DB instance read replicas](#).
- The DB instance is a read replica. You can promote the read replica, and then move the standalone DB instance to a new VPC. For more information, see [Promoting a read replica to be a standalone DB instance](#).
- The subnet group in the target VPC doesn't have subnets in the DB instance's the Availability Zone. You can add subnets in the DB instance's Availability Zone to the DB subnet group, and then move the DB instance to the new VPC. For more information, see [Working with DB subnet groups](#).

## Scenarios for accessing a DB instance in a VPC

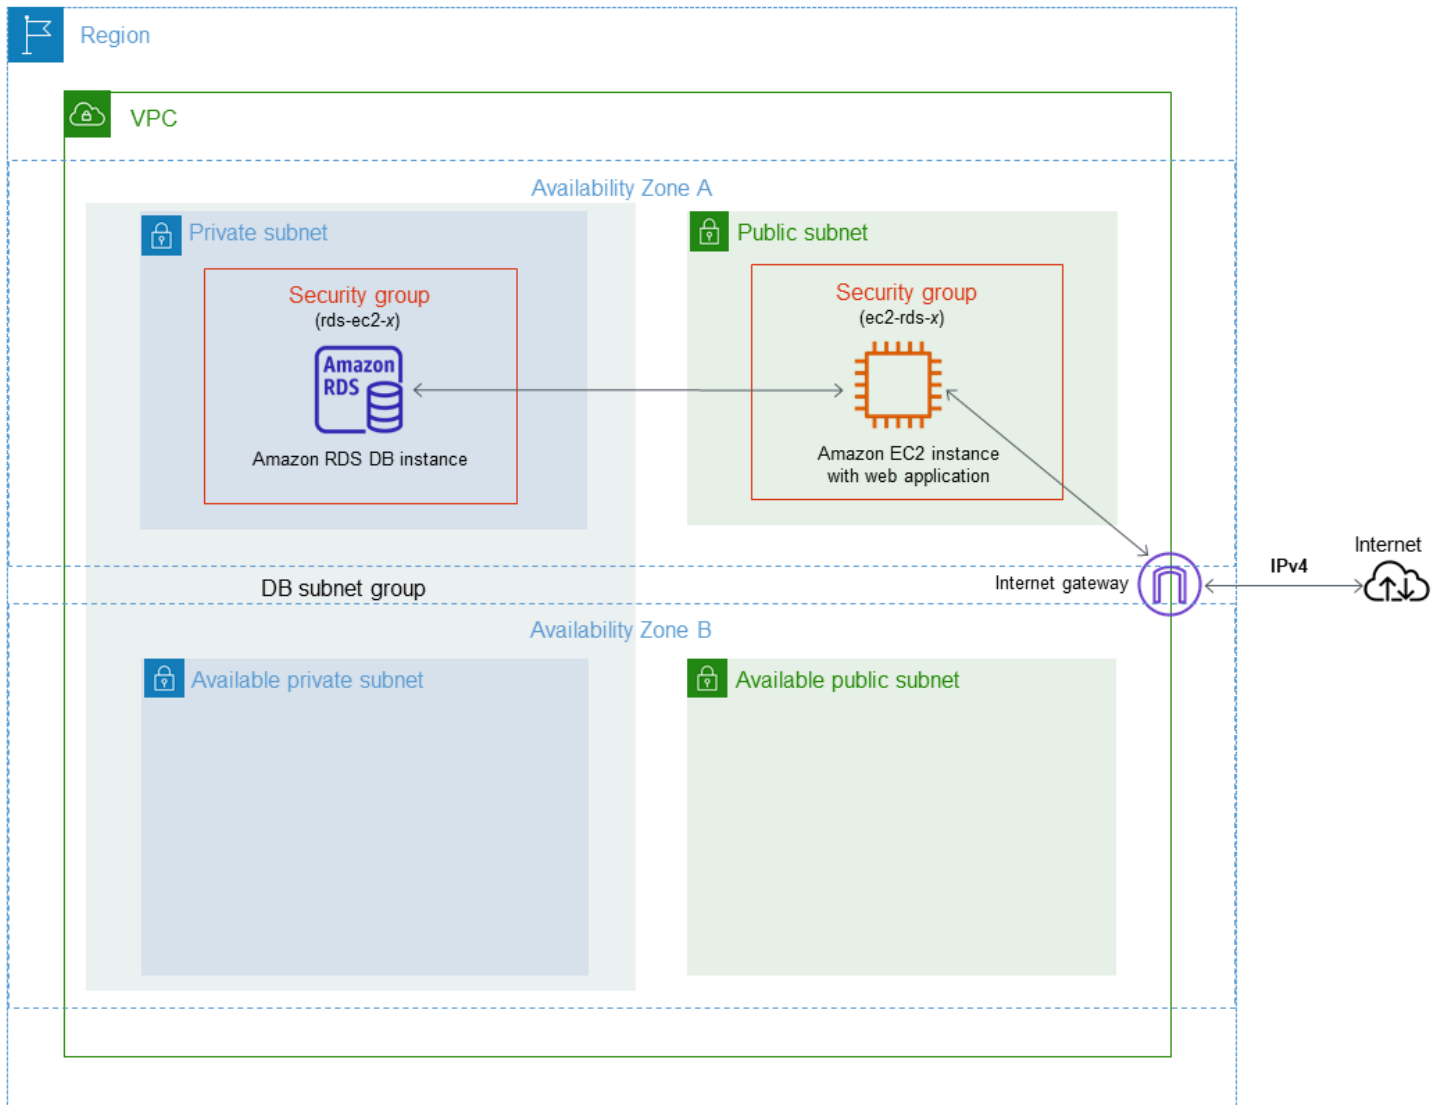

Amazon RDS supports the following scenarios for accessing a DB instance in a VPC:

- [An EC2 instance in the same VPC](#)
- [An EC2 instance in a different VPC](#)
- [A client application through the internet](#)
- [A private network](#)

## A DB instance in a VPC accessed by an EC2 instance in the same VPC

A common use of a DB instance in a VPC is to share data with an application server that is running in an EC2 instance in the same VPC.

The following diagram shows this scenario.

The simplest way to manage access between EC2 instances and DB instances in the same VPC is to do the following:

- Create a VPC security group for your DB instances to be in. This security group can be used to restrict access to the DB instances. For example, you can create a custom rule for this security group. This might allow TCP access using the port that you assigned to the DB instance when you created it and an IP address you use to access the DB instance for development or other purposes.
- Create a VPC security group for your EC2 instances (web servers and clients) to be in. This security group can, if needed, allow access to the EC2 instance from the internet by using the VPC's routing table. For example, you can set rules on this security group to allow TCP access to the EC2 instance over port 22.
- Create custom rules in the security group for your DB instances that allow connections from the security group you created for your EC2 instances. These rules might allow any member of the security group to access the DB instances.

There is an additional public and private subnet in a separate Availability Zone. An RDS DB subnet group requires a subnet in at least two Availability Zones. The additional subnet makes it easy to switch to a Multi-AZ DB instance deployment in the future.

For a tutorial that shows you how to create a VPC with both public and private subnets for this scenario, see [Tutorial: Create a VPC for use with a DB instance \(IPv4 only\)](#).

**Tip**

You can set up network connectivity between an Amazon EC2 instance and a DB instance automatically when you create the DB instance. For more information, see [Configure automatic network connectivity with an EC2 instance](#).

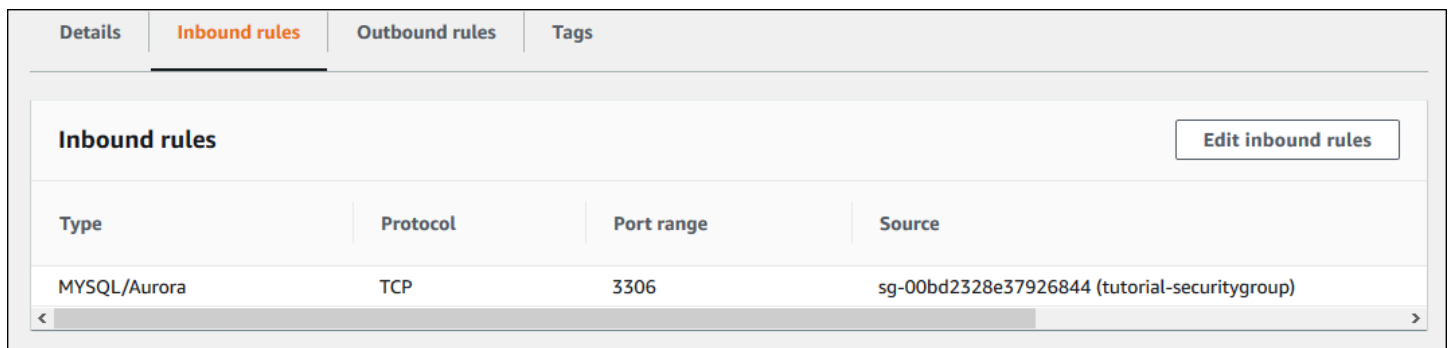

**To create a rule in a VPC security group that allows connections from another security group, do the following:**

1. Sign in to the AWS Management Console and open the Amazon VPC console at <https://console.aws.amazon.com/vpc>.
2. In the navigation pane, choose **Security groups**.

3. Choose or create a security group for which you want to allow access to members of another security group. In the preceding scenario, this is the security group that you use for your DB instances. Choose the **Inbound rules** tab, and then choose **Edit inbound rules**.
4. On the **Edit inbound rules** page, choose **Add rule**.
5. For **Type**, choose the entry that corresponds to the port you used when you created your DB instance, such as **MYSQL/Aurora**.
6. In the **Source** box, start typing the ID of the security group, which lists the matching security groups. Choose the security group with members that you want to have access to the resources protected by this security group. In the scenario preceding, this is the security group that you use for your EC2 instance.
7. If required, repeat the steps for the TCP protocol by creating a rule with **All TCP** as the **Type** and your security group in the **Source** box. If you intend to use the UDP protocol, create a rule with **All UDP** as the **Type** and your security group in **Source**.
8. Choose **Save rules**.

The following screen shows an inbound rule with a security group for its source.

Type	Protocol	Port range	Source
MYSQL/Aurora	TCP	3306	sg-00bd2328e37926844 (tutorial-securitygroup)

For more information about connecting to the DB instance from your EC2 instance, see [Connecting to an Amazon RDS DB instance](#).

## A DB instance in a VPC accessed by an EC2 instance in a different VPC

When your DB instances is in a different VPC from the EC2 instance you are using to access it, you can use VPC peering to access the DB instance.

The following diagram shows this scenario.

A VPC peering connection is a networking connection between two VPCs that enables you to route traffic between them using private IP addresses. Resources in either VPC can communicate with each other as if they are within the same network. You can create a VPC peering connection between your own VPCs, with a VPC in another AWS account, or with a VPC in a different AWS Region. To learn more about VPC peering, see [VPC peering](#) in the *Amazon Virtual Private Cloud User Guide*.

## A DB instance in a VPC accessed by a client application through the internet

To access a DB instances in a VPC from a client application through the internet, you configure a VPC with a single public subnet, and an internet gateway to enable communication over the internet.

The following diagram shows this scenario.

We recommend the following configuration:

- A VPC of size /16 (for example CIDR: 10.0.0.0/16). This size provides 65,536 private IP addresses.
- A subnet of size /24 (for example CIDR: 10.0.0.0/24). This size provides 256 private IP addresses.
- An Amazon RDS DB instance that is associated with the VPC and the subnet. Amazon RDS assigns an IP address within the subnet to your DB instance.
- An internet gateway which connects the VPC to the internet and to other AWS products.
- A security group associated with the DB instance. The security group's inbound rules allow your client application to access to your DB instance.

For information about creating a DB instances in a VPC, see [Creating a DB instance in a VPC](#).

## A DB instance in a VPC accessed by a private network

If your DB instance isn't publicly accessible, you have the following options for accessing it from a private network:

- An AWS Site-to-Site VPN connection. For more information, see [What is AWS Site-to-Site VPN?](#)
- An AWS Direct Connect connection. For more information, see [What is AWS Direct Connect?](#)
- An AWS Client VPN connection. For more information, see [What is AWS Client VPN?](#)

The following diagram shows a scenario with an AWS Site-to-Site VPN connection.

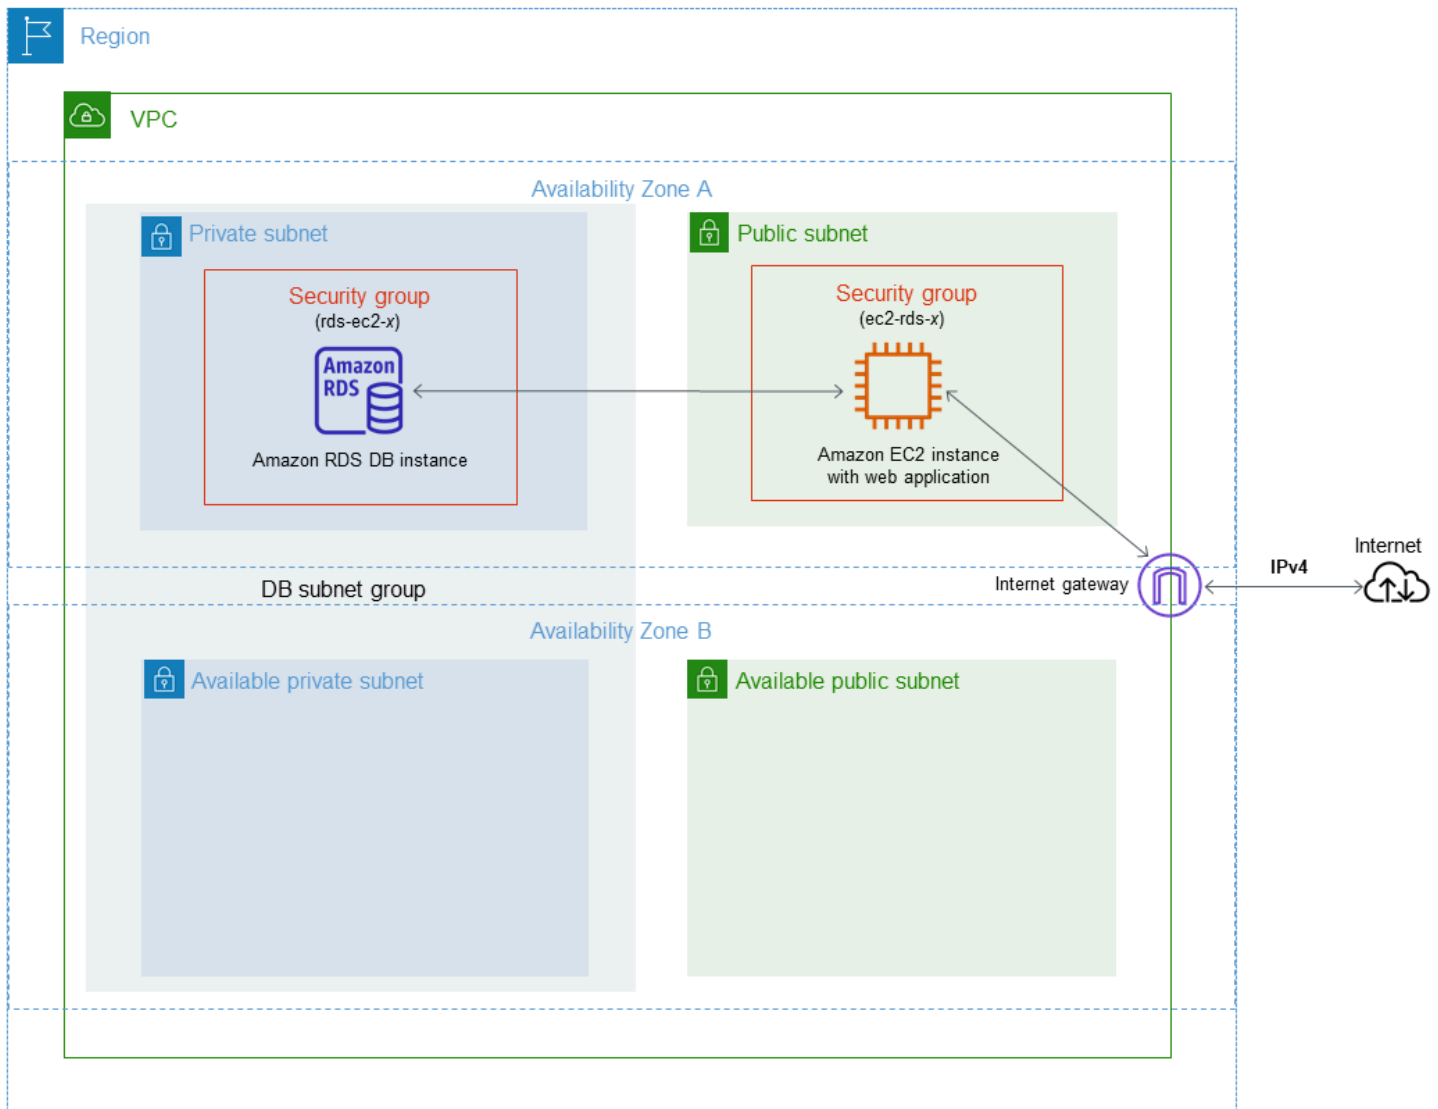

For more information, see [Internet traffic privacy](#).

## Tutorial: Create a VPC for use with a DB instance (IPv4 only)

A common scenario includes a DB instance in a virtual private cloud (VPC) based on the Amazon VPC service. This VPC shares data with a web server that is running in the same VPC. In this tutorial, you create the VPC for this scenario.

The following diagram shows this scenario. For information about other scenarios, see [Scenarios for accessing a DB instance in a VPC](#).

Your DB instance needs to be available only to your web server, and not to the public internet. Thus, you create a VPC with both public and private subnets. The web server is hosted in the public subnet, so that it can reach the public internet. The DB instance is hosted in a private subnet. The web server can connect to the DB instance because it is hosted within the same VPC. But the DB instance isn't available to the public internet, providing greater security.

This tutorial configures an additional public and private subnet in a separate Availability Zone. These subnets aren't used by the tutorial. An RDS DB subnet group requires a subnet in at least two Availability Zones. The additional subnet makes it easier to switch to a Multi-AZ DB instance deployment in the future.

This tutorial describes configuring a VPC for Amazon RDS DB instances. For a tutorial that shows you how to create a web server for this VPC scenario, see [Tutorial: Create a web server and an Amazon RDS DB instance](#). For more information about Amazon VPC, see [Amazon VPC Getting Started Guide](#) and [Amazon VPC User Guide](#).

### Tip

You can set up network connectivity between an Amazon EC2 instance and a DB instance automatically when you create the DB instance. The network configuration is similar to the one described in this tutorial. For more information, see [Configure automatic network connectivity with an EC2 instance](#).

## Create a VPC with private and public subnets

Use the following procedure to create a VPC with both public and private subnets.

### To create a VPC and subnets

1. Open the Amazon VPC console at <https://console.aws.amazon.com/vpc/>.
2. In the top-right corner of the AWS Management Console, choose the Region to create your VPC in. This example uses the US West (Oregon) Region.
3. In the upper-left corner, choose **VPC dashboard**. To begin creating a VPC, choose **Create VPC**.
4. For **Resources to create** under **VPC settings**, choose **VPC and more**.
5. For the **VPC settings**, set these values:
  - **Name tag auto-generation** – **tutorial**
  - **IPv4 CIDR block** – **10.0.0.0/16**
  - **IPv6 CIDR block** – **No IPv6 CIDR block**
  - **Tenancy** – **Default**
  - **Number of Availability Zones (AZs)** – **2**
  - **Customize AZs** – **Keep the default values.**

- **Number of public subnet** – 2
- **Number of private subnets** – 2
- **Customize subnets CIDR blocks** – Keep the default values.
- **NAT gateways (\$)** – None
- **VPC endpoints** – None
- **DNS options** – Keep the default values.

 **Note**

Amazon RDS requires at least two subnets in two different Availability Zones to support Multi-AZ DB instance deployments. This tutorial creates a Single-AZ deployment, but the requirement makes it easier to convert to a Multi-AZ DB instance deployment in the future.

6. Choose **Create VPC**.

## Create a VPC security group for a public web server

Next, you create a security group for public access. To connect to public EC2 instances in your VPC, you add inbound rules to your VPC security group. These allow traffic to connect from the internet.

### To create a VPC security group

1. Open the Amazon VPC console at <https://console.aws.amazon.com/vpc/>.
2. Choose **VPC Dashboard**, choose **Security Groups**, and then choose **Create security group**.
3. On the **Create security group** page, set these values:
  - **Security group name:** **tutorial-securitygroup**
  - **Description:** **Tutorial Security Group**
  - **VPC:** Choose the VPC that you created earlier, for example: **vpc-*identifier*** (**tutorial-vpc**)
4. Add inbound rules to the security group.
  - a. Determine the IP address to use to connect to EC2 instances in your VPC using Secure Shell (SSH). To determine your public IP address, in a different browser window or tab,

you can use the service at <https://checkip.amazonaws.com>. An example of an IP address is `203.0.113.25/32`.

In many cases, you might connect through an internet service provider (ISP) or from behind your firewall without a static IP address. If so, find the range of IP addresses used by client computers.

**⚠ Warning**

If you use `0.0.0.0/0` for SSH access, you make it possible for all IP addresses to access your public instances using SSH. This approach is acceptable for a short time in a test environment, but it's unsafe for production environments. In production, authorize only a specific IP address or range of addresses to access your instances using SSH.

- b. In the **Inbound rules** section, choose **Add rule**.
  - c. Set the following values for your new inbound rule to allow SSH access to your Amazon EC2 instance. If you do this, you can connect to your Amazon EC2 instance to install the web server and other utilities. You also connect to your EC2 instance to upload content for your web server.
    - **Type:** SSH
    - **Source:** The IP address or range from Step a, for example: `203.0.113.25/32`.
  - d. Choose **Add rule**.
  - e. Set the following values for your new inbound rule to allow HTTP access to your web server:
    - **Type:** HTTP
    - **Source:** `0.0.0.0/0`
5. Choose **Create security group** to create the security group.

Note the security group ID because you need it later in this tutorial.

## Create a VPC security group for a private DB instance

To keep your DB instance private, create a second security group for private access. To connect to private DB instances in your VPC, you add inbound rules to your VPC security group that allow traffic from your web server only.

### To create a VPC security group

1. Open the Amazon VPC console at <https://console.aws.amazon.com/vpc/>.
2. Choose **VPC Dashboard**, choose **Security Groups**, and then choose **Create security group**.
3. On the **Create security group** page, set these values:
  - **Security group name:** **tutorial-db-securitygroup**
  - **Description:** **Tutorial DB Instance Security Group**
  - **VPC:** Choose the VPC that you created earlier, for example: **vpc-*identifier*** (**tutorial-vpc**)
4. Add inbound rules to the security group.
  - a. In the **Inbound rules** section, choose **Add rule**.
  - b. Set the following values for your new inbound rule to allow MySQL traffic on port 3306 from your Amazon EC2 instance. If you do this, you can connect from your web server to your DB instance. By doing so, you can store and retrieve data from your web application to your database.
    - **Type:** **MySQL/Aurora**
    - **Source:** The identifier of the **tutorial-securitygroup** security group that you created previously in this tutorial, for example: **sg-9edd5cfb**.
5. Choose **Create security group** to create the security group.

### Create a DB subnet group

A *DB subnet group* is a collection of subnets that you create in a VPC and that you then designate for your DB instances. A DB subnet group makes it possible for you to specify a particular VPC when creating DB instances.

### To create a DB subnet group

1. Identify the private subnets for your database in the VPC.

- a. Open the Amazon VPC console at <https://console.aws.amazon.com/vpc/>.
- b. Choose **VPC Dashboard**, and then choose **Subnets**.
- c. Note the subnet IDs of the subnets named **tutorial-subnet-private1-us-west-2a** and **tutorial-subnet-private2-us-west-2b**.

You need the subnet IDs when you create your DB subnet group.

2. Open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.

Make sure that you connect to the Amazon RDS console, not to the Amazon VPC console.

3. In the navigation pane, choose **Subnet groups**.
4. Choose **Create DB subnet group**.
5. On the **Create DB subnet group** page, set these values in **Subnet group details**:
  - **Name:** `tutorial-db-subnet-group`
  - **Description:** `Tutorial DB Subnet Group`
  - **VPC:** `tutorial-vpc (vpc-identifier)`
6. In the **Add subnets** section, choose the **Availability Zones** and **Subnets**.

For this tutorial, choose **us-west-2a** and **us-west-2b** for the **Availability Zones**. For **Subnets**, choose the private subnets you identified in the previous step.

7. Choose **Create**.

Your new DB subnet group appears in the DB subnet groups list on the RDS console. You can choose the DB subnet group to see details in the details pane at the bottom of the window. These details include all of the subnets associated with the group.

#### Note

If you created this VPC to complete [Tutorial: Create a web server and an Amazon RDS DB instance](#), create the DB instance by following the instructions in [Create an Amazon RDS DB instance](#).

## Deleting the VPC

After you create the VPC and other resources for this tutorial, you can delete them if they are no longer needed.

### Note

If you added resources in the VPC that you created for this tutorial, you might need to delete these before you can delete the VPC. For example, these resources might include Amazon EC2 instances or Amazon RDS DB instances. For more information, see [Delete your VPC](#) in the *Amazon VPC User Guide*.

### To delete a VPC and related resources

1. Delete the DB subnet group.
  - a. Open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
  - b. In the navigation pane, choose **Subnet groups**.
  - c. Select the DB subnet group you want to delete, such as **tutorial-db-subnet-group**.
  - d. Choose **Delete**, and then choose **Delete** in the confirmation window.
2. Note the VPC ID.
  - a. Open the Amazon VPC console at <https://console.aws.amazon.com/vpc/>.
  - b. Choose **VPC Dashboard**, and then choose **VPCs**.
  - c. In the list, identify the VPC that you created, such as **tutorial-vpc**.
  - d. Note the **VPC ID** of the VPC that you created. You need the VPC ID in later steps.
3. Delete the security groups.
  - a. Open the Amazon VPC console at <https://console.aws.amazon.com/vpc/>.
  - b. Choose **VPC Dashboard**, and then choose **Security Groups**.
  - c. Select the security group for the Amazon RDS DB instance, such as **tutorial-db-securitygroup**.
  - d. For **Actions**, choose **Delete security groups**, and then choose **Delete** on the confirmation page.

- e. On the **Security Groups** page, select the security group for the Amazon EC2 instance, such as **tutorial-securitygroup**.
  - f. For **Actions**, choose **Delete security groups**, and then choose **Delete** on the confirmation page.
4. Delete the VPC.
    - a. Open the Amazon VPC console at <https://console.aws.amazon.com/vpc/>.
    - b. Choose **VPC Dashboard**, and then choose **VPCs**.
    - c. Select the VPC you want to delete, such as **tutorial-vpc**.
    - d. For **Actions**, choose **Delete VPC**.

The confirmation page shows other resources that are associated with the VPC that will also be deleted, including the subnets associated with it.

- e. On the confirmation page, enter **delete**, and then choose **Delete**.

## Tutorial: Create a VPC for use with a DB instance (dual-stack mode)

A common scenario includes a DB instance in a virtual private cloud (VPC) based on the Amazon VPC service. This VPC shares data with a public Amazon EC2 instance that is running in the same VPC.

In this tutorial, you create the VPC for this scenario that works with a database running in dual-stack mode. Dual-stack mode to enable connection over the IPv6 addressing protocol. For more information about IP addressing, see [Amazon RDS IP addressing](#).

Dual-stack network instances are supported in most regions. For more information see [Region and version availability](#). To see the limitations of dual-stack mode, see [Limitations for dual-stack network DB instances](#).

The following diagram shows this scenario.

For information about other scenarios, see [Scenarios for accessing a DB instance in a VPC](#).

Your DB instance needs to be available only to your Amazon EC2 instance, and not to the public internet. Thus, you create a VPC with both public and private subnets. The Amazon EC2 instance is hosted in the public subnet, so that it can reach the public internet. The DB instance is hosted in a private subnet. The Amazon EC2 instance can connect to the DB instance because it's hosted within the same VPC. However, the DB instance is not available to the public internet, providing greater security.

This tutorial configures an additional public and private subnet in a separate Availability Zone. These subnets aren't used by the tutorial. An RDS DB subnet group requires a subnet in at least two Availability Zones. The additional subnet makes it easy to switch to a Multi-AZ DB instance deployment in the future.

To create a DB instance that uses dual-stack mode, specify **Dual-stack mode** for the **Network type** setting. You can also modify a DB instance with the same setting. For more information, see [Creating an Amazon RDS DB instance](#) and [Modifying an Amazon RDS DB instance](#).

This tutorial describes configuring a VPC for Amazon RDS DB instances. For more information about Amazon VPC, see [Amazon VPC User Guide](#).

## Create a VPC with private and public subnets

Use the following procedure to create a VPC with both public and private subnets.

### To create a VPC and subnets

1. Open the Amazon VPC console at <https://console.aws.amazon.com/vpc/>.
2. In the upper-right corner of the AWS Management Console, choose the Region to create your VPC in. This example uses the US East (Ohio) Region.
3. In the upper-left corner, choose **VPC dashboard**. To begin creating a VPC, choose **Create VPC**.
4. For **Resources to create** under **VPC settings**, choose **VPC and more**.
5. For the remaining **VPC settings**, set these values:
  - **Name tag auto-generation** – **tutorial-dual-stack**
  - **IPv4 CIDR block** – **10.0.0.0/16**
  - **IPv6 CIDR block** – **Amazon-provided IPv6 CIDR block**
  - **Tenancy** – **Default**
  - **Number of Availability Zones (AZs)** – **2**
  - **Customize AZs** – Keep the default values.
  - **Number of public subnet** – **2**
  - **Number of private subnets** – **2**
  - **Customize subnets CIDR blocks** – Keep the default values.
  - **NAT gateways (\$)** – **None**
  - **Egress only internet gateway** – **No**
  - **VPC endpoints** – **None**
  - **DNS options** – Keep the default values.

**Note**

Amazon RDS requires at least two subnets in two different Availability Zones to support Multi-AZ DB instance deployments. This tutorial creates a Single-AZ deployment, but the requirement makes it easy to convert to a Multi-AZ DB instance deployment in the future.

**6. Choose Create VPC.****Create a VPC security group for a public Amazon EC2 instance**

Next, you create a security group for public access. To connect to public EC2 instances in your VPC, add inbound rules to your VPC security group that allow traffic to connect from the internet.

**To create a VPC security group**

1. Open the Amazon VPC console at <https://console.aws.amazon.com/vpc/>.
2. Choose **VPC Dashboard**, choose **Security Groups**, and then choose **Create security group**.
3. On the **Create security group** page, set these values:
  - **Security group name:** **tutorial-dual-stack-securitygroup**
  - **Description:** **Tutorial Dual-Stack Security Group**
  - **VPC:** Choose the VPC that you created earlier, for example: **vpc-*identifier*** (**tutorial-dual-stack-vpc**)
4. Add inbound rules to the security group.
  - a. Determine the IP address to use to connect to EC2 instances in your VPC using Secure Shell (SSH).

An example of an Internet Protocol version 4 (IPv4) address is `203.0.113.25/32`.

An example of an Internet Protocol version 6 (IPv6) address range is

`2001:db8:1234:1a00::/64`.

In many cases, you might connect through an internet service provider (ISP) or from behind your firewall without a static IP address. If so, find the range of IP addresses used by client computers.

**⚠ Warning**

If you use `0.0.0.0/0` for IPv4 or `::0` for IPv6, you make it possible for all IP addresses to access your public instances using SSH. This approach is acceptable for a short time in a test environment, but it's unsafe for production environments. In production, authorize only a specific IP address or range of addresses to access your instances.

- b. In the **Inbound rules** section, choose **Add rule**.
  - c. Set the following values for your new inbound rule to allow Secure Shell (SSH) access to your Amazon EC2 instance. If you do this, you can connect to your EC2 instance to install SQL clients and other applications. Specify an IP address so you can access your EC2 instance:
    - **Type:** SSH
    - **Source:** The IP address or range from step a. An example of an IPv4 IP address is **203.0.113.25/32**. An example of an IPv6 IP address is **2001:DB8::/32**.
5. Choose **Create security group** to create the security group.

Note the security group ID because you need it later in this tutorial.

## Create a VPC security group for a private DB instance

To keep your DB instance private, create a second security group for private access. To connect to private DB instances in your VPC, add inbound rules to your VPC security group. These allow traffic from your Amazon EC2 instance only.

### To create a VPC security group

1. Open the Amazon VPC console at <https://console.aws.amazon.com/vpc/>.
2. Choose **VPC Dashboard**, choose **Security Groups**, and then choose **Create security group**.
3. On the **Create security group** page, set these values:
  - **Security group name:** **tutorial-dual-stack-db-securitygroup**
  - **Description:** **Tutorial Dual-Stack DB Instance Security Group**

- **VPC:** Choose the VPC that you created earlier, for example: **vpc-*identifier* (tutorial-dual-stack-vpc)**
4. Add inbound rules to the security group:
    - a. In the **Inbound rules** section, choose **Add rule**.
    - b. Set the following values for your new inbound rule to allow MySQL traffic on port 3306 from your Amazon EC2 instance. If you do, you can connect from your EC2 instance to your DB instance. Doing this means that you can send data from your EC2 instance to your database.
      - **Type:** **MySQL/Aurora**
      - **Source:** The identifier of the **tutorial-dual-stack-securitygroup** security group that you created previously in this tutorial, for example **sg-9edd5cfb**.
  5. To create the security group, choose **Create security group**.

## Create a DB subnet group

A *DB subnet group* is a collection of subnets that you create in a VPC and that you then designate for your DB instances. By using a DB subnet group, you can specify a particular VPC when creating DB instances. To create a DB subnet group that is DUAL compatible, all subnets must be DUAL compatible. To be DUAL compatible, a subnet must have an IPv6 CIDR associated with it.

### To create a DB subnet group

1. Identify the private subnets for your database in the VPC.
  - a. Open the Amazon VPC console at <https://console.aws.amazon.com/vpc/>.
  - b. Choose **VPC Dashboard**, and then choose **Subnets**.
  - c. Note the subnet IDs of the subnets named **tutorial-dual-stack-subnet-private1-us-west-2a** and **tutorial-dual-stack-subnet-private2-us-west-2b**.

You will need the subnet IDs when you create your DB subnet group.

2. Open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.

Make sure that you connect to the Amazon RDS console, not to the Amazon VPC console.

3. In the navigation pane, choose **Subnet groups**.
4. Choose **Create DB subnet group**.

5. On the **Create DB subnet group** page, set these values in **Subnet group details**:
  - **Name:** `tutorial-dual-stack-db-subnet-group`
  - **Description:** `Tutorial Dual-Stack DB Subnet Group`
  - **VPC:** `tutorial-dual-stack-vpc (vpc-identifier)`
6. In the **Add subnets** section, choose values for the **Availability Zones** and **Subnets** options.  
  
For this tutorial, choose **us-east-2a** and **us-east-2b** for the **Availability Zones**. For **Subnets**, choose the private subnets you identified in the previous step.
7. Choose **Create**.

Your new DB subnet group appears in the DB subnet groups list on the RDS console. You can choose the DB subnet group to see its details. These include the supported addressing protocols and all of the subnets associated with the group and the network type supported by the DB subnet group.

## Create an Amazon EC2 instance in dual-stack mode

To create an Amazon EC2 instance, follow the instructions in [Launch an instance using the new launch instance wizard](#) in the *Amazon EC2 User Guide*.

On the **Configure Instance Details** page, set these values and keep the other values as their defaults:

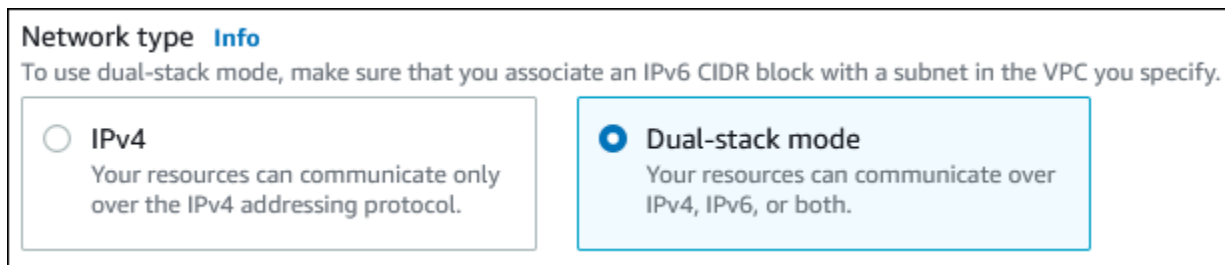

- **Network** – Choose an existing VPC with both public and private subnets, such as `tutorial-dual-stack-vpc (vpc-identifier)` created in [Create a VPC with private and public subnets](#).
- **Subnet** – Choose an existing public subnet, such as `subnet-identifier | tutorial-dual-stack-subnet-public1-us-east-2a | us-east-2a` created in [Create a VPC security group for a public Amazon EC2 instance](#).
- **Auto-assign Public IP** – Choose **Enable**.
- **Auto-assign IPv6 IP** – Choose **Enable**.
- **Firewall (security groups)** – Choose **Select an existing security group**.
- **Common security groups** – Choose an existing security group, such as the `tutorial-securitygroup` created in [Create a VPC security group for a public Amazon EC2 instance](#). Make sure that the security group that you choose includes inbound rules for Secure Shell (SSH) and HTTP access.

## Create a DB instance in dual-stack mode

In this step, you create a DB instance that runs in dual-stack mode.

### To create a DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the upper-right corner of the console, choose the AWS Region where you want to create the DB instance. This example uses the US East (Ohio) Region.
3. In the navigation pane, choose **Databases**.
4. Choose **Create database**.
5. On the **Create database** page, make sure that the **Standard create** option is chosen, and then choose the MySQL DB engine type.
6. In the **Connectivity** section, set these values:
  - **Network type** – Choose **Dual-stack mode**.

Network type **Info**  
To use dual-stack mode, make sure that you associate an IPv6 CIDR block with a subnet in the VPC you specify.

IPv4  
Your resources can communicate only over the IPv4 addressing protocol.

Dual-stack mode  
Your resources can communicate over IPv4, IPv6, or both.

- **Virtual private cloud (VPC)** – Choose an existing VPC with both public and private subnets, such as **tutorial-dual-stack-vpc** (vpc-*identifier*) created in [Create a VPC with private and public subnets](#).

The VPC must have subnets in different Availability Zones.

- **DB subnet group** – Choose a DB subnet group for the VPC, such as **tutorial-dual-stack-db-subnet-group** created in [Create a DB subnet group](#).
- **Public access** – Choose **No**.
- **VPC security group (firewall)** – Select **Choose existing**.
- **Existing VPC security groups** – Choose an existing VPC security group that is configured for private access, such as **tutorial-dual-stack-db-securitygroup** created in [Create a VPC security group for a private DB instance](#).

Remove other security groups, such as the default security group, by choosing the **X** associated with each.

- **Availability Zone** – Choose **us-west-2a**.

To avoid cross-AZ traffic, make sure the DB instance and the EC2 instance are in the same Availability Zone.

7. For the remaining sections, specify your DB instance settings. For information about each setting, see [Settings for DB instances](#).

## Connect to your Amazon EC2 instance and DB instance

After you create your Amazon EC2 instance and DB instance in dual-stack mode, you can connect to each one using the IPv6 protocol. To connect to an Amazon EC2 instance using the IPv6 protocol, follow the instructions in [Connect to your Linux instance](#) in the *Amazon EC2 User Guide*.

To connect to your RDS for MySQL DB instance from the Amazon EC2 instance, follow the instructions in [Connect to a MySQL DB instance](#).

## Deleting the VPC

After you create the VPC and other resources for this tutorial, you can delete them if they are no longer needed.

If you added resources in the VPC that you created for this tutorial, you might need to delete these before you can delete the VPC. Examples of resources are Amazon EC2 instances or DB instances. For more information, see [Delete your VPC](#) in the *Amazon VPC User Guide*.

### To delete a VPC and related resources

1. Delete the DB subnet group:
  - a. Open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
  - b. In the navigation pane, choose **Subnet groups**.
  - c. Select the DB subnet group to delete, such as **tutorial-db-subnet-group**.
  - d. Choose **Delete**, and then choose **Delete** in the confirmation window.
2. Note the VPC ID:
  - a. Open the Amazon VPC console at <https://console.aws.amazon.com/vpc/>.

- b. Choose **VPC Dashboard**, and then choose **VPCs**.
  - c. In the list, identify the VPC you created, such as **tutorial-dual-stack-vpc**.
  - d. Note the **VPC ID** value of the VPC that you created. You need this VPC ID in subsequent steps.
3. Delete the security groups:
  - a. Open the Amazon VPC console at <https://console.aws.amazon.com/vpc/>.
  - b. Choose **VPC Dashboard**, and then choose **Security Groups**.
  - c. Select the security group for the Amazon RDS DB instance, such as **tutorial-dual-stack-db-securitygroup**.
  - d. For **Actions**, choose **Delete security groups**, and then choose **Delete** on the confirmation page.
  - e. On the **Security Groups** page, select the security group for the Amazon EC2 instance, such as **tutorial-dual-stack-securitygroup**.
  - f. For **Actions**, choose **Delete security groups**, and then choose **Delete** on the confirmation page.
4. Delete the NAT gateway:
  - a. Open the Amazon VPC console at <https://console.aws.amazon.com/vpc/>.
  - b. Choose **VPC Dashboard**, and then choose **NAT Gateways**.
  - c. Select the NAT gateway of the VPC that you created. Use the VPC ID to identify the correct NAT gateway.
  - d. For **Actions**, choose **Delete NAT gateway**.
  - e. On the confirmation page, enter **delete**, and then choose **Delete**.
5. Delete the VPC:
  - a. Open the Amazon VPC console at <https://console.aws.amazon.com/vpc/>.
  - b. Choose **VPC Dashboard**, and then choose **VPCs**.
  - c. Select the VPC that you want to delete, such as **tutorial-dual-stack-vpc**.
  - d. For **Actions**, choose **Delete VPC**.

The confirmation page shows other resources that are associated with the VPC that will also be deleted, including the subnets associated with it.

6. Release the Elastic IP addresses:
  - a. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
  - b. Choose **EC2 Dashboard**, and then choose **Elastic IPs**.
  - c. Select the Elastic IP address that you want to release.
  - d. For **Actions**, choose **Release Elastic IP addresses**.
  - e. On the confirmation page, choose **Release**.

## Moving a DB instance not in a VPC into a VPC

Some legacy DB instances on the EC2-Classic platform are not in a VPC. If your DB instance is not in a VPC, you can use the AWS Management Console to easily move your DB instance into a VPC. Before you can move a DB instance not in a VPC, into a VPC, you must create the VPC.

EC2-Classic was retired on August 15, 2022. If you haven't migrated from EC2-Classic to a VPC, we recommend that you migrate as soon as possible. For more information, see [Migrate from EC2-Classic to a VPC](#) in the *Amazon EC2 User Guide* and the blog [EC2-Classic Networking is Retiring – Here's How to Prepare](#).

### Important

If you are a new Amazon RDS customer, if you have never created a DB instance before, or if you are creating a DB instance in an AWS Region you have not used before, in almost all cases you are on the *EC2-VPC* platform and have a default VPC. For information about working with DB instances in a VPC, see [Working with a DB instance in a VPC](#).

Follow these steps to create a VPC for your DB instance.

- [Step 1: Create a VPC](#)
- [Step 2: Create a DB subnet group](#)
- [Step 3: Create a VPC security group](#)

After you create the VPC, follow these steps to move your DB instance into the VPC.

- [Updating the VPC for a DB instance](#)

We highly recommend that you create a backup of your DB instance immediately before the migration. Doing so ensures that you can restore the data if the migration fails. For more information, see [Backing up, restoring, and exporting data](#).

The following are some limitations to moving your DB instance into the VPC.

- **Previous generation DB instance classes** – Previous generation DB instance classes might not be supported on the VPC platform. When moving a DB instance to a VPC, choose a db.m3 or db.r3 DB instance class. After you move the DB instance to a VPC, you can scale the DB instance to use a later DB instance class. For a full list of VPC supported instance classes, see [Amazon RDS instance types](#).
- **Multi-AZ** – Moving a Multi-AZ DB instance not in a VPC into a VPC is not currently supported. To move your DB instance to a VPC, first modify the DB instance so that it is a single-AZ deployment. Change the **Multi-AZ deployment** setting to **No**. After you move the DB instance to a VPC, modify it again to make it a Multi-AZ deployment. For more information, see [Modifying an Amazon RDS DB instance](#).
- **Read replicas** – Moving a DB instance with read replicas not in a VPC into a VPC is not currently supported. To move your DB instance to a VPC, first delete all of its read replicas. After you move the DB instance to a VPC, recreate the read replicas. For more information, see [Working with DB instance read replicas](#).
- **Option groups** – If you move your DB instance to a VPC, and the DB instance is using a custom option group, change the option group that is associated with your DB instance. Option groups are platform-specific, and moving to a VPC is a change in platform. To use a custom option group in this case, assign the default VPC option group to the DB instance, assign an option group that is used by other DB instances in the VPC you are moving to, or create a new option group and assign it to the DB instance. For more information, see [Working with option groups](#).

## Alternatives for moving a DB instance not in a VPC into a VPC with minimal downtime

Using the following alternatives, you can move a DB instance not in a VPC into a VPC with minimal downtime. These alternatives cause minimum disruption to the source DB instance and allow it to serve user traffic during the migration. However, the time required to migrate to a VPC will vary based on the database size and the live workload characteristics.

- **AWS Database Migration Service (AWS DMS)** – AWS DMS enables the live migration of data while keeping the source DB instance fully operational, but it replicates only a limited set of DDL statements. AWS DMS doesn't propagate items such as indexes, users, privileges, stored procedures, and other database changes not directly related to table data. In addition, AWS DMS doesn't automatically use RDS snapshots for the initial DB instance creation, which can increase migration time. For more information, see [AWS Database Migration Service](#).

- **DB snapshot restore or point-in-time recovery** – You can move a DB instance to a VPC by restoring a snapshot of the DB instance or by restoring a DB instance to a point in time. For more information, see [Restoring to a DB instance](#) and [Restoring a DB instance to a specified time](#).

# Quotas and constraints for Amazon RDS

Following, you can find a description of the resource quotas and naming constraints for Amazon RDS.

## Topics

- [Quotas in Amazon RDS](#)
- [Naming constraints in Amazon RDS](#)
- [Maximum number of database connections](#)
- [File size limits in Amazon RDS](#)

## Quotas in Amazon RDS

Each AWS account has quotas, for each AWS Region, on the number of Amazon RDS resources that can be created. After a quota for a resource has been reached, additional calls to create that resource fail with an exception.

The following table lists the resources and their quotas per AWS Region.

Name	Default	Adjustable	Description
Authorizations per DB security group	Each supported Region: 20	No	Number of security group authorizations per DB security group
Custom engine versions	Each supported Region: 40	<a href="#">Yes</a>	The maximum number of custom engine versions allowed in this account in the current Region
DB cluster parameter groups	Each supported Region: 50	No	The maximum number of DB cluster parameter groups
DB clusters	Each supported Region: 40	<a href="#">Yes</a>	The maximum number of Aurora clusters allowed

Name	Default	Adjustable	Description
			in this account in the current Region
DB instances	Each supported Region: 40	<a href="#">Yes</a>	The maximum number of DB instances allowed in this account in the current Region
DB subnet groups	Each supported Region: 50	<a href="#">Yes</a>	The maximum number of DB subnet groups
Data API HTTP request body size	Each supported Region: 4 Megabytes	No	The maximum size allowed for the HTTP request body.
Data API maximum concurrent cluster-secret pairs	Each supported Region: 30	No	The maximum number of unique pairs of Aurora Serverless v1 DB clusters and secrets in concurrent Data API requests for this account in the current AWS Region.
Data API maximum concurrent requests	Each supported Region: 500	No	The maximum number of Data API requests to an Aurora Serverless v1 DB cluster that use the same secret and can be processed at the same time. Additional requests are queued and processed as in-process requests complete.

Name	Default	Adjustable	Description
Data API maximum result set size	Each supported Region: 1 Megabytes	No	The maximum size of the database result set that can be returned by the Data API.
Data API maximum size of JSON response string	Each supported Region: 10 Megabytes	No	The maximum size of the simplified JSON response string returned by the RDS Data API.
Data API requests per second	Each supported Region: 1,000 per second	No	The maximum number of requests to the Data API per second allowed for this account in the current AWS Region. This quota only applies to Amazon Aurora Serverless v1 clusters.
Event subscriptions	Each supported Region: 20	<a href="#">Yes</a>	The maximum number of event subscriptions
IAM roles per DB cluster	Each supported Region: 5	<a href="#">Yes</a>	The maximum number of IAM roles associated with a DB cluster
IAM roles per DB instance	Each supported Region: 5	<a href="#">Yes</a>	The maximum number of IAM roles associated with a DB instance
Integrations	Each supported Region: 100	No	The maximum number of integrations allowed in this account in the current AWS Region

Name	Default	Adjustable	Description
Manual DB cluster snapshots	Each supported Region: 100	<a href="#">Yes</a>	The maximum number of manual DB cluster snapshots
Manual DB instance snapshots	Each supported Region: 100	<a href="#">Yes</a>	The maximum number of manual DB instance snapshots
Option groups	Each supported Region: 20	<a href="#">Yes</a>	The maximum number of option groups
Parameter groups	Each supported Region: 50	<a href="#">Yes</a>	The maximum number of parameter groups
Proxies	Each supported Region: 20	<a href="#">Yes</a>	The maximum number of proxies allowed in this account in the current AWS Region
Read replicas per primary	Each supported Region: 15	<a href="#">Yes</a>	The maximum number of read replicas per primary DB instance. This quota can't be adjusted for Amazon Aurora.
Reserved DB instances	Each supported Region: 40	<a href="#">Yes</a>	The maximum number of reserved DB instances allowed in this account in the current AWS Region
Rules per security group	Each supported Region: 20	No	The maximum number of rules per DB security group
Security groups	Each supported Region: 25	<a href="#">Yes</a>	The maximum number of DB security groups

Name	Default	Adjustable	Description
Security groups (VPC)	Each supported Region: 5	No	The maximum number of DB security groups per Amazon VPC
Subnets per DB subnet group	Each supported Region: 20	No	The maximum number of subnets per DB subnet group
Tags per resource	Each supported Region: 50	No	The maximum number of tags per Amazon RDS resource
Total storage for all DB instances	Each supported Region: 100,000 Gigabytes	<a href="#">Yes</a>	The maximum total storage (in GB) on EBS volumes for all Amazon RDS DB instances added together. This quota does not apply to Amazon Aurora, which has a maximum cluster volume of 128 TiB for each DB cluster.

### Note

By default, you can have up to a total of 40 DB instances. RDS DB instances, Aurora DB instances, Amazon Neptune instances, and Amazon DocumentDB instances apply to this quota.

The following limitations apply to the Amazon RDS DB instances:

- 10 for each SQL Server edition (Enterprise, Standard, Web, and Express) under the "license-included" model
- 10 for Oracle under the "license-included" model
- 40 for Db2 under the "bring-your-own-license" (BYOL) licensing model

- 40 for MySQL, MariaDB, or PostgreSQL
- 40 for Oracle under the "bring-your-own-license" (BYOL) licensing model

If your application requires more DB instances, you can request additional DB instances by opening the [Service Quotas console](#). In the navigation pane, choose **AWS services**. Choose **Amazon Relational Database Service (Amazon RDS)**, choose a quota, and follow the directions to request a quota increase. For more information, see [Requesting a quota increase](#) in the *Service Quotas User Guide*.

For RDS for Oracle, the read replica limit is 5 per source database for each Region. Backups managed by AWS Backup are considered manual DB snapshots, but don't count toward the manual snapshot quota. For information about AWS Backup, see the [AWS Backup Developer Guide](#).

If you use any RDS API operations and exceed the default quota for the number of calls per second, the Amazon RDS API issues an error like the following one.

ClientError: An error occurred (ThrottlingException) when calling the *API\_name* operation: Rate exceeded.

Here, reduce the number of calls per second. The quota is meant to cover most use cases. If higher quotas are needed, you can request a quota increase by using one of the following options:

- From the console, open the [Service Quotas console](#).
- From the AWS CLI, use the [request-service-quota-increase](#) AWS CLI command.

For more information, see the [Service Quotas User Guide](#).

## Naming constraints in Amazon RDS

The naming constraints in Amazon RDS are as follows:

- DB instance identifier:
  - Must contain 1–63 alphanumeric characters or hyphens.
  - First character must be a letter.
  - Can't end with a hyphen or contain two consecutive hyphens.

- Must be unique for all DB instances per AWS account, per AWS Region.
- Initial database name:
  - Database name constraints differ for each database engine. For more information, see the available settings when creating each DB instance.
  - SQL Server – Create your databases after creating your DB instance.
- Master username – Master username constraints differ for each database engine. For more information, see the available settings when creating the DB instance.
- Master password:
  - The password for the database master user can include any printable ASCII character except /, ', ", @, or a space.

For Oracle, & is an additional character limitation.

- The password can contain the following number of printable ASCII characters depending on the DB engine:
  - Db2: 8–255
  - MariaDB and MySQL: 8–41
  - Oracle: 8–30
  - SQL Server and PostgreSQL: 8–128
- DB parameter group:
  - Must contain 1–255 alphanumeric characters.
  - First character must be a letter.
  - Hyphens are allowed, but the name cannot end with a hyphen or contain two consecutive hyphens.
- DB subnet group:
  - Must contain 1–255 characters.
  - Alphanumeric characters, spaces, hyphens, underscores, and periods are allowed.

## Maximum number of database connections

The maximum number of simultaneous database connections varies by the DB engine type and the memory allocation for the DB instance class. The maximum number of connections is generally set in the parameter group associated with the DB instance. The exception is Microsoft SQL Server,

where it is set in the server properties for the DB instance in SQL Server Management Studio (SSMS).

Database connections consume memory. Setting one of these parameters too high can cause a low memory condition that might cause a DB instance to be placed in the **incompatible-parameters** status. For more information, see [Diagnosing and resolving incompatible parameters status for a memory limit](#).

If your applications frequently open and close connections, or keep a large number of long-lived connections open, we recommend that you use Amazon RDS Proxy. RDS Proxy is a fully managed, highly available database proxy that uses connection pooling to share database connections securely and efficiently. To learn more about RDS Proxy, see [Using Amazon RDS Proxy](#).

**Note**

For Oracle, you set the maximum number of user processes and user and system sessions. For Db2, you can't set maximum connections. The limit is 64000.

The following table shows information about the maximum database connections for different DB engines.

DB engine	Parameter	Allowed values	Default value	Description
MariaDB and MySQL	max_connections	1–100000	Default for all MariaDB and MySQL versions except for MariaDB version 10.5 and 10.6:  {DBInstanceClassMemory/12582880}  The formula is effectively equivalent to MB/12.  Default for MariaDB version 10.5 and 10.6:	Number of simultaneous client connections allowed

DB engine	Parameter	Allowed values	Default value	Description
			$\text{LEAST}(\{\text{DBInstanceClassMemory}/25165760\}, 12000)$  The formula is effectively equivalent to MB/25.  In either case, if the default value calculation results in a value greater than 16,000, Amazon RDS sets the limit to 16,000 for MariaDB and MySQL DB instances.	
Oracle	processes	80–20000	$\text{LEAST}(\{\text{DBInstanceClassMemory}/9868951\}, 20000)$	User processes
Oracle	sessions	100–65535	Not applicable	User and system sessions
PostgreSQL	max_connections	6–8388607	$\text{LEAST}(\{\text{DBInstanceClassMemory}/9531392\}, 5000)$	Maximum number of concurrent connections
SQL Server	Maximum number of concurrent connections	0–32767	0 (unlimited)	Maximum number of concurrent connections

DBInstanceClassMemory is in bytes. For details about how this value is calculated, see [Specifying DB parameters](#). Because of memory reserved for the operating system and RDS management processes, this memory size is smaller than the value in gibibytes (GiB) shown in [Hardware specifications for DB instance classes](#).

For example, some DB instance classes have 8 GiB of memory, which is 8,589,934,592 bytes. For a MySQL DB instance running on a DB instance class with 8 GiB of memory, such as db.m7g.large, the equation that uses the total memory would be  $8589934592/12582880=683$ . However, the variable `DBInstanceClassMemory` automatically subtracts the amounts reserved to the operating system and the RDS processes that manage the DB instance. The remainder of the subtraction is then divided by 12,582,880. This calculation results in approximately 630 for the value of `max_connections` instead of 683. This value depends on the DB instance class and DB engine.

When a MariaDB or MySQL DB instance is running on a small DB instance class, such as db.t3.micro or db.t3.small, the total memory available is low. For these DB instance classes, RDS reserves a significant portion of the available memory, which affects the value `max_connections`. For example, the default maximum number of connections for a MySQL DB instance running on a db.t3.micro DB instance class is approximately 60. You can determine the `max_connections` value for your DB MariaDB or MySQL DB instance by connecting to it and running the following SQL command:

```
SHOW GLOBAL VARIABLES LIKE 'max_connections';
```

## File size limits in Amazon RDS

File size limits apply to certain Amazon RDS DB instances. For more information, see the following engine-specific limits:

- [MariaDB file size limits in Amazon RDS](#)
- [MySQL file size limits in Amazon RDS](#)
- [Oracle file size limits in Amazon RDS](#)

# Troubleshooting for Amazon RDS

Use the following sections to help troubleshoot problems you have with DB instances in Amazon RDS and Amazon Aurora.

## Topics

- [Can't connect to Amazon RDS DB instance](#)
- [Amazon RDS security issues](#)
- [Troubleshooting incompatible-network state](#)
- [Resetting the DB instance owner password](#)
- [Amazon RDS DB instance outage or reboot](#)
- [Amazon RDS DB parameter changes not taking effect](#)
- [Amazon RDS DB instance running out of storage](#)
- [Amazon RDS insufficient DB instance capacity](#)
- [Freeable memory issues in Amazon RDS](#)
- [MySQL and MariaDB issues](#)
- [Can't set backup retention period to 0](#)

For information about debugging problems using the Amazon RDS API, see [Troubleshooting applications on Amazon RDS](#).

## Can't connect to Amazon RDS DB instance

When you can't connect to a DB instance, the following are common causes:

- **Inbound rules** – The access rules enforced by your local firewall and the IP addresses authorized to access your DB instance might not match. The problem is most likely the inbound rules in your security group.

By default, DB instances don't allow access. Access is granted through a security group associated with the VPC that allows traffic into and out of the DB instance. If necessary, add inbound and outbound rules for your particular situation to the security group. You can specify an IP address, a range of IP addresses, or another VPC security group.

**Note**

When adding a new inbound rule, you can choose **My IP** for **Source** to allow access to the DB instance from the IP address detected in your browser.

For more information about setting up security groups, see [Provide access to your DB instance in your VPC by creating a security group](#).

**Note**

Client connections from IP addresses within the range 169.254.0.0/16 aren't permitted. This is the Automatic Private IP Addressing Range (APIPA), which is used for local-link addressing.

- **Public accessibility** – To connect to your DB instance from outside of the VPC, such as by using a client application, the instance must have a public IP address assigned to it.

To make the instance publicly accessible, modify it and choose **Yes** under **Public accessibility**. For more information, see [Hiding a DB instance in a VPC from the internet](#).

- **Port** – The port that you specified when you created the DB instance can't be used to send or receive communications due to your local firewall restrictions. To determine if your network allows the specified port to be used for inbound and outbound communication, check with your network administrator.
- **Availability** – For a newly created DB instance, the DB instance has a status of `creating` until the DB instance is ready to use. When the state changes to `available`, you can connect to the DB instance. Depending on the size of your DB instance, it can take up to 20 minutes before an instance is available.
- **Internet gateway** – For a DB instance to be publicly accessible, the subnets in its DB subnet group must have an internet gateway.

**To configure an internet gateway for a subnet**

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Databases**, and then choose the name of the DB instance.

3. In the **Connectivity & security** tab, write down the values of the VPC ID under **VPC** and the subnet ID under **Subnets**.
4. Open the Amazon VPC console at <https://console.aws.amazon.com/vpc/>.
5. In the navigation pane, choose **Internet Gateways**. Verify that there is an internet gateway attached to your VPC. Otherwise, choose **Create Internet Gateway** to create an internet gateway. Select the internet gateway, and then choose **Attach to VPC** and follow the directions to attach it to your VPC.
6. In the navigation pane, choose **Subnets**, and then select your subnet.
7. On the **Route Table** tab, verify that there is a route with  $0.0.0.0/0$  as the destination and the internet gateway for your VPC as the target.

If you're connecting to your instance using its IPv6 address, verify that there is a route for all IPv6 traffic ( $::/0$ ) that points to the internet gateway. Otherwise, do the following:

- a. Choose the ID of the route table (rtb-xxxxxxx) to navigate to the route table.
- b. On the **Routes** tab, choose **Edit routes**. Choose **Add route**, use  $0.0.0.0/0$  as the destination and the internet gateway as the target.

For IPv6, choose **Add route**, use  $::/0$  as the destination and the internet gateway as the target.

- c. Choose **Save routes**.

Also, if you are trying to connect to IPv6 endpoint, make sure that client IPv6 address range is authorized to connect to the DB instance.

For more information, see [Working with a DB instance in a VPC](#).

For engine-specific connection issues, see the following topics:

- [Troubleshooting connections to your SQL Server DB instance](#)
- [Troubleshooting connections to your Oracle DB instance](#)
- [Troubleshooting connections to your RDS for PostgreSQL instance](#)
- [Maximum MySQL and MariaDB connections](#)

## Testing a connection to a DB instance

You can test your connection to a DB instance using common Linux or Microsoft Windows tools.

From a Linux or Unix terminal, you can test the connection by entering the following. Replace *DB-instance-endpoint* with the endpoint and *port* with the port of your DB instance.

```
nc -zv DB-instance-endpoint port
```

For example, the following shows a sample command and the return value.

```
nc -zv postgresql1.c6c8mn7fake0.us-west-2.rds.amazonaws.com 8299

Connection to postgresql1.c6c8mn7fake0.us-west-2.rds.amazonaws.com 8299 port [tcp/vvvr-data] succeeded!
```

Windows users can use Telnet to test the connection to a DB instance. Telnet actions aren't supported other than for testing the connection. If a connection is successful, the action returns no message. If a connection isn't successful, you receive an error message such as the following.

```
C:\>telnet sg-postgresql1.c6c8mntfake0.us-west-2.rds.amazonaws.com 819

Connecting To sg-postgresql1.c6c8mntfake0.us-west-2.rds.amazonaws.com...Could not
open
connection to the host, on port 819: Connect failed
```

If Telnet actions return success, your security group is properly configured.

### Note

Amazon RDS doesn't accept internet control message protocol (ICMP) traffic, including ping.

## Troubleshooting connection authentication

In some cases, you can connect to your DB instance but you get authentication errors. In these cases, you might want to reset the master user password for the DB instance. You can do this by modifying the RDS instance.

For more information about modifying a DB instance, see [Modifying an Amazon RDS DB instance](#).

## Amazon RDS security issues

To avoid security issues, never use your AWS account root user email address and password for a user account. Best practice is to use your root user to create users and assign those to DB user accounts. You can also use your root user to create other user accounts, if necessary.

For information about creating users, see [Creating an IAM user in your AWS account](#). For information about creating users in AWS IAM Identity Center, see [Manage identities in IAM Identity Center](#).

### Error message "failed to retrieve account attributes, certain console functions may be impaired."

You can get this error for several reasons. It might be because your account is missing permissions, or your account hasn't been properly set up. If your account is new, you might not have waited for the account to be ready. If this is an existing account, you might lack permissions in your access policies to perform certain actions such as creating a DB instance. To fix the issue, your administrator needs to provide the necessary roles to your account. For more information, see [the IAM documentation](#).

## Troubleshooting incompatible-network state

The incompatible-network state means that the database might still be accessible at the database level but you can't modify or reboot it.

### Causes

The incompatible-network state of your DB instance could be a result of one of the following actions:

- Modifying the DB instance class.
- Modifying the DB instance to use Multi-AZ DB cluster deployment.
- Replacing a host due to a maintenance event.
- Launching a replacement DB instance.
- Restoring from a snapshot backup.

- Starting a DB instance that was stopped.

## Resolution

### Use start-db-instance command

To fix a database that is in an incompatible-network state, follow these instructions:

1. Open the <https://console.aws.amazon.com/rds/> and choose **Databases** from the navigation pane.
2. Choose the DB instance that is in the incompatible-network state and note the DB instance identifier, VPC ID, and subnet IDs from the **Connectivity & Security** tab.
3. Use the AWS CLI to run the `start-db-instance` command. Specify the `--db-instance-identifier` value.

#### Note

Running this command when your database is in incompatible mode might cause some downtime.

The `start-db-instance` command does not resolve this issue for RDS for SQL Server DB instances.

Your database status changes to **Available** if the command executes successfully.

If your database restarts, the DB instance might execute the last operation run on the instance before it was moved to incompatible-network state. This might move the instance back to the incompatible-network state.

If the `start-db-instance` command is unsuccessful or the instance moves back to incompatible-network state, open the **Databases** page in the RDS console and select the database. Navigate to the **Logs & events** section. The **Recent events** section displays further resolution steps to follow. The messages are classified as follows:

- **INTERNAL RESOURCE CHECK:** There might be issues with your internal resources.
- **DNS CHECK:** Check DNS resolution and hostnames for the VPC in the VPC console.
- **ENI CHECK:** The elastic network interface (ENI) for your database might not exist.

- **GATEWAY CHECK:** The internet gateway for your publicly available database is not attached to the VPC.
- **IP CHECK:** There are no free IP addresses in your subnets.
- **SECURITY GROUP CHECK:** There are no security groups associated with your database or the security groups are invalid.
- **SUBNET CHECK:** There are no valid subnets in your DB subnet group or there are issues with your subnet.
- **VPC CHECK:** The VPC associated with your database is invalid.

## Perform point-in-time recovery

It is best practice to have a backup (snapshot or logical), in case your database enters incompatible-network state. See [Introduction to backups](#). If you turned on automated backups, then temporarily stop any writes to the database and perform a point-in-time recovery.

### Note

After an instance enters the incompatible-network state, the DB instance might not be accessible to perform a logical backup.

If you didn't turn on automated backups, create a new DB instance. Then migrate the data using [AWS Database Migration Service \(AWS DMS\)](#), or by using a backup and restore tool.

If this does not resolve the issue, contact AWS Support for further assistance.

## Resetting the DB instance owner password

If you get locked out of your DB instance, you can log in as the master user. Then you can reset the credentials for other administrative users or roles. If you can't log in as the master user, the AWS account owner can reset the master user password. For details of which administrative accounts or roles you might need to reset, see [Master user account privileges](#).

You can change the DB instance password by using the Amazon RDS console, the AWS CLI command [modify-db-instance](#), or by using the [ModifyDBInstance](#) API operation. For more information about modifying a DB instance, see [Modifying an Amazon RDS DB instance](#).

## Amazon RDS DB instance outage or reboot

A DB instance outage can occur when a DB instance is rebooted. It can also occur when the DB instance is put into a state that prevents access to it, and when the database is restarted. A reboot can occur when you manually reboot your DB instance. A reboot can also occur when you change a DB instance setting that requires a reboot before it can take effect.

A DB instance reboot occurs when you change a setting that requires a reboot, or when you manually cause a reboot. A reboot can occur immediately if you change a setting and request that the change take effect immediately. Or it can occur during the DB instance's maintenance window.

A DB instance reboot occurs immediately when one of the following occurs:

- You change the backup retention period for a DB instance from 0 to a nonzero value or from a nonzero value to 0. You then set **Apply Immediately** to `true`.
- You change the DB instance class, and **Apply Immediately** is set to `true`.
- You change the storage type from **Magnetic (Standard)** to **General Purpose (SSD)** or **Provisioned IOPS (SSD)**, or from **Provisioned IOPS (SSD)** or **General Purpose (SSD)** to **Magnetic (Standard)**.

A DB instance reboot occurs during the maintenance window when one of the following occurs:

- You change the backup retention period for a DB instance from 0 to a nonzero value or from a nonzero value to 0, and **Apply Immediately** is set to `false`.
- You change the DB instance class, and **Apply Immediately** is set to `false`.

When you change a static parameter in a DB parameter group, the change doesn't take effect until the DB instance associated with the parameter group is rebooted. The change requires a manual reboot. The DB instance isn't automatically rebooted during the maintenance window.

To see a table that shows DB instance actions and the effect that setting the **Apply Immediately** value has, see [Modifying an Amazon RDS DB instance](#).

## Amazon RDS DB parameter changes not taking effect

In some cases, you might change a parameter in a DB parameter group but don't see the changes take effect. If so, you likely need to reboot the DB instance associated with the DB parameter

group. When you change a dynamic parameter, the change takes effect immediately. When you change a static parameter, the change doesn't take effect until you reboot the DB instance associated with the parameter group.

You can reboot a DB instance using the RDS console. Or you can explicitly call the [RebootDBInstance](#) API operation. You can reboot without failover if the DB instance is in a Multi-AZ deployment. The requirement to reboot the associated DB instance after a static parameter change helps mitigate the risk of a parameter misconfiguration affecting an API call. An example of this is calling `ModifyDBInstance` to change the DB instance class. For more information, see [Modifying parameters in a DB parameter group in Amazon RDS](#).

## Amazon RDS DB instance running out of storage

If your DB instance runs out of storage space, it might no longer be available. We highly recommend that you constantly monitor the `FreeStorageSpace` metric published in CloudWatch to make sure that your DB instance has enough free storage space.

If your database instance runs out of storage, its status changes to `storage-full`. For example, a call to the `DescribeDBInstances` API operation for a DB instance that has used up its storage outputs the following.

```
aws rds describe-db-instances --db-instance-identifier mydbinstance

DBINSTANCE mydbinstance 2009-12-22T23:06:11.915Z db.m5.large mysql8.0 50 sa
storage-full mydbinstance.c11a4j4jgyph.us-east-1.rds.amazonaws.com 3306
us-east-1b 3
SECGROUP default active
PARAMGRP default.mysql8.0 in-sync
```

To recover from this scenario, add more storage space to your instance using the `ModifyDBInstance` API operation or the following AWS CLI command.

For Linux, macOS, or Unix:

```
aws rds modify-db-instance \  
  --db-instance-identifier mydbinstance \  
  --allocated-storage 60 \  
  --apply-immediately
```

For Windows:

```
aws rds modify-db-instance ^
  --db-instance-identifier mydbinstance ^
  --allocated-storage 60 ^
  --apply-immediately
```

```
DBINSTANCE mydbinstance 2009-12-22T23:06:11.915Z db.m5.large mysql8.0 50 sa
storage-full mydbinstance.c1la4j4jgyph.us-east-1.rds.amazonaws.com 3306
us-east-1b 3 60
SECGROUP default active
PARAMGRP default.mysql8.0 in-sync
```

Now, when you describe your DB instance, you see that your DB instance has modifying status, which indicates the storage is being scaled.

```
aws rds describe-db-instances --db-instance-identifier mydbinstance
```

```
DBINSTANCE mydbinstance 2009-12-22T23:06:11.915Z db.m5.large mysql8.0 50 sa
modifying mydbinstance.c1la4j4jgyph.us-east-1.rds.amazonaws.com
3306 us-east-1b 3 60
SECGROUP default active
PARAMGRP default.mysql8.0 in-sync
```

After storage scaling is complete, your DB instance status changes to available.

```
aws rds describe-db-instances --db-instance-identifier mydbinstance
```

```
DBINSTANCE mydbinstance 2009-12-22T23:06:11.915Z db.m5.large mysql8.0 60 sa
available mydbinstance.c1la4j4jgyph.us-east-1.rds.amazonaws.com 3306
us-east-1b 3
SECGROUP default active
PARAMGRP default.mysql8.0 in-sync
```

You can receive notifications when your storage space is exhausted using the DescribeEvents operation. For example, in this scenario, if you make a DescribeEvents call after these operations you see the following output.

```
aws rds describe-events --source-type db-instance --source-identifier mydbinstance
```

```
2009-12-22T23:44:14.374Z mydbinstance Allocated storage has been exhausted db-  
instance  
2009-12-23T00:14:02.737Z mydbinstance Applying modification to allocated storage db-  
instance  
2009-12-23T00:31:54.764Z mydbinstance Finished applying modification to allocated  
storage
```

## Amazon RDS insufficient DB instance capacity

The `InsufficientDBInstanceCapacity` error can be returned when you try to create, start, or modify a DB instance. It can also be returned when you try to restore a DB instance from a DB snapshot. When this error is returned, a common cause is that the specific DB instance class isn't available in the requested Availability Zone. You can try one of the following to solve the problem:

- Retry the request with a different DB instance class.
- Retry the request with a different Availability Zone.
- Retry the request without specifying an explicit Availability Zone.

For information about troubleshooting instance capacity issues for Amazon EC2, see [Insufficient instance capacity](#) in the *Amazon EC2 User Guide*.

For information about modifying a DB instance, see [Modifying an Amazon RDS DB instance](#).

## Freeable memory issues in Amazon RDS

*Freeable memory* is the total random access memory (RAM) on a DB instance that can be made available to the database engine. It's the sum of the free operating-system (OS) memory and the available buffer and page cache memory. The database engine uses most of the memory on the host, but OS processes also use some RAM. Memory currently allocated to the database engine or used by OS processes isn't included in freeable memory. When the database engine is running out of memory, the DB instance can use the temporary space that is normally used for buffering and caching. As previously mentioned, this temporary space is included in freeable memory.

You use the `FreeableMemory` metric in Amazon CloudWatch to monitor the freeable memory. For more information, see [Monitoring tools for Amazon RDS](#).

If your DB instance consistently runs low on freeable memory or uses swap space, consider scaling up to a larger DB instance class. For more information, see [DB instance classes](#).

You can also change the memory settings. For example, on RDS for MySQL, you might adjust the size of the `innodb_buffer_pool_size` parameter. This parameter is set by default to 75 percent of physical memory. For more MySQL troubleshooting tips, see [How can I troubleshoot low freeable memory in an Amazon RDS for MySQL database?](#)

## MySQL and MariaDB issues

You can diagnose and correct issues with MySQL and MariaDB DB instances.

### Topics

- [Maximum MySQL and MariaDB connections](#)
- [Diagnosing and resolving incompatible parameters status for a memory limit](#)
- [Diagnosing and resolving lag between read replicas](#)
- [Diagnosing and resolving a MySQL or MariaDB read replication failure](#)

- [Diagnosing and resolving point-in-time restore failures](#)
- [Replication stopped error](#)
- [Read replica create fails or replication breaks with fatal error 1236](#)

## Maximum MySQL and MariaDB connections

The maximum number of connections allowed to an RDS for MySQL or RDS for MariaDB DB instance is based on the amount of memory available for its DB instance class. A DB instance class with more memory available results in a larger number of connections available. For more information on DB instance classes, see [DB instance classes](#).

The connection limit for a DB instance is set by default to the maximum for the DB instance class. You can limit the number of concurrent connections to any value up to the maximum number of connections allowed. Use the `max_connections` parameter in the parameter group for the DB instance. For more information, see [Maximum number of database connections](#) and [Parameter groups for Amazon RDS](#).

You can retrieve the maximum number of connections allowed for a MySQL or MariaDB DB instance by running the following query.

```
SELECT @@max_connections;
```

You can retrieve the number of active connections to a MySQL or MariaDB DB instance by running the following query.

```
SHOW STATUS WHERE `variable_name` = 'Threads_connected';
```

## Diagnosing and resolving incompatible parameters status for a memory limit

A MariaDB or MySQL DB instance can be placed in **incompatible-parameters** status for a memory limit when the following conditions are met:

- The DB instance is restarted at least three times in one hour or at least five times in one day when the DB instance status is **Available**.
- An attempt to restart the DB instance fails because a maintenance action or monitoring process couldn't restart the DB instance.
- The potential memory usage of the DB instance exceeds 1.2 times the memory allocated to its DB instance class.

When a DB instance is restarted for the third time in one hour or for the fifth time in one day, it performs a check for memory usage. The check makes a calculation of the potential memory usage of the DB instance. The value returned by the calculation is the sum of the following values:

- **Value 1** – The sum of the following parameters:
  - `innodb_additional_mem_pool_size`
  - `innodb_buffer_pool_size`

You can modify the value for `innodb_buffer_pool_size`. However, the value won't always match what you input. This mismatch occurs for several reasons. First, if the DB instance is a micro DB instance, then we override the default value and set it to 256 MB. For more information, see [Overriding innodb\\_buffer\\_pool\\_size](#).

Second, we make sure that 500 MB of memory is reserved on the DB instance for the host manager, the engine, the operating system, and the kernel.

Last, we optimize `innodb_buffer_pool_size` by dividing it into units. The host manager rounds down to the closest multiple of those units. The units are calculated by multiplying

`innodb_buffer_pool_chunk_size` by `innodb_buffer_pool_instances`. For more information, see [Configuring InnoDB Buffer Pool Size](#) in the MySQL documentation.

The default for `innodb_buffer_pool_instances` is 8, unless `innodb_buffer_pool_size` is less than 1 GB. If `innodb_buffer_pool_size` is less than 1 GB, then the default for `innodb_buffer_pool_instances` is 1. The default for `innodb_buffer_pool_chunk_size` is 128 MB.

- `innodb_log_buffer_size`
- `key_buffer_size`
- `query_cache_size` (MySQL version 5.7 only)
- `tmp_table_size`
- **Value 2** – The `max_connections` parameter multiplied by the sum of the following parameters:
  - `binlog_cache_size`
  - `join_buffer_size`
  - `read_buffer_size`
  - `read_rnd_buffer_size`
  - `sort_buffer_size`
  - `thread_stack`
- **Value 3** – If the `performance_schema` parameter is enabled, then multiply the `max_connections` parameter by 429498.

If the `performance_schema` parameter is disabled, then this value is zero.

So, the value returned by the calculation is the following:

Value 1 + Value 2 + Value 3

When this value exceeds 1.2 times the memory allocated to the DB instance class used by the DB instance, the DB instance is placed in **incompatible-parameters** status. For information about the memory allocated to DB instance classes, see [Hardware specifications for DB instance classes](#).

The calculation multiplies the value of the `max_connections` parameter by the sum of several parameters. If the `max_connections` parameter is set to a large value, it might cause the check to return an inordinately high value for the potential memory usage of the DB instance. In this case, ~~consider lowering the value of the `max_connections` parameter.~~

To resolve the problem, complete the following steps:

1. Adjust the memory parameters in the DB parameter group associated with the DB instance. Do so such that the potential memory usage is lower than 1.2 times the memory allocated to its DB instance class.

For information about setting parameters, see [Modifying parameters in a DB parameter group in Amazon RDS](#).

2. Restart the DB instance.

For information about setting parameters, see [Starting an Amazon RDS DB instance that was previously stopped](#).

## Diagnosing and resolving lag between read replicas

After you create a MySQL or MariaDB read replica and the replica is available, Amazon RDS first replicates the changes made to the source DB instance from the time the read replica create operation started. During this phase, the replication lag time for the read replica is greater than 0. You can monitor this lag time in Amazon CloudWatch by viewing the Amazon RDS `ReplicaLag` metric.

The `ReplicaLag` metric reports the value of the `Seconds_Behind_Master` field of the MariaDB or MySQL `SHOW REPLICA STATUS` command. For more information, see [SHOW REPLICA STATUS Statement](#) in the MySQL documentation.

When the `ReplicaLag` metric reaches 0, the replica has caught up to the source DB instance. If the `ReplicaLag` metric returns -1, replication might not be active. To troubleshoot a replication error, see [Diagnosing and resolving a MySQL or MariaDB read replication failure](#). A `ReplicaLag` value of -1 can also mean that the `Seconds_Behind_Master` value can't be determined or is NULL.

### Note

Previous versions of MariaDB and MySQL used `SHOW SLAVE STATUS` instead of `SHOW REPLICA STATUS`. If you are using a MariaDB version before 10.5 or a MySQL version before 8.0.23, then use `SHOW SLAVE STATUS`.

The `ReplicaLag` metric returns -1 during a network outage or when a patch is applied during the maintenance window. In this case, wait for network connectivity to be restored or for the maintenance window to end before you check the `ReplicaLag` metric again.

The MySQL and MariaDB read replication technology is asynchronous. Thus, you can expect occasional increases for the `BinLogDiskUsage` metric on the source DB instance and for the `ReplicaLag` metric on the read replica. For example, consider a situation where a high volume of write operations to the source DB instance occur in parallel. At the same time, write operations to the read replica are serialized using a single I/O thread. Such a situation can lead to a lag between the source instance and read replica.

For more information about read replicas and MySQL, see [Replication implementation details](#) in the MySQL documentation. For more information about read replicas and MariaDB, see [Replication overview](#) in the MariaDB documentation.

You can reduce the lag between updates to a source DB instance and the subsequent updates to the read replica by doing the following:

- Set the DB instance class of the read replica to have a storage size comparable to that of the source DB instance.
- Make sure that parameter settings in the DB parameter groups used by the source DB instance and the read replica are compatible. For more information and an example, see the discussion of the `max_allowed_packet` parameter in the next section.
- Disable the query cache. For tables that are modified often, using the query cache can increase replica lag because the cache is locked and refreshed often. If this is the case, you might see less replica lag if you disable the query cache. You can disable the query cache by setting the `query_cache_type` parameter to 0 in the DB parameter group for the DB instance. For more information on the query cache, see [Query cache configuration](#).
- Warm the buffer pool on the read replica for InnoDB for MySQL or MariaDB. For example, suppose that you have a small set of tables that are being updated often and you're using the InnoDB or XtraDB table schema. In this case, dump those tables on the read replica. Doing this causes the database engine to scan through the rows of those tables from the disk and then cache them in the buffer pool. This approach can reduce replica lag. The following shows an example.

For Linux, macOS, or Unix:

```
PROMPT> mysqldump \
```

```
-h <endpoint> \  
--port=<port> \  
-u=<username> \  
-p <password> \  
database_name table1 table2 > /dev/null
```

For Windows:

```
PROMPT> mysqldump ^  
-h <endpoint> ^  
--port=<port> ^  
-u=<username> ^  
-p <password> ^  
database_name table1 table2 > /dev/null
```

## Diagnosing and resolving a MySQL or MariaDB read replication failure

Amazon RDS monitors the replication status of your read replicas. RDS updates the **Replication State** field of the read replica instance to `ERROR` if replication stops for any reason. You can review the details of the associated error thrown by the MySQL or MariaDB engines by viewing the **Replication Error** field. Events that indicate the status of the read replica are also generated, including [RDS-EVENT-0045](#), [RDS-EVENT-0046](#), and [RDS-EVENT-0057](#). For more information about events and subscribing to events, see [Working with Amazon RDS event notification](#). If a MySQL error message is returned, check the error in the [MySQL error message documentation](#). If a MariaDB error message is returned, check the error in the [MariaDB error message documentation](#).

Common situations that can cause replication errors include the following:

- The value for the `max_allowed_packet` parameter for a read replica is less than the `max_allowed_packet` parameter for the source DB instance.

The `max_allowed_packet` parameter is a custom parameter that you can set in a DB parameter group. The `max_allowed_packet` parameter is used to specify the maximum size of data manipulation language (DML) that can be run on the database. In some cases, the `max_allowed_packet` value for the source DB instance might be larger than the `max_allowed_packet` value for the read replica. If so, the replication process can throw an error and stop replication. The most common error is `packet bigger than 'max_allowed_packet' bytes`. You can fix the error by having the source and read replica use DB parameter groups with the same `max_allowed_packet` parameter values.

- Writing to tables on a read replica. If you're creating indexes on a read replica, you need to have the `read_only` parameter set to `0` to create the indexes. If you're writing to tables on the read replica, it can break replication.
- Using a nontransactional storage engine such as MyISAM. Read replicas require a transactional storage engine. Replication is only supported for the following storage engines: InnoDB for MySQL or MariaDB.

You can convert a MyISAM table to InnoDB with the following command:

```
alter table <schema>.<table_name> engine=innodb;
```

- Using unsafe nondeterministic queries such as `SYSDATE()`. For more information, see [Determination of safe and unsafe statements in binary logging](#) in the MySQL documentation.

The following steps can help resolve your replication error:

- If you encounter a logical error and you can safely skip the error, follow the steps described in [Skipping the current replication error](#). Your MySQL or MariaDB DB instance must be running a version that includes the `mysql_rds_skip_repl_error` procedure. For more information, see [mysql.rds\\_skip\\_repl\\_error](#).
- If you encounter a binary log (binlog) position issue, you can change the replica replay position with the `mysql_rds_next_master_log` command. Your MySQL or MariaDB DB instance must be running a version that supports the `mysql_rds_next_master_log` command to change the replica replay position. For version information, see [mysql.rds\\_next\\_master\\_log](#).
- You might encounter a temporary performance issue due to high DML load. If so, you can set the `innodb_flush_log_at_trx_commit` parameter to `2` in the DB parameter group on the read replica. Doing this can help the read replica catch up, though it temporarily reduces atomicity, consistency, isolation, and durability (ACID).
- You can delete the read replica and create an instance using the same DB instance identifier. If you do this, the endpoint remains the same as that of your old read replica.

If a replication error is fixed, the **Replication State** changes to **replicating**. For more information, see [Troubleshooting a MySQL read replica problem](#).

## Creating triggers with binary logging enabled requires SUPER privilege

When trying to create triggers in an RDS for MySQL or RDS for MariaDB DB instance, you might receive the following error.

```
"You do not have the SUPER privilege and binary logging is enabled"
```

To use triggers when binary logging is enabled requires the SUPER privilege, which is restricted for RDS for MySQL and RDS for MariaDB DB instances. You can create triggers when binary logging is enabled without the SUPER privilege by setting the `log_bin_trust_function_creators` parameter to true. To set the `log_bin_trust_function_creators` to true, create a new DB parameter group or modify an existing DB parameter group.

You can create a new DB parameter group so you can create triggers in your RDS for MySQL or RDS for MariaDB DB instance with binary logging enabled. To do so, use the following CLI commands. To modify an existing parameter group, start with step 2.

### To create a new parameter group to allow triggers with binary logging enabled using the CLI

1. Create a new parameter group.

For Linux, macOS, or Unix:

```
aws rds create-db-parameter-group \  
  --db-parameter-group-name allow-triggers \  
  --db-parameter-group-family mysql8.0 \  
  --description "parameter group allowing triggers"
```

For Windows:

```
aws rds create-db-parameter-group ^  
  --db-parameter-group-name allow-triggers ^  
  --db-parameter-group-family mysql8.0 ^  
  --description "parameter group allowing triggers"
```

2. Modify the DB parameter group to allow triggers.

For Linux, macOS, or Unix:

```
aws rds modify-db-parameter-group \  
  --db-parameter-group-name allow-triggers \  
  --db-parameter-group-family mysql8.0 \  
  --description "parameter group allowing triggers"
```

```
--db-parameter-group-name allow-triggers \  
--parameters "ParameterName=log_bin_trust_function_creators,  
ParameterValue=true, ApplyMethod=pending-reboot"
```

For Windows:

```
aws rds modify-db-parameter-group ^  
--db-parameter-group-name allow-triggers ^  
--parameters "ParameterName=log_bin_trust_function_creators,  
ParameterValue=true, ApplyMethod=pending-reboot"
```

3. Modify your DB instance to use the new DB parameter group.

For Linux, macOS, or Unix:

```
aws rds modify-db-instance \  
--db-instance-identifier mydbinstance \  
--db-parameter-group-name allow-triggers \  
--apply-immediately
```

For Windows:

```
aws rds modify-db-instance ^  
--db-instance-identifier mydbinstance ^  
--db-parameter-group-name allow-triggers ^  
--apply-immediately
```

4. For the changes to take effect, manually reboot the DB instance.

```
aws rds reboot-db-instance --db-instance-identifier mydbinstance
```

## Diagnosing and resolving point-in-time restore failures

### Restoring a DB instance that includes temporary tables

When attempting a point-in-time restore (PITR) of your MySQL or MariaDB DB instance, you might encounter the following error.

```
Database instance could not be restored because there has been incompatible database  
activity for restore
```

functionality. Common examples of incompatible activity include using temporary tables, in-memory tables, or using MyISAM tables. In this case, use of Temporary table was detected.

PITR relies on both backup snapshots and binary logs (binlogs) from MySQL or MariaDB to restore your DB instance to a particular time. Temporary table information can be unreliable in binlogs and can cause a PITR failure. If you use temporary tables in your MySQL or MariaDB DB instance, you can decrease the possibility of a PITR failure by performing more frequent backups. A PITR failure is most probable in the time between a temporary table's creation and the next backup snapshot.

## Restoring a DB instance that includes in-memory tables

You might encounter a problem when restoring a database that has in-memory tables. In-memory tables are purged during a restart. As a result, your in-memory tables might be empty after a reboot. We recommend that when you use in-memory tables, you architect your solution to handle empty tables in the event of a restart. If you're using in-memory tables with replicated DB instances, you might need to recreate the read replicas after a restart. This might be necessary if a read replica reboots and can't restore data from an empty in-memory table.

For more information about backups and PITR, see [Introduction to backups](#) and [Restoring a DB instance to a specified time](#).

## Replication stopped error

When you call the `mysql.rds_skip_repl_error` command, you might receive an error message stating that replication is down or disabled.

This error message appears because replication is stopped and can't be restarted.

If you need to skip a large number of errors, the replication lag can increase beyond the default retention period for binary log files. In this case, you might encounter a fatal error due to binary log files being purged before they have been replayed on the replica. This purge causes replication to stop, and you can no longer call the `mysql.rds_skip_repl_error` command to skip replication errors.

You can mitigate this issue by increasing the number of hours that binary log files are retained on your replication source. After you have increased the binlog retention time, you can restart replication and call the `mysql.rds_skip_repl_error` command as needed.

To set the binlog retention time, use the [mysql.rds\\_set\\_configuration](#) procedure. Specify a configuration parameter of 'binlog retention hours' along with the number of hours to retain

binlog files on the DB cluster, up to 720 (30 days). The following example sets the retention period for binlog files to 48 hours.

```
CALL mysql.rds_set_configuration('binlog retention hours', 48);
```

## Read replica create fails or replication breaks with fatal error 1236

After changing default parameter values for a MySQL or MariaDB DB instance, you might encounter one of the following problems:

- You can't create a read replica for the DB instance.
- Replication fails with `fatal error 1236`.

Some default parameter values for MySQL and MariaDB DB instances help to make sure that the database is ACID compliant and read replicas are crash-safe. They do this by making sure that each commit is fully synchronized by writing the transaction to the binary log before it's committed. Changing these parameters from their default values to improve performance can cause replication to fail when a transaction hasn't been written to the binary log.

To resolve this issue, set the following parameter values:

- `sync_binlog = 1`
- `innodb_support_xa = 1`
- `innodb_flush_log_at_trx_commit = 1`

## Can't set backup retention period to 0

There are several reasons why you might need to set the backup retention period to 0. For example, you can disable automatic backups immediately by setting the retention period to 0.

In some cases, you might set the value to 0 and receive a message saying that the retention period must be between 1 and 35. In these cases, check to make sure that you haven't set up a read replica for the instance. Read replicas require backups for managing read replica logs, and therefore you can't set a retention period of 0.

# Amazon RDS API reference

In addition to the AWS Management Console and the AWS Command Line Interface (AWS CLI), Amazon RDS also provides an API. You can use the API to automate tasks for managing your DB instances and other objects in Amazon RDS.

- For an alphabetical list of API operations, see [Actions](#).
- For an alphabetical list of data types, see [Data types](#).
- For a list of common query parameters, see [Common parameters](#).
- For descriptions of the error codes, see [Common errors](#).

For more information about the AWS CLI, see [AWS Command Line Interface reference for Amazon RDS](#).

## Topics

- [Using the Query API](#)
- [Troubleshooting applications on Amazon RDS](#)

## Using the Query API

The following sections briefly discuss the parameters and request authentication used with the Query API.

For general information about how the Query API works, see [Query requests](#) in the *Amazon EC2 API Reference*.

## Query parameters

HTTP Query-based requests are HTTP requests that use the HTTP verb GET or POST and a Query parameter named `Action`.

Each Query request must include some common parameters to handle authentication and selection of an action.

Some operations take lists of parameters. These lists are specified using the `param.n` notation. Values of `n` are integers starting from 1.

For information about Amazon RDS Regions and endpoints, go to [Amazon Relational Database Service \(RDS\)](#) in the Regions and Endpoints section of the *Amazon Web Services General Reference*.

## Query request authentication

You can only send Query requests over HTTPS, and you must include a signature in every Query request. You must use either AWS signature version 4 or signature version 2. For more information, see [Signature Version 4 signing process](#) and [Signature version 2 signing process](#).

## Troubleshooting applications on Amazon RDS

Amazon RDS provides specific and descriptive errors to help you troubleshoot problems while interacting with the Amazon RDS API.

### Topics

- [Retrieving errors](#)
- [Troubleshooting tips](#)

For information about troubleshooting for Amazon RDS DB instances, see [Troubleshooting for Amazon RDS](#).

## Retrieving errors

Typically, you want your application to check whether a request generated an error before you spend any time processing results. The easiest way to find out if an error occurred is to look for an `Error` node in the response from the Amazon RDS API.

XPath syntax provides a simple way to search for the presence of an `Error` node. It also provides a relatively easy way to retrieve the error code and message. The following code snippet uses Perl and the `XML::XPath` module to determine if an error occurred during a request. If an error occurred, the code prints the first error code and message in the response.

```
use XML::XPath;
my $xp = XML::XPath->new(xml =>$response);
if ( $xp->find("//Error") )
{print "There was an error processing your request:\n", " Error code: ",
$xp->findvalue("//Error[1]/Code"), "\n", " ",
$xp->findvalue("//Error[1]/Message"), "\n\n"; }
```

## Troubleshooting tips

We recommend the following processes to diagnose and resolve problems with the Amazon RDS API:

- Verify that Amazon RDS is operating normally in the AWS Region that you're targeting by checking <http://status.aws.amazon.com>.
- Check the structure of your request.

Each Amazon RDS operation has a reference page in the *Amazon RDS API Reference*. Double-check that you are using parameters correctly. For ideas about what might be wrong, look at the sample requests or user scenarios to see if those examples do similar operations.

- Check AWS re:Post.

Amazon RDS has a development community where you can search for solutions to problems others have experienced along the way. To view the topics, go to [AWS re:Post](#).

# Document history

**Current API version:** 2014-10-31

The following table describes important changes in each release of the *Amazon RDS User Guide* after May 2018. For notification about updates to this documentation, you can subscribe to an RSS feed.

## Note

You can filter new Amazon RDS features on the [What's New with Database?](#) page. For **Products**, choose **Amazon RDS**. Then search using keywords such as **RDS Proxy** or **Oracle 2023**.

Change	Description	Date
<a href="#">Amazon RDS supports MariaDB 10.11.9, 10.6.19, and 10.5.26</a>	You can now create Amazon RDS DB instances running MariaDB version 10.11.9, 10.6.19, and 10.5.26. For more information, see <a href="#">MariaDB on Amazon RDS versions</a> .	September 4, 2024
<a href="#">Amazon RDS for Oracle supports the OEM, OEMAGENT, and OLS options for the CDB architecture</a>	You can now use Oracle Enterprise Manager and Oracle Label Security with RDS for Oracle CDB instances . For more information, see <a href="#">Oracle Enterprise Manager and Oracle Label Security</a> .	September 4, 2024
<a href="#">RDS Custom for SQL Server is available in additional Regions</a>	RDS Custom for SQL Server is now available in the US West (N. California) Region, Asia Pacific (Osaka) Region,	August 29, 2024

and Europe (Paris) Region.

For more information, see [Supported Regions and DB engines for RDS Custom](#) .

[Amazon RDS Extended Support version 5.7.44-RDS.20240808 for RDS for MySQL](#)

The RDS Extended Support version 5.7.44-RDS.20240808 is now available for RDS for MySQL. For more information, see [Amazon RDS Extended Support versions for RDS for MySQL](#).

August 29, 2024

[Amazon RDS is available in the Asia Pacific \(Malaysia\) Region](#)

Amazon RDS is now available in the Asia Pacific (Malaysia) Region. For more information, see [Regions and Availability Zones](#).

August 22, 2024

[Amazon RDS supports MySQL 8.0.39](#)

You can now create Amazon RDS DB instances running MySQL version 8.0.39. For more information, see [MySQL on Amazon RDS versions](#).

August 12, 2024

[Update to existing policy](#)

Amazon RDS removed `sns:Publish` permission from the `AmazonRDSPreviewServiceRolePolicy` of the `AWSServiceRoleForRDSPreview` service-linked role. For more information, see [Amazon RDS updates to AWS managed policies](#).

August 7, 2024

---

<a href="#">Update to existing policy</a>	Amazon RDS removed <code>sns:Publish</code> permission from the <code>AmazonRDSBetaServiceRolePolicy</code> of the <code>AWSServiceRoleForRDSBeta</code> service-linked role. For more information, see <a href="#">Amazon RDS updates to AWS managed policies</a> .	August 7, 2024
<a href="#">Amazon RDS supports MySQL 8.4 in the Database Preview environment</a>	MySQL 8.4 is now available in the Database Preview environment in the US East (Ohio) AWS Region. For more information, see <a href="#">MySQL version 8.4 in the Database Preview environment</a> .	August 1, 2024
<a href="#">Update to IAM service-linked role permissions</a>	The <code>AmazonRDSCustomServiceRolePolicy</code> policy now grants additional permissions to communicate with Amazon RDS services in another AWS Region and copy EC2 images. For more information, see <a href="#">Amazon RDS updates to AWS managed policies</a> .	July 18, 2024
<a href="#">Amazon RDS supports MariaDB 11.4 in the Database Preview environment</a>	MariaDB 11.4 is now available in the Database Preview environment in the US East (Ohio) AWS Region. For more information, see <a href="#">MariaDB version 11.4 in the Database Preview environment</a> .	July 18, 2024

---

<a href="#">AWS ODBC Driver for MySQL generally available</a>	The Amazon Web Services (AWS) ODBC Driver for MySQL is a client driver designed for the high availability of RDS for MySQL. For more information, see <a href="#">Connecting to RDS for MySQL with the Amazon Web Services (AWS) ODBC Driver for MySQL</a> .	July 18, 2024
<a href="#">Update to existing policy</a>	Amazon RDS removed <code>sns:Publish</code> permission from the AmazonRDS ServiceRolePolicy of the <code>AWSServiceRoleForRDS</code> service-linked role. For more information, see <a href="#">AWS managed policy: Amazon RDSServiceRolePolicy</a> .	July 2, 2024
<a href="#">AWS Marketplace private offer for Db2</a>	AWS Marketplace now supports private offers for a Db2 license through AWS Marketplace for Amazon RDS for Db2. For more information, see <a href="#">Obtaining a private offer</a> .	July 1, 2024
<a href="#">Export Multi-AZ DB cluster snapshot data to Amazon S3</a>	You can now export Multi-AZ DB cluster snapshot data to Amazon S3. For more information, see <a href="#">Exporting DB snapshot data to Amazon S3</a> .	June 27, 2024

[Amazon RDS for Oracle supports preconfigured r6i memory optimized instance classes](#)

The db.r6i Oracle DB instance classes are optimized for workloads that require additional memory, storage, and I/O per vCPU. For example, db.r6i.8xlarge.tpc2.mem4x has multithreading turned on and provides 4 times as much memory as db.r6i.8xlarge. For more information, see [RDS for Oracle instance classes](#).

June 21, 2024

[Amazon RDS Extended Support version 5.7.44-RDS.20240529 for RDS for MySQL](#)

The RDS Extended Support version 5.7.44-RDS.20240529 is now available for RDS for MySQL. For more information, see [Amazon RDS Extended Support versions for RDS for MySQL](#).

June 20, 2024

[Amazon RDS supports MySQL 8.0.37](#)

You can now create Amazon RDS DB instances running MySQL version 8.0.37. For more information, see [MySQL on Amazon RDS versions](#).

June 18, 2024

[Amazon RDS supports MariaDB 10.11.8, 10.6.18, 10.5.25, and 10.4.34](#)

You can now create Amazon RDS DB instances running MariaDB version 10.11.8, 10.6.18, 10.5.25, and 10.4.34. For more information, see [MariaDB on Amazon RDS versions](#).

June 14, 2024

[Amazon RDS is ending support for the db.m4, db.r4, and db.t2 DB instance classes](#)

For the RDS for MariaDB, RDS for MySQL, and RDS for PostgreSQL DB engines, you can no longer create DB instances that use the db.m4, db.r4, and db.t2 instance classes. RDS is automatically upgrading existing DB instances that use these classes to a newer generation. For more information, see [DB instance class types](#).

June 4, 2024

[Multi-AZ DB clusters are available in additional AWS Regions](#)

You can create Multi-AZ DB clusters in more AWS Regions. For a table that shows all supported Regions, see [Supported Regions and DB engines for Multi-AZ DB clusters in Amazon RDS](#).

May 29, 2024

[AWS Python Driver generally available](#)

The Amazon Web Services (AWS) Python Driver is designed as an advanced Python wrapper. This wrapper is complementary to and extends the functionality of the open-source Psycopg driver. For more information, see [Connecting to DB instances with the AWS drivers](#).

May 23, 2024

[RDS Proxy is available in more Regions](#)

RDS Proxy is now available in the Asia Pacific (Hyderabad), Asia Pacific (Melbourne), Middle East (UAE), Israel (Tel Aviv), Canada West (Calgary), and Europe (Zurich) regions. For more information about RDS Proxy, see [Using Amazon RDS Proxy](#).

May 21, 2024

[Db2 license through AWS Marketplace](#)

With Db2 license through AWS Marketplace, you can now pay an hourly rate to subscribe to Db2 licenses for Amazon RDS for Db2. For more information, [Amazon RDS for Db2 licensing options](#).

May 21, 2024

[Amazon RDS supports fine-grained access for Performance Insights](#)

You can now allow or deny access to individual dimensions in Performance Insights. This fine-grained access can be used for `GetResourceMetrics`, `DescribeDimensionKeys`, and `GetDimensionKeyDetails` actions. For more information, see [Granting fine-grained access for Performance Insights](#).

May 21, 2024

---

<a href="#">Amazon RDS Extended Support versions for RDS for MySQL</a>	You can view all releases of RDS Extended Support for RDS for MySQL versions. For more information, see <a href="#">Amazon RDS Extended Support versions for RDS for MySQL</a> .	May 16, 2024
<a href="#">Amazon RDS supports MySQL 8.3 in the Database Preview environment</a>	MySQL 8.3 is now available in the Database Preview environment in the US East (Ohio) AWS Region. For more information, see <a href="#">MySQL version 8.3 in the Database Preview environment</a> .	April 30, 2024
<a href="#">Amazon RDS for Db2 supports time zones</a>	RDS for Db2 now supports setting local time zones for new RDS for Db2 DB instances . For more information, see <a href="#">Local time zones for Amazon RDS for Db2 DB instances</a> .	April 25, 2024
<a href="#">Update to IAM service-linked role permissions</a>	The AmazonRDSCustomServiceRolePolicy policy now grants additional permissions to associate a service role as an instance profile to a RDS Custom instance. For more information, see <a href="#">Amazon RDS updates to AWS managed policies</a> .	April 19, 2024

[Amazon RDS for Oracle supports Oracle Data Guard switchover in all AWS Regions](#)

You can now use Oracle Data Guard switchover in all supported Regions. For more information, see [Overview of Oracle Data Guard switchover](#).

April 16, 2024

[RDS Custom for Oracle supports Oracle Standard Edition 2](#)

You can now create DB instances using Standard Edition 2 on Oracle Database 12c Release 1 (12.1), 12c Release 2 (12.2), 18c, and 19c. You can create both CDBs and non-CDBs. For more information, see [Edition and licensing support for RDS Custom for Oracle](#).

April 11, 2024

[Amazon RDS for Oracle supports Oracle APEX version 23.2.v1](#)

You can use APEX 23.2.v1 with Oracle Database 19c and higher. For more information, see [Oracle Application Express](#).

April 11, 2024

[Update to RDS Custom service-linked role permissions](#)

The AmazonRDSCustomServiceRolePolicy now grants additional permissions to allow RDS Custom for SQL Server to get EC2 instance type information and modify DB host instance type. For more information, see [Updates to AWS managed policies](#).

April 8, 2024

[Amazon RDS Custom for Oracle supports the db.x2iezn DB instance class](#)

You can now use the db.x2iezn instance class for RDS Custom for Oracle DB instances. For more information, see [DB instance class support for RDS Custom for Oracle](#).

March 26, 2024

[Amazon RDS supports the db.c6gd instance classes for Multi-AZ DB clusters](#)

You can now use the db.c6gd instance classes for Multi-AZ DB cluster deployments. For more information, see [Instance class availability for Multi-AZ DB clusters](#).

March 21, 2024

[Amazon RDS Extended Support](#)

Creating or restoring an RDS for MySQL 5.7 or RDS for PostgreSQL 11 database now automatically enrolls that database into Amazon RDS Extended Support so your existing applications continue to work as they are. You can opt out of RDS Extended Support to avoid charges after the RDS end of standard support date for your database engine. For more information, see [Using Amazon RDS Extended Support](#).

March 21, 2024

[RDS for Db2 integration with AWS License Manager](#)

RDS for Db2 is now integrated with AWS License Manager. If you use the Bring Your Own License model, the AWS License Manager integration aids in monitoring your Db2 license usage within your organization. For more information, see [Integrating with AWS License Manager](#).

March 20, 2024

[CA certificate rotation for Multi-AZ DB clusters](#)

You can now rotate the CA certificates for your Multi-AZ DB clusters. Consider using one of the new CA certificates `rds-ca-rsa2048-g1`, `rds-ca-rsa4096-g1`, or `rds-ca-ecc384-g1`. For more information, see [Rotating your SSL/TLS certificate](#).

March 6, 2024

[Amazon RDS supports io2 Block Express storage](#)

You can now create RDS DB instances that use the `io2 Block Express` storage type. For more information, see [io2 Block Express storage](#).

March 6, 2024

[RDS Custom for SQL Server supports the db.r5b and db.x2iedn DB instance classes](#)

You can now use the `db.r5b` and `db.x2iedn` instance classes for RDS Custom for SQL Server DB instances. For more information, see [DB instance class support for RDS Custom for SQL Server](#).

March 4, 2024

[RDS Custom for Oracle is available in the Middle East \(UAE\) Region](#)

You can create RDS Custom for Oracle DB instances in the Middle East (UAE) Region. For a table that shows all supported AWS Regions, see [Supported Regions and DB engines for RDS Custom for Oracle](#).

March 4, 2024

[New AWS managed policy](#)

Amazon RDS added a new managed policy named AmazonRDS Custom InstanceProfileRolePolicy to allow RDS Custom to perform automation actions and database management tasks through an EC2 instance profile. For more information, see [Amazon RDS updates to AWS managed policies](#).

February 27, 2024

[Amazon RDS supports MariaDB 10.11.7, 10.6.17, 10.5.24, and 10.4.33](#)

You can now create Amazon RDS DB instances running MariaDB version 10.11.7, 10.6.17, 10.5.24, and 10.4.33. For more information, see [MariaDB on Amazon RDS versions](#).

February 26, 2024

[Amazon RDS Multi-AZ DB clusters support the Amazon EBS gp3 storage volume](#)

Multi-AZ DB clusters now support gp3 SSD-based EBS volumes. For more information, see [gp3 storage](#).

February 26, 2024

[Amazon RDS support for AWS Secrets Manager in the Israel \(Tel Aviv\) Region](#)

Amazon RDS supports Secrets Manager in the Israel (Tel Aviv) Region. For more information, see [Password management with Amazon RDS and AWS Secrets Manager](#).

February 21, 2024

[Amazon RDS for Db2 supports audit logging](#)

RDS for Db2 now supports database-level audit logging. When you enable audit logging for an RDS for Db2 database, Amazon RDS records the database activity and stores the audit logs in Amazon S3. For more information, see [Db2 audit logging](#).

February 15, 2024

[Amazon RDS Extended Support](#)

Amazon RDS now automatically enables Amazon RDS Extended Support when RDS for MySQL and RDS for PostgreSQL major engine versions in your DB instances and Multi-AZ DB clusters reach the RDS end of standard support date. For more information, see [Using Amazon RDS Extended Support](#).

February 15, 2024

---

<a href="#">Amazon RDS supports MySQL 8.0.36</a>	You can now create Amazon RDS DB instances running MySQL version 8.0.36. For more information, see <a href="#">MySQL on Amazon RDS versions</a> .	February 12, 2024
<a href="#">Amazon RDS supports EBCDIC collation for RDS for Db2</a>	You can now create Db2 databases that use EBCDIC collation sequences to sort content in the databases. For more information, see <a href="#">EBCDIC collation for Db2 databases on Amazon RDS</a> .	January 29, 2024
<a href="#">Update to default CA Certificate</a>	The default CA certificate is set to <code>rds-ca-rsa2048-g1</code> . For more information, see <a href="#">Using SSL/TLS to encrypt a connection to a DB instance</a> .	January 26, 2024
<a href="#">Amazon RDS for PostgreSQL supports two new crates for PL/Rust, roaring-rs and num-bigint</a>	You can use two new crates in Amazon RDS for PostgreSQL. For more information, see <a href="#">Using crates with PL/Rust</a> .	January 24, 2024
<a href="#">Amazon RDS for PostgreSQL supports TLS version 1.3</a>	You can use Transport Layer Security (TLS) version 1.3 in RDS for PostgreSQL. For more information, see <a href="#">Using SSL with a PostgreSQL DB instance</a> .	January 24, 2024

[RDS Custom for SQL Server supports Microsoft SQL Server 2022](#)

You can now create RDS Custom for SQL Server DB instances that use SQL Server 2022. For more information, see [Working with RDS Custom for SQL Server](#).

January 22, 2024

[Update to AWS managed policy permissions](#)

The AmazonRDSServiceRolePolicy of the AWSServiceRoleForRDS service-linked role has new statement IDs. For more information, see [Amazon RDS updates to AWS managed policies](#).

January 19, 2024

[RDS Custom for Oracle supports the Europe \(Paris\) Region](#)

You can create RDS Custom for Oracle DB instances in the Europe (Paris) Region. For more information, see [Supported Regions and DB engines for RDS Custom for Oracle](#).

January 18, 2024

[Amazon RDS for MySQL supports multi-source replication](#)

You can now use multi-source replication on RDS for MySQL DB instances. For more information, see [Configuring multi-source replication on RDS for MySQL](#).

January 16, 2024

---

<a href="#">Amazon RDS supports MySQL 8.2 in the Database Preview environment</a>	MySQL 8.2 is now available in the Database Preview environment in the US East (Ohio) AWS Region. For more information, see <a href="#">MySQL version 8.2 in the Database Preview environment</a> .	January 11, 2024
<a href="#">RDS Proxy is available in the Europe (Spain) Region</a>	RDS Proxy is now available in the Europe (Spain) region. For more information about RDS Proxy, see <a href="#">Using Amazon RDS Proxy</a> .	January 8, 2024
<a href="#">Amazon RDS is available in the Canada West (Calgary) Region</a>	Amazon RDS is now available in the Canada West (Calgary) Region. For more information, see <a href="#">Regions and Availability Zones</a> .	December 20, 2023
<a href="#">Amazon RDS for Db2 supports 5,000 local users</a>	You can now add up to 5,000 local users to an authorization list. For more information, see <a href="#">rdsadmin.add_user</a> .	December 20, 2023
<a href="#">Amazon RDS supports viewing and responding to recommendations</a>	Amazon RDS recommendations now includes threshold based proactive and machine learning based reactive recommendations for RDS for PostgreSQL. For more information, see <a href="#">Recommendations from Amazon RDS</a> .	December 19, 2023

<a href="#">Amazon RDS supports MariaDB 10.11.6, 10.6.16, 10.5.23, and 10.4.32</a>	You can now create Amazon RDS DB instances running MariaDB version 10.11.6, 10.6.16, 10.5.23, and 10.4.32. For more information, see <a href="#">MariaDB on Amazon RDS versions</a> .	December 12, 2023
<a href="#">Amazon RDS introduces zero-ETL integrations with Amazon Redshift (preview)</a>	Zero-ETL integrations provide a fully managed solution for making transactional data available in Amazon Redshift within seconds of it being written to an RDS for MySQL DB instance. For more information, see <a href="#">Working with Amazon RDS zero-ETL integrations with Amazon Redshift (preview)</a> .	November 28, 2023
<a href="#">Amazon RDS supports IBM Db2 database engines</a>	You can now run IBM Db2 database engines in Amazon RDS. For more information, see <a href="#">Amazon RDS for Db2</a> .	November 27, 2023
<a href="#">RDS for PostgreSQL supports major version upgrades to PostgreSQL 16.1 and minor version upgrades to 15.5, 14.10, 13.13, 12.17, and 11.22</a>	With RDS for PostgreSQL, you can now upgrade the DB engine to major version 16.1 and minor version upgrades to 15.5, 14.10, 13.13, 12.17, and 11.22. For more information, see <a href="#">Upgrading the PostgreSQL DB engine for Amazon RDS</a> .	November 17, 2023

[RDS Custom for Oracle supports option groups](#)

You can create or modify an option group and associate it with an RDS Custom for Oracle DB instance. The Timezone option is now supported. For more information, see [Working with option groups in RDS Custom for Oracle](#).

November 17, 2023

[Amazon RDS for MySQL supports the Group Replication plugin](#)

You can now set up an active-active cluster with RDS for MySQL version 8.0.35 or higher DB instances by using the Group Replication plugin developed and maintained by the MySQL community . For more information, see [Configuring active-active clusters for RDS for MySQL](#).

November 17, 2023

[Amazon RDS Proxy supports RDS for PostgreSQL 16.1](#)

You can now create proxies using RDS Proxy for RDS for PostgreSQL 16.1 DB instances . For more information, see [Using Amazon RDS Proxy](#).

November 17, 2023

[RDS Custom for SQL Server supports Microsoft SQL Server 2019 Developer edition](#)

You can create RDS Custom for SQL Server DB instances that use SQL Server 2019 Developer edition. For more information, see [Bring Your Own Media with RDS Custom for SQL Server](#).

November 16, 2023

[Minor version upgrades of Multi-AZ DB clusters with minimal downtime](#)

When you perform a minor version upgrade of a Multi-AZ DB cluster, Amazon RDS now upgrades the reader DB instances before the writer instance, thereby significantly reducing downtime. You can further reduce downtime to one second or less by using RDS Proxy. For more information, see [Upgrading the engine version of a Multi-AZ DB cluster](#).

November 16, 2023

[RDS for SQL Server supports Microsoft SQL Server 2022](#)

You can now create RDS DB instances that use SQL Server 2022. For more information, see [Microsoft SQL Server versions on Amazon RDS](#).

November 15, 2023

[RDS for MySQL supports upgrading snapshots from version 5.7 to 8.0](#)

You can now upgrade the engine version of an RDS for MySQL snapshot from version 5.7 to version 8.0. You can do so by using the AWS Management Console, or the `ModifyDBSnapshot` operation of the RDS API or AWS CLI. For more information, see [Upgrading a MySQL DB snapshot engine version](#).

November 15, 2023

[RDS Custom for SQL Server supports point in time recovery of 1,0000 databases](#)

You can now make up to 1,000 databases eligible for full backup and point in time recovery on your RDS Custom for SQL Server DB instance. For more information, see [Restoring an RDS Custom for SQL Server instance to a point in time](#).

November 15, 2023

[RDS Custom for SQL Server supports a using a Service Master Key](#)

RDS Custom for SQL Server now supports using a Service Master Key (SMK). An SMK allows you to encrypt objects such as credentials, and use SQL Server features like TDE and column-encryption. For more information, see [Using a Service Master Key with RDS Custom for SQL Server](#).

November 13, 2023

[Amazon RDS supports MySQL 8.1 in the Database Preview environment](#)

MySQL 8.1 is now available in the Database Preview environment in the US East (Ohio) AWS Region. For more information, see [MySQL version 8.1 in the Database Preview environment](#).

November 10, 2023

[RDS supports MySQL 8.0.35 and MySQL 5.7.44](#)

You can now create Amazon RDS DB instances running MySQL version 8.0.35 and 5.7.44. For more information, see [MySQL on Amazon RDS versions](#).

November 9, 2023

[RDS Proxy supports Multi-AZ DB clusters](#)

RDS Proxy now supports connecting to Multi-AZ DB clusters. For more information, see [Working with Amazon RDS Proxy endpoints](#).

November 9, 2023

[RDS Custom for Oracle is available in the AWS GovCloud \(US\) Regions](#)

Amazon RDS is now available in the AWS GovCloud (US) Regions. For more information, see [Supported Regions and DB engines for RDS Custom for Oracle](#).

November 9, 2023

[Amazon RDS Optimized Writes supports the db.m5 DB instance class](#)

Amazon RDS Optimized Writes now supports the db.m5 DB instance class. For more information, see [Improving write performance with Amazon RDS Optimized Writes for MariaDB and Improving write performance with Amazon RDS Optimized Writes for MySQL](#).

November 9, 2023

[Amazon RDS for Oracle supports the multi-tenant configuration of the CDB architecture](#)

With the RDS for Oracle multi-tenant feature, RDS delivers a fully managed Oracle multitenant architecture and experience for your Oracle databases. You can use RDS APIs to create multiple PDBs, called *tenant databases*, in a CDB. RDS offers the multi-tenant configuration of the CDB architecture as an alternative to the legacy single-tenant configuration. For more information, see [Multi-tenant configuration of the CDB architecture](#).

November 8, 2023

[Amazon RDS exports Performance Insights metrics to Amazon CloudWatch](#)

Performance Insights lets you export the preconfigured or custom metrics dashboards to Amazon CloudWatch. The exported metrics dashboards are available to view in the CloudWatch console. You can also export a selected Performance Insights metric widget and view the metrics data in the CloudWatch console. For more information, see [Exporting Performance Insights metrics to CloudWatch](#).

November 8, 2023

[Amazon RDS Custom for Oracle allows you to upgrade the operating system on a DB instance](#)

You can now upgrade the database or operating system (OS) for an RDS Custom for Oracle DB instance using the CLI command `modify-db-instance` . For more information, see [Upgrading a DB instance for Amazon RDS Custom for Oracle](#).

November 7, 2023

[RDS Proxy supports Extended Protocol for RDS for PostgreSQL](#)

You can now execute extended query protocols on an RDS for PostgreSQL DB instance. For more information, see [Using Amazon RDS Proxy](#).

November 6, 2023

[RDS for PostgreSQL support for RDS Blue/Green Deployments](#)

You can now create a blue/green deployment from an RDS for PostgreSQL DB instance. For more information, see [Using Amazon RDS Blue/Green Deployments for database updates](#).

October 26, 2023

[Update to AWS managed policies](#)

The `AmazonRDSPerformanceInsightsReadOnly` and `AmazonRDSPerformanceInsightsFullAccess` managed policies now includes `Sid` (statement ID) as an identifier in the policy statement. For more information, see [Amazon RDS updates to AWS managed policies](#).

October 23, 2023

[RDS Custom for Oracle supports the Europe \(Milan\) Region](#)

For more information, see [Supported Regions and DB engines for RDS Custom for Oracle](#).

October 23, 2023

[Enable RDS Optimized Writes on existing databases](#)

You can now enable RDS Optimized Writes on an existing DB instance even if it was created with an engine version, DB instance class, or file system configuration that doesn't support the feature. For more information, see [Enabling RDS Optimized Writes on an existing database](#) for RDS for MySQL, and [Enabling RDS Optimized Writes on an existing database](#) for RDS for MariaDB.

October 19, 2023

[Amazon RDS supports using a dedicated log volume \(DLV\).](#)

You can now use a dedicated log volume (DLV) with RDS for MariaDB, RDS for MySQL, and RDS for PostgreSQL. DLVs are ideal for databases with large allocated storage, high I/O per second (IOPS) requirements, or latency-sensitive workloads. For more information, see [Using a dedicated log volume \(DLV\)](#).

October 17, 2023

[Amazon RDS for PostgreSQL, MySQL, and MariaDB support new DB instance classes](#)

You can create Amazon RDS DB instances running PostgreSQL, MySQL, and MariaDB that use the db.m6.in, db.m6idn, db.r6.in, and db.r6.idn DB instance classes. For more information, see [Supported DB engines for all available DB instance classes](#).

October 12, 2023

[Amazon RDS for PostgreSQL supports pgactive](#)

The pgactive extension is available in Amazon RDS for PostgreSQL. For more information, see [Using PostgreSQL extensions with Amazon RDS for PostgreSQL](#).

October 9, 2023

[RDS Custom for Oracle is available in the Asia Pacific \(Jakarta\) Region](#)

You can create RDS Custom for Oracle DB instances in the Asia Pacific (Jakarta) Region. For more information, see [Supported Regions and DB engines for RDS Custom for Oracle](#).

October 5, 2023

[RDS Custom for SQL Server supports new server-level collations](#)

RDS Custom for SQL Server now supports a wide range of server collations, both in traditional and UTF-8 encoding, for the SQL\_Latin, Japanese, German, and Arabic locales. For more information, see [Collation and character support for RDS Custom for SQL Server DB instances](#).

September 26, 2023

[Update to AWS managed policy permissions](#)

The AmazonRDSCustomServiceRolePolicy of the AWSServiceRoleForRDSCustom service-linked role has new permissions that allow RDS Custom to create, modify, and delete EventBridge Managed Rules. For more information, see [Amazon RDS updates to AWS managed policies](#).

September 20, 2023

[Amazon RDS publishes Performance Insights counter metrics to Amazon CloudWatch](#)

The **DB\_PERF\_INSIGHTS** metric math function in the CloudWatch console allows you to query Amazon RDS for Performance Insights counter metrics. For more information, see [Creating CloudWatch alarms to monitor Amazon RDS](#).

September 20, 2023

[Performance Insights supports digest-level statistics for SQL Server](#)

When you use Performance Insights, you can view SQL statistics both at the statement and digest level for Amazon RDS for SQL Server. For more information, see [Analyzing running queries in SQL Server](#).

September 18, 2023

[Amazon RDS for PostgreSQL, MySQL, and MariaDB support the db.m6.id and db.r6.id DB instance class types](#)

You can now create Amazon RDS DB instances running PostgreSQL, MySQL, and MariaDB that use the memory-optimized db.m6.id and db.r6.id DB instance class types. These types offer local NVMe-based SSD storage. For more information, see [Supported DB engines for all available DB instance classes](#).

September 11, 2023

[Major version upgrade support for RDS for PostgreSQL Multi-AZ DB clusters](#)

You can now perform major version upgrades of your RDS for PostgreSQL Multi-AZ DB clusters. For more information, see [Upgrading the engine version of a Multi-AZ DB cluster](#).

September 7, 2023

[Amazon RDS supports MariaDB 10.11.5, 10.6.15, 10.5.22, and 10.4.31](#)

You can now create Amazon RDS DB instances running MariaDB version 10.11.5, 10.6.15, 10.5.22, and 10.4.31. For more information, see [MariaDB on Amazon RDS versions](#).

September 7, 2023

[Amazon RDS Extended Support](#)

Amazon RDS announces the upcoming ability to continue running RDS for MySQL and RDS for PostgreSQL major engine versions in your DB instances past the RDS end of standard support date. For more information, see [Using Amazon RDS Extended Support](#).

September 1, 2023

[RDS Custom supports starting and stopping an RDS Custom for SQL Server DB instance](#)

RDS Custom now supports starting and stopping an RDS Custom for SQL Server DB instance. For more information, see [Starting and stopping an RDS Custom for SQL Server DB instance](#).

August 31, 2023

[Amazon RDS Optimized Writes supports the db.r5 DB instance class](#)

Amazon RDS Optimized Writes now supports the db.r5 DB instance class. For more information, see [Improving write performance with Amazon RDS Optimized Writes for MariaDB and Improving write performance with Amazon RDS Optimized Writes for MySQL](#).

August 31, 2023

[Amazon RDS for Oracle supports timezone file autoupgrade for CDBs](#)

With the `TIMEZONE_FILE_AUTOUPGRADE` option, you can upgrade the current time zone file to the latest version on your RDS for Oracle container database (CDB). For more information, see [Oracle time zone file autoupgrade](#).

August 29, 2023

[Amazon RDS Optimized Writes supports the db.m6g and db.m6i DB instance classes](#)

Amazon RDS Optimized Writes now supports the db.m6g and db.m6i DB instance classes. For more information, see [Improving write performance with Amazon RDS Optimized Writes for MariaDB and Improving write performance with Amazon RDS Optimized Writes for MySQL](#).

August 28, 2023

[Amazon RDS supports MariaDB 10.11](#)

You can now create Amazon RDS DB instances running MariaDB version 10.11. For more information, see [MariaDB on Amazon RDS versions](#).

August 21, 2023

[Update to AWS managed policy permissions](#)

The AmazonRDSCustomServiceRolePolicy of the AWSServiceRoleForRDSCustom service-linked role has new permissions that allow RDS Custom to create network interfaces. For more information, see [Amazon RDS updates to AWS managed policies](#).

August 18, 2023

[Update to AWS managed policy permissions](#)

The AmazonRDSFullAccess managed policy has new permissions that allows you to generate, view, and delete the performance analysis report for a time period. For more information, see [Amazon RDS updates to AWS managed policies](#).

August 17, 2023

[Update to AWS managed policy permissions](#)

The addition of new permissions to AmazonRDSPerformanceInsightsReadOnly managed policy and addition of new managed policy AmazonRDSPerformanceInsightsFullAccess allows you generate a DB load analysis report for a time period. For more information, see [Amazon RDS updates to AWS managed policies](#).

August 16, 2023

[Amazon RDS supports performance analysis for a period of time](#)

Performance Insights allows you to create and view performance analysis reports for a specific period of time. The report provides the insights identified and recommendations to resolve the performance issues. For more information, see [Analyzing DB load for a period of time](#).

August 16, 2023

[Amazon RDS Custom for Oracle supports the db.r5b and db.x2iedn DB instance classes](#)

You can now use the db.r5b and db.x2iedn instance classes for RDS Custom for Oracle DB instances. For more information, see [DB instance class support for RDS Custom for Oracle](#).

August 16, 2023

[Amazon RDS Custom for Oracle supports the db.m6i, db.r6i, and db.t3 DB instance classes](#)

You can now use the db.m6i, db.r6i, and db.t3 instance classes for RDS Custom for Oracle DB instances. For more information, see [DB instance class support for RDS Custom for Oracle](#).

August 15, 2023

[Amazon RDS for PostgreSQL now supports PostgreSQL version 16 Beta 3 in the database preview environment](#)

PostgreSQL version 16 Beta 3 is now available in the database preview environment in the US East (Ohio) AWS Region. For more information, see [Working with the database preview environment](#).

August 11, 2023

[Amazon RDS supports MySQL 8.0.34 and 5.7.43](#)

You can now create Amazon RDS DB instances running MySQL version 8.0.34 and 5.7.43. For more information, see [MySQL on Amazon RDS versions](#).

August 9, 2023

[RDS for SQL Server supports OS metrics view for the standby replica](#)

You can now view OS metrics for standby replica for RDS for SQL Server. For more information, see [Viewing OS metrics in the RDS console](#).

August 3, 2023

[RDS for Oracle supports Oracle Data Guard for CDBs](#)

RDS for Oracle supports Data Guard read replicas for Oracle Database 19c and 21c container databases (CDBs). You can create, manage, and promote read replicas in a CDB, just as you can in a non-CDB, using the existing RDS APIs. For more information, see [Multitenant read replicas](#).

August 1, 2023

[Amazon RDS is available in the Israel \(Tel Aviv\) Region](#)

Amazon RDS is now available in the Israel (Tel Aviv) Region. For more information, see [Regions and Availability Zones](#).

August 1, 2023

[Amazon RDS supports Oracle APEX version 23.1.v1](#)

You can use APEX 23.1.v1 with Oracle Database 19c and higher. For more information, see [Oracle Application Express](#).

July 26, 2023

[Amazon RDS Custom for Oracle supports a nondefault Oracle SID](#)

When you create an RDS Custom for Oracle DB instance using Oracle Database 19c, you can specify a nondefault Oracle system identifier (Oracle SID). This value is also the name of the CDB. For more information, see [Multitenant architecture considerations](#).

July 21, 2023

[RDS for SQL Server supports Self Managed Active Directory](#)

You can now use Self Managed Active Directory to directly join your RDS for SQL Server DB instances to your Microsoft Active Directory (AD) domains. Self-managed AD domains can be on-premises or in the cloud. For more information, see [Working with Self Managed Active Directory](#).

July 7, 2023

[PostgreSQL logical replication support for Multi-AZ DB clusters](#)

You can now use PostgreSQL logical replication with your Multi-AZ DB cluster to replicate and synchronize individual tables rather than an entire database instance. For more information, see [Using PostgreSQL logical replication with Multi-AZ DB clusters](#).

July 6, 2023

[Amazon RDS for PostgreSQL now supports PostgreSQL version 16 Beta 2 in the database preview environment](#)

PostgreSQL version 16 Beta 2 is now available in the database preview environment in the US East (Ohio) AWS Region. For more information, see [Working with the database preview environment](#).

July 6, 2023

[Update to AWS managed policy permissions](#)

The AmazonRDSCustomServiceRolePolicy of the AWSServiceRoleForRDSCustom service-linked role has new permissions that allow RDS Custom for Oracle to use snapshots. For more information, see [Amazon RDS updates to AWS managed policies](#).

June 23, 2023

[RDS supports MariaDB 10.6.14, 10.5.21, and 10.4.30](#)

You can now create Amazon RDS DB instances running MariaDB version 10.6.14, 10.5.21, and 10.4.30. For more information, see [MariaDB on Amazon RDS versions](#).

June 22, 2023

[RDS supports MySQL 8.0.33 and 5.7.42](#)

You can now create Amazon RDS DB instances running MySQL version 8.0.33 and 5.7.42. For more information, see [MySQL on Amazon RDS versions](#).

June 15, 2023

[RDS supports MariaDB 10.6.13, 10.5.20, 10.4.29, and 10.3.39](#)

You can now create Amazon RDS DB instances running MariaDB version 10.6.13, 10.5.20, 10.4.29, and 10.3.39. For more information, see [MariaDB on Amazon RDS versions](#).

June 15, 2023

[RDS for Oracle supports transportable tablespaces](#)

You can migrate data from an on-premises Oracle database into an RDS for Oracle DB instance using transportable tablespaces. This technique doesn't require additional licensing and is the migration technique with the least downtime. For more information, see [Migrating using Oracle transportable tablespaces](#).

June 15, 2023

[Amazon RDS supports RDS Proxy with RDS for MariaDB version 10.6](#)

You can now create an RDS Proxy with an RDS for MariaDB version 10.6 database. For more information about RDS Proxy, see [Using Amazon RDS Proxy](#).

June 15, 2023

[RDS Custom for SQL Server supports Bring Your Own Media \(BYOM\)](#)

You can now create a Custom Engine Version (CEV) using your own SQL Server media. For more information, see [Bring Your Own Media with RDS Custom for SQL Server](#).

June 8, 2023

[RDS for Oracle can convert an Oracle Database 19c non-CDB to a CDB](#)

If your DB instance runs Oracle Database 19c with the April 2021 or higher RU, you can convert a non-CDB to a CDB (container database). After you convert the architecture, you can upgrade your 19c CDB to a 21c CDB. This step is necessary because you can't upgrade your database and convert the architecture using a single command. For more information, see [Converting an RDS for Oracle non-CDB into a CDB](#).

May 31, 2023

[Multi-AZ DB clusters available in the China Regions](#)

Multi-AZ DB clusters are now available in the AWS Regions China (Beijing) and China (Ningxia). For more information, see [Supported Regions and DB engines for Multi-AZ DB clusters in Amazon RDS](#).

May 30, 2023

[Amazon RDS Optimized Reads support for Multi-AZ DB clusters](#)

Amazon RDS Optimized Reads now supports Multi-AZ DB clusters. For more information, see [Improving query performance for RDS for MySQL with Amazon RDS Optimized Reads](#) and [Improving query performance for RDS for PostgreSQL with Amazon RDS Optimized Reads](#).

May 30, 2023

[RDS Custom for Oracle supports the Asia Pacific \(Jakarta\) Region](#)

For more information, see [Supported Regions and DB engines for RDS Custom for Oracle](#).

May 29, 2023

[Create a DB instance read replica with a source RDS for PostgreSQL Multi-AZ DB cluster](#)

You can now create a DB instance read replica with an RDS for PostgreSQL Multi-AZ DB cluster as the source. Previously, only RDS for MySQL was supported. For more information, see [Creating a DB instance read replica from a Multi-AZ DB cluster](#).

May 24, 2023

[Amazon RDS provides combined Performance Insights and CloudWatch metrics in the Performance Insights dashboard](#)

Amazon RDS now provides a consolidated view of Performance Insights and CloudWatch metrics in the Performance Insights dashboard. For more information, see [Viewing combined metrics with the Performance Insights dashboard](#).

May 24, 2023

[Amazon RDS Optimized Reads available in the China Regions](#)

Amazon RDS Optimized Reads is now available in the AWS Regions China (Beijing) and China (Ningxia). For more information, see [Improving query performance for RDS for MariaDB with Amazon RDS Optimized Reads](#) and [Improving query performance for RDS for MySQL with Amazon RDS Optimized Reads](#).

April 24, 2023

[Amazon RDS support for AWS Secrets Manager in the China Regions](#)

Amazon RDS supports Secrets Manager in the China (Beijing) and China (Ningxia) Regions. For more information, see [Password management with Amazon RDS and AWS Secrets Manager](#).

April 20, 2023

[RDS Custom for Oracle supports reuse of AMI IDs for new CEVs](#)

When you create a custom engine version (CEV), RDS Custom for Oracle defaults to the most recent Amazon Machine Image (AMI) available. Now you can specify an AMI ID that was used in a previous CEV. For more information, see [Creating a CEV](#).

April 19, 2023

[Amazon RDS supports publishing events with tags to topic subscribers](#)

Amazon RDS event notifications sent to Amazon Simple Notification Service (Amazon SNS) or Amazon EventBridge now contain event tags in the message body. These tags provide the resource data that was affected by the service event. For more information, see [Amazon RDS event notification tags and attributes](#).

April 17, 2023

[Purchase reserved instances for a Multi-AZ DB cluster](#)

You can now purchase reserved DB instances for a Multi-AZ DB cluster. For more information, see [Reserved DB instances for a Multi-AZ DB cluster](#).

April 12, 2023

[Amazon RDS supports the db.m7g and db.r7g instance classes](#)

You can now use the db.m7g and db.r7g instance classes for RDS for MySQL, RDS for MariaDB, and RDS for PostgreSQL DB instances. For more information, see [Supported DB engines for DB instance classes](#).

April 12, 2023

[Update to Amazon RDS Custom service-linked role permissions](#)

The AmazonRDSCustomServiceRolePolicy now grants additional permissions to allow RDS Custom for SQL Server to use Amazon SQS and create snapshots. For more information, see [Updates to AWS managed policies](#).

April 6, 2023

[Migrate to an RDS for MySQL Multi-AZ DB cluster using a read replica](#)

You can now use a read replica to migrate an RDS for MySQL Single-AZ deployment or Multi-AZ DB instance deployment to an RDS for MySQL Multi-AZ DB cluster deployment with reduced downtime. For more information, see [Migrating to a Multi-AZ DB cluster using a read replica](#).

April 6, 2023

[Create a DB instance read replica from a Multi-AZ DB cluster](#)

You can now create a DB instance read replica from a Multi-AZ DB cluster in order to scale beyond the compute capacity of the source cluster. For more information, see [Creating a DB instance read replica from a Multi-AZ DB cluster](#).

April 6, 2023

[Amazon RDS Custom for SQL Server supports Multi-AZ](#)

You can create a Multi-AZ deployment with RDS Custom for SQL Server. For more information, see [Managing a Multi-AZ deployment for RDS Custom for SQL Server](#).

April 6, 2023

[Update to AWS managed policy permissions](#)

The AmazonRDSFullAccess and AmazonRDSReadOnlyAccess policies now grants additional permissions to allow the display of Amazon DevOps Guru findings in the RDS console. For more information, see [Amazon RDS updates to AWS managed policies](#).

March 30, 2023

[Amazon RDS supports Oracle APEX version 22.2.v1](#)

You can use APEX 22.2.v1 with all supported versions of Oracle Database. For more information, see [Oracle Application Express](#).

March 30, 2023

[Amazon DevOps Guru available for RDS for PostgreSQL](#)

RDS for PostgreSQL alerts you to recent anomalies detected by Amazon DevOps Guru. The database details page of the console alerts you to current and anomalies that occurred in the past 24 hours. DevOps Guru publishes proactive insights with recommendations to help address issues in your RDS for PostgreSQL databases before they are predicted to happen. For more information, see [How DevOps Guru for RDS works](#).

March 30, 2023

[RDS Custom supports the Amazon EBS gp3 storage volume](#)

RDS Custom for Oracle and RDS Custom for SQL Server both support the io1, gp2, and gp3 SSD-based EBS volumes. For more information, see [General requirements for RDS Custom for Oracle](#) and [General requirements for RDS Custom for SQL Server](#).

March 29, 2023

[Update to AWS managed policy permissions](#)

The AmazonRDSFullAccess and AmazonRDSReadOnlyAccess policies now grants additional permissions to Amazon CloudWatch. For more information, see [Amazon RDS updates to AWS managed policies](#).

March 16, 2023

[RDS Proxy is available in the China Regions](#)

RDS Proxy is now available in the China (Beijing) and China (Ningxia) regions. For more information about RDS Proxy, see [Using Amazon RDS Proxy](#).

March 15, 2023

[RDS Proxy is available in the Asia Pacific \(Jakarta\) Region](#)

RDS Proxy is now available in the Asia Pacific (Jakarta) Region. For more information about RDS Proxy, see [Using Amazon RDS Proxy](#).

March 8, 2023

[Amazon RDS Optimized Writes improves the performance of write transactions for RDS for MariaDB](#)

You can improve the performance of write transactions for RDS for MariaDB DB instances with Amazon RDS Optimized Writes. For more information, see [Improving write performance with Amazon RDS Optimized Writes for MariaDB](#).

March 7, 2023

[Amazon RDS for PostgreSQL versions 15.2](#)

New features in Amazon RDS for PostgreSQL 15.2 include the SQL standard "MERGE" command for conditional SQL queries, performance improvements for both in-memory and disk-based sorting, and support for two-phase commit and row/column filtering for logical replication.

February 27, 2023

[RDS Custom for Oracle is available in the Canada \(Central\) Region and South America \(São Paulo\) Regions](#)

For a table that shows all supported AWS Regions, see [Supported Regions and DB engines for RDS Custom for Oracle](#).

February 22, 2023

[Amazon RDS supports cross-Region automated backups for RDS for MariaDB and RDS for MySQL](#)

You can now replicate DB snapshots and transaction logs between AWS Regions for RDS for MariaDB and RDS for MySQL DB instances. For more information, see [Replicating automated backups to another AWS Region](#).

February 22, 2023

[Amazon RDS for Oracle supports advance notice of automatic minor version upgrades](#)

RDS notifies you in advance of the date when a new minor version of the RDS for Oracle engine will become available . RDS begins scheduling automatic minor version upgrades of your RDS for Oracle DB instances on the availability date. For more information, see [Before an automatic minor version upgrade is scheduled](#).

February 21, 2023

[Amazon RDS for SQL Server supports Database Activity Streams](#)

You can now monitor a SQL Server DB instance using Database Activity Streams. A SQL Server database instance has the server audit which is managed by Amazon RDS. You can define the policies to record server events in the server audit specification. You can create a database audit specification and define the policies to record database events. The stream of activity is collected and transmitted to Amazon Kinesis. From Kinesis, you can monitor the activity stream for further analysis. For more information, see [Monitoring Amazon RDS with Database Activity Streams](#).

February 15, 2023

[RDS supports MySQL 8.0.32 and 5.7.41](#)

You can now create Amazon RDS DB instances running MySQL version 8.0.32 and 5.7.41. For more information, see [MySQL on Amazon RDS versions](#).

February 7, 2023

[Amazon RDS for Oracle supports new cipher suites for SSL](#)

If you run Oracle Database 19c or 21c, you can specify six new cipher suites in the SSL option for RDS for Oracle. These suites support FIPS and are FedRAMP-complaint. For more information, see [Oracle Secure Sockets Layer](#).

February 3, 2023

[Amazon RDS for Oracle supports new cipher suites for Oracle Enterprise Manager](#)

You can use four new FedRAMP-compliant cipher suites for the OEM option. For more information, see [Oracle Management Agent for Enterprise Manager Cloud Control](#).

February 3, 2023

[RDS for Oracle supports Database Activity Streams in the Asia Pacific \(Hyderabad\), Europe \(Spain\), and Middle East \(UAE\) Regions](#)

For more information, see [Supported Regions and DB engines for database activity streams in Amazon RDS](#).

January 27, 2023

[Migrate to an RDS for PostgreSQL Multi-AZ DB cluster using a read replica](#)

By using a read replica, you can migrate an RDS for PostgreSQL Single-AZ deployment or Multi-AZ DB instance deployment to an RDS for PostgreSQL Multi-AZ DB cluster deployment with reduced downtime. For more information, see [Migrating to a Multi-AZ DB cluster using a read replica](#).

January 23, 2023

[Amazon RDS is available in the Asia Pacific \(Melbourne\) Region](#)

Amazon RDS is now available in the Asia Pacific (Melbourne) Region. For more information, see [Regions and Availability Zones](#).

January 23, 2023

[RDS for MariaDB supports enforcing SSL/TLS connections](#)

RDS for MariaDB now supports enforcing SSL/TLS connections by setting the `require_secure_transport` parameter to ON. For more information, see [Requiring SSL/TLS for all connections to a MariaDB DB instance](#).

January 19, 2023

[Amazon RDS Optimized Reads improves query performance for RDS for MariaDB](#)

You can achieve faster query processing for RDS for MariaDB DB instances with Amazon RDS Optimized Reads. For more information, see [Improving query performance for RDS for MariaDB with Amazon RDS Optimized Reads](#).

January 11, 2023

[Restore a Multi-AZ DB cluster snapshot to a DB instance](#)

You can now restore a Multi-AZ DB cluster snapshot to a Single-AZ deployment or Multi-AZ DB instance deployment. For more information, see [Restoring from a Multi-AZ DB cluster snapshot to a DB instance](#).

January 10, 2023

[Specify certificate authority \(CA\) during DB instance creation](#)

You can now specify which CA to use for a DB instance's server certificate during DB instance creation. For more information, see [Certificate authorities](#).

January 5, 2023

[RDS Custom for SQL Server supports custom engine versions](#)

A custom engine version (CEV) for RDS Custom for SQL Server is an Amazon Machine Image (AMI) with Microsoft SQL Server pre-installed. You choose an Amazon EC2 Windows AMI to use as a base image and can install other software on the operating system (OS). You can customize the configuration of the OS and SQL Server to meet your enterprise needs. For more information, see [Working with custom engine versions for RDS Custom for SQL Server](#).

December 28, 2022

---

<a href="#">Use Amazon RDS Blue/Green Deployments available in additional AWS Regions</a>	The Blue/Green Deployments feature is now available in the China (Beijing) and China (Ningxia) Regions. For more information, see <a href="#">Using Amazon RDS Blue/Green Deployments for database updates</a> .	December 22, 2022
<a href="#">Update to IAM service-linked role permissions</a>	The AmazonRDSServiceRolePolicy policy now grants additional permissions to AWS Secrets Manager. For more information, see <a href="#">Amazon RDS updates to AWS managed policies</a> .	December 22, 2022
<a href="#">Amazon RDS supports renaming a Multi-AZ DB cluster</a>	You can now rename a Multi-AZ DB cluster. For more information, see <a href="#">Renaming a Multi-AZ DB cluster</a> .	December 22, 2022
<a href="#">Amazon RDS integrates with AWS Secrets Manager for password management</a>	Amazon RDS can manage the master user password for a DB instance or Multi-AZ DB cluster in Secrets Manager. For more information, see <a href="#">Password management with Amazon RDS and AWS Secrets Manager</a> .	December 22, 2022

[Amazon RDS Optimized Writes supports the db.r6g and db.r6gd DB instance classes](#)

Amazon RDS Optimized Writes now supports the db.r6g and db.r6gd DB instance classes. For more information, see [Improving write performance with Amazon RDS Optimized Writes](#).

December 22, 2022

[Amazon RDS Custom for Oracle supports new AWS Regions](#)

You can create RDS Custom for Oracle DB instances in the Asia Pacific (Seoul) and Asia Pacific (Osaka) Regions. For more information, see [Supported Regions and DB engines for RDS Custom for Oracle](#).

December 21, 2022

[Amazon RDS on AWS Outposts supports read replicas](#)

You can now create a read replica from an RDS on Outposts MySQL or PostgreSQL DB instance. For more information, see [Creating read replicas for Amazon RDS on AWS Outposts](#).

December 19, 2022

[RDS Custom for Oracle supports modifying the DB instance class](#)

You can now change the instance class of your RDS Custom for Oracle DB instance. For more information, see [Modifying your RDS Custom for Oracle DB instance](#).

December 16, 2022

[RDS for MySQL and RDS for PostgreSQL support db.x2iedn DB instance classes](#)

You can now use the db.x2iedn DB instance classes for RDS for MySQL and RDS for PostgreSQL DB instances . For more information, see [Supported DB engines for DB instance classes](#).

December 14, 2022

[Amazon RDS Optimized Writes supports db.x2iedn DB instance classes](#)

Amazon RDS Optimized Writes now supports db.x2iedn DB instance classes. For more information, see [Improving write performance with Amazon RDS Optimized Writes](#).

December 14, 2022

[Amazon RDS supports copying DB option groups when copying DB snapshots](#)

You can now copy an option group across AWS accounts as part of a snapshot copy request on RDS for Oracle databases. For more information, see [Option group considerations](#).

December 13, 2022

[Amazon RDS supports RDS Proxy with RDS for PostgreSQL version 14](#)

You can now create an RDS Proxy with an RDS for PostgreSQL version 14 database. For more information about RDS Proxy, see [Using Amazon RDS Proxy](#).

December 13, 2022

[Amazon RDS for Oracle supports db.x2idn, db.x2iedn, and db.x2iezn instance classes](#)

You can now use the db.x2idn, db.x2iedn, and db.x2iezn instance classes for Amazon RDS for Oracle DB instances. For more information, see [Supported DB engines for DB instance classes](#) and [Supported RDS for Oracle instance classes](#).

December 12, 2022

[RDS for PostgreSQL DB instances support Trusted Language Extensions for PostgreSQL](#)

Trusted Language Extensions for PostgreSQL is an open source development kit that allows you to build high performance PostgreSQL extensions and safely run them on your RDS for PostgreSQL DB instance. For more information, see [Working with Trusted Language Extensions for PostgreSQL](#).

November 30, 2022

[Use Amazon RDS Blue/Green Deployments for database updates](#)

You can make changes to a DB instance in a staging environment and test the changes without affecting your production DB instance. When you are ready, you can promote the staging environment to be the new production environment, with minimal downtime. For more information, see [Using Amazon RDS Blue/Green Deployments for database updates](#).

November 27, 2022

[Amazon RDS Optimized Writes improves the performance of write transactions for RDS for MySQL](#)

You can improve the performance of write transactions for RDS for MySQL DB instances with Amazon RDS Optimized Writes. For more information, see [Improving write performance with Amazon RDS Optimized Writes for MySQL](#).

November 27, 2022

[Amazon RDS Optimized Reads improves query performance for RDS for MySQL](#)

You can achieve faster query processing for RDS for MySQL DB instances with Amazon RDS Optimized Reads. For more information, see [Improving query performance with Amazon RDS Optimized Reads](#).

November 27, 2022

[Amazon RDS is available in the Asia Pacific \(Hyderabad\) Region](#)

Amazon RDS is now available in the Asia Pacific (Hyderabad) Region. For more information, see [Regions and Availability Zones](#).

November 22, 2022

[RDS supports MariaDB 10.6.11, 10.5.18, 10.4.27, and 10.3.37](#)

You can now create Amazon RDS DB instances running MariaDB versions 10.6.11, 10.5.18, 10.4.27, and 10.3.37. For more information, see [MariaDB on Amazon RDS versions](#).

November 18, 2022

[RDS Custom for Oracle supports setting nondefault installation parameters in a custom engine version \(CEV\)](#)

When you create a CEV, you can set nondefault values for the Oracle base, Oracle home, UNIX user name and ID, and UNIX group name and ID. In this way, you gain more control over the database installation on your RDS Custom for Oracle DB instance. For more information, see [Preparing the CEV manifest](#).

November 18, 2022

[Amazon RDS supports Oracle APEX version 22.1.v1](#)

You can use APEX 22.1.v1 with all supported versions of Oracle Database. For more information, see [Oracle Application Express](#).

November 18, 2022

[RDS for SQL Server supports cross-Region read replicas](#)

You can now create a cross-Region read replica to enhance disaster recovery capability, reduce application read latency, and offload read workloads from the primary DB instance. For more information, see [Creating a read replica in a different AWS Region](#).

November 16, 2022

[Amazon RDS is available in the Europe \(Spain\) Region](#)

Amazon RDS is now available in the Europe (Spain) Region. For more information, see [Regions and Availability Zones](#).

November 16, 2022

[RDS for SQL Server supports linked servers for Oracle database](#)

You can now create a linked server to access external Oracle databases to read data and execute SQL commands. For more information, see [Linked Servers with Oracle OLEDB with RDS for SQL Server](#).

November 15, 2022

### [RDS Custom for Oracle supports Oracle Multitenant](#)

You can create an RDS Custom for Oracle DB instance as a container database (CDB). After creation, the CDB contains the CDB root, PDB seed, and one PDB. You can add more PDBs manually using Oracle SQL. For more information, see [Overview of Amazon RDS Custom for Oracle architecture](#).

November 15, 2022

### [Amazon RDS for Oracle supports Amazon EFS integration](#)

If you add the EFS\_INTEGRATION option to your option group, you can transfer files between your RDS for Oracle DB instance and an Amazon EFS file system. For more information, see [Amazon EFS](#).

November 15, 2022

### [RDS supports MySQL 8.0.31 and 5.7.40](#)

You can now create Amazon RDS DB instances running MySQL version 8.0.31 and 5.7.40. For more information, see [MySQL on Amazon RDS versions](#).

November 10, 2022

### [Amazon RDS is available in the Europe \(Zurich\) Region](#)

Amazon RDS is now available in the Europe (Zurich) Region. For more information, see [Regions and Availability Zones](#).

November 9, 2022

[Access to transaction log backups is now available for RDS for SQL Server](#)

You can now view and copy database transaction log backups to an Amazon S3 bucket. For more information, see [Access to transaction log backups](#).

November 7, 2022

[Multi-AZ DB clusters supported in additional AWS Regions](#)

Multi-AZ DB clusters are now available in additional AWS Regions. For more information, see [Supported Regions and DB engines for Multi-AZ DB clusters in Amazon RDS](#).

November 4, 2022

[Amazon RDS supports gp3 storage](#)

You can now create Amazon RDS DB instances that use Amazon EBS General Purpose SSD (gp3) storage volumes, which let you customize storage performance independently of storage capacity. For more information, see [General Purpose SSD storage](#).

November 4, 2022

[Amazon RDS supports a new event for operating system updates](#)

Amazon RDS now supports a new DB instance event, RDS-EVENT-0230, under the event category of security patching. This new event alerts you when an operating system update is available for your DB instance. For more information, see [Monitoring Amazon RDS events](#) and [Working with operating system updates](#).

October 28, 2022

[Amazon RDS for Oracle supports preconfigured r5b memory optimized instance classes](#)

The db.r5b Oracle DB instance classes are optimized for workloads that require additional memory, storage, and I/O per vCPU. For example, db.r5b.4xlarge.tpc2.mem2x has multithreading turned on and provides twice as much memory as db.r5b.4xlarge. For more information, see [RDS for Oracle instance classes](#).

October 27, 2022

[Amazon RDS supports 15 read replicas for RDS for MariaDB, MySQL, and PostgreSQL DB instances](#)

You can now create up to 15 read replicas for RDS for MariaDB, MySQL, and PostgreSQL DB instances. For more information about read replicas, see [Working with read replicas](#).

October 20, 2022

[Amazon RDS for PostgreSQL now supports PostgreSQL version 15 RC 3 in the database preview environment](#)

PostgreSQL version 15 Beta 3 is now available in the database preview environment in the US East (Ohio) AWS Region. For more information, see [Working with the database preview environment](#).

October 18, 2022

[Amazon RDS supports automatically setting up connectivity between an RDS database and an EC2 instance](#)

You can use the AWS Management Console to set up connectivity between an existing RDS DB instance or Multi-AZ DB cluster and an EC2 instance. For more information, see [Connecting an EC2 instance and an RDS database automatically](#).

October 14, 2022

[AWS JDBC Driver for PostgreSQL generally available](#)

The AWS JDBC Driver for PostgreSQL is a client driver designed for RDS for PostgreSQL. The AWS JDBC Driver for PostgreSQL is now generally available. For more information, see [Connecting with the AWS JDBC Driver for PostgreSQL](#).

October 6, 2022

[Amazon RDS for Oracle supports Oracle APEX version 21.2.v1](#)

APEX 21.2 includes patch 33420059. For more information, see [APEX version requirements](#).

October 3, 2022

[RDS supports MySQL 5.7.39](#)

You can now create Amazon RDS DB instances running MySQL versions 5.7.39. For more information, see [MySQL on Amazon RDS versions](#).

September 29, 2022

[RDS supports MariaDB 10.6.10](#)

You can now create Amazon RDS DB instances running MariaDB versions 10.6.10. For more information, see [MariaDB on Amazon RDS versions](#).

September 29, 2022

[RDS Proxy supports RDS for SQL Server](#)

You can now create an RDS Proxy for an RDS DB instance that runs Microsoft SQL Server version 2014 or higher. For more information about RDS Proxy, see [Using Amazon RDS Proxy](#).

September 19, 2022

[RDS supports MariaDB 10.5.17, 10.4.26, and 10.3.36](#)

You can now create Amazon RDS DB instances running MariaDB versions 10.5.17, 10.4.26, and 10.3.36. For more information, see [MariaDB on Amazon RDS versions](#).

September 15, 2022

[Amazon RDS for Oracle supports local instance storage for temporary data](#)

You can now launch Amazon RDS for Oracle on Amazon EC2 db.r5d and db.m5d instance types with the temporary tablespace and Database Smart Flash Cache (the flash cache) configured to use an instance store. By storing temporary data locally, you can achieve lower read and write latencies when compared to standard storage based on Amazon EBS. For more information, see [Storing temporary Oracle data in the instance store](#).

September 14, 2022

[Performance Insights shows the top 25 SQL queries](#)

In the Performance Insights dashboard, the **Top SQL** tab shows the 25 SQL queries that are contributing the most to DB load. For more information, see [Overview of the Top SQL tab](#).

September 13, 2022

[RDS supports MySQL 8.0.30](#)

You can now create Amazon RDS DB instances running MySQL version 8.0.30. For more information, see [MySQL on Amazon RDS versions](#).

September 9, 2022

[Amazon RDS is available in the Middle East \(UAE\) Region](#)

Amazon RDS is now available in the Middle East (UAE) Region. For more information, see [Regions and Availability Zones](#).

August 30, 2022

[Amazon RDS for SQL Server supports SSRS Email subscriptions](#)

You can now use the SQL Server Reporting Services (SSRS) Email extension to send reports to users and subscribe to reports on the report server. For more information, see [Support for SQL Server Reporting Services in RDS for SQL Server](#).

August 26, 2022

[RDS for Oracle supports read replica backups](#)

You can turn on automatic backups and create manual snapshots of RDS for Oracle replicas. For more information, see [Working with RDS for Oracle replica backups](#).

August 23, 2022

[RDS for Oracle supports Oracle Data Guard switchover](#)

A switchover is a role reversal between a primary database and a mounted or open Oracle replica. During a switchover, the original primary database transitions to a standby role, while the original standby database transitions to the primary role. For more information, see [Performing an Oracle Data Guard switchover](#).

August 23, 2022

[Amazon RDS supports automatically setting up connectivity with an EC2 instance](#)

When you create a DB instance or Multi-AZ DB cluster, you can use the AWS Management Console to set up connectivity between an Amazon Elastic Compute Cloud instance and the new DB instance or DB cluster. For more information, see [Configure automatic network connectivity with an EC2 instance](#) for a new DB instance and [Configure automatic network connectivity with an EC2 instance](#) for a new DB cluster.

August 22, 2022

[RDS Custom for Oracle supports promotion of Oracle replicas](#)

If you use RDS Custom for Oracle, you can promote your managed Oracle replicas by using the `promote-read-replica` CLI command. Also, you can delete your primary DB instance, which causes RDS Custom for Oracle to promote your managed Oracle replicas to standalone instances. For more information, see [Working with Oracle replicas for RDS Custom for Oracle](#).

August 5, 2022

[RDS for MySQL supports enforcing SSL/TLS connections](#)

RDS for MySQL now supports enforcing SSL/TLS connections by setting the `require_secure_transport` parameter to ON. For more information, see [Requiring an SSL/TLS connection to a MySQL DB instance](#).

August 1, 2022

[Amazon RDS has deprecated support for Oracle Database 12c Release 1 \(12.1.0.2\)](#)

Support for version 12.1.0.2 is deprecated for both the BYOL and LI licensing models. On August 1, 2022, RDS for Oracle begins automatic upgrades of 12c Release 1 (12.1.0.2) DB instances and restored 12.1.0.2 snapshots to Oracle Database 19c. For more information, see the end of support timeline on [AWS re:Post](#).

August 1, 2022

[RDS Proxy supports RDS for MariaDB](#)

You can now create an RDS Proxy for an RDS DB instance that runs MariaDB version 10.2, 10.3, 10.4, or 10.5. The MariaDB support is included under the MySQL engine family. For more information about RDS Proxy, see [Using Amazon RDS Proxy](#).

July 26, 2022

[RDS for MariaDB supports the db.r5b DB instance classes](#)

You can now create RDS for MariaDB DB instances that use the db.r5b DB instance classes. For more information, see [Supported DB engines for DB instance classes](#).

July 25, 2022

[RDS for Oracle supports modifying database activity streams](#)

If you use RDS for Oracle, you can change the audit policy state of a database activity stream to either locked (default) or unlocked. Instead of stopping an activity stream, you can unlock its policy state, customize your audit policy, and then relock the policy state. For more information, see [Modifying a database activity stream](#).

July 22, 2022

[Performance Insights supports the Asia Pacific \(Jakarta\) Region](#)

Formerly, you couldn't use Performance Insights in the Asia Pacific (Jakarta) Region. This restriction has been removed. For more information, see [Supported Regions and DB engines for Performance Insights in Amazon RDS](#).

July 21, 2022

[Microsoft SQL Server 2012 has reached its end of support on Amazon RDS](#)

Microsoft SQL Server 2012 has reached its end of support, coinciding with the Microsoft plan to end extended support for this version on July 12, 2022. Any existing Microsoft SQL Server 2012 instances are to be automatically upgraded to the latest minor version of Microsoft SQL Server 2014 starting on June 1, 2022. For more information, see [Microsoft SQL Server 2012 support on Amazon RDS](#).

July 12, 2022

[RDS supports MariaDB 10.6.8, 10.5.16, 10.4.25, 10.3.35, and 10.2.44](#)

You can now create Amazon RDS DB instances running MariaDB versions 10.6.8, 10.5.16, 10.4.25, 10.3.35, and 10.2.44. For more information, see [Supported MariaDB versions on Amazon RDS](#).

July 8, 2022

[RDS Performance Insights supports additional retention periods](#)

Previously, Performance Insights offered only two retention periods: 7 days (default) or 2 years (731 days). Now, if you need to retain your performance data for longer than 7 days, you can specify from 1–24 months. For more information, see [Pricing and data retention for Performance Insights](#).

July 1, 2022

[RDS Custom supports the Asia Pacific \(Mumbai\) and Europe \(London\) Regions](#)

You can create RDS Custom for Oracle and RDS Custom for SQL Server DB instances in two new AWS Regions: Asia Pacific (Mumbai) and Europe (London). For more information, see [AWS Region support for RDS Custom for Oracle](#) and [AWS Region support for RDS Custom for SQL Server](#).

June 21, 2022

[RDS Custom for Oracle supports Oracle Database 18c and 12c Release 2 \(12.2\)](#)

You can now create a CEV for RDS Custom for Oracle using installation files for Oracle Database 18c and 12c Release 2 (12.2). You can use these CEVs to create an RDS Custom for Oracle DB instance. For more information, see [Working with custom engine versions for Amazon RDS Custom for Oracle](#).

June 21, 2022

[Multi-AZ DB clusters support the db.m5d and db.r5d DB instance classes](#)

You can now create Multi-AZ DB clusters that use the db.m5d and db.r5d DB instance classes. For more information, see [Multi-AZ DB cluster deployments](#) and [DB instance class types](#).

June 21, 2022

[Multi-AZ DB clusters available in additional AWS Regions](#)

You can now create Multi-AZ DB clusters in the following Regions: Europe (Frankfurt) and Europe (Stockholm). For more information, see [Multi-AZ DB cluster deployments](#).

June 21, 2022

[RDS for Microsoft SQL Server supports migration of databases that use Transparent Data Encryption \(TDE\)](#)

RDS for SQL Server now supports migrating Microsoft SQL Server databases with TDE turned on, using native backup and restore. For more information, see [Support for Transparent Data Encryption in SQL Server](#).

June 14, 2022

[Amazon RDS supports publishing events to encrypted Amazon SNS topics](#)

Amazon RDS can now publish events to Amazon Simple Notification Service (Amazon SNS) topics that have server-side encryption (SSE) enabled, for additional protection of events that carry sensitive data. For more information, see [Subscribing to Amazon RDS event notification](#).

June 1, 2022

---

<a href="#">RDS supports MySQL 5.7.38</a>	You can now create Amazon RDS DB instances running MySQL version 5.7.38. For more information, see <a href="#">MySQL on Amazon RDS versions</a> .	May 31, 2022
<a href="#">RDS for PostgreSQL supports cascading read replicas</a>	You can now use cascading read replicas with RDS for PostgreSQL version 14.1 and higher releases. For more information, see <a href="#">Working with PostgreSQL read replicas in Amazon RDS</a> .	May 4, 2022
<a href="#">Amazon RDS on AWS Outposts supports scale storage and autoscaling operations</a>	You can now change the storage sizes of DB instances on your Outpost and use storage autoscaling. For more information, see <a href="#">Amazon RDS on AWS Outposts support for Amazon RDS features</a> .	May 2, 2022
<a href="#">Multi-AZ DB clusters available in additional AWS Regions</a>	You can now create Multi-AZ DB clusters in the following Regions: Asia Pacific (Singapore) and Asia Pacific (Sydney). For more information, see <a href="#">Multi-AZ DB cluster deployments</a> .	April 29, 2022

[Amazon RDS supports dual-stack mode](#)

DB instances can now run in dual-stack mode. In dual-stack mode, resources can communicate with the DB instance over IPv4, IPv6, or both. For more information, see [Amazon RDS IP addressing](#).

April 29, 2022

[Amazon RDS publishes usage metrics to Amazon CloudWatch](#)

The AWS/Usage namespace in Amazon CloudWatch includes account-level usage metrics for your Amazon RDS service quotas. For more information, see [Amazon CloudWatch usage metrics for Amazon RDS](#).

April 28, 2022

[Amazon RDS for MySQL supports the db.m6i and db.r6i DB instance classes](#)

You can now use the db.m6i and db.r6i DB instance classes for Amazon RDS DB instances running MySQL. For more information, see [Supported DB engines for DB instance classes](#).

April 28, 2022

[Amazon RDS for PostgreSQL supports the db.m6i and db.r6i DB instance classes](#)

You can now use the db.m6i and db.r6i DB instance classes for Amazon RDS DB instances running PostgreSQL. For more information, see [Supported DB engines for DB instance classes](#).

April 27, 2022

[Amazon RDS for MariaDB supports the db.m6i and db.r6i DB instance classes](#)

You can now use the db.m6i and db.r6i DB instance classes for Amazon RDS DB instances running MariaDB. For more information, see [Supported DB engines for DB instance classes](#).

April 26, 2022

[Amazon RDS on AWS Outposts supports Multi-AZ deployments](#)

You can now create a standby DB instance on a different Outpost. For more information, see [Amazon RDS on AWS Outposts support for Amazon RDS features](#).

April 19, 2022

[Amazon RDS for Oracle supports the db.m6i and db.r6i instance classes](#)

If you run Oracle Database 19c, you can use the db.m6i and db.r6i instance classes. The db.m6i classes are general-purpose instance classes that are well suited for a broad range of workloads. For more information, see [RDS for Oracle instance classes](#).

April 8, 2022

[Amazon RDS for SQL Server supports SQL Server Agent job replication](#)

When you turn on this feature, SQL Server Agent jobs created, modified, or deleted on the primary host are automatically synchronized to the secondary host in a Multi-AZ configuration. For more information, see [Using SQL Server Agent](#).

April 7, 2022

[Amazon RDS supports RDS Proxy with RDS for PostgreSQL version 13](#)

You can now create an RDS Proxy with an RDS for PostgreSQL version 13 database. For more information about RDS Proxy, see [Using Amazon RDS Proxy](#).

April 4, 2022

[Amazon RDS plans to deprecate Oracle Database 12c](#)

Oracle Database 12c is on a deprecation path. Oracle Corporation will no longer provide patches for Oracle Database 12c releases after the end-of-support dates. Amazon RDS plans to begin automatically upgrading Oracle Database 12c DB instances to Oracle Database 19c.

March 22, 2022

[Amazon RDS for PostgreSQL Release Notes](#)

There is now a separate guide for the Amazon RDS for PostgreSQL release notes. For more information, see [Amazon RDS for PostgreSQL Release Notes](#).

March 22, 2022

[Amazon RDS for Oracle Release Notes](#)

There is now a separate guide for the Amazon RDS for Oracle release notes. For more information, see [Amazon RDS for Oracle Release Notes](#).

March 22, 2022

### [Multi-AZ DB clusters available in additional AWS Regions](#)

You can now create Multi-AZ DB clusters in the following Regions: US East (Ohio) and Asia Pacific (Tokyo). For more information, see [Multi-AZ DB cluster deployments](#).

March 15, 2022

### [Amazon RDS for PostgreSQL versions 14.2, 13.6, 12.10, 11.15, and 10.20](#)

RDS for PostgreSQL now supports versions 14.2, 13.6, 12.10, 11.15, and 10.20. Version 14.2 and 13.6 add support for two new foreign data wrappers. The `mysql_fdw` extension lets PostgreSQL work with data stored in MySQL, MariaDB, and Aurora MySQL databases. The `tds_fdw` extension lets PostgreSQL work with data stored in SQL Server databases. For more information, see [Supported PostgreSQL database versions](#).

March 12, 2022

### [RDS supports MySQL 5.7.37](#)

You can now create Amazon RDS DB instances running MySQL version 5.7.37. For more information, see [MySQL on Amazon RDS versions](#).

March 11, 2022

[Amazon RDS for SQL Server supports new DB instance classes](#)

You can now create Amazon RDS DB instances running Microsoft SQL Server that use the db.m6i and db.r6i DB instance classes. For more information, see [DB instance class support for Microsoft SQL Server](#).

March 9, 2022

[Amazon RDS for Oracle supports Oracle Database 21c](#)

You can now create Amazon RDS DB instances running Oracle Database 21c (21.0.0.0). This is the first Oracle Database release that supports only the multitenant (CDB) architecture. For more information, see [Oracle Database 21c with Amazon RDS](#).

March 7, 2022

[RDS supports MariaDB 10.6.7, 10.5.15, 10.4.24, 10.3.34, and 10.2.43](#)

You can now create Amazon RDS DB instances running MariaDB versions 10.6.7, 10.5.15, 10.4.24, 10.3.34, and 10.2.43. For more information, see [MariaDB on Amazon RDS versions](#).

March 3, 2022

[AWS JDBC Driver for MySQL generally available](#)

The AWS JDBC Driver for MySQL is a client driver designed for RDS for MySQL. The AWS JDBC Driver for MySQL is now generally available. For more information, see [Connecting with the Amazon Web Services JDBC Driver for MySQL](#).

March 2, 2022

[Multi-AZ DB clusters generally available](#)

A Multi-AZ DB cluster deployment is a high availability deployment mode of Amazon RDS with two readable standby DB instances. Multi-AZ DB clusters are now generally available. For more information, see [Multi-AZ DB cluster deployments](#).

March 1, 2022

[RDS supports MySQL 8.0.28](#)

You can now create Amazon RDS DB instances running MySQL version 8.0.28. For more information, see [MySQL on Amazon RDS versions](#).

February 28, 2022

[Amazon RDS for Oracle supports new settings for native network encryption \(NNE\)](#)

To control whether clients can connect with non-secure encryption and checksumming methods, set `SQLNET.ALLOW_WEAK_CRYPTOCIPHERS` and `SQLNET.ALLOW_WEAK_CRYPTO` in the NNE option. Examples of insecure methods include DES, 3DES, RC4, and MD5. For more information, see [NNE option settings](#).

February 25, 2022

[Amazon RDS for SQL Server supports Always On Availability Groups for Microsoft SQL Server 2017 Standard Edition](#)

When you create a DB instance using the Multi-AZ configuration on SQL Server 2017 Standard Edition 14.00.3401.7 and higher versions, RDS automatically uses Availability Groups. For more information, see [Multi-AZ deployments for Microsoft SQL Server](#).

February 18, 2022

[RDS for Oracle supports Database Activity Streams in the Asia Pacific \(Jakarta\) Region](#)

For more information, see [Support for AWS Regions for database activity streams](#).

February 16, 2022

[Amazon RDS Custom for Oracle support for Oracle Database 12.1](#)

You can now create custom engine versions for RDS Custom for Oracle that use Oracle Database 12.1 Enterprise Edition. For more information, see [Working with custom engine versions for Amazon RDS Custom for Oracle](#).

February 4, 2022

[Amazon RDS for MariaDB supports a new major version](#)

You can now create Amazon RDS DB instances running MariaDB version 10.6. For more information, see [MariaDB 10.6 support on Amazon RDS](#).

February 3, 2022

[Performance Insights supports plan capture for Oracle queries](#)

The Performance Insights console supports a new plan dimension for top SQL. When you slice by plan, you can see which plans your top Oracle queries are using. If a query uses multiple plans, you can compare the plans side by side in the console and determine which plan is most efficient. You can also drill down to see which steps in a plan have the highest cost. For more information, see [Analyzing Oracle execution plans using the Performance Insights dashboard](#).

January 27, 2022

[Performance Insights supports new APIs](#)

Performance Insights supports the following APIs: `GetResourceMetadata`, `ListAvailableResourceDimensions`, and `ListAvailableResourceMetrics`. For more information, see [Retrieving metrics with the Performance Insights API](#) in this manual and the [Amazon RDS Performance Insights API Reference](#).

January 12, 2022

[RDS Proxy supports events](#)

RDS Proxy now generates events that you can subscribe to and view in CloudWatch Events or configure to send to Amazon EventBridge. For more information, see [Working with RDS Proxy events](#).

January 11, 2022

[Amazon RDS for SQL Server supports SSAS Multidimensional mode](#)

RDS for SQL Server supports running SQL Server Analysis Services (SSAS) in Tabular or Multidimensional mode. For more information, see [Support for SQL Server Analysis Services in RDS for SQL Server](#).

January 7, 2022

[RDS Proxy available in additional AWS Regions](#)

RDS Proxy is now available in the following Regions: Africa (Cape Town), Asia Pacific (Hong Kong), Asia Pacific (Osaka), Europe (Milan), Europe (Paris), Europe (Stockholm), Middle East (Bahrain), and South America (São Paulo). For more information about RDS Proxy, see [Using Amazon RDS Proxy](#).

January 5, 2022

[RDS supports MySQL 8.0.27](#)

You can now create Amazon RDS DB instances running MySQL version 8.0.27. For more information, see [MySQL on Amazon RDS versions](#).

December 21, 2021

[Amazon RDS is available in the Asia Pacific \(Jakarta\) Region](#)

Amazon RDS is now available in the Asia Pacific (Jakarta) Region. For more information, see [Regions and Availability Zones](#).

December 13, 2021

[Amazon RDS supports MariaDB 10.5.13, 10.4.22, 10.3.32, and 10.2.41](#)

You can now create Amazon RDS DB instances running MariaDB versions 10.5.13, 10.4.22, 10.3.32, and 10.2.41. For more information, see [MariaDB on Amazon RDS versions](#).

December 8, 2021

[Amazon RDS Custom for SQL Server](#)

Amazon RDS Custom is a managed database service for legacy, custom, and packaged applications that require access to the underlying operating system and database environment. With Amazon RDS Custom, you get the automation of Amazon RDS and the flexibility of Amazon EC2. For more information, see [Working with Amazon RDS Custom](#).

December 1, 2021

---

<a href="#">Multi-AZ DB clusters (preview)</a>	You can now create Multi-AZ DB clusters for RDS for MySQL and RDS for PostgreSQL. A Multi-AZ DB cluster deployment is a high availability deployment mode of Amazon RDS with two readable standby DB instances. Multi-AZ DB clusters are in preview. For more information, see <a href="#">Multi-AZ DB cluster deployments (preview)</a> .	November 23, 2021
<a href="#">Amazon RDS supports RDS Proxy with RDS for PostgreSQL version 12</a>	You can now create an RDS Proxy with an RDS for PostgreSQL version 12 database. For more information about RDS Proxy, see <a href="#">Using Amazon RDS Proxy</a> .	November 22, 2021
<a href="#">Amazon RDS on AWS Outposts supports local backups</a>	You can store automated backups and manual snapshots in your AWS Region or locally on your Outpost. For more information, see <a href="#">Amazon RDS on AWS Outposts support for Amazon RDS features</a> .	November 22, 2021
<a href="#">Amazon RDS support for cross-account AWS KMS keys</a>	You can use a KMS key from a different AWS account for encryption when exporting DB snapshots to Amazon S3. For more information, see <a href="#">Exporting DB snapshot data to Amazon S3</a> .	November 3, 2021

---

<a href="#">Amazon RDS on AWS Outposts supports publishing database engine logs to CloudWatch Logs</a>	RDS on Outposts now supports publishing database engine logs to CloudWatch Logs. For more information, see <a href="#">Amazon RDS on AWS Outposts support for Amazon RDS features</a> .	November 2, 2021
<a href="#">Amazon RDS Custom for Oracle</a>	Amazon RDS Custom is a managed database service for legacy, custom, and packaged applications that require access to the underlying operating system and database environment. With Amazon RDS Custom, you get the automation of Amazon RDS and the flexibility of Amazon EC2. For more information, see <a href="#">Working with Amazon RDS Custom</a> .	October 26, 2021
<a href="#">Support for delayed replication for RDS for MySQL version 8.0</a>	Starting with RDS for MySQL version 8.0.26, you can configure delayed replication for RDS for MySQL version 8.0 DB instances. For more information, see <a href="#">Configuring delayed replication with MySQL</a> .	October 25, 2021
<a href="#">Support for MySQL 8.0.26</a>	You can now create Amazon RDS DB instances running MySQL version 8.0.26. For more information, see <a href="#">MySQL on Amazon RDS versions</a> .	October 25, 2021

---

<a href="#">Support for GTID-based replication for RDS for MySQL version 8.0</a>	Starting with RDS for MySQL version 8.0.26, you can configure GTID-based replication for RDS for MySQL version 8.0 DB instances. For more information, see <a href="#">Using GTID-based replication for RDS for MySQL</a> .	October 25, 2021
<a href="#">Amazon RDS supports RDS Proxy with RDS for MySQL 8.0</a>	You can now create an RDS Proxy for an RDS for MySQL 8.0 database instance. For more information, see <a href="#">Using Amazon RDS Proxy</a> .	October 21, 2021
<a href="#">Amazon RDS on AWS Outposts supports additional RDS for MySQL versions</a>	RDS on Outposts now supports RDS for MySQL versions 8.0.23 and 8.0.25. For more information, see <a href="#">Amazon RDS on AWS Outposts support for Amazon RDS features</a> .	October 20, 2021
<a href="#">Amazon RDS for PostgreSQL now supports PostgreSQL version 14 RC 1 in the database preview environment</a>	PostgreSQL version 14 RC 1 is now available in the database preview environment in the US East (Ohio) AWS Region. For more information, see <a href="#">Working with the database preview environment</a> .	October 19, 2021

[Amazon RDS supports Performance Insights in additional AWS Regions](#)

Performance Insights is available in the Middle East (Bahrain), Africa (Cape Town), Europe (Milan), and Asia Pacific (Osaka) Regions. For more information, see [Supported Regions and DB engines for Performance Insights in Amazon RDS](#).

October 5, 2021

[Performance Insights supports digest-level statistics for Oracle](#)

When you use Performance Insights, you can view SQL statistics both at the statement and digest level for Amazon RDS for Oracle. For more information, see [Analyzing running queries in Oracle](#).

October 4, 2021

[Amazon RDS on AWS Outposts supports additional RDS for PostgreSQL versions](#)

RDS on Outposts now supports RDS for PostgreSQL versions 12.8 and 13.4. For more information, see [Amazon RDS on AWS Outposts support for Amazon RDS features](#).

October 1, 2021

[Amazon RDS supports Oracle APEX version 21.1.v1](#)

You can use APEX 21.1.v1 with all supported versions of Oracle Database. For more information, see [Oracle Application Express](#).

September 24, 2021

[Amazon RDS for Oracle supports client-side encryption for NNE](#)

When you configure NNE, you might want to avoid forcing encryption on the server side. For example, you might not want to force all client communications to use encryption because the server requires it. In this case, you can force encryption on the client side using the `SQLNET.*CLIENT` options. For more information, see [Oracle native network encryption](#).

September 24, 2021

[Amazon RDS for MySQL and RDS for PostgreSQL support new DB instance classes](#)

You can now use the `db.r5b`, `db.t4g`, and `db.x2g` instance classes to create Amazon RDS DB instances running MySQL or PostgreSQL. For more information, see [Supported DB engines for DB instance classes](#).

September 15, 2021

[Amazon RDS for Microsoft SQL Server supports Java Database Connectivity \(JDBC\) with Microsoft Distributed Transaction Coordinator \(MSDTC\)](#)

JDBC XA transactions are now supported with MSDTC for SQL Server 2017 version 14.00.3223.3 and higher, and SQL Server 2019. For more information, see [Support for Microsoft Distributed Transaction Coordinator in RDS for SQL Server](#).

September 7, 2021

[Amazon RDS supports MariaDB 10.5.12, 10.4.21, 10.3.31, and 10.2.40](#)

You can now create Amazon RDS DB instances running MariaDB versions 10.5.12, 10.4.21, 10.3.31, and 10.2.40. For more information, see [MariaDB on Amazon RDS versions](#).

September 2, 2021

[Amazon RDS has ended support for Oracle Database 18c](#)

You can create DB instances only for Oracle Database 12c and Oracle Database 19c. If you have Oracle Database 18c snapshots, upgrade them to a later release. For more information, see [Upgrading an Oracle DB snapshot](#).

August 17, 2021

[Amazon RDS for SQL Server supports automatic minor version upgrades](#)

You can now have your RDS for SQL Server DB instances automatically upgraded to the latest minor version. For more information, see [Upgrading the Microsoft SQL Server DB engine](#).

August 13, 2021

[Amazon RDS for PostgreSQL now supports PostgreSQL version 14 beta 2 in the database preview environment](#)

For more about PostgreSQL version 14 beta 1, see [PostgreSQL 14 beta 1 release notes](#). For more about PostgreSQL version 14 beta 2, see [PostgreSQL 14 beta 2 release notes](#). For information on the Database Preview Environment, see [Working with the database preview environment](#).

August 9, 2021

[Amazon RDS supports RDS Proxy in a shared VPC](#)

You can now create an RDS Proxy in a shared VPC. For more information about RDS Proxy, see "Managing Connections with Amazon RDS Proxy" in the [Amazon RDS User Guide](#) or the [Aurora User Guide](#).

August 6, 2021

[Amazon RDS supports MariaDB 10.2.39](#)

You can now create Amazon RDS DB instances running MariaDB versions 10.2.39. For more information, see [MariaDB on Amazon RDS versions](#).

August 4, 2021

[Amazon RDS for Oracle adds the TIMEZONE\\_FILE\\_AUTO\\_UPGRADE option](#)

With this option, you can upgrade the current time zone file to the latest version on your Oracle DB instance. For more information, see [Oracle time zone file autoupgrade](#).

July 30, 2021

[Amazon RDS extends support for cross-Region automated backups](#)

You can now replicate DB snapshots and transaction logs between more AWS Regions. For more information, see [Replicating automated backups to another AWS Region](#).

July 19, 2021

[Support for MySQL 5.7.34](#)

You can now create Amazon RDS DB instances running MySQL version 5.7.34. For more information, see [MySQL on Amazon RDS versions](#).

July 8, 2021

[Amazon RDS on AWS Outposts supports additional RDS for PostgreSQL versions](#)

RDS on Outposts now supports RDS for PostgreSQL versions 12.7 and 13.3. For more information, see [Amazon RDS on AWS Outposts support for Amazon RDS features](#).

July 8, 2021

[Amazon RDS for PostgreSQL supports oracle\\_fdw](#)

You can now use the oracle\_fdw extension to provide a foreign data wrapper for access to Oracle databases. For more information, see [Accessing external data with the oracle\\_fdw extension](#).

July 8, 2021

[Amazon RDS supports Oracle Management Agent \(OMA\) version 13.5](#)

You can use Oracle Management Agent (OMA) version 13.5 with Oracle Enterprise Manager (OEM) Cloud Control 13c Release 5 and higher. Amazon RDS for Oracle installs OMA, which then communicates with your Oracle Management Service (OMS) to provide monitoring information. If you run OMS 13.5, you can manage databases by installing OMA 13.5. For more information, see [Oracle Management Agent for Enterprise Manager Cloud Control](#).

July 7, 2021

[Amazon RDS for Oracle supports downloading logs from Amazon S3](#)

If archived redo logs aren't on your instance but are protected by your backup retention period, you can use `rdsadmin.rdsadmin_archive_log_download` to download them from Amazon S3. RDS for Oracle saves the logs to the `/rdsdbdata/log/arch` directory on your DB instance. For more information, see [Downloading archived redo logs from Amazon S3](#).

July 2, 2021

[Amazon RDS supports MariaDB 10.4.18 and 10.5.9](#)

You can now create Amazon RDS DB instances running MariaDB versions 10.4.18 and 10.5.9. For more information, see [MariaDB on Amazon RDS versions](#).

June 30, 2021

[Amazon RDS for Oracle supports Database Activity Streams](#)

You can now monitor an Oracle DB instance using Database Activity Streams. An Oracle database writes audit records to the unified audit trail. When you start a database activity stream on an Oracle DB instance, Amazon Kinesis streams all activities that match the Oracle Database audit policies. For more information, see [Monitoring Amazon RDS with Database Activity Streams](#).

June 23, 2021

[Amazon RDS for Oracle introduces memory optimized instance classes](#)

New Oracle DB instance classes are optimized for workloads that require additional memory, storage, and I/O per vCPU. For more information, see [RDS for Oracle instance classes](#).

June 23, 2021

[Support for MySQL 8.0.25](#)

You can now create Amazon RDS DB instances running MySQL version 8.0.25. For more information, see [MySQL on Amazon RDS versions](#).

June 18, 2021

[Amazon RDS on AWS Outposts supports additional RDS for PostgreSQL versions](#)

RDS on Outposts now supports RDS for PostgreSQL versions 12.5, 12.6, 13.1, and 13.2. For more information, see [Amazon RDS on AWS Outposts support for Amazon RDS features](#).

May 28, 2021

[Amazon RDS supports MariaDB 10.2.37 and 10.3.28](#)

You can now create Amazon RDS DB instances running MariaDB versions 10.2.37 and 10.3.28. For more information, see [MariaDB on Amazon RDS versions](#).

May 27, 2021

[Amazon RDS for Oracle supports multitenant container database \(CDB\)](#)

A multitenant architecture enables an Oracle database to be a CDB. In Oracle Database 19c, your CDB can include a single PDB. The user experience with a PDB is mostly identical to the user experience with a non-CDB. For more information, see [RDS for Oracle architecture](#).

May 25, 2021

[Amazon RDS on AWS Outposts supports Amazon RDS for SQL Server](#)

RDS on Outposts now supports Amazon RDS for SQL Server. For more information, see [Amazon RDS on AWS Outposts support for Amazon RDS features](#).

May 11, 2021

[Amazon RDS extends support for cross-Region automated backups](#)

You can now configure Amazon RDS database instances running Microsoft SQL Server to replicate DB snapshots and transaction logs to a different AWS Region. For more information, see [Replicating automated backups to another AWS Region](#).

May 7, 2021

[Amazon RDS supports cross-Region automated backups for encrypted DB instances](#)

You can now replicate DB snapshots and transaction logs to a different AWS Region for encrypted Amazon RDS database instances running Oracle or PostgreSQL. For more information, see [Replicating automated backups to another AWS Region](#).

May 3, 2021

[Amazon RDS on AWS Outposts supports Amazon CloudWatch monitoring](#)

RDS on Outposts now supports Amazon CloudWatch monitoring. For more information, see [Amazon RDS on AWS Outposts support for Amazon RDS features](#).

April 21, 2021

[RDS for PostgreSQL supports AWS Lambda functions](#)

You can now invoke AWS Lambda functions for your RDS for PostgreSQL DB instances. For more information, see [Invoking an AWS Lambda function from an RDS for PostgreSQL DB instance](#).

April 13, 2021

[RDS for SQL Server supports extended events](#)

You can use SQL Server extended events to capture debugging and troubleshooting information. For more information, see [Using extended events with Amazon RDS for Microsoft SQL Server](#).

April 8, 2021

[Support for MySQL 8.0.23, 5.7.33, and 5.6.51](#)

You can now create Amazon RDS DB instances running MySQL version 8.0.23, 5.7.33, and 5.6.51. For more information, see [MySQL on Amazon RDS versions](#).

March 31, 2021

[Automatic rollback on failed Amazon RDS for MySQL upgrade](#)

If a DB instance upgrade from MySQL version 5.7 to MySQL version 8.0 fails, Amazon RDS rolls back the changes performed for the upgrade automatically. After the rollback, the MySQL DB instance is running MySQL version 5.7. For more information, see [Rollback after failure to upgrade from MySQL 5.7 to 8.0](#).

March 18, 2021

[Amazon RDS supports cross-Region read replicas in opt-in Regions](#)

You can now replicate DB instances to opt-in Regions. For more information, see [Creating a read replica in a different AWS Region](#).

March 18, 2021

[Amazon RDS plans to deprecate Oracle Database 18c](#)

Oracle Database 18c (18.0.0.0 ) is on a deprecation path. Oracle Corporation will no longer provide patches for Oracle Database 18c after the end-of-support date. On July 1, 2021, Amazon RDS plans to begin automatically upgrading Oracle Database 18c instances to Oracle Database 19c. Before the automatic upgrades begin, we highly recommend that you manually upgrade your existing Oracle Database 18c instances to Oracle Database 19c. For more information, see [Preparing for the automatic upgrade of Oracle Database 18c](#).

March 11, 2021

[Amazon RDS has ended support for Oracle Database 11g](#)

You can only create DB instances for Oracle Database 12c Release 1 (12.1.0.2) and later. If you have Oracle Database 11g snapshots , upgrade them to a later release. For more information, see [Upgrading an Oracle DB snapshot](#).

March 11, 2021

[Amazon RDS supports continuous backups of DB instances in AWS Backup](#)

You can now create automated backups in AWS Backup and restore DB instances from these backups to a specified time. For more information, see [Using AWS Backup to manage automated backups](#).

March 10, 2021

[Amazon RDS supports Oracle Management Agent \(OMA\) version 13.4](#)

You can use Oracle Management Agent (OMA) version 13.4 with Oracle Enterprise Manager (OEM) Cloud Control 13c Release 4 Update 9. Amazon RDS for Oracle installs OMA, which then communicates with your Oracle Management Service (OMS) to provide monitoring information. If you run OMS 13.4, you can manage databases by installing OMA 13.4. For more information, see [Oracle Management Agent for Enterprise Manager Cloud Control](#).

March 10, 2021

### [RDS Proxy endpoint enhancements](#)

You can create additional endpoints associated with each RDS proxy. Creating an endpoint in a different VPC enables cross-VPC access for the proxy. Proxies for Aurora MySQL clusters can also have read-only endpoints. These reader endpoints connect to reader DB instances in the clusters and can improve read scalability and availability for query-intensive applications. For more information about RDS Proxy, see "Managing Connections with Amazon RDS Proxy" in the [Amazon RDS User Guide](#) or the [Aurora user guide](#).

March 8, 2021

### [Amazon RDS extends supports for cross-Region automated backups](#)

You can now configure Amazon RDS database instances running PostgreSQL to replicate DB snapshots and transaction logs to a different AWS Region. For more information, see [Replicating automated backups to another AWS Region](#).

March 8, 2021

[Replication filters for Amazon RDS for MariaDB and MySQL supported in the China \(Beijing\) Region and China \(Ningxia\) Region](#)

Replication filtering is now supported in the China (Beijing) Region and China (Ningxia) Region. For more information, see [Configuring replication filters with MariaDB](#) and [Configuring replication filters with MySQL](#).

March 5, 2021

[Amazon RDS supports cross-Region DB snapshot copy in opt-in Regions](#)

You can now copy DB snapshots to and from opt-in AWS Regions. For more information, see [Copying snapshots across AWS Regions](#).

March 4, 2021

[Amazon RDS for SQL Server supports Always On Availability Groups for Standard Edition](#)

When you create a DB instance using the Multi-AZ configuration on SQL Server 2019 for the Standard Edition database engine, RDS automatically uses Availability Groups. For more information, see [Multi-AZ deployments for Microsoft SQL Server](#).

February 23, 2021

[Amazon RDS for Oracle introduces advisor-related procedures](#)

The `rdsadmin_util` package includes the procedures `advisor_task_set_parameter` , `advisor_task_drop` , and `dbms_stats_init` . You can use these procedures to modify, stop, and re-enable advisor tasks such as `AUTO_STATS_ADVISOR_TASK` . For more information, see [Setting parameters for advisor tasks](#).

February 23, 2021

[Amazon RDS provides failover reasons for Multi-AZ DB instances](#)

You can now see more detailed explanations when a Multi-AZ DB instance fails over to a standby replica. For more information, see [Failover process for Amazon RDS](#).

February 18, 2021

[Amazon RDS extends support for exporting snapshots to Amazon S3](#)

You can now export DB snapshot data to Amazon S3 in China. For more information, see [Exporting DB snapshot data to Amazon S3](#).

February 17, 2021

[Replication filters for Amazon RDS for MariaDB and MySQL](#)

You can configure replication filters for MySQL and MariaDB instances. Replication filters specify which databases and tables are replicated in a read replica. You can create lists of databases and tables to include or exclude for each read replica. For more information, see [Configuring replication filters with MariaDB](#) and [Configuring replication filters with MySQL](#).

February 12, 2021

[RDS for Oracle supports APEX 20.2.v1](#)

You can use APEX 20.2.v1 with all supported versions of Oracle Database. For more information, see [Oracle Application Express](#).

February 2, 2021

[Amazon RDS for SQL Server supports local instance storage for the tempdb database](#)

You can now launch Amazon RDS for SQL Server on Amazon EC2 db.r5d and db.m5d instance types with the tempdb database configured to use an instance store. By placing tempdb data files and log files locally, you can achieve lower read and write latencies when compared to standard storage based on Amazon EBS. For more information, see [Instance store support for the tempdb database on Amazon RDS for SQL Server](#).

January 27, 2021

[Amazon RDS for PostgreSQL supports pg\\_partman and pg\\_cron](#)

Amazon RDS for PostgreSQL now supports the pg\_partman and pg\_cron extensions. For more information on the pg\_partman extension, see [Managing PostgreSQL partitions with the pg\\_partman extension](#). For more information on the pg\_cron extension, see [Scheduling maintenance with the PostgreSQL pg\\_cron extension](#).

January 12, 2021

[Amazon RDS supports publishing the Oracle Management Agent log to Amazon CloudWatch Logs](#)

The Oracle Management Agent log consists of emctl.log, emdctlj.log, gcagent.log, gcagent\_errors.log, emagent.nohup, and secure.log. Amazon RDS publishes each of these logs as a separate CloudWatch log stream. For more information, see [Publishing Oracle logs to Amazon CloudWatch Logs](#).

December 28, 2020

[Amazon RDS on AWS Outposts supports additional database versions](#)

RDS on Outposts now supports additional MySQL and PostgreSQL versions. For more information, see [Amazon RDS on AWS Outposts support for Amazon RDS features](#).

December 23, 2020

[Amazon RDS on AWS Outposts supports CoIPs](#)

RDS on Outposts now supports customer-owned IP addresses (CoIPs). CoIPs provide local or external connectivity to resources in your Outpost subnets through your on-premises network. For more information, see [Customer-owned IP addresses for RDS on Outposts](#).

December 22, 2020

[Amazon RDS for Oracle plans upgrade of 11g BYOL instances to 19c](#)

On January 4, 2021, we plan to begin automatically upgrading all editions of Oracle Database 11g instances on the Bring Your Own License (BYOL) model to Oracle Database 19c. All Oracle Database 11g instances, including reserved instances, will move to the latest available Release Update (RU). For more information, see [Preparing for the automatic upgrade of Oracle Database 11g BYOL](#).

December 11, 2020

[Amazon RDS supports replicating automated backups to another AWS Region](#)

You can now configure your Amazon RDS database instances to replicate snapshots and transaction logs to a destination AWS Region of your choice. For more information, see [Replicating automated backups to another AWS Region](#).

December 4, 2020

[Amazon RDS for Oracle and Microsoft SQL Server support a new DB instance class](#)

You can now use the db.r5b instance class to create Amazon RDS DB instances running Oracle or SQL Server. For more information, see [Supported DB engines for DB instance classes](#).

December 4, 2020

[Support for MariaDB 10.2.32](#)

You can now create Amazon RDS DB instances running MariaDB version 10.2.32. For more information, see [MariaDB on Amazon RDS versions](#).

November 25, 2020

[Amazon RDS for SQL Server supports the Microsoft Business Intelligence Suite on SQL Server 2019](#)

You can now run SQL Server Analysis Services, SQL Server Integration Services, and SQL Server Reporting Services on DB instances using the latest major version. For more information, see [Options for the Microsoft SQL Server database engine](#).

November 24, 2020

[Amazon RDS for PostgreSQL version 13 in the database preview environment](#)

Amazon RDS for PostgreSQL now supports PostgreSQL version 13 in the database preview environment. For more information, see [PostgreSQL 13 versions](#).

November 24, 2020

[Amazon RDS Performance Insights introduces new dimensions](#)

You can group database load according to the dimension groups for database (PostgreSQL, MySQL, and MariaDB), application (PostgreSQL), and session type (PostgreSQL). Amazon RDS also supports the dimensions db.name (PostgreSQL, MySQL, and MariaDB), db.application.name (PostgreSQL), and db.session\_type.name (PostgreSQL). For more information, see [Top load table](#).

November 24, 2020

[Amazon RDS for MariaDB supports a new major version](#)

You can now create Amazon RDS DB instances running MariaDB version 10.5. For more information, see [MariaDB on Amazon RDS versions](#).

November 23, 2020

[Support for MySQL 5.6.49](#)

You can now create Amazon RDS DB instances running MySQL version 5.6.49. For more information, see [MySQL on Amazon RDS versions](#).

November 20, 2020

[Support for MySQL 5.5.62](#)

You can now create Amazon RDS DB instances running MySQL version 5.5.62. For more information, see [MySQL on Amazon RDS versions](#).

November 20, 2020

[Performance Insights supports analyzing statistics for running PostgreSQL queries](#)

You can now analyze statistics for running queries with Performance Insights for PostgreSQL DB instances. For more information, see [Statistics for PostgreSQL](#).

November 18, 2020

[Amazon RDS extends support for storage autoscaling](#)

You can now enable storage autoscaling when creating a read replica, restoring a DB instance to a specified time, or restoring a MySQL DB instance from an Amazon S3 backup. For more information, see [Managing capacity automatically with Amazon RDS storage autoscaling](#).

November 18, 2020

[Amazon RDS for SQL Server supports Database Mail](#)

With Database Mail you can send email messages from your Amazon RDS for SQL Server database instance. After specifying the email recipients, you can add files or query results to the message you send. For more information, see [Using Database Mail on Amazon RDS for SQL Server](#).

November 4, 2020

---

<a href="#">Support for MySQL 8.0.21</a>	You can now create Amazon RDS DB instances running MySQL version 8.0.21. For more information, see <a href="#">MySQL on Amazon RDS versions</a> .	October 22, 2020
<a href="#">Amazon RDS extends support for exporting snapshots to Amazon S3</a>	You can now export DB snapshot data to Amazon S3 in all commercial AWS Regions. For more information, see <a href="#">Exporting DB snapshot data to Amazon S3</a> .	October 22, 2020
<a href="#">Amazon RDS for PostgreSQL supports read replica upgrades</a>	With Amazon RDS for PostgreSQL, when you do a major version upgrade of the primary DB instance, read replicas are also automatically upgraded. For more information, see <a href="#">Upgrading the PostgreSQL DB engine</a> .	October 15, 2020
<a href="#">Amazon RDS for MariaDB, MySQL and PostgreSQL support the Graviton2 DB instance classes</a>	You can now use the Graviton2 DB instance classes db.m6g.x and db.r6g.x to create Amazon RDS DB instances running MariaDB, MySQL or PostgreSQL. For more information, see <a href="#">Supported DB Engines for All Available DB instance Classes</a> .	October 15, 2020

[Amazon RDS for SQL Server supports upgrades to SQL Server 2019](#)

You can upgrade your SQL Server DB instances to SQL Server 2019. For more information, see [Upgrading the Microsoft SQL Server DB Engine](#).

October 6, 2020

[Amazon RDS for Oracle supports specifying the national character set](#)

The national character set, also called the NCHAR character set, is used in the NCHAR, NVARCHAR2, and NLOB data types. When you create a database, you can specify either AL16UTF16 (default) or UTF8 as the NCHAR character set. For more information, see [Oracle character sets supported in Amazon RDS](#).

October 2, 2020

[Support for MySQL 5.7.31](#)

You can now create Amazon RDS DB instances running MySQL version 5.7.31. For more information, see [MySQL on Amazon RDS versions](#).

October 1, 2020

[Amazon RDS for PostgreSQL supports exporting data to Amazon S3](#)

You can query data from a PostgreSQL DB instance and export it directly into files stored in an Amazon S3 bucket. For more information, see [Exporting data from an RDS for PostgreSQL DB instance to Amazon S3](#).

September 24, 2020

[Amazon RDS for MySQL 8.0 supports Percona XtraBackup](#)

You can now use Percona XtraBackup to restore a backup into an Amazon RDS for MySQL 8.0 DB instance. For more information, see [Restoring a backup into a MySQL DB instance](#).

September 17, 2020

[Amazon RDS for SQL Server supports native backup and restore on DB instances with read replicas](#)

You can restore a SQL Server native backup onto a DB instance that has read replicas configured. For more information, see [Importing and exporting SQL Server databases](#).

September 16, 2020

[Amazon RDS for SQL Server supports additional time zones](#)

You can match your DB instance time zone with your chosen time zone. For more information, see [Local time zone for Microsoft SQL Server DB instances](#).

September 11, 2020

[Amazon RDS for PostgreSQL version 13 beta 3 in the database preview environment](#)

Amazon RDS for PostgreSQL now supports PostgreSQL Version 13 Beta 3 in the Database Preview Environment. For more information, see [PostgreSQL 13 versions](#).

September 9, 2020

[Amazon RDS for SQL Server supports trace flag 692](#)

You can now use trace flag 692 as a startup parameter using DB parameter groups. Enabling this trace flag disables fast inserts while bulk loading data into heap or clustered indexes. For more information, see [Disabling fast inserts during bulk loading](#).

August 27, 2020

[Amazon RDS for SQL Server supports Microsoft SQL Server 2019](#)

You can now create RDS DB instances that use SQL Server 2019. For more information, see [Microsoft SQL Server versions on Amazon RDS](#).

August 26, 2020

[RDS for Oracle supports mounted replica database](#)

When creating or modifying an Oracle replica, you can place it in mounted mode. Because the replica database doesn't accept user connections, it can't serve a read-only workload. The mounted replica deletes archived redo log files after it applies them. The primary use for mounted replicas is cross-Region disaster recovery. For more information, see [Overview of Oracle replicas](#).

August 13, 2020

[RDS for Oracle plans upgrade of 11g SE1 LI instances](#)

On November 1, 2020, we plan to begin automatically upgrading Oracle Database 11g SE1 License Included (LI) instances to Oracle Database 19c for Amazon RDS for Oracle. All 11g instances, including reserved instances, will move to the latest available Oracle Release Update (RU). For more information, see [Preparing for the automatic upgrade of Oracle Database 11g SE1](#).

July 31, 2020

[Amazon RDS supports new Graviton2 DB instance classes in preview release for PostgreSQL and MySQL](#)

You can now create Amazon RDS DB instances running PostgreSQL or MySQL that use the db.m6g.x and db.r6g.x DB instance classes. For more information, see [Supported DB engines for all available DB instance classes](#).

July 30, 2020

[RDS for Oracle supports APEX 20.1v1](#)

You can use APEX 20.1v1 with all supported versions of Oracle Database. For more information, see [Oracle application Express](#).

July 28, 2020

[Support for MySQL 8.0.20](#)

You can now create Amazon RDS DB instances running MySQL version 8.0.20. For more information, see [MySQL on Amazon RDS versions](#).

July 23, 2020

[Amazon RDS for MariaDB and MySQL support new DB instance classes](#)

You can now create Amazon RDS DB instances running MariaDB and MySQL that use the db.m5.16xlarge, db.m5.8xlarge, db.r5.16xlarge, and db.r5.8xlarge DB instance classes. For more information, see [Supported DB engines for all available DB instance classes](#).

July 23, 2020

[RDS for SQL Server supports disabling old versions of TLS and ciphers](#)

You can turn certain security protocols and ciphers on and off. For more information, see [Configuring security protocols and ciphers](#).

July 21, 2020

[RDS supports Oracle Spatial on SE2](#)

You can use Oracle Spatial in Standard Edition 2 (SE2) for all versions of 12.2, 18c, and 19c. For more information, see [Oracle Spatial](#).

July 9, 2020

[Amazon RDS supports AWS PrivateLink](#)

Amazon RDS now supports creating Amazon VPC endpoints for Amazon RDS API calls to keep traffic between applications and Amazon RDS in the AWS network. For more information, see [Amazon RDS and interface VPC endpoints \(AWS PrivateLink\)](#).

July 9, 2020

---

<a href="#">Amazon RDS for PostgreSQL versions 9.4.x has reached its end of support.</a>	Amazon RDS for PostgreSQL no longer supports versions 9.4.x. For supported versions, see <a href="#">Supported PostgreSQL database versions</a> .	July 8, 2020
<a href="#">Support for MariaDB 10.3.23 and 10.4.13</a>	You can now create Amazon RDS DB instances running MariaDB version 10.3.23 and 10.4.13. For more information, see <a href="#">MariaDB on Amazon RDS versions</a> .	July 6, 2020
<a href="#">Amazon RDS on AWS Outposts</a>	You can create Amazon RDS DB instances on AWS Outposts. For more information, see <a href="#">Working with Amazon RDS on AWS Outposts</a> .	July 6, 2020
<a href="#">Amazon RDS for Oracle creates inventory files automatically</a>	To open service requests for BYOL customers, Oracle Support requests inventory files generated by Opatch. Amazon RDS for Oracle automatically creates inventory files every hour in the BDUMP directory. For more information, see <a href="#">Accessing Opatch files</a> .	July 6, 2020
<a href="#">Support for MySQL 5.7.30 and 5.6.48</a>	You can now create Amazon RDS DB instances running MySQL version 5.7.30 and 5.6.48. For more information, see <a href="#">MySQL on Amazon RDS versions</a> .	June 25, 2020

### [Amazon RDS for Oracle supports ADRCI](#)

The Automatic Diagnostic Repository Command Interpreter (ADRCI) utility is an Oracle command-line tool that you use to manage diagnostic data. By using the functions in the Amazon RDS package `rdsadmin_adrci_util`, you can list and package problems and incidents, and also show trace files. For more information, see [Common DBA diagnostic tasks for Oracle DB instances](#).

June 17, 2020

### [Support for MySQL 8.0.19](#)

You can now create Amazon RDS DB instances running MySQL version 8.0.19. For more information, see [MySQL on Amazon RDS versions](#).

June 2, 2020

### [MySQL 8.0 supports lower case table names](#)

You can now set the `lower_case_table_names` parameter to 1 for Amazon RDS DB instances running MySQL version 8.0.19 and higher 8.0 versions. For more information, see [MySQL parameter exceptions for Amazon RDS DB instances](#).

June 2, 2020

[Amazon RDS for Microsoft SQL Server supports SQL Server Integration Services \(SSIS\)](#)

SSIS is a platform for data integration and workflow applications. You can enable SSIS on existing or new DB instances. It's installed on the same DB instance as your database engine. For more information, see [Support for SQL Server Integration Services in SQL Server](#).

May 19, 2020

[Amazon RDS for Microsoft SQL Server supports SQL Server Reporting Services \(SSRS\)](#)

SSRS is a server-based application used for report generation and distribution. You can enable SSRS on existing or new DB instances. It's installed on the same DB instance as your database engine. For more information, see [Support for SQL Server Reporting Services in SQL Server](#).

May 15, 2020

[Amazon RDS for Microsoft SQL Server supports S3 integration on Multi-AZ instances](#)

You can now use Amazon S3 with SQL Server features such as bulk insert on Multi-AZ DB instances. For more information, see [Integrating an Amazon RDS for SQL Server DB instance with Amazon S3](#).

May 15, 2020

[Amazon RDS for Oracle supports purging the recycle bin](#)

The `rdsadmin.rdsadmin_util.purge_dba_recyclebin` procedure purges the recycle bin. For more information, see [Purging the recycle bin](#).

May 13, 2020

[Amazon RDS for Oracle improves manageability of Automatic Workload Repository \(AWR\)](#)

The `rdsadmin.rdsadmin_diagnostic_util` procedures generate AWR reports and extract AWR data into dump files. For more information, see [Generating performance reports with Automatic Workload Repository \(AWR\)](#).

May 13, 2020

[Amazon RDS for Microsoft SQL Server supports Microsoft Distributed Transaction Coordinator \(MSDTC\)](#)

Amazon RDS for SQL Server supports distributed transactions between hosts. For more information, see [Support for Microsoft Distributed Transaction Coordinator in SQL Server](#).

May 4, 2020

[Amazon RDS for Microsoft SQL Server supports new versions](#)

You can now create Amazon RDS DB instances running SQL Server versions 2017 CU19 14.00.3281.6, 2016 SP2 CU11 13.00.5598.27, 2014 SP3 CU4 12.00.632 9.1, and 2012 SP4 GDR 11.0.7493.4 for all editions. For more information, see [Microsoft SQL Server versions on Amazon RDS](#).

April 28, 2020

[Amazon RDS available in the Europe \(Milan\) Region](#)

Amazon RDS is now available in the Europe (Milan) Region. For more information, see [Regions and Availability Zones](#).

April 28, 2020

[Amazon RDS support for Local Zones](#)

You can now launch DB instances into a Local Zone subnet. For more information, see [Regions, Availability Zones, and Local Zones](#).

April 23, 2020

[Amazon RDS available in the Africa \(Cape Town\) Region](#)

Amazon RDS is now available in the Africa (Cape Town) Region. For more information, see [Regions and Availability Zones](#).

April 22, 2020

[Amazon RDS for Microsoft SQL Server supports SQL Server Analysis Services \(SSAS\)](#)

SSAS is an online analytical processing (OLAP) and data mining tool that is installed within SQL Server. You can enable SSAS on existing or new DB instances. It's installed on the same DB instance as your database engine. For more information, see [Support for SQL Server Analysis Services in SQL Server](#).

April 17, 2020

[Amazon RDS proxy for PostgreSQL](#)

Amazon RDS Proxy is now available for PostgreSQL. You can use RDS Proxy to reduce the overhead of connection management on your DB instance and also the chance of "too many connections" errors. The RDS Proxy is currently in public preview for PostgreSQL. For more information, see [Managing connections with Amazon RDS proxy \(preview\)](#).

April 8, 2020

[Amazon RDS for Oracle supports Oracle APEX version 19.2.v1](#)

Amazon RDS for Oracle now supports Oracle Application Express (APEX) version 19.2.v1. For more information, see [Oracle application Express](#).

April 8, 2020

[Amazon RDS for MariaDB supports a new major version](#)

You can now create Amazon RDS DB instances running MariaDB version 10.4. For more information, see [MariaDB on Amazon RDS versions](#).

April 6, 2020

[Amazon RDS Performance Insights is available for Amazon RDS for MariaDB 10.4](#)

Amazon RDS Performance Insights is now available for Amazon RDS for MariaDB version 10.4. For more information, see [Using Amazon RDS performance insights](#).

April 6, 2020

[Amazon RDS for PostgreSQL versions 9.3.x has reached its end of support](#)

Amazon RDS for PostgreSQL no longer supports versions 9.3.x. For supported versions, see [Supported PostgreSQL database versions](#).

April 3, 2020

[Amazon RDS for Microsoft SQL Server supports read replicas](#)

You can now create read replicas for SQL Server DB instances. For more information, see [Working with read replicas](#).

April 3, 2020

[Amazon RDS for Microsoft SQL Server supports multifile backups](#)

You can now back up databases to multiple files using SQL Server native backup and restore. For more information, see [Backing up a database](#).

April 2, 2020

[Amazon RDS for Oracle integration with AWS License Manager](#)

Amazon RDS for Oracle is now integrated with AWS License Manager. If you use the Bring Your Own License model, AWS License Manager integration makes it easier to monitor your Oracle license usage within your organization. For more information, see [Integrating with AWS License Manager](#).

March 23, 2020

[Support for 64 TiB on db.r5 instances in Amazon RDS for MariaDB and MySQL](#)

You can now create Amazon RDS DB instances for MariaDB and MySQL that use the db.r5 DB instance class with up to 64 TiB of storage. For more information, see [Factors that affect storage performance](#).

March 18, 2020

[Support for MySQL 8.0.17](#)

You can now create Amazon RDS DB instances running MySQL version 8.0.17. For more information, see [MySQL on Amazon RDS versions](#).

March 10, 2020

[Amazon RDS Performance Insights is available for Amazon RDS for MySQL 8.0](#)

Amazon RDS Performance Insights is now available for Amazon RDS for MySQL version 8.0.17 and higher 8.0 versions. For more information, see [Using Amazon RDS performance insights](#).

March 10, 2020

[Support for MySQL 5.6.46](#)

You can now create Amazon RDS DB instances running MySQL version 5.6.46. For more information, see [MySQL on Amazon RDS versions](#).

February 28, 2020

[Amazon RDS Performance Insights is available for Amazon RDS for MariaDB 10.3](#)

Amazon RDS Performance Insights is now available for Amazon RDS for MariaDB version 10.3.13 and higher 10.3 versions. For more information, see [Using Amazon RDS performance insights](#).

February 26, 2020

[Support for MySQL 5.7.28](#)

You can now create Amazon RDS DB instances running MySQL version 5.7.28. For more information, see [MySQL on Amazon RDS versions](#).

February 20, 2020

[Support for MariaDB 10.3.20](#)

You can now create Amazon RDS DB instances running MariaDB version 10.3.20. For more information, see [MariaDB on Amazon RDS versions](#).

February 20, 2020

[Amazon RDS for Microsoft SQL Server supports a new DB instance class](#)

You can now create Amazon RDS DB instances running SQL Server that use the db.z1d DB instance class. For more information, see [DB instance class support for Microsoft SQL Server](#).

February 19, 2020

[Support for cross-account, cross-VPC Active Directory domains in Amazon RDS for SQL Server](#)

Amazon RDS for Microsoft SQL Server now supports associating DB instances with Active Directory domains owned by different accounts and VPCs. For more information, see [Using Windows authentication with a Microsoft SQL Server DB instance](#).

February 13, 2020

[Oracle OLAP option](#)

Amazon RDS for Oracle now supports the On-line Analytical Processing (OLAP) option for Oracle DB instances. You can use Oracle OLAP to analyze large amounts of data by creating dimensional objects and cubes in accordance with the OLAP standard. For more information, see [Oracle OLAP](#).

February 13, 2020

[FIPS 140-2 support for Oracle](#)

Amazon RDS for Oracle supports the Federal Information Processing Standard Publication 140-2 (FIPS 140-2) for SSL/TLS connections. For more information, see [FIPS support](#).

February 11, 2020

[Amazon RDS for PostgreSQL supports new DB instance classes](#)

You can now create Amazon RDS DB instances running PostgreSQL that use the db.m5.16xlarge, db.m5.8xlarge, db.r5.16xlarge, and db.r5.8xlarge DB instance classes. For more information, see [Supported DB engines for all available DB instance classes](#).

February 11, 2020

[Performance Insights supports analyzing statistics of running MariaDB and MySQL queries](#)

You can now analyze statistics of running queries with Performance Insights for MariaDB and MySQL DB instances. For more information, see [Analyzing statistics of running queries](#).

February 4, 2020

[Support for exporting DB snapshot data to Amazon S3 for MariaDB, MySQL, and PostgreSQL](#)

Amazon RDS supports exporting DB snapshot data to Amazon S3 for MariaDB, MySQL, and PostgreSQL. For more information, see [Exporting DB snapshot data to Amazon S3](#).

January 23, 2020

[Amazon RDS for MySQL supports Kerberos authentication](#)

You can now use Kerberos authentication to authenticate users when they connect to your Amazon RDS for MySQL DB instances. For more information, see [Using Kerberos authentication for MySQL](#).

January 21, 2020

[Amazon RDS Performance Insights supports viewing more SQL text for Amazon RDS for Microsoft SQL Server](#)

Amazon RDS Performance Insights now supports viewing more SQL text in the Performance Insights dashboard for Amazon RDS for Microsoft SQL Server DB instances. For more information, see [Viewing more SQL text in the Performance Insights dashboard](#).

December 17, 2019

[Amazon RDS proxy](#)

You can reduce the overhead of connection management on your cluster, and reduce the chance of "too many connections" errors, by using the Amazon RDS Proxy. You associate each proxy with an RDS DB instance or Aurora DB cluster. Then you use the proxy endpoint in the connection string for your application. The Amazon RDS Proxy is currently in a public preview state. It supports the RDS for MySQL database engine. For more information, see [Managing connections with Amazon RDS proxy \(preview\)](#).

December 3, 2019

[Amazon RDS on AWS Outposts \(preview\)](#)

With Amazon RDS on AWS Outposts, you can create AWS-managed relational databases in your on-premises data centers. RDS on Outposts enables you to run RDS databases on AWS Outposts. For more information, see [Amazon RDS on AWS Outposts \(preview\)](#).

December 3, 2019

[Amazon RDS for Oracle supports cross-region read replicas](#)

Amazon RDS for Oracle now supports cross-region read replicas with Active Data Guard. For more information, see [Working with read replicas](#) and [Working with Oracle read replicas](#).

November 26, 2019

[Performance Insights supports analyzing statistics of running Oracle queries](#)

You can now analyze statistics of running queries with Performance Insights for Oracle DB instances. For more information, see [Analyzing statistics of running queries](#).

November 25, 2019

[Amazon RDS for Microsoft SQL Server supports publishing logs to CloudWatch Logs](#)

You can configure your Amazon RDS for SQL Server DB instance to publish log events directly to Amazon CloudWatch Logs. For more information, see [Publishing SQL Server logs to Amazon CloudWatch Logs](#).

November 25, 2019

[Amazon RDS for Microsoft SQL Server supports new DB instance classes](#)

You can now create Amazon RDS DB instances running SQL Server that use the db.x1e and db.x1 DB instance classes. For more information, see [DB instance class support for Microsoft SQL Server](#).

November 25, 2019

[Amazon RDS for Microsoft SQL Server supports differential and log restores](#)

You can restore differential backups and logs using SQL Server native backup and restore. For more information, see [Using native backup and restore](#).

November 25, 2019

[Multi-AZ supported on Amazon RDS for Microsoft SQL Server in new regions](#)

Multi-AZ on SQL Server is now available in China, Middle East (Bahrain), and Europe (Stockholm). For more information, see [Multi-AZ deployments for Microsoft SQL Server](#).

November 22, 2019

[Amazon RDS for Microsoft SQL Server now supports bulk insert and S3 integration](#)

You can transfer files between a SQL Server DB instance and an Amazon S3 bucket. Then you can use Amazon S3 with SQL Server features such as bulk insert. For more information, see [Integrating an Amazon RDS for SQL Server DB instance with Amazon S3](#).

November 21, 2019

[Performance Insights counters for Amazon RDS for Microsoft SQL Server](#)

You can now add performance counters to your Performance Insights charts for Microsoft SQL Server DB instances. For more information, see [Performance Insights counters for Amazon RDS for Microsoft SQL Server](#).

November 12, 2019

[Amazon RDS for Microsoft SQL Server supports new DB instance class sizes](#)

You can now create Amazon RDS DB instances running SQL Server that use the 8xlarge and 16xlarge instance sizes for the db.m5 and db.r5 DB instance classes. Instance sizes ranging from small to 2xlarge are now available for the db.t3 instance class. For more information, see [DB instance class support for Microsoft SQL Server](#).

November 11, 2019

[Support for PostgreSQL snapshot upgrades](#)

If you have existing manual DB snapshots of your Amazon RDS PostgreSQL DB instances, you can now upgrade them to a later version of the PostgreSQL database engine. For more information, see [Upgrading a PostgreSQL DB snapshot](#).

November 7, 2019

[Amazon RDS for Oracle supports a new major version](#)

You can now create Amazon RDS DB instances running Oracle Database 19c (19.0). For more information, see [Oracle Database 19c with Amazon RDS](#).

November 7, 2019

[Amazon RDS for PostgreSQL version 12.0 in the database preview environment](#)

Amazon RDS for PostgreSQL now supports PostgreSQL Version 12.0 in the Database Preview Environment. For more information, see [PostgreSQL version 12.0 in the database preview environment](#).

November 1, 2019

[Amazon RDS for PostgreSQL supports Kerberos authentication](#)

You can now use Kerberos authentication to authenticate users when they connect to your Amazon RDS DB instance running PostgreSQL. For more information, see [Using Kerberos authentication with Amazon RDS for PostgreSQL](#).

October 28, 2019

[OEM Management Agent database tasks for Oracle DB instances](#)

Amazon RDS for Oracle DB instances now support procedures to invoke certain EMCTL commands on the Management Agent. For more information, see [OEM agent database tasks](#).

October 24, 2019

[Amazon RDS for PostgreSQL supports PostgreSQL transportable databases](#)

PostgreSQL Transportable Databases provide an extremely fast method of migrating an RDS PostgreSQL database between two DB instances. For more information, see [Transporting PostgreSQL databases between DB instances](#).

October 8, 2019

[Amazon RDS for Oracle supports Kerberos authentication](#)

You can now use Kerberos authentication to authenticate users when they connect to your Amazon RDS DB instance running Oracle. For more information, see [Using Kerberos authentication with Amazon RDS for Oracle](#).

September 30, 2019

[Amazon RDS for PostgreSQL version 12 beta 3 in the database preview environment](#)

Amazon RDS for PostgreSQL now supports PostgreSQL Version 12 Beta 3 in the Database Preview Environment. For more information, see [PostgreSQL version 12 beta 3 on Amazon RDS in the database preview environment](#).

August 28, 2019

[Support for MySQL 8.0.16](#)

You can now create Amazon RDS DB instances running MySQL version 8.0.16. For more information, see [MySQL on Amazon RDS versions](#).

August 19, 2019

[Amazon RDS for Oracle supports a new major version](#)

You can now create Amazon RDS DB instances running Oracle Database 18c (18.0). For more information, see [Oracle Database 18c with Amazon RDS](#).

August 15, 2019

[Management Agent for OEM 13c release 3](#)

Amazon RDS for Oracle DB instances now support the Management Agent for Oracle Enterprise Manager (OEM) Cloud Control 13c Release 3. For more information, see [Oracle Management Agent for Enterprise Manager cloud control](#).

August 7, 2019

[Amazon RDS for PostgreSQL version 12 beta 2 in the database preview environment](#)

Amazon RDS for PostgreSQL now supports PostgreSQL Version 12 Beta 2 in the Database Preview Environment. For more information, see [PostgreSQL version 12 beta 2 on Amazon RDS in the database preview environment](#).

August 6, 2019

[Amazon RDS supports server collations for SQL Server](#)

Amazon RDS for SQL Server supports a selection of collations for new DB instances. For more information, see [Collations and character sets for Microsoft SQL Server](#).

July 29, 2019

[Amazon RDS for Oracle supports Oracle APEX version 19.1.v1](#)

Amazon RDS for Oracle now supports Oracle Application Express (APEX) version 19.1.v1. For more information, see [Oracle application Express](#).

June 28, 2019

[Amazon RDS for PostgreSQL version 13 beta 1 in the database preview environment](#)

Amazon RDS for PostgreSQL now supports PostgreSQL Version 13 Beta 1 in the Database Preview Environment. For more information, see [PostgreSQL 13 versions](#).

June 22, 2019

[Amazon RDS storage autoscaling](#)

Storage autoscaling for Amazon RDS DB instances enables Amazon RDS to automatically expand the storage associated with a DB instance to reduce the chance of out-of-space conditions. For information about storage autoscaling, see [Working with storage for Amazon RDS DB instances](#).

June 20, 2019

[Amazon RDS for Oracle supports db.z1d DB instance classes](#)

You can now create Amazon RDS DB instances running Oracle that use the db.z1d DB instance classes. For more information, see [DB instance class](#).

June 13, 2019

[Amazon RDS Performance Insights supports viewing more SQL text for Amazon RDS for Oracle](#)

Amazon RDS Performance Insights now supports viewing more SQL text in the Performance Insights dashboard for Amazon RDS for Oracle DB instances. For more information, see [Viewing more SQL text in the Performance Insights dashboard](#).

June 10, 2019

[Amazon RDS adds support native restores of SQL Server databases up to 16 TB](#)

You can now do native restores of up to 16 TB from SQL Server to Amazon RDS. For more information, see [Amazon RDS for SQL Server: Limitations and recommendations](#).

June 4, 2019

[Amazon RDS adds support for Microsoft SQL Server audit](#)

Using Amazon RDS for Microsoft SQL Server, you can audit server and database level events using SQL Server Audit, and view the results on your DB instance or send the audit log files directly to Amazon S3. For more information, see [SQL Server Audit](#).

May 23, 2019

[Improvements to Amazon RDS recommendations](#)

Amazon RDS has improved its automated recommendations for database resources. For example, Amazon RDS now provides recommendations for database parameters. For more information, see [Using Amazon RDS recommendations](#).

May 22, 2019

[Support for more databases per DB instance for Amazon RDS for SQL Server](#)

You can create up to 30 databases on each of your DB instances running Microsoft SQL Server. For more information, see [Limits for Microsoft SQL Server DB instances](#).

May 21, 2019

[Support for 64 TiB and 80k IOPS of storage for Amazon RDS for MariaDB, MySQL and PostgreSQL](#)

You can now create Amazon RDS DB instances for MariaDB, MySQL and PostgreSQL with up to 64 TiB of storage and up to 80,000 provisioned IOPS. For more information, see [DB instance storage](#).

May 20, 2019

[Amazon RDS for MySQL supports upgrade prechecks](#)

When you upgrade a DB instance from MySQL 5.7 to MySQL 8.0, Amazon RDS performs prechecks for incompatibilities. For more information, see [Prechecks for upgrades from MySQL 5.7 to 8.0](#).

May 17, 2019

[Support for the MySQL password validation plugin](#)

You can now use the MySQL `validate_password` plugin for improved security of Amazon RDS for MySQL DB instances. For more information, see [Using the Password Validation Plugin](#).

May 16, 2019

[Performance Insights counters for Amazon RDS for Oracle](#)

You can now add performance counters to your Performance Insights charts for Oracle DB instances. For more information, see [Performance Insights counters for Amazon RDS for Oracle](#).

May 8, 2019

[Support for per-second billing](#)

Amazon RDS is now billed in 1-second increments in all AWS Regions except AWS GovCloud (US) for on-demand instances. For more information, see [DB instance billing for Amazon RDS](#).

April 25, 2019

[Support for importing data from Amazon S3 for Amazon RDS for PostgreSQL](#)

You can now import data from Amazon S3 file into a table in an RDS PostgreSQL DB instance. For more information, see [Importing Amazon S3 data into an RDS PostgreSQL DB instance](#).

April 24, 2019

[Support for restoring 5.7 backups from Amazon S3](#)

You can now create a backup of your MySQL version 5.7 database, store it on Amazon S3, and then restore the backup file onto a new Amazon RDS DB instance running MySQL. For more information, see [Restoring a backup into a MySQL DB instance](#).

April 17, 2019

[Support for multiple major version upgrades for Amazon RDS for PostgreSQL](#)

With Amazon RDS for PostgreSQL, you can now choose from multiple major versions when you upgrade the DB engine. This feature enables you to skip ahead to a newer major version when you upgrade select PostgreSQL engine versions. For more information, see [Upgrading the PostgreSQL DB engine](#).

April 16, 2019

[Support for 64 TiB of storage for Amazon RDS for Oracle](#)

You can now create Amazon RDS DB instances for Oracle with up to 64 TiB of storage and up to 80,000 provisioned IOPS. For more information, see [DB instance storage](#).

April 4, 2019

[Support for MySQL 8.0.15](#)

You can now create Amazon RDS DB instances running MySQL version 8.0.15. For more information, see [MySQL on Amazon RDS versions](#).

April 3, 2019

[Support for MariaDB 10.3.13](#)

You can now create Amazon RDS DB instances running MariaDB version 10.3.13. For more information, see [MariaDB on Amazon RDS versions](#).

April 3, 2019

[Microsoft SQL Server 2008 R2 has reached its end of support on Amazon RDS](#)

Microsoft SQL Server 2008 R2 has reached its end of support, coinciding with the Microsoft plan to end extended support for this version on July 9, 2019. Any existing Microsoft SQL Server 2008 R2 snapshots are to be automatically upgraded to the latest minor version of Microsoft SQL Server 2012 starting on June 1, 2019. For more information, see [Microsoft SQL Server 2008 R2 support on Amazon RDS](#).

April 2, 2019

[Always On availability groups supported in Microsoft SQL Server 2017](#)

You can now use Always On Availability Groups in SQL Server 2017 Enterprise Edition 14.00.3049.1 or later. For more information, see [Multi-AZ deployments for Microsoft SQL Server](#).

March 29, 2019

---

<a href="#">View volume metrics</a>	You can now view metrics for the Amazon Elastic Block Store (Amazon EBS) volumes, which are the physical devices used for database and log storage. For more information, see <a href="#">Viewing Enhanced Monitoring</a> .	March 20, 2019
<a href="#">Support for MySQL 5.7.25</a>	You can now create Amazon RDS DB instances running MySQL version 5.7.25. For more information, see <a href="#">MySQL on Amazon RDS versions</a> .	March 19, 2019
<a href="#">Amazon RDS for Oracle supports RMAN DBA tasks</a>	Amazon RDS for Oracle now supports Oracle Recovery Manager (RMAN) DBA tasks, including RMAN backups. For more information, see <a href="#">Common DBA Recovery Manager (RMAN) tasks for Oracle DB instances</a> .	March 14, 2019
<a href="#">Amazon RDS for PostgreSQL supports version 11.1</a>	You can now create Amazon RDS DB instances running PostgreSQL version 11.1. For more information, see <a href="#">PostgreSQL version 11.1 on Amazon RDS</a> .	March 12, 2019
<a href="#">Multiple-file restore is available in Amazon RDS for SQL Server</a>	You can now restore from multiple files with Amazon RDS for SQL Server. For more information, see <a href="#">Restoring a database</a> .	March 11, 2019

[MariaDB 10.2.21](#)

You can now create Amazon RDS DB instances running MariaDB version 10.2.21. For more information, see [MariaDB on Amazon RDS versions](#).

March 11, 2019

[Amazon RDS for Oracle supports read replicas](#)

Amazon RDS for Oracle now supports read replicas with Active Data Guard. For more information, see [Working with read replicas](#) and [Working with Oracle read replicas](#).

March 11, 2019

[Amazon RDS Performance Insights is available for Amazon RDS for MariaDB](#)

Amazon RDS Performance Insights is now available for Amazon RDS for MariaDB. For more information, see [Using Amazon RDS Performance Insights](#).

March 11, 2019

[MySQL 8.0.13 and 5.7.24](#)

You can now create Amazon RDS DB instances running MySQL versions 8.0.13 and 5.7.24. For more information, see [MySQL on Amazon RDS versions](#).

March 8, 2019

[Amazon RDS Performance Insights is available for Amazon RDS for SQL Server](#)

Amazon RDS Performance Insights is now available for Amazon RDS for SQL Server. For more information, see [Using Amazon RDS Performance Insights](#).

March 4, 2019

[Amazon RDS for Oracle supports Amazon S3 integration](#)

You can now transfer files between an Amazon RDS for Oracle DB instance and an Amazon S3 bucket. For more information, see [Integrating Amazon RDS for Oracle and Amazon S3](#).

February 26, 2019

[Amazon RDS for MySQL and Amazon RDS for MariaDB support db.t3 DB instance classes](#)

You can now create Amazon RDS DB instances running MySQL or MariaDB that use the db.t3 DB instance classes. For more information, see [DB instance class](#).

February 20, 2019

[Amazon RDS for MySQL and Amazon RDS for MariaDB support db.r5 DB instance classes](#)

You can now create Amazon RDS DB instances running MySQL or MariaDB that use the db.r5 DB instance classes. For more information, see [DB instance class](#).

February 20, 2019

[Performance Insights counters for RDS for MySQL and PostgreSQL](#)

You can now add performance counters to your Performance Insights charts for MySQL and PostgreSQL DB instances. For more information, see [Performance Insights dashboard components](#).

February 19, 2019

[Amazon RDS for PostgreSQL now supports adaptive autovacuum parameter tuning](#)

Adaptive autovacuum parameter tuning with Amazon RDS for PostgreSQL helps prevent transaction ID wraparound by adjusting autovacuum parameter values automatically. For more information, see [Reducing the likelihood of transaction ID wraparound](#).

February 12, 2019

[Amazon RDS for Oracle supports Oracle APEX versions 18.1.v1 and 18.2.v1](#)

Amazon RDS for Oracle now supports Oracle Application Express (APEX) versions 18.1.v1 and 18.2.v1. For more information, see [Oracle application Express](#).

February 11, 2019

[Amazon RDS Performance Insights supports viewing more SQL text for RDS for MySQL](#)

Amazon RDS Performance Insights now supports viewing more SQL text in the Performance Insights dashboard for MySQL DB instances. For more information, see [Viewing more SQL text in the Performance Insights dashboard](#).

February 6, 2019

[Amazon RDS for PostgreSQL supports db.t3 DB instance classes](#)

You can now create Amazon RDS DB instances running PostgreSQL that use the db.t3 DB instance classes. For more information, see [DB instance class](#).

January 25, 2019

[Amazon RDS for Oracle supports db.t3 DB instance classes](#)

You can now create Amazon RDS DB instances running Oracle that use the db.t3 DB instance classes. For more information, see [DB instance class](#).

January 25, 2019

[Amazon RDS Performance Insights supports viewing more SQL text for Amazon RDS PostgreSQL](#)

Amazon RDS Performance Insights now supports viewing more SQL text in the Performance Insights dashboard for Amazon RDS PostgreSQL DB instances. For more information, see [Viewing more SQL text in the Performance Insights dashboard](#).

January 24, 2019

[Amazon RDS for Oracle supports a new version of SQLT](#)

Amazon RDS for Oracle now supports SQLT version 12.2.180725. For more information, see [Oracle SQLT](#).

January 22, 2019

[Amazon RDS for PostgreSQL supports db.r5 DB instance classes](#)

You can now create Amazon RDS DB instances running PostgreSQL that use the db.r5 DB instance classes. For more information, see [DB instance class](#).

December 19, 2018

[Amazon RDS for PostgreSQL now supports restricted password management](#)

Amazon RDS for PostgreSQL enables you to restrict who can manage user passwords and password expiration changes by using the parameter `rds.restrict_password_commands` and the role `rds_password`. For more information, see [Restricting password management](#).

December 19, 2018

[Amazon RDS for PostgreSQL supports uploading database logs to Amazon CloudWatch Logs](#)

Amazon RDS for PostgreSQL supports uploading database logs to CloudWatch Logs. For more information, see [Publishing PostgreSQL logs to CloudWatch Logs](#).

December 10, 2018

[Amazon RDS for Oracle supports db.r5 DB instance classes](#)

You can now create Amazon RDS DB instances running Oracle that use the db.r5 DB instance classes. For more information, see [DB instance class](#).

November 20, 2018

[Retain backups when deleting a DB instance](#)

Amazon RDS supports retaining automated backups when you delete a DB instance. For more information, see [Working with backups](#).

November 15, 2018

[Amazon RDS for PostgreSQL supports db.m5 DB instance classes](#)

You can now create Amazon RDS DB instances running PostgreSQL that use the db.m5 DB instance classes. For more information, see [DB instance class](#).

November 15, 2018

[Amazon RDS for Oracle supports a new major version](#)

You can now create Amazon RDS DB instances running Oracle version 12.2.

November 13, 2018

[Amazon RDS for SQL Server supports Always On](#)

Amazon RDS for SQL Server supports Always On Availability Groups. For more information, see [Multi-AZ deployments for Microsoft SQL Server](#).

November 8, 2018

[Amazon RDS for PostgreSQL supports outbound network access using custom DNS servers](#)

Amazon RDS for PostgreSQL supports outbound network access using custom DNS servers. For more information, see [Using a custom DNS server for outbound network access](#).

November 8, 2018

[Amazon RDS for MariaDB, MySQL, and PostgreSQL supports 32 TiB of storage](#)

You can now create Amazon RDS DB instances with up to 32 TiB of storage for MySQL, MariaDB, and PostgreSQL. For more information, see [DB instance storage](#).

November 7, 2018

[Amazon RDS for Oracle supports extended data types](#)

You can now enable extended data types on Amazon RDS DB instances running Oracle. With extended data types, the maximum size is 32,767 bytes for the VARCHAR2, NVARCHAR2, and RAW data types. For more information, see [Using extended data types](#).

November 6, 2018

[Amazon RDS for Oracle supports db.m5 DB instance classes](#)

You can now create Amazon RDS DB instances running Oracle that use the db.m5 DB instance classes. For more information, see [DB instance class](#).

November 2, 2018

[Amazon RDS for Oracle migration from SE, SE1, or SE2 to EE](#)

You can now migrate from any Oracle Database Standard Edition (SE, SE1, or SE2) to Oracle Database Enterprise Edition (EE). For more information, see [Migrating between Oracle editions](#).

October 31, 2018

[Amazon RDS can now stop Multi-AZ instances](#)

Amazon RDS can now stop a DB instance that is part of a Multi-AZ deployment. Formerly, the stop instance feature had a limitation for multi-AZ instances. For more information, see [Stopping an Amazon RDS DB instance temporarily](#).

October 29, 2018

[Amazon RDS Performance Insights is available for Amazon RDS for Oracle](#)

Amazon RDS Performance Insights is now available for Amazon RDS for Oracle. For more information, see [Using Amazon RDS Performance Insights](#).

October 29, 2018

[Amazon RDS for PostgreSQL supports PostgreSQL version 11 in the database preview environment](#)

Amazon RDS for PostgreSQL now supports PostgreSQL version 11 in the Database Preview Environment. For more information, see [PostgreSQL version 11 on Amazon RDS in the database preview environment](#).

October 25, 2018

[MySQL supports a new major version](#)

You can now create Amazon RDS DB instances running MySQL version 8.0. For more information, see [MySQL on Amazon RDS versions](#).

October 23, 2018

[MariaDB supports a new major version](#)

You can now create Amazon RDS DB instances running MariaDB version 10.3. For more information, see [MariaDB on Amazon RDS versions](#).

October 23, 2018

[Amazon RDS for Oracle supports Oracle JVM](#)

Amazon RDS for Oracle now supports the Oracle Java Virtual Machine (JVM) option. For more information, see [Oracle Java virtual machine](#).

October 16, 2018

[Custom parameter group for restore and point in time recovery](#)

You can now specify a custom parameter group when you restore a snapshot or perform a point in time recovery operation. For more information, see [Restoring from a DB snapshot](#) and [Restoring a DB instance to a specified time](#).

October 15, 2018

[Amazon RDS for Oracle supports 32 TiB storage](#)

You can now create Oracle RDS DB instances with up to 32 TiB of storage. For more information, see [DB instance storage](#).

October 15, 2018

[Amazon RDS for MySQL supports GTIDs](#)

Amazon RDS for MySQL now supports global transaction identifiers (GTIDs), which are unique across all DB instances and in a replication configuration. For more information, see [Using GTID-based replication for RDS for MySQL](#).

October 10, 2018

[MySQL 5.7.23, 5.6.41, and 5.5.61](#)

You can now create Amazon RDS DB instances running MySQL versions 5.7.23, 5.6.41, and 5.5.61. For more information, see [MySQL on Amazon RDS versions](#).

October 8, 2018

[Amazon RDS for Oracle supports a new version of SQLT](#)

Amazon RDS for Oracle now supports SQLT version 12.2.180331. For more information, see [Oracle SQLT](#).

October 4, 2018

---

<a href="#">Amazon RDS for PostgreSQL now supports IAM authentication</a>	Amazon RDS for PostgreSQL now supports IAM authentication. For more information see <a href="#">IAM database authentication for MySQL and PostgreSQL</a> .	September 27, 2018
<a href="#">You can enable deletion protection for your Amazon RDS DB instances</a>	When you enable deletion protection for a DB instance, the database cannot be deleted by any user. For more information, see <a href="#">Deleting a DB instance</a> .	September 26, 2018
<a href="#">Amazon RDS for MySQL and Amazon RDS for MariaDB support db.m5 DB instance classes</a>	You can now create Amazon RDS DB instances running MySQL or MariaDB that use the db.m5 DB instance classes. For more information, see <a href="#">DB instance class</a> .	September 18, 2018
<a href="#">Amazon RDS now supports upgrades to SQL Server 2017</a>	You can upgrade your existing DB instance to SQL Server 2017 from any version except SQL Server 2008. To upgrade from SQL Server 2008, first upgrade to one of the other versions first. For information, see <a href="#">Upgrading the Microsoft SQL Server DB engine</a> .	September 11, 2018

[Amazon RDS for PostgreSQL now supports PostgreSQL version 11 beta 3 in the database preview environment](#)

In this release, the Write-Ahead Log (WAL) segment size (`wal_segment_size`) is now set to 64MB. For more about PostgreSQL version 11 Beta 3, see [PostgreSQL 11 beta 3 released](#). For information on the Database Preview Environment, see [Working with the database preview environment](#).

September 7, 2018

[Amazon Aurora User Guide](#)

The [Amazon Aurora User Guide](#) describes all Amazon Aurora concepts and provides instructions on using the various features with both the console and the command line interface. The *Amazon RDS User Guide* now covers non-Aurora database engines.

August 31, 2018

[Amazon RDS Performance Insights is available for RDS for MySQL](#)

Amazon RDS Performance Insights is now available for RDS for MySQL. For more information, see [Using Amazon RDS Performance Insights](#).

August 28, 2018

[Aurora PostgreSQL-Compatible Edition now supports Aurora Auto Scaling](#)

Auto Scaling of Aurora replicas is now available for Aurora PostgreSQL-Compatible Edition. For more information, see [Amazon Aurora auto scaling with Aurora replicas](#).

August 16, 2018

[Aurora Serverless for Aurora MySQL](#)

Aurora Serverless is an on-demand, autoscaling configuration for Amazon Aurora. For more information, see [Using Amazon Aurora Serverless](#).

August 9, 2018

[MySQL 5.7.22 and 5.6.40](#)

You can now create Amazon RDS DB instances running MySQL versions 5.7.22 and 5.6.40. For more information, see [MySQL on Amazon RDS versions](#).

August 6, 2018

[Aurora is now available in the China \(Ningxia\) region](#)

Aurora MySQL and Aurora PostgreSQL are now available in the China (Ningxia) region. For more information, see [Availability for Amazon Aurora MySQL](#) and [Availability for Amazon Aurora PostgreSQL](#).

August 6, 2018

[Amazon RDS for MySQL supports delayed replication](#)

Amazon RDS for MySQL now supports delayed replication as a strategy for disaster recovery. For more information, see [Configuring delayed replication with MySQL](#).

August 6, 2018

[Amazon RDS Performance Insights is available for Aurora MySQL](#)

Amazon RDS Performance Insights is now available for Aurora MySQL. For more information, see [Using Amazon RDS Performance Insights](#).

August 6, 2018

<a href="#">Amazon RDS Performance Insights integration with Amazon CloudWatch</a>	Amazon RDS Performance Insights automatically publishes metrics to Amazon CloudWatch. For more information, see <a href="#">Performance Insights metrics published to CloudWatch</a> .	August 6, 2018
<a href="#">Amazon RDS recommendations</a>	Amazon RDS now provides automated recommendations for database resources. For more information, see <a href="#">Using Amazon RDS recommendations</a> .	July 25, 2018
<a href="#">Incremental snapshot copies across AWS Regions</a>	Amazon RDS supports incremental snapshot copies across AWS Regions for both unencrypted and encrypted instances. For more information, see <a href="#">Copying snapshots across AWS Regions</a> .	July 24, 2018
<a href="#">Amazon RDS Performance Insights is available for Amazon RDS for PostgreSQL</a>	Amazon RDS Performance Insights is now available for Amazon RDS for PostgreSQL. For more information, see <a href="#">Using Amazon RDS Performance Insights</a> .	July 18, 2018
<a href="#">Amazon RDS for Oracle supports Oracle APEX version 5.1.4.v1</a>	Amazon RDS for Oracle now supports Oracle Application Express (APEX) version 5.1.4.v1. For more information, see <a href="#">Oracle application Express</a> .	July 10, 2018

[Amazon RDS for Oracle supports publishing logs to Amazon CloudWatch Logs](#)

Amazon RDS for Oracle now supports publishing alert, audit, trace, and listener log data to a log group in CloudWatch Logs. For more information, see [Publishing Oracle logs to Amazon CloudWatch Logs](#).

July 9, 2018

[MariaDB 10.2.15, 10.1.34, and 10.0.35](#)

You can now create Amazon RDS DB instances running MariaDB versions 10.2.15, 10.1.34, and 10.0.35. For more information, see [MariaDB on Amazon RDS versions](#).

July 5, 2018

[Aurora PostgreSQL 1.2 is available and compatible with PostgreSQL 9.6.8](#)

Aurora PostgreSQL 1.2 is now available and is compatible with PostgreSQL 9.6.8. For more information, see [Version 1.2](#).

June 27, 2018

[Read replicas for Amazon RDS PostgreSQL support Multi-AZ deployments](#)

RDS read replicas in Amazon RDS PostgreSQL now support multiple Availability Zones. For more information, see [Working with PostgreSQL read replicas](#).

June 25, 2018

[Performance Insights available for Aurora PostgreSQL](#)

Performance Insights is generally available for Aurora PostgreSQL, with support for extended retention of performance data. For more information, see [Using Amazon RDS performance insights](#).

June 21, 2018

[Aurora PostgreSQL available in western US \(northern California\) region](#)

Aurora PostgreSQL is now available in the western United States (Northern California) region. For more information, see [Availability for Amazon Aurora PostgreSQL](#).

June 11, 2018

[Amazon RDS for Oracle now supports CPU configuration](#)

Amazon RDS for Oracle supports configuring the number of CPU cores and the number of threads for each core for the processor of a DB instance class. For more information, see [Configuring the processor of the DB instance class](#).

June 5, 2018

## Earlier updates

The following table describes the important changes in each release of the *Amazon RDS User Guide* before June 2018.

Change	Description	Date changed
Amazon RDS for PostgreSQL now supports PostgreSQL Version 11 Beta 1 in the Database Preview Environment	<p>PostgreSQL version 11 Beta 1 contains several improvements that are described in <a href="#">PostgreSQL 11 beta 1 released!</a></p> <p>For information on the Database Preview Environment, see <a href="#">Working with the Database Preview environment.</a></p>	May 31, 2018
Amazon RDS for Oracle now supports TLS versions 1.0 and 1.2	Amazon RDS for Oracle supports Transport Layer Security (TLS) versions 1.0 and 1.2. For more information, see <a href="#">TLS versions for the Oracle SSL option.</a>	May 30, 2018
Aurora MySQL supports publishing logs to Amazon CloudWatch Logs	Aurora MySQL now supports publishing general, slow, audit, and error log data to a log group in CloudWatch Logs. For more information, see <a href="#">Publishing Aurora MySQL to CloudWatch Logs.</a>	May 23, 2018
Database Preview Environment for Amazon RDS PostgreSQL	You can now launch a new instance of Amazon RDS PostgreSQL in a preview mode. For more information about the Database Preview Environment see, <a href="#">Working with the Database Preview environment.</a>	May 22, 2018
Amazon RDS for Oracle DB instances support new DB instance classes	Oracle DB instances now support the db.x1e and db.x1 DB instance classes. For more information, see <a href="#">DB instance classes</a> and <a href="#">RDS for Oracle DB instance classes.</a>	May 22, 2018
Amazon RDS PostgreSQL now supports	You can now use postgres_fdw to connect to a remote server from a read replica. For more information see, <a href="#">Using the postgres_fdw extension to access external data.</a>	May 17, 2018

Change	Description	Date changed
postgres_fdw on a read replica.		
Amazon RDS for Oracle now supports setting sqlnet.ora parameters	You can now set sqlnet.ora parameters with Amazon RDS for Oracle. For more information, see <a href="#">Modifying connection properties using sqlnet.ora parameters</a> .	May 10, 2018
Aurora PostgreSQL available in Asia Pacific (Seoul) region.	Aurora PostgreSQL is now available in the Asia Pacific (Seoul) region. For more information, see <a href="#">Availability for Amazon Aurora PostgreSQL</a> .	May 9, 2018
Aurora MySQL supports backtracking	Aurora MySQL now supports "rewinding" a DB cluster to a specific time, without restoring data from a backup. For more information, see <a href="#">Backtracking an Aurora DB cluster</a> .	May 9, 2018
Aurora MySQL supports encrypted migration and replication from external MySQL	Aurora MySQL now supports encrypted migration and replication from an external MySQL database. For more information, see <a href="#">Migrating data from an external MySQL database to an Amazon Aurora MySQL DB cluster</a> and <a href="#">Replication between Aurora and MySQL or between Aurora and another Aurora DB cluster</a> .	April 25, 2018
Aurora PostgreSQL-Compatible Edition support for the Copy-on-Write protocol.	You can now clone databases in an Aurora PostgreSQL database cluster. For more information see, <a href="#">Cloning databases in an Aurora DB cluster</a> .	April 10, 2018

Change	Description	Date changed
MariaDB 10.2.12, 10.1.31, and 10.0.34	You can now create Amazon RDS DB instances running MariaDB versions 10.2.12, 10.1.31, and 10.0.34. For more information, see <a href="#">MariaDB on Amazon RDS versions</a> .	March 21, 2018
Aurora PostgreSQL Support for new regions	Aurora PostgreSQL is now available in the EU (London) and Asia Pacific (Singapore) regions. For more information, see <a href="#">Availability for Amazon Aurora PostgreSQL</a> .	March 13, 2018
MySQL 5.7.21, 5.6.39, and 5.5.59	You can now create Amazon RDS DB instances running MySQL versions 5.7.21, 5.6.39, and 5.5.59. For more information, see <a href="#">MySQL on Amazon RDS versions</a> .	March 9, 2018
Amazon RDS for Oracle now supports Oracle REST Data Services	Amazon RDS for Oracle supports Oracle REST Data Services as part of the APEX option. For more information, see <a href="#">Oracle Application Express (APEX)</a> .	March 9, 2018
Amazon Aurora MySQL-Compatible Edition available in new AWS Region	Aurora MySQL is now available in the Asia Pacific (Singapore) region. For the complete list of AWS Regions for Aurora MySQL, see <a href="#">Availability for Amazon Aurora MySQL</a> .	March 6, 2018
Amazon RDS DB instances running Microsoft SQL Server support change data capture (CDC)	DB instances running Amazon RDS for Microsoft SQL Server now support change data capture (CDC). For more information, see <a href="#">Change data capture support for Microsoft SQL Server DB instances</a> .	February 6, 2018

Change	Description	Date changed
Aurora MySQL supports a new major version	You can now create Aurora MySQL DB clusters running MySQL version 5.7. For more information, see <a href="#">Amazon Aurora MySQL database engine updates 2018-02-06</a> .	February 6, 2018
Publish MySQL and MariaDB logs to Amazon CloudWatch Logs	You can now publish MySQL and MariaDB log data to CloudWatch Logs. For more information, see <a href="#">Publishing MySQL logs to Amazon CloudWatch Logs</a> and <a href="#">Publishing MariaDB logs to Amazon CloudWatch Logs</a> .	January 17, 2018
Multi-AZ support for read replicas	You can now create a read replica as a Multi-AZ DB instance. Amazon RDS creates a standby of your replica in another Availability Zone for failover support for the replica. Creating your read replica as a Multi-AZ DB instance is independent of whether the source database is a Multi-AZ DB instance. For more information, see <a href="#">Working with DB instance read replicas</a> .	January 11, 2018
Amazon RDS for MariaDB supports a new major version	You can now create Amazon RDS DB instances running MariaDB version 10.2. For more information, see <a href="#">MariaDB 10.2 support on Amazon RDS</a> .	January 3, 2018
Amazon Aurora PostgreSQL-Compatible Edition available in new AWS Region	Aurora PostgreSQL is now available in the EU (Paris) region. For the complete list of AWS Regions for Aurora PostgreSQL, see <a href="#">Availability for Amazon Aurora PostgreSQL</a> .	December 22, 2017
Aurora PostgreSQL supports new instance types	Aurora PostgreSQL now supports new instance types. For the complete list of instance types, see <a href="#">Choosing the DB instance class</a> .	December 20, 2017

Change	Description	Date changed
Amazon Aurora MySQL-Compatible Edition available in new AWS Region	Aurora MySQL is now available in the EU (Paris) region. For the complete list of AWS Regions for Aurora MySQL, see <a href="#">Availability for Amazon Aurora MySQL</a> .	December 18, 2017
Aurora MySQL supports hash joins	This feature can improve query performance when you need to join a large amount of data by using an equijoin. For more information, see <a href="#">Working with hash joins in Aurora MySQL</a> .	December 11, 2017
Aurora MySQL supports native functions to invoke AWS Lambda functions	You can call the native functions <code>lambda_sync</code> and <code>lambda_async</code> when you use Aurora MySQL. For more information, see <a href="#">Invoking a Lambda function from an Amazon Aurora MySQL DB cluster</a> .	December 11, 2017
Added Aurora PostgreSQL HIPAA eligibility	Aurora PostgreSQL now supports building HIPAA compliant applications. For more information, see <a href="#">Working with Amazon Aurora PostgreSQL</a> .	December 6, 2017
Additional AWS Regions available for Amazon Aurora with PostgreSQL compatibility	Amazon Aurora with PostgreSQL compatibility is now available in four new AWS Regions. For more information, see <a href="#">Availability for Amazon Aurora PostgreSQL</a> .	November 22, 2017
Modify storage for Amazon RDS DB instances running Microsoft SQL Server	You can now modify the storage of your Amazon RDS DB instances running SQL Server. For more information, see <a href="#">Modifying an Amazon RDS DB instance</a> .	November 21, 2017

Change	Description	Date changed
Amazon RDS supports 16 TiB storage for Linux-based engines	You can now create MySQL, MariaDB, PostgreSQL, and Oracle RDS DB instances with up to 16 TiB of storage. For more information, see <a href="#">Amazon RDS DB instance storage</a> .	November 21, 2017
Amazon RDS supports fast scale up of storage	You can now add storage to MySQL, MariaDB, PostgreSQL, and Oracle RDS DB instances in a few minutes. For more information, see <a href="#">Amazon RDS DB instance storage</a> .	November 21, 2017
Amazon RDS supports MariaDB versions 10.1.26 and 10.0.32	You can now create Amazon RDS DB instances running MariaDB versions 10.1.26 and 10.0.32. For more information, see <a href="#">MariaDB on Amazon RDS versions</a> .	November 20, 2017
Amazon RDS for Microsoft SQL Server now supports new DB instance classes	You can now create Amazon RDS DB instances running SQL Server that use the db.r4 and db.m4.16xlarge DB instance classes. For more information, see <a href="#">DB instance class support for Microsoft SQL Server</a> .	November 20, 2017
Amazon RDS for MySQL and MariaDB now supports new DB instance classes	You can now create Amazon RDS DB instances running MySQL and MariaDB that use the db.r4, db.m4.16xlarge, db.t2.xlarge, and db.t2.2xlarge DB instance classes. For more information, see <a href="#">DB instance classes</a> .	November 20, 2017
SQL Server 2017	You can now create Amazon RDS DB instances running Microsoft SQL Server 2017. You can also create DB instances running SQL Server 2016 SP1 CU5. For more information, see <a href="#">Amazon RDS for Microsoft SQL Server</a> .	November 17, 2017

Change	Description	Date changed
Restore MySQL backups from Amazon S3	You can now create a backup of your on-premises database, store it on Amazon S3, and then restore the backup file onto a new Amazon RDS DB instance running MySQL. For more information, see <a href="#">Restoring a backup into a MySQL DB instance</a> .	November 17, 2017
Auto Scaling with Aurora Replicas	Amazon Aurora MySQL now supports Aurora Auto Scaling. Aurora Auto Scaling dynamically adjusts the number of Aurora Replicas based on increases or decreases in connectivity or workload. For more information, see <a href="#">Amazon Aurora Auto Scaling with Aurora replicas</a> .	November 17, 2017
Oracle default edition support	Amazon RDS for Oracle DB instances now supports setting the default edition for the DB instance. For more information, see <a href="#">Setting the default edition for a DB instance</a> .	November 3, 2017
Oracle DB instance file validation	Amazon RDS for Oracle DB instances now supports validating DB instance files with the Oracle Recovery Manager (RMAN) logical validation utility. For more information, see <a href="#">Validating database files in RDS for Oracle</a> .	November 3, 2017
Management Agent for OEM 13c	Amazon RDS for Oracle DB instances now support the Management Agent for Oracle Enterprise Manager (OEM) Cloud Control 13c. For more information, see <a href="#">Oracle Management Agent for Enterprise Manager Cloud Control</a> .	November 1, 2017
Storage reconfiguration for Microsoft SQL Server snapshots	You can now reconfigure the storage when you restore a snapshot to an Amazon RDS DB instance running Microsoft SQL Server. For more information, see <a href="#">Restoring to a DB instance</a> .	October 26, 2017

Change	Description	Date changed
Asynchronous key prefetch for Aurora MySQL-Compatible Edition	Asynchronous key prefetch (AKP) improves the performance of noncached index joins, by prefetching keys in memory ahead of when they are needed. For more information, see <a href="#">Working with asynchronous key prefetch in Amazon Aurora</a> .	October 26, 2017
MySQL 5.7.19, 5.6.37, and 5.5.57	You can now create Amazon RDS DB instances running MySQL versions 5.7.19, 5.6.37, and 5.5.57. For more information, see <a href="#">MySQL on Amazon RDS versions</a> .	October 25, 2017
General availability of Amazon Aurora with PostgreSQL compatibility	Amazon Aurora with PostgreSQL compatibility makes it simple and cost-effective to set up, operate, and scale your new and existing PostgreSQL deployments, thus freeing you to focus on your business and applications. For more information, see <a href="#">Working with Amazon Aurora PostgreSQL</a> .	October 24, 2017
Amazon RDS for Oracle DB instances support new DB instance classes	Amazon RDS for Oracle DB instances now support memory optimized next generation (db.r4) instance classes. Amazon RDS for Oracle DB instances also now support the following new current generation instance classes: db.m4.16xlarge, db.t2.xlarge, and db.t2.2xlarge. For more information, see <a href="#">DB instance classes</a> and <a href="#">RDS for Oracle DB instance classes</a> .	October 23, 2017

Change	Description	Date changed
New feature	Your new and existing Reserved Instances can now cover multiple sizes in the same DB instance class. Size-flexible reserved instances are available for DB instances with the same AWS Region, database engine, and instance family, and across AZ configuration. Size-flexible reserved instances are available for the following database engines: Amazon Aurora, MariaDB, MySQL, Oracle (Bring Your Own License), PostgreSQL. For more information, see <a href="#">Size-flexible reserved DB instances</a> .	October 11, 2017
New feature	You can now use the Oracle SQLT option to tune a SQL statement for optimal performance. For more information, see <a href="#">Oracle SQLT</a> .	September 22, 2017
New feature	If you have existing manual DB snapshots of your Amazon RDS for Oracle DB instances, you can now upgrade them to a later version of the Oracle database engine. For more information, see <a href="#">Upgrading an Oracle DB snapshot</a> .	September 20, 2017
New feature	You can now use Oracle Spatial to store, retrieve, update, and query spatial data in your Amazon RDS DB instances running Oracle. For more information, see <a href="#">Oracle Spatial</a> .	September 15, 2017
New feature	You can now use Oracle Locator to support internet and wireless service-based applications and partner-based GIS solutions with your Amazon RDS DB instances running Oracle. For more information, see <a href="#">Oracle Locator</a> .	September 15, 2017
New feature	You can now use Oracle Multimedia to store, manage, and retrieve images, audio, video, and other heterogeneous media data in your Amazon RDS DB instances running Oracle.	September 15, 2017

Change	Description	Date changed
New feature	You can now export audit logs from your Amazon Aurora MySQL DB clusters to Amazon CloudWatch Logs. For more information, see <a href="#">Publishing Aurora MySQL logs to Amazon CloudWatch Logs</a> .	September 14, 2017
New feature	Amazon RDS now supports multiple versions of Oracle Application Express (APEX) for your DB instances running Oracle. For more information, see <a href="#">Oracle Application Express (APEX)</a> .	September 13, 2017
New feature	You can now use Amazon Aurora to migrate an unencrypted or encrypted DB snapshot or MySQL DB instance to an encrypted Aurora MySQL DB cluster. For more information, see <a href="#">Migrating an RDS for MySQL snapshot to Aurora</a> and <a href="#">Migrating data from a MySQL DB instance to an Amazon Aurora MySQL DB cluster by using an Aurora read replica</a> .	September 5, 2017
New feature	You can use Amazon RDS for Microsoft SQL Server databases to build HIPAA-compliant applications. For more information, see <a href="#">Compliance program support for Microsoft SQL Server DB instances</a> .	August 31, 2017
New feature	You can now use Amazon RDS for MariaDB databases to build HIPAA-compliant applications. For more information, see <a href="#">Amazon RDS for MariaDB</a> .	August 31, 2017
New feature	You can now create Amazon RDS DB instances running Microsoft SQL Server with allocated storage up to 16 TiB, and Provisioned IOPS to storage ranges of 1:1–50:1. For more information, see <a href="#">Amazon RDS DB instance storage</a> .	August 22, 2017

Change	Description	Date changed
New feature	You can now use Multi-AZ deployments for DB instances running Microsoft SQL Server in the EU (Frankfurt) region. For more information, see <a href="#">Multi-AZ deployments for Amazon RDS for Microsoft SQL Server</a> .	August 3, 2017
New feature	You can now create Amazon RDS DB instances running MariaDB versions 10.1.23 and 10.0.31. For more information, see <a href="#">MariaDB on Amazon RDS versions</a> .	July 17, 2017
New feature	Amazon RDS now supports Microsoft SQL Server Enterprise Edition with the License Included model in all AWS Regions. For more information, see <a href="#">Licensing Microsoft SQL Server on Amazon RDS</a> .	July 13, 2017
New feature	Amazon RDS for Oracle now supports Linux kernel huge pages for increased database scalability. The use of huge pages results in smaller page tables and less CPU time spent on memory management, increasing the performance of large database instances. You can use huge pages with your Amazon RDS DB instances running all editions of Oracle versions 12.1.0.2 and 11.2.0.4. For more information, see <a href="#">Turning on HugePages for an RDS for Oracle instance</a> .	July 7, 2017
New feature	Updated to support encryption at rest (EAR) for db.t2.small and db.t2.medium DB instance classes for all non-Aurora DB engines. For more information, see <a href="#">Availability of Amazon RDS encryption</a> .	June 27, 2017
New feature	Updated to support Amazon Aurora in the Europe (Frankfurt) region. For more information, see <a href="#">Availability for Amazon Aurora MySQL</a> .	June 16, 2017

Change	Description	Date changed
New feature	You can now specify an option group when you copy a DB snapshot across AWS regions. For more information, see <a href="#">Option group considerations</a> .	June 12, 2017
New feature	You can now copy DB snapshots created from specialized DB instances across AWS regions. You can copy snapshots from DB instances that use Oracle TDE, Microsoft SQL Server TDE, and Microsoft SQL Server Multi-AZ with Mirroring. For more information, see <a href="#">Copying a DB snapshot</a> .	June 12, 2017
New feature	Amazon Aurora now allows you to quickly and cost-effectively copy all of your databases in an Amazon Aurora DB cluster. For more information, see <a href="#">Cloning databases in an Aurora DB cluster</a> .	June 12, 2017
New feature	Amazon RDS now supports Microsoft SQL Server 2016 SP1 CU2. For more information, see <a href="#">Amazon RDS for Microsoft SQL Server</a> .	June 7, 2017
Preview	Public preview of Amazon Aurora with PostgreSQL Compatibility. For more information, see <a href="#">Working with Amazon Aurora PostgreSQL</a> .	April 19, 2017
New feature	Amazon Aurora now allows you to run an ALTER TABLE <i>tbl_name</i> ADD COLUMN <i>col_name</i> <i>column_definition</i> operation nearly instantaneously. The operation completes without requiring the table to be copied and without materially impacting other DML statements. For more information, see <a href="#">Altering tables in Amazon Aurora using fast DDL</a> .	April 5, 2017
New feature	We have added a new monitoring command, SHOW VOLUME STATUS, to display the number of nodes and disks in a volume. For more information, see <a href="#">Displaying volume status for an Aurora DB cluster</a> .	April 5, 2017

Change	Description	Date changed
New feature	You can now use your own custom logic in your custom password verification functions for Oracle on Amazon RDS. For more information, see <a href="#">Creating custom functions to verify passwords</a> .	March 21, 2017
New feature	You can now access your online and archived redo log files on your Oracle DB instances on Amazon RDS. For more information, see <a href="#">Accessing online and archived redo logs</a> .	March 21, 2017
New feature	You can now copy both encrypted and unencrypted DB cluster snapshots between accounts in the same region. For more information, see <a href="#">Copying a DB cluster snapshot across accounts</a> .	March 7, 2017
New feature	You can now share encrypted DB cluster snapshots between accounts in the same region. For more information, see <a href="#">Sharing a DB cluster snapshot</a> .	March 7, 2017
New feature	You can now replicate encrypted Amazon Aurora MySQL DB clusters to create cross-region Aurora Replicas. For more information, see <a href="#">Replicating Aurora MySQL DB clusters across AWS Regions</a> .	March 7, 2017
New feature	You can now require that all connections to your DB instance running Microsoft SQL Server use Secure Sockets Layer (SSL). For more information, see <a href="#">Using SSL with a Microsoft SQL Server DB instance</a> .	February 27, 2017
New feature	You can now set your local time zone to one of 15 additional time zones. For more information, see <a href="#">Supported time zones</a> .	February 27, 2017

Change	Description	Date changed
New feature	You can now use the Amazon RDS procedure <code>msdb.dbo.rds_shrink_tempdbfile</code> to shrink the tempdb database on your DB instances running Microsoft SQL Server. For more information, see <a href="#">Shrinking the tempdb database</a> .	February 17, 2017
New feature	You can now compress your backup file when you export your Enterprise and Standard Edition Microsoft SQL Server database from an Amazon RDS DB instance to Amazon S3. For more information, see <a href="#">Compressing backup files</a> .	February 17, 2017
New feature	Amazon RDS now supports custom DNS servers to resolve DNS names used in outbound network access on your DB instances running Oracle. For more information, see <a href="#">Setting up a custom DNS server</a> .	January 26, 2017
New feature	Amazon RDS now supports creating an encrypted read replica in another region. For more information, see <a href="#">Creating a read replica in a different AWS Region</a> and <a href="#">CreateDBInstanceReadReplica</a> .	January 23, 2017
New feature	Amazon RDS now supports upgrading a MySQL DB snapshot from MySQL 5.1 to MySQL 5.5.	January 20, 2017
New feature	Amazon RDS now supports copying an encrypted DB snapshot to another region for the MariaDB, MySQL, Oracle, PostgreSQL, and Microsoft SQL Server database engines. For more information, see <a href="#">Copying a DB snapshot</a> and <a href="#">CopyDBSnapshot</a> .	December 20, 2016

Change	Description	Date changed
New feature	<p>Amazon Aurora MySQL now supports spatial indexing.</p> <p>Spatial indexing improves query performance on large datasets for queries that use spatial data. For more information, see <a href="#">Amazon Aurora MySQL and spatial data</a>.</p>	December 14, 2016
New feature	<p>Amazon RDS now supports outbound network access on your DB instances running Oracle. You can use <code>utl_http</code>, <code>utl_tcp</code>, and <code>utl_smtp</code> to connect from your DB instance to the network. For more information, see <a href="#">Configuring UTL_HTTP access using certificates and an Oracle wallet</a>.</p>	December 5, 2016
New feature	<p>Amazon RDS has retired support for MySQL version 5.1. However, you can restore existing MySQL 5.1 snapshots to a MySQL 5.5 instance. For more information, see <a href="#">Supported storage engines for RDS for MySQL</a>.</p>	November 15, 2016
New feature	<p>Amazon RDS now supports Microsoft SQL Server 2016 RTM CU2. For more information, see <a href="#">Amazon RDS for Microsoft SQL Server</a>.</p>	November 4, 2016
New feature	<p>Amazon RDS now supports major version upgrades for DB instances running Oracle. You can now upgrade your Oracle DB instances from 11g to 12c. For more information, see <a href="#">Upgrading the RDS for Oracle DB engine</a>.</p>	November 2, 2016
New feature	<p>You can now create DB instances running Microsoft SQL Server 2014 Enterprise Edition. Amazon RDS now supports SQL Server 2014 SP2 for all editions and all regions. For more information, see <a href="#">Amazon RDS for Microsoft SQL Server</a>.</p>	October 25, 2016

Change	Description	Date changed
New feature	Amazon Aurora MySQL now integrates with other AWS services: You can load text or XML data into a table from an Amazon S3 bucket, or invoke an AWS Lambda function from database code. For more information, see <a href="#">Integrating Aurora MySQL with other AWS services</a> .	October 18, 2016
New feature	You can now access the tempdb database on your Amazon RDS DB instances running Microsoft SQL Server. You can access the tempdb database by using Transact-SQL through Microsoft SQL Server Management Studio (SSMS), or any other standard SQL client application. For more information, see <a href="#">Accessing the tempdb database on Microsoft SQL Server DB instances on Amazon RDS</a> .	September 29, 2016
New feature	You can now use the UTL_MAIL package with your Amazon RDS DB instances running Oracle. For more information, see <a href="#">Oracle UTL_MAIL</a> .	September 20, 2016
New features	You can now set the time zone of your new Microsoft SQL Server DB instances to a local time zone, to match the time zone of your applications. For more information, see <a href="#">Local time zone for Microsoft SQL Server DB instances</a> .	September 19, 2016
New feature	You can now use the Oracle Label Security option to control access to individual table rows in your Amazon RDS DB instances running Oracle Database 12c. With Oracle Label Security, you can enforce regulatory compliance with a policy-based administration model, and ensure that an access to sensitive data is restricted to only users with the appropriate clearance level. For more information, see <a href="#">Oracle Label Security</a> .	September 8, 2016

Change	Description	Date changed
New feature	You can now connect to an Amazon Aurora DB cluster using the reader endpoint, which load-balances connections across the Aurora Replicas that are available in the DB cluster. As clients request new connections to the reader endpoint, Aurora distributes the connection requests among the Aurora Replicas in the DB cluster. This functionality can help balance your read workload across multiple Aurora Replicas in your DB cluster. For more information, see <a href="#">Amazon Aurora endpoints</a> .	September 8, 2016
New feature	You can now support the Oracle Enterprise Manager Cloud Control on your Amazon RDS DB instances running Oracle. You can enable the Management Agent on your DB instances, and share data with your Oracle Management Service (OMS). For more information, see <a href="#">Oracle Management Agent for Enterprise Manager Cloud Control</a> .	September 1, 2016
New feature	This release adds support to get an ARN for a resource. For more information, see <a href="#">Getting an existing ARN for Amazon RDS</a> .	August 23, 2016
New feature	You can now assign up to 50 tags for each Amazon RDS resource, for managing your resources and tracking costs. For more information, see <a href="#">Tagging Amazon RDS resources</a> .	August 19, 2016

Change	Description	Date changed
New feature	<p>Amazon RDS now supports the License Included model for Oracle Standard Edition Two. For more information, see <a href="#">Creating an Amazon RDS DB instance</a>.</p> <p>You can now change the license model of your Amazon RDS DB instances running Microsoft SQL Server and Oracle. For more information, see <a href="#">Licensing Microsoft SQL Server on Amazon RDS</a> and <a href="#">RDS for Oracle licensing options</a>.</p>	August 5, 2016
New feature	<p>Amazon RDS now supports native backup and restore for Microsoft SQL Server databases using full backup files (.bak files). You can now easily migrate SQL Server databases to Amazon RDS, and import and export databases in a single, easily-portable file, using Amazon S3 for storage, and AWS KMS for encryption. For more information, see <a href="#">Importing and exporting SQL Server databases using native backup and restore</a>.</p>	July 27, 2016
New feature	<p>You can now copy the source files from a MySQL database to an Amazon Simple Storage Service (Amazon S3) bucket, and then restore an Amazon Aurora DB cluster from those files. This option can be considerably faster than migrating data using <code>mysqldump</code>. For more information, see <a href="#">Migrating data from an external MySQL database to an Aurora MySQL DB cluster</a>.</p>	July 20, 2016

Change	Description	Date changed
New feature	You can now restore an unencrypted Amazon Aurora DB cluster snapshot to create an encrypted Amazon Aurora DB cluster by including an AWS Key Management Service (AWS KMS) encryption key during the restore operation. For more information, see <a href="#">Encrypting Amazon RDS resources</a> .	June 30, 2016
New feature	You can use the Oracle Repository Creation Utility (RCU) to create a repository on Amazon RDS for Oracle. For more information, see <a href="#">Using the Oracle Repository Creation Utility on RDS for Oracle</a> .	June 17, 2016
New feature	Adds support for PostgreSQL cross-region read replicas. For more information, see <a href="#">Creating a read replica in a different AWS Region</a> .	June 16, 2016
New feature	You can now use the AWS Management Console to easily add Multi-AZ with Mirroring to a Microsoft SQL Server DB instance. For more information, see <a href="#">Adding Multi-AZ to a Microsoft SQL Server DB instance</a> .	June 9, 2016
New feature	You can now use Multi-AZ Deployments Using SQL Server Mirroring in the following additional regions: Asia Pacific (Sydney), Asia Pacific (Tokyo), and South America (São Paulo). For more information, see <a href="#">Multi-AZ deployments for Amazon RDS for Microsoft SQL Server</a> .	June 9, 2016
New feature	Updated to support MariaDB version 10.1. For more information, see <a href="#">Amazon RDS for MariaDB</a> .	June 1, 2016
New feature	Updated to support Amazon Aurora cross-region DB clusters that are read replicas. For more information, see <a href="#">Replicating Aurora MySQL DB clusters across AWS Regions</a> .	June 1, 2016

Change	Description	Date changed
New feature	Enhanced Monitoring is now available for Oracle DB instances. For more information, see <a href="#">Monitoring OS metrics with Enhanced Monitoring</a> and <a href="#">Modifying an Amazon RDS DB instance</a> .	May 27, 2016
New feature	Updated to support manual snapshot sharing for Amazon Aurora DB cluster snapshots. For more information, see <a href="#">Sharing a DB cluster snapshot</a> .	May 18, 2016
New feature	You can now use the MariaDB Audit Plugin to log database activity on MariaDB and MySQL database instances. For more information, see <a href="#">Options for MariaDB database engine</a> and <a href="#">Options for MySQL DB instances</a> .	April 27, 2016
New feature	In-place, major version upgrades are now available for upgrading from MySQL version 5.6 to version 5.7. For more information, see <a href="#">Upgrading the MySQL DB engine</a> .	April 26, 2016
New feature	Enhanced Monitoring is now available for Microsoft SQL Server DB instances. For more information, see <a href="#">Monitoring OS metrics with Enhanced Monitoring</a> .	April 22, 2016
New feature	Updated to provide an Amazon Aurora <b>Clusters</b> view in the Amazon RDS console. For more information, see <a href="#">Viewing an Aurora DB cluster</a> .	April 1, 2016
New feature	Updated to support SQL Server Multi-AZ with mirroring in the Asia Pacific (Seoul) region. For more information, see <a href="#">Multi-AZ deployments for Amazon RDS for Microsoft SQL Server</a> .	March 31, 2016

Change	Description	Date changed
New feature	Updated to support Amazon Aurora Multi-AZ with mirroring in the Asia Pacific (Seoul) region. For more information, see <a href="#">Availability for Amazon Aurora MySQL</a> .	March 31, 2016
New feature	PostgreSQL DB instances have the ability to require connections to use SSL. For more information, see <a href="#">Using SSL with a PostgreSQL DB instance</a> .	March 25, 2016
New feature	Enhanced Monitoring is now available for PostgreSQL DB instances. For more information, see <a href="#">Monitoring OS metrics with Enhanced Monitoring</a> .	March 25, 2016
New feature	Microsoft SQL Server DB instances can now use Windows Authentication for user authentication. For more information, see <a href="#">Working with AWS Managed Active Directory with RDS for SQL Server</a> .	March 23, 2016
New feature	Enhanced Monitoring is now available in the Asia Pacific (Seoul) region. For more information, see <a href="#">Monitoring OS metrics with Enhanced Monitoring</a> .	March 16, 2016
New feature	You can now customize the order in which Aurora Replicas are promoted to primary instance during a failover. For more information, see <a href="#">Fault tolerance for an Aurora DB cluster</a> .	March 14, 2016
New feature	Updated to support encryption when migrating to an Aurora DB cluster. For more information, see <a href="#">Migrating data to an Aurora DB cluster</a> .	March 2, 2016
New feature	Updated to support local time zone for Aurora DB clusters. For more information, see <a href="#">Local time zone for Aurora DB clusters</a> .	March 1, 2016
New feature	Updated to add support for MySQL version 5.7 for current generation Amazon RDS DB instance classes.	February 22, 2016

Change	Description	Date changed
New feature	Updated to support <i>db.r3</i> and <i>db.t2</i> DB instance classes in the AWS GovCloud (US-West) region.	February 11, 2016
New feature	Updated to support encrypting copies of DB snapshots and sharing encrypted DB snapshots. For more information, see <a href="#">Copying a DB snapshot</a> and <a href="#">Sharing a DB snapshot</a> .	February 11, 2016
New feature	Updated to support Amazon Aurora in the Asia Pacific (Sydney) region. For more information, see <a href="#">Availability for Amazon Aurora MySQL</a> .	February 11, 2016
New feature	Updated to support SSL for Oracle DB instances. For more information, see <a href="#">Using SSL with an RDS for Oracle DB instance</a> .	February 9, 2016
New feature	Updated to support local time zone for MySQL and MariaDB DB instances. For more information, see <a href="#">Local time zone for MySQL DB instances</a> and <a href="#">Local time zone for MariaDB DB instances</a> .	December 21, 2015
New feature	Updated to support Enhanced Monitoring of OS metrics for MySQL and MariaDB instances and Aurora DB clusters. For more information, see <a href="#">Viewing metrics in the Amazon RDS console</a> .	December 18, 2015
New feature	Updated to support <i>db.t2</i> , <i>db.r3</i> , and <i>db.m4</i> DB instance classes for MySQL version 5.5. For more information, see <a href="#">DB instance classes</a> .	December 4, 2015
New feature	Updated to support modifying the database port for an existing DB instance.	December 3, 2015
New feature	Updated to support major version upgrades of the database engine for PostgreSQL instances. For more information, see <a href="#">Upgrading the PostgreSQL DB engine for Amazon RDS</a> .	November 19, 2015

Change	Description	Date changed
New feature	Updated to support modifying the public accessibility of an existing DB instance. Updated to support db.m4 standard DB instance classes.	November 11, 2015
New feature	Updated to support manual DB snapshot sharing. For more information, see <a href="#">Sharing a DB snapshot</a> .	October 28, 2015
New feature	Updated to support Microsoft SQL Server 2014 for the Web, Express, and Standard editions.	October 26, 2015
New feature	Updated to support the MySQL-based MariaDB database engine. For more information, see <a href="#">Amazon RDS for MariaDB</a> .	October 7, 2015
New feature	Updated to support Amazon Aurora in the Asia Pacific (Tokyo) region. For more information, see <a href="#">Availability for Amazon Aurora MySQL</a> .	October 7, 2015
New feature	Updated to support db.t2 burst-capable DB instance classes for all DB engines and the addition of the db.t2.large DB instance class. For more information, see <a href="#">DB instance classes</a> .	September 25, 2015
New feature	Updated to support Oracle DB instances on R3 and T2 DB instance classes. For more information, see <a href="#">DB instance classes</a> .	August 5, 2015
New feature	Microsoft SQL Server Enterprise Edition is now available with the License Included service model. For more information, see <a href="#">Licensing Microsoft SQL Server on Amazon RDS</a> .	July 29, 2015
New feature	Amazon Aurora has officially released. The Amazon Aurora DB engine supports multiple DB instances in a DB cluster. For detailed information, see <a href="#">What is Amazon Aurora?</a> .	July 27, 2015

Change	Description	Date changed
New feature	Updated to support copying tags to DB snapshots.	July 20, 2015
New feature	Updated to support increases in storage size for all DB engines and an increase in Provisioned IOPS for SQL Server.	June 18, 2015
New feature	Updated options for reserved DB instances.	June 15, 2015
New feature	Updated to support using Amazon CloudHSM with Oracle DB instances using TDE.	January 8, 2015
New feature	Updated to support encrypting data at rest and new API version 2014-10-31.	January 6, 2015
New feature	Updated to include the new Amazon DB engine: Aurora. The Amazon Aurora DB engine supports multiple DB instances in a DB cluster. Amazon Aurora is currently in preview release and is subject to change. For detailed information, see <a href="#">What is Amazon Aurora?</a>	November 12, 2014
New feature	Updated to support PostgreSQL read replicas.	November 10, 2014
New API and features	Updated to support the GP2 storage type and new API version 2014-09-01. Updated to support the ability to copy an existing option or parameter group to create a new option or parameter group.	October 7, 2014
New feature	Updated to support InnoDB Cache Warming for DB instances running MySQL version 5.6.19 and later.	September 3, 2014
New feature	Updated to support SSL certificate verification when connecting to MySQL version 5.6, SQL Server, and PostgreSQL database engines.	August 5, 2014

Change	Description	Date changed
New feature	Updated to support the db.t2 burstable DB instance classes.	August 4, 2014
New feature	Updated to support the db.r3 memory optimized DB instance classes for use with the MySQL (version 5.6), SQL Server, and PostgreSQL database engines.	May 28, 2014
New feature	Updated to support SQL Server Multi-AZ deployments using SQL Server Mirroring.	May 19, 2014
New feature	Updated to support upgrades from MySQL version 5.5 to version 5.6.	April 23, 2014
New feature	Updated to support Oracle GoldenGate.	April 3, 2014
New feature	Updated to support the M3 DB instance classes.	February 20, 2014
New feature	Updated to support the Oracle Timezone option.	January 13, 2014
New feature	Updated to support replication between MySQL DB instances in different regions.	November 26, 2013
New feature	Updated to support the PostgreSQL DB engine.	November 14, 2013
New feature	Updated to support SQL Server transparent data encryption (TDE).	November 7, 2013
New API and new feature	Updated to support cross region DB snapshot copies; new API version, 2013-09-09.	October 31, 2013
New features	Updated to support Oracle Statspack.	September 26, 2013
New features	Updated to support using replication to import or export data between instances of MySQL running in Amazon RDS and instances of MySQL running on-premises or on Amazon EC2.	September 5, 2013

Change	Description	Date changed
New features	Updated to support the db.cr1.8xlarge DB instance class for MySQL 5.6.	September 4, 2013
New feature	Updated to support replication of read replicas.	August 28, 2013
New feature	Updated to support parallel read replica creation.	July 22, 2013
New feature	Updated to support fine-grained permissions and tagging for all Amazon RDS resources.	July 8, 2013
New feature	Updated to support MySQL 5.6 for new instances , including support for the MySQL 5.6 memcached interface and binary log access.	July 1, 2013
New feature	Updated to support major version upgrades from MySQL 5.1 to MySQL 5.5.	June 20, 2013
New feature	Updated DB parameter groups to allow expressions for parameter values.	June 20, 2013
New API and new feature	Updated to support read replica status; new API version, 2013-05-15.	May 23, 2013
New features	Updated to support Oracle Advanced Security features for native network encryption and Oracle Transparent Data Encryption.	April 18, 2013
New features	Updated to support major version upgrades for SQL Server and additional functionality for Provisioned IOPS.	March 13, 2013
New feature	Updated to support VPC By Default for RDS.	March 11, 2013
New API and feature	Updated to support log access; new API version 2013-02-12	March 4, 2013
New feature	Updated to support RDS event notification subscriptions.	February 4, 2013

Change	Description	Date changed
New API and feature	Updated to support DB instance renaming and the migration of DB security group members in a VPC to a VPC security group.	January 14, 2013
New feature	Updated for AWS GovCloud (US-West) support.	December 17, 2012
New feature	Updated to support m1.medium and m1.xlarge DB instance classes.	November 6, 2012
New feature	Updated to support read replica promotion.	October 11, 2012
New feature	Updated to support SSL in Microsoft SQL Server DB instances.	October 10, 2012
New feature	Updated to support Oracle micro DB instances.	September 27, 2012
New feature	Updated to support SQL Server 2012.	September 26, 2012
New API and feature	Updated to support provisioned IOPS. API version 2012-09-17.	September 25, 2012
New features	Updated for SQL Server support for DB instances in VPC and Oracle support for Data Pump.	September 13, 2012
New feature	Updated for support for SQL Server Agent.	August 22, 2012
New feature	Updated for support for tagging of DB instances.	August 21, 2012
New features	Updated for support for Oracle APEX and XML DB, Oracle time zones, and Oracle DB instances in a VPC.	August 16, 2012
New features	Updated for support for SQL Server Database Engine Tuning Advisor and Oracle DB instances in VPC.	July 18, 2012

<b>Change</b>	<b>Description</b>	<b>Date changed</b>
New feature	Updated for support for option groups and first option, Oracle Enterprise Manager Database Control.	May 29, 2012
New feature	Updated for support for read replicas in Amazon Virtual Private Cloud.	May 17, 2012
New feature	Updated for Microsoft SQL Server support.	May 8, 2012
New features	Updated for support for forced failover, Multi-AZ deployment of Oracle DB instances, and nondefault character sets for Oracle DB instances.	May 2, 2012
New feature	Updated for Amazon Virtual Private Cloud (VPC) Support.	February 13, 2012
Updated content	Updated for new Reserved Instance types.	December 19, 2011
New feature	Updated for Oracle engine support.	May 23, 2011
Updated content	Console updates.	May 13, 2011
Updated content	Edited content for shortened backup and maintenance windows.	February 28, 2011
New feature	Added support for MySQL 5.5.	January 31, 2011
New feature	Added support for read replicas.	October 4, 2010
New feature	Added support for AWS Identity and Access Management (IAM).	September 2, 2010
New feature	Added DB engine Version Management.	August 16, 2010
New feature	Added Reserved DB instances.	August 16, 2010
New Feature	Amazon RDS now supports SSL connections to your DB instances.	June 28, 2010

Change	Description	Date changed
New Guide	This is the first release of the Amazon RDS User Guide.	June 7, 2010

# AWS Glossary

For the latest AWS terminology, see the [AWS glossary](#) in the *AWS Glossary Reference*.
